Preface

If there has been something like a magnificent failure of a theory in psychology, then it must imply something about the opposite, namely, a significant success.

The purpose of this encyclopedia is to present to the scientific community a unique coverage of the history of psychological theories. The subject matter of this work addresses current theoretical and political issues such as agency, realism, objectivity, subjectivism, structuralism, postmodernism, and multiculturalism. The encyclopedia deals with various aspects of the history of psychological theories by providing the reader with the following:

- Brief discussions of concurrent trends and definitions cited in the literature
- Historical background, especially for the more technical and conceptual topics
- Key Issues: The topics of major relevance to the development of psychological theories
- International perspectives such as cross-national similarities or differences
- Future Directions: Brief overviews of current knowledge and outlook for the future
- References: To facilitate the reader in searching the topic further
- Cross- references: To direct the reader to related topics

In general, the work includes the following types of content:

- Subject Matter Entries: These entries cover practically all the important theories.
- Biographies: Biographies of persons who made significant contributions to the different psychological theories are included.
- Department Histories: This includes most of the well-known institutions which have made important contributions to the development of the field of psychology.

I would like to thank Sharon Panulla for suggesting that I edit this work and all the members of the editorial board who have been so helpful in both contributing entries and suggesting possible authors.

Abney, William

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: July 24, 1843; Died: December 2, 1920.

William Abney, son of a clergyman in Derby, England, was commissioned in the Royal Engineers in 1861 and served in India through 1867. After his return to England, he was posted to the Royal Engineering School at Chatham, was promoted to Captain in 1873, and retired from service in 1881. He was elected to the Royal Society in 1876. He continued his career as an independent scientific investigator until his death. Knighted in 1900, he served in several official capacities in science and education and was also concerned with practical applications of visual science.

Major Accomplishments/Contributions

Abney brought a multifarious set of interests and skills to bear on a variety of scientific subjects. During his early engineering career, he devised a variation on the Locke hand level, the Abney level, adaptable to measuring inclination and grade. Teaching at Chatham led him to writing a chemistry textbook for engineers which was widely used. The most significant skill he developed was photography, which he had learned firsthand during the 1850s from his father Edward Abney who was friends with some of the first photographers in Britain. The Army encouraged Abney's photographic interests and at Chatham he offered a course in photography for which he wrote, in 1871, a pioneering textbook, *Instruction in Photography*.

An early culmination of his skills occurred in connection with his expedition to Egypt in 1874 to photograph the transit of Venus. Out of this emerged his improvements to the dry plate process, along with a book of photographs of historic temples at Thebes. Over the next decade, Abney made several lasting contributions to photography including the introduction of hydroquinone as a developing agent, the silver gelatin citrochloride process, and improved photographic printing papers (Ward 2008). He also published *A Treatise on Photography* which became a standard reference and went into ten editions. His astronomical and chemical interests intersected in his development of emulsions to capture the far infrared spectrum, for which he won the Rumford Medal in 1882. Abney's photometric researches on the visible spectrum, carried on the 1880s with his colleague E.R. Festing, resulted in several papers on chromatic photometry. He also wrote on the transmission of light in different atmospheric media and also supplied modifications to the Bunsen–Roscoe reciprocity law as applied to the exposure times of light sensitive materials. At this point in his career, his interest and writing became more specifically psychological as he considered color vision, on the one hand, and the perception of spectral lights on the other. His researches on color vision were eventually collated in his book *Colour Vision* (Abney 1895), which also went into several editions through 1913 and which E. G. Boring recommended, in his *History of Sensation and Perception in Experimental Psychology*, as a general reference. Abney was a proponent of trichromatic theory against the opponent-colors hypothesis. However, he was strongest in providing precise measurements of phenomena bearing on color vision, for instance, of the disappearance of hue sensations with increasing retinal eccentricity, which fed the ambiguity of the theoretical discussion. Abney was an

assiduous gatherer of facts and phenomena, and proposed several laws relating to visual phenomena which have in one way or another persisted in the study of perception. The first of the two best-known of these is called Abney's Law, which states that the luminance of a compounded stimulus equals the sum of the luminances of the contributing components. Abney and others proposed that this additivity would extend to brightness, but this eventually proved not to be correct (Cohen 2001). The second is his description of the regular change of perceived hue with increasing desaturation of spectral colors, termed the Abney Effect (Abney 1909). By varying the amount of red, green, and blue light in the white light he added, Abney demonstrated that the hue change was due to the red and green components. This quite striking effect has proved elusive of explanation since its proposal as it is not directly related either to retinal or central activity. Another "Abney Effect," more cryptic in terms of exposition and explanation, describes the apparent expansion and contraction of light in the visual field on sudden illumination (American Psychological Association 2008). Abney is also cited in connection with several other visual phenomena, for instance the circle of confusion in photography and microscopy. He also figured in the early history of color photography, inventing a camera for the purpose. And he was also interested in applications of color and visual science: for instance, toward the end of his career, he chaired a commission investigating the incidence of cataracts among glassblowers.

Ach, N.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: 29 October 1871; Died: 25 July 1946.

Son of a physician, Narziss Ach was born in Ermershausen, Bavaria, near Würzburg, and studied medicine and philosophy, obtaining his M.D. in 1895. He worked for a short time afterward with Kraepelin in Heidelberg and also traveled as a ship's doctor to America and East Asia, studying seasickness. On his return to Germany, he turned to the study of psychology, first in Strasbourg and then again in Würzburg with Oswald Külpe, where he obtained his Ph.D. in 1901. Then he studied with Müller at Göttingen, was posted as lecturer in Marburg in 1904, as professor in Berlin in 1906, and then in Königsberg for 15 years beginning in 1907. He succeeded Müller at Göttingen in 1922 and retired emeritus in 1937.

Major Accomplishments/Contributions

Ach is usually grouped with the psychologists of the "Würzburg School," including his teacher Külpe, Karl Marbe, and Karl Bühler, who were instrumental in introducing the study of central cognitive processes into experimental psychology. Ach did not view experimental psychology as a natural science because its subject matter is mental processes, though it uses scientific methods to access these processes. Ach's particular contributions to method centered around the will and were presented in several books, the most prominent of which were *Über die Willenstätigkeit und das Denken* (1905), *Über den Willen* (1910), and *Über den Willensakt und das Temperament* (1910), along with a much cited handbook chapter from later in his career, *Analyse des Willens* (Ach 1935). He utilized a combination of self-report on conscious states before, during, and after presentation of stimuli, along with chronoscopic measurement of reaction times, by which he claimed to have isolated and quantified the act of will. This he accomplished by extensive pretraining of

experimental participants in an associative learning and reporting task similar to those employed earlier by Ebbinghaus in his experiments on learning and memory. Then Ach varied the task so that the instructions to report resulted either in conflicts or conformity with previously learned patterns of response. Comparison of response times, for which Ach utilized the Hipp Chronoscope as well as instruments which he devised himself specifically for charting changes in will strength, revealed inferentially the presence of what Ach termed the “determining tendency,” an analog of the will, variable in strength and sensitive to the amount of resistance established by prior training (Teo 2000). The determining tendency was one of the component ideas that led to the concept of mental set. Ach conceived of the will as a goal-setting instrument which embodied free choice among the narrow ranges of possible alternative responses. He also observed that feelings of pleasure and frustration connected with, respectively, the achievement or thwarting of determining tendencies or acts of will. Ach’s influence was quite broad: he was often cited in American texts for his conception of the determining tendency and also as a more general representative of the Würzburg School, particularly in connection with the imageless thought controversy. Kurt Lewin took Ach as a starting point in formulating his gestalt field theory of goal achievement in the face of frustrating environmental barriers (Heckhausen and Heckhausen 2006). In contradistinction to the more “pure science” approaches to psychology in Germany at the time, Ach’s will psychology expressed moral and motivational sentiments as well. Noting that will strength could improve with training in both facilitating and frustrating conditions, Ach noted that “for our daily life, a struggle wherein success and failure occur is quite favorable” (Ach 1910/2006). He also related different patterns in persistence of struggle toward goals to personality types and offered suggestions for counteracting various weaknesses of will contingent on constitutional factors. Ach eventually became one of the central figures in German psychology as it changed from an introspective laboratory affair to an applied science: he was a member, after his move to Göttingen, of the Executive Committee of the Verband deutscher praktischer Psychologen (Association of German Practical Psychologists) and

contributed to efforts in the applied area well after his retirement, editing a 1944 handbook volume on the subject (Ach 1944). He signed the *Bekanntnis der Professoren und den deutschen Universitäten und Hochschulen zu Adolf Hitler und dem nationalsozialistische Staat* in 1933, in essence a loyalty oath to the Nazi regime, and the ascent of that regime, with its focus on will and action, gave new life and, unfortunately, new depth of meaning to Ach’s psychology.

Activation Network Theories, History of

MARK E. MATTSON

Fordham University, New York, NY, USA

There are very few candidates for Grand Unified Theories of all cognition, and activation network theories qualify. Whether called cell assemblies, perceptrons, semantic networks, neural networks, connectionist models, parallel distributed processing, or other names, the common elements of these theories are (a) that knowledge is represented by networks of units and (b) that processing is carried out by activating these units. For example, units or nodes may represent the features of a stimulus, letters, words, visual images, memories, sounds, people, ideas, actions, etc. Each unit has an activation value. The more activated a unit is, the greater its impact on connected units. The impact

could be excitatory, making connected units more active, or inhibitory, making connected units less active.

The history of activation network theories exemplifies an interdisciplinary approach to theory, with three primary disciplinary threads: Philosophical/Psychological, Neurobiological, and Computational.

Philosophical/Psychological: Philosophical Associationism, beginning with Aristotle and developed by the British Associationists/Empiricists, is one thread. Locke, Berkeley, and Hume wrote about the association of ideas as the basis of a new epistemology, and described the laws of association: contiguity and similarity. Hartley attempted a physiological theory of association. In the late nineteenth century, psychologists Ebbinghaus and Calkins tested the laws of association. When Behaviorism became dominant in American psychology, association of ideas was replaced by learning as establishing associations between stimuli and responses. For example, classical conditioning was viewed as establishing an association between the conditioned stimulus and conditioned response due to contiguity.

Neurobiological: Another thread is neurobiology, from Hartley's vibratiuncles to the notion of networks of neurons connected by synapses as developed by Golgi, Ramon y Cajal, and Sherrington. An important landmark in the neurobiological and psychological history of activation network theories is Hebb's (1949) *Organization of Behavior*, which proposed cell assemblies and a learning rule as a way to integrate behaviorist learning theory and Gestalt psychology. The Hebb learning rule says that when two cells are active at the same time (contiguity), they become more efficient at making each other more active. This led to the development of mutually reinforcing cell assemblies representing higher level organized entities: perceptual wholes or gestalts. Konorski (1967) similarly advanced a neural network theory, with hundreds of modules composed of about four layers of cells. Within layers, cells laterally inhibited each other, while between layers, connections were generally excitatory.

Computational: The twentieth century brought advances in the study of computation, especially the work of Turing, which also had an impact on activation network theories. McCulloch and Pitts' (1943) biophysical and computational analysis showed that networks could be constructed that were equivalent to

a Turing machine in computational power: able in principle to compute any finite logical expression. But not every network can compute every function, and even networks that can compute the same function may differ in completion time and/or efficiency. Some of the computational limitations on simple networks for learning were explored by Minsky and Papert (1969) in *Perceptrons*.

Cognitive Science – Interdisciplinary Research: Collins and Quillian (1969) brought Quillian's work in Artificial Intelligence to a psychological audience with reaction time studies of an activation network theory of semantic memory. The 1970s witnessed a number of research programs blending psychological experiments and computer models of activation network models of memory, including later work by Collins, the LNR Research Group, and John Anderson. These theories had localized representations, with a single unit representing (for example) CAT, linked to a cat's properties, superordinate and subordinate units.

In the 1980s, localized network theories were applied in many areas of psychology outside memory: for example, visual, auditory, and musical perception, speech production, skilled typing, cognitive maps, and classical conditioning. At the same time, distributed representations were becoming more common in memory and learning theory. In distributed representations, no single unit represents CAT – instead, the representation of CAT is a particular pattern of activation across a number of units, which are often conceptualized as the features of CAT. The two volumes of *Parallel Distributed Processing* (1986) edited by Rumelhart and McClelland (1986) included both local and distributed activation network theories. A lab manual with software to run simulations of the models was also published. The major theoretical breakthroughs were methods for learning that transcended the limitations of the perceptron: the auto-associator and back propagation. The PDP books took an explicitly interdisciplinary approach, with chapters focusing on biological, psychological, and computational aspects of activation networks.

Textbooks took a while to catch up with these developments. Martindale's (1991) *Cognitive Psychology: A Neural Network Approach* filled this gap in coverage until the late 1990s, when cognitive textbooks finally began to incorporate more than just semantic

networks. Ellis and Humphrey's (1999) *Connectionist Psychology: A Text with Readings* reviewed the field and is a fitting closing for a history of activation network theories in the twentieth century.

Adams, D. K.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: Mar. 6, 1902; Died: May, 1971.

Donald Adams attended Yale and obtained his Ph. D. in 1927, studying with Yerkes. He was from the outset interested in the potentiality of mind in animals. In his earliest publications, he held forth for a comparative method based on rigorous self-observation to infer the existence of mind in other organisms, rather than ruling it out of hand immediately as a nonparsimonious hypothesis (Adams 1928). In his early experimental work with cats, in which he utilized many variations on puzzle boxes and other problems, he criticized the views of Thorndike that cats lacked sophisticated mental functions. Instead he conceptualized cats' behavior in terms of "foresight" and "practical ideas" (Adams 1929) and advanced the ideas and

interpretations of McDougall, Tolman, and Yerkes regarding the complexity, adaptiveness, and purposiveness of animal behavior. He held these views through his career: much later, he affirmed the view that "analogomorphic" processes similar to Gestalt perceptual mechanisms exist for perception of others' subjective states, a sort of empathic direct perception (Adams 1962). Adams was called to Duke University as chair in the early 1930s, when psychology was split off from philosophy in the department, and remained there for the rest of his career.

Major Accomplishments/Contributions

While at Duke, Adams came into conflict with J. B. Rhine, who had been brought to Duke by William McDougall during his move from Harvard. Rhine had been assisting McDougall in a series of Lamarckian experiments and had also begun an extensive program of parapsychological research. Along with his colleagues Karl Zener and Helge Lundholm, Adams successfully demanded that Rhine be removed from the psychology department to an independent institute on the periphery of the psychological enterprise at Duke (Klopfer 1999). Adams later wrote an unpublished essay in which he admitted that he wanted Rhine to fail and harbored a prejudice toward him, which discomfited him as a scientist (Adams, n. d., quoted in Horn 2009). Adams had some postgraduate experience in Germany and, with Zener, who had come into contact with Kurt Lewin during a postgraduate year in Berlin, translated Lewin's *A Dynamic Theory of Psychology*. Gestalt ideas of organization in action fit well with Adams's understanding of the logical and purposive nature of animal behavior. He was a trenchant critic of some of the reigning, non-Gestaltist behavior theories of his time. In one of the earliest criticisms of Hull's hypothetico-deductive system, Adams identified fundamental flaws in that approach, chief among which was, in Adams's view, Hull's reliance on the logical fallacy of affirming the consequent rather than adopting a procedure which would allow for falsification of hypotheses. He also criticized the large number of undefined primary terms in Hull's system (Adams 1937). Later, Adams (1948) also critiqued Guthrie and Horton, noting that the graphic results of cats' behavior in their otherwise superior puzzle boxes did not allow

disambiguation of purposive from accidental behavior. On the other hand, Adams was magnanimous in his estimation of McDougall, for whom he wrote an obituary (Adams 1939). He did not gloss over McDougall's Lamarckism, but at the same time he commended his purposivism and mentalism, which he saw as ahead of its time. Indeed, Adams took over McDougall's idea of "sentiment," an organized system of emotional dispositions relative to objects, and placed it at the center of his writings on personality in the early 1950s. Adams was a participant in the 1953 Kentucky Symposium on Personality (Adams 1954b) and expressed the view that interconnected sentiments, all instrumentally focused on a central idea or aim, connoted an integrated personality (Adams 1953). A strong Lewinian influence regarding the valency of situations and the theoretical importance of conflict was evident in Adams's views (Adams 1954c). Adams also suggested that personality, conceived as a unique adjustment to the world through learning, might be a property not only of humans but of any organisms that learn (Adams 1954a). In the mid-1940s Adams served as Chief Clinical Psychologist at a Veterans Administration Branch Office alongside his professorship at Duke: his *Reflections from a Branch Office* (Adams 1947) is a pointed observation of the impediments facing psychologists entering the medical environment of the VA under emergency conditions at the end of the Second World War. At the close of his career, Adams cofounded the Field Station for Animal Behavior Studies at Duke and spent a sabbatical at Seewiesen, Bavaria, with Konrad Lorenz. Among the many species represented at the station were Adams' favorite, wild turkeys (Klopfer 1999).

Adler, Alfred

MICHAEL MEIR

TCI College, New York, NY, USA

Basic Biography

Alfred Adler was born on February 7, 1870, in Penzing, Austria. His early childhood was plagued with disease, including rickets and pneumonia, which heavily

influenced his decision to become a physician. In 1895 he received his medical degree from the University of Vienna, where he met his wife, Raissa Timofeyewna Epstein, a Russian student who was also an intellectual and social activist.

Starting out as an ophthalmologist, he quickly switched to primary care. His clientele came from the lower strata of society, including workers from the combination amusement park and circus close to his office. In 1902 he met Sigmund Freud and became part of the psychoanalytic movement he had created, rising to become President of the Vienna Psychoanalytic Society in 1910. However, since his ideas were often at odds with Freud's, a year later Adler and his supporters formally broke with the psychoanalytic school. Adler believed that the exterior or social realm was as important as the interior realm.

Shortly thereafter, Adler published a book titled *The Neurotic Constitution*, in which he promoted the idea of individual psychology. Linking this concept with that of holism, a subject dear to his heart for many years, Adler developed an approach to psychotherapy that emphasized the patient as a whole, rather than a collection of subcomponents such as the id that required separate analysis. Moreover, the patient was considered not in isolation, but rather in the context of family, work colleagues, and society. This approach became known as the "school of individual psychology."

Adler's ideas were further shaped by his brutal experiences as a physician in the Austrian Army in World War I and later at a children's hospital. He theorized that war, which engendered extreme violence, social conflict, and terrible suffering, could be viewed through the lens of individuals whose personality dysfunctions rooted in childhood perpetuated such horrors once they reached adulthood.

After the war, Adler founded a number of child guidance clinics in Vienna. His observations led him to believe that three key factors shaped a child – *pampering*, *neglect*, and *birth order*. These, he said, were responsible for children developing a story about themselves in which a series of partial truths represented the beliefs of the young child and later formed the basis for adult decision making and interaction with the world. In Adler's view, people's stories could be changed, if they were not serving them well, through a Socratic and equal dialog in which the

analyst laid bare the elements of the story for the patients to see clearly for the first time.

During extensive travel throughout the 1920s in Europe and the United States, Adler began to refine a number of concepts. For example, Adler strongly believed that birth order in a family had a profound effect on a child's belief systems, despite the lack of scientific evidence at the time for this concept. In Adler's theory, the eldest child was likely at first to be pampered and then forced to help raise younger siblings while being deprived of focal attention. Youngest children, however, were likely to be overindulged, leading to a lack of social empathy, while middle children had the best chance of being balanced, even though they might later rebel due to feeling left out. Adler also cautioned against corporal punishment and encouraged parents to walk the thin line between too much pampering and inadvertent neglect. By making children feel part of the family, Adler reasoned, they would be less likely to feel isolated and develop neurotic personalities.

In 1927 Adler became a visiting professor at Columbia University, and then took a similar position at Long Island College of Medicine in 1932. His move from Europe to the United States was hastened by the gathering power of the Nazis, who forced him to close his clinics in Vienna because of his Jewish heritage and emigrate with his family in 1934. He died of a heart attack on May 28, 1937, in Aberdeen, Scotland, where he had been lecturing.

Accomplishments

Adler was a profound communicator in his scholarly works, books, and lectures to his colleagues as well as the public, demonstrating uncommon insight into mental illness in a clarity of style that is rare today. He demonstrated uncommon insight into mental illness. He strongly believed that encouragement caused individuals to feel capable and appreciated, thus leading to positive and cooperative behaviors. Discouragement, he claimed, caused withdrawal, excessive competition, or quitting altogether. Most important, Adler maintained that one's relationship and behavior toward the world are dominated by a schema developed in childhood, a belief system that is created from childhood experiences such as constant neglect, one's "station" within the family, or traumatic/humiliating events. His student and then

colleague Rudolf Dreikurs popularized and extended these concepts after Adler's death.

Of the three great Viennese influences over modern psychology (Freud, Jung, and Adler), Adler has probably had the broadest and longest-lasting impact. For example, the noted psychologists Erich Fromm, Abraham Maslow, Rollo May, and Karen Horney have all been influenced by his ideas. Today many schools follow his teachings, including the Adler School of Professional Psychology in the United States.

In the Adlerian approach, one's style of life is the "master plan" from which thoughts, emotions, and behaviors can be understood. When a person is balanced, the personality dynamic is one of striving toward socially useful significance or superiority in the face of difficulty; in the case of mental health disorders, in contrast, it is subverted toward an exaggerated significance or a goal of superiority over others. If the sum of childhood experience is one of inferiority, the individual is pushed toward compensatory behaviors designed to bring about success and future security. By analyzing birth order (and its consequences), repeated coping patterns, and traumatic incidents in childhood, therapists are able to characterize patients' goals and lead them into fuller understanding. Then patients can be directed toward a sense of connectiveness and more socially beneficial paths, thus counteracting feelings of insecurity. This is accomplished through a Socratic dialog in which patients' current beliefs, attitudes, behaviors, and feelings are first examined and then challenged. Modifications take place through encouragement, which brings about possibilities for change, the development of confidence and growth, and a feeling of fulfillment. As they replace self-protection and self-enhancement mechanisms with avenues for more socially desirable goals, individuals can become more integrated into society.

In addition to his own life experiences, Adler was influenced by the philosophies of Kant, Nietzsche, and Virchow, as well as the statesman Jan Smuts, who created the concept of holism. Although a proponent of Marxism, he tended to focus on the social idealism embodied in this movement, stressing the importance of community and social interest (*Gemeinschaftsgefühl*) in which actions are taken for the common good. He was also an advocate of parent, teacher, and social worker training that could enhance child development,

so that children could learn to reason and exercise power within the framework of cooperation with others. In addition, Adler supported feminism to the extent that feelings of superiority or inferiority could be perceived as gender related and possibly cause problems for women. While he was opposed to homosexuality in his early career, regarding it as an inferiority complex toward one's own gender, there is some evidence from his later years in New York that his feelings on the subject might have changed into a *laissez faire* attitude, except for those patients who actively sought help in changing their sexual orientation.

Adorno, T. W.

ROBERT J. KELLY

Brooklyn College, Brooklyn, NY, USA

One of the most important and influential thinkers in the twentieth century, Theodor W. Adorno was an influential philosopher, psychologist, sociologist, and musicologist in Germany before and after World War II. His influence is based largely on the interdisciplinary quality of his research and writing within the circle of the Frankfurt School of Critical Theory which was a seminal group of intellectuals with Marxist orientations that continues to exert influence on contemporary thought in much the same way that the famed Vienna Circle did in Central Europe after World War I.

Apart from his intellectual activity, which consisted principally of philosophical critiques and analyses of

Western scholarly traditions, he is best known for his radical Marxist dissections of contemporary Western societies built upon liberal/conservative capitalist foundations.

Theodor Wiesengrund Adorno was born in Frankfurt to a wealthy German wine merchant of assimilated Jewish background. His mother, Maria Calvelli-Adorno was Catholic and was also an accomplished singer-musician. His education was elitist; he studied music composition under Allan Berg and social philosophy with Siegfried Kracauer (Adorno 1992; Adorno and Tiedemann 1998, 2003). In 1931 at the age of 28, he received his doctorate in philosophy at Goethe University, on the aesthetics of the Danish philosopher, Soren Kierkegaard under the supervision of the theologian/philosopher, Paul Tillich. Two years later Adorno was expelled from Goethe University by the Nazis along with other Jewish professors and others espousing left-wing views. Thereupon, he changed his father's surname into a middle initial and adopted "Adorno," his maternal surname by which he became known (Kelly 2007).

The Institute of Social Research: The Frankfurt School

The agenda of this intellectual think tank focused on Marxist Scholarship and its understanding of political economy. While the Institute never produced a unitary social theory, many of its distinguished members shared a critical view of modern capitalism but did not embrace Soviet Communism as a derivative political model of Marxism. Eventually, the school's cultural critiques and eclectic theories of mass society inspired by the works of Adorno and Max Horkheimer deeply influenced the new left during the 1950s and 1960s (Jay 1984a; Martin 1996).

When Germany found itself submerged in the Nazi ideology and the European war, the Frankfurt school went into exile with Adorno and Horkheimer working and teaching in American universities. At Columbia University in New York, Adorno worked with Paul Lazarsfeld, an important sociologist who laid the groundwork for modern communications research that is so vital in retail commercial activity, opinion surveys, and contemporary electoral political polling. The experiences in the USA – particularly with the Princeton University Radio Research project – enabled

Adorno to articulate his ideas about the "culture industry" and what he called, the "administered society" (Adorno 2002b, g).

After returning to Frankfurt in 1949, Adorno resumed teaching and research in the revived and reformed Institute of Social Research located in Goethe University.

The history of the Frankfurt school would be woefully inadequate and shortsighted if it failed to accord major significances to Freud's ideas in the development of Critical theory – the main intellectual thrust of the Frankfurt school's institute (Rainer 1994). Freudian thought played a central role in the works of Horkheimer, Marcuse, and Habermas, but none was more influenced by him than Adorno. In some ways, Adorno was an orthodox Freudian: Early on, he supported instinct theory, in contrast with the psychoanalytical revisionism of Erich Fromm and Karen Horney who objected to Freud's biological determinism. He challenged the views of some leading American proponents of sociological functionalism such as Talcott Parsons of Harvard, who sought to integrate psychoanalysis into a more comprehensive socio-psychological theory of "social action" that Parsons and his influential circle in Harvard were developing (Alvin 1972; Cook 2005). Yet Adorno, always the closet Kantian, parted ways with some of Freud's views believing that Freud tended to collapse or reduce external reality into a purely psychological universe. Still, not withstanding his reservations with some of Freud's views, he remained impressed with the Freudian methodologies and the epistemological mechanics of Freud's metaphysical orientations. For Adorno, Freud did not seem to fully appreciate the issue laid out by Kant in his *Critique of Pure Reason* as to what the requirements had to be (if knowledge were possible at all) that would enable us to acquire knowledge (Adorno 1959, 1965). Adorno saw Freud's psychological atomism as mistaken because it minimized the importance of social factors in shaping the meanings attached to sensate experience which represents the initial steps of knowledge production in the experiential stages of cognitive growth and consciousness (Adorno 1990). Indeed, as he later argued in other works, under advanced capitalism, individuals can be reduced to isolated monads. Freud, ironically, appears to be right even when he was wrong (Adorno and Horkheimer 1947/2002).

Though Marxism is deeply suffused as intellectual data throughout Adorno's works, the main features of his version of critical theory can be said to be Freudian. He did not lose sight of the fact that every object is the product of history and that the subject plays an active role in the acquisition of knowledge. This idea fits well with psychological thought which, while inheriting some principles of nineteenth century empiricism and materialism, is fully hermeneutical in its clinical application and in the way in which it adheres to a nonpositivist conception of truth. For example, rather than prescribing a neutral analyst, some types of psychoanalytical practice require an active intervention on the part of the therapist. The idea is that some objectivity about the patient's emotions and mental states is best achieved through interactions in the clinical sessions. Getting a closer picture of the patient's emotional and mental conditions is best achieved intersubjectively. Likewise, in Adorno's notions of Critical theory, the object is observed from an immanent, interior viewpoint, not from a transcendent perspective like that adopted in the positivist-oriented sociology of knowledge. And this is Adorno's point of view about some of the elemental conceptualizations of psychoanalysis, where it attempts to make conscious the social determinants of individual pathologies by seeking to discover or unravel the complex dynamics of those determinants not in the external world but rather through the imprints they leave on the mental and emotional life of the patient (Whitebrook 1995).

Another comparison that illustrates the conceptual convergences of Adorno's Critical theory – which may be generally described as a sociopolitical, cultural critique of social institutions – and Freudian psychoanalysis can be found in the principle of nonidentity. The view here is that under extant social conditions (capitalism) no synthesis can unite subject and object, particular and universal – or put more concretely, what disparate, inherently conflictful are the individual's aspirations to happiness and the unforgiving imperatives of society (Herbert 1955). The critiques of culture and personality Adorno developed were based on two psychoanalytic categories: projection and identification. The affinities between the two and Adorno's overarching sociological schemas owe much to Freud's thinking.

Through identification (or the socialization process described by many social psychologists and symbolic interactionists such as Erving Goffman (Kelly 2007) within societies with nuclear-type family structures that are typical of Western societies, the individual is acculturated into its customs, folkways, and social norms. In projection, the individual protrudes, expels into the larger social world, impulses, emotions, and ideas. Identification is essential for an individual's social integration, and projection is a necessary requisite for the individual's acquisition of cultural knowledge, which occurs as the individual reacts to societal demands and adjusts his affective behavior and ideas accordingly. In the social models elaborated within the complex sociocultural maze ways characteristic of Western societies, they may appear to tolerate greater autonomy, but are likely to produce false identification, where individuality may be effaced. Similarly, with real projection, the subject can acquire knowledge of the real world by processing the social data that socialization skills make available; while with false projection, the subject perceives an illusory reality that portrays his or her inner emptiness (Adorno 1983).

The two components of Adorno's theory – the critique of culture and the theory of personality – are transparently complementary. His critique of culture is focused on advanced, industrial societies with a close scrutiny to their institutional mechanisms for stabilizing and reproducing themselves at the expense of the mental or emotional health of its members. Institutional survival is achieved by creating psychological states conducive to rigid conformity. Social psychological studies in the USA in the 1950s described some of these conditions. David Reisman's *The Lonely Crowd* and his other works offer dynamic descriptions of the alienation of modern Americans in the 1950s – a postwar period of enormous urban and industrial/corporate development (David 1952, 1954). Adorno developed his perspectives using conceptual tools borrowed from Freud (Harkheimer and Adorno 2002). Perhaps today Adorno's reliance on Freud may seem anarchistic, but then, his discussions revealed the power of analyses that utilize a mix of disciplines to achieve a deeper understanding of the impact of society on individuals.

The Authoritarian Personality

In the post–World War II years, Adorno and his American colleagues at the University of California, Berkeley, conducted studies that addressed questions concerning personality structure and attitudes about social and political problems (Adorno et al. 1950). These investigations drew much of their intellectual energy and perspectives from Freud. A study was designed as an empirical survey that would explore a complex of issues about personality and beliefs as these related to particular social and political issues. The concept of an “authoritarian personality” constituted the principal orientation of the study. It was to focus on parental authority, child rearing, and personality development within the nuclear family unit. The concept was rooted in the practical realities of everyday family life in the postwar 1950s milieu.

What did Adorno and his colleagues hope to show in the survey of American family life about the authority of parents and significant others on the personality formation of children? Another issue concerned the prevalence of a certain type of child rearing apparently prevalent in working class and lower-class families that were beleaguered by poverty, lack of occupational opportunities, and poor education backgrounds. Adorno probably did subscribe to the view that the family was a miniature of society and its culture. But what kind of family did Adorno have in mind? Was it mainly urban, somewhat literate, but hard-pressed, or more middle class, comfortably situated in a decent physical environment with all the requisite accoutrements of acceptable schools, parks, transport, etc.? Were the families in the study to be not too prosperous but not too impoverished; typically working class and lower middle class? The issues of demographic sampling in the study would haunt its reliability for many social scientists that agreed with the basic premises of the work but were concerned over the viability of its databases.

The Authoritarian Personality sought to undercover what Emile Durkheim called a “collective or common conscience” – beliefs and customs acting upon one another; habits rather than institutions that animate social processes rather than social structure, which may be construed as a determinate system that has its own life, that is diffused throughout a society (Emile 1975).

Adorno’s sociopsychological portrait of American family life promised to be a valid picture of the materialist character of the prosaic American family. However, this collective image of family moral geography that he sought to discover proved to be fugitive and elusive. It turned out that the work appeared to lack “objectivity”; it was not perceived as a disinterested analysis of socialization and child rearing into the cultural values that influenced American family dynamics. Like its forerunner, *An American Dilemma* (1944) produced by the Swedish sociologist Gunnar Myrdal who examined the causes and consequences of racism in American society, *The Authoritarian Personality* was advertised as a deep diagnosis of the culturally deformities of family life in a society dominated by a capitalist political ethos. The psychological ramifications of a capitalist system promoted in the authors’ views, a proto-fascist personality. Adorno and his colleagues set about to measure and delineate the dimensions of this personality disposition or syndrome.

According to Adorno and his colleagues, authoritarianism is a personality type that is a result of childhood experiences defined by at least nine traits clustered together. It was hypothesized that excessively harsh and punitive parenting lay at the base of the syndrome which predisposes individuals to destructiveness, cynicism, aggressiveness, toughness, and submissiveness to authority figures – all characteristics of a pre-fascist personality. The authors led by Adorno developed the study’s “F” scale that personally identified the key dimensions of the pro-fascist personality. The battery of questionnaires was administered to nearly 100 respondents who were randomly selected for the study. The methods of the study and statements about authority would display, it was believed, characteristics of this personality type. Respondents were asked to agree or disagree with assertion such as the following: “obedience and respect for authority are the most important virtues children should learn” (an indicator of submissiveness); “homosexuality is a particularly rotten form of delinquency and ought to be severely punished” (aggression and sex).

In addition to the measures of proto-fascist tendencies in *The Authoritarian Personality* (TAP), other research techniques were utilized to measure ethnocentrism; the researchers also administered thematic

appreciation tests in which subjects were asked to react to pictures of others; also the research relied upon clinical interviews that resembled psychotherapeutic sessions. Clearly, the research project sought to be thorough. However, critics of the study found numerous flaws in the methodology. For one, sampling the population of respondents was virtually nonexistent. The questionnaires were filled with inexact, flawed wording; long open-ended interviews were loaded in schedules that were too subjective. What subjects reported about themselves could not always be verified. The F scale in short lacked coherence and firm empirical grounding. Further, a prominent sociologist from the University of Chicago wondered if one could write meaningfully about the psychological phenomenon of authoritarianism by focusing exclusively on the political right. It was pointed out, based on historical studies, that an analysis that failed to recognize that the extremists of left and right ideological orientations were similar in their authoritarianism could only be factually flawed.

Despite such short comings, Adorno and associates insisted that a clinical account of those personality traits that predisposed individuals toward rigidity in beliefs and judgments, that demonstrated a lack of tolerance for others who were different racially, religiously, ethnically, politically, and different in terms of educational background, and evening aesthetic tastes was needed in order to be able to construct corrective therapies. Clearly, individual treatment would need to be supplemented by significant reorientations in the social units – principally the nuclear family – that nurtured extremist tendencies in personality formation. A modification of the family was only the initial step in massive social reconstruction.

Adorno and his colleagues drew some radical conclusions about their findings. They believed that in order for democracy to protect itself better against political extremism, the social structure and organization of society would have to be changed. However, Adorno concluded that the tendencies of authoritarian personalities are too rigid to change, to be significantly altered by the technique of psychotherapeutic interventions. The authoritarian personality was a product of the total organization of society; Adorno and his colleagues concluded that the authoritarian personality was an expression of the cultural deformities of late capitalism.

A central psychological idea of *The Authoritarian Personality* derives from Freudian psychoanalytic theory with its emphasis on early childhood experiences as the driving force of personality formation. In its general form, psychoanalytic theory suggests that young children internalize the values of the significant others in their lives, including their biological parents and members of their nuclear family and even members of family groups. In the case of punitive parents, children who are exposed to them are bound to acquire some of their traits and coping strategies. For Adorno, the collaborative efforts that produced *The Authoritarian Personality* (TAP) furnished much intellectual satisfaction despite the negative criticisms concerning research techniques, population samples, and interpretations of the data. However, he wrote that if TAP did anything it was not to be found in the conclusions or methodologies and measurements in the study, but rather in the conception of the problem. Following these groundbreaking efforts, other projects emerged seeking to empirically test psychoanalytic theorems. The intent behind TAP, according to Adorno, resembles the scientifically oriented impulses driving psychoanalysis as a practice: to determine the origins and bases in the psychic structure of opinions and dispositions. Adorno and his colleagues were interested in the fascist potential; this was a central motif in the project. Practically speaking, in order to confront that dangerous potential, the researchers believed it was necessary to understand what clusters of factors contribute to the emergence of the authoritarian personality syndrome. Adorno and his coworkers conceived of their efforts as a pilot study – more of an exploration of possibilities than a collection of irrefutable results. Nonetheless, he believed the results were significant enough to justify the conclusions (Adorno 1998). Adorno's use of Freudian theory in *The Authoritarian Personality* illustrates the power and relevance of Freud's ideas in areas of research that go beyond the constrictions of conventional psychotherapy.

Yet, Adorno parted ways with Freud in some respects: he believed that Freud tended to collapse external reality into a pure psychological universe or space. But even here, Adorno continued to respect Freud. Though he thought Freud's psychological atomism mistaken because it tended to minimize the importance of social factors as a force shaping behavior and

personally, Adorno still thought the Freudian project basically correct in the practical terms of everyday life. Under advanced capitalism, however, he believed humans were reduced to isolated social and psychological monads – in modern terms, isolated, alienated, often angry persons gripped by the fear that they are alone in a frightful world. Thus, Freud was right even when he was wrong (Sheratt 2002).

Though Marxism also motivated Adorno's thought, the main structures of his critical theory are Freudian. Adorno's social constructivism never loses sight of the perspective, which argues that all sense data are historically conditioned and that the agency of the individual, the subject, plays an active role in the acquisition and assessment of knowledge. Such a view squares well with classical psychoanalytic thought, which while inheriting some principles of nineteenth century empiricism and materialism, is fully hermeneutical in its clinical applications (Ricoeur 1985).

Freud's relevance extended well beyond his psychotherapeutic insight, themes, and methodologies. Some of the more profound views of Freud concern how civilization itself, produces its dialectical opposite – anti-civilization. Adorno believed that the “popular” essays like *Civilization and Its Discontents* and *Group Psychology and The Analysis of the Ego* deserved the broadest dissemination. If barbarism itself is inscribed in the principle of civilization, then there may be something rather desperate in attempts to use against it. Auschwitz, the symbol of genocide, cannot therefore be dismissed as an aberration, as a superficial or fortuitous phenomenon to be disregarded when compared to the dynamic progress of the Enlightenment and the supposed growth of humanitarianism that it fostered. Indeed, for Adorno, genocide resurrected itself under the guise of nationalism at the end of the nineteenth century when the full swing of robust nationalism was strengthened by a toxic alchemy of progress and science that took root in Western Europe and that seemed initially to be both politically and economically liberating (Adorno 1967, 2003).

Since the possibilities of changing these objective, historical conditions are limited, we are left with attempts to works against the repetition of Auschwitz – meaning in a contemporary context, genocide. Unfortunately, appeals to eternal values and humanistic impulses are ignored by those inclined to mass murder

who merely shrug their shoulders. What is always doomed to failure are appeals to spare the victims. The roots for change, according to Adorno, must be sought in the persecutors themselves, not in the victims (Frantz 1959). This point is powerfully made in Frantz Fanon's books on the appalling brutality of colonialism. In general, one must come to know the mechanism that enables people to become capable of such deeds such as mass murder, torture, and systematic violence. Adorno believed in the findings of depth psychology that argued that all personalities, even those who commit atrocities in later life, are formed in early childhood. Thus, the possibility of hope for change is real if formative qualities permeate the psychic structures of persons.

Freudian Theory and Fascist Propaganda

In *Group Psychology and the Analysis of the Ego* Freud foresaw the rise and nature of fascist mass movements in purely psychological categories. Adorno has a high place for Freud's ideas given the dramatic growth and expansion of mass politics in fascist contexts that was neither foreseen nor ignored by orthodox Marxists. Adorno's principal interest in psychoanalysis was its delineation of social trauma that broadened the range and flexibility of psychotherapeutic practice and which made emotional stress a social health issue that could be treated – as Fanon was able to demonstrate in his psychiatric practice among oppressed natives in the colonial settings of Algeria after World War II. The focus on social trauma constituted a step forward toward the healing of the individual within society, to the extent that diagnosis precedes cure. This is not to suggest Adorno's interest was with psychoanalytic therapy per se, which addressed the individual psyche and whose healing or curative process was not applicable to the social whole – which would constitute the central object of interest of a sociologically oriented social scientist and philosopher. While the diagnosis Adorno sought was social not individual, the specific detail of individual psychosis elaborated by Freud and his collaborators could in turn inform a broader, collective social diagnosis. As he put it in the Dedication of *Minima Moralia* “society is essentially the substance of the individual” – a classic Durkheimian idea (Adorno 2002c). He also believed with Marx that the

inexorable outcome of the fetishism of commodities is the nightmare of a world congealed into products. Inexplicably, benign men who have subjugated themselves into the malignant grip of capitalist oppression have compounded the ensuing immiseration of the masses. In this Marxist gloom of economic enslavement, Freud seems like a lifeguard poised to rescue his disconsolate patients in order to restore their equanimity from the squalls of anxiety, depression, and the alienation that dehumanizes them. Adorno, Marx, Freud, and even this nineteenth century novelist William Thackeray are kindred roles in this regard: each has attempted to show not so much the way in which the individual enters history, but the way in which history – accidentally, fortuitously, calamitously, and unpredictably – enters the individual.

In his political writings, Adorno focused on fascism and its destructive ideologies seeing them as a bizarre mix of hocus-pocus, preposterous conspiracy theories, simplistic interpretations of Nietzsche, and violent anti-Semitism. Nor did he not ignore some of the pathologies associated with the politicized versions of Marxism – including the Leninist contempt for the decadent West, for Jewish merchants, for traditional religion, for the “backward” peasantry. He understood that both Nazi and Bolsheviks experienced World War I as a kind of apocalypse, an event that proved that Christian morality had failed, and that something totally new had to be put in place. As a result, violence and radicalism were more common in the 1920s and 1930s Europe than we choose to remember.

Music and Psychology: The Poetic Fallacy

Because musical genius may be found among political monsters such as Richard Wagner, that does not mean that the intrinsic quality of their cultural products may be so tainted that they need to be censored. Or does it? For example, some American liberal culture publications persist in treating Stalinist terror with a measure of equivocation that Nazi terror does not permit. Stalin killed more Ukrainians than Hitler killed Jews, but music celebrating Hitler will not be performed in New York anytime soon. Doing so would transgress a moral line.

Adorno believed that time might very well erode that line and alter how music is heard, or how pictures

are perceived, or books read, so that art glorifying, say, Assyrian tyrants, French despots, or American robber barons may eventually strike us as beautiful because we have come to accept, tacitly, or unconsciously, some moral acquiescence that time and opinion have eroded (Adorno 2002a). But cultural historians still have a professional and ethical obligation to point out where the line against sordid art once was.

In various writings, musicologist Richard Taruskin claims that most musicians and music listeners are inclined to turn a blind eye on morally and politically dubious aspects of serious music (Taruskin 2006, 2007). This implies that the main legitimate object of praise or censure in art is the quality of its production. Sustaining a work in the categories of high art may have little to do with the political predilections of the author/composer and more to do with an ambivalence or an enthusiasm for it dependent upon specific artistic contexts. The artistic context constitutes a presentational format for a work and not only is it crucial in a work’s performance but also in its appreciation no matter what circumstances affects its provenance.

Adorno’s attitude toward Wagner’s art is particularly relevant because it reflects a profound change of heart (Adorno 2002d). In a poignant essay, he declares that Wagner no longer possesses the boundless authority of earlier times.

Even the stormy applause a listener may encounter following a performance of *Die Meistersinger*, there is still something about it of the old virulent evil. With some apprehension, in strained, convoluted language Adorno makes the point that Wagner’s music speaks the language of Fascism (Adorno 1984). With uncharacteristic candor, Adorno declared: “as the National Socialist potential continues to smolder within the German reality, now as then, so it is still present in Wagner. The question of whether and how Wagner should be performed can be separated only wrenchingly from the acknowledgment of such demagoguery. At an earlier time I attempted to localize this demagoguery precisely in the purely musical-aesthetic form. But if I am allowed to express myself so personally, perhaps my criticism has now earned me the right to emphasize what has outlasted it. The position of consciousness toward Wagner that I experience as my own whenever I encounter him . . . is . . . deserving of the appellation ‘ambivalent’” (Adorno 2002e).

Furthermore in another version of the essay: “The attitude toward Wagner. . . is ambivalent. [Like] a pendulum swinging between attraction and repulsion” (Adorno 2003).

Adorno steps aside from consideration of moral responsibility in art. Perhaps what is worse is Adorno’s appearance of sentimental complacency regarding Wagner’s mixture of genius and rabid anti-Semitism. Though Adorno obfuscates the issue in his essay and its revision on Wagner published a year later by his executors, the painful question remains: are we not debased and diminished, as artist and human beings, by commitment to “abstract” musical worth? Can art inflict harm? Is it simply morally blameless? Might totalitarian regimes control art because they believe it to have significant political and psychological consequences? In modern times, the Taliban in Afghanistan and Pakistan certainly believes this and not because they are ill-advised or artistically churlish; perhaps we are historically blind or sanctimonious in thinking that classical music is indispensable and culturally superior. Short of morally indicting himself over Wagner, Adorno preferred to live with the tensions induced by his aesthetic dilemmas.

Adorno’s assimilation of Freud’s psychology into his social theories functions as a shield against the unexpected use of fascist mass politics which was largely underestimated and unforeseen by many otherwise prescient orthodox Marxists (Jay 1984a). In point of fact, Adorno’s primary interest in psychoanalysis was its brilliantly elaborated delineation of socially induced trauma. It makes good intellectual sense that after Marx’s powerful descriptions of the baneful effects of capitalism on social organization, that Freud would depict the emotional consequences and pernicious costs of these omnipotent socioeconomic systems on the psychic life of the individual. One might say that to identify and analyze social trauma and its particular features constituted a step forward in the healing of the individual within society to the extent that diagnosis precedes but does not presume a cure. This is not to suggest that Adorno held more than an abiding interest with psychoanalytic therapy which addresses the individual psyche and whose healing remained at least theoretically distinct from the social whole. The diagnoses Adorno sought in Freud was social not individual, though the specific details of individual psychosis

could in turn inform social diagnostics. As he put it in *Minima Moralia*, “society is essentially the substance of the individual.” (Adorno 1978) Adorno’s social psychology is much governed by studies of the family as a kind of sociopsychological middle ground between the individual and the larger society. More importantly, Freudian psychoanalysis which is primarily a historical and based on a biological premise nonetheless “expressed, at best metaphorically one aspect of the nonidentity of man in an unreconciled totality (Martin 1985).

Freud’s intellectual career as a gifted and important psychological researcher and therapist was launched by the publication of *The Interpretation of Dreams* at the turn of the twentieth century. It was a groundbreaking meditation and exploration of parts of the psychic life labeled under the rubric of “dreams.” During his lifetime, Adorno was fascinated by his dreams and transcribed those he could recall. His book, *Dream Notes* (Adorno 2007) contains his select writings on dreams that cover the later decades of his life. Unlike his other works on philosophy, music, culture, and social theory, those writings are very subjective, frank, and often uninhibited accounts of his inner, emotional life, presented without the ornamental apparatus of high-powered, lofty philosophical prose, or scathing polemic filled with speculative gusto and dialectical fireworks for which he was well known. Nor is there any attempt at hermeneutical interpretation enveloped in his famous rebarbative density; nor was it a psychoanalytically oriented self-analysis. He mundanely asked whether dreams might simply be fictitious, or autobiographical, or psychic activity seeking to capture a pre-rational, mythic slate of consciousness. No clear answer emerges from these considerations. Freud’s intellectual career as a gifted and important psychological researcher and therapist was launched by the publication of *The Interpretation of Dreams* at the turn of the twentieth century. It was a groundbreaking meditation and exploration of parts of psychic life labeled under the rubric of “dreams.”

Adorno’s critique of culture and the personality theories had intellectual consistency. The cultural analysis reported in such works as *The Culture Industry* (2001) shows that his work was neither pure philosophy, sociology, or psychology, but belonged rather to a class of sociopsychological reflection on society and

the self to be found in the works of Eric Fromm and Herbert Marcuse whose intellectual taste was also Marxist and Freudian.

For a writer with wide-ranging interest, the essay form was suited to Adorno because it permitted spontaneity and intellectuals play that in their own form, replicate the spirit of emancipation and function as a magnifying glass (Adorno 2002f; NicholSEN 1997).

Adorno's critique of culture focused on postindustrial society and its numerous mechanisms, institutes, organizations, and agencies for stabilizing and reproducing itself on both cultural and psychological levels. At the core of his theory of personality is a kind of human being that postindustrial society requires and sustains in order to perpetuate itself. In the explanatory essay and works describing and analyzing the processes of the phenomenon, Adorno utilized conceptual tools borrowed from Freud. Today, in the twenty-first century, exclusive references to Freud, may appear anachronistic in terms of contemporary thought, but even here, such references and deferences to the intellectual fecundity and authority of psychoanalysis in the body of works or important social thinkers like Adorno certifies the importance of Freud in coming to grips with the social dynamics and conflicts of modern society.

When Adorno returned to Frankfurt University after World War II to resume his work there, he observed that his American exile was notable for the culture shocks it induced. His life was molded in Germany before he became an émigré, just as his alienating years in America reshaped his sojourn back to Germany (Jay 1984b).

The musical dimensions of Adorno's life and career are too often neglected in considering his importance as a political commentator. Of his entire oeuvre (20 volumes) comprising 10,000 printed pages, more than 4,000 concern music. Adorno wrote long monographs on his former teacher/mentor, the composer Allen Berg, Gustav Mahler, and Richard Wagner; he left unfinished at the time of his death a career-long project on Beethoven (Adorno 1984, 1988, 1991, 1998). Musically, his concerns were almost exclusively Western European, and he rarely investigated music prior to Bach. Even his philosophical and political admirers in this regard have often noted Adorno's eurocentrism (Said 1991). He worked to revise the Institute of Social

Research, which housed the bevy of intellectuals and professors engaged in the production of "Critical theory." The criticism of the theory's lack of a social agenda to organize, institutionalize, and drive the theories of social change and justice ahead were epitomized by George Lukacs who wryly observed that Adorno and his colleagues enjoyed the good life in the comfortable insulation of the ivory tower/institute they inhabited savoring the pessimism and disjointed social unrest they triggered by their descriptions of the misery they recognized. This led to a chorus of similar critiques insinuating that Adorno and his crowd took up residence in the "Grand Hotel Abyss" – a beautiful hotel, equipped with every comfort, on the edge of an abyss, of nothingness, of absurdity" (Georg 1971).

It seems odd that the student movement protest that Adorno and his colleagues should have vigorously supported were, oddly, largely ignored by the "radical" professors in the Institute. The public critique of Critical Theory and Adorno occurred in 1966–1967 when student protests focused on federal school reform. The first point of violence occurred when a student was killed by police in a Berlin demonstration protesting against the visit of the Shah of Iran. Shortly thereafter, Adorno demanded a public inquiry but left his intervention in the affair to that benign gesture of demanding a hearing into the events. It was seen as an ivory tower response, or, worse, a betrayal of the ideals underlying Critical Theory which had in the past furnished students with the intellectual training in social justice and culture. Critical Theory seemed to fail in practice.

In the face of students' attacks on what they regarded as Adorno's quietism, he wrote a brief essay at the end of his life where he staked out one last time the argument that valorizes that aesthetic qualities of life as the foreground for happiness. This failed to please people shaped by the thoroughly saturated raw politics of the Cold War and its aftermath along with a century of global mass culture imperiously linked to the modes and values of advertising, as Adorno himself pointed out so powerfully in his books. He died of a heart attack in 1969, perhaps heart broken that he could not reconcile with his students and critics. However, his appropriation of Freud and psychological theory into the perspectives of cultural and sociological

theory has deeply enriched the conceptual vigor of social science.

Epilogue

In 1967, Adorno wrote an essay titled “Education After Auschwitz.” In it, he argued that the moral corruption and ethical despair that made the holocaust possible remained, or as he put it, “largely unchanged” and that “the mechanisms that render people capable of such deeds, must be uncovered, examined, and critiqued through education”. Schools had to teach more than skills. They had to teach values. If they failed to do so, another Auschwitz was always possible.

“All political instruction should be centered upon the idea that Auschwitz should never happen again.” He went on to say that:

- ▶ This would be possible only when it devotes itself openly, without fear of offending any authorities, to this most important of problems. To do this, education must transform itself into sociology, that is, it must teach about the societal play of forces that operates beneath the surface of political forms (Adorno and Tiedemann 2003).

If we fail to grasp the “societal play of forces that operates beneath the surface of political forms,” we will be cursed with a more ruthless form of corporate power, one that does away with artifice and the seduction of a consumer society, and wields power through naked repression.

Adorno knew that radical evil was possible only with the collaboration of a timid, cowed, and confused population such as existed in Germany; with a system of propaganda and mass media that offered little more than spectacle and entertainment – also such as existed in Germany in the 1930s and 1940s, and an educational system that did not transmit transcendent values or nurture the capacity for individual conscience – these were the ingredients for mass deception, repression, and genocide. He rightly feared a culture that banished the anxieties and complexities of moral choice and embraced a childish hyper masculinity. “This educational ideal of hardness, in which many may believe without reflecting about it, is utterly wrong” Adorno wrote. “The idea that virility consists in the maximum degree of endurance long ago became a screen-image for masochism that, as psychology has

demonstrated, aligns itself all too easily with sadism” (Adorno 1959, 1965).

Does sadism, as Adorno implies, dominate the culture? Intuitively, one could sense that it runs like an electric current through reality T.V. and trash-talk programs; it is at the core of the multi-billion dollar pornography business, and fuels the compliant, corporate collective. Corporatism – a longtime fetish-like preoccupation of many social scientist and political writers – is laced with the emotional energies of sadism insofar as it is about crushing the individual capacity for moral choice that diminishes the individual forcing him or her into the conformity and silence of an ostensibly harmonious collective.

The logical fruition of the hypermasculinity is Abu Ghraib; not Monday night Football, but the wars in Iraq and Afghanistan, and our lack of compassion for our poor, mentally and physically ill, and the unemployed.

The crux of this problem for Adorno is educational: the political and economic forces which were not as mature and powerful as they are today are mediated by educational forces. We have bought hook, line, and sinker into the idea that education is about training and success defined in terms of dollars, prestigious status, and the other accoutrements of material success.

The corporate state holds up as our ideal what Adorno called the “manipulative character.” (Adorno 1959, 1965, 1990) With the notion of the manipulative character, one thinks of C. Wright Mills’ descriptions of the power elite in this connection and their superb organizational skills who nonetheless seem unable to have authentic human experiences. He or she is an emotional cripple. The manipulative type is a systems manager trained to sustain the corporate structure which may explain why our elites wasted huge amounts of public tax levies on large finance corporations.

It especially difficult to fight against it, wanted Adorno, because manipulative people who are incapable of true experience, for that very reason show an unresponsiveness that makes them seem to the psychologically trained somewhat mentally ill or psychotic. Much of this is discernible to the sociologically and anthropologically sensitive observer like C Wright Mills. An examination of their backgrounds and educational experiences reveals that the insulated status groups elites inhabit plus their specialized

educations has a tendency to perpetuate the extant social stratification that is widespread across society and harmful in that opportunities and occasions for contact and communication across class boundaries are restricted. Elite power has a blind belief in a decaying political and financial system that has nurtured, enriched, and empowered it. As Adorno realized, the elites with their authoritarian bluster cannot solve our problems.

“The mindless tasks imposed by authoritarian culture on the subject classes can be performed only at the cost of permanent regression. Their formlessness is, precisely the product of social form” (Adorno et al. 1950).

Ainsworth, Mary D.

ASHLEY SCARLETT BUJALSKI

Marymount Manhattan College, New York, NY, USA

Mary Ainsworth was a researcher, experimenter, author, and prominent contributor to the field of personality and developmental psychology. She is most recognized for her involvement in early emotional attachment, and her development of the Attachment Theory.

Basic Biographical Information

Mary Ainsworth was born into a strong and supportive family in Glendale, Ohio in 1913. Her mother and father both had educational degrees, and her father received a promotion which required the family to move to Canada when Ainsworth was 5 years old. Ten years later, at age 15, Ainsworth read a book entitled *Character and the Conduct of Life*, by William McDougall, which changed her life forever, setting the path for her career in psychology.

In 1935, Mary Ainsworth graduated from the University of Toronto, along with honors in psychology. In 1936, she earned her master's degree, and finally her Ph.D. in 1939 all from the same college. She met Leonard Ainsworth in 1950, and they married and moved to London. Around this time, Ainsworth met John Bowlby, who was the director of a research team in England where Ainsworth enrolled. She quickly became involved in a project he was conducting that sought to discover the effects of early separation from a mother on children's personality development.

Mary Ainsworth furthered her research when her husband accepted a job position in Uganda in 1954. Ainsworth went with him, where she had the opportunity to study how mother and infants acted in their natural settings. From her findings, Ainsworth came to the conclusion that several attachment patterns form between a mother and a child. Later on, Ainsworth

wrote that the type of pattern, whether it is conflicted or secure, all stems from the affection and attention that mothers showed their infants in the first few months after their birth.

Major Contributions

From the information Ainsworth gathered, she coined the term and developed the procedure called "Strange Situation" in 1960. Still used today, the goal is for the researcher to be able to evaluate differences in the reactions of infants to several separations and reunions with their mothers. The researcher needs to create an environment that an infant would feel comfortable enough to explore in, and one that would generate the need for security. The child is taken to an unfamiliar room filled with toys, and is left alone with his or her mother. The researcher then enters, and minutes later the mother is told to leave. The mother returns a little later, and the researcher records how the child reacts to both this separation and return. From the "Strange Situation" procedure that Ainsworth conducted, she was able to observe four major different types of reactions, which were all included in her Attachment Theory.

The first category in the theory is called "secure attachment." The type of children that would fall under this category would be those that explore the room without fear. When the stranger enters the room, the child is not scared to engage with the researcher. When the mother, or primary caregiver, of the child leaves, the child becomes distressed and stops interacting with the researcher. Upon return of the mother, the child no longer withdraws and goes back to exploring.

The next category is titled "anxious-resistant insecure attachment." Even though the caregiver of the child is in the room when the stranger enters, the child is still troubled by the presence of the stranger. He or she stays close to their mother in the first few minutes, and when she leaves becomes highly distressed. The child becomes even more upset when the mother returns, acting in an indignant way, and rejecting her closeness.

"Anxious-avoidant insecure attachment" is the third category. In this stage, a child will be indifferent to the environment and people present. The mother, caregiver, and researcher will not receive any attention

from the child. When the mother both leaves and returns, the child shows little or no interest. Mary Ainsworth noted that this is the category children belong in when a detached relationship between mother and child is present.

Finally, the last category is the “disorganized/disorientated attachment” stage. Although not originally noted by Mary Ainsworth, she later approved her colleague, Mary Main, to add it to the theory. Here, children have mothers that have gone through some sort of traumatic experience after the birth of their baby. The mothers were depressed, effecting the emotional development of the child. Around strangers, the child is upset and confused. When the mother leaves, the child will cry, but upon return the child will freeze or fall.

During the years Mary Ainsworth was researching, she and her husband went through a rough divorce. She became depressed, and began to become interested in Sigmund Freud after participating in psychoanalytic therapy. Regardless of her painful divorce, her love for teaching and exploration never stopped. She taught as a psychology professor at John Hopkins University for many years, and in 1975 transferred to the University of Virginia to work as a teacher and to continue her developmental research. Mary Ainsworth also wrote and printed many articles and books, the most well-known ones being the 1965 book *Child Care and the Growth of Love, Infancy in Uganda* in 1967, and *Patterns of Attachment* in 1978.

During the 1970s, Mary Ainsworth was a member of the American Psychological Association (APA), the British Psychological Association, the Virginia Psychological Association, The Eastern Psychological Association, and from 1977 to 1979 was the head of the Society for Research in Child Development.

From the 1980s all the way to the late 1990s, Mary Ainsworth began to become recognized and awarded for her important role and work in psychology. The APA awarded her the G. Stanley Hall Award in 1984 for her work in developmental psychology. She was awarded again by the APA in 1987, when she received the Award for Distinguished Professional Contribution to Knowledge, and again in 1989, with the Distinguished Scientific Contribution. Her biggest achievement was in 1998, when she was honored with the Gold Medal for Scientific Contributions by the American Psychological Foundation.

One year after her last award, in 1999, Ainsworth was still a professor at the University of Virginia. That year, she also passed away at the age of 86, leaving an inerascable and significant mark on the world of psychology.

Allport, G. W.

THOMAS F. CLOONAN

Fordham University, Bronx, NY, USA

Basic Biographical Information

Gordon Willard Allport was born November 11, 1897, in Montezuma, Indiana. His father was a country physician who was of English descent, his mother of German and Scottish heritage. He was the youngest of four sons. One of his brothers, Floyd, who was a student at Harvard University, was influential in Gordon's seeking admission to Harvard University. He referred to his home life as, “marked by plain Protestant piety and hard work.” In the context of the American demographic profile of 1897, there was nothing especially uncommon about Gordon W. Allport's family background. By the time of his death on October 9, 1967, however, in the context of mainstream American psychology of the first two thirds of the twentieth century there was everything quite uncommon about the psychology proposed by Gordon W. Allport.

Crucial to his development as a psychologist were what Allport described in his autobiographical essay (1967) as “two intellectual dawns.” The first dawn was

his experience at Harvard University, an ongoing experience beginning with undergraduate days there, through Harvard's conferral of the Ph.D. in psychology on him in 1922, and subsequent years totaling to a 50-year association with the university. In his autobiographical essay (1967), Allport refers to his association with Harvard as, "a deep attachment . . . an infatuation." Despite the oxymoron inherent in this description, the long-lived character of Allport's association with Harvard University evidenced itself in that association lasting until his death in 1967.

The second intellectual dawn occurred with the awarding of the Sheldon Traveling Fellowship that enabled Allport to study for 2 years abroad. He spent the first year in Germany where he was attracted to the new Gestalt school. He spent the second year in England where Frederic Bartlett provided facilities for him to work. With his return to the USA, in 1925 he married Ada Lufkin Gould whom he had met at Harvard. Ada worked in the field of clinical psychology. Robert Bradlee was born 2 years later. The son eventually became a pediatrician.

The two intellectual dawns that Allport experienced, the one of intellectual inquiry in Harvard and the other of experiencing different intellectual perspectives in Europe, occasioned a stretch in the formation of Allport's maturity as a psychologist. The European dimension of the second dawn, specifically, was a sensitization to social contexts and to new schools of psychology. Allport's research psychology with its insistence on the priority of personality and social psychology had, perhaps, its origins from the life experiences of these "dawns."

Major Accomplishments/ Contributions

Allport's interests in personality and social psychology were reflected early on in his dissertation, "An Experimental Study of the Traits of Personality: With Special Reference to the Problem of Social Diagnosis." His commitment to these areas of psychology was further reflected in his editorship of *The Journal of Personality and Social Psychology* for 12 years and then from 1949 until his death in 1967 in his associate editorship of that journal.

Allport's two major publications on personality were *Personality: A psychological interpretation* (1937)

and *Pattern and growth in personality* (1961). With respect to personality and the psychoanalytic theory on development and the unconscious, in his autobiographical sketch Allport famously recounts an anecdote of an encounter with Sigmund Freud that took place in Vienna in 1920, when Allport had stopped off there at the invitation of his brother Fayette who was a member of the USA trade commission in Vienna. Allport describes the encounter with Freud almost as a confrontation with orthodox psychoanalytic theory, in which theory "manifest motivation" (i.e., conscious motivation) is accorded less consideration than unconscious factors. Allport's dissociation from psychoanalytic theory with respect to personality formation, as well as his dissociation, to a considerable degree, from the natural science approach in mainstream psychology, insured for him an idiosyncratic place in American mainstream psychology.

With research experience as proximate occasion and with the motivation deriving from his two "dawns" as remote antecedent, Allport articulated personality and motivation concepts such as functional autonomy, proprium, and propiety striving. He also promoted discussion of traits and personal dispositions. Allport was coauthor of the Allport-Vernon-Lindzey Study of Values (SOV) personality test, whose value categories are based on Eduard Spranger's (German philosopher and psychologist) typology. He advanced the distinction between idiographic and nomothetic approaches to research – a distinction sorely needed in a discipline so heavily influenced by a tradition of natural science concern with, and prioritization of, participant samplings with *N*s greater than one that are then available to statistical treatment.

Allport's work and interest in social psychology were of a significance not far from that of his work in personality. Topics of concern to him were attitude, rumor, religious beliefs, and intergroup prejudice. These topics continue to receive prominent attention in social psychology texts years after Allport's presentation of them.

Allport's work in personality and in social psychology, with his special interest in the topics referred to above – all established a position for him in American psychology that humanistic psychologists would claim theirs as well. Gordon W. Allport is considered one of the first strong representatives of the humanistic psychology school in modern psychology.

Allport's courage of intellect and exposition of that which is important though novel to psychological research found expression in his *The Use of Personal Documents in Psychological Science* (Allport 1942). Allport insisted, "If you want to know something about a person, why not first ask him?" His influence was considerable. Among his doctoral students were, for example, Alfred Baldwin, Jerome Bruner, Hadley Cantril, Gardner Lindzey, Thomas Pettigrew, Leo Postman, Brewster Smith, and Philip Vernon.

Despite positions he took that were not always aligned with mainstream psychology, Allport was acknowledged for the important contributions of his work. He was, for example, president of both the American Psychological Association and the Society for the Psychological Study of Social Issues. In 1963, he received the Gold Medal of the American Psychological Foundation. Gordon W. Allport's work in psychology, indeed, stands out as uncommon.

America, History of Popular Psychology in

LUDY T. BENJAMIN, JR.
Texas A&M University, College Station, TX, USA

Introduction

On April 19, 2000, the death of a child made front page news in Colorado. Candace Newmaker was 10 years old and weighed approximately 70 lb. On the day she would die, she was wrapped tightly in a sheet and laid on the floor while four so-called trained therapists, *not one of whom was licensed by the State of Colorado to*

provide any form of mental health service, used pillows and their own bodies – 670 lb of adult bodies – to press down on her. The “therapy” session lasted 70 min and when the sheet was removed, Candace was dead (Mercer et al. 2003).

Candace had been adopted and, according to her adoptive mother Jeane, was a problem child who had not accepted her as her new mother. Jeane read about a condition called “attachment disorder” which led her to discover the practice of “rebirthing therapy,” an unlicensed and unresearched therapy technique whose proponents claimed would establish normal parent–child attachments. Jeane paid the sum of \$7,000 in advance for the treatment. Part of the therapy was a “rebirthing” procedure in which the child was wrapped in sheets and blankets while the therapists pressed down on her, forcing her to struggle through the “birth canal” and be born again. During the therapy Candace said that she could not move and was having trouble breathing. The “therapists” told her to struggle harder. She said that she had vomited, which in fact she had done. As conditions got worse for Candace, she begged to be released, saying that she was dying. One of the therapists said to her, “You want to die? Okay, then die. Go ahead; die right now.” And she did (Crowder and Lowe 2000, p. 2 M).

Rebirthing therapy is one of hundreds of untested, invalid psychotherapy programs offered to uninformed people, often desperate in their search for cures for themselves or their loved ones. Most of these bogus therapies likely do little damage other than stealing money from the clients. Yet clearly, some of these treatments are dangerous, even deadly. These therapies are not the treatments used by licensed psychiatrists or psychologists in their efforts to ameliorate psychological problems. Instead, they are part of the domain of popular psychology, a psychology of the public that exists outside the boundaries of the science of psychology and the psychological practice that is based, in part, on that science.

These pseudo-therapies have likely been around since humans developed language. In the beginnings of human history when individuals faced a life beset with hardships and dangers that could hardly be imagined today and perhaps a life expectancy of 30 years, these early people were no doubt in need of human comfort, reassurance, empathy, and guidance. And

where there is demand, there is supply. There must have been individuals who provided services of a psychological nature to their fellow humans. These early therapists practiced their craft under a variety of names such as sorcerer, wizard, charmer, shaman, medicine man, enchanter, seer, and priest. Their trade involved a combination of medicine, religion, and psychology. Although they often held positions of authority and respect within their tribes, they could lose that social standing, and indeed their very lives, if they were judged to be incompetent or ineffective in their healing arts. With the passage of centuries, specialization occurred leading to separate professions of medicine, religion, and psychology, although it can be easily argued that these three remain linked in various ways in modern practice. And in the realm of popular psychology, both today and throughout its history, it is often the case that religion and medicine play important roles in the public's psychology.

Who Owns Psychology?

The question "Who owns psychology?" reflects the tension between scientific psychology, what psychologists regard as the "real" psychology, which is the validated principles and phenomena of an experimentally based discipline, and popular psychology, which is regarded as pseudoscience and psychobabble by psychologists, yet is embraced as the psychology of the lay public – a popular psychology. This tension is evidenced in an experience that has occurred for anyone who earned a doctoral degree in psychology and, indeed, for most students who at some time majored in psychology. When in casual conversation between two people one person says "I am a psychologist" or "I am studying psychology," the other individual replies, "Oh, I bet that you can read my mind." Such a comment reflects the public's association of psychology with paranormal practices such as mind reading, foretelling the future, reading personal auras, causing objects to move by mental powers, and communicating with spirits.

Popular psychology is rampant in twenty-first-century American life and has been for nearly 200 years. Today it is manifested in many forms. It is the mainstay of television, particularly in talk shows, soap operas, and so-called reality programs, but also is paramount in news programs, situation comedies, and

dramatic programs. Psychology is the stuff of the internet, radio, plays, country music, movies, novels, sports, newspapers (especially the tabloid versions), magazines, and churches. Stories on human behavior and misbehavior are ubiquitous. The public's interest in human nature seemingly knows no bounds. Imagine two events occurring on the same day. One story involves the economic collapse of the banking industry. The other story reveals the sexual indiscretions of a popular golfer. Which story will the network and cable news channels lead with? It would be no contest. Although one could argue that the banking industry collapse is a psychological story as well, perhaps the result of unmitigated greed, such national and global events will rarely eclipse the interest value of "who shot who" or "who cheated on whom."

For the public there is no popular psychology or public psychology, there is just psychology. It is psychology as they understand it. It is their psychology. *They own it.* Psychologists regularly lament this fact, wondering why the public would not embrace a more scientific psychology. Why the public cannot distinguish between "real" psychologists and those who claim to have psychological expertise yet have no formalized education and training in psychology? Consider the issue of information about romantic relationships, especially about how to have a successful marriage. On this subject many Americans have turned to the advice of John Gray, author of *Men Are from Mars, Women Are from Venus* (1992), a book purported to be a guide to helping couples improve their relationships. Gray identifies himself as being a Ph.D., which was earned via correspondence from Columbia Pacific University, an unaccredited college. Gray has no scientific background whatsoever nor has he done any scientific research on couples. Contrast him with John Gottman whose Ph.D. in psychology was earned at the University of Illinois and who has spent his distinguished academic career studying couples' relationships, especially marital satisfaction. Gottman has offered practical advice based on his work and on the work of other scholars in the field in several books written for the public, including *Why Marriages Succeed or Fail* (1994). The books often differ in their advice about what makes marriages work, Gottman claiming that his prescriptions come from years of exacting longitudinal research with couples, whereas

Gray's advice comes from intuition and observation. As of 2010, Gray's Mars-Venus books – there are 16 of them now – have reportedly sold more than 40 million copies, whereas Gottman's several marriage books have sold fewer than 100,000 copies. Some of Gray's key advice to couples is in direct opposition to the findings from psychological science. Acknowledging this paradox, Marano (1997) has written that "Gottman is the gold *standard*, while Gray is the gold *earner*. Gottman creates top psychology, while Gray mines pop psychology" (p. 28). Science and academic credentials aside, the public has voted with its pocketbook. Gray is the marriage guru.

Who owns psychology? The public does. And the public is not likely to look to psychological science for answers to psychological problems. As a result pop psychology flourishes via the books, seminars, tapes, cruises, DVDs, newsletters, Web sites, and radio and television broadcasts of John Gray, Melody Beattie, Wayne Dyer, Dr. Phil (McGraw), Tony Robbins, Dr. Laura (Schlessinger), and many others, all of whom are willing to share their psychological expertise with the public, a "calling" that has earned each of them millions of dollars.

Origins of Popular Psychology

A search of internet sources on popular psychology finds evidence of the lack of a sense of history. Popular psychology is often characterized as having its origins in the 1960s, associated with what has been called the human potential movement, an outgrowth of the humanistic psychology of Abraham Maslow, Carl Rogers, and Rollo May. The 1960s was clearly a decade of considerable social upheaval and change, a time in which the very fabric of American life was questioned. It was a decade of war, race riots, psychedelic drugs, and changing sexual mores, a decade that defined the concept of generation gap. Thus the 1960s can easily be identified as a decade in which psychological issues were of seminal importance; nevertheless, there is a public psychology that predates it by more than a century.

Although the Civil War would tear America apart in the middle of the century, the nineteenth century was largely one of optimism, if not prosperity, for many Americans, at least those of European origins. Many had come to the New World in search of a better life

and many had found it in the abundant opportunities of agriculture, commerce, and the trades. Land was still cheap for those adventurous enough to push westward, and dreams of great fortunes to be made were reinforced by tales from the great cities of the East and from the goldfields of the West. Of course there was much poverty and human misery as well, particularly in the cities, but this was America, the land where dreams of riches and success sometimes did come true. In pursuit of their dreams, Americans put their faith in religion and education as a means for personal and financial betterment. Yet other institutions offered hope as well, including a host of practitioners of varying pseudosciences that offered personal counseling promising health, happiness, and success.

Whereas popular psychologies are as old as written records, the first half of the nineteenth century was an especially productive era in which several "systems" of psychology became part of popular culture in Europe and America, producing practitioners who promised a better life. These public psychologies included phrenology, physiognomy, mesmerism, spiritualism, and the New Thought or Mind Cure Movements that gave rise to mental healing and self-improvement. Practitioners in these psychologies were engaged in exactly the kinds of psychological activities in which professional psychologists are engaged today. They sought to assist people in enjoying a better life. One can argue about the validity of their methods, and certainly there was little science as underpinnings. And no doubt some of these practitioners were charlatans whose treatments were a sham intended only to line the pockets of the practitioner. Yet there were many whose motives were laudable, who sought to meet the psychological needs of their clients.

Phrenology

In nineteenth century America, "having your head examined" was big business, largely due to the enterprising efforts of two brothers. Having your head examined meant phrenology, certainly the best known of the applied psychologies of the nineteenth century. Phrenology originated with a German physician and anatomist, Franz Josef Gall (1758–1828), who argued that different parts of the brain were responsible for different emotional, intellectual, and behavioral functions. He believed that talents and defects of an

individual could be assessed by measuring the bumps and indentations of the skull caused by overdevelopment or underdevelopment of certain brain areas. Phrenology was popularized in Europe and America by Johann Spurzheim (1776–1832), who collaborated with Gall on anatomical research on the brain and later promoted his own brand of phrenology consisting of 21 emotional faculties and 14 intellectual ones. Spurzheim died in Boston in 1832 on a lecture trip popularizing phrenology. His work was continued by a Scottish lawyer turned phrenologist, George Combe (1788–1858), whose 1828 book, *The Constitution of Man*, established him as the leading voice of phrenology. Combe continued Spurzheim’s American lecture trip, selling his books, and establishing phrenological societies in the major cities of his travels. Although by 1832 there were critics of the scientific legitimacy of phrenology, Americans, by and large, accepted it, and its proponents, particularly Combe, were praised for the practical benefits to individuals and society that phrenology offered.

Combe (1835) adhered to the categorization of 35 faculties as described by Spurzheim. In describing the basis for his practical phrenology he wrote:

- ▶ Observation proves that each of these faculties is connected with a particular portion of the brain, and that the power of manifesting each bears a relation to the size and activity of the organ. The organs differ in relative size in different individuals, and hence their differences of talents and dispositions. This fact is of the greatest importance in the philosophy of man. . . . These faculties are not all equal in excellence and authority . . . Human happiness and misery are resolvable into the gratification, or denial of gratification, of one or more of our faculties . . . Every faculty is good in itself, but all are liable to abuse. Their manifestations are right only when directed by enlightened intellect and moral sentiment. (pp. 54–56)

What phrenology offered was not only the cranial measurement that identified the talents and dispositions but, more important, a course of action designed to strengthen the faculties and bring the overall complex of emotional and intellectual faculties into a harmony that would ensure happiness and success. This was practical phrenology, that is, phrenology applied.

In the United States, no one was more strongly identified with applying phrenological “science” than the Fowler brothers, Orson (1809–1887) and Lorenzo (1811–1896), who opened clinics in New York, Boston, and Philadelphia in the late 1830s. They franchised their business to other cities, principally through the training of phrenological examiners, and provided phrenological supplies to the examiners such as phrenology busts for display and teaching, calipers of varying sizes for measurements, display charts for the wall, manuals to sell to the customers, and, for the itinerant phrenologists, carrying cases for tools and supplies. They began publication of the *American Phrenological Journal* in 1838, a magazine for phrenologists and people interested in phrenology, which enjoyed an existence of more than 70 years. For years its masthead carried the phrase “Home truths for home consumption.”

Some historical accounts have stated that the Fowlers were unconcerned with the arguments over the scientific validity of phrenology, and instead simply accepted it as valid. Their magazine, however, was filled with articles and testimonials intended to attest to the scientific basis of their subject. The Fowlers and others dedicated to phrenology recognized that it was not an accepted science, and there were some efforts aimed in increasing its respectability. For example, several of the phrenological societies, with the support of the Fowlers, sought to have phrenology taught as one of the sciences in the public schools and offered as a subject in colleges. Such efforts were not successful. The rejection of the scientific community notwithstanding, the Fowlers never doubted the validity of phrenology, at least not in public, and they promoted the subject as divine truth, selling its applications. They “did a thriving business advising employers about employees, fiancés about fiancées, and everyone about himself” (Leahey and Leahey 1983, p. 64). Their business also included public lectures; classes in phrenology for those wishing to take up the profession, but also classes for ordinary curious citizens, including children; and countless publications including books, pamphlets, and magazines.

Giving examinations or “readings,” as they were often called, was the business of the phrenologist. Some operated from clinics where clients could make appointments for their examinations. A phrenologist might test a potential suitor at the request of an anxious father. Parents also sought out help for raising children,

especially children who presented behavioral problems. Couples contemplating marriage might be tested for compatibility. Individuals could be tested for vocational suitability. Businesses might use the phrenological clinics as a kind of personnel department, matching individuals to jobs or selecting workers with managerial skills or sales skills. In areas where clinics did not exist, there were traveling phrenologists who advertised their arrival in advance and rented space for the duration of their stay.

A lack of scientific respectability notwithstanding, phrenologists were not without skills. What they may not have been able to judge from their cranial measurements, they likely determined from their powers of observation, honed by the examination of many clients. In the best empirical tradition, they used the knowledge of their senses to inform their diagnoses and their counsel. Regarding their powers of observation, historian Michael Sokal (2001) has written:

- ▶ After all, they had great opportunities to practice these powers on the individuals they examined. They spent a fair amount of time with their subjects, often in close physical contact. They spoke with these clients – and, especially, listened to them – as they introduced themselves and took in their accents and use of words. They shook their hands and felt their calluses. They observed their dress, and noted its style, cleanliness, and usage. They observed their subjects' carriage as they entered and walked about the examining room and read their "body language." They stood over and behind them as they moved their hands about their heads. And in a less clean age, they especially noted their subjects' odor. (pp. 38–39)

Thus there was much that could be learned about a client from a discerning phrenologist. Such observations likely improved the quality of the phrenologist's counsel while at the same time raising the client's confidence in the skills of the phrenologist. That confidence was important in gaining greater client compliance with the recommendations of the examiner and, of course, in creating good word-of-mouth advertising for the examiner's services.

Although phrenology came under increasing attack from the scientific community, it remained popular in America throughout the nineteenth century as a kind

of counseling, clinical, and industrial psychology. By the beginning of the twentieth century its popularity had declined considerably, as it was being replaced by other methods, many of which were being drawn from the new science of psychology.

Physiognomy

There are, no doubt, many people today who would profess to being able to judge a person's character by looking at the person's face. The origins of that belief surely date back thousands, perhaps tens of thousands, of years. The system of judging a person's character from facial features is called physiognomy (sometimes referred to as characterology), and its invention, at least in modern times, is attributed to a Swiss theologian, Johann Lavater (1741–1801). Lavater's book, *Essays on Physiognomy*, was published in 1775/1789. It was thus a precursor to Gall's work, although there is no evidence that it influenced Gall. Lavater's system emphasized the eyes, nose, forehead, and chin as the chief indicators of intelligence, morality, and many other characteristics. For example, about the nose, Lavater wrote:

- ▶ Noses which are much turned downward are never truly good, truly cheerful, noble, or great. Their thoughts and inclinations always tend to earth. They are close, cold, heartless, incommunicative; often maliciously sarcastic, ill-humored, or extremely hypochondriac or melancholic. When arched in the upper part they are fearful and voluptuous. (Lavater, as cited in Wells 1866, p. 36)

Lavater's book, which contained more than 800 illustrations, some of them taken from famous artists, was exceptionally popular. Originally published in German, the book was soon translated into virtually every European language. Physiognomy's popularity ranged from its use as a parlor game at fashionable gatherings to its claims as the science of determining character. It spread over Europe in the late eighteenth century and to America shortly thereafter. Its popularity continued into the first half of the twentieth century as American businesses used physiognomy in hiring and promoting employees.

The Fowler brothers were also marketers of physiognomy, giving lectures on the subject, including many

articles about it in their phrenological magazines, and publishing books and pamphlets on the topic. One of the more successful books was authored by Samuel Wells (1820–1875), a partner with and brother-in-law of the Fowlers. Wells's book, which appeared in 1866, was entitled, *New Physiognomy or Signs of Character as Manifested Through Temperament and External Forms and Especially in the Human Face Divine*. Wells's "New Physiognomy" was an adaptation of a system proposed by James W. Redfield, a New York physician. The system identified 184 separate areas of the face, each corresponding to a different character or trait, for example, kindness, eloquence, sympathy, inquisitiveness, cheerfulness, patriotism, and perseverance.

In addition to being the science of character, physiognomy, like phrenology, was used to "validate" and thus perpetuate ethnic and racial stereotypes. For example, in describing the "Jewish nose," Wells (1866) wrote, "it indicates worldly shrewdness, insight into character, and ability to turn that insight to a profitable account." Other facial features led Wells to the following summary of a Jew. "He is religious; he is fond of trade; he is thrifty; he is unconquerably true to his racial proclivities; he is persistent in everything he undertakes. He is the type of stability and permanence – the model of steadfastness; but at the same time he is prejudiced, bigoted, stern, stubborn, irascible, exacting, secretive, and unrelenting." The sub-Saharan African nose was described by Wells as a "snubnose," a nose of "weakness and underdevelopment." He wrote, "Such a shortened and flattened proboscis can not . . . have made any legible mark on the records of the world's progress. Its wearers have never conquered realms and enslaved nations, like the owners of the royal Roman nose, or built magnificent temples and adorned them with works of high art, like the Greek-nosed children of genius" (p. 196).

The eyes of devout Roman Catholics were said to indicate humility and penitence. Scots were characterized as economical, sensitive, and religious. The Irish were described as patriotic, fond of sport, witty, combative, and generous. The French were said to be vigorous and friendly, but low in moral standards. Spaniards were viewed as cunning, vindictive, and sullen, but also brave, noble, passionate, and courteous. All of those characteristics were, of course, supposedly

observed from the features of the face, at least they were observable for anyone who believed in the "science" of physiognomy.

Reading Wells and other similar treatises on physiognomy would allow you to learn that hazel-eyed women were more intelligent than romantic, that large mouths indicated more character than small ones, that coarse lips were a sign of strength and power, whereas fine lips were a sign of mental delicacy and susceptibility, and that murderers always had big necks. The last example ties physiognomy to criminology, a linkage that has a long history, especially in the work of Cesare Lombroso (1835–1909), but will not be covered here (see Lombroso 1911; Lombroso and Ferrero 1899).

You may find yourself wondering how people could have believed in the tenets of physiognomy. To understand that system and phrenology, you must understand them in the context of their times. Science was a relatively new enterprise in the nineteenth century and most people did not have a clear basis for distinguishing science from nonscience. Surveys of scientific literacy today show that many people still cannot make such a distinction. And even if they could, whether these systems were validated by scientific research was not a concern for the great majority of consumers. People had needs, whether it was to find a suitable marriage partner, choose an occupation, hire a worker, or raise a child. They looked to experts for help, and like today, it was not easy for people to make judgments about who was or was not an expert.

Whereas phrenology was organized around the nucleus of the Fowlers' operations that controlled the *American Phrenological Journal* and had formal ties to phrenological clubs and societies around the country, there was no such nucleus for physiognomy, which instead operated as a number of independent systems. Likely that is why physiognomy, although in vogue for more than 100 years in the United States, never attained the popularity and visibility enjoyed by phrenology. In addition, phrenology had greater status because it could at least lay claim to some neuroanatomical basis because mental and moral faculties were identified with specific brain areas. No such neural or anatomical claims were made for physiognomy.

Mesmerism

Franz Anton Mesmer (1734–1815) was an Austrian physician who in 1774 discovered that he could relieve a number of medical and psychological symptoms in his patients by treating them with magnets. He named his procedure animal magnetism, although later it would be better known by the eponym mesmerism. In treating his first patient with the magnets, Mesmer described a kind of fainting spell, a crisis state, that lasted for a brief time, after which the symptoms abated for several hours. The spell was likely a hypnotic trance. In treating subsequent cases, Mesmer would tell his patients what they would experience, including this trance state, and many of them complied with his suggestions, thus going into a trance. Mesmer believed that the fluids in the human body were magnetized and that they could get out of alignment. The purpose of passing the magnets over the body was to move the fluids around and thus restore harmonious alignment to the body. Soon he abandoned the magnets altogether and just passed his hands over his patients' bodies, inducing trance states and affecting cures. He assumed that he was now serving as a powerful magnet and could produce the cures without need of the magnets.

Mesmer had become quite the sensation in Paris in the early 1780s, holding group sessions that allowed him to treat a dozen or more people at once (which allowed persons in the group to watch the behavior of others and thus see what they were “supposed” to do) and still charge outrageous fees. His treatments were for the wealthier citizens, and Mesmer found himself ensconced in Parisian high society. Animal magnetism became very popular as other practitioners began to practice this healing art. And, of course, there were those who opposed mesmerism as fraudulent. These opponents, mostly from the medical community, brought pressure on King Louis XVI to appoint a group to investigate its validity. The blue ribbon commission appointed by the king in 1784 included, among others, Benjamin Franklin, as president of the commission; the famous chemist Antoine Lavoisier; and a French physician, Joseph Guillotin, whose invention of the guillotine would soon be used in France's Reign of Terror to remove the heads of many in the aristocracy, including the head of Lavoisier. The commission's report was quite damning. It argued that no animal magnetic fluids existed, nor was there any

healing due to magnetic forces. The report did not result in any formal actions by the French government and so the fallout was mostly Mesmer's bruised ego.

Mesmer's work is generally viewed as the starting point for the history of modern hypnosis, although one can find written accounts of hypnotically induced states that precede Mesmer. It is not our purpose here to discuss the history of hypnosis. Instead we have presented this discussion of Mesmer because of the popularity of mesmerism in nineteenth century America and because of related treatments that involved magnetism and suggestion. Many of these approaches were directed at medical ills, that is, physical ailments, but psychological problems and needed behavioral changes figured prominently in the work of the mesmerists as well.

Mesmerism came to the United States in the 1830s. One of its practitioners was Charles Poyen, a French physician who traveled throughout the northeastern United States in 1836 giving demonstrations of its powers. The following year Poyen immigrated to the United States, settling in Providence, Rhode Island. He was a charismatic figure who drew a large number of converts to mesmerism. He began publication of *The Psychodinamist*, a magazine for mesmerists in the United States.

What did American mesmerists do? In general they were involved with healing and encouraging self-improvement. They lectured widely in America, promoting their science and offering demonstrations of the effectiveness of their methods (Schmit 2005). They relied on techniques that in some way attempted to create a trance state during which suggestions would be made by the mesmerist. Suggestion can be a powerful force. No doubt many clients went to mesmerists, not in a skeptical mood, but with expectations that they would be helped. After all, they often paid considerable fees for that help. Clients went to mesmerists for many different reasons: family problems, problems in the workplace, health problems. After the sessions the clients often confessed to feeling spiritually invigorated. They possessed a new energy and a will to solve the problems that had been plaguing them. Clients often reported that they had been set free by their treatments. Psychologist Philip Cushman (1995) described it this way: “Mesmerism was first and foremost an ideology of personal, *inner* liberation. It emphasized the inherent

goodness of the inner self and led to the development of practices that were designed to expand, revitalize, and finally liberate the natural spirituality” (p. 119). Of course the Fowler brothers would get into this act as well. Toward the end of the nineteenth century they began to promote lectures and courses in “personal magnetism” that promised a pleasing personality; the cultivation of success; how to succeed in love, courtship, and marriage; how to prevent disease; how to build character; and how to become a great power in the world (see, for example, Dumont 1913).

Mesmerism became quite popular in America in the last half of the nineteenth century and persisted as a lesser force into the early twentieth century. Its impact on other nineteenth- and twentieth-century pseudosciences was considerable. It has even been regarded as the beginning of psychotherapy in America. Cushman (1995) wrote, “In certain ways, mesmerism was the first secular psychotherapy in America, a way of ministering psychologically to the great America unchurched. It was an ambitious attempt to combine religion with psychotherapy, and it spawned ideologies such as mind-cure philosophy, the New Thought movement, Christian Science, and American spiritualism” (p. 119).

Spiritualism

In the 1850s in a darkened room, people sat around a table, hands joined, with each other and with the individual serving as the medium who was the conduit to the other world, that is, to persons in the afterlife. There would be mysterious sounds – sometimes noises, sometimes voices – and ghostlike forms would appear, and the table would move on its own, and the windows would rattle, and the medium might have a seizure or at least would go into a trance state. These séances were the modus operandi of the practicing spiritualists, and they were part of the psychological scene in America during the last half of the twentieth century. Among those interested in spiritualism was William James (1842–1910), arguably the most important figure in the history of American psychology. James wrote one of the most influential books in psychology’s history, *Principles of Psychology* (1890), and he established the psychology program at Harvard University. Although he was prominently identified with the new science of psychology, he had other intellectual interests that

proved to be an embarrassment to many of his psychological colleagues (see Coon 1992). For more than 25 years, James studied paranormal events in an attempt to provide scientific evidence for a number of psychical phenomena including the actions of spiritualist mediums. In 1885 he met Mrs. Leonore Piper, a famous medium, and over the next 25 years he frequently attended séances she directed. In the initial séances Mrs. Piper is said to have told James and his wife intimate details about their lives, details that the Jameses felt sure no one could have known but them. Such revelations convinced James that Mrs. Piper had paranormal abilities but he was never able to satisfy himself about the origin of those abilities, that is, did her information come from the spirit world, from some kind of exceptional sensory skills, or from mental telepathy? James was apparently convinced that there was no trickery involved in the performances of Mrs. Piper, but that was not the opinion of several other scientists who visited her séances (Murphy and Ballou 1961).

Interestingly, the origin of spiritualism in America can be defined both in time and place – March 31, 1848, at a farm near Hydesville, New York – under what can only be called extraordinarily bizarre circumstances for the beginnings of a movement with such religious overtones. Two young sisters, Margaret (age 13) and Kate Fox (age 12), discovered that they could make weird noises by cracking the joints in their toes, and they used this ability to trick their superstitious mother into believing that a ghost was present.

- ▶ After several days of this mild poltergeisting, they tried questioning the “spirit” and ascertained that it was the ghost of a peddler who had been murdered in the vicinity of their cabin before they had moved in. Word of these amazing events soon spread. So many visitors came to their cabin that the older sister, Leah Fox Fish, noticed the financial possibilities of going into the ghost business. (Leahey and Leahey 1983, p. 162)

Leah took her two younger sisters to Rochester, New York, where they set up a shop, holding séances, acting as mediums, bringing forth spirits of the deceased to communicate with the paying customers who were eager to make contact with lost loved ones. Initially the spirits were manifested by rapping noises on tables or by movements of the séance table. As those techniques lost their appeal, mediums added a board

(the planchette, a forerunner of the Ouija board) that could be used to spell out the messages of the spirits, megaphones for spirit voices, and the spirit cabinet, a large piece of furniture from which sounds could be heard and from which visual apparitions would appear (and in which confederates could sometimes hide).

With so many Americans dead as a result of the Civil War, there were thousands of loved ones who longed to make contact once more. The demand for mediums rose and there were plenty of willing individuals, mostly women, ready to assume the role. In 1888, Margaret Fox confessed her chicanery and that of her sister, an action that diminished interest in spiritualism. Yet there would be another resurgence of interest in 1918 after World War I and the influenza epidemic had taken so many lives. Although the bread and butter of mediums was contact with the dead and the relief and joy that connection could bring to their clients, they also provided other psychological services as counselor and adviser to their clients who might be suffering depression, anxiety disorders, difficulties in marriage, problems in the workplace, and troubles with their children.

Spiritualism was not connected with any specific religion although it may have seemed religious in nature because it was predicated on a belief in an afterlife. Yet organized religion opposed spiritualism and argued that belief in spirits was an act of heresy. “By claiming to produce empirical evidence of survival [after death], Spiritualism denied the need for faith. By claiming that there was no hell, and that a pleasant afterlife was in store for everyone, it denied the fear of God and of hellfire on which organized Christianity depends” (Leahey and Leahey 1983, p. 166). Spiritualism did not diminish in popularity because of the opposition of organized religion in America. Its demise in the 1920s was due, no doubt, to multiple causes, perhaps chief among them that many of the professional mediums were eventually exposed as frauds. Of course spiritualism did not disappear entirely. There are seers, mystics, and mediums working today who offer the promise of contact with the dearly departed. And there are many others – some trained in science and some not – who offer the other counseling psychological services.

New Thought Movement: Mental Healing and Self Improvement

What is generally referred to as the New Thought or Mind Cure Movements began in New England in the 1850s. Its mental healing origins are attributed to a clockmaker, Phineas Parkhurst Quimby (1802–1866), who, after studying and practicing mesmerism for a decade, formulated his own theory and method of mental healing. Quimby believed that many diseases had causes that were wholly mental and that other diseases were exacerbated by mental conditions. His experiences with his own illnesses and his treatment by physicians left him convinced of the inadequacy of medical practice. Indeed, Quimby believed that physicians did as much good by what they said to patients and the way they said it as they did through medicines or surgeries.

Quimby was a keen observer and evidently had great powers of concentration. He listened intently as his clients told him about their problems. He established a close rapport with them from the beginning, something that he felt was crucial to affecting a cure. Quimby believed that many physical and psychological problems were caused by negative thinking and that those negative thoughts were often induced in individuals by physicians. Quimby’s task was to help clients see the “truth,” to achieve wisdom about their lives, and to reach a spiritual healing. Quimby believed that disease was:

- ▶ due to false reasoning in regard to sensations, which man unwittingly develops by impressing wrong thoughts and mental pictures upon the subconscious spiritual matter. As disease is due to false reasoning, so health is due to knowledge of the truth. To remove disease permanently, it is necessary to know the cause, the error which led to it. The explanation is the cure. (Anderson 1993, p. 40)

In essence, Quimby believed that cure resided within the mental powers of the individual and not in the medical practices of physicians. Individuals could cure themselves if they could be shown the way to right thinking.

In 1859, Quimby moved to Portland, Maine, where he spent the last 6 years of his life dedicated to his mental healing practice. He is said to have treated

more than 12,000 individuals (Caplan 1998). Among those he cured was a woman who became one of his early disciples. Her name was Mary Baker Eddy (1821–1910), who in 1879 founded the Church of Christ, Scientist, better known today as Christian Science. Eddy was not only cured by Quimby but she was greatly influenced by his views on illness and healing. They maintained a frequent correspondence until Quimby's death in 1866.

The growth of mental healing spread throughout the United States in the 1860s. There were many different schools of the “mind cure movement” including Eddy's. “The movement enlisted the support of tens of thousands of American women and men. Literally hundreds of books and pamphlets in addition to scores of periodicals proclaimed the dawning of a New Age in which mind and spirit would achieve domain over matter and crude materialism” (Caplan 1998, p. 69).

Mental healing was part of that new age, also called the New Thought Movement, that emphasized the power of mind. Another component of the movement encouraged self-help, stressing especially the power of positive thinking for self-improvement. Scottish author Samuel Smiles (1812–1904) is often cited as the chief impetus of this movement following the publication of his widely popular book, *Self-Help; with Illustrations of Character and Conduct* (1859). The book sold over 20,000 copies in its first year and was translated into many languages making Smiles an international authority on self-improvement (Richards 1982; Travers 1977). Emphasizing the paramount value of self-help, Smiles (1859) wrote:

- ▶ Heaven helps those who help themselves' is a well-worn maxim, embodying in a small compass the results of vast human experience. The spirit of self-help is the root of all genuine growth in the individual; and exhibited in the lives of many, it constitutes the true source of national vigour and strength. Help from without is often enfeebling in its effects, but help from within invariably invigorates. (p. 1)

Smiles's book had considerable influence on the New Thought Movement in America, principally through the writings of Orison Swett Marden (1850–1924). Orphaned at the age of seven, Marden's life was one of bare subsistence and prospects for a grim future.

That changed when he discovered a copy of Smiles's *Self-Help* in an attic. Smiles's proscriptors for self-improvement changed his life. Marden eventually earned a medical degree from Harvard University in 1881, but his achievements were in publishing, both as an author and editor. His first book, *Pushing to the Front* (1894) added his own ideas about how to achieve success to those of Smiles. And he followed that with a dozen other books touting the powers of positive thinking for self-improvement and success, such as *How to Succeed or, Stepping-Stones to Fame and Fortune* (1896) and *Every Man a King or, Might in Mind* (1906). He founded and edited *Success* magazine in 1897, which is still published today. Marden wrote that he wanted to be the American Smiles, and he likely achieved that, inspiring a self-help industry of books and magazines in twentieth-century America. He is often dubbed the father of the modern self-help movement. Several of his books are still in print today, and his writings are frequently cited in contemporary works on positive thinking, self-help, and salesmanship (Connolly 1925; Parker 1973).

By 1910 the craze of the mind-cure movement had largely ended, although mental healing continued, both in organized religion, such as Christian Science, and in home clinics where mental healers practiced. As mesmerism can be thought of as a precursor to contemporary psychotherapy, so too were the mind cures important in establishing belief in the importance of what today would be called the therapeutic relationship or therapeutic alliance, key concepts in evaluating the effectiveness of psychotherapy today. The self-improvement industry of Smiles and Marden continued to prosper throughout the twentieth century as a part of the public's psychology.

The New Psychology

In the universities, psychology had been a subfield of philosophy for centuries. With the rise of British empiricism, beginning with John Locke in the 1600s, psychology would coalesce as an academic discipline labeled mental philosophy, a discipline that covered topics such as sensation, perception, attention, learning, memory, reasoning, consciousness, imagination, emotion, and will, subjects that are still discussed in contemporary introductory psychology courses (Fuchs 2000). In the

late nineteenth and early twentieth centuries, this empirical psychology would be replaced by an experimental psychology – the “new psychology” – imported from the German university laboratories in Berlin, Göttingen, and especially Leipzig under the direction of Wilhelm Wundt (1832–1920). This new psychology would bring the methods of neurophysiology, sensory physiology, and psychophysics to bear on the questions explored in mental philosophy. Psychology was, by the 1880s, a science that many of the early pioneers hoped would join with the natural sciences in seeking to reveal the secrets of the human mind (Benjamin 2007).

American psychology laboratories were in existence only a few years after their European counterparts with the first psychology laboratory appearing at Johns Hopkins University in 1883 and others following shortly thereafter at Indiana and Columbia Universities and the Universities of Wisconsin, Kansas, Nebraska, and Pennsylvania. By 1900 there were approximately 40 psychology laboratories in North America, and most of those offered doctoral degrees in the new science (Benjamin 2000).

In an effort to educate the American public about the nature of the new science, psychologists organized an exhibition at the Chicago World’s Fair in 1893 and followed that with a smaller public presence at the 1904 World’s Fair held in St. Louis. These early experimental psychologists were all too aware of the public psychology that associated the term psychology with mind reading, phrenology busts, hypnosis, séances, and mental healing (Coon 1992). These public exhibitions were a concerted effort to change the public’s view of psychology, to get the public to acknowledge psychology’s scientific status and university-based psychologists as the arbiters of psychology, and to reject the false claims from the pseudosciences that had long been the mainstay of popular psychology. The new psychologists published their experimental work in newly founded journals that were not really for public access. Yet they also wrote magazine articles, books, and newspaper columns as a means to translate their experimental work for public understanding or to offer their opinions as psychological experts (see, for example, Hall 1901; Jastrow 1900; Münsterberg 1908). No one did this with greater frequency or with greater controversy than Harvard University’s Hugo Münsterberg

(1863–1916) who became America’s best known psychologist as a result of his frequent appearances in the popular press.

Münsterberg’s role as a media darling began following his publication of an 1898 *Atlantic Monthly* article in which he argued that the new experimental psychology had nothing to offer the field of education. This article created a firestorm with his psychologist colleagues but garnered a great deal of public attention for Münsterberg (Benjamin 2006). As a writer, he stirred interest and emotions, a fact that led editors (including *McClure’s Magazine’s* Willa Cather) to invite numerous contributions from his pen. For the rest of his life, Münsterberg was a frequent contributor to the popular press through numerous magazine articles, newspaper columns, and a series of popular books. These publications established him as America’s psychological expert, and it seems that he never found a topic on which he felt unable to comment. Invitations for public lectures, inquiries from the press, and consulting opportunities in business increasingly came his way. Münsterberg had a knack for sensationalism and he was often quoted in the press, partly because of his willingness to say outrageous things. In essence he was what reporters call “good press.”

In a span of fewer than 20 years Münsterberg wrote on a multitude of popular subjects such as the personality of Americans, school reform, hypnotism, women as unacceptable jurors, lie detection, criminality, democracy, native Americans, African Americans, political parties, the Monroe Doctrine, the Philippines, journalistic inaccuracy, motion pictures, psychotherapy, art and artists, communicating with the dead, murderers, gambling, prohibition, Christian Science, beauty, nervousness, vocational choice, bookstores, patriotism, coeducation, home economics, insanity, the subconscious, and being a scientific expert. Not surprisingly some of these articles and interviews angered and dismayed his colleagues, but Münsterberg loved the public attention and evidently was willing to endure the wrath of his fellow psychologists. At times Charles Eliot, President of Harvard University, probably felt he needed a press secretary just to deal with the trouble caused by Münsterberg’s utterances. He reminded Münsterberg that he should not feel compelled to comment on every question he was asked. In a 1909 letter to him Eliot wrote:

- ▶ You seem to me to work with too much intensity and too constantly, and to work on topics which are peculiarly stirring and exciting. I hope you will moderate your rate of work and of publication, and will take up some systematic course of interesting out-of-door exercise, with frequent absences from Cambridge between Friday night and Monday morning for change of scene and change of thoughts. (Eliot 1909, April 30)

In addition to translating their science for the public, these pioneering psychologists, such as G. Stanley Hall, John Watson, James McKeen Cattell, and Münsterberg, also openly challenged the pseudopsychologies extant at the turn of the twentieth century. Consider, for example, a physiognomic system that enjoyed popularity in early twentieth century American businesses.

Katherine Blackford was an American physician who marketed her system to businesses, principally as a selection measure for employees. Blackford wrote several books in the first quarter of the twentieth century, almost all directed at personnel issues for business (Blackford and Newcomb 1914, 1916). This was a time in America in which there was great interest in vocational guidance. The urbanization of America, new waves of immigration, industrialization that created more factory jobs, changes in labor laws protecting children, and advertising and marketing strategies that were national in scope changed the nature of American business, creating a greater diversity of occupations. Thus occupational choice had a meaning that it had not possessed before. Frank Parsons' landmark book on vocational guidance, *Choosing a Vocation*, appeared in 1909; the National Vocational Guidance Association was established in 1913; and the National Vocational Education Act was passed in 1917, a law designed to ensure better guidance counseling in public schools. Vocational aptitudes and vocational choice were not new issues; they had been a chief part of the phrenologists' business success in the nineteenth century. In the early twentieth century, however, there was widespread public concern that young people have access to quality vocational guidance and thus there was widespread interest in America regarding career choices. Blackford wrote that her books were intended "to add our voice to those of many others in calling for more scientific vocational guidance of the

young. . . [and] to arouse interest among all thoughtful people, and especially among parents, employers, teachers, and workers, in the possibilities of character analysis by the observational method" (Blackford and Newcomb 1914, p. vii). Blackford's methods were very popular judging by the number of reprintings of her books. She caused concern among psychologists who noted her appeal to businesses and were dubious of her techniques. Yet for many American businesses in the early twentieth century, the science of psychology didn't hold any more authority in solving the problems of business than did the "science" of characterology (Blackford's preferred label) or physiognomy. Blackford stressed the importance of the hiring decision. She claimed that businesses wasted too much time and money in hiring people who should never have been hired, or placed people in jobs for which they were ill suited. Blackford's system began by looking at the shape of the face as a whole, viewed in profile. From these profiles she identified some faces as convex, some as concave, and some as plane (meaning a flat plane). She wrote that the possessor of a convex face has:

- ▶ Superabundance of energy. . . [is] keen, alert, quick, eager, aggressive, impatient, positive, and penetrating . . . will express his energy in a practical manner. . . He will demand facts, and will act upon facts quickly and rapidly, being too impatient to wait for reasons and theories. . . [this type will] speak frankly and at times even sharply and fiercely, without much regard for tact or diplomacy. As indicated by his type of chin, the pure convex is impulsive, expends his energy too rapidly for his limited endurance, and, owing to his lack of self-control and disinclination to deliberate and reason, frequently blunders, and expends his energy uselessly or unprofitably or even harmfully. (Blackford and Newcomb 1914, pp. 154–155)

The concave face is, of course, the opposite. This individual would be characterized by mildness, slow thought, careful-thinking, reason-seeking, sometimes daydreaming, deliberateness, determination, and persistence. "What the convex wins or gains by his aggressiveness, keenness, and superabundance of energy, the concave wins or gains by his diplomacy and unwavering persistence and endurance" (Blackford and Newcomb 1914, p. 156). The plane face was

a balance of the other two and was the most common of the three types of faces.

For Blackford, these faces defined different types of people, and that information could be put to good use in hiring, or what Parsons had preached as the first law of vocational guidance, matching the person's talents with the job requirements. Thus a businessperson might want to hire an aggressive person for a sales job but not for a customer service job. So for Blackford, individuals with blond hair, because they were more likely to have convex faces, were to be preferred for sales jobs, where their qualities of aggressiveness, impulsiveness, persistence, and high energy would pay off. Blonds and brunettes also figured in Blackford's views on criminal physiognomy:

- ▶ Prison statistics show that the blond is most frequently guilty of crimes of passion and impulse, crimes arising from his gambling propensities and ill-considered promotion schemes; while the brunette is more likely to commit crimes of deliberation, specialization, detail, such as murder, counterfeiting, forgeries, conspiracy, etc. Because the blond is healthy, optimistic, and naturally good-humored, he eliminates anger, hatred, melancholy, discouragement, and all other negative feelings . . . easily. . . . Because he is naturally slow, cautious, conservative, and inclined to be serious and thoughtful, the brunette is far more liable to harbor resentment, to cherish a grudge, to plan revenge, to see the dark side of life, and often to be melancholy and pessimistic. (Blackford and Newcomb 1914, pp. 140–141)

With the rise of the status of science at the beginning of the twentieth century, pseudoscientific practices came under greater criticism. Psychology, as a science, benefitted as well from the public's perception of science as a source of validation, and practices such as phrenology, physiognomy, and spiritualism declined. As the applied specialties of the new psychology developed – clinical psychology, counseling psychology, school psychology, industrial psychology – they successfully challenged some of the public psychologies, such as Blackford's system, eventually convincing businesses to adopt some of the selection practices developed by industrial psychologists as a better means for hiring.

Psychoanalysis Comes to America

Perhaps psychologists felt they were making progress with public understanding of their new science. And then Freud came to town! Sigmund Freud (1856–1939) made his only visit to America in 1909 at the invitation of G. Stanley Hall. The occasion was the 20th anniversary celebration of Clark University where Hall was president. Freud gave five lectures at Clark on the subject of psychoanalysis (Evans and Koelsch 1985; Rosenzweig 1994). Before his arrival, few in America knew much about his work. Arguably his most important book, *The Interpretation of Dreams* (1900), had not been reviewed in any American journal, and none of his books had been translated into English. His visibility in America would change radically following his visit. Freud's Clark lectures were published in Hall's journal, the *American Journal of Psychology*, in 1910. This publication stirred considerable interest in Freud's ideas and led to English translations of his most important works including *The Interpretation of Dreams* in 1913 and *The Psychopathology of Everyday Life* in 1914 (Fancher 2000). The American Psychoanalytic Association was founded in 1911, only 2 years after Freud's visit, and the first of many American psychoanalytic journals, *Psychoanalytic Review*, began publication in 1913. Psychoanalysis was alive and well in America, even if still in its infancy. Although experimental psychologists largely rejected Freud's ideas as unscientific, the American public showed a growing fascination with psychoanalysis. A battle was underway.

Psychologist and historian Gail Hornstein (1992) has written that it was a battle to determine “which field would ultimately dictate the ground rules for a science of the mind?” (p. 254). She described the opening salvos as follows:

- ▶ Psychoanalysts thrust themselves directly into the middle of this scene, brazenly trying to supplant the new psychology at the moment of its greatest promise. At first psychologists stood aside, astonished, as the analysts, bursting with self-importance and an almost frightening zealotry, pronounced themselves the real scientists of the mind. By the time psychologists began to take this threat seriously, psychoanalysis had so captured the public imagination that even its pretensions could not be ignored. (p. 254)

As Hornstein noted, many psychologists ignored psychoanalysis, perhaps assuming that the public would reach a similar conclusion about its scientific legitimacy, and it would go the way of phrenology, losing any scientific credibility it had achieved, perhaps continuing in some marginal existence as a parlor amusement. Yet other psychologists attacked it in print, especially during World War I when anything identified with Germany was a ready target for Americans. Writing in *The Nation* in 1916, Christine Ladd-Franklin referred to the absurdities of the Freudian doctrine calling psychoanalysis “a prostitution of logic” (p. 373) and warning that “Unless means can speedily be found to prevent its spread. . . the prognosis for civilization is unfavorable (p. 374). Robert Woodworth (1917) in discussing psychoanalysis as treatment argued that not only was the treatment art and not science, but it was decorative art at that. Increasingly strident criticisms of psychoanalysis were published by psychologists in the 1920s and 1930s including books and articles by leading psychologists such as James McKeen Cattell, Joseph Jastrow, John Watson, and Knight Dunlap. Nevertheless, by the 1930s mainstream psychology found itself at odds with a popular psychology infused with dream interpretation, repression, neuroses, Oedipal complexes, and sexual frustration. There were psychoanalytic movies (*The Cultural Psychology of Motion Pictures: Dreams That Money Can Buy*), psychoanalytic plays, psychoanalytic novels, and even psychoanalytic music such as the 1925 ballad *Don't Tell Me What You Dreamed Last Night (For I've Been Reading Freud)* written by Franklin Adams and Brian Hooker.

Although psychoanalysis was a visible part of American popular psychology in the 1920s and later, it was by no means the defining system. The growth of applied psychology following World War I; the public euphoria sweeping America in the 1920s; the changing social mores of the 1920s, especially regarding sexuality; and a search for spiritual fulfillment outside of the church were all factors that saw an explosion of interest in psychology in the 1920s.

An “Outbreak” of Psychology in America

The 1920s in America were called the “Roaring Twenties,” “the Jazz Age,” and, by politicians, “the

New Era.” The economy was soaring, industrial production was up 64%, nearly six times as much as the previous decade; automobiles were more affordable than ever; after nearly 150 years as a nation, American women finally had the right to vote; Babe Ruth was swatting home runs; Rudolph Valentino and Mary Pickford were thrilling moviegoers; and booze was still available in gin joints, speakeasies, and from moonshiners, despite the 18th Amendment to the US Constitution (Dumenil 2001). In the midst of these post-war good times, everywhere Americans turned they heard the message touting the importance of psychology in their lives.

Popular science writer Albert E. Wiggam (1871–1957) was one of many individuals in the 1920s who promoted the value of psychology. In a 1928 newspaper column he wrote:

- ▶ Men and women never needed psychology so much as they need it to-day. Young men and women need it in order to measure their own mental traits and capacities with a view to choosing careers early and wisely . . . businessmen need it to help them select employees; parents and educators need it as an aid in rearing and educating children; all need it in order to secure the highest effectiveness and happiness. You cannot achieve these things in the fullest measure without the new knowledge of your own mind and personality that the psychologists have given us. (p. 13)

British historian and author, H. G. Wells (1866–1946), was similarly enamored about the prospects of psychology for the public good. In a 1924 article in *American Magazine* Wells wrote:

- ▶ The advances that have been made in psychology . . . have been enormous. The coming hundred years or so will be, I believe, essentially a century of applied psychology. . . It will mark a revolution in human affairs altogether more profound and more intimate than that merely material revolution of which our great-grandparents saw. . . and amidst whose achievements we live. (p. 190)

Psychologists too, overly impressed with the significance of their contributions in World War I, joined in the promotion of their discipline, touting the myriad ways psychology could benefit everyday life. Writing for the public in 1925, behaviorist John Watson offered

parents a guarantee on the value of psychology for child rearing.

- ▶ Give me a dozen healthy infants, well-formed, and my own specified world to bring them up in and I'll guarantee to take any one at random and train him to become any type of specialist I might select – doctor, lawyer, artist, merchant-chief and, yes, even beggar-man and thief, regardless of his talents, penchants, tendencies, abilities, vocations, and race of his ancestors. (p. 82)

In making this promise, Watson was offering every parent the American Dream, made possible by the science of psychology. No matter ones race, no matter ones social station, no matter ones wealth, if someone had access to the right environmental circumstances, then there was no limit to what that individual could achieve. And psychology was the science that understood how to arrange the environmental conditions in such a favorable way. With messages such as these directed at an upwardly mobile public ready to secure their place in the Promised Land, is it any wonder that psychology was the subject of the hour? But not everyone was on the psychology band wagon. There were those who were wary of the promises and guarantees.

One of the doubters was Canadian humorist Stephen Leacock who, in a 1924 article in *Harper's* magazine, lamented that America was suffering from an outbreak of psychology. He wrote:

- ▶ In the earlier days this science was kept strictly confined to the colleges . . . It had no particular connection with anything at all, . . . and did no visible harm to those who studied it. . . All this changed. As part of the new researches, it was found that psychology can be used. . . for almost everything in life. There is now not only psychology in the academic or college sense, but also a Psychology of Business, Psychology of Education, Psychology of Salesmanship, Psychology of Religion. . . and a Psychology of Playing the Banjo. . . For almost every juncture of life we now call in the services of an expert psychologist as naturally as we send for an emergency plumber. In all our great cities there are already, or soon will be, signs that read "Psychologist – Open Day and Night." (pp. 471–472)

Leacock's skepticism, although offered tongue-in-cheek, was shared by a number of psychologists as well who believed that the discipline was promising far more

than it could deliver. The American public, however, was not interested in hearing from these doubters. Health, happiness, and success were just over the horizon, and psychology was the vehicle needed to get there.

Leacock was right about the outbreak of psychology in America in the 1920s. It may not have included signs advertising the availability of psychologists day and night, but it was evidenced in many other ways. For those individuals who wanted psychological training or credentials there were "schools" of psychology, short-courses, home-study courses, and bogus mail-order doctoral degrees. Popular psychology books and, especially, popular psychology magazines appeared with much greater frequency. And if you wanted to share your interests in psychology with like-minded individuals, cities all over America were establishing psychology clubs.

Popular Psychology Magazines

Popular psychology magazines began publication in the nineteenth century. There were magazines for phrenology, physiognomy, mesmerism, spiritualism, and especially for the New Thought Movement. Perhaps the first American popular magazine to have the word "psychology" in the title was *Suggestion: The New Psychology Magazine* that began publication in August, 1898. A year later *Price's Magazine of Psychology* appeared. Its masthead indicated that it was "Devoted in General to Psychic, Scientific, and Philosophic Research." Articles focused especially on spiritualism, mental telepathy, mental suggestion, and hypnosis. The editor was W. R. Price who used the magazine to promote his school of psychology located in Atlanta. The Dr. W. R. Price's School of Psychology was a mail-order business that offered courses of instruction in a variety of popular psychologies as indicated in an advertisement for the school that read as follows:

- ▶ The New Psychology, Hypnotism, Mesmerism, Animal Magnetism, Telepathy, or Mind Reading, Suggestive Therapeutics, Scientifically Explaining Christian Science, Mental Science, Spiritism, Witchcraft, Osteopathy, Divine Healing And all mysterious phenomena, teaching you how to control yourself and others by learning a profession that will enable you to make from \$2 to \$5 per day the balance of your life. (Price 1900, inside front cover).

There were other early twentieth century popular magazines such as *Mind*, *Personality*, and *The Psychogram: A Magazine of Christian and Practical Psychology*. Even though these magazines appeared after the establishment of the new psychology laboratories in America, their content did not reflect the science of psychology. That would change in the 1920s, or at least it was alleged to change.

The 1920s, a decade that James Steel Smith (1963) has labeled the “decade of the popularizers,” witnessed the publication of nearly a dozen new popular psychology magazines, many of them with the word “psychology” in their titles: *Golden Rule Magazine: The New Psychology* (which actually appeared in 1919), *Popular Psychology: The Magazine of Straight Thinking* (1920), *Herald of Psychology* (1921), and *Psychological Review of Reviews* (1923). Yet none of these magazines sought to deliver the findings of scientific psychology. Although psychology was part of their title, thus capitalizing on the growing popularity of the subject, their content was similar to the popular psychology magazines of the previous century. There was one other magazine founded in the 1920s, however, that claimed to be different. It announced to its readers that psychology was the most practical of all sciences, that great strides were being made in this field, and that the purpose of the magazine was to translate this science into language and prescriptions that would be of use to laypersons. *Psychology: Health, Happiness, Success* began publication in April, 1923, and appeared monthly, with a few exceptions until its demise in 1939. The publisher and founding editor was Henry Knight Miller (1891–1950), a Methodist minister in Brooklyn, New York, who, after realizing some popularity from his self-help sermons, decided to leave his pulpit and launch a new magazine. Miller, echoing the popular writers of his time, touted the value of scientific psychology for health, happiness, and success. He wrote:

- ▶ In *Psychology* magazine we have been applying the principles of scientific psychology to the actual problems and needs of human life. We have sought to build up a sound synthetic psychology, taking what is valid from all schools of psychological thought, simplifying it in expression and applying it to the problems of personal life. (Miller 1928, p. 11)

In actuality there was very little of scientific psychology that found its way into the pages of Miller’s magazine. Academic psychologists did not write for this magazine, nor did they write for the other popular psychology magazines of the time. They wrote articles for popular magazines, such as *Harper’s*, *Cosmopolitan*, *Atlantic Monthly*, and *Collier’s*, but not for these “psychology” magazines.

When the stock market crashed in 1929, the public euphoria of the 1920s gave way to the Great Depression that had profoundly disastrous consequences both economically and psychologically. Psychology received some negative press in the 1930s from writers who were especially critical of the field, noting that psychologists had plenty of advice to offer during the heady times of the 1920s, but now in times of trouble, they were conspicuously silent (Adams 1934; Stolberg 1930). A 1934 *New York Times* editorial criticized psychology as the only trade or profession that had not made public its solutions to the problems of the Depression (as cited in Napoli 1981). Napoli has argued that psychologists seemed content to resume their research “and watch the economists and other social scientists try to solve America’s problems” (p. 64).

One might assume that the public lost faith in psychology as well, and that the psychology magazines would disappear. Yet the message of psychology’s value for self improvement, for the betterment of one’s life, was evidently well engrained in the public’s psyche. These were times when psychology was needed more than ever. And even though two or three dollars might not be an insignificant sum for many Americans down on their luck, it was a small price to pay for a year’s subscription to a magazine that might put them on the road to economic and psychological recovery. At least 13 new American magazines began publication in the 1930s with “psychology” in the title, for example, *Current Psychology and Successful Living*, *Practical Psychology Monthly*, *Psychology and Inspiration*, and *Self-Help Psychology*.

Several of the psychology magazines of the 1920s and 1930s had ties to other entities, some real and some fictitious, yet always designed to promote the credibility of the magazine and increase its circulation. Some magazines advertised themselves as the “official organ” of some society or institute. It is likely that, in most cases, perhaps all, these societies did not exist.

These liaisons were typically announced on the magazine's cover or appeared on the table of contents pages. Thus the magazine *Current Psychology and Successful Living* was the "Official organ of the Psychology Institute of America," and the *Psychological Review of Reviews* was the "Official organ of the International Society of Applied Psychology." The home-study courses used a similar ploy.

Warren Hilton (1920), a lawyer and psychology popularizer, wrote 12 small volumes, each around 100 pages, entitled *Applications of Psychology to the Problems of Personal and Business Efficiency*. The books, intended as a home-study course in psychology, were published "under the auspices of . . . The Society of Applied Psychology" (title page) of which Hilton was president. The purchaser of these 12 books received a large certificate from the Society with the person's name added in attractive script: "This certifies that _____ has been accepted as an Associate Member of the Society for Applied Psychology and is entitled to all the privileges of such Membership."

Psychology Clubs

The other tactic employed by the psychology magazines was designed to increase circulation of the magazines and often to sell other products, typically books and pamphlets that were associated with the magazine. In the 1920s, psychology clubs emerged in cities all over America. In fact, there were some in existence in the previous decade, but in the 1920s their numbers expanded considerably. The magazines sought to establish ties with the various clubs. If all members of the club agreed to purchase subscriptions to a particular magazine, then the magazine would be sold at a discount to all members. Further, the magazine included a regular section that reported "news" from the psychology clubs, which gave visibility and publicity to the activities of the clubs while cementing the magazine-club relationship. Henry Knight Miller's magazine was particularly successful in building such relationships. Some clubs organized within states or with clubs in nearby states. For example, the psychology clubs of Texas and Oklahoma joined together in a federation. The pamphlets describing their activities announced on their covers that the magazine *Psychology*, Miller's magazine, was "Adopted as the Federation's Official Organ."

Not much is known about these clubs because about the only records that have been located are the news items that appeared in the magazines. Thus we know from the March 1924 issue of *Psychology: Health, Happiness, Success* that Bret Barber was the President of the Fort Worth, Texas Club of Applied Psychology. He reported that the club's recent programs included lectures on the effect of anger on digestion, how temperature affects mood, personality in selling, why deafness depresses, and exercises that build happiness. These topics were typical of the content of the club meetings.

Some of the larger clubs met in some kind of meeting hall, but most were small in membership and typically met at someone's house. Programs usually featured a lecture (rarely from a psychologist) and discussion, or discussion of a book or article. Miller was a great organizer of the clubs in America and often traveled to larger cities speaking at joint meetings or conventions of the clubs. Based on the entries in magazines, these clubs may have been composed equally of males and females in the 1920s, but by the 1940s, membership was likely heavily female. This trend appears to have been mirrored in Great Britain as well where popular psychology was labeled practical psychology (Benjamin 2009).

The practical psychology movement in Great Britain began in the early 1920s, partly stimulated by the organizing activities of an American, Anna Maud Hallam, who began her practical psychology program in Cleveland, Ohio, in 1921. She assisted Miller in the early years of his magazine, and her photograph appeared on the cover of his fourth issue (August, 1923). Hallam spread her practical psychology to Canada (Bengough 1923) and to Great Britain reminding her listeners that "your heritage from God is health, happiness, and success" (Hallam 1925, p. 4). The mantra that became a feature in her inspirational lectures and a rallying cry for her audiences was – You can be well! You can be happy! You can be a success! Hallam (n.d.) wrote:

- ▶ It is possible for you to learn how to make life a complete success. The reason why so many people are deficient, unpopular and failures at the present time is because they do not understand the law of life. The science of human life has not been taught in the schools, the home, the clubs, or anywhere else, and

so people have had no chance to learn it. . . I am putting into the common language of every day life the knowledge of the great university class rooms and laboratories. My Psychological Lesson Course covers everything which you need to know to enable you to live up to the perfection of your special type of personality. (p. 5)

In 1925 Hallam founded the second of the practical psychology magazines in England, a monthly magazine entitled *The Practical Psychologist*. She was the author of several books on practical psychology (Hallam 1922a, 1922b) and the founder of the International Anna Maud Hallam Clubs of Practical Psychology which gathered annually in North America for a congress. She made trips to England and Scotland in 1922 to establish clubs and made later trips to South Africa and India to organize clubs there as well. News of activities of these clubs was published regularly in the pages of the British magazines. Historian Matthew Thompson (2006) has described the clubs as a central feature of the practical psychology movement noting that these clubs “provided a site for regular lectures and meetings, libraries of psychological literature, courses of self-improvement, and perhaps even therapeutic attention” (p. 32).

It is not known how long these clubs lasted. The last reports for the American clubs appeared in the late 1940s and for the British clubs in the early 1950s. Several of the magazines that were affiliated with the clubs, including Miller’s and Hallam’s magazines, ceased publication, but the clubs continued their meetings, sometimes with new magazine partnerships. The popularity of psychology remained strong through those decades with new psychology magazines appearing in each. No doubt these clubs served a social function, bringing people together who likely were well educated and who saw in psychology a means for self-improvement. There is no evidence of the existence of these clubs in the 1960s, a decade that can be seen as one in which psychological questions were paramount.

Popular Psychology and Religion

Thomson (2001) has written that the appeal of practical psychology was that it made itself “attractive to a broad spectrum of people, ranging from convinced Christians to those looking for a wholly secularized

religiosity” (p. 121). It was thus offered as a religion to the church and to the unchurched as well. The movement’s religiosity was often veiled; it seemed secular but could also be seen as non-secular. This was a fine line that magazine editors and club organizers walked on both sides of the Atlantic (Cheshire and Pilgrim 2004). Thomson (2006) noted that practical psychology distanced itself from the clearly religious emphases of the New Thought Movement, reminding recruits that practical psychology was based on science. Hallam reinforced this position: “Applied psychology does not affect your religion. It is equally applicable to all classes of people. Psychology is a science, and as such, keeps within the bounds of demonstrable fact and repeatable phenomena” (n.d., pp. 6–7).

But the various popular psychologies of the 1920s and 1930s were certainly sympathetic to religion, and especially so to Christianity. In one of the British magazines in 1924 a columnist made the connection between practical psychology and Christianity even more explicit, describing practical psychology as the “sane exposition of Psychology from the definitely Christian standpoint as the basis upon which the whole structure of human character must rest” (Anonymous 1924, p. 3). A. Myddleton, editor of the first of the practical psychology magazines in Britain, described practical psychology’s role with respect to religion: “Modern Practical Psychology is an enlargement of Christianity to the point that it may minister to every human need both spiritual and temporal. . . The fundamental truths of Christianity were faith, love, peace, joy, power, truth, spiritual healing; and Psychology came along to show us how to turn these ideals into realities” (Myddleton 1925, p. 3). In the United States, religious messages, especially Christian in nature, were common themes in the popular magazines, and in the 1930s three popular magazines began publication whose content was popular psychology as seen in the framework of Christianity.

American society was a contradiction in religious terms in the 1920s. Immigration in that decade was heavily from Ireland and Italy, adding more Catholics to a predominantly protestant America. The Ku Klux Klan, professing their need to carry out the will of God, grew in numbers and power, opposing African Americans, Catholics, and Jews. Sexual mores loosened in a country that banned the production and sale of

alcohol. Urban centers grew in economic and political power over their country cousins. There were battles between science and religion that came to a head in Dayton, Tennessee in 1925 in the Scopes trial challenging the teaching of evolution in public schools.

A number of historians have characterized the 1920s as a decade of individualism that began long before Herbert Hoover gave his famous rugged individualism speech in 1928. Sociologist Irene Thomson (1989) has argued that the individualism of the 1920s fostered the development of “new religious movements and flourishing popular psychologies” (p. 851). The double tragedies of the flu pandemic and World War I had led many Americans to question their religious faiths. They were not ready to abandon belief in a God but they were searching for something that promised betterment of the human condition. For many, science was seen as the provider of new truths, but it could not be a godless science. The new popular psychology fit the bill in all ways. It was said to be grounded in science but despite its adherence to experimental methods and its break with moral philosophy, it had not lost its soul. Pickren (2000) has written that the early experimental psychologists, for example, Hall, James Rowland Angell, and John Dewey, took pains in their writings for the popular press to state explicitly a role for religion in their new science: “The popular press became an arena in which psychologists sought to gain support for their science, to allay public fears about its materialistic implications by emphasizing its harmony with religious faith, and to stress the moral qualities of their work” (p. 1024).

Self-improvement through Home Study of Psychology

Popular psychology promised self-betterment, arguing that the improvement of the self was a holy pursuit. Self-improvement was not a goal to be pursued for selfish reasons, for material wealth, or increased popularity. Self-improvement was about achieving ones God-given potential, about striving for perfection, about achieving a personal state of ability, purpose, and confidence that not only bettered the individual but those who came into contact with that person. Hallam promised self-improvement from her lectures and books, Miller proclaimed it as the focus of his magazine and as the central purpose of his lectures

and books. He published *Practical Psychology* (1924) a home-study course in “Human Efficiency, Health, Happiness and Achievement” in seven pamphlets, 14 lessons. The goal of the lessons was to help the reader achieve a “more abundant life” through self improvement, for example, improving memory, dealing with negative emotions, being a better parent, cultivating optimism, using constructive autosuggestions, and increasing powers of observation.

Besides Hallam and Miller, there were others who marketed their versions of practical psychology such as two attorneys, Daniel A. Simmons and Edwin C. Coffee, who, on their letterhead, identified themselves as “Psychologists, Psychotherapists, Psychoanalysts.” Their address indicated that the home-study product came from their American Institute of Psychology in Jacksonville, Florida. Their program was entitled “The Realization System of Practical Psychology.” It bore some relationship to a system by the same name that was developed by Robert Heap in Britain, editor of one of the popular psychology magazines, but it does not appear that Simmons and Coffee were using materials developed by Heap. Instead, they wrote their own lessons, distributing them first in 1921. The advertising emphasized personal happiness and success: “You can be anything you want to be, have anything you desire, and accomplish anything not in violation of natural law that you wish to accomplish” (American Institute of Psychology 1927, p. 8). The 12 lessons were mimeographed and mailed to subscribers individually with a cover letter for the lesson, culminating with a series of questions. These lessons were billed as “private lessons” indicating to the subscribers that each one had been assigned an individual tutor (Simmons 1936). Subscribers completed the tests and mailed them to the American Institute. The student papers were marked and returned to them along with the next lesson. If students had questions, including those of a personal nature or those regarding how to apply the lessons of the course, they were encouraged to contact their tutor.

One of the most successful of the popularizers, arguably the most successful, was Sidney A. Weltmer (1858–1930) who studied mesmerism as a boy, medicine as a young man, and later became a minister, hypnotist, and faith healer in Nevada, Missouri. He established The Weltmer Institute in 1886, a 17-room facility for his treatments of “suggestive therapeutics.”

The motto of the Institute was “Where every known disease is cured without medicine or surgery.” By 1901 the Institute was seeing as many as 400 patients per day, and another 150,000 individuals per year were being advised by Weltmer and his associates by mail. Notable visitors to the Institute included President and Mrs. William McKinley, Harry Houdini, Luther Burbank, and John Philip Sousa (Brophy 1997). Weltmer also developed a 16-lesson home-study course entitled “Suggestotherapy” (1921) that offered lessons on such subjects as thinking, practical healing, concentration, suggestion, prayer, and forgiveness. One source says that he awarded a half million diplomas from the Institute for his home-study graduates as well as those who attended his many seminars (Brophy 1997).

Even some psychologists got in on the home-study programs. A very ambitious course of 40 lessons was published beginning in 1932 under the editorship of psychologist William Henry Mikesell (1887-) of the University of Wichita. The course, intended for 2 years of study, was entitled “Psychology and Life,” and was published in 10 attractively bound volumes, averaging 320 pages per book or about 80 pages per lesson. The editorial board included a number of identifiable psychologists: Edmund Conklin, Adam Gilliland, Coleman Griffith, and Abraham Roback. The argument for the validity of the course contrasted the authorship of these lessons with what was labeled false psychology written by non-psychologists: “Much of what has appeared under the name of psychology in magazines and in correspondence courses takes its place alongside fake medicines sold on the street corner” (Mikesell 1932, p. 2 of preface).

The purpose of the course, as explained in the preface to the first volume, sounds no different from that of the other popular psychology offerings:

- ▶ These ten volumes present comprehensive discussions of the workings of the human mind. Anyone who reads them will have a splendid working basis for understanding himself in order to correct the inefficient elements of his mind...Every practical problem of the mind that affects the average human being is presented...This comprehensive course enables one to sweep clean the dark, ugly, and troublesome corners of the mind, and to find hope, buoyancy, optimism, and success. (p. 3 of preface)

These volumes do not constitute an introductory psychology course. They draw more heavily on the science of psychology than the other home-study programs discussed but they also offer some of the questionable psychology they criticize in other sources. Consider some of the titles of the lessons: the fulfillment of the individual’s greatest need, the fundamental need of the human being (which, according to the author, is happiness), the all around human being, how to get rid of our faults, the human being as machine, the slave driven human being, the psychology of the as if, and types of human beings (which includes poetical and practical types, endocrine types, the persevering type, the resolving type, and so forth). The intent was to sell this series to the public, and the writing style and content were consistent with that goal. This home-study program mimicked the others in another way as well. Inside the front cover of the first volume was a colorful certificate on parchment, with Mikesell’s actual signature, a space for the student’s name to be added, and suitable for framing.

In truth, psychologists who ventured into writing for the popular media were not able to stay within the bounds of their science. Consider the case of University of Wisconsin psychologist Joseph Jastrow (1863–1944) who wrote a daily newspaper column in the 1920s entitled “Keeping Mentally Fit.” His columns, more often than not, described a psychology that was indistinguishable from that offered by the non-psychologists. In a column on the sporting instinct, Jastrow (1928) wrote:

- ▶ Sport is rather definitely a masculine need. Perhaps some women take to flirtation and bargain-hunting as indoor sport. For hunting is pursuit and that is the second trait in the sporting make-up. When the business man grows tired of chasing dollars in the office because the routine of it gets dull and wearing, he takes his recreation by chasing a golf ball. (p. 220)

And another column on “The art of being happy” offered this explanation:

- ▶ You are happy when your mental or emotional going is with the grain of your make-up; when the mind machine is running free. There are some common cross-grain disturbers of daily happiness. There is fatigue, which puts you out of gas, and makes slow, jolty going to the

next filling station. There is obstruction, which is the other fellow getting in your way. There is worry, which is one of a hundred kinds of engine trouble. (Jastrow 1928, pp. 19–20)

Along with Münsterberg, who died in 1916 before the golden era of popular psychology, Jastrow was one of the psychologists most involved in translating psychology for the public. He wrote approximately 10 books on popular psychology including such titles as *Piloting Your Life: The Psychologist as Helmsman* (1930) and *Effective Thinking* (1931), many of them authored when he was retired and living in New York City. Donald Laird, a psychologist at Colgate University, produced a similar number of books, written principally for the business community on topics such as leadership, increasing personal efficiency, and supervising women in the workplace (e.g., Laird and Laird 1942).

Popular Psychology and the Great Depression

The Great Depression, the only depression that gets capitalized, marked one of the bleakest periods in American history. If you read histories of that Depression – and there are many – you will find them focused on banking policies, politics, business practices, economic theories, and agricultural production. Too often these histories omit the people in the story, the people who lost their jobs (more than 25% of Americans were unemployed at one time), lost their farms, lost their homes, lost their families, and lost their dignity and self-respect. The human cost was unlike anything anyone could remember, certainly worse than the recognized tragedies of World War I. How did the average American, if there was such a person, react to such a dramatic change in life? One view argued that:

- ▶ People were sullen rather than bitter, despairing rather than violent. They sat at home, rocked dispiritedly in their chairs and blamed conditions. Some argue that the unemployed blamed themselves for their plight. Imbued with the success ethic and the American Dream, the unemployed felt that they, not the system, had somehow failed. . . There is in the average American a profound humbleness. People seem to blame themselves. (Badger 1989, p. 38)

An opposing view argued that the conditions of the Depression produced mass rebellions among the

unemployed. These people were dismayed with failed government policies that they believed had produced the Depression and, of greater significance, they were angered by agencies that seemed not to care about the millions of people who were now disenfranchised. Some historians have written that it was the violence from the riots that “eventually coerced welfare concessions from the New Deal” (Badger 1989, p. 38). Either explanation could be seen as supporting a self-help popular psychology, although the self-blame attitude would be particularly in need of something that would promise self-betterment.

As noted earlier, academic psychology received some criticism in articles and editorials during the 1930s, principally faulting psychology for failing to live up to its many promises given the economic and psychological depression that had engulfed the nation. There is evidence (based on article counts in the *Reader’s Guide to Periodical Literature* and *Psychological Abstracts*) that during the decade, academic psychologists reduced their writings for the public and greatly increased their output in their professional journals. It seems obvious that they retreated to the safety inside the ivy covered walls. Whereas psychologists might have been reluctant to write for the public, that was not true of the popular psychologists. Their presence was everywhere in books, magazine articles, home-study courses, and lectures. Recall that there were more than a dozen new popular psychology magazines that began publication in the United States in the 1930s.

Popular psychology books that had multiplied in the 1920s continued to be a major genre throughout the Depression with a newer emphasis, perhaps, on preventing or curing psychological disorders. Leonard Bisch’s (1936) book *Be Glad You’re Neurotic* informed his readers that virtually everyone is neurotic, and it included a test they could take to find out just how neurotic they were. He urged his readers to follow five simple rules: “study yourself, stop reproaching yourself, be proud of what you are, turn your handicaps into assets, profit by your neurosis – then BE GLAD!” (p. 201). Beran Wolfe’s (1933) book, *Calm Your Nerves: The Prevention and Cure of Nervous Breakdown*, counseled the afflicted to “Grit your teeth at symptoms, and go on. Remember that the pain and the adversity of today make your happiness sweeter tomorrow. Throw

off the shackles of the past, and don't worry about the future. Live today. Live now. I give you courage, hope and the will to get well!" (p. 240). Frank Whitesell's (1932) *The Cure for Depression* warned readers that "the writings of men leave the reader hungry and dissatisfied. Only one book satisfies – The Bible. . . All who trust in Him are partakers of His Joy, and their depressions will soon be everlastingly ended" (pp. 123–124).

Still there were hundreds, no doubt thousands, of books, on self-improvement, that would have been especially attractive to those people "imbued with the success ethic and the American Dream." There were books on improving one's personality, on being more assertive (or using the language of the time, having "spunk" or "gumption"), on getting rich, on raising children, on sex in marriage, on succeeding in business, on training for other jobs, and all the other topics that had defined the core of popular psychology since its inception. There were, however, two 1930s books in the self-help genre that became popular, no doubt, beyond their authors' wildest dreams. Both are thought to have sold between 15 and 30 million copies today, and both have been continuously in print since their original publication dates. The first was a book by Dale Carnegie (1888–1955) entitled *How to Win Friends and Influence People* (1936) and the other followed a year later, Napoleon Hill's (1883–1970) *Think and Grow Rich* (1937). Both offered Depression sufferers the promise of self-improvement that could lead to a better life and perhaps to riches. These books are very much in the tradition of the New Thought Movement and what would become known as positive thinking movement, wrongly attributed to Norman Vincent Peale's (1898–1993) best-selling book, *The Power of Positive Thinking* (1952). The idea of positive thinking was at the heart of New Thought and, as noted earlier, embodied as well in the self-help writing of Samuel Smiles nearly a century before Peale (see Ehrenreich 2009, for her thesis on how positive thinking has undermined America).

Conclusion

The story of popular psychology continues into the twentieth century, of course, but is beyond the space limitations of this account. The popular psychology of today, and indeed of the past 70 years, is not very different from the versions offered in the 1920s and 1930s. The psychology clubs may have disappeared but

the other components remain in place. Popular psychology books are abundant, offering success in six easy steps, creativity in five, optimism in nine, and happiness in seven, a genre of self-help books that psychologist Leigh Shaffer (1981) has referred to as recipe knowledge. Psychology magazines still exist, with *Psychology Today*, founded in 1967, being the best known. Popular psychology is found in many other magazines as well, whether labeled psychology or not. Home-study courses have been replaced by on-line courses from legitimate universities as well as bogus ones. And sometimes it is difficult for the consumer to tell the difference. Public lectures and symposia are abundant, a billion dollar industry today, providing thousands of motivational speakers whose lectures promise to teach you:

- ▶ How to get everything you want, how to embrace your struggles and come out on top, how to project a powerful and confident image, how to be recognized and rewarded for your effort, how to score often and big, how to make yourself a valuable asset, how to overcome unforeseen challenges, how to balance your personal and professional priorities, how to rapidly expand your circle of influence, how to develop take-charge leadership, and how to have grace under fire. (*Houston Chronicle*, 2010, p. A9)

It is the public's psychology, and its general nature has not changed much in the past two centuries. People want to improve their relationships, they want to be more successful in the workplace, to be healthier, to raise their kids well, to be popular, to be optimistic, to be positive, to be happier, and to be rich. Samuel Smiles and others who promoted self-help and positive thinking established the model still used by most pop psychologists today, that of personal testimony and case study anecdotes.

Megachurches have enjoyed a phenomenal growth in America in the past several decades. They are Christian, evangelical, and boast huge congregations. Many of these charismatic pastors, like Henry Knight Miller 80 years earlier, offer a gospel of health, happiness, and success. They are among the new generation of pop psychologists. Many preach what has been called prosperity gospel, the belief that God wants his believers to be wealthy, to enjoy an elegant lifestyle. No one demonstrates that better than Joel Osteen, pastor of the

Lakewood Church in Houston, Texas, an evangelical Christian church that enjoys a weekly attendance of more than 40,000 and whose services are broadcast to millions of viewers via television in the United States and many other countries. Osteen's message is relentlessly positive – “God wants you to be happy, God wants you to be healthy, God wants you to be successful, Gods wants you to have a nice home and a fine car.” A time magazine poll in 2006 found that “17% of all American Christians of whatever denomination or church size, said they consider themselves to be part of a ‘prosperity gospel’ movement and a full 61 % agreed with the statement that ‘God wants people to be prosperous’” (Ehrenreich 2009, p. 124). And how is that prosperity to be achieved? “Not through the ancient technique of prayer but through positive thinking” (p. 124). Popular psychology and religion continue to have strong ties.

As noted at the beginning of this chapter, psychology is everywhere today. Arguably the field has never been more ubiquitous, even in the golden era of the 1920s. Psychologists today mirror their colleagues of more than a century ago by decrying the many psychologies that they see as bogus, especially all of the invalidated therapies: energy breathing, past lives therapy, primal scream therapy, facilitated communication, neural organization techniques, thought field therapy, hypnotic age regression, neuro-linguistic programming, and many, many others. Oh, and don't forget, rebirthing therapy. Labeled psychobabble and biobunk by psychologist and author Carol Tavris (2000), these therapies are a part of the public psychology that cast doubt on the validity of the science of psychology. Rarely, if ever, are these therapies endorsed by any legitimate psychologist, and, sadly, most are never broadly condemned by the psychological community. Instead, they are mostly ignored. Perhaps psychologists have concluded that they can do no harm, or that they would disappear if people would only use their intelligence, recognizing the bogus therapies for what they are.

The perceived credibility of psychology as a science was a concern for the pioneering psychologists in the 1880s who established the first laboratories in America. And it remains a concern today for contemporary psychologists who can be found as second-class

scientific citizens in their universities, housed in colleges of liberal arts or social sciences and rarely grouped with the “real” sciences of physics, chemistry, and biology. There are many examples of a lack of confidence in psychology as a science. When President Ronald Reagan assumed office in 1980 he called for an elimination of all National Science Foundation (NSF) funds for psychology, a field that he viewed as a pseudoscience (then why did he listen to his wife's advice based on her astrologer's reports?). Through some lobbying efforts, Congress was able to restore 50% of that funding immediately. But it would be years before psychology reached the level of NSF funding it had enjoyed before the Reagan presidency. In 2006, Senator Kay Bailey Hutchinson from Texas introduced an amendment to an appropriations bill that called for an elimination of all funds for psychology and the other social sciences for the NSF budget. Fortunately for psychologists (and sociologists, economists, anthropologists, and political scientists) that amendment was defeated. In another show of psychology's status in the scientific community, the year 2009 was declared “The Year of Science” in the United States. To celebrate that designation, the National Academy of Sciences featured a different scientific emphasis on its website for each of the 12 months of the year. Not one of the 12 features was about any one of the social sciences, all of which belong to the National Academy of Sciences.

The public may not be able to distinguish the science of psychology from a host of pseudopsychologies but Congress, the Executive Office, and federal agencies need to be able to do so. If psychology is to receive its fair share of federal funding, if psychologists are to be involved in national policy decisions where human behavior is a key concern, if psychology is to be a player in health care where most of the leading killers today (heart disease, cancer, stroke) have important behavioral components as part of their etiology, if we want to get people to behave more ethically, reduce violence, improve parenting, improve education, prevent and cure addictions, reduce pollution, improve communication networks, and reduce prejudice, then psychology has to be respected and supported as a science that can be a key player in the twenty-first century where so many of the problems that face America and the world are behavioral problems.

In the past decade both the American Psychological Association and the Association for Psychological Science have established programs to improve the public's understanding of psychology. But as should be abundantly clear by now, this is not an easy task. Indeed it may be a hopeless task (see Burnham 1987). Jill Morawski and Gail Hornstein (1991) have wondered why psychology has had such difficulty in "establishing themselves as the arbiters of psychological knowledge" (p. 127). Other disciplines have succeeded in becoming experts in their own fields. So why not psychology? Morawski and Hornstein suggested that:

- ▶ ...part of the problem has to do with the subject matter of psychology. People seem to feel acutely ambivalent about giving the analysis of their private experience over to outsiders, alternatively seeking and rejecting the opinions of these "experts." For psychology to succeed in garnering for itself hegemony over the psychological realm, it would have to persuade people that they were entirely incapable of understanding the conduct and meaning of their own lives. (p. 127)

So acknowledge that the public owns its psychology. Given the explanation offered above and the various reports on scientific illiteracy in America the situation is unlikely to change.

A better strategy for organized psychologists within APA, APS, and other psychology organizations would be to target the policymakers and funding agencies in government, health, science, and education, helping them understand the potential of psychological science and practice, and translating the research in ways that are useful to those and other entities. As psychologist George Miller (1969) said more than 40 years ago, "The most urgent problems of the world today are the problems we have made for ourselves. They have not been caused by some heedless or malicious inanimate Nature, nor have they been imposed on us as punishment by the will of God. They are human problems whose solutions will require us to change our behavior and our social institutions" (p. 1063). The need for psychological science is great, but there has to be recognition of its validity if it is to realize its potential. Psychologists can do something about that, and they need to do it now.

American Mental Philosophy (1820–1860), History of

ALFRED H. FUCHS

Bowdoin College, Brunswick, ME, USA

Introduction

Between 1820 and 1860, roughly from the decade following the end of the War of 1812 until the eve of the Civil War, textbooks with the titles of *Intellectual Philosophy*, *Mental Philosophy*, or *Psychology* were written by professors in American colleges to introduce their students to the study of the human mind. Whatever the title, the study of mental philosophy was a significant part of the education of college juniors and seniors in the nineteenth century. The authors of the textbooks modified the philosophies of mind inherited from the British intellectual tradition to accord with the conclusions they reached from examinations of their own minds.

The appearance of textbooks written to introduce the study of mind to college undergraduates and students in academies (secondary schools) was a departure from the practice of the colonial and early federal periods in the United States during which students read the philosophical treatises of English and Scottish authors, most commonly John Locke's *Essay on Human Understanding* (Locke 1975) and Dugald Stewart's *Elements of the Philosophy of the Human Mind* (Stewart 1833). Stewart's *Elements*, together with Thomas Reid's *Essays on the Intellectual Powers of Man* (Reid 1857) and Thomas Brown's *Lectures on the Philosophy of the Human Mind* (Brown 1826), represented Scottish common sense realism, a position that affirmed the reality of the external world and the appropriateness of investigating it with the methods of science. That method was extended to the study of the human mind. The Scottish philosophy and the Presbyterian/Congregationalism theology associated with it provided the philosophic and religious context for the study of mind as the nineteenth century began.

The Scottish tradition was supplemented in some textbooks with German philosophy in the middle decades of the century, but prevailed relatively unaffected in others until after the Civil War. The American

professors whose classroom lectures comprised the textbooks attempted to interest and educate those students who heard their lectures or read their textbooks by providing them with what their authors hoped was a fresh, independent understanding of the nature of mind. The spirit of independent inquiry inherited from the British Enlightenment made them confident in the potential of the mind to understand the natural world, the relation of human beings to it and their Creator, and to understand the mind itself.

Although the texts varied in their approach to mind and the description of its processes, they nevertheless had a great deal in common. The textbooks shared a sense of building on the past to achieve something new, appropriate to a new nation only recently removed from colonial status. The earliest texts and those that appeared in the decades that followed were part of a general movement in the United States to match political independence from Great Britain with intellectual and cultural independence. Americans, in seeking a standing among the nations of the world in the arts, literature, philosophy and science sought to make distinctly American contributions that surpassed those of the Old World. For example, the variety of flora and fauna found in the United States challenged British and European classificatory schemes that led to additions to, and changes in, taxonomy. Organizing the results of observations of the natural world into orderly taxonomies characterized the developing sciences, such as biology, geology, and mineralogy, and was the task undertaken by the philosophers of the human mind as they identified and classified the mental processes that their examination of the mind revealed to them.

Science held a significant place in the hierarchy of American values in the early decades of the nineteenth century, such that virtually all disciplines were pursued as science, including theology and philosophy. Natural theology, the science that studied the world and its life forms as the products of creation, was pursued as a source of knowledge about the Creation and the Creator that supplemented that which was revealed in the Bible. The philosophers of mind, graduates of seminaries and trained for service as ministers, brought to their subject a similar commitment to pursue the investigation of mental life as natural science, free from past dogmas.

The science of the time was that represented by Francis Bacon and Isaac Newton. The ancient approach of the Scholastics, who sought truths through deductions from fixed principles, was replaced by induction from observations of the natural world to arrive at truths. Newton had followed this path to arrive at the laws of planetary motion and a fresh conception of a universe guided by laws, arrived at inductively. The first task facing the theologically trained mental philosophers as they began their attempt to develop their philosophies of mind was to observe the content and processes of their own minds and attempt to discern the laws that governed them. They avoided adopting any earlier philosophy of mind (although they borrowed freely from past philosophies) in favor of constructing one consistent with their own observations, supplemented with supporting evidence from many sources, such as examples from recorded history, literature, the Bible, medical and legal cases, inferences from comparisons between normal and imperfect minds, the young and old, and human and animal behavior.

Identifying and describing the processes of the mind constituted the first step in building a philosophy of mind. Just as observations of the natural world were categorized, such as separating flora from fauna and arranging for subcategories within the larger groupings, so too the processes of mind were labeled and organized into a comprehensible taxonomy. In their textbooks, the mental philosophers adopted and adapted the nomenclature for mental operations that formed the basis of the common discourse on mind as embedded in past philosophies and common language. There were many different systems from which to choose, but the textbooks, heavily reliant on the British empirical tradition and Scottish common sense realism, were nevertheless eclectic.

The phenomena of mind identified through conscious examination comprised a wide range of conscious experience, designated by commonly accepted terms: sensation, perception, images, ideas, memory, imagination, reasoning, abstraction, association, feeling, emotion, instinct, desire, will, and more, with some requiring differentiation, as with different kinds of memory, and other phenomena requiring the adoption of now less familiar terms, such as conceptions. Although some textbooks addressed the phenomena as

independent processes, others attempted to group them, as intellectual processes, different from feelings and motives. Will presented a special problem: was it subsumed under motives and determined by them, or free? And how did such processes relate to each other to produce coherence in consciousness and in conduct? In arranging the processes of mind into a workable system, differences arose among the mental philosophers, in adopting different labels for the same mental process, or assigning the same process to a different taxonomic category.

The authors of the textbooks were also mindful of Bacon's exhortation that the results of science should be useful to those who study it. Accordingly, the textbooks proclaimed the study of mind to aid in self-understanding and to be helpful in practical affairs, such as assisting parents and teachers in meeting responsibilities for shaping the minds and the behavior of those in their care. Advice was offered for engendering good habits of moral behavior as well as for the task of studying and learning, the more immediate concern of the students who read the textbooks. This further justification of the usefulness of the study of mind helped to affirm the place of the study of the philosophy of mind in the curricula of American colleges at that time and in the future.

Although a wide variety of textbooks devoted to the understanding of mind and its processes were published in this period, the present essay describes the philosophies of mind offered by only some of the more widely used and influential textbooks. They illustrate the approach to the study of mind and the resultant philosophies that were embodied in the introductory textbooks of the period. The philosophies of mind represented were shaped by the philosophical past, the science of Francis Bacon and Isaac Newton, and the theology of Protestant America. The textbooks introduced students to the issues and difficulties inherent in the study of mind, offered a substantive account of the state of knowledge of mental processes, provided taxonomies that organized these processes to reflect a coherent and unitary mind, and suggested ways in which the successful understanding of mind and its operations could be usefully applied to individual lives. As such, they constitute a survey of the processes of mental life as complete as the methods and knowledge of the time permitted.

Textbooks of the Antebellum Period

The First Textbook

Thomas Cogswell Upham (1799–1872), a graduate of Dartmouth College (1819) and Andover Seminary (1821), was appointed, in 1824, as Professor of Metaphysics and Ethics (a title later changed to Professor of Mental and Moral Philosophy) at Bowdoin College. He was well educated in philosophy, theology, the languages of the Bible (Greek, Latin, and Hebrew) and German, the language of Biblical criticism, and German philosophy. His education for the ministry prepared him to become a professor in an era when professors were generalists, before specialized graduate education in academic disciplines became the standard for college teaching.

As he completed his pastoral duties as Pastor of the First Congregational Church of Rochester, New Hampshire, he prepared lectures for his first year of teaching. His *Elements of Intellectual Philosophy* (1827; second edition, 1828) is considered to be the first American textbook offered for use in colleges and secondary schools. It embodied an eclectic philosophy of mind that borrowed ideas freely from any source, even, he confessed, using another author's own words when he thought them the most felicitous for his purpose. He avoided metaphysical speculation, emphasized induction from observations, and suggested applications of the knowledge of mind to practical affairs. He specifically rejected past allocations of mental processes into larger categories, such as *Understanding* and *Will*, or *Intellectual* and *Active Powers*, on the grounds that there was a lack of clarity in the basis for assigning processes to these insufficiently differentiated categories.

As a result, the chapters in the first two editions of Upham's textbook comprise a variety of topics without providing a coherent philosophy of mind. Topics devoted to mental processes, the senses, perception, attention, memory, simple and complex ideas, the nature of thought, reasoning, imagination, emotion and will, would be expanded and developed in subsequent editions, but other topics, such as rules for debate, would not survive. Upham continued to work toward a systematic statement of mind, sifting through his material as his system took shape. For example, one topic, language, was introduced in the

first edition of *Intellectual Philosophy* (1827) as part of his chapter on thought; language gave expression to the content of mind and permitted its communication to others. In an independent chapter, Upham addressed the origins of language, oral and written, from gestures and graphic representations to the characteristics of language and rules for translating from one language to another. In the second (1828) edition, the discussion of language was expanded into several chapters, separating language from thought. Upham did not identify language with thought, as James Rush had done, nor did he, like Rush, make it a separate department of mind (Ostwald and Rieber 1980). Rather, he treated language as an outward expression of internal thought, similar to a physical act that might be initiated by thought to serve the ends of a motive and/or the will. Chapters on language appeared within his category of intellectual processes when Upham adopted a two-part division of the mind (Upham 1831) but were ultimately relegated to an appendix in the three-volume edition of his complete system by (Upham 1840b, c). He omitted the chapters from the abridged edition of his work (Upham 1840a).

The adoption of a two-part taxonomy of mind, *Intellect* and *Sensibilities*, in the two-volume third edition of his textbook *Elements of Mental Philosophy* (1831; abridged edition, 1832) was the first step toward his complete system of mind by giving equal status to the intellect and the sensibilities (feelings and emotion) as taxonomic categories. In 1834, he wrote *A Philosophical and Practical Treatise on the Will* in which he examined the issues of the freedom and power of the will. The *Will* was added as the third taxonomic category to complete his organized system of mental philosophy to expand it beyond the narrow rubric of intellectual philosophy.

Upham was prompted to add the *Will* as his third department of mind, “the keystone that completed the arch,” by his reading of Asa Burton’s *Essays on Some of the First Principles of Metaphysics, Ethicks, and Theology* (1824). The essays of Burton (1752–1836), Pastor of the Church of Christ in Thetford, Vermont, formed the core of a course of study designed to prepare prospective ministers for their professional role. Knowledge of the principles under which the mind operated could aid a minister in his attempt to comprehend and cope with the behavioral vicissitudes

of members of his congregation and assist him to guide them to appropriate moral behavior. Moreover, Burton believed that because the mind of human beings, like their physical form, was created in the image of God, understanding the human mind presented the possibility of understanding the mind of the Creator.

Each of Burton’s three faculties represented a capacity, or preparedness, of the mind to perform an operation, such as perceiving (the operation of *Understanding*), feeling (the operation of *Taste*), and volition (the operation of *Will*). Previous classifications had subsumed *Will* under *Taste*; freeing *Will* from *Taste* enabled Burton to argue for the liberty of volitions, guided, but not strictly determined by, feelings or motives, so that that human beings, obligated to choose between good and evil, were held responsible for choices made.

The final form of Upham’s system reflects his reading of Burton, although the development of his tripartite taxonomy of mind went beyond Burton in its development and thoroughness. Upham’s three “departments” of mind represented different modes of activity in which a unitary mind acted. He was skeptical of popular phrenology and the divisions of mind on which it was based, not only because of the materialism represented by the assignment of specific operations of mind to localized parts of the brain, but also because he rejected the notion that an immaterial mind could be subdivided into independent units. The task of the philosopher was to identify the many processes of mind revealed in consciousness, distinguish among them, place them within the appropriate department of mind, describe how they operated within consciousness to determine human behavior, while recognizing that the mind functioned as a whole.

Within the *Intellect*, the senses provided conscious experience of a real world outside the mind. Auditory, visual, olfactory, tactual, and gustatory sensations formed the basis of perception. Mental contents of external origin constituted one division within the *Intellect*; external stimulation produced knowledge of the world outside the mind and shaped awareness of it. Internal processes inherent in the *Intellect* provided knowledge through reasoning, suggestion and the laws of association (e.g., resemblance or contrast) that govern relations among mental contents. The sensory and perceptual experiences provided by the senses

included conceptions (images) of preexisting sensations or perceptions, or dreams that arise from stimulation during sleep, as when cold feet may generate a dream of walking in snow. The processes of internal origin (e.g., doubting, or belief, or certainty) provide knowledge that does not rely directly on the senses. The notion of the mind itself is considered by Upham to be suggested by our experience of its various feelings and operations, including a sense of personal identity. Other processes originating from within the mind itself include attention, reasoning, memory, and the laws of association that regulate the train of conscious experiences.

Upham also divided the *Sensibilities* into two components: (1) the natural sensibilities of emotions, desires and instincts, and (2) the moral sensibilities, emotions of moral approval (conscience), and feelings of moral obligation. The distinction recognizes the emotional and motivational processes of mind (e.g., instincts, appetites, and desires) that are shared with animals. Emotions vary in strength and in kind, joy and grief, for example, and more complex emotions as well, while desires include instincts and appetites. Feelings attributable to conscience, however, are presumed to be uniquely human, part of the moral nature of the human mind provided by the Deity, and capable of being strengthened through moral and religious education. As moral agents, human beings are held responsible for their actions. It is in this division between natural and moral sensibilities that Upham provides the essential basis for choices presented to the operation of will.

The *Will* represented the final mode in which mind operated. Its sole mental process was that of volition, a mental state that varied in power (like other mental states) and is manifest in the capacity of the mind to direct attention, control passion, and persist in the face of obstacles and to carry out complex plans. Acts of will have some object or purpose, are future oriented and related to mental acts, such as, for example, directing attention, or behavior, as in catching a ball. In Upham's model of the mind, behavior originates when an intellectual process, of either an external or internal source, stimulates an emotion, natural or moral, that prompts the will to put forth a volition. The primary issue concerning the will is whether it is free.

For Upham, to assert that the will was completely free seemed to contradict the universality of the natural

law that governed the world as Divinely created. He argued that ideas of God imply prescience and foresight; prediction of future acts in Biblical prophecy is evidence of foreknowledge, and hence they demonstrate lawfulness. In human affairs, the prediction of future events and the reasonableness of expectations are possible only if events follow a law or principle that regulates behavior. Being able to carry out plans, the apparent consistency and predictability of the future actions of individuals and groups, in at least some spheres of activity, imply the operation of laws governing the operation of will.

At the same time, Upham also argued, the evidence of consciousness suggests that the will is free; its freedom is implied in the moral nature inherent in human beings, consistent with ideas of right and wrong and the sense of moral obligation that is part of conscious experience and essential to moral accountability. To the argument that will is governed by the strongest motive, and therefore not free, Upham replies that it is a mere tautology to suggest that will is governed by the motive by which it is governed. He suggests that the freedom to choose among motives is the essence of the freedom of the will. Yet, law and liberty go hand in hand, and without the regulation of law, human behavior would be capricious and chaotic. Thus, Upham concludes, the will is both governed and free, but how this can be possible may be beyond the comprehension of the human mind, a mystery that nevertheless represents the reality of the human condition.

Finally, in addressing the mental processes that he described and cataloged, he noted, with evidence from direct observation and his reading of legal and medical sources, instances of imperfect and disordered mental functioning. Seeing apparitions, for example, suggested a disorder of perception; excessive appetites or immoral actions evidenced disorders of the natural or moral sensibilities; an inability to resist impulses to immoral action or acts of depravity indicated an imperfect or disordered will. The causes of mental disorders, Upham suggested, were to be found in the mind, body, or the connections between them. Bodily effects on mind were apparent in the decline of the senses in advanced age that resulted in the decline of sensory experience, perception, and/or memory; drugs and noxious gases might produce temporary mental disorders.

The effects of mind on the body might be found in disturbed behavior or overheated blood from an excess of passion or excited imagination. Explanations of disordered mental action did not simply invoke materialism and the action of the central nervous system. Although he was willing to accept the possibility that insanity was wholly a result of a physical condition, Upham also suggested that extreme disorders of mental processes might be the result of secret impulses of the interior nature of mind itself that were not available to conscious experience. Treatment alternatives included the medical practice of bloodletting, for example, for a case of a body overheated by passion, or education and moral suasion to strengthen a defective will. Any measures that might restore or improve the health of the body, especially the central nervous system, or mental training to correct imperfections in mental processes were thought to be useful in treating an imperfect mind. Upham published the chapters from his text in a small volume addressed to the general public, the first attempt outside medical treatises to consider problems of mental disorders: *Outlines of Imperfect and Disordered Mental Action* (Upham 1840d). In the same year, he published the three-volume *Elements of Mental Philosophy* (Upham 1840b, c) that represents his completed system (an abridgment of his system under the same title containing the three departments was published by Harper's in 1869).

The German Influence

Upham's text was widely adopted in colleges and universities during the nineteenth century (it was in print and advertised as late as 1892). It was a thorough and comprehensive examination of mind carefully considered that evolved from his first textbook of 1827 to the completed system of 1840. In that year, *Psychology; or, A View of the Human Soul, Including Anthropology* (Rauch 1840) was published, the first American textbook to have "psychology" in its title. Its author, Frederick Augustus Rauch (1806–1841), a graduate of the University of Marburg (1827), was on the point of being promoted, while still in his mid-twenties, to a professorship in metaphysics at Heidelberg when he was advised to emigrate because of his criticism of policies of the government. In the United States, he taught music and German at Lafayette College, for 1 year, qualified for the ministry in

the Reformed Church, and became Professor of Biblical Literature in the German Reformed Theological Seminary in York, PA. When a classical school was added to the Seminary and, later, chartered as Marshall College in 1836, Rauch was named its first president (Marshall College was merged in 1853 with Franklin College to become Franklin and Marshall College).

Rauch's textbook, the published version of his lectures to the Junior Class, was also addressed to members of the general public who, like his students, stood to benefit from a greater understanding of the mind and its role in their lives. In his textbook, he sought to unite German and American mental philosophies, in part by bringing psychology and anthropology together as complementary disciplines in the study of mind. Psychology examined mind in relation to itself, while anthropology examined the connection of mind to body and their reciprocal influences. Immanuel Kant had argued that psychology could not become a true natural science because mental events could not be measured or weighed and, moreover, introspection distorted the mental events being observed. To improve its status as science, Kant suggested that psychology adopt the methods of anthropology and observe human activity in realistic settings as public, observable manifestations of mind as a supplement to the results of introspective explorations of mental processes. Rauch embraced Kant's suggestion, as the title of his textbook makes clear.

Like the other theologically trained authors of textbooks, Rauch approached his analysis of mind from a Judeo-Christian perspective. Human beings, as descendants of Adam and Eve, constituted the common subjects of both psychology and theology; without religion, human beings are merely animals. More than other textbooks of the era, Rauch defended the special status for humans as created in God's image and used the comparisons between human beings and animals to introduce anthropology as a discipline that could aid in understanding the nature of mind. Animals, he argued, have sensations and perceptions, but in animals, one sense tends to dominate, while in humans, all senses are used with equal facility. Cognitive awareness of objects not immediately present (i.e., having a mnemonic image) characterizes humans, who alone are capable of apperceptions or thoughts that involve making judgments and drawing conclusions. And while

animals may feel pleasure or pain, they are incapable, Rauch believed, of the distinctly human feelings of hope or joy. Animal instincts reveal the prescience of the Creator in providing animals with operations analogous to reasoning for their survival, which they accomplish without reason or self-consciousness (the awareness of their own mental activities).

In examining the connection between mind and body, Rauch suggested that the mind was influenced by such physical characteristics as race, including the effects of the environments in which different races originated and resided and the effects of differences between the sexes. Transient influences on mind, such as age, sleep, and dreaming, and states induced through animal magnetism (hypnosis) represent temporary mental conditions. Temperaments, such as those imparted through physical characteristics, as induced by bodily humors (e.g., a choleric temperament as a result of an excess of blood) also shaped mind and conscious experience. Rauch's discussion of these influences, and the examples and anecdotes that he employed as evidence of them, reflect the state of knowledge, beliefs, and opinion of the time. For example, he repeats nineteenth-century views on the relation of differences in physical structures between men and women to differences in the minds of each sex and to the roles in social life to which these mental and physical attributes of women and men fitted them. The effects of age on mind are described in terms of changes from childhood to maturity and the eventual decline of mental powers in old age.

In discussing the effects of mind on the body, he accepted anecdotal accounts of the effects of experience, such as an instance in which severe fright to the mind of a mother produced a physical disfigurement on a developing embryo, or the supposed effects of a wicked heart on the physiognomy of an adult. He leaves open the possibility, suggested by phrenologists, that the power of the mind, in exercising its capacities, can enlarge parts of the brain and have the effects of its exercise known through the shape of the skull. In pursuing the study of mind in the context of anthropology and addressing external influences on the mind–body relationship, Rauch placed those influences into greater focus than many of his contemporaries, who noticed them, if at all, in passing, as they discussed their primary concerns, viz., the operations of mind itself.

Psychology, as distinct from anthropology, examined the internal operations of mind by looking inward to examine itself, to recognize the difference between the sensations produced by an object and the external object itself (through attention and judgment), and to comprehend that an individual object may represent a general class of objects. Such operations within consciousness are not considered by Rauch to be faculties, but, like Upham and his contemporaries, he rejects the notion that mind consists of a bundle of separate, mechanical operations, each with a distinct consciousness: he is at pains to emphasize the operation of mind as a whole. Although he approaches an understanding of mind through discussions of *Reason* and *Will*, he emphasizes that the two are essentially one: *Will* is *Reason* with a “practical tendency.”

Rauch's discussion of *Reason* begins with the consciousness of feelings and sensations that depend upon the senses and constitute the origin of knowledge. Conceptions are images of past sensations that may be connected by the laws of association (e.g., cause and effect, contrast or resemblance); images may be modified through imagination to construct images of things never before seen. Images are connected to words, and words to images, through memory; in this, Rauch may be considered a pioneer in semeiotics (Roback 1952). Ultimately, however, what the mind makes of the contents and products of consciousness depends on pure thinking, a process that is more than abstraction and generalization, but a contentless process (pure thought, not images) that seeks the true nature of things, as exemplified by, for example, Isaac Newton, and is not necessarily engaged in by everyone. Pure thinking is characterized by comprehension, judgment, and syllogism/conclusion (thus making pure thinking akin to, if not the equivalent of logic, as taught in the texts of his day). The activities of mind that he describes are those common to the texts of the descendents of the British philosophers, available to common experience and embodied in language. The consideration of pure thinking bespeaks the influence of Kant and the German philosophers.

Will, in Rauch's analysis, encompasses the emotional and motivational contents of mind, such as passion, many kinds of desires and love, and complexities of emotions. But the emotional–motivational states are related to *natural*, as distinct from *moral*, will.

The latter operates with respect to law, moral obligations, rights and duties. Natural will is governed by motives and emotions and accomplishes for human beings what instinct does for animals. The moral will, however, is free to choose. In this way, Rauch attempts to resolve the problem of the debate between the freedom of the will and determinism, in that, for him, freedom of action is possible only with respect to moral choice.

Finally, Rauch concludes his textbook by considering the relation of human beings to their Creator. He argues that religion rests on faith, a gift of God. Heathen religions, he holds, are created by the minds of human beings, perhaps through superstition and imagination, but a true religion connects God to those to whom He has given faith. In concluding his text with this discussion of religion, Rauch reinforces his general view of the place of human beings and their mental life in a theological context, in which anthropology and psychology may aid in the understanding of the influences on the operations of mind, but that these sciences are part of a larger understanding of the place of human beings in the world as created.

Rauch's textbook, with its attempt to unite German and British philosophical traditions in the philosophy of mind, was not alone in reflecting the influence of German philosophy. Laurens Perseus Hickok (1798–1888), born in Bethel, Connecticut, approached the study of psychology from a perspective influenced by his reading of the German philosophers and of Rauch' textbook. He graduated from Union College in 1820, studied theology, was ordained, served as Pastor to two Connecticut congregations and was appointed Professor of Theology at a college in Hudson, Ohio, that later became part of Western Reserve University. In 1844, he was appointed Professor of Theology at the Auburn Theological Seminary where he published his first book, *Rational Psychology; or, The Subjective Idea and the Subjective Law of All Intelligence* (1848; revised edition, 1861). He was called to his *alma mater*, Union College, as Professor of Mental and Moral Philosophy and Vice President of the College where he published several books, most notably, for his place in the history of psychology, *Empirical Psychology; or The Human Mind as Given in Consciousness* (1854). After he retired in 1868, he moved to Amherst, Massachusetts where, with his nephew, Julius Seelye, President of Amherst

College, revisions of his *Empirical Psychology* (Hickok 1882) continued in print through the end of the nineteenth century.

Hickok's *Rational Psychology* attempted to establish an epistemology for psychology by identifying the principles and laws that make experience possible and intelligible, principles and laws that transcend experience. In his *Empirical Psychology*, in contrast, he attempted to ascertain the facts of conscious experience and arrange them in an orderly system. He contrasts the rational vs. empirical approaches to psychology with an analogy to astronomy: the laws and principles under which the solar system operates is akin to a rational psychology; gathering facts about the system and the stars and planets within it is akin to an empirical psychology. The laws of gravitation require that the solar system *be as it is* (the rational underpinning of the system); describing the system *as it is* represents the empirical science. In applying this distinction to psychology, Hickok devoted 700 or more pages of his *Rational Psychology* to describing the principles that dictate that the experiences of consciousness *must be* as they are. His *Empirical Psychology* describes the facts of experience as they *are*, as revealed in consciousness. Empirical psychology describes the mental phenomena and their interrelations as observed in the clear light of consciousness, which he described as a "psycography" of mind, rather than a philosophy of it, with no claim to being a pure science.

The description of mind that Hickok offered in his *Empirical Psychology* was little different from the facts and organization of mind to be found in the textbooks by his contemporaries. However, Hickok was more sensible of the difficulties that faced the philosopher of mind in collecting and arranging the facts of mind. He noted, for example, that turning attention inward, away from the customary attention to the external world, to identify and label fleeting and nonmaterial mental events, is an unaccustomed activity that might, as a result, lead to superficial examinations of consciousness. He also pointed out that errors can arise by mistaking the spurious for the real, through the ambiguity of language: the use of terms appropriate to the physical world to describe the mental world could result in erroneously ascribing qualities of the physical world to conscious experiences, a problem that would persist into the last quarter of the nineteenth

century (Richards 2004). Similarly, physical laws that govern the external world might be mistakenly applied to operations of the internal world of the mind, whose laws and operating principles are inherent in it and not necessarily the same as, or analogous to, laws that govern the physical world. Despite these difficulties, Hickok argued that the facts of mind must be found in each individual's consciousness and he warned against trusting too readily the testimony of others. He counseled that practice in shutting out the external world and focusing the senses on the internal world of consciousness was requisite to develop the habit of introspection necessary to a reliable account of the nature of mind.

Introspection was difficult, but not impossible, as a means to arrive at a philosophy of mind; it required a methodology through which the inner sense might provide a picture of the facts of mind that another could verify by a similar investigation. Investigations of mind focus on single facts, such as a thought, or emotion, or volition; each fact requires completing a detailed examination of it before another fact is examined. Considering each fact carefully is the basis for comparing facts, for noting their similarities and differences, and for ascertaining the relations among them. Facts of mind, so gathered, require classification based on their characteristics as revealed in consciousness. Although the validity of the facts of consciousness and their classification rests on each individual consciousness, disputes about them that may arise may be resolved by appeals to common consciousness, common sense, the evidence provided by history and/or by language. Hickok was attempting to make the method of observation (introspection) as reliable as observations of the events of the world outside consciousness. In recognizing the potential pitfalls of introspection and in suggesting a method to avoid those pitfalls, Hickok anticipated later attempts to make introspection a method for the rigorous examination of consciousness in psychological laboratories of the late nineteenth and early twentieth centuries.

Like Rauch, Hickok began his account of psychology by considering the significance of anthropology for the study of mind, especially with respect to the influences of the body on the mind. Hickok, also like Rauch, described the physical variations of race that arose from the environments in which each evolved,

but he attributed no particular mental differences among the races to those environments or to inherent differences among races. Differences in the minds of men and women were described in ways that accorded with differences in the stereotypical roles according to each sex in Hickok's era and individuals were held to differ in varying degrees with regard to temperament (sanguine, melancholy, choleric, or phlegmatic). Because the mind develops to maturity as the body does, the quality of mind varies with age. Other influences of the bodily constitution on the mind that Hickok noted include transient influences such as sickness, the sleep-waking cycle, and the incitement of strong emotion. His account is much like that of Rauch (1840).

Hickok laid the groundwork for his empirical psychology by describing what he termed the general and primitive facts of mind. The former included such characteristics of mind as its permanence (its persistence through time) and its ability to distinguish itself from its experiences. The mind is self-active, set in motion by its Creator, and unchanging through time. Consciousness is not the same as mind, but constitutes "an inner illumination." The primitive facts of mind include consciousness, sensation, and the mental states that form the basis for knowing (Intellect), feeling (Susceptibility), and choosing (Willing), and constitute the three divisions in which the facts of mind are considered. The first function of the Intellect is *Sense*: knowing, feeling, and willing come into play when sensory impressions blend with an emotion, which, when further blended with a purpose, might result in an act of will. For example, the sight of a rose in bloom excites pleasure, which, when joined with the purpose of smelling it, might lead to the act of walking toward the rose to take in its fragrance. The *Intellect* receives impressions from the external world through the sense organs by actively observing and focusing attention on objects in the world. Information about the quality, quantity, and location in space of objects is provided by sensation and attention, which together combine to form a perception. An internal sense, parallel to the external senses, provides the capacity for knowing the inner workings of the mind in its different modes.

The second function of the Intellect *Understanding*, through which the observation of an individual object may be integrated into a conception, such as

the general notion of “house,” as opposed to a particular house. Memory, as part of the understanding, constitutes representations of phenomenon previously represented in consciousness and organized through the laws of associations (e.g., contiguity, similarity, etc.) by which they may be recalled to consciousness. Reflection constitutes the ability of the mind to turn in on itself to examine conscious mental events at, perhaps, greater leisure than the initial experience of those events might have allowed; association may bring past events to mind, but reflection allows for the examination of the relations among memories more closely. Judgments represent the processes of forming connections among objects and experiences, through analysis, synthesis, the use of syllogisms, and induction and deduction. Finally, imagination forms part of the Intellect; in forming images of objects previously seen, it is reproductive imagination, and of something wholly original, it is productive imagination. Imagination differs from fancy, which refers to the capacity of mind to conjure mental images in the absence of external sensory stimulation, as in daydreaming, or phantasms of sleep, or the extremes of *delirium tremens*.

The third function of the *Intellect* is *Reason*. Were the Intellect to be confined to the sense, it could not move beyond its own perceptions; with the addition of the *Understanding*, the Intellect might employ judgment to assess the connections among its perceptions and engage in logical processes or abstract thinking. Through *Reason*, the *Intellect* is able to study its own mental operations and develop insight into both sense and understanding, philosophize about the process of knowing and what is known, and thus approach knowing as science. Reason may modify the processes of sense and understanding and in that way raise humans above brutes.

The *Susceptibility*, the second category of mind, encompasses the range of feelings that the mind is capable of experiencing, including subjective motives that prompt voluntary action. Feelings may derive from organic sensations prior to conscious awareness or subsequent to conscious awareness, as in emotions. Hickok is clear about the need to distinguish among feelings and motives with regard to the will and voluntary action, especially with regard to moral responsibility, and so he divides Susceptibility into Animal, Rational, and Spiritual Susceptibilities.

Animal Susceptibilities include sensations that he categorizes as blind feelings, antecedent to conscious awareness that produce impulses to action in a particular direction: in short, instincts. Rational Susceptibilities are of a higher order, and involves emotions categorized as Aesthetic, the love of the beautiful, as manifest in the fine arts; Scientific, the love of truth; Ethical, the basis of conscience; Theistic, the recognition of the existence of a personal Deity. Finally, Spiritual Susceptibilities represent the moral character and disposition of the mind as it experiences religious feelings of a mind connected with a Christian God.

The third division of mind is the *Will*. The distinguishing characteristic of the will, that which differentiates it from the Intellect and the Susceptibility, is that it is confronted with alternatives. Will is a capacity to choose between or among alternatives. That the will is free to choose is attested to by consciousness itself. The sense of responsibility that is part of the mind argues that choices are not governed merely by the motives and passions of animals. In acts of will, there is always an alternative in kind, a different end, than the one chosen. This awareness of the freedom of the will is acknowledged in history, in human language, and the common consciousness of mankind.

Hickok concludes his examination of the mind by asking what the mind is *for*. Its purpose, Hickok contended, is to counter the animal portion of our being to achieve spiritual worthiness. In this way, the mind can attempt to overcome the sinful nature of mankind, engendered by Adam’s fall and the resultant original sin. Hickok was not sanguine that it was possible to achieve spiritual worthiness, but the purpose of the mind was to make the effort to do so. In the later editions of *Empirical Psychology* published with Julius Seelye, this section of the book was omitted and a discussion of the role of psychology as an open door to philosophy was substituted instead. Editions of *Empirical Psychology* (Hickok 1882) published with Seelye as coauthor after the Civil War removed much of the theological concerns from the book, shortened it considerably, and attempted to make it more accessible to, and accepted by, the students and teachers of the last decades of the nineteenth century.

In all its iterations, Hickok’s psychology is of a piece with other attempts of his era to use an examination of conscious experience as the basis for a scientific

understanding of mind. In the decade that followed the 1840 appearances of the textbooks of Upham and Rauch, Haven's *Mental Philosophy* (1857) was published. Joseph Haven (1816–1874) graduated from Amherst College (AB, 1835; MA, 1838), studied at the Union Theological Seminary and at Andover Theological Seminary, was ordained and, after a brief career as a minister, was appointed Professor of Mental and Moral Philosophy at Amherst College in 1851. His textbook was translated into Japanese in 1875 and, in 1889, into Chinese, the first western textbook in that language (Kodama 1991). Haven adopted a tripartite division of mind: *Intellectual Faculties*, the *Sensibilities*, and the *Will*, noting that the arrangement had come into use earlier in America, had been generally adopted as well in Europe, notably in France and Germany, and was well supported by the reasons advanced for this division by Professor Upham. His textbook, like Hickok's *Empirical Psychology* evidences indebtedness to Rauch and German philosophy as well as to Upham and the British philosophical tradition.

Because the subject of mental philosophy had often included other disciplines (e.g., economics, sociology anthropology), Haven proposed that the term *psychology* be employed for the philosophy of mind as a more definite designation for the discipline. Even so, he retained the title *Mental Philosophy* for his textbook; “psychology” did not become commonplace in denoting the study of mind until later in the century, despite its earlier use by Rauch (1840). By whatever name it was to be ultimately known, mental philosophy was, for Haven, like his contemporaries, a natural science that gathered facts of mind from experience, observation, and employed induction to arrive at the laws under which the mind operates. Observations of our own mental phenomena, reports of the observations by others of their conscious experience and inferences from behavior were the sources of information about mind. Its study was important for its own sake and for the practical benefits that might result from knowledge gained to such widely diverse fields as education, oratory, medicine, theology, and other areas of human activity.

The three divisions of mind into which Haven organized mental processes represented modes of mental activity in which the mind operated as a whole. The awareness of its operations and of its

contents constitutes consciousness, a general property of mind that includes attention and conceptions, all of which underlie the operations of the faculties. Haven defended his choice of these terms and the meanings that he gives to them, contrasting his position with those who held different views and noting those whose positions were consistent with his own. The system that he proposed covered the same ground as other textbooks of the time, as competing introductory textbooks in psychology do now, but provided different terms, emphases, and allocated operations to the three modes somewhat differently.

The *Intellectual Faculties* included four properties that Haven termed “powers” of the mind. The *Presentative Power* included the senses and the perception of sense, an awareness of objects and their properties external to us, “presented” to consciousness by the several senses. The *Representative Power* encompassed memory and imagination, in which the mind becomes aware of representations of objects previously sensed or perceived; the representations, or conceptions, may be connected through suggestions, as governed by the laws of association. The *Reflective Power* included the power to make generalizations from particular objects or instances to form a classification that includes all such objects or instances. Similarly, the *Reflective Power* included the processes of abstraction and judgment, as well as the analytic process, or reasoning, operations of the mind that provide the basis for rational thinking and rational behavior. Finally, the *Intuitive Power* is that by which the mind has contained within it primary truths and conceptions, such as ideas of space, time, identity, cause, ideas of the beautiful, ideas of right. Haven finds no clear line between Upham's ideas of internal and external origins, but observes that all depend upon experience, the external source of which may be clear and obvious in some instances but obscure in others.

Before proceeding to his next division of the mind, Haven addressed two issues as “Supplementary Topics.” The first of these, following Rauch, was the nature of the difference between the intelligence, or mental capacities, of humans and animals. The nature of the mind of the latter can only be inferred; the mind of animals is considered in relation to the concept of instinct, understood to be an innate law of action prompted by blind impulse. Animals are not moral

beings and not therefore accountable to a higher power; reason, memory, and other intellectual powers are either absent or present to a lesser degree than such powers in humans, who retain their status as the special creation of God. The second supplementary topic addressed by Haven is that of the influence of states of the nervous system and brain on the mind, with the aim of rescuing this topic from the physiologists to ensure that the study of mind is not merely a series of cerebral activities (materialism). The phenomena so addressed included sleep, dreams, somnambulism, and disordered mental action. He rejects theories that suggest that the powers of mind are suspended in these states, but, as evidenced by dreaming, active, but without the action of the senses and the will. This concern, like the distinction between humans and animals, is ancillary to cataloging and classifying mental processes, but serves to defend the traditional status of mind as independent of the activities of the nervous system and the materialistic interpretation of mind.

Of the 583 pages of Haven's text, 391 are devoted to the discussion and analyses of the *Intellectual Faculties*. Only 123 pages are devoted to the *Sensibilities*, states of mind that may be categorized as agreeable or disagreeable (feelings), and separate from the *Intellectual Faculties* as feeling differs from thinking in conscious experience. Three categories of mental processes are subsumed in the category of the *Sensibilities: Simple Emotions*, (instinctive emotions, the joys and sorrows of everyday life, and rational emotions, aesthetic and moral feelings); *Affections* (benevolent feelings, or the manifestations of love, and malevolent affective processes, manifestations of hate; passions, more intense feelings, are included here as well); *Desires* (those arising from the physical constitution such as animal appetites, and those arising from the rational, or mental, constitution, such as the desire for knowledge). These processes are interdependent with processes of the *Intellectual Faculties*, in that, for example, the power of feelings may overwhelm judgment or rational thinking, and memories may initiate feelings. Haven makes no claim to have exhausted describing all the subtleties of feelings that might be included within the *Sensibilities*, but declared his analysis sufficient to his purpose.

In approaching the faculty of the *Will*, the shortest section of his book (69 pages), Haven recognized the ways in which discussions of the will were embedded in

philosophy and theology, especially with respect to the question of the freedom of the will. He addressed the will as the third category of mind purely in terms of psychology (but added a historical sketch of the relation of the concept of will to philosophy and theology to the conclusion of his book). Haven concludes that the will is free when specific actions are not hindered, as when an individual is not hindered in putting forth volitions, or when an individual is free to do as that individual pleases. He notes the universality of belief in the freedom of the will, the consciousness of the freedom to act, the implication of that freedom in the moral nature of human beings and cites the opinion of many philosophers of mind who support the opinion that the will is free. The opposite of freedom, fatalism, implies the denial of moral obligation and accountability; remorse, for example, can only arise from the realization that one had been free to act differently, and therefore argues for the freedom of the will. The freedom of the will, for Haven, lies not in the physical act that may rest on a volition but in the putting forth of that volition freely, as we choose, to please ourselves. The power of the will varies in strength among individuals; although its power may be part of our natural endowment, education and the development of habits and strength of purpose in life's activities may strengthen the will.

Haven's textbook provides suggestions for reading the philosophers of the past and the textbooks that were contemporary with his own. In considering the categories of mind and the processes that he assigns to each, he provides not only his reasons for the categories and the processes included in them, but also cites authors that agree or disagree with his position. In that way, Haven's textbook provides a convenient and accessible source for assessing some of the differences that were abroad in mid-nineteenth century as the mental philosophers *cum* psychologists wrestled with describing and understanding the nature of the human mind, its contents and processes.

Scottish Philosophy Redux

The tradition established by the Scottish philosophical tradition of the previous century remained alive and well in textbooks until late in the nineteenth century. A late nineteenth-century textbook representative of that tradition, not influenced by German philosophy,

was *Elements of Intellectual Philosophy* (1854) written by Francis Wayland (1796–1865). Wayland graduated from Union College in 1813, apprenticed to become a doctor, and attended medical lectures; in 1816, however, he experienced a religious conversion that prompted him to enter Andover Theological Seminary. After 1 year, he left to serve briefly as Tutor at Union College until he accepted a call to become the minister of the First Baptist Church of Boston, where he was ordained. He became prominent in Baptist circles, was awarded an honorary degree by Brown University in 1822 and was elected Fellow of the Corporation in 1825. In 1826, he was chosen to be the fourth president of the University, a position he held until his retirement in 1855.

Presidents were also professors. Wayland's lectures, read to his students and published as his textbook, were devoted to eight faculties of the *Intellect*. The *Perceptive* faculties reveal the external world to the mind; consciousness makes the mind aware of its own operations and reflection, made possible by an act of volition, focuses the intellect on a continuous thought. *Original Suggestion* connects individual acts of perception or ideas through the mind's intuitive nature. *Abstraction* is the power of the mind to move from the individual instance to the general concept. *Memory* consists of the retention of ideas from the past that may be recalled in the present. *Reason* is that power by which the mind makes use of the knowledge obtained through the other faculties to proceed to new knowledge. *Imagination* is that power to form, at will, new and complex mental images. These seven faculties are those to which Dugald Stewart's *Elements of the Philosophy of the Human Mind* (1833) is devoted. Wayland added an eighth chapter, *Taste*, because he believed the acquisition of knowledge by the faculties of the *Intellect* to be intimately associated with feeling, and *Taste* is the sensibility by which we experience pleasure or pain from nature or art. Although Wayland noted that the soul possessed other powers, namely, a conscience, a will, emotions and motives, his references to these powers, if they occur at all, were made only in the explication of the operation of the intellectual faculties.

Evidence of Wayland's early interest in, and preparation for, the medical profession can be seen in his descriptions of the physiological mechanisms of the

individual senses of the perceptive faculties, from the excitation of the organs of sense to the stimulation of the brain. But Wayland is no materialist. The senses are those with which the Creator has endowed the mind, not the brain; it is the mind that senses, perceives, thinks, and carries out intellectual functions. Sensory impressions of a single quality become perceptions when combined with other qualities to form an awareness of something external to the mind. The knowledge that there *is* an external world is provided spontaneously by the senses of sight and touch, but how the material excitation of the nerves and brain is conveyed to the immaterial soul or mind is, to Wayland, beyond the limits of the mind's understanding.

The mind, for Wayland and his contemporaries, was so created that there is an inherent belief in the truth conveyed by the senses, unless, as in the case of illusions, the beliefs are shown to be false. When an object is no longer perceived, the mind may still retain a *conception* of it, that is, a representation of it that is formed when it is an object of thought. The term *conception* implies more than mnemonic images; abstractions, such as mathematical axioms, and acts of imagination are also conceptions. An act of will may direct attention to a perceived object or to a conception in the mind and, in this regard, Wayland encourages students to develop habits of exercising attention and reflection as they experience the world around them, to reflect on those experiences and, especially, to write about mental experiences as an extension of the habit of reflection. As a further example of his earlier interest in medicine, he also admonishes students that these faculties function best in a healthy body, so he encourages good diet and the avoidance of harmful indulgences.

The perceptual faculties provide evidence of the external world; the resultant mental contents are connected through *Original Suggestion*. Cause and effect relationships are not sensed, not derived from experience, but arise from the intuition that is part of the mind's constitution. The intuition that change is dependent upon some cause is the basis of scientific thinking and experimentation to determine cause and effect relations. *Suggestion* also provides the idea of God as cause, not experienced or sensed. When suggested ideas are combined with emotions, experiences of the beautiful, the sublime, and ideas of morality may result.

Abstraction refers to the intellectual power to analyze, to form generalizations and abstractions. Abstraction forms the basis for the sciences, in systems of classification and the formation of general principles that underlay scientific laws. Abstraction also serves the imagination in the creation of works of art, in poetry or sculpture, for example. Perceptions and conceptions may provide the raw materials, but abstraction moves beyond those to make achievements in the arts and sciences possible

Memory provides the basis for trains of thought, organized by the laws of association (e.g., resemblance, contiguity, contrast, cause and effect) and based on the retention and recall of past events. Memory also is the basis for personal identity, in that the recall of the past in the present implies the continuity of experience of an individual. Memory varies in degree and kind among individuals, changes with age, disease, and injury; such effects on memory, Wayland suggests, deserve further study. Students are urged to strengthen their faculty of memory through practice in recalling past events, or information that they want to remember, to pay attention to events to aid in their later recall, to utilize the principles of association to connect events to time and/or place, and to seek methodological arrangements to facilitate recall. In a concluding note, he conveys his judgment that artificial mnemonic systems do not work.

Reasoning is that impulse, endowed in the mind by God, which uses knowledge acquired by other faculties of the intellect to arrive at new knowledge. The faculties considered prior to reasoning observe, feel, generalize, classify, and remember, but it is reason that uses the data provided to the mind to seek and find new truths. The model for reasoning is that of geometry, in which, from observations of basic elements, reason arrives at larger truths embodied in axioms and general principles. Reasoning moves from the known to the unknown, with certainty in the example of mathematics, or probable certainty in the more practical affairs of life. Deductive logic in syllogistic reasoning exemplifies the manner in which reasoning is carried out, proceeding from accepted truth to new truths.

Imagination is that faculty that takes simple conceptions, changes and combines them, to arrive at complex wholes or images. Abstraction moves from individual conceptions to a general concept, while

imagination creates a singular, individual conception (e.g., the former may create a general conception of a horse, but the artist creates a conception of a particular horse), as the poetic imagination combines individual images into new, original images. Philosophical imagination starts with general truths or laws of nature and combines them into more complicated, complex, more general truths. The poetic imagination is connected with taste or feeling, while the philosophical imagination is connected with understanding, and with scientific truth, often with questions that yield “yes or no” answers. To improve in the use of philosophical imagination, Wayland advises a thorough acquaintance with the known, as a clue to the unknown, in nature.

The use of the intellectual faculties is inevitably accompanied by feelings of pleasure or displeasure. It is through the sensibility of *Taste* that we experience feelings in response to the beauties or deformities of nature and art. *Imagination* may create art, but taste decides on its beauty. Feelings are also involved in the emotions that accompany judgments of right and wrong in matters of conscience. Wayland notes that taste in art and nature changes with time, but also that taste may be improved by acquaintance with, and the study of, the classics, not to copy them, but to emulate them.

The description and analysis of the mind that Wayland presents does not differ in its essentials from that offered by Stewart in his *Elements* of 1833. As a textbook written for undergraduates, it leaves more complex philosophical issues for the supplementary readings suggested at the end of each chapter. In avoiding substantial issues associated with the relationship of faculties of the *Intellect* to those of *Taste*, or attempting to address the role of *Will*, free or determined, in relation to other mental processes, he offers only a partial view of mind. The textbook, in addressing the intellectual processes of mind, provides students with an emphasis most relevant to their role as students, with suggestions designed to aid them in their pursuit of education. Although Wayland had hoped to address other components of mind in subsequent editions of his textbook, he failed to do so. As it stands, Wayland’s textbook testifies to the persistence of the influence of the Scottish common sense realism throughout the nineteenth century.

Summary

The mental philosophers of the antebellum period in the United States approached the study of mind as a science that proceeded inductively from observations organized into taxonomic categories, much as the natural sciences of geology and botany had proceeded in their early periods of development. They buttressed their taxonomies of mind with evidence of the manifestations of mind in human activity, as in the behavior of those afflicted with imperfect or disordered minds, or as recorded in history, literature, or the annals of law or medicine. Their textbooks were designed to provide their students and other readers with a comprehensive catalog of the facts of mind, suitably arranged, to suggest useful applications for improving the mind and behavior.

The pursuit of the proper taxonomy of mind through introspection was supplemented by examining external influences on mental processes and their development, in passing in some texts and at somewhat greater length in others. These “anthropological” concerns raised a number of issues regarding the origin of mind, the relation of mind to the brain, and the differences between the minds of human beings and those of animals. These issues prompted a defense of the special creation of the human mind (as well as the body), the superiority of the human mind over that of animals, and the denial of the materialist position that equated the mind with the brain. These issues broadened the concerns of mental philosophy as the name of the discipline became more frequently designated as psychology.

Postscript

In the aftermath of the American Civil War, many Americans traveled to Europe to expand their horizons through an immersion in European culture and the pursuit of graduate studies not yet available in the United States. Professors of philosophy and theology at German universities had achieved renown and attracted many concerned to advance the study of mind. In the sciences, great strides had been made in physics, chemistry and, especially, in the physiology of the special senses, an area of keen interest to students of mental philosophy. American students were introduced to, and became enthusiastic champions of, the new laboratory experiments introduced to advance the science of mind. They were led, inevitably, to reflect on

the contrast between what they found in the heady atmosphere of the European universities and the colleges that they had left behind. Their conversion to the new psychology facilitated their rejection of the old mental philosophy

The textbooks of the antebellum period continued to be assigned in colleges and universities in the United States after the Civil War. Transitional textbooks, such as Noah Porter’s *The Human Intellect* (1868) incorporated aspects of German idealist philosophy and the new physiological knowledge. James McCosh (*The Cognitive Powers* 1886; *The Motive Powers*, 1887) welcomed the results of the physiological laboratory and incorporated them into his textbooks, but preserved the philosophical tradition of common sense realism and affirmed for his readers that *The Cognitive Powers* was not a textbook of physiological psychology.

G. T. Ladd, trained in philosophy and theology, gathered results produced by the new psychology laboratories for his *Elements of Physiological Psychology* (1888), written from the “physical and experimental point of view” in the service of the older philosophy. He gave credit to the mental philosophers for having identified the mental processes that provided the basis for further progress in psychology, but saw the past attempts to arrange them into taxonomic categories a “barren task” that described, but did not explain, the mental phenomena they so carefully categorized.

G. Stanley Hall, like Ladd, trained in philosophy and theology, returned from Germany to play a significant role in the development of the new psychology in America. He criticized (Hall 1879) the continued use of the insular, old-fashioned, out-of-date textbooks by Upham, Haven, Hickok, Wayland, and others in American colleges and universities. For Hall and his contemporaries, these were the philosophies of the past; the philosophy of the future (Hall 1878) had arisen in the physiological laboratories that provided the basis for a new and invigorated psychology. Similarly, John Dewey (1884) welcomed the new psychology as the dawn of a new age. The old philosophies, in classifying and pigeon-holing mental processes had exhausted the possibilities for discovering new facts about mind and its operations. Science had moved past the stage of taxonomies of mind to raising questions for which experimental trials could be devised to discover new mental facts. Adopting the method of science to the

philosophy of mind meant quantification, replication, and the hope for scientific laws. The experiments of the laboratory had become the *sine qua non* of science.

The new psychologists saw in the methods of the laboratory an opportunity to develop a science that could answer both old and new questions about the nature of mind. Introspection under laboratory conditions was pursued as a valid and objective method to replace the “armchair” analyses of mind characteristic of the “old” psychology while also devising measures of responses that would explicate aspects of behavior and performance that might address the questions of the influences on mind and its functions.

In the last decade of the nineteenth century and the early decades of the twentieth century, psychologists astonished their philosophical brethren with their assault on the citadel of the mind with their brass instruments and laboratory procedures. Psychology gradually emerged during the twentieth century from its academic home within departments of philosophy to an independent academic discipline in a new academic department. Psychologists carried the subject matter of mind and the terms designating its content and processes from the old, mental philosophy to their new laboratories; the methods had changed but the mind had not. The mental processes identified by the introspective examination of consciousness by the mental philosophers of the past constitute many of the chapter headings of contemporary textbooks in psychology, and the investigation of their nature and operation form the content of those chapters.

Analytic Psychology of Carl Jung

EUGENE I. TAYLOR

Harvard Medical School, Boston, MA, USA
 Saybrook University, San Francisco, CA, USA
 Massachusetts General Hospital, Boston, MA, USA

Carl Jung was one of the most important theorists of the Classical period during the growth and proliferation of

dynamic theories of personality (Taylor 2009). The way the psychoanalytic historians tell it, however, and according to Freud's official biographer, Ernest Jones, as well as even the most contemporary article in the encyclopedias, is that Jung was a student and disciple of Freud. Nothing could be further from the truth. Jung himself had said that his Complex Psychology had been in place long before he met Freud (Jung 2009, p. 196). Jung did acknowledge his debt to Freud for introducing him to the symbolism of the hysteric, but Freud was only interested in the content of the image and how that can be traced back to early childhood sexual memories, while Jung wanted to know what function it served in the larger psycho-spiritual life of the person.

In this quest Jung had already gained important clues during the years of his scientific study of the word association test, which he had developed working with schizophrenics. He had designed it after studying the works of Francis Galton, Wilhelm Wundt, and Gustav Aufschafftenberg on the suggestion of Eugen Bleuler, for whom he worked at the Burgholzi Asylum. Bleuler hoped that it would have some diagnostic value, but Jung soon discovered that it was a valuable tool for exploring the patient's unconscious. A list of 100 common words was given to a subject, who was asked to respond with the first word that came into his mind. A stopwatch was used to see how long it took for this response to occur. The response words with the longest latencies turned out to tell a coherent story about the subject's current unconscious mental life in symbolic form, oftentimes to the complete surprise of the subject. What was revealed were the subject's unconscious complexes at work in the immediate moment.

At the same time, Jung eventually took the method of symbolism much further into the mythic dimensions of the Collective Unconscious. In fact, Jung scholars have already established that Jung may have been the twentieth-century exponent of the symbolic hypothesis, but his ideas regarding consciousness derived from the late nineteenth-century psychologies of transcendence around such figures as William James, F.W.H. Myers, Theodore Flournoy, Pierre Janet and the French experimental psychology of the subconscious (Taylor 1996).

What Jung later called his Complex Theory, otherwise known as Analytical Psychology (Jung v.d.), derives from this earlier tradition. Jean Martin Charcot

had demonstrated that under hypnosis a physical symptom such as a paralyzed arm could be induced through posthypnotic suggestion by implanting an idea in the subconscious. Hippolyte Bernheim then demonstrated that this method had both diagnostic and therapeutic applications in the treatment of hysteria (Bernheim 1889). Pierre Janet, Charcot's pupil, with whom Jung worked in the winter of 1902–1903, had demonstrated earlier in 1894 what came to be called the psychogenic hypothesis. Here, the idea was buried in the form of an image, which Breuer and Freud later corroborated (James 1894). The buried idea was the result of an unintegrated fragment of the waking state, such as an unacceptable traumatic experience that had been cast into the subconscious, where it floats around, autonomously acting according to laws of its own, drawing similar experiences to it. When it accrues enough energetic power, the complex can then burst forth into the field of waking consciousness as a physical or mental symptom, or even appear as a full-blown alternating personality (Janet 1894).

Jung, following the reigning dissociation theory of the era, posited that the average person is beset with numerous such complexes as a normal occurrence, for as William James also maintained, each of us has not one but many selves (James 1890). Pierre Janet, Alfred Binet, Theodore Flournoy, and others all subscribed to this theory. The complex becomes a psychic center with its own physiology; it disrupts the emotional apparatus and disturbs a train of thought or action; it acts just like an independent ego, because, as Haule points out (2011 p. 119), the ego itself is just another complex; complexes show themselves in hallucinations, and, finally, they completely victimize the insane. Later in his career, Jung would show how dealing with one's unconscious complexes through a confrontation between consciousness and the unconscious could lead to the spiritual transformation of personality.

Though he died in 1961, Jung, himself, began as a man of the nineteenth century. Named after his grandfather who had been a physician and alleged illegitimate child of Goethe, he was born in Kesswil, Switzerland in July 1875 and raised outside Zurich. His father, a minister and scholar of Semitic languages, was a *seesorg*, appointed to a local asylum, and had a library of both religious and psychiatric texts, while his mother, who came from a well-to-do Swiss family,

was prone to visions and promoted the reality of spiritualistic phenomena among her extensive family members, many of whom showed a similar gift of psychic second sight. One was Hélène Preiswerk, or Helly, as she was called, daughter of her sister and the subject of Jung's medical dissertation.

Jung's decision to become a physician pushed him in the direction of the medical sciences, but in 1898, when he was considering what specialty to enter, he was drawn to psychiatry because he thought it would address some of the burning questions he had been pondering about the dynamics of human consciousness, to which he had already been exposed. The true question for Jung was to become, "where did personality get its motivational force?" (Bair 2003, p. 45).

At first, he was somewhat hesitant, as psychiatry was in the grip of the lesion theory of disease, where all mental symptoms were believed to have an underlying organic cause, and all mental disorders were quickly being reduced to Kraepelin's new psychiatric classification, which later became the foundation for the DSM. The only sources for a truly dynamic psychology of personality he found in Passavant, DuPrell, Swedenborg, and others, eighteenth- and nineteenth-century authors dealing with the interior life of the mind and especially in Swedenborg's case, not only psychopathology but also the spiritual transformation of everyday consciousness (Taylor 2007). *Dreams of a Spirit Seer* (1899), Kant's attack on Swedenborg, first published in 1766, was particularly influential in Jung's thinking. Then Jung read Richard von Krafft-Ebing's *Psychopathia Sexualis* (1892) just before his state examination granting medical certification in 1900. Led by these influences, Jung committed himself to the course in psychiatry.

Immediately after passing his exam, Jung reported to the Burghölzli, the cantonal psychiatric hospital associated with the University of Zurich, to become an assistant to Eugen Bleuler (1857–1939). Bleuler practiced *Anstaltspsychiatrie*, institutionalized treatment characterized by a close relationship between patient and physician. Thus, the entire regime at the hospital was over regulated with regard to daily examinations and reports. Every physician was expected to know everything about every patient. Inmates also participated in the governance of the hospital. The psychotherapeutic treatment of the psychoses became

Bleuler's specialty, in which he emphasized not only contact, but the establishment of rapport, in delivery of therapy to patients who had experienced a complete break with reality. Bleuler had studied with Charcot and Magnan in Paris and Bernard von Gudden in Munich and developed the approach called *affektiver*, rapport, or emotional connection to the schizophrenic patient. But Bleuler was chiefly known as a student of August Forel, the former superintendent. A world-class myrmecologist and brain neuropathologist, Forel had, during his tenure before Bleuler, established the Burghölzli as a world-class institution and at the same time participated as a major player introducing Swiss psychiatry into American psychotherapeutic circles (Bair 2003).

In his new position, Jung spent his first 6 months without going out once. He was introduced to the association experiments of Wundt and Galton, and the recently published *Interpretation of Dreams* (1900) by Freud, although he paid scant attention to Freud's ideas at the time. He was more interested in séances and mediumistic trances and to his surprise, was encouraged by Bleuler, who was also interested in the subject. Out of this interest, Jung began to summarize a year of séances he had held with cousin Helly, which became the core of his dissertation, *On the Psychology and Pathology of so-called Occult Phenomena* (1901).

Jung began this dissertation with a summary of research on the topic by William James, before he turned to Charcot, Flournoy, and Bleuler. He then presented Hélène Preiswerk as his single case study. His position was that psychic powers are perfectly normal accompaniments of certain states of consciousness and do not derive from the supernatural. He believed the investigation of the séance would be transformative for experimental psychology, as it would lead to the development of a more mature psychology of the unconscious. As the Jung scholar Sonu Shamdasani has put it, Jung's medical dissertation focused on the psychogenesis of spiritualistic phenomena, and, agreeing with William James and Theodore Flournoy, Jung believed, regardless of their veracity, that the investigation of psychic phenomena "enables far reaching insight into the constitution of the Subliminal, and hence into human psychology as a whole" (Shamdasani, in Jung, 2009, p. 195). It was approved by the medical faculty in 1901 and published in 1902.

After launching his experimental studies on The Association Test at the Burghölzli (Jung 1906), Jung also engaged in the psychotherapeutic treatment of psychotic patients and summarized his research in *The Psychology of Dementia Praecox* (Jung 1907). Bleuler had assigned him to read Freud's *Interpretation of Dreams*, which he went back and reviewed, and when Jung's book on *Dementia Praecox* came out, he wrote to Freud offering him a copy, also praising Freud, remarking where in the new text Jung had cited him. Freudians later took this as a Freudian text but that was a misreading and also part of the Freudo-centric impression Freud's disciples gave to the early history of psychoanalysis, as if nothing had come before Freud except Charcot. In 1907 Jung traveled to Vienna with his friend and colleague, Ludwig Binswanger, and met Freud in person for the first time. They spent the good part of a day talking, in which Jung described all that he was into, suggesting that Freud never heard anything at the end of their relationship that he had not heard at the very beginning. Myers had died by then. Jung had already studied with Janet, James had passed off into philosophy, and Flournoy was aging. Freud was the only new voice on the horizon, so, despite many differences Jung became absorbed into the psychoanalytic movement. Freud and Jung corresponded frequently, and their letters were preserved in published form by William McGuire, (McGuire 1974). A close reading of their exchange reveals a relationship that might be characterized as a *folie à deux*, a case of mutual excessive projections in which the identity of each was absorbed into the other. Jung was 20 years younger than Freud, but often Freud would subsume himself under Jung, while in later letters Jung would subsume himself under Freud. The point is, that from this vantage point, one cannot call Jung Freud's disciple or even his student, as later analyst-turned-historians have tried to do.

Jung soon was appointed to positions of power and authority, and rose quickly to a position of favor with Freud, such that Jung was declared by Freud as the heir apparent to the psychoanalytic movement. Jung persisted in this vein from 1907 to 1912, without publishing any original research of his own, until he produced *Wandlung und Symbole der Libido* (1912). In my opinion, this was Jung's attempt to accept the mantle Freud had offered him and to do it by producing his own statement deepening and expanding on the

depth psychology of the era and widening the purview of Freud's own version of psychoanalysis.

Jung, as also interpreted by Adler, understood psychoanalysis to be a general rubric that applied to an international movement that had many branches. There was the Zurich School of Jung, the Adlerian School, and the Freudian school of Vienna, for instance. What these independent members of Freud's inner circle failed to comprehend, however, was that they had associated psychoanalysis with a general movement, when in reality, according to Freud, the term belonged to Freud alone, as if he had a personal copyright on it. When Jung published *Wandlung und Symbols der Libido*, Freud took immediate steps to vent his displeasure. He said that he could tolerate differences in their private discussions among themselves, but to contradict The Master in print was unforgivable. In other words, whatever the plans were before, Jung was now out. Their last contact was in 1913.

The Red Book

By 1913, Jung had resigned all his institutional appointments and, while keeping a small private practice, entered into a psychic state of creative isolation. Ellenberger called it a state of creative illness and compared it to Freud's similar inward journey beginning with the death of Freud's father in 1896. For Jung it was a period of extended trance consciousness in which he was able to carry on outwardly as if normal, but the majority of his attention was taken up by a stream of insights and visionary hallucinations in which the depths of his own psyche opened into a deep chasm, revealing what seems to have been like a journey through the Heavens and Hells, now ecstatic and now one of great pain and anxiety. He saw himself presented as a man who had lost his soul and was on a journey to recover it. He was pulled in this regard between "The Spirit of the Times," and "The Spirit of the Deep." The struggle between these two forces returned again and again as he encountered his muse and protectorate, Philemon, and other beings representative of his own psyche. In the end, he had indeed, rediscovered himself, but in a totally new way from the journey he had been on before meeting Freud.

He chronicled his experiences in the style of a continuous stream of charismatic utterances, and, along

with primitive drawings beginning in 1913, codified them in a series of Black Books, which he later painstakingly copied over by hand into ornate Old German script, including elaborate and extraordinarily beautiful full color paintings of mythic symbolism from his own unconscious. This new rendering he called *Liber Novus*, a "new beginning," the original handwritten edition of which he contained in an oversized book bound in red leather, hence, the name The Red Book, as it came to be called (Jung 2009).

Jung worked on this volume into the 1920s, but then set it aside, only occasionally showing it to a few close associates, after being introduced by his friend and Sinologist, Richard Wilhelm, to a Chinese alchemical text, which led Jung back to his own indigenous European alchemical tradition. There are numerous indications that Jung intended to publish The Red Book, though he never did. A draft copy of the text was made at one point, which eventually ended up in the Beineke Rare Manuscript Library at Yale, but that was not discovered until the Jung scholar Sonu Shamdasani found it in 1996. Until then, the original Red Book remained in a drawer in Jung's study at his home at Kusnacht, and when he died in 1961, his heirs eventually transferred it to a vault in a Swiss bank, where it remained unopened for more than 30 years. Sonu Shamdasani, now Professor of Jung History at the University of London, Wellcome Center for the History of Medicine, entered into an arrangement with the Jung heirs to bring *Liber Novus* to print. Providing the painstaking editorial work and acting as a co-translator with Mark Kybertz and John Peck, Shamdasani shepherded The Red Book into print. But it was no regular book. It was a facsimile edition, complete with ornate Old German script and Jung's dramatic paintings in color, with an English translation. The book is 11 1/2" by 15 1/5" and retailed when it came out for \$200. The original printings have already surpassed 60,000 copies and it has since been translated into a dozen languages.

Why is it important? There has always been much speculation about where Jung's ideas came from, Freud being the erroneous but default source. Jung himself said of it in 1957:

- ▶ The years, of which I have spoken to you, when I pursued the inner images, were the most important

time of my life. Everything else is to be derived from this. It began at that time, and the later details hardly matter any more. My entire life consisted in elaborating what had burst forth from the unconscious and flooded me like an enigmatic stream and threatened to break me. That was the stuff and material for more than one life. Everything later was merely the outer classification, the scientific elaboration, and the integration into life. But the numinous beginning, which contained everything, was then. (Jung 2009, p. vii)

There is no Freudian psychoanalysis in this document, which makes it likely the most important piece of evidence that Jung was not merely a student and disciple of Freud. Additionally, though he did not publish it at the time, *The Red Book* served as a model for Jung's patients, whom Jung encouraged to express their inner journey toward wholeness in a variety of artistic endeavors, including the construction of the Oriental Mandala, or the representation of archetypes in the form of paintings and drawings. At the same time, as he has said, it was the *ur*-text for all his later psychology.

Jung's The Architecture of the Psyche

Out of *The Red Book*, the structure of the psyche as Jung eventually saw it began with the persona. This is the mask that we all wear and project out onto the world. It is the most superficial aspect of personality because it is the way we see ourselves as we believe the world sees us, or as we would like the world to see us. The persona protects the ego from full disclosure of oneself to others. The ego, meanwhile, holds a similar executive function to the ego in Freud's model and can be equated with normal everyday waking rational consciousness, to the extent to which most of us are able to achieve it. It is the reality principle, the I or the me about which the cognitive behaviorists make their primary observations.

At the same time, the ego and the personal unconscious remain separated by the shadow, which is represented by all the undeveloped characteristics of personality that the ego denies or is conscious of enough to want to hide from the external world. However, the shadow is also the guardian of the inner door. It prevents material from the personal unconscious from flooding the field of waking consciousness,

except that the barrier is permeable, in the sense that memories, dreams, and other kinds of imagery do get through. It also admits the impressions of daily experience.

Thus, the personal unconscious functions much like Freud's conception of the preconscious, to a large extent. It is also the medium through which the archetypes make their way into the field of waking rational consciousness in symbolic form. The anomaly is that they come from within, from the collective reservoir, and not from external sources. The archetypes, Jung maintained, are inborn psychic structures that condition outer perception and are the means by which the collective unconscious is represented to waking consciousness. There is one's mother, for instance, which has specific significance to the person. We remember her calling our name; we see her face; we remember when she took us to the beach, but then there is also Motherhood, that domain of experience where all mothers share a common motherhood in the most abstract sense of the term. We might refer to this latter as the archetype of the Mother. We might do the same with fathers. There is our father, but there is also Fatherhood, that fraternity that links all fathers as a deep inward experience. Jung posits a variety of these different conceptualizations – the archetype of the Wise Old Man, the archetype of the Eternal Youth, the archetype of the Deity, the archetype of Transformation, the archetype of the Self, and so on. These structures exert a powerful influence on our thought. They are the substance of a culture's fairy tales and children's songs. They embody the myths of each culture. For Jung they dominate our dreams, subtly influencing the stereotypes we employ in our everyday perception of events.

Possibly the most significant archetypes of personality functioning are, respectively, the animus and the anima. The animus is the archetype of the masculine, while the anima is the archetype of the feminine. The masculine principle, which dominates the masculine personality in waking rational consciousness has an unconscious feminine element, just as the Feminine archetype, which dominates the feminine personality, has an unconscious masculine component. In the course of a normal life, the relationship between consciousness and the unconsciousness might remain relatively stable, so each person operates out of

whatever has been the biological and psychological roll of the dice. Engaging in what Jung called the process of individuation, where dialogue begins between consciousness and the unconscious and the ego is challenged by the Self for supremacy of the person's interior life, begins by an encounter of the animus with his unconscious anima, and in women, a confrontation between the anima of the feminine principle and her unconscious animus. The development of a more mature understanding between these elements of the person proceeds through the transcendence of the opposites to a higher and deeper state of consciousness that Jung called individuation – the coming to selfhood of the person, and the achievement of an authenticity unique to the individual.

JUNG'S ARCHITECTURE OF THE PSYCHE

THE EXTERNAL WORLD

THE PERSONA

THE EGO

THE SHADOW

THE PERSONAL UNCONSCIOUS

THE ANIMUS AND ANIMA

THE COLLECTIVE UNCONSCIOUS

©Taylor, 1999

As these experiences occur, the psychic energy embodied in the archetype, conditioning our stereotypes in everyday perception, is liberated, and free to the individual for continued creative growth. We are likewise liberated from our slavery to our stereotypes. If there is no spiritual evolution of the person, then the door to the collective reservoir remains closed, except

indirectly through spontaneous irruptions on the surface of waking rational conscious.

This process can be better understood through Jung's conceptualization of the function of the animus and anima. They are both guardians of the inner door linking the personal unconscious to the collective unconscious. As we have said, insofar as the personal unconscious accrues memories from outward experiences, the psyche also to one degree or another has access to internal images derived from the Collective Unconscious that have no external origin. The Collective Unconscious he posits as a universal substrate in the normal personality that links individual consciousness to a deep, inward universal reservoir of our humanity. In this manner, ontogeny recapitulates phylogeny. In the same way that the evolution of the fetus during gestation through the various stages of biological evolution to the present individual's brain and body, the internal life of the person carries with it the entire mental evolution of the species. Logically, this would likely begin within the person through the gemmates during reproduction, at the moment of fertilization. There is thus an alternative to living one's life only in the outward environment, adopting others' opinions, being defined by one's job and one's material possessions, or one's place in the caste system. One can elect to live more mythically within, where the self-actualizing needs of the person, what Jung called the process of individuation, are not necessarily identical to the adjustment needs of society.

Aside from "Seven Sermons to the Dead," an essay, the only work of Jung's that was written during the period of *The Red Book's* composition that was later published, was Beatrice Hinkle's English language translation of *Wandlung und symbole der libido*, the text in 1912 that had precipitated the break with Freud. Hinkle's title was *The Psychology of the Unconscious* (1916), in which she translated the mythic dimensions of Jung's interpretation of the so-called Miller Fantasies, a collection of tableaux done by Miss Frank Miller, an actress who performed on stages all over the world, acting out scenarios from the Northwest Indians of the United States to the settings of ancient Egypt along the Nile. Hinkle's translation was reviewed in newspapers large and small across the United States, reinforcing fears of the orthodox psychoanalysts that Jung might take the entire

psychoanalytic movement with him when he had left the fold, though this did not happen.

Then in 1921 Jung published *Psychological Types* (Jung 1923), a work that became a classic in type-theory. Individuals were identified by psychic tendencies to extend themselves outwardly as extroverts, or inwardly, as introverts. He further elaborated the types in what functions were predominant – thinking, feeling, sensing, and intuiting. Compensation was always the key, as whatever was dominant had an unconscious opposite that had to be dealt with and analyzed in the process of personal growth, just as every man had buried within him an anima, and every woman an animus.

In my opinion, the primary function of *Psychological Types* for Jung personally was to make a place for himself on the map as an introvert, which for the rest of his life he developed into more and more. In the 1920s, he produced some papers on the technique and theory of what was by then called Analytical Psychology, and undertook to write in manuscript form about The Vision Seminar, which was finally published a half century later. Toward the end of the 1920s he was then introduced by Richard Wilhelm to the Chinese Taoist text on spiritual alchemy called *The Secret of the Golden Flower* (Wilhelm 1931), for which Jung wrote a psychological commentary to accompany its publication. This led him back to the European alchemical tradition, which he worked on for the rest of his life, as in it, he found the historic link he had been searching for tying contemporary consciousness to the primordial roots of consciousness itself as far as Western civilization was concerned. Texts on *Psychology and Alchemy* (1953) and the final work of his career *Mysterium Coniunctionis* (1964), found among his Collected Works, were the result of this effort to understand the inner alchemy of personal transformation.

The Ethics of Transcendence

John Haule described how Jung's followers understood Jung on ethics. (Haule 2011, v.1, 184–185). People who live in relative ignorance of their inner lives almost exclusively follow the laws laid down by others, which they have introjected. Their sense of right and wrong is dictated through their family, their religion, the clan, the neighborhood, and the milieu in which they live from day to day, but presented in mythic form, from

which they gain their power over the person. According to Haule, Erik Neumann has called this the ethics of the masses. They tend to be self-righteous and resentful of those who break their introjected ethical laws. A second level of ethical behavior comes from elites who interpret the external laws and morays and values, not in terms of the behavior of others, but in terms of themselves. Whenever they break a rule, they chastise themselves and try to do better. They look up to others who have spoken with a prophetic voice, such as Jesus, Mohammad, or Buddha. They are the saints to the masses who are striving for self-development through outward forms. The third level of attainment is where, within the dialogue between the ego and the Self, consciousness plumbs the depths, and ethical decisions are always made against this inner norm, the goal of which is individuation.

Individuation by Means of the Transcendent Function

The *summum bonum* of Jung's dynamic theory of personality was his concept of individuation by means of the transcendent function (Jung 1963). Individuation for Jung meant the actualization of one's uniqueness as a fully functioning person, a process that might begin any time, intentionally, or by accident at some crucial moment in a person's life. As we have alluded, it is the beginning of a dialogue between consciousness and the unconscious in such a way that the ego cedes control of personality to the Self as the person reaches true spiritual maturity. One acknowledges the rational, but adopts a more sophisticated attitude toward the nonrational. One moves from a lower state of ego conscious integration to a higher state spiritual integration. The means by which this is accomplished is through the juxtaposition of the opposites. As consciousness confronts the unconscious, the animus in man integrates and transcends the anima within himself, just as the anima in a woman confronts her own unconscious animus and resolves the antinomy by transcending to a higher level of awareness. Jung contends that this can occur in the face of the paradox of the opposites, if one would but sustain one's attention on that process. The result is not a rational and logical conclusion, but an insight into the nature of the whole that is resolved by the experience of transcendence. Artists seem more prone to handle this

naturally, while scientists who function almost exclusively according to the rational ordering of sense data alone usually cannot. Individuation by means of the transcendent function remains one of Jung's most lasting contributions to depth psychology, as well as to the psychology of religion, but it is a construct found neither in mainstream experimental psychology nor in orthodox Freudian psychoanalysis.

Jung's orbit during the course of his lifetime, aside from the early University and asylum work, centered around his library at his home in Kusnacht, just outside of Zurich, and Bollingen, a stone house that he built on the edge of Lake Zurich. There was also the Analytical Psychology Club of Zurich, where Jung lectured to colleagues, students, patients, and "the fur coat ladies" (Shamdasani 1998). For years, he traveled to Lake Maggiore at the Swiss-Italian border to a conference center called Eranos, started by Olga Froebe-Kaptyne in 1933 (Quaglino et al. 2007). The annual conferences, which focused on religion, philosophy, folklore, and spirituality, attracted the likes of Marcia Eliade, Roberto Assagioli, Henry Corbin, Paul Tillich, and others, and became a platform from which Jung launched several of his most important papers. He also traveled widely, visiting Africa, India, England, and various German-speaking countries, including Vienna. He had a particularly wide following in the United States. *The Cambridge Companion to Carl Jung* (Young-Eisendrath and Dawson 1997) identifies three schools of Jungian thought. With the exception of Jung's impact on the British psychoanalysts, such as Michael Fordham, there is the Zurich School, centered around the C. G. Jung Institute, representing the orthodox view of Jungian psychology (Cambray and Carter 2004), the school started by Maria von Franz (1992), and the lineage of Archetypal Psychology defined by James Hillman (1975, 2004). Beyond these distinct lineages in the Jungian tradition there are literally hundreds of thousands of people who have read Jung to reinforce their own idiosyncratic journey toward spiritual self-realization as a life-time practice. In addition, though we now live in a Post-Freudian era, Jung's psychology seems to be coming more into its own as a vehicle by which western spiritual consciousness can gain entry into the indigenous psychology of non-western epistemologies in an attempt to assess the

contribution that non-technological cultures have to make toward a definition of world mental health.

Anastasi, Anne

HAROLD TAKOOSHIAN

Fordham University, New York, NY, USA

Anastasi, Anne (December 19, 1908–May 4, 2001) was known internationally as a pioneering psychologist, psychometrician, author, teacher, consultant and, in 1987, the first psychologist to receive the US National Medal of Science in Psychology.

Anne Anastasi was the only child born to first-generation Italian-American parents – Anthony and Theresa (Gaudiosi) Anastasi – in Bronx, New York, in 1908. Anthony died when Anne was 1 year old, and her single mother's family home-schooled Anne. A gifted student, Anne entered Columbia University at age 16, completing her B.A. with honors in 1928 at age 19, and her Ph.D. in 1930 at age 21. Her initial goal was mathematics, but she was inspired to shift into psychology in Columbia, and combine these two fields for the remainder of her career, summarized in [Table 1](#).

Even among other legendary psychologists, Anne's career stood out in several ways. (1) *Longevity*. From 1930 to 2001, Anne's long career of 71 years spanned over half of the 130-year history of psychology itself. (2) *Breadth*. Despite growing specialization, no psychologist exhibited a broader ken, which seemed to span all of the many specialties within psychology. Throughout her three classic *magnum opus* – *Differential Psychology* (three editions), *Psychological Testing* (seven editions), and *Fields of Applied Psychology* (two editions) – readers could not help but be impressed by her flawless knowledge of all of her field. (3) *Diversity*. No one psychologist has occupied more diverse roles within psychology – teacher, researcher, mentor, administrator, and consultant. She taught for 49 years – from 1930 to 1979. She was a prolific scientist and author of over 200 award-winning books, monographs, articles, and other publications. Her leadership of many groups included the Presidency of the American Psychological Association in 1972. As an expert consultant to the Educational Testing Service and similar groups, she was one of the architects who shaped educational testing in the Twentieth Century, making the USA the world leader in this area. (4) *Cross-cultural*. As far back as the first edition of her tome *Differential Psychology* in 1937, Anne was a prescient champion of cross-cultural psychology long before diversity became a central value within psychology. At the same time her own work on psychological testing was translated into a dozen languages worldwide, even in nations like Russia and Iran where western tests were suspect. (5) *New York*. Anne was a petit woman whose long life of 91 years was lived entirely in a 12-mile radius within New York City – at Barnard (1930–1939), Queens College (1939–1947), and Fordham (1947–2001). Meanwhile, few psychologists were more widely known worldwide, and so many overseas psychologists visiting the USA made a pilgrimage to the Bronx for an audience with Anne that some psychologists dubbed her university “Anastasi U.” (6) *Love of students*. After radiation therapy for ovarian cancer left Anne infertile in her 20s, she explained to colleagues how this led her to focus totally on psychology, and regard her students as children. Years before Anne's death, she carefully established the Anne Anastasi Foundation, to ensure her multimillion-dollar estate would directly benefit

Anastasi, Anne. Table 1 Anne Anastasi (1908–2001)

1908, Dec 19: Born in Bronx, NY, home-schooled by her mother Theresa, a widow	
1928: BA with honors, Barnard College, age 19	
1929: Attends the 9th International Congress, Yale	
1930: Ph.D., with Henry Garrett, Columbia, age 21	
1930–1939: Taught at Barnard	
1933: Married John Porter Foley, I-O psychologist	
1934: Survived radium therapy for cervical cancer	
1937: Debut #1: <i>Differential Psychology</i> (three editions)	
1939–1947: Chair of psychology, Queens College	
1946: President, Eastern Psychological Association	
1947–1979: Professor of psychology, Fordham	
1954: Debut #2: <i>Psychological testing</i> (seven editions)	
1956: President, APA Division of General Psychology	
1964: Debut #3: <i>Fields of Applied Psychology</i> (two editions)	
1965: President, APA Division of Testing	
1972: President, American Psychological Association	
1977: ETS Award, Disting. Svc. to Measurement	
1979: Honorary D.Sc., Fordham (1 of 5)

Angell, James Rowland

ERWIN V. JOHANNINGMEIER

University of South Florida, Tampa, FL, USA

Basic Biographical Information

Angell, known for his exposition and advocacy of psychological functionalism as opposed to the structuralism of Edward Bradford Titchener (1867–1927), was born in Burlington, Vermont, on May 8, 1869, and died on March 4, 1949, in Camden, Connecticut. That he chose an academic career – 27 years as a teacher and a researcher and 17 years as an educational administrator – that culminated in his election to the presidency of Yale University seems not surprising, for his father James Burrill Angell (1829–1916) served as president of the University of Vermont and then the University of Michigan, and his maternal grandfather Alexis Caswell (1799–1877) served as president of Brown University.

Like others of his era, Angell “had come up to psychology through philosophical channels” (Angell 1930, p. 23), for he began his study when the separation of psychology as a scientific discipline separate from and distinct from philosophy was well underway, but not yet complete. He began his university studies at the University of Michigan where during his second year he

studied logic and psychology. The study of psychology based on John Dewey’s (1859–1952) recently published text (most likely Dewey’s *Psychology* published by Harper & Bros., 1887) “opened up a new world” for him. Besides work in the usual branches of philosophy – ethics, aesthetics, and metaphysics – he took Dewey’s course on Hegel’s (1770–1831) logic and James H. Tufts (1863–1942) course on the history of philosophy. He took Dewey’s advice and remained at Michigan to earn a master’s degree in 1891. As a graduate student, he took Dewey’s seminar devoted to William James’ (1842–1910) newly published *Principles of Psychology*, a work that “unquestionably affected [his] thinking for the next 20 years more profoundly than any other” (Angell 1930, 5). He then again took Dewey’s advice and enrolled in the Graduate School at Harvard where his studies were divided between work under James and Josiah Royce (1885–1916). With Royce he took a seminar on Kant (1724–1824). With James he took a seminar devoted to abnormal psychology and worked in the laboratory that James had established, the laboratory that Hugh Münsterberg (1863–1916) made famous.

After his year at Harvard, Angell had an interest in studying abroad in Wilhelm Wundt’s (1832–1920) laboratory at Leipzig and with Münsterberg at Freiburg. However, Münsterberg was then on his way to Harvard, and there were no places available in Wundt’s laboratory. He then went on to Berlin for a semester and then to Halle where he completed a thesis on how Imanuel Kant (1724–1824) treated freedom in his *Critique of Pure Reason* and his *Critique of Practical Reason*. His thesis was conditionally accepted. The authorities wanted it presented into more acceptable German. However, rather than rewriting his thesis, he accepted a position as an instructor of psychology and philosophy at the University of Minnesota. There he taught elementary psychology, metaphysical ideas, laboratory methods, and organized the psychological laboratory. His tenure at Minnesota was brief, for he accepted an invitation to join Tufts and George Herbert Mead (1863–1931) at the University of Chicago where Dewey had just become chair of the department that included philosophy, psychology, and pedagogy. He was appointed as an assistant professor in charge of the psychology courses and the psychological laboratory for which he had an assistant.

Major Accomplishments/ Contributions

Angell, probably the most important and most influential functionalist in psychology, can be said to have developed his functionalism on the basis of Dewey's 1884 exposition of the new psychology and his 1896 article on the reflex arc concept. He early rejected the notion that the individual was "a neatly dovetailed psychical machine who may be taken as an isolated individual, laid on the dissecting table of analysis and duly anatomized" (Dewey 1884, 278). Functionalists recognized "mental life as an organic unitary process developing according to the laws of all life, and not a theater for the exhibition of independent autonomous faculties, or a *rendezvous* in which isolated, atomic sensations and ideas may gather, hold external converse, and then forever part" (Dewey 1884, 285). Dewey had no difficulty with the reflex arc concept that psychologists had borrowed from physiology, but with the reading into it old conceptions that rendered it into a "patchwork of disjointed parts, a mechanical principle of unallied processes" (Dewey 1896, 358). The functionalists opposed reducing reflexive behavior into simple component parts such as stimulus and response and rejected the claim that they could be studied apart from one another.

Angell's first effort at explaining functional psychology as opposed to structural psychology appeared in 1903. In 1904, he published his text, *Psychology: An Introductory Study of the Structure and Function of Human Relations*, in which he observed that the current fashion in psychology was moving away from investigating mind's structure and its component parts and toward investigating "how consciousness develops and how it operates" (Angell 1904, iii). His most often cited statement on functional psychology was his 1907 article based on his 1906 presidential address to the American Psychological Association. He then explained that functional psychology was interested in discerning and portraying "the typical operations of consciousness under actual life conditions" as opposed to analyzing and describing "its elementary and complex contents" (Angell 1907, 62–63). He later related that functionalism was "concerned first with the identification and description of mental *operations*, rather than with the mere *stuff* of mental experience" (Angell 1930, 28).

Angell explained that according to the functionalists, "reflective consciousness and the philosophical disciplines are seen as having a necessary and essentially organic relationship to one another." Those who studied "the adaptive functions of conscious process" were inevitably themselves considering "the realistic logic, ethics, and aesthetics of our daily deal" (Angell 1930, 29). Just as Angell's functionalism can be seen as based on Dewey's earlier work in psychology, so can Dewey's philosophy be seen as having benefited from Angell's functionalism. As Jane Dewey reported in her biography of her father, Angell's functionalism "played a part developing the logical theories of Dewey and in making a bridge from his logical to his moral theory" (Dewey 1939, 32).

Ansbacher, Heinz

ANGELA H. PFAFFENBERGER

Innerhealth, Salem, OR, USA

Biography

Heinz Ansbacher was born October 21, 1904, in Frankfurt am Main, Germany, the son of a banker. He left college after 2 years and emigrated to the United States in 1924, where he first took a job on Wall Street. Ansbacher first encountered Alfred Adler while the latter lectured at Columbia in 1930. Upon Adler's suggestion,

Ansbacher enrolled in Columbia and earned his Ph.D. in psychology there in 1937. He wrote his doctoral dissertation on the perception of number as affected by the monetary value of objects. Adler also introduced Ansbacher to his later wife, the psychologist and coauthor Rowena Ripin Ansbacher. The couple had four sons.

Ansbacher served on the faculty of Brown University from 1940 through 1943 and worked for Walter S. Hunter as an editor for Psychological Abstracts. Following this time period, Ansbacher was employed by the Office of War Information writing air-drop leaflets to convince German soldiers to give up the war effort.

Ansbacher joined the faculty of the University of Vermont (UVM) at Burlington in 1947 and resided there until his death in 2006. Ansbachers' children Max (UVM'57), Ben, Ted (UVM'68), and Charles Ansbacher have given the University of Vermont an endowed gift of \$350,000 to establish the Heinz and Rowena Ansbacher Green and Gold Professorship in psychology. The professorship will be awarded to a faculty member whose teaching and scholarship focuses upon the enhancement of individual and collective human strengths, virtues, and citizenship as exemplified in the teachings of Alfred Adler.

Accomplishments

Heinz and Rowena Ansbacher both worked directly with Alfred Adler as scholars and editors and are considered among the leading early followers of the Adlerian school of thought. Adler, along with Freud and Jung, was a founder of European depth psychology. Adler eventually broke with Freud, a fellow Austrian, over the predominant role that Freud gave to sexual desire and repression in neurosis and abnormal behavior. Adler developed the theory of the inferiority complex, its role in the drive for power, and he emphasized the importance of social interest and relations in regard to human development and pathology. Though his ideas eventually gained wide acceptance, Adler had difficulty translating them into readily comprehensible writings. It was here that Heinz Ansbacher and his wife were able to help.

Together with his wife Rowena, Ansbacher wrote *The Individual Psychology of Alfred Adler: A Systematic Presentation in Selections from His Writings* (Ansbacher and Ansbacher 1956), which was published in 1956 and remains the basic reference in the field. They also

authored *Superiority and Social Interest* (Ansbacher and Ansbacher 1964) and, they edited and translated *Cooperation Between the Sexes* (Adler 1978).

In 1958, Heinz Ansbacher took over the editorship of *The Individual Psychology News* and renamed the periodical the *Journal of Individual Psychology*. Under his editorship, which continued until 1974, the journal maintained high academic standards and was devoted to “a holistic, phenomenological, teleological, field theoretical, and socially oriented approach to psychology and related fields” endeavoring to “continue the tradition of Alfred Adler’s Individual Psychology.”

Among his distinctions and honors were being named a Fulbright lecturer at the University of Kiel, Germany, and serving as president of the North American Society of Adlerian Psychology. Heinz and Rowena Ansbacher were awarded honorary Doctors of Letters degrees by the University of Vermont in 1980 in recognition of their “major contributions . . . and many years of service.”

Anthropology and Psychology, Case of W. H. R. Rivers

GERALD SULLIVAN

Collin College, McKinney, TX, USA

- “A body of organized processes which can be described and classified, and their relations in space and time studied.” (Rivers [1916]1926, p. 4)

On her way back from Samoa in 1926, Margaret Mead (1972, p. 157) “met a young New Zealand psychologist, Reo Fortune, who had just won a 2-year fellowship to Cambridge University as a prize for an essay he had written on dreams.” According to Mead (1972, p. 158), Fortune “had saturated himself in the work of W. H. R. Rivers, the Cambridge don whose work in physiology, psychoanalysis, and ethnology had excited people right round the world.” Rivers had died, unexpectedly and quite alone in his college rooms, in 1922 at the age of 58. Nonetheless, Rivers “was the man under whom [both Mead and Fortune] would have liked to have studied.”

Mead’s (1928) doctoral dissertation, completed on the basis of library research prior to her journey to Samoa, shows Rivers’ influence. She would surely have known of Rivers’ (1914a, Vol. 1, pp. 363ff) comments on Samoa and his extensive writings on kinship (especially Rivers 1900, 1910, 1914a, Vol. 2, pp. 556ff, b).

Fortune would surely have known Rivers’ book, *Conflict and Dream*, originally published in 1923. Fortune (1927) would shortly publish his own book on dreams.

Fortune was not the only person in Mead’s circle impressed by Rivers. Rivers’ biographer, Richard Slobodin, studied at Columbia University under Ruth Benedict late in her life. Both he (Slobodin 1978, p. 140) and Ruth Benedict’s biographer, Margaret Caffrey (1989, pp. 142, 180), note that Benedict thought highly of Rivers. Benedict was part of a group of professors, according to Slobodin, who convinced the graduate students, in principle, to side with Rivers (1900, 1910, 1914b) against A. L. Kroeber (1909) on key matters of kinship and social organization. Kroeber, like Benedict, was a preeminent student of Franz Boas and a leader of the movements in American anthropology which arose from the department at Columbia. Caffrey (1989, p. 142) makes special mention of Benedict’s regard for, even debts to, Rivers’ book *Instinct and the Unconscious* published in 1920 and reissued in a second edition in 1922, of which more later. More recently, Virginia Young (2005, pp. 289, 293, 307, 315) has reconstituted several of Benedict’s late life lectures which make several highly complementary references to Rivers.

Benedict made explicit reference to Rivers in *Patterns of Culture* of 1934. For Benedict (1934, p. 232), Rivers had been among the first to get to the crux of

cultural selection by which some “behavior under consideration [passes] through the needle’s eye of social acceptance.” “It is not merely psychology which is in question, it is history,” a history not discoverable through introspection (Benedict 1934, p. 232). Thus, Rivers

- ▶ pointed out that instead of trying to understand the blood feud from vengeance, it was necessary rather to understand vengeance from the blood feud. In the same way it is necessary to study jealousy from its conditioning by local sexual regulations and property institutions. (Benedict 1934, p. 232; cf. Rivers [1916] 1926, pp. 8ff)

Nor was the circle around Benedict, of which Fortune was to become a part after his marriage to Mead, the only one in which Rivers has been treated with great respect. In his essay, “Do Dual Organizations Exist?,” Claude Lévi-Strauss ([1956]1963, p. 162) proclaimed, “Anthropology found its Galileo in Rivers, its Newton in Mauss.” He continued, hoping that “the rare so-called dual organizations still functioning may find their Einstein before they—less enduring than the planets—disintegrate.”

Dual organization refers to a sort of kinship organization. Such societies are divided into two sections or moieties, these sections being exogamous so that a person’s spouse must belong to the other moiety. Kin terminology classifies groups of people together so that a man would often use the same term for his wife and his mother’s brother’s daughter (and all women of her moiety and generation), while a woman would likely use the same term for her husband and her father’s sister’s son (and all men of his moiety and generation). Indeed these two cousins, matrilineal cross-cousins, often marry.

Rivers also garnered great respect among psychologists. Charles S. Myers (1923) devoted his presidential address to the Psychology Section of the British Association to a lengthy and detailed assessment of Rivers’ work and influence. Myers (1936, p. 228) credited Rivers with doing much “to promote the scientific status and recognition of [psychology] in Great Britain.” Myers (1936, p. 228) continued:

- ▶ It always seemed to me that his [i.e. Rivers’] earlier laboratory work, carried out when he was much more

diffident and cautious than later, was of immensely greater value and reliability. To him I owe the great importance which... I have come to attach to a strict training of the experimental psychologist in the psychological methods. To him I owe, too, the great interest I have always taken in individual mental differences and the balance I have striven to hold between the value of the results obtained from each individual and the value of the blurred, often meaningless, though statistically reliable, data obtained from large mass studies.

Sir Frederick Bartlett (1936, pp. 40, 41), defining himself as a Cambridge psychologist, noted that the Cambridge Expedition to the Torres Straights “put a social and ethnological stamp upon Cambridge psychology and this has done more than anything else to make Cambridge psychology human as well as scientific.” He noted that the expedition “brought Myers permanently over to psychology” and took “Rivers definitely over to anthropology.” Thus, Rivers exercised great influence over Cambridge psychology.

Titchener (1916), founder of Cornell University’s psychological laboratory, reviewed the work Rivers undertook with William McDougall on color vision and bodily sensation as part of the Cambridge Expedition to the Torres Straights. Titchener treated this work as worthy of lengthy discussion, if only to make clear his reservations concerning Rivers’ and McDougall’s conclusions.

Ernest Jones (1920) devoted a lengthy review to Rivers’ book *Instinct and the Unconscious* of 1920. Jones (1920, p. 470, see also Rivers 1922, p. 119) noted that Rivers aimed “to provide a foundation for a biological theory of the psycho-neuroses.” *Instinct and the Unconscious* was unique in attention to the war neuroses (see below). “The fact that exceedingly few psycho-analyses of war-neuroses could be made, not one of which has been published, speaks for itself” (Jones 1920, p. 471). Nonetheless, “Dr. Rivers has produced a work that is interesting, stimulating, and in many respects original” despite “an imperfect investigation of an aberrant form of neurosis” (Jones 1920, p. 471). The result was “a notable attempt to correlate the principles of biology, physiology, psychology, and psycho-analysis in relation to the problems of the neuroses” even if Jones (1920, p. 476) would

have preferred Rivers to have stated “his conclusions in a more tentative manner” and with greater adherence to Freudian terminology.

Edward Sapir (1921) also wrote a timely, if not as flattering review of *Instinct and the Unconscious*.

Many of Rivers’ (1923a, b, 1924b, 1926a) essays were gathered together posthumously and published as part of the prestigious International Library of Psychology, Philosophy, and Scientific Method. Another volume (Rivers 1924a) appeared as part of the History of Civilization series. David Schneider and Sir Raymond Firth considered Rivers important enough that they brought out a new edition of *Kinship and Social Organization*, adding their own commentaries as well as including Rivers’ essay “The Genealogical Method of Anthropological Inquiry” in 1968 (see Rivers 1910, 1914b).

Thus Rivers, whether one agreed with him or not, was a figure of significant importance.

A Professional Life, Briefly

Originally trained as a physician and a neurologist, in 1892 Rivers studied for a time in Jena, “attending the lectures of Eucken, Zeilen, Binswanger, and others” (Myers 1923, p. 152). Rivers later worked under Hughlings Jackson, a founder of British neurology especially well known for his work on epilepsy, at the National Hospital, Queens Square. Fluent in German from his time in Jena, Rivers also worked and co-authored an article with Emil Kraepelin, the pre-eminent psychiatric nosologist of the day, on their joint researches concerning fatigue and rest (Kraepelin and Rivers 1896). On the basis of his reputation as a careful and thorough experimenter, Rivers became the first lecturer at the psychological laboratory at Cambridge University.

His work brought him to the attention of Alfred Cort Haddon who invited Rivers to take part in the Cambridge Torres Straights Expedition of 1898. Reluctant at first, Rivers recommended his students Myers and McDougall, before joining them and Haddon, among others, on the expedition himself. Rivers took charge of the experiments on the discernment of colors as well as a systematic study of kinship terminology and its relations to social organization. This was perhaps the first systematic study of kinship since the work of Lewis Henry Morgan (1877) over 20 years before. I will

return to Rivers on kinship below. The Torres Straights Expedition was a regional survey, rather than the sort of intensive field study that Rivers would pioneer among the Todas during the next decade (on the Cambridge Straights Expeditions, see Herle and Rouse 1998; Stocking 1995, pp. 98ff, 184ff; on the Todas, see Rivers 1906). Rivers returned to Cambridge relatively quickly, spending 6 months in the Straights. He returned to Melanesia at least twice more.

Beginning in 1903, Rivers undertook a pioneering experiment in nerve regeneration with Henry Head.

At Cambridge, Rivers' students and younger protégées included both anthropologists, such as A. R. Brown (later Radcliffe-Brown), and psychologists, such as Bartlett, who like Rivers would continue an interest in both psychology and anthropology while at Cambridge's psychological laboratory.

Among Bartlett's protégées, one must count Gregory Bateson, Mead's third husband, and yet another figure with a great interest in both psychology and anthropology. Gregory Bateson did not study with Rivers. Rather his older brother Martin Bateson did, while Gregory Bateson came under the influence of Haddon and Bartlett, Rivers' close friends (see Lipset 1980, pp. 80, 82, 102, 122, 124).

Myers (1923, p. 167) reported that "In 1915 [Rivers'] psychological and ethnological researches were recognized by the award to him of a Royal Medal by the Royal Society, of which he had been elected a Fellow in 1908."

During the first World War, Rivers served in the Royal Army Medical Corps as a psychiatrist, first among private soldiers at Maghull, near Liverpool, and later among officers at Craiglockhart, in Edinburgh. He subsequently worked with aviators, acting as a "consulting psychologist to the Royal Air Force, being attached to the Central Hospital at Hampstead" (Myers 1923, p. 167), taking himself through the rigors of flight in order to understand better their particular experiences. The war, thus, put a halt to Rivers' work on kinship, but not to his interest in the relations between psychology and social organization.

During this era, Rivers began a reading and critique of the work of Sigmund Freud, a subject to which he returned not only in *Instinct and the Unconscious* but also in both *Conflict and Dream* and a series of lectures published as *Medicine, Magic and Religion*. In this

work, Rivers reformulated Freud's notion of the unconscious to include the operations of such instincts, as Rivers called them, as self-preservation and its allied emotion of fear as well as gregariousness with its associated senses of loyalty and shame. Rivers did this while considering the circumstances of trench warfare and the generation of those neurosis and psychosis associated therewith under the "unfortunate and misleading term 'shell-shock'" (Rivers 1922, p. 2), in dreamwork and in medical practice more broadly. I shall return to this latter work, especially a portion of *Instinct and the Unconscious*, as it shows well Rivers' interest in the relation of emotion and social circumstance, of psychology and social organization, as well as prefiguring Bateson's ([1956]2000) conception of the double-bind.

After the War, Rivers returned to Cambridge University. His friends and colleagues found him noticeably more outgoing. He lectured widely and served on important national committees. He took part in reorganizing materials to better standardize the methods used in anthropological and psychological researches. At his death in 1922, Rivers was running for a seat in Parliament as a member of the Labor Party.

The Fate of Rivers' Reputation

For all his many accomplishments, Rivers is now largely forgotten. He is perhaps better known today through the novels of Pat Barker (1991, 1993, 1995) than because of his own published works. Reputations fade with time not necessarily because better theories are formulated but because of neglect and the pride of those who come later.

The sorts of experiments which Rivers undertook on vision have long since ceased to be replicated. Even before his death, Rivers' memory was being effaced. In 1920, an unsigned commentary Anonymous (1920) on Henry Head's *Studies in Neurology* which appeared in *The British Medical Journal*, Rivers' name appeared only in the footnote providing publishing information, even though Rivers had been directly involved in certain of the experiments undertaken with Head. By the time Paul Whittle (1997) felt it necessary to revive memory of Rivers within the Department of Experimental Psychology at Cambridge, these experiments were associated with Head alone.

Despite Jones' review, Rivers has vanished from the history of psychoanalysis. He goes unmentioned in

Reuben Fine's (1979) *A History of Psychoanalysis*, for instance. Nathan G. Hale, Jr (1995, p. 22) reports that Rivers' "lukewarm endorsement of Freud" in *Instinct and the Unconscious*

- ▶ angered the *New York Times*. In an article that may have been inspired by [A. A.] Brill [Freud's American translator], Rivers was accused of at once disparaging Freud and adopting his views. He was a Freudian without honestly admitting it, a superb specimen of Freudian "conflict and repression."

Brill's reaction, if Hale is to be accepted, thus, differed from Myers (1923, p. 169) view that Rivers "had the courage to defend much of Freud's new teaching when it was condemned *in toto* by those in authority."

In anthropology we find a similar process, with a few more elaborations.

In his Presidential Address to the Anthropological section of the British Association for the Advancement of Science in 1911, Rivers broke publicly with the social evolutionism then prevalent among anthropologist. In Britain, Sir Edward Burnett Tylor had published studies suggesting that animism begat religion which in turn gave way to science. In America, Morgan's work on kinship suggested a development from a promiscuous horde via group marriage to monogamy. There were still other examples. Such unilineal social evolutionary theories should not to be confused with biological evolution in the work of Charles Darwin and others.

In social evolution's place, Rivers put history. His notion of the movement of peoples and the diffusion of sets of practices and ideas across the landscape plainly differentiates Rivers' idea of the complexity of history from the comparative simplicity of unilineal evolutionary schemes, with their insistence upon a single unfolding teleology, independent invention, and the pre-logical or irrational mentality of the more "primitive" or "ruder" communities of humanity. Like Boas before him, Rivers' experience of such technologically simpler societies had convinced him of the very precise and logical thought of such people, of their careful observation of natural phenomenon. In this Rivers, again like Boas, prefigured Lévi-Strauss.

Rivers (1926c, p. 261) hoped his version of a speculative history would stimulate further research. Rivers (1914a, Vol. 1, p. vi) did not expect the complicated "scheme of Melanesian history. . ." he advanced would

- ▶ be fully confirmed by further research; it may even have to suffer radical change as new facts come to our knowledge, but it is my hope that such modification, or even destruction if it comes, will be due, not to faults of method, but to the insufficiency of the facts to which these methods have been applied.

Rivers only entertained two sorts of possibilities: diffusion (which he associated with history and the contact of migratory peoples) and independent invention (which implied for him "the crude evolutionary doctrine of the time" [Rivers 1914a, Vol. 1, p. vi]). He did not give any apparent consideration to the possibilities or consequences suggested by notions of convergent evolution where similar circumstances and constraints tend to yield similar solutions to similar problems, as did prominent Boasians such as Robert Lowie (1912) and especially Goldenweiser (1913).

Rivers (1926d, p. 272) could consider "an element of culture acquired by the megalithic people in the course of their travels and transported by them to their original home[.]" such as the cultivation of taro, only as part of a megalithic complex. This complex conjoined megaliths, if not also pyramids, mummification or some form of the preservation of the dead, a sun cult and irrigation. He had yet to consider more fully the possibilities of cultural selection, as Benedict (1934, p. 42) would do later, even if a more current reading of his materials suggests precisely such a range of selection in conjunction with diffusion and even independent invention.

Instead, Rivers became allied with two younger colleagues, William Perry and Grafton Elliott Smith, and their theory that all civilization diffused out of Egypt. Rivers' support for Perry and Elliott Smith's notion was perhaps tentative. Still it appears in several essays concerned with a range of topics, including megaliths in Indonesia, the peopling of the Pacific, the range of taro production as well as the means thereof, and especially a traveling lecture Rivers gave in Britain and America during the last 3 years of his life: *The Aims of Ethnology* (Rivers 1923c).

Prior to the requisite archaeological studies, Rivers (1914b) attempted to reconstruct the history of the peopling of Melanesia. Peter Bellwood (1979, pp. 275, 279n166), the noted archaeologist of the region, writes, "Finally, we might ask if the combined results of

modern archaeology, linguistics, and physical anthropology can really tell the ‘truth’ about Melanesian culture history.” Making special reference in his note to Rivers, Bellwood notes that his archaeological finding differs from “the multiple migration waves postulated by the historical ethnologists of the past.”

- It has become fashionable in these hopefully more objective days to reject many of these old theories, but I [Bellwood] suspect that with further investigative research in all fields, certain aspects of them may one day be shown to be valid in the context of modern knowledge. (Bellwood 1979, p. 275)

Rivers study of Melanesian history likely influenced Mead’s (1928) doctoral thesis, with its examination of three complexes of interrelated practices. Mead demurred. Boas’ student Robert Lowie (1937, pp. 169–176), for example, in his *History of Ethnological Theory* of 1937, largely dismissed Rivers because of this attempt at speculative reconstruction. Perhaps more importantly, in his introduction to Fortune’s (1932) *Sorcerers of Dobu*, itself an unjustly forgotten ethnography of a Melanesian community, Bronislaw Malinowski (1932, pp. xxiii, xxvii) twice disparaged Rivers, calling his theory of kinship “farfetched” and his vision of “Melanesian communism” a “myth.” After Rivers’ death in 1922 and with Radcliffe-Brown away in the provinces and America, Malinowski rose to be head of the British anthropologists. Unlike Rivers’ theories (on which, see more below), Malinowskian functionalism famously begins with the needs of the individual, and therefore individual desire and psychology, rather than the institutional organization of society.

Much later, Radcliffe-Brown’s student, E. E. Evans-Pritchard (1981, pp. 199–200) in his posthumously published *A History of Anthropological Thought* referred to Rivers only in his notes and comments on Malinowski and then only as an impediment, “a vast edifice of anthropological theory” from which Malinowski sought to free himself.

As a part of this process, many anthropologists came to trace their research methods – ethnographic participant observation – to Malinowski and his stay in Kiriwina among the Trobriand Islanders during World War I and Malinowski’s (1922) resulting great book: *Argonauts of the Western Pacific*. Anthropologists forgot Rivers’ earlier fieldwork among the Todas of India’s

Nilgiri hills and his published study entitled *The Todas* of 1906, itself almost 20 years older than *Argonauts*.

Forgotten Accomplishments: Psychology and Sociology

In an essay originally published in 1916 entitled *Sociology and Psychology*, Rivers sought to clarify a distinction between the two disciplines that he did not find in McDougall’s definition of psychology: that is psychology as “the science of the behavior of living things” (Rivers [1916]1926, p. 4). Instead, knowing full well that psychologists would think him begging important questions, Rivers ([1916]1926, p. 3) preferred to “use the term ‘psychology’ for the science which deals with mental phenomena, conscious and unconscious.” This allowed him to reserve sociology for that science studying “human actions [which] are carried out in conjunction with others, or involve the social welfare of others” (Rivers [1916]1926, p. 4).

- These social actions as a whole form a body of organized processes which can be described and classified, and their relations in space and time studied. It is this description and classification, together with the study of these relations, which [he] regard[ed] as the special subject-matter of sociology. (Rivers [1916]1926, p. 4)

Hence, one could write a sociology without making reference to instincts, motives, or emotions, that is to the “mental phenomena, conscious and unconscious” appropriate to psychological science. As the sciences of psychology and sociology were then just at their beginning, this distinction should be understood as one of method, “the final aim of the study of society [being] the explanation of social behavior in terms of psychology” (Rivers [1916]1926, p. 5). In the end, these two ways of proceeding would demonstrate many connections, but in 1916 the time was not yet ripe.

Rivers was then working among British soldiers suffering from psychoses and neuroses attendant upon the war experience. In 1918, he published his report for the Medical Research Committee on “War-Neurosis and Military Training” in the journal *Mental Hygiene*; this report is one of several appendices to *Instinct and the Unconscious* (Rivers [1920]1922, pp. 205–227).

There were many differences between a Melanesian blood feud, as considered by Rivers and by extension

Benedict, and modern, especially trench, warfare; those most easily grasped have to do with the scale of violence. The blood feud arose out of a concern with reciprocity, with what Mauss ([1950]1990, pp. 13ff) would later term the obligations to give, to receive, and to give back, and hence with a generalized exchange of life and death; once the requisite number of victims had been slain and balance achieved, the combatants retired with no concern for whether the recent victim had previously killed or belonged to the group of the previous killer. In this sense the blood feud resembles headhunting among the Ilongot of the Philippines as described by Renato and Michele Rosaldo (1980a, b) or warfare among the Dani of highland New Guinea as seen in the film *Dead Birds*. Many of the frustrations of the trenches had much to do with the endless stagnation, a forced but unintended balancing of a general destruction without the asymmetric release of enforcing victory or suffering defeat.

Bearing this distinction between the blood feud and the trenches in mind, Rivers' discussion in "War-Neurosis and Military Training" concerns those ways in which training, drill, giving and receiving orders, attitudes toward the avoidance of any expression of fear inculcated on the public school rugby fields and so forth disposed men to react to horrendous destruction. These men were of differing classes, but with a similar sense of themselves as free Britons whatever their class. They gave themselves over to the loyalties, asymmetrical though these loyalties between officers and men were, which the military training sought to instill. In that the training and, indeed, the War involved "human actions [which were] carried out in conjunction with others," and could and often did "involve the social welfare of others" at the expense of still other human beings (Rivers [1916]1926, p. 4), both the training and the War should be counted as social actions. Such social actions could be regarded as "a body of organized processes which can be described and classified, and their relations in space and time studied" (Rivers [1916]1926, p. 4) without reference to "mental phenomena, conscious and unconscious" ([1916]1926, p. 3), without instincts, emotions, and the like, that is without psychology. Social actions could not be so lived.

In the main text of *Instinct and the Unconscious*, Rivers ([1920]1922) examined mechanisms by which memories become suppressed (his preferred term), wittingly, half-wittingly, or unwittingly. Being suppressed by whatever means, they are unconscious but not inactive. As with Freud, the primary reason for suppression is the protection of the self, either deliberately or without deliberate effort, from those memories. As again with Freud, suppression is not discreet. Rather suppression takes whole sets of associated memories even at the cost of yet greater discomforts as when a small child confronted and penned in by a dog in a small space and later set to sleep in cramped quarters unable to move for fear of disturbing his older brother later became claustrophobic, a fact that man did not think even unusual until he saw others react quite differently to the enclosed world of the trenches.

Unlike at least the pre-war Freud, Rivers did not trace much of the mental life of those he treated at Maghull or Craiglockhart to *eros*, reduced as too often it was to sexual life. Nor did he postulate *thanatos*. The success of Rivers' psychiatric practice required rather, that he explain to many soldiers that the matters they sought to understand did not concern unfortunate sexual events. These unconscious but powerful memories were attached to a conflict between the instincts for self-preservation and gregariousness. Self-preservation brought its allied emotions of fear and terror and its impetus to a range of responses from flight to holding still to the incapacity to control one's own body. Military training sought to channel if not outrightly suppress at least portions of this instinct. With gregariousness came the impetus to loyalty and fellow feeling which military training sought to harness. Free Britons so trained to gregariousness lived through dug-outs collapsing, finding themselves waking up with their faces in the bellies of the dead and the juices thereof in their mouths, seeing their friends die right next to them while they themselves were physically unimpaired and so on for a time without apparent end. The resulting symptoms varied, but the conflict between the demands of self-preservation and gregarious could only be resolved through debilitating symptoms. Much later, Gregory Bateson ([1956]2000) would call this sort of dilemma a double-bind.

Kinship and the Debate with Kroeber

We can look elsewhere in Rivers' work and find his concerns with the relations between psychology and social action. In his posthumously published lectures found in *Social Organization* of 1924, Rivers (1924a, pp. 63–64) contended that rather than being “a mere collection of terms of address” the terms of “the classificatory system. . . a system of nomenclature” “connote definite social functions, specific duties, privileges and restrictions on conduct and that these social functions apply to relatives in the classificatory sense.” Given the ensuing expansion of ethnographic knowledge, it is perhaps not difficult to understand how later luminaries – Lévi-Strauss, Benedict and Mead, for example, – could have been so impressed by Rivers. It is only a small theoretic move from Rivers to Lévi-Strauss' ([1972] 1976) notion of the atom of kinship with its regular and systematic patterns of preferences and stresses. Nor is it difficult to find in Benedict's (1934) accounts of the variable patterns of kinship, folklore and myth, in the distinctive integrations and selections of cultures spread out along her great arc, more than echoes of Rivers' functions, duties, privileges, and restrictions. Benedict said each pattern produced a distinct ethos – her term before it was Bateson's. Such ethos provided the backgrounds within and against which activity evokes or discourages emotion, as Mead and Bateson would contend, differently depending upon circumstance. Their point would not have been lost on Rivers.

Rivers (1900, p. 74) began developing the genealogical method as a part of his psychological experiments during the Cambridge Torres Straights Expedition. Like his other experimental practices, the genealogical method proceeds systematically.

Rivers began by simplifying his terminology, using only descriptive terms: father, mother, husband, wife, and child. Aware that various peoples categorize kin relations in distinctly different ways, he approached each household. He recorded what he found about each household on a sheet of paper specific to that household using a consistent system of notation: men's names in capital letters on the left with their wives names in lower case on the right. He asked for the names of each of the household's members real

father and real mother as well as the names of any other children. He repeated this procedure as he learned of each previous generation. Below each person's name, he indicated clan membership or totemic association.

Once he has this information for all the households in a given community, Rivers could compare the collected genealogies. His comparisons lead Rivers to understand that these genealogies were remarkably internally consistent. He, thus, knew how members of differing households were related to one another, often over several generations. He could then examine consist uses of reciprocal local terminologies, gathering thereby which people categorized which other people in consistent ways, patrilineal and matrilineal descent, permissible marriages and the like. With reports from several communities, he could analyze how their respective systems for reckoning kinship and its social consequences differed from place to place.

This work led Rivers to return to Morgan (1877). Further, Rivers (1914a, Vol. 1, p. vi) “intended” *The Todas* (Rivers 1906) “to be a sample of scientific method applied to the collection and recording of ethnographic facts[,]” especially those found by use of the genealogical method. He also used this method as well as on a journey to Melanesia he undertook with A. M. Hocart in 1908.

By contrast, Kroeber (1909) sought to dispel an unnecessary distinction between classificatory and descriptive systems of kinship. All such systems classify.

- ▶ The English word cousin denotes both men and women cousins; cousins on the father's or on the mother's side; cousins descended from the parent's brother or the parent's sister; cousins respectively older and younger than one's self, or whose parents are respectively older or younger than the speaker's parents; and cousins of men and women. Thirty-two different relationships are therefore denoted by this one English word. If the term is not strictly limited to the significance of first cousin, the number of distinct ideas it is capable of expressing is many times thirty-two. (Kroeber 1909, p. 77)

This class, therefore, is not particularly precise. “No language possesses different terms for all. . . or even for any considerable proportion” of the genealogically

possible relationships (Kroeber 1909, p. 77). For Kroeber the greater generality of English kin classes made it more classificatory than many other languages. As such, all terminological systems are descriptive of general possible types of relationship, but not in the same sorts of ways.

Kroeber (1909, pp. 77–78) discerned eight possible broad principles: generation; collaterality; age within a generation; sex of the relative; speaker's sex; sex of the person connecting two other people; blood viz marriage; life condition of the connecting person. English makes use of fewer principles (sex, generation, shared substance; marriage) than certain Native American languages with which Kroeber was familiar. Hence, "English is simple, consistent, and, so far as it goes, complete[.]" save for the class of cousins (Kroeber 1909, p. 80), though one should add aunt and uncle to Kroeber's analysis. By comparison, "[t]he Indian systems of relationship all start from a more elaborate basis, but carry out their scheme less completely" (Kroeber 1909, p. 80).

- ▶ The so-called descriptive [i.e., European] systems express a small number of categories of relationship completely; the wrongly named classificatory systems express a larger number of categories with less regularity. (Kroeber 1909, p. 80)
- ▶ The reason why the vague and unsatisfactory idea of a classificatory system of consanguinity [shared substance] has found such wide acceptance is not so much to be sought in any primary interest in designations of relationship as such, but in the fact that terms of relationship have usually been regarded principally as material from which conclusions as to the organization of society and conditions of marriage could be inferred. (Kroeber 1909, p. 82)

For Kroeber, terminology was merely linguistic. Kroeber's primary target appears to be Morgan, though Kroeber did not say so. Kroeber (1909, pp. 83–84) drew four conclusions. The fourth of these was that "[t]erms of relationship reflect psychology, not sociology. They are determined primarily by language and can be utilized for sociological inferences only with extreme caution."

Rivers extensive genealogies and extensive studies among the Todas, in Melanesia, the British Isles and

Egypt showed otherwise. The classes referred not to logical possibilities determined according to some external, genetic grid, but rather to groups of people in relation to yet other groups of people. Further, his genealogies showed that even though systems differed from people to people, the members of given communities were often very consistent in their designations of both particular and classificatory relations. The classes had to be sociological rather than individual. By contrast, our terms cousin, aunt, and uncle would appear hopelessly muddled to many a Melanesian. In that, these terms also designated how members of particular classes should behave toward members of other classes, the sociological relations organized behavioral and psychological relations in a wide variety of ways still in need of exploration.

Rivers (1914b, see also 1910) responded to Kroeber directly and extensively in *Kinship and Social Organization*, showing not only relations between terminology and cross-cousin marriage but to other forms of preferential marriage as well. The siblings who join two cross-cousins are respectively of differing sex and the parents of those cousins. A mother's-brother's daughter and a father's-sister's son are matrilineal cross-cousins. A mother's-brother's son and a father's-sister's daughter are patrilineal cross-cousins. Such cousins are never members of the same matrilineage or patrilineage. But neither are they solely, single individuals necessarily, as all members of a given clan, sex, and generation may occupy such relations one to the other, as Rivers well knew.

As such any given terminology referred to "a body of organized processes which can be described and classified, and their relations in space and time studied" (Rivers [1916]1926, p. 4) without reference to "mental phenomena, conscious and unconscious" ([1916]1926, p. 3), without instincts, emotions, and the like, that is without psychology per se. Rivers (1916[1926], p. 2) formulation of this distinction between sociology and psychology corrected a possible ambiguity reflected in his use of sociology and psychology in *Kinship and Social Organization*. But his point holds. Only once, one knows something of the relations defined by a particular terminology and the way the terminology, thus, classifies sets of people can one begin to understand the "mental phenomena, conscious and unconscious" evoked for those persons by other persons who

embody those categories. The categories, themselves, are not mere appendages of language, but “a body of organized processes which can be described and classified, and their relations in space and time studied” (Rivers [1916]1926, p. 4), that is a means to organize those very relationships between classes of people and the consequences of those relations for groups of persons so organized.

As seems always the case, some of Rivers work now appears dated. But much of that work retains the power to instruct and inspire. He remained cautious and prudent methodologically, at least, to the end. He thought carefully about issues others have passed over too quickly. If for no other reason, his reputation deserves revival.

Apfelbaum, Erika

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/ Major Contributions

- I feel that my life in social psychology has been well worth living. (Erika Apfelbaum 2009, p. 34)

Erika Apfelbaum, French experimental social psychologist, was born in 1934 in Germany. She was the chief architect of a theory of power which has influenced the thinking and practice of several researchers, both in France and in the United States, Canada, and Africa. The seminal years for Apfelbaum’s work were those she spent at the Laboratory of Experimental Social Psychology, Sorbonne University, where for more than 30 years she was senior professor and then head of the social psychology unit at the prestigious scientific research center CNRS (Centre National de la Recherche Scientifique). During the golden years of the 1960s, a quiet passion for ideas led her to construct an alternative body of theory to that which might be offered by social psychologists as a base discipline for psychology teaching and research. Apfelbaum was concerned with larger questions than those generally posed by social psychologists. She wanted to explore the relationships between power and interpersonal conflict, and between anti-colonial struggle, liberation movements, and aggression. She was drawn to the hot topics of social psychology such as power struggle, interpersonal conflict, struggles against oppression, anti-colonial struggle, feminist movements, black consciousness, revolts, riots, aggression, social injustice, poverty, racism, authoritarian personality, and social change. These topics were fueled by the zeitgeist of the revolts of May 1968. Apfelbaum’s whole cast of mind was strongly interdisciplinary. Her works touched researchers, psychologists, and social activists in many parts of the English-speaking world, and in several parts of the world her works have informed official policy.

Her own life work comprises at least six main stages: (1) growing up in the dark times; (2) the Sorbonne and the potential of knowledge; (3) social psychology in the 1950s; (4) social psychology in 1960s; (5) breaking away and shifting paradigm; (6) finally, the importance of creating a new social psychology that is fully grounded in history and culture.

Apfelbaum was surrounded by a network of researchers and social psychologists who were together part of a collaborative project within the Laboratory of Experimental Social Psychology as a base. But her personal and intellectual influence on this group (Robert Pagès, Gerard Lemaine, Jean-Marie Lemaine, Jean-Pierre Deconchy, Roger Lambert, André Duflos, Maryla Zaleska, Michel Pêcheux, Jorge Da Gloria, Bernard Personnaz) should not be underestimated.

Apfelbaum is truly a woman of heroic, yes of epic proportions. She is very influential in the feminist movement and a role model too. Here is Apfelbaum in her own words, “I am part of a whole generation of psychologists who have been significantly affected in one way or another by the changes in the socio-political and intellectual climate of the 1960’s – the counter-cultural movements, the anti-psychiatry movement, the civil rights, as well as the feminist movements” (2009, p. 32).

Archives of the History of American Psychology

DAVID B. BAKER, NICHOLAS JOYCE

The University of Akron, Akron, OH, USA

The year 1965 was a remarkable year for the history of psychology (Baker and Benjamin 2008). The American Psychological Association inaugurated Division 26, History of Psychology (now the Society for the History of Psychology), the *Journal of the History of the Behavioral Sciences* was published, and the Archives of the History of American Psychology (AHAP) was founded at The University of Akron (Poplestone and McPherson 2000).

The AHAP was the creation of psychology professors John Poplestone and Marion White McPherson of the University of Akron. They realized that the availability of primary sources and research in the history of psychology was limited and could be improved by having a dedicated archive. This came to fruition in October 1965 when the Board of Trustees of The University of Akron approved the establishment of the AHAP. The founding involved no budget, a desk in an office within the library, and a student assistant (Poplestone and McPherson 2000).

The Case for Archives

The mission of the AHAP is to “promote research in the history of psychology by collecting, cataloguing, and preserving the historical record of psychology” (www.uakron.edu/ahap, 2009). As a subject matter archives, the AHAP seeks material from all fields of psychology and from all psychologists. In order to control and manage the collections, the focus has been limited to American psychology and influences that bear upon it.

Before the founding of the AHAP, university archives and special collections took care of their own faculty. For example, the papers of William James and B. F. Skinner are found at Harvard University. Professional psychologists, who work largely outside the academy, have always been less likely to have their papers archived, and as a result, such records often remain in a state of uncertainty; relegated to basements, garages,

and other less-than adequate quarters (Popplestone and McPherson 2000). The AHAP was designed to give all such papers a home.

Archival repositories such as the AHAP serve a central role in historical research. In all sciences, research depends on a supply of raw data that is transformed into results that answer a variety of questions. Primary source material is the gold standard for historical research; it provides the raw data that historians use to craft narratives of history. The most important source of such data is archival repositories. Within such repositories, one can find records of individuals (referred to as manuscript collections) and organizations (termed archival collections). Manuscript collections preserve and provide access to unique documents such as correspondence, lab notes, drafts of manuscripts, grant proposals, and case records. Archival collections of organizations contain materials such as membership records, minutes of meetings, convention programs, and the like. Archival repositories provide, in essence, the “inside story,” free of editorial revision or censure and marked by the currency of time as opposed to suffering the losses and distortion of later recall. In much the same way, still images, film footage, and artifacts such as apparatus and instrumentation aid in the process of historical discovery.

As sources of data, archival materials provide many important functions. One of these is to help elucidate context. Individuals and events do not exist in a vacuum; rather they exist in a time and place and are subject to the influences of that particular context (Benjamin and Baker 2009). Many students in psychology know there was a behavioral revolution and later a cognitive one, but may have little understanding of the events and context that created such changes or the meaning of those events for the psychology of today. For instance, it is a fact that David Shakow was a founder of the scientist-practitioner model in professional psychology. However, without a contextual understanding of the ways in which World War II focused attention on the lack of a trained national mental health workforce in America, we are left with a naïve understanding of how the most dominant training model of professional psychologists came into being (Baker and Benjamin 2000; Cautin 2008). Appreciation of historical context allows us to examine and modify our current practices.

AHAP Holdings

The AHAP contains the personal papers of over 740 psychologists. There are papers of those representing experimental psychology (Leo and Dorothea Hurvich, Kenneth Spence, Ward Halstead, Mary Ainsworth, Frank Beach, Knight Dunlap, Dorothy Rethlingshafer, and Hans Lukas-Tuber), and professional psychology (David Shakow, Edgar Doll, Leta Stetter Hollingworth, Herbert Freudenberger, Sidney Pressey, Joseph Zubin, Erika Fromm, Jack Bardon, Robert Waldrop, Marie Crissey, and Morris Viteles), and just about everything in between. In addition, there are records of over 50 psychological organizations including Psi Chi and Psi Beta honor societies, regional associations such as the Midwestern Psychological and Western Psychological Associations, divisions of the American Psychological Association such as the Society for Industrial and Organizational Psychology, and papers of other groups including the Association for Women in Psychology and the American Group Psychotherapy Association. Individual oral histories and histories of departments of psychology are also well represented in the AHAP collection.

The AHAP is home to a wide array of objects including the simulated shock generator used in Stanley Milgram’s seminal obedience experiments (Milgram 1963), a prison door, guard uniforms and related objects from the Stanford Prison experiments (Zimbardo 1972), numerous brass and glass era instruments such as chronoscopes, Koenig cylinders, and memory drums, as well as a version of B. F. Skinner’s air crib designed for better care of infants (Benjamin and Nielsen-Gammon 1999). The media collection includes more than 8,000 films, 20,000 still images, and 2,000 audio recordings. Highlights include home movies of Sigmund Freud and footage of Pavlov’s research institute.

The assessment of individual difference is a hallmark of American psychology and is well represented at the AHAP. The test collection contains over 8,000 tests of personality, intelligence, aptitude, and ability. Rounding out the AHAP holdings is a rare book collection of more than 5,000 titles dating back to the sixteenth century.

The growth of the AHAP has been substantial. Since its modest beginning in 1965, it has grown into the largest collection of its kind in the world. In 2002, the

AHAP was named a Smithsonian Affiliate, the first archive to achieve this designation. As the AHAP has grown, so too has the need for a larger facility. In August 2010, the AHAP moved into the Center for the History of Psychology, a newly renovated building on the campus of The University of Akron. The center includes a museum, reading room, space for visiting scholars, and greatly expanded space for processing and storing archival material. The facility will continue the AHAP's tradition of promoting the history of psychology.

For over 4 decades, the AHAP has supported research in the history of psychology. It provides both on-site and off-site services to aid researchers. The key to research in the AHAP is the use of finding aids. A finding aid is a tool that tells a researcher what a collection contains. A list of finding aids for collections at the AHAP can be found at www.uakron.edu/ahap. Finding aids come in different levels of specificity. Some finding aids include a description of everything in a folder such as "letter from A. Person to T. Person" while others are more general, listing just the folder contents such as "personal correspondent 1950–1951." Typical information found in a finding aid includes (from Baker and Benjamin 2008):

- Collection dates (date range of the material)
- Size of collection (expressed in linear feet)
- Provenance (place of origin of a collection; previous ownership)
- Access (if any part of the collection is restricted)
- Finding aid preparer name and date of preparation
- Biographical/historical note (a short, succinct note about the collection's creator)
- Scope and content note (general description and highlights of the collection)
- Series descriptions (headings used to organize records of a similar nature)
- Inventory (description and location of contents of a collection)

In addition to providing assistance to researchers, the AHAP maintains an active program of educational outreach. Every semester the AHAP sponsors a colloquium series and every other year sponsors a major conference. The AHAP has a strong commitment to ensuring that the historical record of psychology is as complete as possible. One example of this was the

convening in 2000 of a national conference to honor Dr. Robert V. Guthrie, a psychologist and historian, and the first psychologist of color to be included in the AHAP's manuscript collection. The presence of traditionally underrepresented groups in the historical record is a priority for the Archives of the History of American Psychology.

The AHAP continues making sources available electronically. The new web site (www.uakron.edu/chap) offers access to a variety of archival materials. Using services such as Flickr and Youtube, the AHAP is able to make pictures and videos available to the general public. Through a joint agreement with the American Psychological Association, many of the books and gray literature (technical reports, newsletters, etc.) from the AHAP's holdings have been digitized and are available through PsycBOOKS and PsycEXTRA. Portions of this digitized content are also available on the AHAP web site. Staff of the AHAP has played a major role in the development of Encoded Archival Description (EAD) in the state of Ohio through the OhioLINK Finding Aid Repository (<http://ead.ohiolink.edu/xtf-ead/>). The Repository provides detailed access to collections housed in archives, special collections and libraries throughout the state of Ohio. EAD provides a powerful and easy-to-use interface for browsing and searching archival collections.

Summary

The Archives of the History of American Psychology was founded in 1965 to preserve and make available the historical record of psychology. The work has continued unabated and the AHAP has grown into the largest collection of its kind in the world. Through the AHAP's collection, students, researchers, and the public can find original source material that informs and educates about the role of psychology in defining who we are as individuals and as members of society. Historical understanding offers many benefits and pleasures not the least of which is assisting in understanding the present and preparing for the future.

Asch, Solomon E.

SALLY CAPANZANO
Pace University, NY, USA

Asch, Solomon Eliot (September 14, 1907 – February 20, 1996), was an American Gestalt psychologist and a pioneer in the field of social psychology, best known for his experiments on social influence and conformity.

Basic Biographical Information

Solomon Eliot Asch was born into a Jewish family in Warsaw, Poland, in 1907. At the time, Warsaw belonged

to the Russian Empire. In 1920, he moved to the United States with his family at the age of 13. He and his family lived in Manhattan's Lower East Side, where they taught themselves the English language by reading the works of Charles Dickens. Asch attended the College of the City of New York, where he received his bachelor's degree in 1928. He then went on to earn his master's degree in 1930 and his Ph.D. in 1932 at Columbia University. While studying at Columbia, Asch was mentored and greatly influenced by psychologist Max Wertheimer, a founder of Gestalt psychology.

After studying at Columbia, he began his career as a psychology professor at Brooklyn College in the 1940s. During this time, World War II was occurring, and Hitler was at the height of his power. Asch studied the concepts of propaganda, indoctrination, and social pressure while teaching at Brooklyn College. He then became a professor for 19 years at Swarthmore College, where he worked with renowned Gestalt psychologist Wolfgang Köhler. He then became both the director and a distinguished professor at the Institute for Cognitive Studies at Rutgers University from 1966 to 1972. In 1972, Asch began to teach at the University of Pennsylvania, where he served as an emeritus professor of psychology before retiring in 1979.

Asch married Florence Miller in 1930. Together, they had a son named Peter, who became a professor of economics at Rutgers University and died in 1990. Asch's wife, Florence, died in 2002. Solomon Eliot Asch died on February 20, 1996, at his home in Haverford, Pennsylvania, at the age of 88.

Major Contributions

During the 1950s, Asch became famous after conducting a series of experiments which demonstrated the power of social influence. These experiments commonly became known as the Asch conformity experiments. The experiment took 123 male participants and placed each participant in a group with 5–7 confederates who, unlike the real participants, knew the true nature of the experiment but acted as though they were real participants, naïve to the true nature of the experiment. The participants were shown a line next to three additional lines. Of the three additional lines, which were labeled A, B, and C, one was of equal length to the first line shown, while the other two were of different lengths. In each trial, the participants, including the confederates, were

asked to choose which of the three lines was of equal length to the first line. The real participant always answered last or near last.

During the first couple of trials, the participants, along with the confederates, chose the obvious, correct answer. However, after the first couple of trials, the confederates began to all state the same wrong answer. The confederates stated the wrong answer in 12 of the 18 trials conducted on each participant. During these 12 critical trials, Asch studied whether the real participant would conform and state the same, obviously wrong answer as the confederates due to social pressure. Asch predicted that most people would not conform and state an obviously wrong answer. Asch found, however, that about 75% of participants conformed at least once and 5% conformed every time. A quarter of participants resisted social pressure and did not conform on any trial. Many participants became confused and upset when the confederates began answering incorrectly. Many participants who chose to conform did so believing the group was wrong but wanted to avoid being different or judged. When interviewed later, participants who conformed to the majority underestimated how frequently they actually did conform.

One variation of Asch's original experiment varied the amount of confederates present in each group. Groups ranged in confederates containing just one confederate to 15 confederates. Asch found that one confederate has almost no influence on the participant, while two confederates have a small influence. Three or more confederates are able to equally influence a participant to conform. Another variation examines the influence having one confederate stating the correct answer, while the others continue to state the wrong answer. Asch found that when the participant was not

alone in stating a minority opinion, the urge to conform to the majority is greatly decreased.

Asch published his famous textbook, "Social Psychology," in 1952. This classic social psychology textbook, which was later reissued in 1987, became a highly influential work in psychology, influencing many later social psychologists.

Solomon Eliot Asch's work greatly influenced the field of social psychology. Asch influenced the work of many of his peers, including Herman Witkin, who studied cognitive and learning psychology. Asch also influenced and supervised the Ph.D. of Stanley Milgram, who studied obedience to authority. Asch's experiments on the influence of social pressure on conformity continue to influence the field of social psychology to this day.

B

Baldwin, J. M.

JOSÉ C. SÁNCHEZ-GONZÁLEZ¹, JOSÉ C. LOREDO-NARCIANDI²

¹Universidad de Oviedo, Oviedo, Asturias, Spain

²Universidad Nacional de Educación a Distancia (UNED), Madrid, Spain

Basic Biographical Information

James Mark Baldwin was born in 1861 to a well-to-do Presbyterian family in South Carolina. He began his career at the University of Princeton within the intellectual atmosphere of the Scottish School of Common Sense advocated by James McCosh. Like other psychologists of his generation, he traveled to Europe and became familiar with the experimental psychology of Wundt. He also came in contact with the philosophy of Spinoza and the French psychology of the time, which he was especially interested in. Otherwise his education developed within the atmosphere of the newly formed school of North American functionalism and was especially concerned with giving a place to psychology within evolution. He was a professor at Lake Forest University, the University of Toronto, Princeton and Johns Hopkins University, as well as the *École des Hautes Études* of Paris.

As a result of the influences that he received, Baldwin distanced himself from the psychology of the faculties that the Scottish School promoted and began to develop the basis of the genetic psychology. This was accomplished by bringing together a solid theoretical background with extensive information of the empirical developments of his time. In different points in his life, Baldwin himself conducted experiments and empirical studies on laterality (the use of the left or right hand in children), optical illusions (the “Baldwin Illusion”), memory (of geometrical figures),

and reaction time (in which he maintained an intense controversy with Titchener). His genetic perspective was also nourished by a good knowledge of the philosophy and social sciences of the times, keeping close contact with some of the most highly regarded figures in these fields.

Genetic psychology sees functions where the Scottish School saw faculties; this is to say that Baldwin did not consider faculties to be something static but rather the result of the complex development of structures from active processes that were initially quite basic (“circular reactions”). The mind, although supported by innate elements, comes to be through active development and this development generates the structures that come to define it. Baldwin puts forward his genetic psychology in the 1894 book *Mental Development in the Child and the Race*, where he deals with the themes typical of developmental psychology such as circular reactions, accommodation (active adaptation), imitation, play, etc.

Shortly thereafter, in an atmosphere of heated discussions about darwinism, lamarckism, and psychology, the article “A New Factor in Evolution” (1896) and the book *Development and Evolution* (1902) relate the evolution of a species with the novel and adaptive behaviors generated throughout the development of an individual. The theory of Organic Selection or the “Baldwin effect” (also formulated by H. Fairfield Osborn and Lloyd Morgan) assumes that the survival of the individual or group is facilitated by the adoption of specific novel adaptive habits in such a way that random hereditary mutations that are either directly or indirectly useful for these habits will be selected for and passed on to the following generations. For example, if in a population of birds, the novel habit of protecting nests by digging in the ground to hide them is generated and propagated, hereditary variations that reinforce an instinctive tendency to dig

would probably be selected. However, other characteristics that are indirectly related such as the shape of the beak or the ability for mimicry would also be selected. In this way, the adaptive behavior –novel, intelligent– is what defines the direction in which evolution proceeds. The theory of Organic Selection, although never completely rejected, not even by Neo-Darwinism, has received growing attention and support in the last 20 years. It has even come to make up the core of Mary Jane West-Eberhard’s general theory of biological evolution (West-Eberhard 2003).

In *Social and Ethical Interpretations in Mental Development* (1897), Baldwin shows the intimate connection that exists between individual development, socialization, and culture (or “social inheritance”). By way of processes of active imitation of diverse degrees of complexity, the individual assimilates social influence in an idiosyncratic manner – it is not mere reception. In a reciprocal way, this individual action reinforces and contributes to the transformation of “social inheritance.” The individual is not a simple product of society nor is society an objective structure that subsists by itself without the participation of individual agents.

Thought and Things, or Genetic Logic, a work published in three volumes in the period 1906–1911, to which in 1915 a book titled *Genetic Theory of Reality* was added, extends, to the fullest extent, Baldwin’s genetic perspective, converting it into a general theory of reality, i.e., an ontology. The theory is formulated from a psychological, but not subjective, point of view. This is to say, the subjects are considered to be as the true constructors of that which we call “real,” and what is real is objective because it is intersubjective for having been stabilized (constructed) historically through the concurrence of a myriad of operations performed by the subjects. In this sense, Baldwin’s constructivism does not tend toward relativism, as do many constructivisms and current constructionisms influenced by postmodernism. The activity of the subjects does not impede objectivity but rather –to the contrary– makes it possible.

In 1909, as the result of a sexual scandal that surrounded him, Baldwin abandoned American academic life. After several stays in Mexico and England, he settled definitively in Paris where he continued his intellectual activity developing his genetic perspective

while in contact with some of the most important French philosophers and psychologists of the time such as Janet or Bergson. He also became involved with the support of the allies in the First World War. He died in Paris in 1934, and his remains were buried in Baltimore (USA).

Major Contributions

James Mark Baldwin is one of the most distinguished psychologists of all time. He developed a general constructivist psychology that includes four components, previously shown through the comments on his main works. These four components can be now summarized as follows:

1. A theory of the active genesis of novel behavior and cognitive innovations in animals and humans. This theory directly influenced the genetic psychology of Piaget (Broughton and Freeman-Moir 1982).
2. A theory of the biological basis of these innovations that explains –without lamarckism– their effect on the very evolution of a species. This theory is known as the “Baldwin effect” or Organic Selection and continues to be present in current evolutionary biology (Hinton and Nowlan 1987; Sánchez and Loredo 2007; Weber and Depew 2003).
3. A theory of the active formation of human individuality by way of socialization and social inheritance that includes an explanation of the genesis of technical and cultural innovations and their historical development. This theory is similar to what Vygotsky proposed (Valsiner and Van der Veer 2000).
4. A constructivist theory of the relation between reality and thought which emphasizes the fact that the history of reality itself is parallel with the history of our institutions and knowledge (Broughton and Freeman-Moir 1982; Wozniak 2009).

Baldwin’s commitment to the institutional development of scientific psychology was also an important theme throughout his career. He founded laboratories in Princeton and Toronto, and two journals (*Psychological Review*, together with J. McKeen Cattell, and *Psychological Bulletin*). He organized congresses, advised educational reforms, directed experiments, and edited a monumental *Dictionary of Philosophy*

and Psychology. His efforts led him to extend, above the base of the new scientific psychology, a general psychology that was able to coordinate consciousness and action, adaptation and cognition, habit and instinct, individual and society, evolution and development, and history and individual human life. After Baldwin, no one of these dualities should be understood in terms of simple opposites.

Although Baldwin was recognized at the beginning of the twentieth century as one of the most eminent North American psychologists, his prominence declined at the same velocity that Neo-Darwinism in biology and experimentalism, professional pragmatism, and behaviorism in psychology grew. Like James, Baldwin was more and more dissatisfied with some of these tendencies. Baldwin's theory is a psychobiology and social psychology that avoids reductionism, empiricism, and geneticism. For him, the autonomy and consistency of psychology does not rest in professional isolation nor in scientific mimicry of other disciplines but rather in having something of its own to contribute to evolutionary biology, sociology, history, and the theory of knowledge. Baldwin's status has slowly come to shine again starting in the 1970s, thanks to historians of psychology, epistemologists, social psychologists, cultural psychologists, biologists and psychologists who are interested in evolution (Broughton and Freeman-Moir 1983; Richards 1987; Wozniak 2009). The bulk of psychology, however, continues away from his figure, surely because it oscillates between isolation and mimicry and because cognitive and computational orientations are not very sensitive to the genesis of cognitive structures.

Bandura, Albert

PEGGY BRADY-AMOON

Seton Hall University, South Orange, NJ, USA

Basic Biographical Information

Albert Bandura was born on December 4, 1925, in Mundare, Alberta, Canada, the youngest of six children and only son. His parents, who had immigrated to Canada from Eastern Europe, valued education although they were not formally educated themselves. In 1949, Albert Bandura was awarded his B.A. in Psychology from the University of British Columbia with the Bolocan Award in Psychology. Inspired by Kenneth Spence, he then enrolled at the University of Iowa,

completing his M.A. in Psychology in 1951. He earned his Ph.D. in Psychology in 1952, focused on learning theory, working with Arthur Benton.

Albert Bandura and Virginia Varns met at the University of Iowa and married in 1952; the same year Dr. Bandura completed a postdoctoral internship at the Wichita (KS) Guidance Center. Their daughters, Mary and Carol, were born in 1954 and 1958, respectively.

In 1953, Albert Bandura joined the faculty at Stanford University on a 1-year appointment as an acting instructor, which was soon upgraded to a 3-year assistant professorship. He advanced quickly and was promoted to full professor in 1964; the same year he was elected Fellow of the American Psychological Association (APA). Ten years later, in recognition of his scholarship, Dr. Bandura was named the David Starr Jordan Professor of Social Sciences in Psychology, an endowed chair he continues to hold.

Major Accomplishments/ Contributions

Albert Bandura is considered one of the world's most famous living psychologists. While he is known for his early work on the development of aggression in adolescents including the well-known Bobo doll experiments that demonstrated the effect of social learning on human behavior, he is better known for his Social Learning Theory (SLT; 1977) and more recently, Social Cognitive Theory (SCT; Bandura 1986, 1997, 2001).

SLT and SCT elements, including self-efficacy and self-regulation, have inspired innovations in clinical practice, including the treatment of phobias and advances in educational and career development (e.g., Social Cognitive Career Theory: SCCT; Lent, Brown & Hackett 1994), as well as a significant body of supportive research.

Bandura (1997) argues compellingly that SCT goes beyond behavioral, cognitive, and social theories in recognizing that human cognition, behavior, feelings – and indeed even physiological response – emanate within people, influenced by a dynamic interplay between their behaviors, thoughts, and feelings about those behaviors, as well as the environment itself, that he refers to as *triadic reciprocal causation*.

Another key aspect of SCT is Bandura's observation that people have *agency*; that is the ability to exercise

control over their own lives (Bandura 1997, 2001). Key aspects of agency are individual and collective self-efficacy, people's belief in their ability to complete a task or reach a goal (Bandura 1997), their intentions, plans, self-awareness, and ability to adapt to external opportunities and challenges (Bandura 2001).

Bandura's work has been applied within psychology and allied fields as well as education, communications, business, and international relations (Bandura 1997). His more recent work is focused on a greater understanding of people's beliefs and belief systems (Pajares 2004).

In addition to his own prodigious scholarship, Albert Bandura is known as a family man, generous colleague, and mentor. He served on the Editorial boards of more than 20 journals, and, as evidence of the respect accorded him by his peers, was elected President of APA in 1974 and of the Western Psychological Association in 1981. He was also named honorary president of the Canadian Psychological Association.

Among his many honors and accolades, Albert Bandura was presented with the APA Award for Distinguished Scientific Contribution, 1980, the 2003–2004 James McKeen Cattell Fellow Award from the Association for Psychological Science (APS), the Outstanding Lifetime Contribution to Psychology Award from APA in 2004, and the American Psychological Foundation (APF) Gold Medal Award for Life Achievement in the Science of Psychology in 2006.

Bartlett, F. C.

VINCENT W. HEVERN

Le Moyne College, Syracuse, NY, USA

Basic Biographical Information

Born on October 20, 1886, at Stow-on-the-Wold in Gloucestershire, Frederic Charles Bartlett was the second son of a successful boot and shoe store merchant. He completed two external degrees from the University of London: an Honors B.A. in philosophy in 1909 and an M.A. (with special distinction) in sociology and ethics in 1911. In 1914 he received an Honors B.A. in the moral sciences tripos from Cambridge University. When *Cyril Burt* left Cambridge's new laboratory of experimental psychology in 1915, Bartlett took over as assistant director to its founder, *Charles Samuel Myers*, and became its director in 1922 on Myers' departure to found the National Institute for Industrial Psychology. As a student and young researcher, Bartlett came under the particular influence of three Cambridge scholars: these include the aforementioned psychiatrist-psychologist *Myers*, as well as the philosopher-psychologist *James Ward*, and the psychiatrist-anthropologist *William H. R. Rivers*. It was Rivers who urged Bartlett toward psychology rather than his own field. Following the sudden death of Rivers in 1922, Bartlett found himself the senior academic in social science at the university. During the First World War and the 1920s he worked to build up the laboratory's facilities and program. These efforts culminated in his appointment to the first chair of experimental psychology at Cambridge in 1931. Until his retirement in 1952, Bartlett shaped the direction of British experimental psychology in fundamental ways both through his own work in memory, perception, thinking, and applied psychology and his direction of a cadre of excellent students, including Kenneth Craik and Donald Broadbent. Following his formal retirement, Bartlett served as a consultant at the university where he continued writing.

In 1920 Bartlett married Emily Mary Smith (1886–1974), an animal behavior experimentalist at the psychology laboratory. The couple had two sons. Bartlett was knighted in 1948 and awarded the Royal Medal in

1952. In the last two decades of his life, Bartlett received multiple honorary doctorates and election to scholarly societies and academies from around the world. He died on September 30, 1969, after a short illness.

Major Accomplishments/Contributions

Three books highlight Bartlett's most important scholarly contributions to psychology. In *Psychology and Primitive Culture* (1923), Bartlett surveyed the work of field anthropologists and social psychologists such as Franz Boas, Edwin W. Smith, William McDougall, and Rivers. He argued that an understanding of human behavior required psychologists to confront how deeply individuals are enmeshed in their social networks and cultural heritage. He especially detailed the dynamics of behavioral change across "primitive" (and modern) peoples through the mechanisms of cultural diffusion as social groups came into contact with each other. He also outlined how social institutions and cultural conventions tended to promote behavioral stability within individuals. Though he later seems to have stepped back from the more radical social framing of this argument to concentrate on the psychology of the individual, Bartlett here anticipated aspects of late twentieth century cultural and cross-cultural psychology.

His most well-known book, *Remembering* (1932), challenged prevailing laboratory-based theories of memory, particularly that of Ebbinghaus and the notion of memories as mental "traces." He employed an innovative research methodology and, as his book's title alludes, argued that memory is an active process of building rather than a static object to be recovered. His experimental method confronted English-born adults with a range of meaningful materials – stories, prose passages, and drawings – which they were asked to reproduce either at multiple sequential intervals or via serial transmission from one subject to another (similar to the American game of "Telephone"). He analyzed the qualitative changes and stabilities in his subjects' reproduction of these materials, particularly their responses to a decidedly singular Native American folk tale ("The War of the Ghosts") taken from Boas. He pointed out the ways his participants tended to assimilate experimental stimuli to their own cultural frameworks. In recounting the ghost story, notions at odds with its listener's cultural knowledge tended to be

“conventionalized” or ignored, and unfamiliar or singular emotions flattened or recast. To explain these findings, Bartlett used the concept of *schema*, adapted explicitly from its earlier use by the neurologist Henry Head to describe regular body movements. Individuals actively deploy their own attitudes, beliefs, and past experiences (their *schemata*) to make sense of the materials they are remembering. Hence, Bartlett argued, memory is a fundamentally reconstructive rather than reproductive act. Later experimenters noted that, if explicitly asked to recall stimuli as precisely as possible (a condition Bartlett did not request of his subjects), they were far more accurate in their responses than Bartlett found. *Remembering* and its conclusions have provoked continuing interpretations and challenges both by cognitive and information processing theorists during the “Cognitive Revolution” as well as social and cultural psychologists of more recent decades.

Bartlett became deeply involved during the Second World War with the demands of aircraft design, control, and production; the training of aircraft personnel; and, beginning in 1944, the Applied Psychology Research Unit of Cambridge’s Medical Research Council. His 1958 book, *Thinking*, reflected these involvements as Bartlett compared thinking to a high-level bodily skill and contrasted closed-system versus adventurous forms of thought. Information processing theorists have found his description of the demands of any closed-system thinking fruitful. Meanwhile, Bartlett’s emphasis upon both individual initiative factors and group or social contexts facilitating the growth of adventurous thought, particularly by experimental scientists, has found particularly traction within late twentieth century approaches to the sociology of knowledge.

Behaviorism

JOHN A. MILLS

University of Saskatchewan, Hornby Island,
BC, Canada

Introduction

To be a behaviorist is to be committed to a set of beliefs about the nature of mind. Unlike someone working in a field such as personality or motivation, a behaviorist has to adopt a specific ideological stance. Danziger (1997) shows that the basis for what amounts to a behaviorist theory of mind was established within the Anglo-American tradition of comparative psychology from the end of the nineteenth century onward. The term *behavior* was used to refer to bodily activity, but not to all such activity. Heart rate, for example, was not called “the heart’s behavior.” Instead, behavior referred to activities which, in a human being, would be called intentional or conscious, such as approach, avoidance, discrimination, or learning. Researchers could study those activities in animals without committing themselves to the belief that a mind controlled them. At the same time, they could take the position that some sort of “inner forces” (drives, motives, or reinforcement) acted as controlling agents. As Danziger writes, “[Behaviorism’s] promiscuous use expressed an assumption that common principles, spanning the biological, psychological and social levels were indeed waiting to be discovered” (Danziger 1997, pp. 95–96). Later, he writes, “Far from being a neutral category, ‘behavior’ had become a preferred vehicle for those who shared the conviction that human problems would be solved only by adopting a natural science approach” (1997, p. 96).

Philosophical Behaviorism

Philosophically, we can distinguish between logical, radical, and methodological behaviorism (e.g., Kim 1996). All those variants of philosophical behaviorism underlay the theories of the mature behaviorists (Mills 1998). Logical behaviorists asserted that any proposition about a mental state could be converted, without loss of meaning, into a proposition about behavior. We can state logical behaviorism as follows, “Psychological

theories must make no reference to inner mental states in formulating psychological explanations” (Kim 1996, p. 43). Methodological behaviorism did not address the issue of the ontological status of mental states; it merely stated that we did not have to make reference to such states in order to understand or predict actions or statements. For example, the “sensation” *redness* could be understood as a disposition to utter the word “red” or the action of stopping at a traffic light when driving, while to say that “John is a vegetarian” is to say that John will refuse meat dishes if offered them or that he will purchase no meat products. Ontological (or radical) behaviorists, in contrast, explicitly denied that there are any “inner” mental states. So, for a radical behaviorist, pain was nothing other than wincing, groaning, and so on. Furthermore, because, according to radical behaviorists, all human activities, whether mental or physical, could be exhaustively defined and understood behaviorally, it was unnecessary to appeal to states of the brain in order to understand, predict, or control behavior.

Within psychology, we can conflate logical and methodological behaviorism. Almost all behaviorists embraced the methodological variety, making Burrhus Frederick Skinner (1904–1990) and his followers almost the only radical behaviorists within the discipline. Once behaviorism matured, methodological behaviorists attempted to analyze behavior in terms of stimuli, responses, drives, and reinforcers. Drives were said to propel animals, both human and nonhuman, into action, whereas reinforcers served to terminate sequences of actions. Most behaviorists (whether methodological or radical) also maintained that reinforcers served to “stamp in” responses, thereby increasing the probability that any given response would recur in the presence of those classes of stimuli associated with it. All behaviorists had to explain why, in crucial situations (especially in the search for food and the avoidance of danger), animals from cephalopods upward displayed seemingly purposive behavior and why it was that identical stimuli (where stimuli are fully defined in physical terms) do not necessarily evoke identical responses in animals of the same species (again, where responses were defined solely in physical terms). All radical and most methodological behaviorists denied that nonhuman animals could foresee the probable consequences of their actions and hence devise means of achieving desired ends (or avoiding

undesirable ones). Instead, they claimed that, within any animal’s history, because particular reinforcers (whether these fulfilled a stamping in or a mere signaling function) became associated with particular classes of responses and with particular classes of stimuli, the animal formed habits and that those habits controlled particular modes of responding in particular situations. They then extended the same type of analysis to humans.

Methodological behaviorists, unlike radical behaviorists, did grant explanatory status to brain states. Thus, we know that, in cats, electrical stimulation of the lateral nucleus of the hypothalamus will trigger stalking and other actions associated with hunting, whereas electrical stimulation of the ventromedial nucleus will trigger aggression. Some methodological behaviorists, however, denied that there were any mental states, while others believed that there were but that psychologists, in their scientific practice, did not need to make any reference to them. In order to understand why methodological behaviorists imposed such a severe restriction on themselves one has to appreciate that, when the science of psychology came into being, science was conceived as comprising, on the one hand, sets of unassailable, publicly verifiable facts and, on the other, sets of inductive inferences from those facts. If the inductive inferences were of sufficiently high level and comprehensive, then they became scientific laws. Because brain states are physical and, thus, in principle observable, methodological behaviorists were prepared to concede their existence. Mental states were banned because they were private.

Moreover, scientific psychologists, whether they are behaviorists or not, have tended to repudiate what they saw as René Descartes’s fundamental error (e.g., Descartes 1637/1960). Damasio put the issue succinctly by stating that Descartes had claimed, “[t]hat thinking, and awareness of thinking, are the real substrates of being. And since we know that Descartes imagined thinking as an activity quite separate from the body, it does celebrate the separation of the mind, the ‘thinking thing’ . . . from the nonthinking body, that which has extension and mechanical parts . . .” (Damasio 1994, p. 248). In addition, early psychologists opposed themselves to the theories of action proposed in the eighteenth and nineteenth centuries whereby internal processes (usually called “associations”) engendered

lifelong connections between sensations and responses. Other internal processes (eventually called “emotions”) supposedly triggered responses to those stimuli associated with them (Peters 1974).

Behaviorists were convinced that if meaning or significance lay solely within the inner, private, or mental realm, then no psychological statements could be verified. Thus, to state that the ultimate meaning of sensing *redness* resides in each person’s private or subjective feeling or sensation of the color red is to say nothing because subjective reports are not open to public verification. Furthermore, behaviorists’ distaste for the mental as an arbiter of meaning had support from philosophers. For example, Kim (1996) cites Ludwig Wittgenstein’s parable of the beetle in a box. Imagine that the only beetles in the world live only singly, each in a box. Every person carries a box and only that person can open the box and look into it. So, nobody can publicly or intersubjectively establish the truth of the answer to the question, “What is in your box?” (in reality, a particular box could contain a locust, but the box’s owner, for unknown reasons, chooses to call the animal in the box a beetle).

However, now consider the activity of writing a check, which is not a mere sequence of responses but a social transaction implying a fairly complex set of obligations (for example, the necessity to retain sufficient funds in one’s bank account so as to ensure that payment can be met). We can imagine situations in which the physical responses called “writing a check” are performed but in which a genuine check is not written. For example, in a well-known joke, a lawyer discharges a debt to a dead person by dropping a check into the open funeral casket; so, the lawyer drops a mere piece of paper, not a check as we understand the concept *check*, into the coffin. In general, we can apply the principle of defeasibility to any form of behaviorism (Kim 1996, pp. 32–25). If we say that a person will perform an action if and only if he or she has belief X, then we can imagine a belief that will counteract the action. More generally, we can say that a person will perform an action only if that person desires a particular outcome and believes that the action will produce or contribute to the production of that outcome. Conversely, if the person believes that the action may well produce an undesirable end-result, then he or she will refrain from the action. For any action whatsoever, we

can imagine beliefs or desires, which promote or nullify the action. Thus, beliefs or desires determine actions and actions cannot be actions unless they result from beliefs and desires.

The Origins of Psychological Behaviorism

American philosophers, especially Edwin Bissell Holt (1873–1946), Ralph Barton Perry (1876–1957), William Pepperell Montague (1873–1953), Walter Taylor Marvin (1872–1944), Walter Boughton Pitkin (1878–1953), Edward Gleason Spaulding (1873–1940), Edgar Arthur Singer (1873–1924), Grace de Laguna (1878–1978), and Frederick James Eugene Woodbridge (1867–1940) – the first six of the philosophers I have named formed the school known as New Realism – had early, and decisive, influences on psychological behaviorism. Mostly that influence was indirect, in that Holt, for example, believed that “consciousness” was merely a way of categorizing collections of objects and that behavior was the only observable psychological category while Perry believed that psychology should address the ways in which entire organisms adjusted to their environments. American philosophers did have some direct influence on psychological behaviorism. Edward Chace Tolman (1886–1959) studied under Perry and Edwin G. Guthrie (1886–1959) under Singer.

Even though some transactions between psychological behaviorists and philosophers did occur in the 1960s and 1970s, psychological behaviorism did not arise from within philosophy and developed independent of it. Moreover, within psychology, *behaviorism* underwent progressive changes in meaning or significance (Danziger 1997). Broadly, we can say that behaviorist principles emerged from American Progressivism (for discussions of Progressivism, see Burnham 1977 and Ross 1991). Progressivism was the birthplace of a particularly American version of the social sciences (Ross 1991). Hence, American psychology had pragmatic rather than conceptual or scientific origins. In addition, the pragmatism from which, initially, behaviorism drew its sustenance was socially directed so that the desire to promote social utility remained a driving force within behaviorism, being only occasionally subordinated to a need to achieve apparent scientific credibility (Mills 1998).

The behaviorist approach to research made its first appearance, in 1909, in American sociology, when Franklin Henry Giddings devised an objective scale of sympathy (Mills 1998, pp. 26–27). Within psychology, Watson (1913), in an article which has since become famous, was the first person to use the word formally. However, historical research and a textual analysis of the article demonstrates that we cannot interpret the article as a “rallying call” to psychology or even give 1913 as the date for the first appearance of psychological behaviorism (Mills 1998; Samuelson 1980). Certainly, it would appear that, in his early writings on the topic, Watson did not use *behaviorism* in any of its later senses. Mills (1998), from an analysis of the correspondence between Watson and his early colleague Robert Mearns Yerkes (1876–1956), concluded that Watson, who started his career as an animal psychologist, used *behavior*, broadly speaking, as an adjective, as in the phrase “behavior men.” That is, he was contrasting his research practices with those of human psychologists.

It is also usually maintained that Watson (1916) carried out psychology’s first behaviorist experiment, a single case study of what, again typically, is interpreted as an instance of aversive conditioning. Samuelson (1980) and Harris (1979) have subjected Watson’s study to a devastating conceptual and methodological critique, while Mills (1998) has shown that Watson’s understanding of conditioning was seriously defective. Moreover, Watson, by resigning his academic post in 1920 (Buckley 1989), removed himself from a research environment, although it must be said that a program on conditioned aversion therapy he undertook with the collaboration of Mary Cover Jones did show distinct promise. Instead, Watson, in his post-academic writings (e.g., Watson 1924), asserted that uncontrolled and unintentional parental (especially maternal) behaviors were the sole influences on the character development of children. Watson exhorted parents (again, especially mothers) to program their interactions with their children in such a way as to produce desirable character development, where “desirable,” broadly construed, meant “socially useful.”

Four praiseworthy things can be said about Watson: (1) his commitment to making a comprehensive attempt to make a behaviorist analysis of all “inner” states inspired psychologists like Hull; (2) he was crucial in laying the groundwork for behavior therapy

(he treated children, including his own, as robots who could be shaped to perform any desired end whatsoever); (3) his early experiments demonstrated, brilliantly, that lower animals learn even though they can neither think nor speak; and (4) his insistence on peripheralism, which had a decisive influence on Hull’s thinking.

Within American academic psychology, behaviorism certainly did flourish in the 1920s. However, it took on a different form from that it was to assume from the 1940s onward. The behaviorism of the 1920s was purely theoretical, made comparatively little use of the concept of conditioning, and was, on the whole, divorced from research. Above all, it made comparatively little reference to learning. Max Meyer (1873–1967), Albert Paul Weiss (1879–1931), Jacob Robert Kantor (1888–1984), Walter Samuel Hunter (1889–1956), and Zing-Yan Kuo (1898–1970) were the leading proponents of this form of behaviorism (Mills 1998, pp. 40–54). All, except Hunter, were very much concerned with philosophical issues and none (except Hunter again) performed experiments with animals. Therefore, with help from de Laguna, they did what behaviorists should have been doing, namely, applying a philosophical behaviorism directly to human beings so that they could construct plausible (but not scientific) explanations for the inner or mental life of human beings based on behaviorist principles.

The Laying of Neo-Behaviorism’s Foundations

Mills (1998) wrote, “Almost all neo-behaviorists were animal scientists, and unlike the early behaviorists, they produced highly sophisticated and, in some cases, comprehensive psychological theories. The major neo-behaviorists, at least, shared the early behaviorists’ commitment to social application, but believed that such applications should be mediated through empirically tested theories, whose ultimate derivation was the highly controlled environment of the animal laboratory” (p. 4).

In order to create such a sophisticated enterprise (which might conceivably be dignified with the title “behavioral science”), neo-behaviorists needed a conceptual base. Specifically, that base comprised: (1) a distinction between classical and operant conditioning; (2) the concept *operationism*, which, it is

crucial to note, is peculiar to certain forms of psychology and goes far beyond the definition of scientific phenomena operationally; (3) the concept *learning* and its operationalization; (4) the terms (or rather concepts) *stimulus* and *response* in an operational form; and (5) the attempt to operationalize what neo-behaviorists believed to be explanatory concepts, such as *reinforcement*. Guthrie, Tolman, and Edward Lee Thorndike (1874–1949) played the required roles. Paradoxically, Guthrie performed only one major experiment, while Thorndike did not call himself a behaviorist and was not treated as one even if those who rejected him relied heavily on some of his basic concepts.

I will start by discussing, in some detail, the distinction between classical and operant conditioning. The former was known from the mid-eighteenth century onward and, in humans was construed as an involuntary expectation of some anticipated pleasure (e.g., salivating when entering a restaurant). By the end of the nineteenth century, a considerable amount of research had been carried out on anticipatory actions in animals (Logan 2002). Operant conditioning can be understood, in common sense terms, as the delivery of reward or punishment following some action. Writers such as Bentham (1983, 1996) claimed that all human actions could be controlled by administering carefully contrived sets of rewards and punishments.

Ivan Petrovich Pavlov (1849–1936) was the first person to carry out systematic research on classical conditioning. It is crucial to note that Pavlov was, in no sense of the word whatever, a learning theorist. He believed that, by studying conditioned reflexes, he could study the brain. He imposed further limitations on those who wished to extrapolate his work to the study of learning by limiting his work almost exclusively to the study of salivary conditioning in dogs. It requires great skill, knowledge, and patience to elicit and maintain the canine salivary reflex. Moreover, Pavlov displayed extraordinary and well-nigh unique skills in the maintenance of what are called “chronic preparations,” that is, animals that have undergone fairly severe surgery so that processes can be observed not just systematically but *in vivo* (Gray 1979).

A conditioned reflex is derived from a neurologically based response of known origin, such as the knee jerk. Salivation is a reflex which, even in human beings, is elicited not just by the placement of food in the mouth

but by its odor, its sight, and, above all by acquired associations (such as reading about food even after one has ingested a large and satisfying meal). Pavlov’s (Pavlov 1960) terminology, at least, did provide a basis for the learning theory whose proponents paid him unwanted compliments. The stimuli that automatically elicited reflexes he called “unconditioned,” while those acquired by association (and which could thus be idiosyncratic) he called “conditioned.” The conditioned response could be adjectivally qualified as either “conditioned” or “unconditioned,” but in any particular situation, conditioned and unconditioned responses were physically identical.

Classical conditioning is best defined by describing a typical experiment from Pavlov’s laboratory. A dog, which had been surgically prepared so that the parotid salivary glands were exposed, would be placed on a stand and in a harness. The handler would then leave the room. A small amount of food (the unconditioned stimulus) would be presented to the dog by an automatic device. The dog would then salivate; in Pavlovian language, the food would elicit salivation (the unconditioned response). The strength of the unconditioned response was measured (again automatically) by recording the number of drops of saliva elicited, its amount, and the response latency. The experiment proper would then begin. A tone (the conditioned stimulus) would be sounded and would be followed a few seconds later by food. What was later to be called “learning” initially manifested itself when the dog salivated before the food was presented and fully manifested itself in the absence of food. However, if the tone was presented in the absence of food, the conditioned response would attenuate and then disappear (a process Pavlov called *extinction*). It was, therefore, said that classical conditioning could occur (in the language of learning theorists could “become a habit”) if and only if the unconditioned stimulus was associated with (reinforced) the conditioned stimulus. Learning theorists were especially excited because acquisition and extinction were not just measurable but could be plotted as an S-shaped function. Once acquired, conditioned responses became a permanent part of an animal’s “mental furniture.” That discovery also excited learning theorists because it suggested that concealed but vital states or processes, such as memory, could be subjected to scientific analysis.

At almost the same time that Pavlov began work in the area that was later to be called classical conditioning, Thorndike (1898), in his famous puzzle box experiments with cats, laid the foundation for operant learning. He couched his account of his results in a language that approximated that of mature neo-behaviorism. The Thorndikian cat, although under severe experimental constraints, had to find its own way out of the difficulties Thorndike imposed upon it. There was one major difference between Thorndike's cats and Pavlov's dogs. The former were severely hungry, the latter consistently well-fed. The neo-behaviorists were to call "making an animal hungry" "placing it under a hunger drive" (thus concealing a commonsensical notion under the stifling mantle of science). Thorndike, so far as I know, remained within the sphere of common sense because he realized that his cats would not do what he wanted them to do unless he made them hungry. Thorndike put the unfortunate cats in various types of puzzle box with a dish of food in plain sight. The cat, frantic with hunger, started to claw the interior of the box. In the course of its clawing, it eventually tripped a mechanism that opened a door, leaving it free to rush at the food. Allowing it to eat very briefly Thorndike, who, given the severe and quite possibly severe consequences of being bitten or clawed by a justifiably angry cat, displayed, at the very least, great courage, replaced it in the box. Eventually, all the cats showed "learning." That is, once a cat had made a correct response, the latency of that response on succeeding trials would progressively decrease and the probability of its emission would progressively increase. Thorndike summarized his findings by positing the Law of Effect, whereby responses were progressively "stamped in" by rewards. In particular, Thorndike believed that he had demonstrated that one-trial learning (insight) in a nonlinguistic animal was impossible. In his later experimental work, he went even further, showing that a progressive stamping process could explain various simple responses in human beings. Conceptually, Thorndikian learning is identical to Pavlovian learning except that, in Thorndike's case, there is no sign of a conditioned or unconditioned stimulus and that some sort of drive is crucial.

I have deliberately written my account of Pavlov's and Thorndike's work so as to emphasize the similarities between them. I have done so because it is difficult,

from a contemporary standpoint, to appreciate the crucial significance neo-behaviorists gave to the supposed difference between classical (Pavlovian) and operant (Thorndikian) conditioning. Oddly, Pavlovian conditioning was never called "Pavlovian learning" and "operant learning" was almost never called, except in the very early phases of neo-behaviorism, "operant conditioning." It is true that a Pavlovian animal was not deliberately placed under a "hunger drive" but it is also true that a non-salivating mammal would be so abnormal in other respects that it could never survive and therefore never exist in the first place.

How, then, did it come about that the differences between Pavlov's and Thorndike's mode of experimentation became so exaggerated that, eventually, neo-behaviorists came to say that each had laid the foundation for the discovery and theoretical elaboration of two irreconcilably different forms of learning (e.g., Kimble 1961)? Or, how was it that trivial but real differences in method became grotesquely overblown and delusory differences in theory? I would suggest that the purportedly crucial differences between operant learning and classical conditioning arose, for the most part, because of Pavlov's and Thorndike's different professions. Pavlov worked as a scientist throughout his life, whereas Thorndike, as soon as he had gained his doctorate, became an educational psychologist. He was among those who revolutionized the American system of public education, especially at the primary level. He, following Ernst Meumann and Herman Ebbinghaus, converted education into graduated sets of drills (Danziger 1990; Mills 1998). Children, while they were in the classroom, were required to become robot-like beings who were forced to learn fixed sequences to preset criteria. They were being socialized into the habits required for routine work such as that carried out on a factory assembly line. Unwittingly, Thorndike was not the first to apply scientific principles in the classroom. Instead, he was reenacting, in close and eerie detail, principles enunciated very early in the nineteenth century by Jeremy Bentham, and his eighteenth century forebears (Bentham 1983). Furthermore, just as Thorndike's children were "children," his cats were "cats" (explanatory concepts fitting into a speculative scheme).

Operant conditioning, then, began as a technology, became a set of hallucinations that was, grotesquely,

called a theory, and reverted to an, albeit marginal, set of techniques. Pavlov, as any great scientist should, established a robust set of techniques that have become an unchanged and unchangeable part of science (Bitterman 2006). This is not to say that Pavlov's techniques could not be adapted to ideological ends. The leading Bolsheviks, especially Lenin and Trotsky, were obsessed by the illusion that they could fashion human beings who would devote their entire being (emotional as well as cognitive) to the creation and maintenance of an ideal society (Service 2007). Lenin, who, like Stalin, undertook the annihilation of the Russian intelligentsia and the creation, *ex nihilo*, of a new social elite, knew of Pavlov's work within 2 years of the Bolshevik revolution (Figs 1996, pp. 732–736; Hosking 1985). He ordered the construction of a spacious, fully modern building in which, for the rest of his life, Pavlov conducted his research.

Operational Definitions

In effect following Thorndike, Guthrie defined learning in terms of successive increases in response strength, where “response strength” was physically measured and construed as frequency, amplitude, latency, etc. Within that framework of thinking, a stimulus must be defined, in principle, as “that which evokes a response,” while a response is defined as “any physically measurable movement.” One immediate problem is that the definition of *stimulus* is circular. Since a response can be defined as any observable act the issue of circularity does not arise (although one has to note that to talk of implicit responses, as Watson and others did, is to talk nonsense). These problems became far more severe when we turn to supposedly explanatory concepts such as reinforcement or learning. To put the matter bluntly, to define such terms operationally is to define nothing. For example, let us take the example of intelligence, which was the first psychological concept to be defined operationally (Mills 1992). If we ask a psychologist who has not yet become skeptical about, or cautious, in the way he talks about the concept or notion of intelligence, “How do you know that Fred is very intelligent?” he might reply “Because his score on the WAIS is two standard deviations above the mean” that is, like Boring (Mills 1992) he is saying, “Intelligence is what the tests test.” He is assuming, tacitly, that something happened because it happened.

The psychologist's reasoning is circular (I am taking my wording from Peter Loptson). Besides being hopelessly inept as a purported scientist of the mind, such a person is dull and unlettered in that he does not know that “explanations” such as his have been an object of mockery for a century. For example, the French playwright Molière mocked Aristotle's theory of forms in one of his plays by having a character say that opium causes drowsiness because it contains a dormative factor. Green (1992) has written a comprehensive critical account of the application of operationism to psychological constructs. Koch (1992) argued that, properly construed, operationism points toward a to-be-discovered meanings rather than the constitution of meanings, while Mills (1992, 1998) has discussed the problems arising from applying operational definitions to psychology at length.

Tolman and Intervening Variables

Tolman showed neo-behaviorists how to apply operationalism comprehensively (Mills 1998; Tolman 1951). He divided his explanatory system into three realms – independent (input) variables, dependent (output) variables, and intervening variables. He claimed that all were real, physical states. He further claimed that the nature and strength of any given intervening variable was a known, physical consequence of the operations required to instantiate it. Habit was a crucial intervening variable for Tolman. Habits, he believed, were dispositions inserted between independent and dependent variables. By controlling habit strength, one could make predictions about animals' behaviors or exert control over them.

However, the cognitive map is the intervening variable for which Tolman is best known. He demonstrated that even the lowly rat creates and retains something which could loosely be called “knowledge” of the nature of the apparatus devised for various experiments and will, if given the opportunity, use that knowledge to its own advantage (Staddon 2001, p. 19). Mills wrote:

- ▶ As a matter of expository convenience we could talk of minds as though they were independent substances. We could portray the concept of such minds as interlocking sets of cognitive maps linked to environmental and bodily input variables (stimuli arising for the physical world outside the body and motivational

factors arising from within the body) and to action systems. Such portrayals . . . were, however, no more than formal devices. (1998, pp. 95–96)

Skinner's Operant Theory

Burrhus F. Skinner (1904–1990) claimed that he was not a theorist. Nevertheless, his terminology demands an analysis in terms of operational definitions especially because, in the course of pursuing his research, Skinner created a particular terminology which demands a theoretical interpretation. In addition, Skinner created a particular style of carrying out animal research which his followers generalized to human research. His central concept was the operant (Skinner's term for an instrumental response), which he contrasted with the respondent. An operant is a voluntary response emitted by an animal; it operates on the environment and is controlled by its consequences (Staddon 2001, p. 33). An operant is emitted, whereas a respondent, which is involuntary, is elicited by a stimulus. Again, non-Skinnerian behaviorists call respondents "classically conditioned responses." Staddon comments:

- ▶ The concept of "emission" of operant behavior is important. It represents Skinner's recognition that operant behavior must occur spontaneously before it can have consequences or be guided by them. But apart from a few general comments about engineered environments that might conduce to "novel repertoires" . . . Skinner never enquired systematically into the process that generates operant behavior in advance of any opportunity for reinforcement . . . By his silence on the problem of origins, Skinner conveyed this message about the range of spontaneous behavioral variation: Variation is generally sufficient to allow for not just some act, but the correct, adaptive, act to be rewarded and strengthened. (2001, p. 35)

Skinner believed that response rate was a measure of response probability. He arrived at that belief, on the one hand, via his creation of the cumulative recorder which allowed investigators to acquire records of animals' moment-to-moment responding and, on the other, via his discovery of schedules of reinforcement. The latter appeared to demonstrate that animals adjusted their rate of reinforcement to the anticipated delivery of reinforcement. Skinnerians were also

excited because it was the nature of the schedule, not the species of the animal, that determined response rates. However, Skinner never defined *rate* or *probability*.

Despite that theoretical shortcoming, Staddon writes:

- ▶ It is important not to underestimate the enormous excitement associated with the discovery of reinforcement schedules. The older, between-groups method estranged the experimenter from his subject matter. He dealt not with animals and acts, but with averages and statistical tests. In this context, the power of Skinnerian techniques and the direct contact they offered with individual experimental subjects was intoxicating. The visible and orderly output generated moment by moment by each subject, the lack of any need for inferential statistics, the amplification of research effort made by automation . . . and the new world of possibilities opened up by the reinforcement-schedule idea generated a heady atmosphere among operant conditioners in the 1950s and 1960s. (2001, p. 38)

Despite his atheoretical protestations, Skinner did, undeniably, have one explanatory concept – reinforcement. The construct was his version of Thorndike's Law of Effect. Skinner defined reinforcement as follows, "The barest possible statement of the process is this: we make a given consequence contingent [dependent] on certain physical properties of behavior . . . and the behavior is then observed to increase in frequency" (Skinner 1953, p. 64). The best example of Skinner's definition of reinforcement came from his study of "superstition" in pigeons. Skinner placed hungry pigeons in a Skinner box (a piece of apparatus in which food or water are delivered automatically) and delivered food at fixed intervals. The pigeons gradually came to engage in whatever activity happened to precede the delivery of food during the entire inter-reinforcement interval.

Frequency and contingency are the two key terms in Skinner's definition. However, reinforcement encompasses more than mere "stamping in." The more likely it is that a response predicts a reinforcer, the stronger (or more probable) it becomes. Thus, a response becomes an act. An operant is not a mere response; operants are classes of responses jointly predicting the occurrence of particular reinforcers. Skinner's version of the Law of Effect is an example of an operational

definition. Operants are defined in terms of the operations (contiguity between response and reinforcer) required to produce them. However, the reinforcers do not produce operants. Instead, we have a relationship between the response and the experimenter-induced consequence (the reinforcer). So, some inner factors control the response and those factors are immune to a Skinner-style scrutiny (which is wholly devoted to factors under the experimenter's control). Skinner's definition is thus immune to potential disproof. He generalized from his superstition experiment. He maintained that the experiment demonstrated that whenever a response appears regularly and predictably, it must be the consequence of reinforcement. However, because he refused to countenance any explanations that were not strictly empirically based, he was unwilling to entertain any explanations in terms of inner factors.

Such explanations are readily available. One area of research was particularly damaging to Skinner's theory. Brown and Jenkins (1968) discovered autoshaping, a procedure whereby Pavlovian procedures can induce key-pecking in pigeons (the procedure can be modified to produce bar-pressing in rats). Thus, the key-peck and the bar-press, the two paradigmatic operants, became respondents. A broader review (Mills 1988) shows that, when hungry or thirsty, rats and pigeons emit instinctively based food- or water-gaining responses. Thus, pigeons peck with the beak closed when they are hungry and the beak open when they are thirsty, while rats will grasp and gnaw at an object associated with food (e.g., the lever in the Skinner box). Cognitive and sociocultural explanations will have to be found to explain human responses to rewards and punishments.

Hull's Theory of Learning

Hull (1942), Hilgard and Bower (1966) attempted to create a deductive system in which all the postulates were anchored to, and referred to, operationally defined variables, so that drive, for example, was defined as the number of hours since food had been ingested. Hull's theory was also a conflation of Thorndike's and Pavlov's work. At the same time, he transformed their terminology. Thus, unlike Thorndike, who had stated merely that appropriate rewards would, under certain circumstances, stamp in preselected responses, Hull defined

reinforcement as the progressive reduction of a physiological need. Just as he took Thorndike into the theoretical realm, Hull transported Pavlov into it as well. He interpreted conditioning as an underlying process not as a mere relationship between a conditioned stimulus and a response. Hull was impelled to overinterpret Pavlov because he asserted that need reduction was both the necessary and sufficient cause for all actions. However, need reduction occurs at the end of a series of actions, so that, apparently, effects preceded their cause. So, in an experiment in maze running, for example, Hull was forced to suppose that each correct turn received, via classical conditioning, a modicum of positive reinforcement, thus impelling the animal to move forward to the next choice point. Furthermore, he had to assume not just that associative bonds connected stimuli and responses but that reinforcement-promoting stimuli (secondary reinforcers) were also linked together in hierarchical chains. To use the example of maze-running again, a correct turn distant from the goal would have less reinforcement value than one distant closer to the goal. In principle, then, Hull's was a predictive system just like Tolman's, although, for Hull, all animals, including humans, were machines under the complete control of drives and reinforcers. For a discussion of the role of robots in Hull's thinking, see Mills (1998, p. 106).

Although, in his early career, Hull did research into human psychology, he never attempted to carry out neo-behaviorist research on humans. Neither he nor his colleagues knew that not only did they have no warrant to generalize from their animal work to human beings but that their animal work itself was, possibly, species bound. In common with much of the neo-behaviorist animal research, Hull and his colleagues derived their data from what came close to a robotic animal, the artificially bred Wistar strain of *Rattus norvegicus* (Logan 2001). They could derive support from the psychologist Norman L. Munn, who had pronounced, "The white rat has become a standard animal for the investigation of many psychological problems . . . it is possible to write an essentially complete outline . . . if the science of animal behavior without going beyond the available data in the rat." (cited in Logan 1999, p. 4).

Wistar rats were convenient in many ways. They were short-lived (with a lifespan of about 3 years) and thus could be produced in large numbers at a relatively

low cost. Because they were bred in a standardized environment individual differences were minimized, allowing for generalization of results from one experimental laboratory to another. The difficulty with accepting the rat as a standard mammal resides in the distinction between organism-based and problem-based disciplines (Logan 1999). The former are defined in terms of the animal studied (primatologists study primates, for example). In the case of a problem-based discipline, a species is selected as a data source (a good example would be the biologist Thomas Morgan's choice of *Drosophila melanogaster* for his genetic studies). Morgan did not, however, make his choice without considering alternative animals and, above all, without knowing that there was a physical structure (the chromosome) to be studied. In the same way, Henry H. Donaldson, who introduced the albino strain of the Norway rat to American laboratories wished to study neurology and chose his experimental animal after canvassing some alternatives (Logan 1999). In principle, then, there is something odd about a theory like Hull's which purported to deal with the human mind but derived all its data from rats together with guinea pigs and the occasional chick. At best, we could say that Hull's theory was problem-based and that he set himself the task of studying various psychophysical states such as drives or secondary reinforcement. He could, quite justifiably, have made the working assumption that those processes were materially the same in all mammals. But before launching on a problem-based enterprise in one species of animal, Hull should have assured himself that his selected processes manifested themselves at some level or other or in several. As it is, it is as if Morgan had undertaken a comprehensive study of genetics in *Drosophila melanogaster* while treating chromosomes as some purely theoretical entity.

Hullian Theory

Like Skinner, Hull had a large group of followers. Unlike the Skinnerians, who merely took over their leader's concepts and concentrated solely on modifications in technique, the Hullians, led by Hull's principal disciple Kenneth W. Spence (1900–1970), enlarged upon and introduced changes to the theory (Mills 1998, pp. 184–187). At the most fundamental level, Spence made signal contributions to the theory of operationism. At a lower level, he worked extensively

on discrimination theory in animals and, in humans, via his studies of eyelid conditioning, on motivation. In discrimination learning, he formulated variety of noncontinuity theory whereby consistency of association between a cue and a reward elicits an approach tendency from an animal whereas an association between a cue and non-reward elicits an avoidance tendency. For a behaviorist, Spence's theory had the advantage that it dispensed with the need to refer to some "mental" model or representation.

In his work on eyelid conditioning, Spence, like Hull, assumed that motivation had both cue and arousal functions. Unlike Hull, who had assigned some degree of arousal to habit strength, Spence restricted habit strength to the mere pairing of stimuli and responses (i.e., he gave it solely a cue function). In consequence, arousal had a larger sphere of application in his theory than it did in Hull's. Mills wrote:

- ▶ "Hull had assumed that drive and incentive exerted multiplicative effects on habit strength. Spence assumed that drive and incentive added their effects to each other and that the sum had a multiplicative effect on habit strength." (1998, p. 186)

Spence believed that scores on the Taylor Manifest Anxiety Scale (MAS), a scale derived from items from the Minnesota Multiphasic Personality Inventory, were a pure measure of drive. Unfortunately, even from within the perspective of Hullian theory, it is not possible to treat MAS scores as a measure of habit strength. At a deeper level, the MAS is a measure of anxiety in purely operational sense. Scores of the MAS predict the likelihood that someone will be more or less anxious on some physical measure of anxiety (e.g., degree of pupillary enlargement). Quite apart from the problem that predictions derived from MAS scores are merely probabilistic it could still be the case that someone with pupillary enlargement could not be in anxious state of mind. To say that MAS scores measure drive is to stretch credulity even further. For a further analysis of those problems, see Wiseman (2000).

Early in his career, Spence was appointed to the University of Iowa, becoming head of the department of psychology in 1942. He created a doctoral program which produced many graduate students, many of whom engaged in lifelong research programs; roughly a quarter of Spence's students undertook research

similar to his once they had graduated (Mills 1998, pp. 187–190). However, their work is seldom referred to today. It is not so much that the work of the Iowa School was overtly disproved but rather that American psychologists both moved away from it into the new area of cognitive psychology. At the same time, the profession became more pluralistic and thus disinclined to subject itself to a hegemonic enterprise like neo-behaviorism (Mills 1998, pp. 190–193).

Behavior Therapy

Mills (1998, pp. 162–164) discussed the reformulation of psychoanalytic concepts in a behaviorist language by Hullians O. Hobart Mowrer and John Dollard, who attempted to formulate a rationale for behavior therapies. The motive for that enterprise was ideological. So, like mesmerism, and its descendants, such as hypnosis, they merely peripherally concern a historian of science, although definitely lying within the purview of a historian of ideas (e. g., Ellenberger 1970). Here, I will take only the case of Joseph Wolpe's (Wolpe 1958) development of reciprocal inhibition because it is an excellent example of the selection of a technique by means of deductive reasoning combined with an experimental demonstration of the effectiveness of the technique (Wolpe 1958).

Wolpe, who was practicing as a psychiatrist in Johannesburg, was introduced to reciprocal inhibition by the South African Hullian theorist James G. Taylor (see Taylor 1975). Taylor had been using a version of reciprocal inhibition on his patients by training them to remain relaxed when experiencing potentially anxiety-provoking episodes or experiences. At Taylor's suggestion, Wolpe carried out an experiment in which he trained cats to continue eating in the presence of a loud sound which initially provoked fear and thus inhibited eating. Taylor derived the rationale for the experiment from Hullian theory. The cats had to be under a hunger drive, meaning that the parasympathetic nervous system predominated. The sound, in contrast, triggered the sympathetic nervous system. Wolpe started to train the cats to eat in the presence of a very low sound. He progressively increased the sound's intensity until, eventually, the cats would eat even though the sound was very loud. Physiologically, the actions of the sympathetic and parasympathetic

nervous systems are antagonistic to each other. By keeping the cats hungry, Wolpe continued to reinforce eating. However, by initially holding the sound level low, he extinguished the fear response and was able to keep it extinguished even when the conditioned stimulus (the sound) was at a high level.

Wolpe applied a purportedly analogous procedure (later called systematic desensitization) to human beings suffering from phobias. The phobic situation played the role of the loud noise while training in relaxation played the role of food. Just as in the case of the cats, human beings could bring themselves to remain calm while in close physical proximity with previously phobic stimuli, provided that the phobic stimulus was initially held psychologically distant or at a low level and only slowly growing in salience. Wolpe (1961) claimed a 91% success rate for systematic desensitization. Even his close followers, like Arnold Lazarus, could not match it. So we have to say that, in the field of supposedly scientifically based therapy anyway, those who start from a purported scientific basis can end up as gurus like Mesmer and those who followed him in the fields of magnetic diseases and hypnotism.

Conclusion

The neo-behaviorists had a perfectly reasonable set of what should have been working assumptions. They followed Thorndike by, implicitly, treating both their experimental animals and human beings as if they were robots. Such an assumption is not harmful. After all, by making the working assumption that the mind resembles a computer one can make discoveries about how minds might function. In order to have functioning theories the neo-behaviorists believed that their basic terms (especially *stimulus*, *response*, *drive*, and *reinforcer*) had to have fixed (operationally defined) meanings.

However, the neo-behaviorists could not have known that the foundations of the science of animal behavior were being laid, largely in Europe, but to a limited extent in America (Kalikow and Mills 1989). The two leading ethologists, Lorenz (1981) and Tinbergen (1969), treated animals as, essentially, carriers of meaning so that basic terms have to be interpreted within currently occurring sets of needs and external pressures. For example, in the spring and early summer, when it is actively defending a territory, the robin, *Turdus*

migratorius, will attack anything red (another robin, its reflection in a window, a red rag on a stick, etc.). In Lorenz's and Tinbergen's terminology, red objects are releasers (species-specific stimuli) which provoke fixed action patterns (chains of behavior appropriate for reaching a particular goal). Outside the breeding season, male robins do not attack each other. A red object, then, is not a conditioned stimulus which automatically elicits a conditioned response. Instead, red objects provoke attacks only when the dominant needs of robins require attack.

It is impossible to explain the operations of releasers and fixed action patterns solely by deploying the principles of classical and operant conditioning. Instead, one has to assume that they are partly genetic and partly derived from early socialization. However, operant and classical conditioning do function during socialization and do help to maintain responses in adult animals. In general, Lorenz and Tinbergen demonstrated that, just as each species of animal has evolved physically, thus allowing it to occupy a specific ecological niche, so it displays the very behavioral patterns required to fit that niche. Furthermore, the work of other ethologists proved that, within any particular order or family, the closer the physical appearance between species the more similarities there are between their patterns of behavior. Moreover, Lorenz, Tinbergen, and their followers deployed unexcelled skill in devising field experiments to support their position.

Ultimately, the theories of the two leading neo-behaviorists, Hull and Skinner, were deeply flawed. Few people doubt that Hull was the greatest theorist of the neo-behaviorist movement. Yet, he was a theorist without any grasp of what it meant to theorize and an empiricist whose experimental work was totally conceptual. Even worse, two covert purposes drove his theorizing. First, without admitting so publicly, he was driven by the desire to show that minds were, in every possible sense, machine-like. That covert theory was materialist rather than behaviorist. Second, he was obsessed by an ideological need to defeat the Gestalt theorists, his only possible rivals. Those imperatives pervaded every aspect of his theory (Mills 1998, pp. 111–122).

Skinner went to great pains to reiterate, publicly and loudly, that he was not a theorist (Mills 1997). Nevertheless, even if he could, as a psychologist, eschew

theory, he could not avoid doing so as a behaviorist. Mills described the essentials of that theory as follows:

- ▶ What is ultimately at stake . . . is the context of meanings in which actions take place. In the Skinnerian laboratory, the context of meaning is one of rigid control of carefully prespecified actions and settings for those actions. In free-living lower animals, the context of meaning is provided by the ecological niche to which any given species has become adapted and the instinctively controlled processes and mechanisms that mediate adaptation. In the higher primates the context for action is complex, subtle, fluid, and, ultimately unique to each individual. (1998, p. 142)

To put the matter briefly, Skinner could not rebut the defeasibility argument. As human beings, our beliefs, intentions, and desires determine our actions.

Acknowledgments

I would like to thank Hank Stam, Peter Loptson, Ann Newdigate, and Larry Stewart for advice on the writing of this article. I am also most grateful to various members of Cheiron who, very generously, provided me with information.

Bekhterev, V. M.

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Bekhterev (1857–1927) was born in Vyatskaya, Russia. He died as a resident of St. Petersburg but in Moscow under mysterious circumstances (see below). Bekhterev earned a medical doctorate in 1881 from the Military Medical Institute in St. Petersburg. After further study with leading physiologists and psychiatrists in Europe, and based on his growing research reputation, he was appointed professor of psychiatry at the University Kazan (1885). There he founded Russia's first psychophysiological laboratory and its first institute for brain research associated with mental disease. As reflected in many ways including his approximately 600 publications and numerous institutes that he founded, Bekhterev showed expertise in anatomy, hypnosis, neurology, neuropathology, neurophysiology, neuropsychology, psychiatry, and psychology. Diseases and

neuroanatomical structures associated with his research bore his name before eponyms began to be replaced by more intrinsically informative names (e.g., Bekhterev's nucleus is now better known as the superior vestibular nucleus).

In psychology, Bekhterev founded *Review of Psychiatry, Neuropathology, and Experimental Psychology* (1896), the first journal to include “experimental psychology” in its title. His three-volume *Objective Psychology* (1907) presented methodology that went well beyond Pavlov's salivary conditioning and that included both instrumental and operant conditioning. However, instead of Pavlov's term “conditioned reflex” (Pavlov used the Russian word for *conditional* but the mistranslation has endured), Bekhterev preferred “association reflex” which arguably embodied a superior heuristic for both men's interests.

Deeming “psychology” too subjective, Bekhterev replaced it with “reflexology” which, nevertheless, encompassed nearly as broad a range as had psychology (Schniermann 1930). For example, Bekhterev's Reflexological Institute had five divisions: *General reflexology*, mostly physiological psychology; *Individual reflexology*, individual differences personality, etc.; *Age reflexology* dealt with physical and psychological abnormalities associated with child development; *Collective reflexology* was social psychology including genetic and evolutionary influences; and *Genetic reflexology* addressed developmental psychology from the onto- and phylogenetic standpoints. Bekhterev has been described as being one of the first experimental social psychologists (Strickland 1991).

Despite Pavlov's Nobel prize, arguably, Bekhterev was far more influential during his lifetime than Pavlov, and Bekhterev's historical importance might have received greater recognition internationally had not his works been suppressed by the Soviet authorities. Thus, it is highly relevant to Bekhterev's legacy to report on his death and its consequences (Shereshevskii 1991).

While visiting Moscow for scholarly purposes and as Russia's premier neuropathologist, Bekhterev, who had earlier treated Lenin, was summoned to examine Stalin's dysfunctional arm. Explaining his tardiness at a subsequent meeting with colleagues, Bekhterev stated, “I was examining a paranoiac with a withered arm.” That came to the attention of the Soviet authorities.

That evening, during intermission of the Bolshoi Ballet, strangers approached Bekhterev, conversed with him, and gave him something to eat (possibly ice cream). Despite being in good health, he died that same evening after complaining of gastric pain. A hastily arranged autopsy by the authorities and questionably limited to the brain, an equally hasty cremation despite family members' objections, and other emerging evidence contribute to the suspicion that Bekhterev was assassinated by poisoning.

Although Bekhterev was among Russia's most accomplished scientists, his works were suppressed by the Soviet authorities until *glasnost* in 1989. One result was that his work was poorly known by American psychologists. However, John B. Watson, father of behaviorism, was greatly influenced by Bekhterev's *Objective Psychology* (1907; never translated into English and available to Watson only in French translation). Watson used it to co-teach with his protégé, Karl Lashley, a winter seminar at Johns Hopkins in 1914–1915, and Lashley was to have studied methods in Bekhterev's laboratory but WWI prevented it. Although Watson's behaviorist methodology closely resembled Bekhterev's, Watson adopted Pavlov's terminology, thus, obscuring Bekhterev's influence. An abbreviated version of *Objective Psychology* published in English translation as *General Principles of Reflexology* (1932; original 1928) was Bekhterev's only book to be translated into English until *Collective Reflexology: The complete edition* (2000).

Further contributing to the disregard for Bekhterev's work was Pavlov's intense dislike of Bekhterev. One can only speculate at motive. Please see “Pavlov's Controversy with Bekhterev” in Babkin's *Pavlov: A biography*. As more of Bekhterev's work becomes available to Western psychologists, undoubtedly his reputation and the value of his theoretical ideas will be increasingly recognized.

Benjamin, Ludy T. Jr.

ALAN J. FELDMAN

Glen Rock High School, Glen Rock, NJ, USA

Basic Biographical Information

Ludy T. Benjamin, Jr. was born on December 26, 1945, at Corpus Christi, Texas. Benjamin is the son of Ludy T. Benjamin (a US Navy photographer and WWII and Korean War veteran) and Mary Kate Jones (a homemaker). He received a B.A. degree in psychology from the University of Texas in 1966 and a Ph.D. degree in experimental psychology from Texas Christian University in 1971 with a specialization in perception. Benjamin is married to Priscilla Kay Finlay, a retired elementary school teacher and librarian. They have two daughters and two grandsons.

Major Contributions

Dr. Benjamin is an American educator (professor and department head, Presidential Professor of Teaching Excellence, Texas A&M University) and researcher best known for his work in the history and teaching of psychology.

Ludy T. Benjamin, Jr. is known for his work in two areas, the history of psychology and the teaching of psychology, and he has received national awards in both fields. Benjamin has written or edited more than 20 books and more than 150 journal articles and book chapters, most of them on the history of psychology.

Benjamin's first academic job was at Nebraska Wesleyan University where he worked from 1970 to 1978. He then served 2 years as Director of Education for the American Psychological Association in Washington, DC, where he was responsible for the gamut of educational settings in psychology including high school psychology, undergraduate education, graduate education and training, and continuing

education and postdoctoral training. In 1980 he joined the Psychology Department at Texas A&M University where he was a professor of psychology until his retirement in 2012.

Benjamin's work in teaching promoted the use of active learning exercises in psychology. He edited the first collections of such teaching activities in what are generally referred to as activity handbooks. A strong interest in the teaching of psychology in secondary schools led to efforts to persuade the College Board to establish an Advanced Placement Exam in Psychology. Benjamin chaired the committee that developed the first AP Psychology Exam that was administered in 1992. To assist high school teachers in offering AP courses, Benjamin directed a series of National Science Foundation supported summer workshops at Texas A&M University that drew more than 150 teachers in a 5-year period.

Benjamin's work in the history of psychology has focused on the history of American experimental psychology as it moved from mental philosophy to experimental science at the end of the nineteenth century and into the next century. In describing that metamorphosis he has written about the establishment of the earliest of the psychology laboratories, about the development of the early psychological organizations and how those fostered the agenda of the new experimental psychology, about the initial applications of experimental psychology to education, business, and clinical practice, and about the ways in which psychologists sought to inform the American public about their science.

Benjamin's biography of Harry Kirke Wolfe (1858–1918), the second of Wundt's American graduates, documented the struggles of the early psychology laboratories in battling the more established sciences in American universities. Benjamin has also written on other Wundt doctorates in America. His research, based on archival records at the University of Leipzig, produced the first comprehensive treatment of Wundt's American students and their subsequent careers.

As one of the markers of a scientific discipline, the early psychological organizations were key to the development of experimental psychology. Benjamin published the first archivally based histories of the Midwestern and Eastern Psychological Associations, which were founded in 1902 and 1903, respectively. He also

has published articles and book chapters on the Psychological Round Table (a somewhat secret organization of experimental psychologists begun in 1936), the American Psychological Association, and Titchener's Experimentalists, a precursor to the Society of Experimental Psychologists. Central to this work on organizational history is an understanding of the roles these societies played in the research careers and social and intellectual lives of those involved (and, in some cases, those who were excluded), and ultimately the role they played in shaping the course of American psychology.

Benjamin has also published extensively on the beginnings of applied psychological research in business (e.g., research on the early forays into advertising and product testing), education (e.g., work on child study and teaching machines), and clinical psychology. This work has documented the nineteenth century origins of applied experimental psychology and is part of a larger scholarship in the history of psychology that has changed current views on the history of psychology's applied ventures.

Benjamin's most recent work emphasizes the history of psychology's public image and popular psychology, focusing on public understanding of psychology and the ways in which psychologists have sought to convey the nature and importance of their science and practice to the public. This work has emphasized the social context in America that shaped the interests of psychologists and in turn shaped America's understanding of and attitudes toward psychology.

Bentley, Madison

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: June 18, 1870; Died: May 29, 1955.

Born in Clinton, Iowa, Madison Bentley spent his early life in Nebraska where he apprenticed in his teen years to a bank, which was his career for several years thereafter. He then attended the University of Nebraska where he came in contact with Harry Kirke Wolfe, who turned him toward psychology. Bentley then completed graduate work at Cornell under Titchener in 1898 with a study of memory fidelity, and remained there as a faculty member for the next 14 years. He then moved to Illinois for another 15 years, returning to Cornell where he finished his career.

Major Accomplishments

His earliest Cornell studies encompassed a variety of experimental and theoretical studies on color and tone perception, fusion of ideas, and motor theories of consciousness. He also was involved to a small extent in comparative psychological research with Margaret Floy Washburn on color vision in fish and with Lucy Day's (E. G. Boring's future wife) research on paramecia in 1911 (Day and Bentley 1911). Disagreement over Bentley's approach to the introductory course and Cornell promotion policies which balked his ambition to a professorship led to Bentley's removal to Illinois in 1912 where he became Psychology department head. There he continued to teach and to develop a systematic approach to psychology which constituted a critique of structuralism. As an insider in Titchener's system and at the same time an outsider exiled from it, he was in a position to know both structuralism's strengths and its significant weaknesses. Among the former he counted its tendency toward simplicity, its insistence on analysis as the only mode of doing science, and its conception of the external stimulus as the determiner of experience (Bentley 1926). He proposed to replace it with a comprehensive synthetic psychology of experience in which psychological phenomena were considered as physical as other body processes. This hybrid theory had at its core a conception of the organism as moving in time, with the stream of its experiences always being modified by new experiences impinging from both outside and inside the organism. This wholistic conception of the organism as the unit of analysis resonated both with Gestalt ideas and with other attempts to create a comprehensive physicalistic psychology encompassing all aspects of experience such as that proposed by E. C. Tolman. Bentley's version, however, was stylistically less attractive and did not gain the same widespread acceptance. Bentley also enumerated the problem areas of psychology which his brand of dynamic functionalism could address: "performance and character of the adult" (personality), comparative study of animals, genetic psychology, individual differences, psychological deficiencies and disorders, and social psychology. A further mark of Bentley's departure from orthodox structuralist psychology was his positive attitude toward applied psychology: among Bentley's students at Illinois was Coleman Griffith, considered the first sports psychologist in America.

In 1928, on Titchener's death, Bentley returned to Cornell where he chaired the department during the 1930s and revised the Cornell curriculum incorporating applied, developmental, and abnormal psychology while continuing the department's strengths in sensation and perception (Ryan 1982). He also continued his activity as a respected editor of several psychological journals: his longest and most prominent association was with the *American Journal of Psychology*. After his return to Cornell, his theoretical work focused mostly on abnormal and developmental aspects of psychology. In connection with the Committee on Psychiatric Investigations of the National Research Council, Bentley coedited, with the anatomist and gerontologist E. V. Cowdry, an extensive collection of papers on psychopathology, published in 1934 as *The Problem of Mental Disorder* (Bentley and Cowdry 1934). Bentley had long-standing interests in history and anthropology and served for a time as head of the NRC's division of Anthropology and Psychology. He also planned but did not complete a comprehensive psycho-anthropological study situating humans in a cultural matrix, though he did publish a prospectus (Bentley 1947). Bentley also wrote on developmental subjects, and had a special interest in adjustment during adolescence and young adulthood (Bentley 1945). Bentley's developmental theories may have had their greatest effect via his mentorship of his doctoral student Robert Lindner, with whom he published on "emoving," the dynamic process of emotion regulation (Lindner and Bentley 1939). Lindner later became a psychoanalyst and went on to write *Rebel Without a Cause* (Lindner 1944) which, heavily adapted and released under the same title, was one of the most influential films about troubled adolescence ever made in America.

Berlyne, Daniel E.

MARISSA E. BARNES

York University, Toronto, ON, Canada

Basic Biographical Information

Daniel Ellis Berlyne was a motivation theorist, an experimentalist on various topics including aesthetics, and an active participant in the North American neobehavioral movement from the 1950s to the early 1970s. Born on April 25, 1924, in Salford, a suburb of Manchester in Northern England, Berlyne held several academic positions before becoming Professor of Psychology at the University of Toronto from 1962 until his death in 1976. Berlyne was truly an international scholar, having traveled all over the European continent and beyond (both in an academic capacity and during multiple posts during his service in World War II) prior to his arriving in Toronto.

In 1941, at the age of 17, Berlyne was awarded a Major Scholarship to Trinity College, Cambridge, to study modern languages. The start of his second year at Cambridge, however, was interrupted in the fall of 1942, because he was called up to serve during World War II. Upon his return to Cambridge, in the fall of 1946, Berlyne decided to switch his area of concentration from modern languages to psychology. He had become familiar with psychology at school through his readings of Freud and during his war period he had found the time to read about the different varieties

of psychology. Cupchik (1988) and Furedy and Furedy (1981) have detailed Berlyne's early life experiences and suggested the impact that this had on the development of his scholarship. Faced with career-prospect concerns, Berlyne felt that the opportunities with a degree in psychology looked more promising than were those with a degree in modern languages; the Experimental Psychology Laboratory at Cambridge was bustling with activity and had acquired a high reputation for its contributions to the war effort. Psychology at Cambridge had been run under Sir Frederic Charles Bartlett (1886–1969), first Professor of Experimental Psychology at the University from 1931 to 1952; his role in the development of the university's laboratory extended outward and influenced the development of psychology throughout Britain (Bunn et al. 2001).

In 1946, Bartlett became Berlyne's supervisor; unfortunately, however, Berlyne was not interested in the work going on in his supervisor's laboratory. As an undergraduate student, Berlyne took a newly offered course on motivation and learned of:

- ▶ The work of Mowrer, because this American group – the learning theory group – the Yale group it was, actually – who were doing animal experiments, were sympathetic in a critical way to Freudian psychology. They were doing rat experiments that purported to be about some of the same processes that Freud was talking about in the human being. Mowrer had a rat analogue of regression . . . and this seemed very exciting. (Berlyne 1973, p. 82)

Stemming from his interest in Freudian notions of motivation, Berlyne was intrigued by the research and the type of psychology being practiced by the neobehaviorists in the USA. Despite his supervisor's disapproval of Freud, Berlyne believed that “Freud was dealing with important questions . . . which were motivational questions,” and that the neobehaviorists in America, “were using scientific method” to deal with these “vital questions” (Berlyne 1973, p. 83). With this interest, Berlyne went on to read not only the work of O. Hobart Mowrer (1907–1982), but also that of Clark L. Hull (1884–1952), Neal E. Miller (1909–2002), and other neobehaviorists at Yale.

Berlyne was accepted into the graduate program at Cambridge in 1947, after obtaining his B.A. degree. And in early 1948, he was offered a full lectureship at

the University of St. Andrews in Fife, Scotland, a 2-year appointment that was to commence in the fall. While at St. Andrews University, Berlyne had access to budgetary funds – he bought two cages, housing six rats each, and continued his experiments on attention in rats. At this time he also continued to develop his theoretical ideas about the concept of interest. In 1949, Berlyne's first paper, "Interest as a Psychological Concept," was accepted for publication in the *British Journal of Psychology*.

Berlyne applied for a fellowship at Yale University, offered by both the English-Speaking Union and Yale University, because he was keenly interested in Clark Hull's research there. Some authors have characterized Berlyne's reading of Hull's (1943) *Principles of Behavior*, as the point of "conversion," while others have referred to him as neither a true stimulus–response (S-R) drive theorist nor a "Hullian disciple," and discussions regarding whether he was (or was not) a "true Hullian theorist" are evident in the literature (Brown 1961; Cupchik 1988; Day 1977; Furedy and Furedy 1981; Konečni 1978; Walker 1961, 1980). What is true is the fact that Berlyne retained an admiration for Hull's theorizing throughout his career (Berlyne 1975) and did integrate a number of significant aspects of Hull's system into his theoretical work.

Berlyne's intention in applying to Yale had been to work with Hull, although in the year prior to his being offered this fellowship, Hull advised him "that Yale wasn't the best place to go for Hullian psychology; Iowa was the place" (Berlyne 1973, p. 115). It was at this time that Kenneth W. Spence (1907–1967) had taken over at Iowa and was, in Hull's view, working the way Hull would have liked. When Berlyne arrived at Yale, he did meet and interact with Hull, who unfortunately was very sick and died the following year. About his time at Yale, Berlyne commented "I did not learn all that much about Hullian learning theory because I had already learned a lot about it . . . but I did learn a lot of things . . . mainly statistics and research design" (Berlyne 1973, p. 116–117). During his second year at Yale, Berlyne taught full time at Brooklyn College in New York City. He received his Ph.D. degree, under the supervision of Carl I. Hovland (1912–1961), in 1953; the title of his doctoral dissertation was "Some Aspects of Human Curiosity." Faced with visa problems after receiving his doctorate, Berlyne was obliged to return

to Great Britain, where he taught at the University of Aberdeen in Scotland from 1953 until 1956.

In 1954, Berlyne was offered a Fellowship at the Center for Advanced Study in the Behavioral Sciences at Palo Alto, California, and he took leave from Aberdeen for this position in 1956. Following his time at the Center, Berlyne resigned from his position at Aberdeen and signed on for a year-long appointment as visiting Associate Professor from 1957 to 1958 at the University of California, Berkeley. Here he continued to work on a book he had begun at Aberdeen (which was later to become his first published book) and also had the opportunity to meet the learning theorist Edward C. Tolman (1886–1959) in the last year of Tolman's life.

In 1959, Berlyne went to Geneva, Switzerland, and spent the year with Jean Piaget (1896–1980), as Membre-résident at the Centre International d'Epistemologie Génétique. Berlyne had first met Piaget in 1948 at the International Congress in Edinburgh, and following subsequent meetings, Piaget had invited Berlyne to the International Centre for Genetic Epistemology. It was at the Centre that Berlyne finished his book, *Conflict, Arousal, and Curiosity* (1960), and also began some theoretical work that he later expanded into his second English language book, *Structure and Direction in Thinking* (1965). During this time, he also collaborated with Piaget on a book in French (*Théorie du comportement et opérations*; Berlyne and Piaget 1960).

After Geneva, Berlyne returned to North America and was invited as a Visiting Scientist to the National Institute for Mental Health (NIMH) in Bethesda, Maryland. There he spent time working on the physiological measurement of the orientation reaction, using the galvanic skin response (GSR) and electroencephalography (EEG). In 1960, he was appointed to a position as Associate Professor at the University of Boston. It was while he was occupying this position that he received a call from Roger Myers (1906–1985), who raised the question of a possible move to the University of Toronto (Berlyne 1973, p. 182). Berlyne accepted a position as Associate Professor in January, 1962, and became a Professor of Psychology at the University of Toronto in the following year.

By the time he had arrived at the University of Toronto, Berlyne had published approximately 27 papers, written one sole authored book and one

coauthored book with Piaget (Day 1977). He had also paid a short visit, in 1961, to the Soviet Union where he had the opportunity to visit a number of laboratories investigating the orientation reaction, as well as other topics in physiology and psychology (Berlyne 1963). Berlyne remained at the University of Toronto from 1962 until his death, with the exception of a sabbatical leave in 1968–1969 during which he held the title of NATO-Heineman Visiting Professor at the Institut d'Esthetique et des Sciences de l'Art at the University of Paris. At this time Berlyne's research interests were converging, in a manner consistent with his theorizing, from interest, curiosity, and thinking, onto the study of aesthetics. At the Institut, he started to write a book entitled *Aesthetics and Psychobiology* (1971), and, back in Toronto he obtained funding for an extensive research program on experimental aesthetics.

Berlyne was diagnosed with cancer in early 1976, and after three unsuccessful surgeries and a very quick physical deterioration, he succumbed to his illness on November 2, 1976, at the age of 52. He left behind Hilde Berlyne, his wife of 23 years, whom he had married while teaching at Brooklyn College, and three children. His distinguished scientific career yielded many honors, including Fellow of the Royal Society of Canada, Fellow of the British Psychological Society, and Fellow (and sometimes President) of several divisions and sections of the American and Canadian Psychological Associations. A biannual Berlyne Memorial Lecture was initiated at the University of Toronto, and Division 10 of the American Psychological Association presents a Berlyne Award each year in recognition of outstanding research on aesthetics by a junior scholar. Berlyne served as both President and Vice President of the International Association of Empirical Aesthetics, an association he had cofounded at the First International Congress in Paris in 1965.

Major Contributions

During his lifetime Berlyne wrote or coauthored seven books and approximately 150 journal articles, book chapters, and review papers (some of which were published posthumously). Moreover, Berlyne's work and research has had a resounding international impact – his work has been translated into at least six different languages; he wrote articles in a number of different languages, for example, French, German,

and Russian; he lectured in eight languages on five continents; and he carried out his research in North and South America, Europe, Africa, and Japan. He is undoubtedly a key historical figure in reconstructing the post-World War II exchange of ideas, both transatlantic and cross-continental.

Berlyne's topics of inquiry were broad, including interest, attention, curiosity, exploratory behavior, physiological arousal, play behavior, humor, knowledge-seeking behavior, thinking, and experimental aesthetics. His first book *Conflict, Arousal, and Curiosity* (1960) expounded the theoretical and experimental building blocks of his general motivation theory of exploration-related phenomena, for example, interest, curiosity, thinking, and aesthetics (Barnes 2007). His intentions were clearly stated from the outset when he wrote: "This book is going to be concerned with the *motivation of perceptual and intellectual activities*" (Berlyne 1960, p. 1, italics in original). According to Berlyne (1960), *curiosity* is caused by various *conflicts* and the intervening variable mediating this relationship is *arousal*. Thus, curiosity is the organism's response to "arousal" (or lack thereof) caused by a conflict about "what to do next?" By prompting the organism to explore the environment, curiosity enables the organism to resolve such a conflict and thereby reduce its associated "arousal" level. It must be noted that the term arousal, although it remained a central mediating construct in Berlyne's theorizing, was associated with connotations that differed over the course of his career (e.g., from an "arousal jag" to optimal levels of arousal; a state of arousal versus "arousal potential"; arousal as a physiological index of general activation; a concept to be used as a replacement to drive).

Berlyne (1960) attempted to generalize his theory of exploratory behavior so as to include what he called "epistemic" or knowledge-seeking behavior. This topic became the focus of his second book, *Structure and Direction in Thinking* (Berlyne 1965). The theoretical system proposed in this book was intended to explain the processes involved in directed thinking. Berlyne (1965) explicitly acknowledged that his ideas on thinking had been influenced by his collaboration with Piaget and by his acquaintance with Eastern European and Soviet physiologists. Berlyne (1965, p. 7) refers to his approach as "integrative neoassociationism,"

primarily to distance himself from what he perceived to be the shortcomings of stimulus–response (S–R) behavior theory. Berlyne (1965, pp. 14–19) listed the features of his integrative neoassociationist behavior theory, and in particular, indicated that a neoassociationist behavior theory refers to changes in the internal conditions of the organism through inferred mediated processes (intervening variables) as both “responses” and as “stimuli” (he referred to intervening variables as “implicit responses” and/or as “internal stimuli”). Berlyne, also indicated that a neoassociationist gives primacy to S–R associations (be they manifest in overt behavioral responses or represented as intervening variables) and in this respect differs from those who describe central mediating process through the use of neurophysiological terms and the use of terms like cognition, expectations, and images.

Berlyne (1965) drew on Hull’s S–R theory concept of the *habit-family hierarchy* to explain how an assembly of response alternatives could be made available to an organism in the process of thinking. A habit-family hierarchy consists of a set of potential chains of behavior, such that (1) every chain can start out from the same initial stimulus situation and (2) every chain can end by achieving the same goal. According to Berlyne, the process of directed thinking is one in which the organism “moves” (internally/implicitly) from habit-structure to habit-structure until the problem solution or desired response for the alleviation of conceptual uncertainty and conflict is arrived at. He suggested various mechanisms whereby a person was able to select an optimum response chain out of the several chains available in the habit-family hierarchy. These mechanisms included what he called *implicit symbolic transformational responses*; these hypothetical constructs correspond roughly to the process of imagining what would happen if any given chain *were* to be responded to.

Berlyne’s work on thinking was succeeded by his development of a theory of aesthetic behavior, a theory that was summarized in *Aesthetics and Psychobiology* (Berlyne 1971). Even his aesthetic theory was rooted in Berlyne’s (1960) views concerning exploratory behavior. It was in the *stimulus selection* process that is necessitated in exploratory behavior, Berlyne argued, that

various stimuli are competing for attention. According to Berlyne (1960), in this competition, various aspects/and or properties are being compared and contrasted; it is during this process, he proposed that the organism *collates* (gathers) information from the stimuli available to it and then selects that stimulus to which a behavioral response will be given. It was in the context of collation activity that Berlyne coined the term *collative variables*. These variables determine what properties are assessed and compared during the perceptual phase of the stimulus selection process. For example, novelty is one property that might lead to the selection of one stimulus rather than another. While his list of the collative variables changed from publication to publication, the ones most commonly referred to were: novelty, uncertainty, surprisingness, complexity, and conflict.

The collative variables he had found useful in his analysis of exploration became equally valuable in his analysis of aesthetic properties of an art object. Berlyne (1971) comprehensively detailed the sources from which he had derived his theoretical views on aesthetics; the role of physiology in aesthetic pleasure; and the methods that can be used to study aesthetics empirically. On the role of physiology, Berlyne attempted to show how stimulus intensity could combine with a subject’s arousal level to determine the hedonic value to be associated with an art object. Berlyne moved from theory to experimentation by initiating, in the 1970s, a robust and productive research program at the University of Toronto, in which many graduate and postdoctoral students participated. They attempted to demonstrate how hedonic quality could be influenced by collative variables that included congruity, ambiguity, complexity, and level of novelty, and multidimensional scaling methods were used to extract important attributes common to works of art. At this point the collative variables were referred to as collative properties, and they were conceptualized as structural stimulus properties of art objects. The collative properties commonly varied along dimensions such as familiar–novel, simple–complex, expected–surprising, and ambiguous–clear (Cupchik 1986). This research program culminated in a volume entitled *Studies in the New Experimental Aesthetics* (1974), edited by Berlyne; in the 12 chapters

of this book, data collected in 31 different experiments were reported.

In modernizing experimental aesthetics, Berlyne's approach was in accordance with Fechner's empirical aesthetics "from below" and with Fechner's psychophysical methods. However, Berlyne was essentially founding a new line of scientific inquiry, and he called this the "new experimental aesthetics" (Berlyne 1974, p. 5). Thirty years after his death, his work still serves as a foundation for innovations and research in this field; according to Silvia (2005), "Modern research on experimental aesthetics still takes inspiration from Berlyne's ideas about how collative variables effect arousal, interest and preference" (p. 119).

Berlyne was unique; he attempted to integrate insights derived from diverse theories such as those of Freud, Pavlov, Bartlett, Hull, Hebb, and Piaget into his ideas about psychology; he was well versed in the traditions of American psychology and also those of Western and Eastern European psychologies; he was broadly educated; and he was able to communicate with scholars in a number of different languages. In an examination of his short life, one finds an inordinate number of ideas worth pursuing, and the significance of Berlyne's contributions to the history of psychology has, as of yet, only marginally been brought to life.

Bettelheim, Bruno

JOHN D. HOGAN, JACQUELINE BORKES
St. John's University, Jamaica, NY, USA

Basic Biographical Information

During his lifetime, Bruno Bettelheim was considered one of the leading experts on the treatment of disturbed children, particularly autistic children. Through his articles and books, he argued that the cause for autism could be found primarily in faulty parenting. His solution was to provide an intensive residential therapy through which autistic children could regain a sense of their autonomy. The period of treatment frequently lasted for years. Over time, his views became increasingly controversial and many of them are now considered outdated (Pollack 1997).

Bruno Bettelheim was born in Vienna on August 28, 1903, to a middle-class Jewish family. After the early death of his father, Bettelheim cut his education short and joined the family lumber business. It was during this period that he and his first wife took in a child who was later described as autistic. Some of Bettelheim's ideas about autism originated from this extended encounter. He later returned to the University of Vienna to resume his studies, eventually receiving a doctoral degree in 1938.

Although Bettelheim grew up in a secular family, he was Jewish by birth, and this was enough for the German authorities to send him to a concentration camp. After being incarcerated in Dachau and Buchenwald for 11 months, he was eventually freed to emigrate to the USA. He would use his experiences in the concentration camp to write his first set of controversial essays, most notably *Individual and Mass Behaviors in Extreme Situations* (1943). In the USA, he went through a series of jobs before being named the principal of the Sonia Shankman Orthogenic School at the University of Chicago. He set out to change the school dramatically and it was in this position that he accomplished his most significant work.

Bettelheim worked with a variety of emotionally disturbed children in the school, but autism was a particular focus of his. He believed that autism was primarily due to a defect in the parenting relationship.

In some ways, he extended the beliefs of Leo Kanner (1894–1981) who first described the autistic syndrome. Kanner had observed that many of the parents in his early sample could be described as “refrigerator parents,” that is, they performed all of the appropriate duties of parents, but were emotionally cold. Bettelheim saw this faulty relationship as a principal cause of the illness (Sutton 1995). Current research in autism differs dramatically from this view, emphasizing the biological origins of the disorder.

As Bettelheim's view became more out of fashion, his writings became equally suspect. He was accused of many things, including being abusive to his charges, falsifying his background and data, and plagiarism. His autocratic personal style did not endear him to everyone. After the death of his wife, Bettelheim became increasingly depressed. He also suffered from a variety of physical problems. Bettelheim died on March 13, 1990, at age 86, a suicide.

Major Accomplishments/Contributions

Bettelheim's beliefs in the causes of autism had a profound effect on the culture at the time. Although he had a pronounced psychoanalytic orientation, he also emphasized the power of the social situation in his work with emotionally disturbed children. He used his experience from the concentration camps to establish his “milieu therapy.” It was his belief that children placed in therapeutic communities such as his, in which they received constant and loving attention, could begin to return from even the most serious emotional illness. The staff at the school went to extraordinary lengths to provide for the children in the treatment center. For autistic children, Bettelheim's goal was to provide them with a sense of autonomy. It was this loss of autonomy he believed that lay at the heart of the disorder. He published data indicating a high success rate for his approach. Although some of his data were questioned, anecdotal reports from parents and filmed records indicated that even if his claims were exaggerated, they nonetheless contained some truth.

In his book, *The Empty Fortress* (Bettelheim 1967), Bettelheim compared children who suffer from autism and schizophrenia to the helpless concentration camp inmates he had studied. Just as the inmates began to

believe that they were worthless and blamed themselves for the position they were in, he believed that children may do the same. He believed that the children enter into a world of their own in order to avoid facing the fact that they are the reason their parents are neglectful toward them. Bettelheim's approach was often interpreted to mean that parents were directly to blame for their children's autistic behavior. Although Bettelheim seemed to support this interpretation, he noted that the cause of autistic behavior might also be found in a clash of temperamental styles between parent and child. In this case, neither parent nor child could be blamed for the poor fit.

Apart from his work with emotionally disturbed children, Bettelheim also wrote a very popular book, *The Uses of Enchantment* (Bettelheim 1976), in which he discussed the role that fairy tales play in the life of children. Using psychoanalytic explanations, Bettelheim tried to show that fairy tales actually helped children to cope with their fears and assist in their growing up. The book was well-received and won several awards (Zimmerman 1997).

Binswanger, Ludwig

DAVID D. LEE

Amsterdam, The Netherlands

Basic Biographical Information

Ludwig Binswanger was born April 13, 1881, in Kreuzlingen (Switzerland) and died on February 5, 1966, in Kreuzlingen (Switzerland). He studied

medicine in Lausanne, Zurich, and Heidelberg, earning his MD from the University of Zurich in 1907. He worked for a year at Zurich's Burghölzli clinic run by Eugen Bleuler where C.G. Jung supervised his medical dissertation. From 1908 he worked at the Bellevue sanatorium in Kreuzlingen founded by his grandfather and then run by his father which he subsequently directed from 1911 (to 1956), transforming it into one of Europe's most modern private psychiatric clinics. His work with Sigmund Freud was crucial to his intellectual development, specifically his combination of phenomenological and psychoanalytic thought into *Daseinsanalyse* (existential analysis).

Major Accomplishments/Contributions

Major Accomplishments: Binswanger became close friends with Sigmund Freud in 1907 and remained friends for the rest of Freud's life despite their theoretical differences (see Correspondence (Fichtner 1992)). Freudian psychoanalysis and phenomenological philosophy were the two main sources of Binswanger's psychology: existential analysis (Seidman 1984). In contrast to theories in the natural sciences which are designed to explain a phenomenon, Binswanger (following Martin Heidegger, Edmund Husserl, and Martin Buber) believed phenomena to be the beginning and end of scientific and philosophical inquiry. The Freudian approach, which focuses on aggression and sexuality, was combined with (a largely Heideggerian) existentialism. In Binswanger's day, scientific theory was designed to regulate the perception and experience of phenomena in order to help comprehend others' experiences. Existential analysis refutes the psychological view of man's being as solely a natural object. Binswanger insisted on comprehending his patients' illnesses within the full context of their lives, including the patient's mode of being in time (*Eigenwelt*), his orientation in space (*Umwelt*), his relation to his body, and to others (*Mitwelt*), how he thinks as well as his fears and anxieties. He also borrowed Freud's focus on language believing that the content of existence was best expressed in and could be best analyzed via language (Binswanger 1922). This naturally focuses attention on consciousness in a new way, for all scientific data are no longer "objective" and "out there," but interpersonal and mediated by consciousness. How this

differed in practice is that unlike most scientific psychological and psychiatric theories in which each symptom presented by a patient is compared and contrasted to previous patients' symptoms and thus categorized, in existential analysis, all behavior and each symptom is understood firstly within the context of the patient's experience. Moreover, existential analytic therapeutic encounters consist of the genuine opening up of one individual's presence (Dasein) to the other. Thus, unlike Freudian or Jungian analysis in which there are (relatively) set meanings for common dream phenomenon, for example, in existential analysis even "obvious" symptoms (slips of the tongue, dreams, etc.) have no meaning until interpreted within the framework of the patient's being-in-the-world (Binswanger and Needleman 1963). On account of its focus, Binswanger had initially called his theory "phenomenological anthropology" only later adopting the term Daseinsanalyse (existential analysis). His ideas influenced many social sciences, particularly psychology, in the years immediately after the Second World War. His was the first application of existential ideas in a therapeutic setting (see Binswanger (1942)). His most famous case history is that of Ellen West, a deeply troubled anorexic whose diaries and poems Binswanger employed in his (ultimately unsuccessful) attempt to treat her. Unlike Freud and Jung who created schools to perpetuate their ideas and provide an organization for their followers, Binswanger shunned university life and the creation of his own school in favor of managing his sanitarium and explicating his ideas in print. Nonetheless, Binswanger's work has been influential on subsequent psychologists such as Rollo May and Viktor Frankl.

Bleuler, Eugen

DAVID D. LEE

Amsterdam, The Netherlands

Basic Biographical Information

Bleuler was born April 30, 1857, in Zollikon (Switzerland) and died July 15, 1939, in Zollikon (Switzerland). He studied medicine in Zurich (and later Paris, London, and Munich), earning his license to practice in 1881 and his MD degree in 1883. He worked as assistant physician in Waldau (near Bern) from 1881 to 1884, then in 1885–1886 as an intern at Zurich's psychiatric state hospital, the Burghölzli, under Auguste Forel. After directing the Heil- und Pflgeanstalt (psychiatric nursing home) at Rheinau (near Zurich) from 1886 to 1898, he was appointed Director of the Burghölzli and Professor of Psychiatry at the University of Zurich in 1898, a post he held until his retirement in 1927. He is best known for coining the terms schizophrenia, ambivalence, and autism, as well as for supporting Sigmund Freud and the psychoanalytic movement in its earliest years.

Major Accomplishments/Contributions

One of the most influential psychologists of his age, Eugen Bleuler was the fifth director of the University of Zurich's psychiatric hospital, named the Burghölzli after the hill upon which it sits just outside the city. His tenure as Director (1898–1927) is considered the institution's most illustrious period due to his transformation of the idea of the psychiatric hospital into a medical research facility whose purpose was to develop treatments for the mental ill (Hell 2001). His greatest contribution was the replacement of Emil Kraepelin's term *dementia praecox* with his own schizophrenia (1908) (Bleuler 1984). The significance

of this lay not only in the designation – dementia praecox means “premature dementia,” while schizophrenia means the “splitting of the mind,” and Bleuler asserted that the splitting symptom of this disease was more important and prominent than its early onset – but also his assertion that the disease was not incurable and that it did not always result in full dementia (see Bleuler 1911). It was during this work that he developed the concepts of autism (loss of contact with reality often via bizarre fantasy) and ambivalence (contradictory tendencies within the psyche). The former has become a field of research of its own and the latter became a core part of psychoanalytic thinking. Bleuler continued Auguste Forel’s tradition of combining French “dynamic” conceptions of the mind with the German biological perspective (Kuhn 2004). He was the first academic psychiatrist to support Sigmund Freud’s psychoanalytic theories, reviewing Freud’s early work with Breuer favorably and assigning Carl Jung the task of reporting on Freud’s *Interpretation of Dreams* in 1900. The Freudian group in Zurich was founded under his auspices in 1907, and the *Jahrbuch für Psychoanalyse und Psychopathologische Forschung* (1910–1913), edited by Jung, was published jointly by Bleuler and Freud. In addition to his own interests, he encouraged others working at the Burghölzli (e.g., Carl Jung, Ludwig Binswanger, Hermann Rorschach, Adolf Meyer) to think and work psychoanalytically. This led directly to extensive association experiments which presupposed an unconscious along lines Freud (and others) had laid out. Jung and Franz Riklin attempted to empirically demonstrate Freud’s theories. Bleuler’s support for Freud’s ideas and movement was critical at this early stage (1900–1910), and his withdrawal of this support (around 1911) was equally crushing (Falzeder 2007). Bleuler also contributed to a number of psychological and psychiatric subfields (hypnotism, aphasia, osteomalacia, moral idiocy, etc.), and his 1916 textbook was reprinted many times over, spreading his take on psychology and psychiatry throughout German-speaking Europe (and farther afield) for many decades thereafter.

Boas, Franz

IVAN MANCINELLI-FRANCONI

Saybrook University, San Francisco, CA, USA

Basic Biography

Franz Uri Boas (July 9, 1858–December 21, 1942) Minden, Germany. German-born American anthropologist and founder of the relativistic, culture-centered school of American anthropology. Married to Marie Krackowizer Boas (1861–1929).

Franz Boas was born on July 9, 1858, in Minden, Westphalia, Germany. His parents, Meier Boas (1823–1899) and Sophie Meyer Boas (1828–1899) were well-to-do Jewish merchants. Beset by poor health as a child, Boas spent much of his time reading books on the natural sciences. He earned his baccalaureate at Heidelberg University in 1881, and the same year received his doctorate in physics and geography from Kiel University, Germany.

In 1883, Boas’ interest on the causes of cultural variation, whether due to physical environment or human migration, led him to conduct geographical research on the impact of the physical environment on the *Inuit* on Baffin Island, Canada. This was one of the many *ethnographic* field trips he would take to the Canadian Pacific Northwest. During this expedition, the harsh *Arctic* winter conditions contributed to Boas

and his traveling companions to become lost. Nearly frozen, they were found by the *Inuit* who taught them how to survive in this harsh environment. The long and lonely *Arctic* winter helped Boas find his true vocation as an anthropologist.

While working in Berlin's Royal Ethnological Museum, Boas met members of the *Nuxálk Nation* of British Columbia, Canada. This encounter established a lifelong interest in the indigenous peoples of the Pacific Northwest. In 1887, on a trip to British Columbia via New York, Boas was hired as assistant editor of the New York-based journal *Science*. The security of employment in the United States, along with his marriage to Marie Krackowizer (with whom he had six children), and the growing anti-Jewish sentiment in Germany contributed to Boas' decision to permanently reside in the United States. In 1889, he was appointed head of the newly-created department of anthropology at Clark University. During the early 1890s, Boas did fieldwork along the North Pacific Coast of North America for several museums, and worked as chief assistant in anthropology to *F.W. Putnam* for the *Chicago World's Fair* (1892–1893) focusing on *Native American* cultures, which he showed with life group displays, or *dioramas*, a concept he pioneered. Hired as curator of anthropology at the American Museum of Natural History in New York, Boas directed and edited reports submitted by the *Morris K. Jesup's North Pacific Expedition*, which investigated cultural and linguistic ties between Siberian and North American aboriginal peoples.

In 1899, Boas became professor of anthropology at Columbia University. Through his efforts, the anthropology department became the foremost anthropology department in the United States.

Boas was a great teacher and mentored several American anthropologists, including *Alfred Kroeber*, *Robert Lowie*, *Ruth Benedict*, *Margaret Mead*, *Melville Herskovits*, and *Edward Sapir*. They would later become renowned in their own disciplines.

Accomplishments

Boas' work revolutionized the scientific community at a time when few scholars believed that the various human races possessed equal capacity for cultural development. Two major concepts are attributed to him,

“*Cultural Relativism*” and “*Historical Particularism*.” The former refers to the idea that all cultures are of equal value needing to be studied from a neutral point of view so they can be understood on their own merit and not another culture's. The latter, “*Historical Particularism*,” is the notion that each culture has a unique history and that universal laws do not necessarily determine how cultures operate. These concepts challenged the “*evolutionist*” view of *Louis Henry Morgan* and *Edward Tylor*, who believed that each culture went through stages (from savagery to culture), during their development. The implications of “*Cultural Relativism*” and “*Historical Particularism*” have had a significant impact on anthropology and the social sciences in general.

Boas' argument that human groups evolved equally but in different ways also clashed with the prevalent theory that skull capacity equated directly with *intelligence*, thus implying that Caucasians, having larger brains, were more intelligent than *Native Americans* and people of black African descent. During that period, it was also thought that *cranial index*, or head form, could be used to distinguish between *races* and *ethnic* groups, and that there was a direct relationship between skull shape and predisposition to *criminality* and *mental illness*. Boas' research (1910–1912) based on the analysis of *cranial forms* collected from European-born immigrants and their American-born children in New York, showed however, that environment and not heredity (*Nature vs Nurture*) determined skull shape. Furthermore, due to the plasticity of the skull, precise distinctions between races, ethnicities, or *intellect* could not be ascertained. His findings are still widely accepted and frequently cited in scientific studies. Boas' book, *The Mind of Primitive Man*, which addressed culture and race, was often cited in the 1920s to justify US immigration restrictions based on racial differences. In 1930s' Germany, the *Nazi Party* denounced “*Jewish Science*” attacking not only Boas' anthropology, but also *Sigmund Freud's* and *Albert Einstein's* theories as well. The *Nazis'* contempt for Jews went as far as to publicly burn Boas' books and rescind his Ph.D. from Kiel University. Boas, who had retired since 1936, responded to the *Nazis'* atrocities and the events of the *Spanish Civil War* by writing articles in popular journals about *racism* based on his

anthropological views. These articles were later compiled in the book “*Race and Democratic Society*” (1945, reissued 1969).

Boas also contributed substantially to *descriptive* and *theoretical linguistics*, *statistical physical anthropology*, and *Native American ethnology*, including *folklore* and *art*. He established the *International Journal of American Linguistics*, was one of the founders of the *American Anthropological Association*, and served as president (1931) of the *American Association for the Advancement of Science*.

Boas was a prolific writer. During his lifetime, he wrote hundreds of books and articles. His most notable books are *Growth of Children (1896–1904)*; *The Mind of Primitive Man, 1938*; *Primitive Art, 1927*; *Anthropology and Modern Life, 1938*; *Race, Language, and Culture, 1940*; and *Dakota Grammar, 1941*.

Boas died of a stroke during a luncheon at the Columbia University Faculty Club on December 21, 1942. One of the most influential and respected scientists of his generation, the German-born American anthropologist pioneered modern anthropology. He is considered the “Father” of *American Anthropology* and *Modern Anthropology*.

Bolton, T. L.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: July 27, 1865; Died: January 3, 1948

Born in Illinois, Thaddeus Lincoln Bolton worked as a school administrator for a year after graduation from the University of Michigan before beginning psychological studies at ► [Clark University, History of Psychology](#) at in 1890, where he worked with ► [Hall, G. Stanley](#) and Edmund C. Sanford. Bolton’s first work was a developmental study of digit span memory: his doctoral work was in the area of rhythmic perception. Using an electric pattern generator, Bolton studied the process by which people group rhythmic patterns and published in 1894 a detailed review of the literature on rhythm as well as a description of his experimental methods (Bolton 1894). After this he began a long period of academic itinerancy, working for short times at a long succession of academic posts. Between 1899 and 1902, he made the by then nearly obligatory laboratory tour of Europe and worked mainly with Kraepelin in Heidelberg (Crabb 2006). On his return he joined the faculty of the University of Nebraska at Lincoln where he conducted several studies of fatigue utilizing the Mosso ergograph and mentored, among others, Edwin Guthrie.

Major Accomplishments/Contributions

His major contribution during this time was an article on the relation of consciousness to muscular tonus (Bolton 1909). His fractious personality and his ambitions toward higher academic office resulted in his moving from Nebraska to university and normal school appointments in Kansas, Arizona, and Montana within an 8-year span. Finally, in 1917, he was able to enter a secure continuing position in the Psychology Department of Temple University, Philadelphia, where he served as chair from 1924 until his retirement in 1937. Bolton’s early work on rhythm was appropriate for its times and well cited, but after that he devolved into sporadic scientific and review activity and eventually

into mostly popular journalism and personal genealogy. He cemented his reputation at Temple by establishing an endowed chair in psychology in his name, even though the development of that Department's considerable scientific and clinical reputation has more to do with the achievements of his contemporaries such as Frederick Lund and O. Spurgeon English. One notable consistency in Bolton's career was his interest in anthropology and especially in race psychology, possibly stemming from his early association with Franz Boas at Clark. Bolton reviewed Boas' *The Mind of Primitive Man* for the *Psychological Bulletin* in 1912, evincing guarded optimism for racial tolerance (Bolton 1912). He later sponsored, via his course in social and racial psychology at Temple, a study by three of his students of one of his conjectures – not uncommon in geopolitical and racial theorizing – that civilization's center was gradually moving northward, possibly even as far as Philadelphia (Aretz et al. 1931). Bolton is an example of how the impetus among historians to seek founders in psychology sometimes uncovers and elevates obscure achievements.

Boring, E. G.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: October 23, 1886; Died: June 1, 1968

Edwin Garrigues Boring came from a family which valued science: his elder sister Alice Middleton Boring was a biologist and zoologist who worked in China for most of her career (Ogilvie 2009). He began as an engineer but switched to psychology, influenced by ▶ [Titchener, Edward Bradford](#) at Cornell. Boring's skill with apparatus served him well in his doctoral work, a heroic study of the sensations of the gastrointestinal tract, involving among other things devices swallowed to provide electric shock to the stomach, intestines, and other regions (Boring 1915). This work is sometimes still cited in connection with pain in internal organs connected with disease. After service in the Army in connection with psychology's war efforts between 1918 and 1919, he went to Clark University for a time and then to Harvard in 1922, where he became the director of the laboratory in 1924 after he displaced Herbert Langfeld, who went to Princeton. He remained at Harvard until his retirement in 1953.

Major Accomplishments/Contributions

Boring's chief administrative achievement was engineering the definitive separation of psychology from philosophy at Harvard. He was trained as an experimentalist in the Titchener mold, and developed into one of the contemporary authorities on classical psychophysics. Boring's intuition of a generalized psychophysical law (Boring 1924) was largely realized in the work of his graduate student, S. S. Stevens, who authored Boring's National Academy of Sciences necrology (Stevens 1973). But Boring's heart was in other things, and he ultimately became known for his achievements in areas not fundamentally experimental (Helson 1970). Boring's view of psychology was closer to Madison Bentley's eclecticism rather than Titchener's strict introspectionistic structuralism, and he was sensitive to changes in the scientific winds. Boring had a fascination with consciousness throughout his career (e.g., Boring 1921), and devoted much time in the early 1930s to accounting for it. He accepted Titchener's classification of conscious experience in terms of extensity, intensity, protensity, and quality, and correlated these with neurophysiological processes of extensity, intensity, duration, and some neural correlate of sensory quality (Boring 1932). A central tenet of Boring's view of consciousness was that

consciousness is dependent on memory, and memory demands relation. Boring observed that behaviorism, rejected by Titchnerian structuralists, paradoxically was closest to the mark in establishing the primacy of consciousness, because it established the scientific validity of the concept of response – that is, relations between organism and environment – as meaning. Within a nervous system specialized for making relations, certain functions necessarily are embodied which taken together comprised, according to Boring, a “cognitive systematic psychology” (Boring 1933). These functions, along with memory, are reaction, response, reflex, discrimination, and differentiation. All of them can be studied experimentally in animals as well as humans, making a behavioristic method the most applicable for a general psychology. Boring indeed embraced behaviorism and his last major faculty acquisition for the Harvard department was B. F. Skinner, who Boring chose when D. O. Hebb turned his offer down in 1947.

Boring was psychology’s greatest booster in America in the twentieth century. He had a phenomenally witty style and was able to capture much of psychology in memorable phrases. One of these, uttered in the context of a very complete and thoughtful popular review of mental testing, was that intelligence is “what the tests test” (Boring 1923). Another was his characterization of the tensions in his own department, and in psychology generally, as between “sociotropes” and “biotropes.” Sloganeering aside, Boring’s biggest roles were as gatekeeper and as historian. Boring knew everyone in the field and knew something about everything that was going on. In a sense, as chair at Harvard, he recreated Titchener’s role as an arbiter of psychological activity. And, in his historical work, he provided a self-image for the field which has endured. *A History of Experimental Psychology* (Boring 1929) occupied Boring from the mid-1920s and was the inaugural book in the Century Series edited by R. M. Elliott. Boring was uniquely equipped to write a comprehensive history of psychology in the modern era, bridging the era of the first and second generation of psychologists who had known Helmholtz and Wundt with the modern era of behaviorism, Gestalt, and nascent cognitivism. Boring’s history differed radically from others in that it took, as its starting point, the time of the dawn of modern experimental science, rather than

seeking sources in ancient philosophy. No history of psychology before or since was able to match its wealth of fine detail nor Boring’s facility in making old controversies relevant and interesting. And few sciences have had such a history written in their early stages which could give a sense of coherence and confident self-definition to their practitioners, though it may be that this sense was as much false as true. Even though Boring’s history glossed over major divisions in the field, slighted social and developmental psychology, and relied on oversimple historical machinery, it was for a long time the leading history of the field, and a great stimulus to further scholarship in the area. Boring was also an eminent teacher of psychology, publishing along with Langfeld and Harry Weld at Cornell an ambitious, multiauthored textbook in several editions beginning in 1935. He was also a proponent of scientific communication, instrumental in founding an important journal of reviews, *Contemporary Psychology*, which began publication in 1956, and among the first psychologists to be televised while teaching. Eventually, he became known as “Mr. Psychology” because of his ubiquity, and his pronouncements had more effect because of this. Thus, his short note on the ambiguous results of his psychoanalysis with Hanns Sachs (Boring 1940) may have added more weight to the anti-Freudian side of the scale than another’s, and his comments on why women were not better represented in science and psychology (Boring 1951) – because, among other things, Boring did not see them as capable of maintaining his preferred pace of an 80-hour workweek – may have inadvertently done much to change attitudes and behavior toward greater gender equality in the field. Altogether he was a protean, extraordinarily influential character and remains a key source for interpreting much of the development of the field during his lifetime.

Bowlby, John

NAVA R. SILTON

Marymount Manhattan College, New York, NY, USA

Bowlby, John Mostyn (February 26, 1907–September 2, 1990) was a British psychologist, psychiatrist, and psychoanalyst, most renowned for his interest in child development and his pioneering work in attachment theory.

Biographical Information

John Mostyn Bowlby was born to an upper-middle class family in London on February 26, 1907. John was the fourth of six children and was primarily reared by a nanny, which was common for a British family of his ilk. Sir Anthony Bowlby, John's father and the first Baronet Bowlby, served as a surgeon to the King's Household but suffered the tragic loss of his own father (John's grandfather) when his father was killed as a war correspondent during the Anglo-Chinese Opium War (Child and Adolescent Developmental Overview). John's mother believed it was perilous to spoil one's children with attention and affection, causing John to only see his mom an hour after her teatime and a bit more over the summer months. John later compared the tragic loss of his mother to the loss of his nanny, his primary caretaker, who left his home when he was 4.

Another difficult time for John was at age 7, when he was shipped off to boarding school. His later work, *Separation: Anxiety and Anger*, divulged how challenging this time was for John and influenced his exceptional sensitivity to the suffering of children throughout the remainder of his life. While he later remarked that “I wouldn't send a dog away to boarding school at age 7,” he did note the potential benefits of boarding schools for children (especially maladjusted children) aged 8 and older.

On April 16, 1930, John married Ursula Longstaff, and they had four children together, one of whom was (Sir) Richard Bowlby, who followed his uncle as the third Baronet Bowlby (Child and Adolescent Developmental Overview). On September 2, 1990, John Bowlby died at his summer home in the Isle of Skye, Scotland.

Major Contributions

John Bowlby began his intellectual career with the study of psychology and preclinical sciences at Trinity College, University of Cambridge. It was not long before Bowlby was recognized for his exceptional performance at Cambridge. Upon completing Cambridge in 1928, Bowlby worked briefly with maladjusted and delinquent children and then attended medical school from age 22 to 26 at the University College Hospital in London. During medical school, Bowlby also attended the Institute for Psychoanalysis. After medical school, he trained in adult psychiatry at Maudsley Hospital and became a psychoanalyst in 1937.

Bowlby served as a Lieutenant Colonel, RAMC during World War II, and as a Deputy Director of the Tavistock Clinic following the war. During the war, there were a variety of circumstances in which young children were separated from their loved ones; including the rescue of Jewish children from the Kindertransport, the evacuation of children from London to protect them from air raids, and the use of group nurseries to ensure that mothers of young children could contribute to war efforts. All of these events coupled with Bowlby's earlier work with maladapted children likely inspired his subsequent work at the Child Guidance Clinic in London. Moreover, it likely aroused his early interest in the topics of: separation and wartime work, evacuees and orphans by Anna Freud, Dorothy Burlingham, and Rene Spitz, respectively (Freud and Burlingham 1943; Spitz 1945).

In 1949, Bowlby was commissioned to write the World Health Organization's report on the mental health of homeless children in postwar Europe based on his earlier work on affectionless and delinquent children and the effects of hospitalization and institutionalized care. In 1950, he became the Mental Health Consultant to the World Health Organization and, in 1951, he published the resulting *Maternal Care and Mental Health*. By the later 1950s, Bowlby amassed a large amount of observational and theoretical work to demonstrate how critical attachment was from birth. He suggested that "the infant and young child should experience a warm, intimate, and continuous relationship with his mother (or permanent mother substitute) in which both find satisfaction." Some strongly disagreed with his notion that maternal (or substitute) love was required to function typically, while others criticized the ambiguity of distinguishing the adverse effects of privation (no primary attachment figure) and deprivation (the loss of a primary attachment figure) on the institutionalized. From the 1950s on, Bowlby shared personal and scientific contact with leading ethologists: Niko Tinbergen, Konrad Lorenz, and Robert Hinde (Blow; Tinbergen and Tinbergen 1972). Armed with these new perspectives, Bowlby rejected the prevailing Cupboard Love Theory of attachment advocated by Psychoanalysis and learning theory and created explanatory hypotheses for human attachment behavior involving the caregiver-child relationship and individual differences in attachment security as environmentally labile methods for adapting to a particular childrearing niche. These theories in turn influenced Ethology and ultimately the development of evolutionary psychology via the cross-fertilization of ethology and attachment theory.

Bowlby hoped to reveal which patterns of family interaction led to healthy or pathological development and to delineate how attachment difficulties may be passed down from one generation to the next. He suggested that attachment behavior was an evolutionary survival need to protect infants from predators. He believed that children's interpersonal relationships were integral to their psychological development. Mary Ainsworth, Bowlby's student, expounded upon Bowlby's "secure base," "stranger wariness," reunion behaviors, and other features of attachment behavior to formulate the "Strange Situation Procedure" for

identifying different attachment styles. Arguably, the three most influential experiences for Bowlby's future career and the development of attachment theory included: (1) his work with maladapted and delinquent children, (2) his 1952 documentary, *A Two-Year Old Goes to the Hospital* with James Robertson relating to the suffering of young children who experienced brief separations from their primary caretakers, and (3) his psychoanalytic training with Melanie Klein, though his perspectives related to the actual life events children were experiencing rather than to the unconscious fantasies that were relevant to the Kleinian outlook.

Despite its critics, attachment theory has been deemed the dominant approach toward comprehending early social development and has inspired substantial empirical work on children's close relationships. Developmental researchers continue to be interested in attachment theory, and the theory was more recently extended to romantic relationships by Cindy Hazan and Phillip Shaver (Hazan and Shaver 1987). In conclusion, attachment theory emphasizes the following principal propositions: (1) It is highly plausible for children between 6 and about 30 months to establish emotional attachments to familiar caregivers, chiefly if the adults are sensitive and responsive to child communications. (2) The emotional attachments of young children are demonstrated behaviorally in their preferences for particular familiar people, their tendency to seek proximity to those individuals, chiefly in times of distress, and their ability to utilize the familiar adults as a secure base from which to explore the environment. (3) The formation of emotional attachments contributes to the foundation of later emotional and personality development; and the type of behavior toward familiar adults exhibited by toddlers has some continuity with the social behaviors they will exhibit in later life. (4) Events that interfere with attachment, such as abrupt separation of the toddler from familiar people or the significant inability of carers to be sensitive, responsive, or consistent in their interactions, have short-term and potential long-term adverse consequences on the child's emotional and cognitive life.

Bréal, Michael

BRIGITTE NERLICH

University of Nottingham, Nottingham, UK

Life

Michael Bréal was born in the German town of Landau on March 26, 1832, to French-Jewish parents. His father, August Bréal, died in 1839 and his widow Caroline Bréal and her children moved to Weißenburg in France. When his mother moved to Metz, Bréal went there as a boarder, before moving to the Lucée Saint-Louis and the Collège Sainte-Barbe in Paris. He then entered the École

Normale, which was a rare achievement for a Jew. After the Agrégation in 1857, he got a stipend which allowed him to study Indoeuropean languages in Berlin under Franz Bopp and Albrecht Weber. Bréal later translated Bopp's main work, a comparative grammar of Indoeuropean languages, into French. After his return to Paris, Bréal got a post at the French national library and obtained his doctorate in 1863 with a thesis on comparative mythology. In 1864 he became professor of comparative grammar at the Collège de France and in 1875 member of the Académie des Inscriptions et Belles-Lettres. He was involved in the foundation of the French Linguistics Society in 1868 and in the foundation of the École Pratique des Hautes Études the same year. In 1867 he married Henriette Bamberger. They had three children who were educated bilingually and provoked reflections on language acquisition and language change. Bréal lived through the 1870/71 Franco-German War and France's defeat triggered a lot of soul searching amongst intellectuals. Bréal became involved in the reform of higher education and wrote treatises and articles on issues of education and pedagogy. In 1890 he was made commander of the Legion of Honour and in the same year his wife Henriette died. To her he devoted his most famous linguistic work, the *Essai de Sémantique* (1897), on the meaning of words, which was translated into English in 1900 by Mrs H. Cust with preface by J. P. Postgate. In 1881, Ferdinand de Saussure, the founding father of general linguistics and structuralism, became his successor at the École Pratique des Hautes Études and in 1905 Antoine Meillet, one of the founding fathers of sociolinguistics, succeeded him at the Collège de France. Bréal died in 1915 (Giessen et al. 2007).

Work

He left an important legacy not only in linguistics (historical linguistics, semantics, and pragmatics) but also in the psychology of language. He changed the study of languages by shifting the focus from single words and their etymology to the study of words in context and use. Bréal's linguistic sparring partners were August Schleicher and Arsène Darmesteter, who were both in different ways influenced by advances in biology. But whereas they regarded languages and words as life forms, that is, organisms that live and die, struggle for survival, and propagate themselves,

Bréal studied languages as parts of what Ludwig Wittgenstein later called “forms of life.” Language is there for the purposes of communication and changes through use in context (see Nerlich 1992).

Language: Origin, Use and Change

Bréal wrote in 1879 that language emerges in the process of trial and error as part of human intellectual evolution: “Human thought, having become capable of the most abstract ideas, introduced notions into names for which those names had not been created. We might compare words to precious vials into which a series of essences is poured. At first they contain merely an ordinary liquid, but the human mind eventually makes them into containers of the most exquisite perfumes” (Bréal 1991: 130). And he went on to say: “I do not believe language had a beginning; rather, language emerged from its first verbal groping after lengthy evolution, the transitions of which are almost indiscernible. If we could witness that evolution we would no doubt see the same laws operating which we find in modern language-change. [...] The same causes which operate in full view today must have worked their influence from the outset” (p. 135). One can here see the influence of thinkers like the geologist Charles Lyell on a new type of linguistic discipline, the study of meaning or semantics. Bréal used the term “sémantique” for the first time in 1883. He also introduced the new term “polysemie” or polysemy into linguistics, first in 1887 in a book review and then more prominently in his *Essai*, to refer to the multiplication of meanings around a word over time and the multiplicity of meanings associated with a word at any moment in time, something that drives language evolution, but does not cause problems for speakers of a language who always hear the word in linguistic and social context. Bréal never lost sight of the human being behind language. As early as 1866 he wrote: “Above and beyond the secondary causes which comprise pronunciation, accent and the grammatical origins, comparative philology should acquaint us with human beings, since language is the most ancient, the most spontaneous, and the most unremitting of their creations” (1991: 62). He also never lost sight of the importance of the human mind in the shaping of language and wrote in 1868: “The mind penetrates the matter of language and fills in its cracks and crevices... It is

not enough, in order to grasp the structure of a language, to analyze its grammar and to reduce its words to their etymological meanings. We must enter into a people’s way of thinking and feeling” (1991: 92).

But most importantly, he never lost sight of the pragmatic, behavioral, and societal aspects of language: “Speech is not made for purposes of description, of narration, of disinterested considerations. To express a desire, to intimate and order, to denote a taking possession of persons or of things – these were the first uses of language” (1964/1900: 238).

Brentano, F. C.

THOMAS F. CLOONAN

Fordham University, Bronx, NY, USA

Basic Biographical Information

Frantz Clemens H. H. Brentano was born in Marienberg, Germany in January 16, 1838, to a Catholic family of comfortable means that had a certain degree of political and cultural influence in nineteenth century Germany. He died in Zurich, Switzerland, on March 17, 1917. His life’s work was the affirmation of philosophy as a scientific discipline, and his considerations of philosophy included explicit viewpoints toward psychology.

Brentano’s early philosophical studies were at Aschaffenburg, Munich, Würzburg, and Berlin. At Berlin and then at Münster, his studies focused on Aristotle. These studies were significant insofar as they laid the foundation for Brentano’s development of the concept of intentionality coming from the scholastic philosophy of the medieval age, which had incorporated the philosophy of Aristotle.

In 1862, Brentano completed his doctoral dissertation at Tübingen, “On the Manifold Sense of Being in Aristotle.” In 1865, Brentano wrote his *Habilitationsschrift* (a qualifying monograph for academic positions), which was on “The Psychology of Aristotle, in Particular his Doctrine of the Active Intellect.” Brentano was a philosopher with a more-than-average concern about psychology. In 1866, Brentano publicly defended the theses of his *Habilitationsschrift* at Würzburg, declaring natural science to be the only correct method of philosophy. From 1866 through the early 1870s, Brentano lectured at Würzburg. Among Brentano’s students at Würzburg were important figures such as Carl Stumpf, Anton Marty, and Antal (Anton) Schütz.

In 1864, Brentano had been ordained a priest. Ordination to the priesthood contributed mightily to the year 1873 as a watershed year in the life of Brentano. In that year, in an ultimate response to the declaration of the doctrine of papal infallibility by Vatican Council I in 1870, Brentano withdrew from the priesthood and resigned from his position at Würzburg. In 1874, he was appointed Professor Ordinarius at the University of Vienna. In 1880 with his renouncing his Austrian citizenship in order to marry as a former priest (not recognized under Austrian law at the time), he gave up his Vienna professorship. In that year, Brentano married Ida von Lieben with a son, Johannes, following 8 years after the marriage.

Brentano subsequently returned to the University of Vienna as a Privatdozent. Included in his student roster in his years at Vienna were Edmund Husserl, Kasimir Twardowski, Alexius Meinong, Christian Von Ehrenfels, Alois Höfler, and Thomas Masaryk, the founder of Czechoslovakia. To be noted is that Sigmund Freud attended some of his lectures. At both Würzburg and Vienna Universities, Brentano’s students numbered among the important and distinguished in the history of his time.

In 1894, Brentano’s wife Ida died. The year after his wife’s death, Brentano retired as Privatdozent at the University of Vienna and decided to leave Austria and to settle in Florence, Italy. He became an Italian citizen (Italy was the origin of his family name). In 1897, he married Emilie Rueprecht. In 1915, he left Italy and moved to Zurich, Switzerland, when Italy entered World War I. He died in Zurich in 1917. His body

was later reinterred in a family plot in Aschaffenburg, Germany.

There is testimony to the personality and character of Franz Brentano. Husserl, for 2 years in attendance at Brentano’s lectures (1884–1886) in Vienna and arguably the most famous and most cited of Brentano’s students, recounts how Brentano’s students found him easy to speak with, and how well Brentano knew how to use questions and objections to guide beginning students. Brentano was a player in the Vienna Chess Club, Husserl reports, and was considered a “clever player” by fellow players. He did wood carvings; he painted and drew. Brentano was abstemious; he did not smoke and he ate and drank moderately. Husserl further comments on Brentano’s “childlike openness and on his childlikeness of genius.”

Despite Brentano’s estrangement from the Catholic Church, Husserl according to his recollections of Brentano never heard him speak of Catholicism without the greatest respect. Brentano was considered to be a pacifist, a citizen of the world. In the context of the era in which Brentano lived, an era of European empire- rivalries and of national chauvinism, this characterization of Brentano certainly stands out as quite noteworthy. Finally, of interest to Husserlian followers and to phenomenological psychologists is Husserl’s claim that Brentano’s example led him to believe philosophy could be scientific and that it was worthwhile for him to leave mathematics and to take up philosophy as his life’s work.

Major Accomplishments/ Contributions

With respect to Brentano’s life’s work and the topics on which he focused, that of intentionality was salient. Intentionality addressed the character of consciousness and Brentano’s development of it from the medieval period of philosophy was later appropriated by Edmund Husserl who further developed the concept of intentionality in the sense of relationality of consciousness for the articulation of philosophical phenomenology. Husserl’s employment of intentionality has continued in the human science tradition of modern psychology and it has its clearest presentation in the school of phenomenological psychology.

In addition to his development of the concept of intentionality in the understanding of consciousness, a second legacy to psychology bequeathed by Brentano

was his articulation of “act psychology.” In this psychology, Brentano promoted the position that the act and content of psychological consciousness processes are separate as functions. Acts rather than contents are to be considered the important concerns of psychology. Act psychology served as a counterpoise to Wilhelm Wundt’s emphasis on contents.

Brentano’s most important work was *Psychology from an empirical standpoint* (1973). According to the historian of the phenomenological movement Herbert Spiegelberg (1972), “the role of psychology in Brentano’s reformed philosophy was central: to provide the scientific foundation for all the branches of his new philosophy, including ethics.” (p. 4) It is not for nothing that Franz Brentano is considered a psychologist as well as a philosopher.

Breuer, Josef

GAIL DONALDSON

Union College, Schenectady, NY, USA

The Austrian physician Josef Breuer was born in Vienna, Austria, on January 15, 1842, and died on June 20, 1925. He received his medical degree from the University of Vienna in 1867 and subsequently conducted research into the physiology of the nervous system while also maintaining a private practice in internal medicine in Vienna. Breuer is most well known as a mentor to Sigmund Freud, the inventor of psychoanalysis, and as a doctor to Bertha Pappenheim, who, under the case name Anna O., became one of the most famous patients in the history of psychoanalysis (Hirschmuller 1990).

As a friend and mentor to the young Dr. Freud Breuer advised him on his career, sent him patients,

and collaborated with him in an investigation into the nature of hysteria, the nervous ailment most commonly diagnosed in their mostly Jewish, upper-middle class, female patients. In their approaches to treatment Freud credits Breuer with the discovery of the importance of abreaction, the discharge of emotions repressed at the time of a traumatic experience, and of insight into the unconscious to relieve symptoms. Their jointly published work *Studies on Hysteria* (1895) presented case studies of several of their patients and laid the foundation for what was to become the theory of psychoanalysis.

The most famous patient discussed in the work is Anna O. who is often considered to be one of the seminal patients in the history of psychoanalysis, despite the fact that she was Breuer’s patient and not Freud’s. Breuer described Anna O. as suffering from a wide variety of unusual symptoms such as hydrophobia, paralysis in several limbs, disturbances in vision, and an inability to eat. Breuer treated her with hypnosis and through talking about her symptoms traced their origins back to the traumatic experience of nursing her father through a long and fatal illness. There is some controversy in the psychoanalytic literature about whether or not Anna O. was “cured” of her symptoms by this treatment, as Breuer claimed in his published case study. Investigations into the life of Bertha Pappenheim by Ellenberger (1972) show that she suffered a relapse and was admitted to a sanatorium soon after the termination of her treatment with Breuer, but later she achieved a successful career as a social worker. How much the treatment by Breuer helped her has been seriously questioned by critics of psychoanalysis. Nevertheless, Anna O. coined the famous term “the talking cure” to describe her treatment by Breuer, which later came to be applied to the treatment of psychoanalysis. Freud and Breuer proposed that the origins of hysteria lay in the unconscious, through the conversion of emotions associated with repressed traumatic experiences into symptoms. Thus, the abreaction, or discharge, of emotions would relieve symptoms by removing the power of those underlying emotions, or insight into the unconscious origins of the symptoms would serve the same purpose. However, as Freud began to investigate what he believed to be the sexual origins of many symptoms and to develop the psychological theory of psychoanalysis Breuer would not follow along. He rejected Freud’s psychological explanation of hysteria and

maintained that it was a disease of the nervous system with a physiological cause. Their collaboration and friendship soon ended. Breuer also soon ended his attempts to treat hysterical patients claiming that they took up too much time in his practice, although historians of psychoanalysis have speculated that he was overwhelmed by the emotional attachments that hysterical patients often developed to their doctors.

Breuer is also known for two important discoveries in physiology: how the sense of balance is mediated by the semi-circular canals inside the ear and the Hering-Breuer reflex, which explains the role of the vagus nerve in regulating respiration.

Brewer, Charles L.

ALAN J. FELDMAN

Glen Rock High School, Glen Rock, NJ, USA

Basic Biographical Information

(Photo legend: Courtesy of Dr. Brewer)

Charles Brewer was born on May 5, 1932, in Pine Bluff, Arkansas. He earned his Doctorate from the University of Arkansas. Prof. Brewer is an American educator (William R. Kenan, Jr., Professor of Psychology, Furman University, Greenville, South Carolina) best known for his contributions to and advocacy for the teaching of psychology and for his leadership in enhancing the teaching of psychology.

Major Accomplishments

More than 200 of Brewer's former students have earned doctoral degrees in psychology. He is an influential member of the American Psychological Association, having served as president of a number of divisions, a member of the Board of Educational Affairs, and the Board of Directors. He is a member of the Board of Trustees for the American Psychological Foundation. He has received numerous teaching awards as well as an APA Presidential Citation as "one of our discipline's most esteemed colleagues" and a Division 2 (Society for the Teaching of Psychology) Presidential Citation.

Brewer received his BA from Hendrix College in Conway, Arkansas, and his MA and Ph.D. from the University of Arkansas in Fayetteville. He has written, coauthored or edited eight books and more than 100 book chapters and articles. He is considered the most knowledgeable scholar of the behaviorist John Broadus Watson. Brewer taught at The College of Wooster (1959–1961) and at Elmira College (1964–1967) before moving to Furman University in 1967. At Furman, he was chair of the Department of Psychology from 1972 to 1984 and was named the William R. Kennan, Jr., Professor of Psychology in 1998.

From 1985 to 1996, he edited *Teaching of Psychology*. In this capacity, he improved thousands of manuscripts by insisting on clarity, conciseness, and felicity of expression. He was given the honorific title of Editor Emeritus in 1996.

Brewer is widely recognized for major contributions to the teaching of undergraduate and high school psychology. He has served as chair of APA's Committee on Undergraduate Education and its Board of Educational Affairs. He was chair of the Curriculum Group for APA's National Conference on Enhancing the Quality of Undergraduate Education in 1991 and worked on the Curriculum Group at APA's national conference

on undergraduate education in psychology in 2008. He participated in nearly every important undergraduate education conference in the last 30 years, including keynote addresses at the International Conference on the Teaching of Psychology in St. Petersburg, Russia, in 2002 and 2008.

Brewer was influential in organizing and sustaining APA's Teachers of Psychology in Secondary Schools (TOPSS) and has served as the college representative for the TOPSS Executive Board. He edited curriculum units for TOPSS and the National Standards for the Teaching of High School Psychology. He was chair of the Advanced Placement Psychology Test Development Committee from 2001 to 2003.

Brewer has coedited numerous books on the teaching of psychology and has served as an educational consultant for over 70 introductory psychology textbooks for 16 publishers. He has had an incalculable impact on the field of psychology for more than 40 years. He was married to Marjorie Suhs Brewer for 45 years, and their daughter, Stephanie Foley, is a museum curator in Gormley, Ontario.

Broadbent, Donald

HARRY LEVITT

Advanced Hearing Concepts, Bodega Bay, CA, USA

Basic Biography

Donald Eric Broadbent was born on May 6, 1926 in Birmingham, England. Although born in England, he identified himself as Welsh since he was of Welsh parentage and lived in Wales for most of his boyhood years. At age 13 he won a scholarship to Winchester College, a prestigious English Public School where he completed his schooling. He joined the Royal Air Force (RAF) during World War II and was sent to the USA to train as a pilot. After his stint in the RAF, he studied psychology at Pembroke College, Cambridge University. On completing his undergraduate studies, he joined the research staff of the Applied Psychology Unit (APU) in Cambridge where he was able to continue his research studies. In 1958, he was appointed director of the unit, a position he held for the next 16 years. In 1961 he began a productive research collaboration with Margaret Gregory, who became his second wife in 1972. The APU grew substantially in both size and scope under his leadership and, tiring of the large administrative load, he moved to Oxford in 1974 where he headed a small research program and was able to concentrate on his own research until he retired in 1991. He died of a heart attack 2 years later on April 10, 1993.

Contributions

Donald Broadbent straddled the gap between applied and theoretical psychology. He was a Renaissance man of the twentieth century. One of his great interests was that of aircraft and flying. As a pilot for the RAF in World War II, he realized the importance of human

psychology in the design of aircraft. The instrument panels and control levers on aircraft were complex and confusing. A wrong reading or misapplied lever could lead to disastrous results, and often did, unfortunately. His experience with complex and confusing human-machine interfaces convinced him of the importance of applied psychology as a science. The head of the psychology department at Cambridge University, Frederick Bartlett, recognized Broadbent's potential as an insightful researcher with an appreciation of the importance of solving practical problems and soon became his mentor. At that time, traditional psychologists looked down on applied psychology from their ivory towers. Bartlett was one of the few champions of applied psychology and was instrumental in providing the support Broadbent needed to pursue his research. Broadbent's earliest experimental work was on the effects of noise on human performance. These early studies laid the groundwork for his subsequent research and he maintained an interest in the topic throughout his career.

Another area of research, with important practical implications, was that of selective listening to competing messages. An impetus for this research was the need for aircraft controllers to attend to messages received simultaneously from two or more aircraft. Information theory, a branch of applied mathematics, had recently been developed and Broadbent was quick to see the implications of this theory for human communication, and perception in general. He used the concepts of information theory, such as information rate and channel capacity, in modeling human selective attention. The outcome was his most influential book, *Perception and Communication* (1958) in which he developed his classic filter theory on the perception of competing stimuli. Although details of his theory have been modified or replaced over the years to account for new experimental findings, the theory provided the bedrock for modeling human perception in quantitative terms based on the concepts of information theory. This general approach to the quantification of information provided a unifying framework for the seemingly incoherent mass of experimental data on selective attention. Not only did his theory provide new insights and new ways of addressing the problem, it also broke down barriers between disciplines, leading to the maturation of applied psychology into the broader, more general

field of cognitive psychology. From small acorns, wisely cultivated, do large oaks grow.

Broadbent developed his filter theory further drawing on concepts from signal detection theory to strengthen and broaden the applicability of his ideas to real-life situations not usually addressed by theoretical psychologists. His book *Decision and Stress* (1971) encapsulated these ideas. Although an important contribution, the book was not as influential as his previous work since it was essentially an extension of ideas he had already developed and was no longer as novel a contribution as *Perception and Communication*. A third significant book, *In Defence of Empirical Psychology* (1973), is a compilation of his lectures at Harvard University and elsewhere in which he defended his nonconformist approach to scientific research – an approach which, in retrospect, has yielded rich rewards.

Although Broadbent's later research contributions were not as influential as his early information-theory-based filter theory, the cumulation of his many contributions to the study of attention and memory led to major advances in cognitive psychology, before the field came to be known by that name. Broadbent's impact on the field did not end with his passing in 1993. His work and style of research continue to influence both young and established researchers to this day. It is also important to bear in mind that it was his emphasis on solving practical problems that led to the development of major new theories.

Honors

Fellow of the Royal Society, 1968

Foreign Associate of the National Academy of Sciences (USA), 1971

Commander of the British Empire (CBE), 1974

Distinguished Scientific Contribution Award, American Psychological Association, 1975

Honorary doctorates from seven British universities (City, Cranfield, Loughborough, York Universities, University of Dundee, University of Southampton, University of Wales), and two Belgian universities (Free University of Brussels, University of Leuven)

The British Psychological Society instituted the annual Broadbent Lecture in his honor, with Donald Broadbent delivering the inaugural lecture in 1991.

Broca, Pierre Paul

ROGER K. THOMAS
University of Georgia, Athens, GA, USA

Basic Biographical Information

Broca (1824–1880) was born in Sainte-Foy-La-Grande near Bordeaux, France. He attended a Calvinist Collège in Bordeaux where he earned a bachelor of letters degree and diplomas in mathematics and physical sciences. He earned the M.D. degree at the University of Paris medical school in 1848 after which he did graduate studies in anatomy, pathology, and surgery. In 1853, Broca became assistant professor on the Faculty of Medicine. He served several years as *professeur agrégé* (highest teaching certification), and in 1867, he was elected chair of *pathologie externe* in the Faculty of Medicine. In 1868, he became professor of clinical surgery. With a growing interest in anthropology, Broca founded the *Société d'Anthropologie* in 1859, the organization where he presented that for which he is best remembered, clinical cases that defined the human speech center in the cerebral cortex. Elected to a life term in the French Senate as a representative for science, he served only 6 months before his death in 1880. At that time, Broca was also vice president for the French Academy of Medicine (Clarke 1970).

Major Accomplishments/Contributions

Broca made so many significant contributions in anthropology, pathology, neuroanatomy, neuropsychology, and neurosurgery, both in methodology and discovery, that only a few can be mentioned. He has been called the “father of anthropology.” His contributions included founding the *Société d'Anthropologie*, the *Revue d'anthropologie*, and the *École d'Anthropologie*, Paris. He studied human and racial origins as well as evolution of the brain (via study of skulls) and intelligence. Combining, neuroanatomy, neurosurgery, and neuropsychology, he identified *le grande lobe limbique* which figured significantly in what became known as the limbic system, the twentieth century's focus in the search for the neuroanatomical substrates of the emotions. Several brain structures bore his name, and at least two have persisted in modern times when neuroanatomists seek to eliminate most eponyms, namely, the diagonal band of Broca and Broca's area or convolution as a cerebral cortical center essential for human speech (area 44 in Brodmann's cytoarchitectural system). His research associated with Broca's area also led to his emphasis on the left hemisphere as the dominant one for language in most humans and that, in turn, contributed to the general concept of cerebral dominance (Schiller 1979).

Among psychological historians, historians of neuroscience, and medical historians in general, Broca is best known for his role in discovery of the speech center. Psychological historians usually misrepresent Broca's role in that discovery (by attributing it *only* to Broca; see Thomas 2007); whereas, other historians usually describe the essential roles performed by Jean-Baptiste Bouillaud and Simon Alexandre Ernest Auburtin. It will be useful to summarize the roles of Broca Bouillaud, and Auburtin.

Based on an accumulation of clinical cases, Bouillaud, a physician and father-in-law of Auburtin, had long advocated that control of human speech resided in the brain's frontal lobes. Auburtin, also a physician, had done important clinical research that supported Bouillaud's argument (Stokey 1954). During meetings of the *Société d'Anthropologie* in Paris in 1861, Auburtin, who was present but Bouillaud was not, asserted Bouillaud's argument that the human speech

center resided in the frontal lobes of the brain. Auburtin also argued for localization of cortical functioning in general. Localization of function was very much a minority view at that time owing to its dismal association with phrenology. Auburtin further asserted that he had a patient upon whom he would risk his argument, and if the patient failed to confirm his position, he would renounce his support for localization. As Secretary for the *Société*, Broca was an active participant in the discussion, but as shown by the quotation below, he took no position on the localization argument.

Using his words, “by strange coincidence,” Broca reported that he had a patient in his care that, upon Auburtin’s approval, he offered as substitute for Auburtin’s patient. Following examination of the patient, Auburtin approved the substitution, but as Leborgne (“Tan”) was Broca’s patient, on April 18, 1861, Broca presented the results of the postmortem examination to the *Société*. On May 2, 1861, Broca again discussed the brain of Leborgne and said, “But, while I inclined towards M. Auburtin’s opinion, I did not intend to take part in the debate. I am expressing myself neither for nor against specific localizations. . . .” (p. 495, Clarke and O’Malley 1968). Thus, Broca’s involvement in discovery of the speech center might not have occurred except “by strange coincidence.”

Broca did not misrepresent the discovery of the speech center; rather it was subsequent, mostly psychological, historians who did. Later in 1861 and unlike Bouillaud and Auburtin, Broca followed through with further research and presented the more convincing case of Lelong whose lesion was small and more definitive of “Broca’s area,” whereas Leborgne’s lesion involved both the frontal and parietal lobes. By 1863, Broca had accumulated a sufficient number of cases to be able to assert left hemisphere dominance for the speech center in most humans. Thus, Broca deserves a full but not exclusive share of the recognition for the discovery of the speech center. Subsequent research showed that Broca’s area is involved mainly with the motor aspects of speech and that other cortical areas also play significant roles in human speech and use of language.

Brown, Thomas

JOHN A. MILLS

University of Saskatchewan, Hornby Island,
BC, Canada

Basic Biographical Information

Thomas Brown was born in Kirkmabreck, Kirkcudbright, Scotland in 1778, the son of a clergyman. He started studying at the University of Edinburgh in 1792, qualifying in medicine in 1806. He practiced medicine briefly but his principal interests were philosophical and literary, resulting in a critique of Erasmus Darwin’s evolutionary theory (1798) and ten volumes of poetry. Via his membership of a private Edinburgh club, the Academy of Physics, he developed libertarian political views and a skeptical approach to metaphysics and religion, while also helping to found the *Edinburgh Review*, one of the most influential British journals in the nineteenth century.

Major Accomplishments/Contributions

In 1808, Dugald Stewart, Professor of Moral Philosophy, University of Edinburgh, became ill. Brown was invited to assume some of his teaching duties, despite manifesting his philosophical unorthodoxy in a series

of books promulgating views on causation similar to Hume's. Brown enunciated his philosophy in his lectures, published posthumously as *Lectures on the Philosophy of the Human Mind*, steering a middle course between Thomas Reid's and Stewart's common-sense metaphysics and Hume's skepticism. Brown was appointed conjoint Professor of Moral Philosophy in 1810.

Like Hume, he espoused mental science, not metaphysics, and asserted that mind and matter were known only in their manifestations. Some of those manifestations (perceptions) arose outside the body. Brown was the first English-speaking philosopher to include muscle sense as a sixth sense, apparently borrowing the category, without acknowledgment, from Destutt de Tracy. Brown classified the states arising from within the body as either *suggestions* or *emotions*. Suggestions, such as thoughts, concepts, and beliefs, were intellectual and active, while emotions were passive.

Successive mental scientists treated the emotions similarly to Brown. Emotion was a relatively new term, appearing only in the mid-eighteenth century, replacing terms such as *passion*. More particularly, Brown treated the will not as a separate, active faculty but merely as one emotion among others, and therefore as passive. Moreover, he claimed we could not experience the will as such but only as realized within some particular conception or situation. Furthermore, he also seemed to believe that, in the case of bodily movements, acts of will were muscle-group specific (if I will my left forefinger to move, then only that finger moves).

The published version of Brown's *Lectures* went into 20 editions and influenced James and John Stuart Mill, who embraced his "mental chemistry" (the analysis of mental states into their components). Others advanced Brown's "mental physics" (charting successive mental states). Several proto-psychologists (e.g., Herbert Spencer, George Henry Lewes, and James McCosh) adopted Brown's division of mental states into sensations, thoughts, and emotions, while also, again following Brown, classifying emotions into retrospective, immediate, and prospective. In particular, Alexander Bain's analysis of motivation was Brownian. He postulated that emotions had bodily origins and that degree of arousal of psychophysical and mental states was automatically conjoined.

Brown did not marry (his household comprised himself and his sisters). He died in London on 2 April, 1820.

Brown, Warner

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: February 9, 1882; Died: February 6, 1956.

Born near Greensboro, Georgia, to New England parents, Brown received his B.A. (1904) and M.A. (1905) from the University of California, majoring in Philosophy, with George H. Howison. His earliest psychological training was with George Stratton, and then he proceeded to doctoral study at Columbia (Ph.D. 1908) with R. S. Woodworth, where he was also influenced by Cattell, Dewey, and F. J. E. Woodbridge. For his doctoral work, he measured voice prosody in poetry via a tambour recorder. He returned to Berkeley, rising through the ranks to professor by 1923 and serving both as Department Chair for 16 years and as Associate Dean in the College of Letters and Science in the late 1920s.

Major Accomplishments/Contributions

Edwin G. Boring, in the second edition of his *History of Experimental Psychology*, styled Brown the senior experimental psychologist at California. His varied

contributions between 1904 and 1920 included short reviews and experimental reports on habit interference in sorting cards, same vs. different sex recognition of faces, incidental memory (one of the earliest studies in this area), color and number naming, and the identification of shades of gray. Work of Brown's on difference judgments and the judgment of very weak stimuli had some persistence in the literature, but his most durable contributions are his later work on sensory cues in human maze learning (Brown 1932; Brown 1937): his work was cited to effect by the philosopher-geographer Yi-Fu Tuan in *Space and Place* (Tuan 1977). Brown also collaborated on the massive Boring, Langfeld and Weld textbook series in the late 1930s, contributing a chapter on spatial perception and wrote, with H. C. Gilhousen, a college text of his own (Brown and Gilhousen 1950). Brown's main effect on the field, however, was as a teacher and administrator, and as such he is representative of many psychologists coming into the academy at and after this time who bolstered early gains of earlier pioneers. In Brown's case, this meant following George M. Stratton and reinforcing the development of the Berkeley department, with its diversity both in points of view and gender. Brown also shared the commitment to a liberal outlook and action characteristic of the Berkeley department. In 1918, he played a role, with Kenyon J. Scudder, in abolishing corporal punishment at the Preston School of Industry at Ione, California, and in 1950 he was one of the members of the Berkeley faculty who along with Edward C. Tolman refused to sign a loyalty oath required by the University of California. Among his students were the influential California investment banker and philanthropist Walter Stern Heller, who studied the effects of advertising with Brown (Heller and Brown 1916), and the eminent methodologist Donald T. Campbell, who chose his first independent research project as an undergraduate member of Brown's Experimental Psychology course. Brown is memorialized at Berkeley by the Warner Brown Memorial Prize, which is awarded for outstanding undergraduate psychology research.

Bugental, James F. T.

GEORGE A. AIKEN

Graduate College of Psychology and Humanistic Studies, Saybrook University, San Francisco, CA, USA

Basic Biographical Information

Born in Fort Wayne, Indiana, on December 25, 1915, James Frederick Thomas Bugental was the son of Richard Francis Bugental, a smart, ambitious, and tough man, who struggled to find work during the depression and Hazel Jeanette Bugental, an aspiring pianist who sacrificed her career to marry, and supported the family by teaching music. Bugental spent his early childhood in Ohio, Illinois, and Michigan, until the family moved to California in 1927, where he finished high school and junior college. An avid reader from an early age, he did well in subjects he enjoyed, and poorly in those he did not like.

After completing junior college, Bugental married, received his B.S. from West Texas Teachers College in 1940, and earned a fellowship to George Peabody College in Nashville, Tennessee, where he received an M.A. in sociology in 1941. In 1943, his doctoral studies in the Peabody psychology department were interrupted by World War II, at which time he became the acting director of the Veteran's Guidance Center at the Georgia School of Technology. In 1945, he was drafted into the army and was assigned as a psychologist to the Lawson Army General Hospital in Atlanta. Bugental was discharged from the army in 1946.

Having been inspired by reading Carl Roger's *Counseling and Psychotherapy*, Bugental attended the doctoral program at Ohio State University under the G.I. bill, where in his own words, he gained a "new confidence in his intellectual abilities." He received his Ph.D. in psychology in 1948 from Ohio State, where he studied under two psychologists who had a significant influence on Jim, and an early influence on the development of humanistic psychology, George Kelly and Victor Raimy.

During his post-doctoral years, Bugental taught and did research at UCLA, concentrating on psychological interviewing. He soon changed directions and became a founding partner of Psychological Service Associates, a psychotherapy practice working with individuals and groups in Los Angeles.

During the 1960s and 1970s, Bugental was divorced and married Elizabeth Bugental, who became a central figure in his life. Also, during this period, he became involved in local, state, and American Psychologist Association (APA) activities. Throughout his career, he taught widely and published extensively on the humanistic and existential-humanistic orientation in psychology. In 2003, Jim suffered a stroke, and in September of 2008, he died at home in Petaluma, CA, at the age of 92.

Major Contributions

James F.T. Bugental played a key role in psychology, and in the early development of humanistic and existential-humanistic therapy. He became the president of the American Psychological Association from 1960 to 1961, and in 1962 and 1963, he was the first president of the Association for Humanistic Psychology (AHP). He wrote the journal article, "Humanistic Psychology: A New Breakthrough," which had a significant and profound influence on the establishment of goals and policies for the newly established AHP.

In 1964, a conference at Wesleyan University in Old Saybrook, CT, established humanistic psychology as a legitimate movement embraced by eminent and respected scholars. Among those present were James Bugental, Gordon Allport, Charlotte Buhler, George Kelly, Clark Moustakas, Abraham Maslow, Rollo May, Carl Rogers, Gardner Murphy, Henry Murray, Robert White, and other notable figures from various

academic fields, including psychology, education, biology, phenomenology, and more.

In 1965, Bugental wrote, *The Search for Authenticity: An Existential-Analytic Approach to Psychotherapy*, which elucidated an existential approach to the psychology of personality. To paraphrase Bugental, the depth existential therapist assists the client in seeking to become aware of and to express in words how she or he identifies her or his self and world. The client is encouraged to seek within for a sense of concern, a recognition of what truly matters to her or him in the very present now. According to Jim, this focus on the immediate present is central to the search for existential identity. "To talk about what matters in one's life is very different from talking out of that experience as it is being lived, even as one speaks."

In 1971, the Association for Humanistic Psychology established the Humanistic Psychology Institute (now known as Saybrook University), a graduate degree granting humanistic psychology institution in San Francisco, CA. Jim Bugental was an early supporter, a member of the executive faculty, eventually became an emeritus faculty member, and was awarded an honorary Doctorate from Saybrook University.

Some of the principle features of Bugental's version of an existential-humanistic psychology include:

1. Self-and-World Construct System – the how of a client/patient's constructed world.
2. Resistance – the client's blocks to being fully in one's being – the very illness which may impel the client to seek psychotherapeutic help.
3. Process Emphasis – giving primary attention to the client's process rather than to the content of her or his dialogue. The therapist monitors facial expressions, gestures, breathing patterns, body language, and much else besides the narrative of what the client is saying. These are signals from the preconscious level of the client's mind, and have therefore not yet been consciously recognized by the patient.
4. Transference – the patient's unconscious attempt to reestablish an earlier, symbiotic relationship with a person important in her or his life. If transference is a reality in the self-and-world construct of the client, and this transference is a form of resistance that prevents authenticity and genuine encounter

with the therapist or in the client's life, then that transference becomes a part of the conversation.

5. The remaining features include the Core Conception, Destiny, Searching, Concern, and the Therapeutic Alliance.

Bugental saw psychotherapy as a window to the human soul, its goal being to help people who are distressed about their lives and try to make their lives more satisfying.

Over the course of his career, James Bugental conducted workshops nationally; lectured internationally; received many prestigious awards; served on the editorial boards of many distinguished journals; and published numerous articles, chapters, books, reviews, and commentaries.

In addition to what has already been mentioned, over the course of his career, James F.T. Bugental was Professor Emeritus at the International Institute for Humanistic Studies; named Fellow of the American Psychological Association in 1955; Emeritus Clinical Faculty Member at Stanford University School of Medicine; a Rockefeller Scholar at the California Institute of Integral Studies; the first recipient of the APA Division 32, Humanistic Psychology, Rollo May Award; author of over 60 articles and chapters on Existential-Humanistic psychology and psychotherapy; author of seven books, including *Search for Authenticity*, *Psychotherapy and Process*, *Intimate Journeys*, *The Art of Psychotherapy* and *Psychotherapy Isn't What You Think*; and the editor of two versions of the *Handbook of Humanistic Psychology*. His books have been translated into many languages, and have been used widely in undergraduate and graduate schools of psychology and psychotherapy.

Bühler, Karl

ADRIAN C. BROCK

University College Dublin, Dublin, Ireland

Basic Biographical Information

Karl Bühler was born in Germany in 1879. After receiving doctorates in medicine and philosophy, he went to the University of Würzburg to work with Oswald Külpe. Külpe was a former student of Wilhelm Wundt who had disagreed with his mentor over the appropriateness of experiments for studying thought. This was the area in which Bühler worked (Bühler 1907). It was the publication of Bühler's work that led to Wundt's famous attack on the methods of the Würzburg School (Wundt 1907). Bühler was not intimidated by the eminence of his critic and vigorously defended his work (Bühler 1908).

Bühler and Külpe must have formed a close bond since they moved together to the University of Bonn in 1909 and to the University of Munich in 1913. Upon the outbreak of the First World War, Bühler joined the German army and worked as a medical doctor on the western front. He was called back to Munich to take temporary charge of the psychology institute after the unexpected death of Külpe in 1915 at the age of 53. A few months later, Bühler married a graduate student from the institute, Charlotte Malachowski, after a whirlwind romance. As Charlotte Bühler, she was to become a famous psychologist in her own right.

Bühler was disappointed to learn that his position in Munich was not made permanent. He subsequently took up an appointment at the Technical University in Dresden. The position at a major university that he wanted came in 1922 when he became director of the psychology institute at the University of Vienna. Here, the Bühlers surrounded themselves with talented colleagues and graduate students, many of whom became

well known in the English-speaking world because of their subsequent emigration to Great Britain and the United States. They include Egon Brunswik, Else Frenkel, Paul Lazarsfeld, Marie Jahoda, and Karl Popper.

Bühler's eminence was recognized in 1929 when he was offered the chair in psychology at Harvard University which had been vacant since William McDougall had moved to Duke University in 1927. He decided to reject the offer. He and his wife were happy in Vienna and had no desire to leave. They were to regret this decision a few years later when they came to the United States as refugees and had a very different reception. Neither was able to obtain a permanent position at a major American university. Part of the problem was that refugees had started to arrive in large numbers from Germany after the Nazi takeover in 1933. The refugees who arrived after the German annexation of Austria in 1938 were relative latecomers, and there were few positions left. Another factor is that Bühler had become famous for his work on language in the 1930s, a topic that was neglected in American psychology during the years of behaviorist domination. It became important with the rise of cognitive psychology in the 1960s, but by then, Bühler was over 80 years old and in poor health.

After several unsuccessful attempts to obtain permanent positions at a major American university, the Böhlers became clinical psychologists at different hospitals in Los Angeles. Charlotte Bühler had a minor resurgence in her career after she became an enthusiastic advocate of humanistic psychology, but her husband was much less able to adapt. He died in relative obscurity in Los Angeles in 1963.

Major Accomplishments

If Bühler is mentioned at all in American textbooks on the history of psychology, it is in connection with his early work in Würzburg. The rest of his work is largely unknown. This stands in sharp contrast to Europe, where Bühler's books have been constantly reissued, and there is a substantial secondary literature on his work (e.g., Eschbach 1984, 1988).

Bühler's appointment in Vienna was largely due to his eminence in developmental psychology. His major work on the subject, *The Mental Development of the*

Child, was published in 1918 and was already in its sixth edition by 1930 (Bühler 1930a). An abridged version of the book, *Outline of the Mental Development of the Child*, was published in 1919 and had reached its fifth edition in 1929 (Bühler 1929a). An English translation of the latter was published in 1930 (Bühler 1930b). Bühler's main work from the 1920s is *The Crisis of Psychology* (1929b). Like many of his contemporaries, he was concerned about the bewildering variety of approaches to psychology that existed and put forward some cogent proposals for how they might be reconciled. Bühler's *Theory of Language* (1934) is generally regarded as his greatest work. It has been massively influential, being cited by scholars as diverse as Karl Popper, Roman Jakobson, and Heinz Werner (Brock 1994). Several Wittgenstein scholars believe that it was an important influence on Wittgenstein's thought (e.g., Bartley 1973). It was belatedly translated into English in 1990 (Bühler 1990).

C

Carmichael, Leonard

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: November 9, 1898; Died: September 16, 1973.

Leonard Carmichael was born in Philadelphia to a family with long ties to Tufts University where he matriculated in 1917. He did his graduate work at Harvard mainly with Walter F. Dearborn, but also garnered influence from E. G. Boring, Leonard Troland, and William MacDougall. For the first half of his career, Carmichael distinguished himself as a researcher; in its last half, he became even more eminent as a representative of public scientific culture, playing leading roles with the Smithsonian Institution and the National Geographic Society.

Major Accomplishments/Contributions

Carmichael's doctoral dissertation centered on the question of the amount and type of behavior that could be proven to be inherited or genetic and gave essential direction to his subsequent work (Carmichael 1925). After visiting several German psychological laboratories as a Sheldon Fellow after obtaining his Ph.D., he joined the Princeton University psychology department, where he became a protégé of Howard C. Warren. There he found that frog embryos, anesthetized during the period in which motor reactions to external stimulation develop, exhibited comparable levels of motor development to control organisms when the anesthesia was removed. This finding, along with his prior theoretical activity, led him to take a radically interactionist position in the heredity-environment debate (Carmichael 1926a). His interest in reflex

physiology led him to contribute historical work on Robert Whytt and especially on Sir Charles Bell: Carmichael even founded a Charles Bell club for colleagues and students (Carmichael 1926b; Pfaffman 1980). On Warren's recommendation in 1927, Carmichael moved to Brown University. At Brown, Carmichael continued his own work and revived the laboratory which became very productive under his direction and after him under Walter S. Hunter, especially in the area of sensory psychology. During the 1930s Carmichael continued his experimental investigations of organized prenatal behavior. Using novel preparations, he studied the development of behavior in utero in several modalities across several organisms ranging from amphibians to cats. These findings were a physiological counterpoise to the dominant behaviorist theories of learning of that time. Over time, Carmichael came to identify more with the maturationists than the environmentalists regarding early development: his contributions to that debate reached their apogee around 1940. After this time, Carmichael became a consummate administrator and turned his energies to the promotion of science and scholarship in a variety of public contexts. He left Brown in 1936 for a brief stint at the University of Rochester as Dean of Arts and Sciences, and then in 1938 became President of his alma mater Tufts, a position he held for 15 years. During the Second World War he was the Director of the National Roster of Scientific and Specialized Personnel, responsible for assigning scientific talent to war-related projects, and he continued to contribute articles about personnel issues in science through the rest of his career. His scientific work during this period focused on perceptual and cognitive issues, including a study of reading and visual fatigue with his old graduate mentor W. F. Dearborn and also studies correlating brain activation measured by EEG activity with cognitive tasks. In mid-life, Carmichael found his calling in managing major

public scientific educational institutions. In 1953, he assumed the Secretaryship of the Smithsonian Institution in Washington D. C. and oversaw a major expansion of its programming including its new Museum of History and Technology in 1964 (now the National Museum of American History). He retired in 1964 and he moved to the National Geographic Society as Vice President for Research and Exploration, where he oversaw several important initiatives including the work of Jane Goodall on chimpanzees in the wild (earlier he had served as one of the scientific directors of the Yerkes Laboratories for Primate Biology) and contributed several forewords and other chapters to Society publications (e.g., Carmichael 1971). Carmichael was a prolific editor, serving as Psychology editor for Houghton Mifflin for many years and in that capacity bringing several psychologists to prominence including Carl Rogers. His expansive and nonpartisan approach to science in general and developmental science in particular was reflected his editorship of two editions of the *Manual for Child Psychology* in 1946 and 1954. He also continued to write on early development in a variety of contexts, including the very early development of the capacity for language (Carmichael 1964). From 1970 until the end of his life, he was President of the American Philosophical Society, where his papers, valuable both for their comprehensiveness and their insights into the development of public science during his career, reside. His vision of public service is also memorialized at Tufts in the Leonard Carmichael Society, a student volunteer community service organization.

Catholics in Psychology

C. KEVIN GILLESPIE

Loyola University of Chicago, Chicago, IL, USA

For centuries the question “What does Athens have to say to Jerusalem?” has framed the perennial issues pertaining to reason’s relationship to faith and science’s relationship to theology. Catholicism, throughout its long tradition, has consistently asked this question seeking to integrate the various dimensions of faith and reason. At the end of the nineteenth century, in its embryonic stage, psychology a word whose etymological roots suggest “the study of the soul” faced this question as it sought to become a scientific discipline. The purpose of this essay is to explore how psychology from its inception as a discipline has evolved in its theoretical relationship to a faith tradition, namely, Roman Catholicism, whose central purpose has involved the salvation of souls. An examination of how this relationship evolved in the last 125 years may be especially useful in framing both the past and contemporary trends in which there have existed conflicts and collaborations between the clinical and experimental disciplines of psychology and relevant Catholic psychological principles and practices.

The relation between faith and reason can be construed in a number of ways. One recent model derived from the faith and reason relationship is a four-category model proposed by John Haught in his book *From Conflict to Conversion* (1995). For Haught, the relationships between science (and for our purposes psychology) and religion (for our purposes Catholicism) may be related in terms of the categories conflict, contrast, contact, and confirmation.

Toward the end of this article, we will return to Haught's model so as to help us understanding the ways in which important ideas and insights of psychology have set a tone of conversation, at times conflicted and at other times collaborative, with Catholic ideas expressed by Catholic individuals and institutions. In this respect, we may find that there continues the perennial conversation between reason and faith, namely, between Athens and Jerusalem.

A historical overview of some of the more significant Catholic individuals and institutions involved in the relations with psychology is in order. We will present this entry within a framework of ideas formulated by Church authorities and carried out by individual Catholic psychologists and scholars. This entry will consider how some influential Catholic psychologists, first in Europe and then in the United States, through their publications and respective institution's programs became bridges between mainstream psychological and Catholic thought. As we shall see, their efforts, while at times fraught with conflict, led to breakthroughs in understanding and ultimately cooperation and collaboration. We will also find that at times some Catholic psychologists may have become too accommodating in some area of psychology (see below the critiques of Vitz and Groeshel) such that "Athens's" gain was "Jerusalem's" loss.

The framework of this study will be threefold, encompassing a consideration of issues pertaining to perennial ideas, pertinent institutions, and individuals who promoted the conversation or provoked controversies relating to Catholicism and psychology. First, we will tackle the initial acceptance and then significant resistance Roman Catholic leaders and thinkers initially had toward the major currents of psychology as they emerged in the later part of the nineteenth and early part of the twentieth centuries. As will be seen, this resistance represented the perennial concerns of philosophy from which a "new psychology" emerged in the later part of the nineteenth century. Next, we will explore how psychology's tendency toward atheism, determinism, materialism, and reductionism, most notably found in Freud and other psychoanalytic writers, prompted often hostile responses from Catholic Church leaders. We will then explore the lessening of these tensions between mainstream psychology and Catholicism during the second half of the twentieth

century to the point where Catholic institutions were promoting and at times requiring many of its clergy and religious to be trained in psychology.

From this brief survey of issues, key individuals whose professional endeavors in psychology enhanced Catholicism's project of balancing issues of faith with the explorations of reason will be presented. Especially considered will be the emergence of Catholic psychological endeavors beginning with developments of The Catholic University of America up to the current institutional response to the crisis of clergy abuse. Consideration will also be given to how the once ambivalent and even antagonistic relationship between mainstream psychology and Roman Catholicism has, at least from the Church's perspective, become an important alliance, both clinically and experimentally. Though Catholics have for decades been involved and even been leaders in disciplines such as counseling, education, psychiatry, and social work incorporating psychological insights and theories into their practices, for the purpose of this entry we will primarily be focused on how Catholicism has related to mainstream experimental and clinical psychology and the latter's auxiliary discipline of psychoanalytic thought.

Catholicism's Response to the New Psychology

When Wilhelm Wundt's experimental laboratory opened in Leipzig in 1879 ushering in the "new psychology" and its systematic experimental methods to study perceptual phenomena and psycho-physiological responses, the Catholic world was also ushering in new systematic philosophical and theological approaches to beliefs and moral values. In 1879, Pope Leo XIII promulgated the encyclical *Aeterni Patris* (On Restoring Christian Philosophy). The encyclical built upon one of the decrees of the First Vatican Council (1869–1870) in which it was asserted that faith and reason rather than at odds mutually support one other. For the pope the mutual relation of faith and reason could be found most persuasively in the thought of the medieval philosopher and theologian Thomas Aquinas (1225–1274). By means of *Aeterni Patris*, the pope formally resurrected Thomistic intellectual thought as a means for encountering the issues of the modern world. In this way, the encyclical served to spearhead a renaissance in Catholic philosophical and theological thought.

Through *Aeterni Patris*, the pope challenged Catholic scholars to acquaint themselves with the changes that the emerging sciences had presented this historical epoch. Such a challenge signaled the beginning of a new era in the relations between science and Catholicism, as it marked a turn from many reactionary stances that the Church had held since the dawn of the Enlightenment. Moreover, the pope sought to promote greater dialogue between the emerging modern sciences and Catholicism. The encyclical, in effect, represented an attempt to depart from the defensive posturing and reactionary stances the Church had taken since the theological disputes of the Reformation, the philosophical problems of the Enlightenment, and the political repercussions of the French Revolution and European nationalism.

In some respects, the pope's efforts were successful. The encyclical served to foster a movement away from Catholicism's medieval scholastic thought and promote a return to scholastic synthesis known as Thomism, which the pope felt combined a greater philosophical depth and anthropological breadth through which the Church could more effectively dialogue with the modern world. In issuing *Aeterni Patris*, then, Pope Leo XIII seemed to offer ways of reconciling the Church with the modern world. The challenge and concern for Catholicism's encounter with the contemporary culture and intellectual world, voiced by Pope Leo XIII in *Aeterni Patris*, were echoed more than a century later by Pope John Paul II in his 1998 encyclical *Fides et Ratio* and in 2006 by Pope Benedict XVI in his controversial address at the University of Regensburg entitled, *Faith, Reason and the University: Memories and Reflections* (2006). In all these instances, the popes reaffirmed the Catholic position of seeking a strong compatibilism between faith and reason and therefore between theology and science.

Toward the end of the nineteenth century, a century in which revolutions in Europe led to Catholic postures of retrenchment, e.g., Pope Pius IX's 1864 promulgation of *The Syllabus of Errors*, Pope Leo XIII (1810–1903) recognized that relations between religion and science needed a renaissance and even reconciliation in their relationship. In his encyclical *Aeterni Patris* (1879), he asserted that a contemporary Catholic conversation with science could only be made through a revitalization of philosophy, which for the pontiff meant an

updating of the philosophical integrative system of Thomas Aquinas (1225–1274).

For the Church, an essential dimension to this unity required a shared understanding of metaphysics. The positivism that emerged in mid-nineteenth century sciences, however, proposed a naturalism whose methods were disassociated from metaphysics. For instance, while Wundt still saw the need for psychology's relation to metaphysics, figures such as Freud, Watson, and even James did not. Given the fact that Church authorities tended to take a critical and even a reactive stance toward the scientific advancements of the period (e.g., Darwin's and Spencer's evolutionary theories), it made it difficult and almost heretical to study a discipline divorced of a metaphysical foundation. As we shall see, exceptions were made and distinctions developed that would allow for the emergence of first experimental and then the clinical dimensions of the "new psychology" within various Catholic institutions and among Catholic scholars and practitioners.

Among the early Catholic proponents engaging in experimental psychology while remaining linked to a Neo-Thomistic perspective were Fr. Desiree Mercier (1851–1926) and Fr. Edward Pace (1861–1938). Both priests were allowed and indeed encouraged by Church authorities to study under Wundt in Leipzig. Mercier, who in 1891 was appointed the director of Louvain's "Institut de philosophie," became a Catholic apologist for both the rational psychology of Thomism and the empirical psychology of Wundt through his three books, *Psychologie* (1892), *Les Origines de la Psychologie Contemporaine* (1897), and *La Psychologie Experimentale et la Philosophie Spiritualiste* (1900). Mercier, the first Catholic priest-psychologist, later was elevated to the rank of a Cardinal in the Church. Furthermore, he became a prominent international figure during and after the First World War and was influential in promoting not only neo-Thomistic thought at Louvain University in his native Belgium, but psychological programs as well. His influence eventually led to Louvain's prominence in European studies in the psychology of religion.

Edward Pace, meanwhile, following his studies in Leipzig returned to become in 1892 one of the first five psychologists elected to the American Psychological Association by its charter members. Later in 1905,

after teaching several courses in psychology through the University's philosophy department, Pace founded the first psychology department at any Catholic institution in America. By establishing this department as well as a department of education at The Catholic University America, Pace influenced generations of Catholic priests, religious brothers, and women religious to be trained in some of the tents of psychology as they applied to education and social work.

At the start of the twentieth century, Catholic scholars were generally sympathetic to the "new psychology." Besides Mercier and Pace, E. Boyd Barrett, an Irish Jesuit scholar, was generally favorable to experimental psychology and in 1911 expressed a complimentary tone to the work of Wundt, James, Kulpe, and Michotte for the popular English Catholic periodical *The Month*, whose readership consisted mostly of priests in Great Britain and in America. Within a short time, however, while the promotion of the "new psychology" by Mercier, Pace, and Barrett would prove influential within certain educational circles, the overall relationship between Catholicism and psychology would become hostile and suspicious. Catholicism's defensiveness became evident in two related movements against modern thought. One, known as Americanism, was specifically applied to progressive Catholic thought in the United States, while another, known as "Modernism," was specifically applied toward progressive Catholic thinkers in Europe. These reactions to progressive Catholic theological thought at the dawn of the twentieth century reinforced the defensive posture of Roman Catholicism to increased antagonism between the fledgling fields of both experimental and clinical psychology and the Church. The most significant antagonism occurred with the emergence of Freud's psychoanalytic writings.

Barrett offered one of Catholicism's first criticisms of Freud's psychoanalytic method and philosophy in an article published in 1921 in *The Month*, an influential Catholic scholarly journal. In the article, Barrett considered issues pertaining to the relations between psychoanalysis and Christian morality and concluded the article with critical concerns about Freud's method of dream interpretation and free association as well as Freud's "sex obsession" and the materialism underlying Freud's philosophy. As we shall see shortly, as the popularity of Freud's psychoanalytic method and

philosophy increased conflicts between psychology and religion grew.

In 1925, as a professor at Georgetown University, Barrett published *The New Psychology*. Here, he presented to a Catholic audience some of the major developments in the "new psychology." His purpose was to respond to Catholic dilemmas about psychology in general and psychoanalysis in particular. Many Catholics wondered for example if it was moral to see a psychoanalyst. Following his earlier criticism of Freud, Barrett expressed reservations about the determinism and materialism inherent in the Freudian philosophy, as well as about Freud's attacks on religious ideas and practices. For instance, Freud was critical of religion in his 1907 essay, "Obsessive Actions and Religious Practices" (1907) and his book, *Totem and Taboo* (1913). What was especially offensive to religious believers was Freud's statement asserting that the origin of religion was essentially the resolution of the Oedipus complex. Consequently, it was not surprising that Catholic writers, as well as writers representing other religious denominations were critical of Freudian theory and therapy. Barrett was one of the first Catholics to voice such criticism, but as will be seen, he certainly was not the last.

Arguably the most significant contribution to Catholic understandings of the emergent fields of psychology was the witness and work of Fr. Thomas Verner Moore (1877–1969). For decades (from 1900 until 1960) no other individual embodied the integration of Catholic identity and psychological research, both clinical and experimental. Not only was Moore trained as an experimental psychologist but he subsequently received training as a psychiatrist; and not only was Moore a priest, but later became a Benedictine monk and eventually a Carthusian monk.

Moore's career in psychology began during the summer of 1896 when he met Pace and later wrote a dissertation under Pace that led to a publication entitled *A Study in Reaction Time and Movement*. In 1903, Moore received his doctorate from Catholic University and then went on to Leipzig where he, like Pace before him, studied under Wundt. Upon his return to the United States in 1906, Moore went to the University of California in Berkeley where, besides serving as a Catholic chaplain at the university, he taught as an adjunct psychology professor. One of the

central motivations for Moore's career in psychology was that he found no incompatibility between the findings of experimental psychology and the principles of Catholicism. During a time when the clouds of conflict between religion and science filled the air, Moore approached psychology in a manner consistent with the principles of neo-Thomistic philosophy and theology and in this respect he sought to create a "neo-scholastic psychology."

Moore's interest in psychology was not to be confined to the experimental realm. Inspired by Lightner Witmer's clinic at the University of Pennsylvania, Moore established a Children's Clinic at Washington's Providence Hospital in 1916. The establishment of this clinic was preceded by Moore's medical training, first at Georgetown University and then in Germany where he attended courses by Kraepelin on psychiatry, Von Muller on neurology, and Kulpe on imagery. Returning to the United States, Moore continued his medical education by enrolling at Johns Hopkins University where he specialized in psychiatry. He completed his medical degree in 1915. It may be readily ascertained that Moore had an enormous impact in Catholicism's appropriation of psychology and psychiatry. For instance, from 1924 until his retirement in 1947 he trained several generations of Catholic teachers, many of them Catholic clergy and nuns. He also presented talks dealing with psychological issues to Catholic organizations as well as published numerous articles in Catholic publications. Through talks and publications, then, Moore reduced the perceptions and even prejudices that many Catholics had toward psychology.

Conflict and Controversies

Perhaps the most notable Catholic antagonists toward psychology were his professional colleagues at Catholic university, the philosophers Rudolf Allers and Fr. Fulton J. Sheen. As we shall see, the former played a critical role in criticizing Freud's method, theory, and philosophy within largely academic circles, while the latter critiqued Freud not only within the Catholic hierarchy, but among Catholic laity and even a larger non-Christian audience. The combined effect of Allers and Sheen's criticisms of Freud made their listeners wary not only of psychoanalysis but psychology in general.

An Austrian psychiatrist, Allers' training included attending Freud's last class at the University of Vienna. He later was significantly influenced by his association with the famous Italian priest-psychologist Agostino Gemelli. In working with Gemelli he witnessed how Catholic categories could absorb clinical and even psychodynamic categories without falling victim to what he considered the extremes of Freudian theory. Instead of Freud, therefore, Allers turned to the psychodynamic work of Alfred Adler and wrote both from psychiatric and philosophical perspectives.

Allers' first notable criticism of Freud came in his book, *The New Psychologies* (1933), where he attacked Freud's theory and method along five fronts. First, he found that psychoanalysis, with its psychoenergetic conception of libido, was based primarily on biological principles and hence was limited in its generalizability to the human condition. Secondly, Allers critiqued psychoanalysis as approaching mental phenomena from a materialistic perspective in explaining mental phenomena to be analyzed into distinct psychic energies. Thirdly, for Allers, Freud's theory of motivation tended to be hedonistic in its emphasis of psychic drives seeking pleasure, especially sexual pleasure. Allers also saw Freud's theory as essentially deterministic leaving no room for human freedom. Finally, Allers believed Freud's position was agnostic leaving no place for the soul. Subsequently in 1939, Allers further criticized Freud in *The Successful Error*. Allers expressed great concern over what he interpreted as Freud's influence as infecting not only psychology but also the fields of education, sociology, and most especially religion.

Allers' criticisms of Freud were supported by his Catholic University colleague, Fr. Fulton Sheen. Having completed a doctorate in theology at Catholic University in 1920 and in philosophy at Louvain in 1923 where he received the Mercier Prize for the outstanding dissertation, Sheen was well acquainted with the Thomistic project for Catholicism called for by Pope Leo XIII's encyclical *Aeterni Patris* and espoused by the "Institut de philosophie" founded at Louvain by Mercier. Trained with a keen philosophical mind and possessing rhetorical persuasive skills, Sheen served as a professor of philosophy at Catholic University from 1926 to 1950. From 1930 to 1950 he broadcast NBC's *The Catholic Hour*. From 1952 to 1957 he was

the ABC television host of *Life Is Worth Living*, which at the time was one of the most popular programs on television. His antagonism toward psychoanalysis combined with his rhetoric led generations of Catholics to be skeptical of psychology in general and what he would refer to as “Freudianism” in particular. Among his first of more than 65 books was *Old Errors and New Labels* (1931) in which he saw the emerging psychology of behaviorism as a new form of mechanism and Freud’s psychoanalysis as ushering in a new Pelagianism. Since the time of Augustine’s and others arguments against the fifth century writings of Pelagius, deemed heretical by the Church, Catholics have been wary of any philosophy that postulated that human beings can achieve fulfillment and perfection through their own efforts and did not need God’s grace to do so. Sheen found the goals of psychoanalysis as having Pelagian purposes. In other writings, Sheen also questioned the Freudian focus on pleasure and sexuality as well as the ethics involved in free association. It seemed that such a practice eliminated the use of one’s conscience.

Sheen, a scholar known for his style of seeking truth through controversy, asserted his best-known attack on psychoanalysis in 1947 when he castigated proponents of psychoanalysis from the pulpit of St. Patrick’s Cathedral, claiming it based on four faulty assumptions, namely, materialism, hedonism, infantilism, and eroticism. Moreover, in response to Joshua Lieberman’s best seller *Peace of Mind* (1946), which incorporated psychoanalytical insights into religious belief, as well as to assert more clearly his concerns about psychoanalysis, Sheen published *Peace of Soul* (1949). In this work, Sheen again expressed his criticism of psychoanalysis, although less antagonistically. Among his concerns was that among Catholics, therapy would soon take the place of confession. Other criticisms that Sheen launched toward psychoanalysis had to do with the ethics of the method of free association, as the practice of “saying anything that comes to your mind” suspended, according to Sheen and others, the use of one’s conscience (i.e., the superego in Freudian terms). For Sheen the purpose in life was not to be found in the pleasure seeking of needs and drive, but in the ends for one’s actions and the virtues by which one lives and pursues them.

For many years, then, Sheen was Catholicism’s most public opponent of psychoanalytic therapy and theory,

whether from the pulpit, in publications, or on his nationally syndicated radio and television shows. While Sheen later refined and even apologized for the vociferousness by which he opposed psychoanalysis, much of American Catholicism’s antagonism toward psychoanalysis and even psychology was the result of Sheen’s persuasive powers.

In Europe, meanwhile, Catholic scholars had similar criticisms of psychoanalysis though this was tempered by a series of publications which led to a greater openness. Perhaps the most significant of these was *Psychoanalytic Method and the Doctrine of Freud* (1936) by Roland Dalbiez (1893–1976). Dalbiez, a French Catholic psychoanalyst, distinguished psychoanalytic method from psychoanalytic philosophy and from the personality of Freud. He saw the contribution the Freudian psychoanalytic method had toward understanding the unconscious though he recognized that psychoanalysis leaves the fundamental problems of the human soul where it found them. Dalbiez’s writings influenced the noted French Thomistic scholar Jacques Maritain and led to Maritain’s significant article, “Freudianism and Psychoanalysis” through which he accepted and popularized among Catholic readers Dalbiez’s distinction of the psychoanalytic method, Freudian psychology, and Freudian philosophy. The former he viewed as acceptable while the latter clashed with Catholic philosophical values and theological tenets.

Dalbiez’s work was complemented in the United States by Gregory Zilboorg. The author of *A History of Medical Psychology* and a prominent psychoanalyst, Zilboorg challenged the atheistic tendency of psychoanalytic theory. For example, in *Freud and Religion* (1958), Zilboorg challenged the interpretation of Freud’s editor, Ernest Jones’, that atheism is necessary for psychoanalysis. For Zilboorg it was possible for psychoanalytic thought to be open to religious values and beliefs. He proposed this nuanced understanding of psychoanalysis to Catholic associates both in Europe and in the United States. He, moreover, served as a colleague of Thomas Verner Moore at the Catholic University. Zilboorg also gave lectures at the Jesuit seminary in Woodstock, Maryland, where he befriended such Jesuit theologians as John Courtney Murray and Gustave Weigel, who were major American Catholic figures during the Second Vatican Council. In addition, Zilboorg presented lectures at the St. John’s

Summer Institute in Collegeville, Minnesota where in 1956 he met and even counseled the noted Catholic author, Thomas Merton.

While psychoanalysts such as Dalbiez and Zilboorg had begun to make important distinctions so that important dimensions of psychoanalysis could be appropriated by Catholicism, the quest for a neo-Thomistic psychology inspired by *Aeterni Patris* and launched by Mercier, Pace, Moore, and others did not fare as well. In his *History of American Psychology* (1952), A.A. Roback critically assessed the value of Catechism's neo-scholastic approach to psychology. He found that mainstream psychology neglected neo-scholastic psychology for two reasons. First, seeking to deal with topics related to the soul was seen by most psychologists as not relevant to the field. For most psychologists the soul was seen as a construct which could not be quantifiably measured or proven. In addition, psychologists like many scientists still viewed the Catholic Church with suspicion recalling how authorities in its past silenced predecessors such as Galileo and Copernicus and even burnt Giordano Bruno at the stake.

Roback, nevertheless, sought to give neo-scholastic psychology a fair hearing by providing an overview of the psychology of Thomas Aquinas and referred to the works of Pace and Moore. At the same time, he found such psychology limited in scope as he concluded that research by Moore and his students at Catholic University under Moore and others often had inadequate standards and meager results. In this respect, Roback's book may be seen as sounding the death knell for neo-scholastic psychology.

On the other hand, in the mid-twentieth century Henryk Mysiak and Virginia M. Staudt (later Sexton) published *Catholics in Psychology: A Historical Survey*. Published in 1954 the book was part of the McGraw-Hill Psychological Series and included an introduction by the noted historian of psychology, Edwin G. Boring (Mysiak and Staudt 1954). In this respect, the book served as both a scholarly effort and a symbolic event. Designed to draw more Catholics to the field of psychology as well as to help non-Catholics understand Catholicism's openness to use of psychological theory, the book served to build bridges.

The same year, Magda Arnold, a psychologist, combined with a Jesuit philosopher, Fr. James Gasson, to

publish an edited book, *The Human Person: An Approach to an Integral Theory of Person* (1954). The book, in which Arnold wrote four chapters, sought to combine personality theory with a Christian, i.e., Thomistic, understanding of human nature. At the time of the book's publication, she was a professor at Loyola University in Chicago but she would then move to Spring Hill College (a Jesuit institution in Mobile, Alabama). She performed groundbreaking research in clinical research in the Thematic Apperception Test as well as in emotions theory. Her book, *Emotion and Personality* (1960), represented an integrative theory of emotions which later came to serve as the foundation for a cognitive appraisal theory of emotions. Incorporating a Thomistic theory of values into her clinical research Arnold demonstrated the relevance of moral theory to a psychology of emotions. In 2006, an entire issue of *Cognitive and Emotion* evaluated Arnold's appraisal theory and its influence on the contemporary cognitive theory of emotions.

Similarly, another female Catholic psychologist, Sr. Annette Walters, provided an important work by editing *Readings in Psychology* (1962). Designed for students at Catholic colleges and universities, Walters selected 121 excerpts from mainstream psychologists and psychoanalysts. While upholding the Catholic principles against atheism, determinism, materialism, positivism, and reductionism, Walters nevertheless introduced her readers to the works of the major psychologists of the period. Among these she included her former professor at the University of Minnesota and lifelong friend, B.F. Skinner. In the introduction of each section Walters critiqued some of the approaches that were inconsistent to Catholic thought. These included psychological determinism which posits that the will is not free but determined by instincts and drives (Freudian) or patterns of reinforcement (Skinner); materialism and its lack of a transcendent teleology; positivism in its tendency to see science as the only path to truth and in its focus on valid theory construction; and operational behaviorism which opposed metaphysics and its negation of other epistemologies.

It should be noted, that Walters, a professor of St. Catherine's College in St. Paul, Minnesota, and later the first Chair of the Psychology Department at St. Ambrose College in Davenport, Iowa, served for four decades as a major conduit of psychology toward

a wide variety of Catholics, most especially her fellow women religious. For example, her position as the Executive Secretary of the Sisters Formation Conference of Catholic Women Religious influenced the spread of psychological testing for applicants to religious life as well as clinical care for nuns who needed it.

Sr. Annette was also one of the organizers of the interreligious St. John's Institute in Collegeville, Minnesota, which from 1954 to 1971 enabled clergy from a variety of denominations to attend workshops from leading psychiatrists, psychologists, and even psychoanalysts of the period. Over the nearly 20 years of the Institute, the clergy received presentations from Walters and Zilboorg as well as prominent psychologists, psychiatrists, and psychoanalysts who included psychological luminaries such as Nathan Ackerman, Leo Bartemeier, Francis Braceland, Dana Farnsworth, Rev. James Gill, S.J., Hyman Lippman, Noel Mailloux, O.P., Elvin Semrad, and Karl Stern.

Perhaps not coincidentally, the Institute began within a year after Pope Pius XII gave his blessing to participants at the International Congress of Psychotherapy and Clinical Psychology that met in Rome in 1954. Although the pope expressed the Church's concerns about the atheism, determinism, and materialism espoused by many psychoanalysts, he, nevertheless, affirmed the significant contribution of clinical psychology noting how practitioners assisted the Church's quest "for the knowledge of the soul." The pope's affirmation of psychology certainly influenced the inauguration in 1954 of the St. John's Summer Institute at St. John's College, Collegeville, Minnesota, where clergy from Catholic and other religious denominations met with leading psychologists and psychiatrists of the era. From 1954–1973 the Institute served to inform a whole generation of Catholic religious leaders on such topics as mental illness, personality dynamics, and the influence of the unconscious.

Curran, much like Thomas Verner Moore, embodied the changes in Catholicism's relations with mainstream psychology more than Fr. Charles Curran. A graduate of Ohio State's psychology department where he trained under Carl Rogers, Curran introduced Roger's client-centered approach to the Catholic culture. His bridge building is evident in that Rogers wrote the introduction to Curran's first book, *Personality*

Factors in Counseling (1942), while Curran's bishop Michael J. Ready wrote the book's preface.

Throughout his 30 years of teaching and research, Curran's thought integrating his psychological expertise with his faith identity evolved. This evolution may best be seen in his movement from a focus on virtue to that of value. For example, his book, *Counseling in Catholic Life and Education* (1952), shows that counseling from a client-centered perspective is consonant with the Thomistic model. In this work, besides introducing his readers (mostly Catholic) to the basics of counseling, he makes reference to moral virtues such as "good counsel" and "prudence." Almost two decades later his post Vatican II book, *Religious Values in Counseling and Psychotherapy*, Curran avoids any Thomistic reference as he shifts from a focus on virtue to values and uses such post-Council catch words as "encounter," "engagement," and "experience."

Catholic scholars had an approach-avoidant attitude to the psychodynamic concepts and methods of Carl Jung. For instance, Fr. Victor White, a British Dominican priest, corresponded with Jung and even had Jung write the foreword to his book *God and the Unconscious* (1953). As one of the first Catholic writers to find value in Jung's approach to religion, White, during the 1940–1950s, wrote eloquently and popularized Jungian concepts to a Catholic audience which also included the book *Soul and Psyche* (1960). The two, however, had a falling out over White's criticism of Jung's theoretical approach to the problem of evil.

Besides White, Fr. Raymond Hostie, S.J., a professor at Louvain, also gave Jung's work serious consideration in the book *Religion and the Psychology of Jung* (1957). Hostie's presentation of Jung became influential within Catholic circles as Catholic scholars and therapists alike began to explore Jung's thought with fewer reservations than they had with Freud. Indeed beginning shortly after the Second Vatican Council Catholic, clergy and religious began to apply Jung's insights to spiritual practices at Catholic retreat houses and in programs of religious formation. For example, Jung's theory of archetypes and symbols were readily used by retreat directors and Catholic liturgists to explore how to tap into the unconscious individually and collectively so as to enhance an individual and a community's life of prayer. The *zeitgeist* of the 1960s, moreover, with its plethora of institutional issues and social changes made

the conversation between Jungian theory and spirituality even more significant. Catholic theologians found in Jungian thought bridges between western and eastern spirituality as well as pathways to revitalize traditional spiritual practices.

Similarly, neo-Freudian developmental constructs found in ego psychology and object relation theories have been appropriated by Catholic scholars, psychologists, and even Catholic moralists. For example, Bernard Haring an influential German moral theologian incorporated humanistic psychology as well as Erikson's eight stages of development into his approach to moral theology. Haring's use of developmental constructs had the effect of incorporating psychological developmental constructs into the Church's approaches to sin, especially those related to sexual maturation, for example, masturbation. Such an approach became used widely by Catholic theologians and taught in Catholic seminaries.

Meanwhile Argentinean psychoanalyst, Ann Marie Rizzuto, made a significant contribution in her *Birth of the Living God* (1979) in which she used D.W. Winnicott's recasting of Freud's concept of illusion to show how a child's image of God emerges. The Jesuit priest, psychiatrist, and psychoanalyst, William Meissner, built upon Rizzuto's use of Winnicott's transitional phenomena to assert in *Psychoanalysis and Religious Experience* (Meissner 1984) that religious belief should not be seen as an escape from reality, but a necessary condition for healthy engagement with reality.

It should be noted that Meissner has spent a lifetime incorporating and integrating constructs from Freudian theory (especially ego psychology and object relations theory) into an integrative dialogue with Catholicism. Since 1961 Meissner has published voluminous collections of articles and books on the psychology and religion. Often relying on the Thomistic axiom *gratia perficit naturam* (grace perfects nature), he has sought to demonstrate the way religious experiences can be effectively described through psychoanalytical constructs. For example, in his 1984 work, *Psychoanalysis and Religious Experience* (for which Meissner received the Oscar Pfitzer award), he reinterprets Freud's *Future of an Illusion* through the lenses of Winnicott's theory of transitional objects and space. Here, Meissner considers illusions as transitional phenomena necessary for psychological growth. In this

respect, Meissner sees religion as providing forms of these transitional phenomena, the experience of which can serve as the basis as well as the supports for ongoing psychological growth.

In a subsequent work, *Life and Faith* (1987), Meissner developed a psychology of grace founded on the position that the order of grace is perfective of the order of nature. He thereby is led to postulate that the actions of grace, while not immediately experienced, can be understood as having influence on the ego which can change a person's relationship to self, others, and to God. Moreover, he asserts that grace, although operating ultimately in mystery and without conscious awareness, does have an intimate influence on psychic functioning, including the unconscious. For Meissner then, while grace cannot be directly experienced, its effects can be both experienced and observed. To demonstrate these assertions in *Ignatius of Loyola: The Psychology of a Saint* (1992), Meissner provided a detailed case study of the conversion experiences of Ignatius of Loyola.

In a later work, *Psychoanalysis and Catholicism-Dialogues in Transformation* (2008), Meissner summarized his efforts of showing the confluences between psychoanalytic concepts and Catholic doctrines. Besides reviewing his work on psychology of grace and his work on Ignatius of Loyola, Meissner also considers the psychological aspects of sacramental theology from a psychoanalytical perspective as well as the cultic origins of the Church. He concludes his overview calling for a dialogue in which psychoanalytic understandings of Catholicism are "more sophisticated and religiously attuned."

Psychology and Catholic Institutions

If it can be presumed that educational institutions embody the beliefs and values of the individual scholars teaching and writing in them, then a picture of how relations between psychology and Catholicism evolved may be viewed from the perspective of how professors at Catholic colleges and universities appropriated the insights of clinical psychology and the findings of experimental psychology. Certainly, while controversies involving psychoanalysis swirled around the Catholic world for decades, programs related to educational and experimental psychology, especially in areas related to child development began to be appropriated by

Catholic educators. As noted above, The Catholic University of America under Pace had the first Catholic psychology department, and under Moore the department expanded its program to include clinical research. In 1912, St. Louis University introduced its first experimental psychology classes and in 1926 formally established a psychology department under the Jesuit psychologists Frs. Herbert Gruender and Raphael McCarthy. Gruender, who obtained doctorate from the University of Bonn, did work at Columbia University under Robert S. Woodworth, while McCarthy earned a combined doctorate in psychology, philosophy, and physiology. Both psychology professors through their publications and presentations became active proponents of incorporating the findings of psychology into the Catholic world.

Prominent psychology departments were also founded at Fordham University and Loyola University of Chicago. As we shall now consider, both departments figured significantly in improving Catholic attitudes toward the field of psychology and the appropriation of many of its methods and theories.

Founded in 1934 by Fr. Walter Sommers, S.J., Fordham's Department of Psychology played an important role in relations between mainstream psychology and Catholicism. Among the notable contributors was Fr. William Bier, S.J. As a doctoral student under T.V. Moore at Catholic University, Bier accepted the challenge of his mentor to develop psychological tests to screen applicants to Catholic convents and seminaries. For his dissertation Bier developed a MMPI scale for such applicants and in 1948 began using it to screen applicants to his Jesuit order. Later, beginning in 1955 and lasting until 1977 Bier directed a series of 11 pastoral psychological programs for Catholic clergy, religious, and laity. Perhaps Bier's most important contribution was his helping to found the American Catholic Psychological Association (ACPA) in 1949 and becoming its first executive secretary. As stated in its charter the ACPA's mission was twofold: (1) to interpret to Catholics the meaning of modern psychology and to advance its acceptance in Catholic circles; (2) to work toward the integration of psychology with Catholic thought and practice. By the time of ACPA's demise in 1969 these goals had largely been achieved. It should be noted that a few years later many members of ACPA helped to form the group

Psychologists Interested in Religious Issues, which in 1975 was approved as Division 36 in the APA and later bore the name of Psychology and Religion. Catholics such as William Bier, Mary Reuder, Virginia Staudt Sexton, and Eugene Kennedy were among the founders of the division. An annual award is given by this division in Bier's name.

During the same period Loyola University's Department of Psychology further developed bridges of collaboration between mainstream psychology and Catholicism. Led by Fr. Vincent Herr, S.J., Departmental Chair from 1945 to 1965, and aided by clinicians and researchers such as Magda Arnold, Charles Curran, Martin D'Arcy, and Eugene Kennedy, the Department was both innovative and industrious in its clinical research. For example, as recipients of a substantial grant from the National Institute of Health, Loyola conducted a psychological study on Catholic seminarians from 1957 to 1962 and then on priests from 1968 to 1972 and supported The National Conference of Catholic Bishops. In 1971 the results were published in *The Catholic Priest in the United States: Psychological Investigations*. The study raised serious questions about the emotional maturity of American Catholic priests and called for significant changes in the psychological preparation of priests. Subsequently aided by another grant, during the mid-1970s Loyola's Department conducted a psychological study using several psychometric tests of 81 active and retired US Catholic bishops including archbishops and cardinals. Among these findings was that compared to the priests, the bishops showed significantly more "trust, successfully formed identity, self-esteem, positive affectual experience, expressiveness and comfort in social contexts."

Vatican II and Its Consequences of Conflict and Collaboration

From 1962 to 1965 a general convocation of Catholic bishops convened at The Second Vatican Council and engaged in a wide-ranging dialogue among themselves as well as representatives from other faith traditions. The outgrowth was a series of documents and promulgations that promoted substantial changes in the way in which the Roman Catholic Church related to the world's religions, cultures, and disciplines of knowledge. Among these changes was how the Church's

authorities, scholars, and institutions appropriated psychological constructs.

For example, the Documents called for “appropriate use” of the secular sciences, especially psychology and sociology. One example of such “appropriate use” was how the Church emphasized the intimate partnership in the sacrament of marriage that required a free and mature capacity for making such a commitment. In cases when a marriage tribunal determined that one or both partners were not psychologically capable of making such a commitment then the sacrament of marriage could be annulled. In order to reach this interpretation, the Church’s diocesan marriage tribunals needed to call upon the expertise of those trained in clinical psychology.

As we have seen earlier in this essay, Catholic authorities such as Bishop Fulton Sheen challenged Freud’s approach to sexuality. Freud’s connecting religion with neurosis and sexual repression certainly made Catholic authorities dismissive of not only Freud but many other psychologists. During the middle of the twentieth century, the conflict between psychological disciplines and Catholicism began to subside. Controversial concerns however flared up again in 1968 when Pope Paul VI published *Humanae Vitae: On the Regulation of Birth*. In which the pope promulgated to Catholics that artificial contraception was an unlawful birth control method. Considerable controversy ensued both within and outside the Church, some of which was due to the fact that the pope went against the advice of the majority of his commission who were asked to consider the issue. Moreover, the American Catholic Psychological Association weighed in on the matter by issuing a statement at its 1968 convention. In the statement the ACPA criticized the encyclical’s understanding of human relationships and psychology of personality. Moreover, ACPA raised questions as to the encyclical’s seemingly lack of awareness of the conscious and unconscious factors involved in marital intimacy. The organization of Catholic psychologists also believed that the pope had organized his conclusion based upon an outmoded faculty psychology.

While many Catholic psychologists challenged the Catholic’s position on artificial contraception, the late 1960s was a period when the Church was removing the last vestiges of hostility toward psychology and

psychoanalysis in particular. During the 1970s it was general practice for candidates for the priesthood or religious life to be given psychological tests, such as the MMPI, Rorschach, and Thematic Apperception test, and to be interviewed by a clinical psychologist. Moreover, many clergy and religious would be encouraged by their religious superiors to see a psychologist or a counselor.

Ongoing and midlife formation programs for priests and religious were encouraged, with many of them having a psychological emphasis. At the same time, pastoral programs in dioceses, parishes, schools, and retreat centers began using the methods and understandings advocated by psychologists in initiating and deepening programs for those considering marriage, those already married, and those who had experienced separation, divorce, or the death of a spouse.

This dialogue between psychological constructs and practices and Catholic moral principles and beliefs took significant twists and turns when there occurred developments in clinical diagnostic categories. In 1973 there occurred the removal of the diagnoses of homosexuality from the DSM (The Diagnostic and Statistical Manual) list of pathological diagnosis. Similarly in 1975 the American Psychological Association instructed its members to avoid the stigma of mental illness associated with individuals having homosexual orientations; significant controversy ensued between the findings of clinical psychology and the principles of Catholic morality. Later, in 1986, one of the Church’s most significant teaching bodies, The Congregation for the Doctrine of the Faith, issued a pastoral statement on the pastoral care of persons with homosexual orientation. Written by Cardinal Joseph Ratzinger (the future Pope Benedict XVI), the statement addressed prejudices against those men and women whose orientation was homosexual. At the same time, the letter set forth distinctions and principles that in subsequent years has led to the Church’s objections not to a person having a homosexual orientation but to his or her practice of homosexual acts. While Church authorities have made pastoral statements against prejudice toward those with homosexual orientations, the Church has, nevertheless, been seen by many in the psychological community as often opposed to the rights of homosexuals and thereby impeding a homosexual’s mental health and self-esteem.

Also significant in the Church's relationship with the psychology community has been the inclusion of the diagnosis of Post Traumatic Stress Disorder (PTSD) in 1980 in DSM II. The incorporation of this diagnosis in the DSM had an enormous effect on the Catholic Church, initially in the United States and then elsewhere for the diagnostic category served to bring to light the amount of abuse suffered at the hands of Catholic clergy and religious. Once some of PTSD's diagnostic symptoms were listed, for example, distress from flashbacks and experiences from a past physical and/or psychological trauma, the courts were more able and willing to respond to the complaints of victims who reported in therapy recalling how they had been sexually abused. By 1982 the clinical diagnostic shift brought the issue from the clinics to the courts. Due to the ecclesiological system of the Catholic Churches with its diocesan and religious order structures, law suits were filed and won not only against the individual perpetrator but against bishops and other religious leaders who were seen as allowing such abuse to continue.

On the other hand, what became known as the clerical abuse scandal has led to a great deal of collaboration between Catholic religious leaders and the clinical psychology community. What in the 1950s may have been seen as an emerging trend toward collaboration between Catholicism and the psychological community became in the 1980s a necessary and even legal requirement. Not only did the Church's vocation offices that served as the gate-keeping offices become more careful in the type of person they admitted, but bishops and religious superiors were also more willing to pay for extended outpatient and even inpatient treatment of priests and religious. Moreover, by 2002, after paying out more than a billion dollars of legal fees the Church had established strict psychological boundary regulations for its priests, religious, and for any of its lay people who work in their ministries. Such regulations, it should be noted, were the result of intensive collaboration with the clinical psychological community.

The post Vatican II Church witnessed a greater number of Catholics engaged in psychological disciplines. What is more is that Catholic psychologists became best-selling authors, not only among Catholics, but in a larger world. The writings of the Dutch priest-

psychologists, Fr. Adrian van Kaam, started the trend as he incorporated his religious training with his clinical training at the Adlerian Institute of Chicago. Another Dutch priest, Henri Nouwen, used his clinical training at the Menninger Clinic to incorporate psychological themes into his more than 40 books on psycho-spiritual themes. Other best-selling Catholic psycho-spiritual authors include Eugene Kennedy, Joyce Rupp, Thomas Moore, and Robert Wicks. Each of their writings demonstrate how psychological themes can be appropriated within a spirituality sympathetic, although not exclusively, to the Catholic faith and its spirituality. On the other hand, two Catholic psychological authors, Paul Vitz (*Psychology as Religion*) and Benedict Groeschel (*The Psychology of Spiritual Development*), have expressed reservations about the over-psychologizing of psychological themes leading to the neglect of faith.

From the clinical research perspective, Edward Shafranske and Len Sperry have made important recent contributions to the field of psychology of religion and by so doing enhanced the dialogue between psychology and Catholicism in particular. Shafranske, a psychoanalyst and former president of APA's Division 36, has written numerous articles pertaining to the relationship between religion and psychology within the clinical context. Perhaps his most significant contribution was his editing of *Religion and the Clinical Practice of Psychology*. Published by the American Psychological Association Press in 1995, the book represented a breakthrough in mainstream psychology's recognition of religious research. It also was one of the first of a series of APA books on the subject. Leo Sperry, meanwhile, has authored more than 300 publications, among them works pertaining to priestly ministry in the Catholic Church. Furthermore, Thomas Plante has also emerged as a leading Catholic psychologist. Among Plante's host of publications in the area of psychology and spirituality is his 2009 publication *Spiritual Practices in Psychotherapy: Thirteen Tools for Enhancing Psychological Health*.

In recent years the field of psychology of religion has produced a large number of articles, books, and journals that has relevance to Catholic beliefs and practices. While not themselves Catholic, the research of Kenneth Pargament about religious factors used in coping, Harold Koenig concerning spiritual factors in aging, Crystal Park pertaining to variables of religion and

meaning-making frameworks, Robert Emmons about gratitude, and Robert Enright and Everett Worthington on forgiveness have proved complementary to Catholic beliefs. Moreover, the research by Catholics such as Michael Donohue's in the area of social-psychological research on sexual abstinence, Ralph Piedmont's psychometrical work on spiritual transcendence scales, Joseph Ciarrocchi on scrupulosity and positive psychology, and Nichole Murray-Swank's work on spiritual struggle have made important contributions to the field that complements their Catholic backgrounds.

Looking ahead to the future of psychology's relations with Catholicism, it should be mentioned that the philosophical contributions of Bernard Lonergan and Charles Taylor have served to enhance Catholicism's theoretical appropriation of scientific thought, including psychology. Lonergan's book, *Insight: A Study of Human Understanding* (1957) has only begun to become assimilated by scholars within and outside the Catholic community as it offers a new epistemology whereby cognitive experiences are seen as experiments in thoughts which in turn have fostered new forms of dialogue between religion and science. Taylor meanwhile through his commentary of the self and identity in *Sources of the Self* (1989) and the individual and community in *A Secular Age* (2007) has opened up pathways of Catholic thought through which Catholic philosophers and theologians can engage the scientific world, including the clinical and experimental disciplines of psychology.

Categorizing and Conclusion

Let us turn now to consider how Haught's four categories of relating science and religion may help us understand the historical interactions of mainstream clinical and experimental psychology with Catholic thought in terms of ideas, individuals, and institutions. The categories are: (1) conflict by which religion is utterly opposed to science or science invalidates religion; (2) contrast by which conflict is impossible since religion and science are clearly different from one another; (3) contact by which science and religion, while distinct, always can have implications and consonance for one another; and (4) confirmation by which it emphasizes ways in which religion supports scientific discovery. The following is a list of some of the events that may be categorized into one of the Haught's four categories.

Conflict: Seen in such Catholic scholars as Rudolf Allers and Fulton Sheen. Conflict surrounded Freudian psychoanalysis due to its tendencies toward atheism, determinism, and mechanism; also Catholicism clashed with psychologist proponents of Behaviorism and Operational Positivism, such as Watson and Skinner, due to the theoretical positions of determinism, materialism, and reductionism; the controversy between Catholic psychologists and theologians and the Catholic hierarchy as a result of Pope Paul VI's encyclical *Humanae Vitae*; the controversy surrounding the diagnosis of homosexual identity being removed as a diagnosis in the Diagnostic Statistical Manual.

Contrast: The emergence of the "new psychology" apart from philosophical psychology; the avoidance of religious topics by psychotherapists or research psychologists.

Contact: Pope Leo XIII's encyclical *Aeterni Patris*; The work of Frs. Mercier, Pace, Moore, and Barrett; the formation of the American Catholic Psychological Association and its success in helping mainstream psychology understand Catholicism and enabling Catholics to understand psychology; the psychoanalytical works of Dalbiez, Zilboorg, Rizzuto, and Meissner; the incorporation of Jung into Catholic thought by White, Hostie, and later others; publication of *Catholics in Psychology* (1954) by Mysiak and Staudt, *The Human Person: An Approach to an Integral Theory of Personality* (1954), Walter's *Readings in Psychology* (1962), and Meissner's *Ignatius of Loyola A Biography of a Saint* (Meissner 1992).

Confirmation: Pope Pius XII's unifying statement "for the knowledge of the soul" in his talk to psychotherapists; St. John's Summer Institute; the studies performed by Herr, Curran, Kennedy, and others at the psychology department at Loyola University involving the psychological testing of seminarians, priests, and bishops; pertinent Documents of the Second Vatican Council that led to a more psychological understanding of marriage; Catholic moral theologians such as Haring using Erikson's stages of development; recent APA publications dealing with religious and spiritual themes

Categorizing some of the more prominent events in this historical overview in terms of Haught's four categories enables us to recognize how psychology as an experimental and clinical discipline has had and still has different ways of relating to Catholic ideas as

embodied in its institutions and its individual representatives. These categories also may help us see more clearly in what ways the reasoning of psychology has and may continue to complement the faith dynamics of Catholics. Seen in the light of this historical overview of ideas, individuals, and institutions that have shaped the conversation between the theories of psychology and the tenets of Catholicism, we may conclude that the respective individuals and institutions are taking each other's positions more seriously and sympathetically. It would seem that gone are the days of an embattled faith reluctant to accept or apply the findings and insights of psychology. At the same time, psychologists generally seem more open to studying religious variables and employing spiritual strategies when appropriate in clinical settings. In this respect, then, we may conclude that Athens and Jerusalem indeed continue to have something to say to one another.

Basic Biography

Raymond B. Cattell was born on March 20, 1905, in Hilltop, England. He described having a positive upbringing throughout his childhood and youth at home and at school. Cattell had a love for the sea and

sailing ships. At the age of 9, World War I broke out and a mansion by his home had been transformed into a hospital for wounded soldiers. This event inspired Cattell to understand the brevity of life and the need to accomplish during one's life. Although his parents did not attend University, Cattell managed to excel in his studies, received his undergraduate degree in chemistry in 1924 at the University of London, and continued there for his Ph.D. in psychology in 1929.

Due to the combination of his overloaded work schedule, unhealthy eating routine, and poor living conditions, Cattell developed a chronic stomach problem. Despite those challenges, he did not let that get in the way of his work.

After teaching and working at a psychology clinic, Raymond Cattell moved to the United States in 1937 to teach at Columbia University, and later in Clark and Harvard Universities. By 1946, he settled teaching in University of Illinois for 27 years.

After retiring in 1973, Cattell moved to Colorado and then to Hawaii where he worked part-time in the University of Hawaii. There, he not only taught, conducted research, and wrote, but also spent family time with his third wife, five children, and two stepchildren.

Numerous factors contributed to Cattell's understanding of the psychology of people. Firstly, the carnage from World War I caused Cattell to question human drives that lead to chaos in society. Secondly, Cattell was highly influenced by Bertrand Russell, George Bernard Shaw, H.G. Wells, Aldous Huxley, and Haldane, all of whom he met with in London. Cattell also related his studies of human nature to the scientific method. He thought he was fortunate to work with people like Charles Spearman.

Cattell remained active in writing even through his weaker days when he was diagnosed with colon cancer, prostate cancer, and heart disease. At the age of 92, Cattell died in February 2, 1998, at his home in Hawaii.

Accomplishments

Cattell studied the multivariate approach to psychology in which he believed that behavior should be studied as a whole rather than broken down into dimensions and studied in isolation. This allowed life events to be studied outside the laboratory, which otherwise would not be able to be studied in an unnatural environment.

Cattell focused on the uniqueness of individuals, or what is known as trait theories. His theory suggests that motivation and learning shape behavior. He also attributed changes in behavior to neurophysiological, genetic, familial, social, and cultural factors.

During WWII, Cattell not only taught, but also worked for the military, creating psychological tests. Throughout his career, he created other such tests that would measure intelligence and personality traits. He is best known for his 16 Personality Factor questionnaire, published in 1949, which is used to profile individuals under 16 different source traits. Cattell measured personality in three ways: L-Data (observing one's life), Q-Data (questionnaire), and T-Data (personality test). Today, Cattell's questionnaires are used by companies and organizations to match individuals with certain occupations, depending on their psychological character.

Additionally, Cattell, together with Horn, created the Theory of Fluid and Crystallized Intelligences. He was an early proponent of using Factor analysis, in which correlations are made from long lists of information to make smaller categories. Cattell also discovered advanced statistical techniques he applied to the study of intelligence. He wrote up the Culture Fair Intelligence Test, with the intentions of it preventing the biases of written language and cultural background from defining one's intelligence.

Cattell was the author or coauthor of more than 50 books and 400 articles. Many of his books were written in collaboration with others. One of his most influential books was *Personality: A Systematic, Theoretical, and Factual Study*, which explained differences in individual's cognition, motivation, and temperament.

In 1960, Cattell brought together numerous international research-oriented psychologists, which later formed the Society for Multivariate Experimental Psychology, and the journal *Multivariate Behavioral Research*. Cattell organized researchers from all over the world to work in his laboratory in the University of Illinois.

Cattell was voted as the 16th most eminent psychologist of the twentieth century influential figure. Among the numerous awards received, Cattell turned down the American Psychological Foundation Gold Medal Award for Lifetime Achievement in the Science of Psychology (1997) because of a controversy.

Cerebral Dominance

STANLEY FINGER

Washington University, St. Louis, MO, USA

The concept of cerebral dominance refers to the functional inequality of the cerebral hemispheres. It does not hold that the right hemisphere controls the muscles of the left side of the body or that it receives the bulk of the sensory information relating to the left side, and that the opposite is true for the left hemisphere. Rather, it relates to differences of a different sort – differences in cognitive functions such as speaking, consciously comprehending spoken language, and dealing with the spatial world, as exemplified by using a map or trying to draw a clock or a house.

The current literature on cerebral dominance is massive and has experienced very rapid growth after the 1950s, stimulated in part by what was being discovered with split-brain patients. It is based on healthy and brain-damaged subjects, and a wide variety of tools. Some of the information gained has come from post-mortems and other anatomical studies, and even more is now coming from physiological studies, especially those using the latest scans to measure cerebral activity under different conditions. What we now know has benefitted greatly from increasingly sophisticated behavioral tools for assessing specific functions.

Large books can and have been written about the latest findings related to cerebral dominance. Yet much

less has been written about how the concept itself emerged in the nineteenth century (for some reviews, see Oppenheimer 1977; Harrington 1985, 1987; Finger 1994). In this contribution, the focus will be on the formative years of cerebral dominance. Needless to say, the idea of hemispheric inequality was not something that made intrinsic sense when it first emerged, and this fact, combined with variability across individuals, clearly hindered its immediate acceptance.

Early Thoughts

Prior to and into the opening decades of the nineteenth century, the general belief had been that the two hemispheres are structurally and functionally identical. The idea of equivalence was based more on philosophical notions and just looking superficially at the hemispheres than on well-organized studies of people with unilateral brain lesions. Indeed, it had long been known that damage to the left side of the brain is more likely to cause a paralysis on the right side of the body, and that damage to the right side of the brain is more likely to affect the left side of the body. Yet there seemed to be little recognition of the fact that speech difficulties are far more likely to be associated with a paralysis the right arm than the left, signifying left-hemispheric damage.

This is not to say that there were no loose speculations about hemispheric differences over this long expanse of time, for there were. The earliest is known from a twelfth-century medical treatise that has roots that date back to about the fourth century BC (Lokhorst 1985, 1996). Its originator is unknown and it is found in a section of the codex dealing with phrenitis, the ancient term for a febrile disorder associated with delirium, frenzy, and raving. To quote: “There are accordingly two brains in the head. The one gives us our intellect, the another provides the faculty of perception. That is to say: the brain on the right side is the one that perceives, whereas the left brain is the one which understands” (trans. in Lokhorst 1996, p. 302). But before we read too much into this thought, it must be noted that the anonymous author then goes on to say that “this is also being done by the heart, which lies under the latter organ, and which is also continually vigilant, hearing and understanding, because it too has ears to hear.”

The Hippocratic physicians, like the Egyptians before them, had observed that unilateral head wounds

tend to result in convulsions and paralyse on the opposite side of the body. In one Hippocratic treatise we even find that, “an incised wound in one temple produces a spasm in the opposite side of the body,” and later, that a loss of speech can occur along with a “paralysis of the tongue or of the arm and the *right side of the body*” (Chadwick and Mann 1950, pp. 263, 248; italics added). From these lines, one would think that loss of speech, right hemiplegia, and damage to the left side of the brain would have been firmly associated with each other in Greek antiquity. But this did not even happen during the Roman Period.

At the height of the Roman Empire, there was greater acceptance of the idea that the cerebral hemispheres control the opposite sides of the body, a fact now supported by examining cases with brain damage. For example, Aretaeus the Cappadocian, who lived into the third century AD, wrote that following damage to one side of the head, there would be a paralysis on the opposite side, owing to the crossing of the nerves. Still, the association between the left-hemispheric damage and speech defects did not gain critical attention at this time (Benton 1976, 1984). One problem was that not everyone was willing to accept a crossing of the nerves to the muscles; another was that a paralysis on the opposite side could always be attributed to overlooked brain damage on the supposedly still healthy side.

Thus, the prevailing view was that the two sides brain simply mirror or duplicate each other, both structurally and functionally. This remained true even when the emphasis shifted to the hollow ventricles, which seemed to have been assigned different higher functions (perception, cognition, and memory) after Galen’s death, which was around 200 AD (Finger 2000). Further, it continued into the Early Modern Period, when some philosophers (e.g., Descartes 1649) went searching for a unitary structure (e.g., the pineal gland) that might serve as the seat of the soul, so as to account for the fact that we have but a single unified consciousness.

Two Minds?

Late in the eighteenth century, the idea that we might have not one but two minds began to emerge, and during the 1800s, speculation grew that the two hemispheres might be associated with two distinct minds. Karl Friedrich Burdach (1826) even suggested that the

corpus callosum might unite the two psyches, writing: “By means of the corpus callosum both hemispheres can act together in perceiving sensations. The activity aroused by impressions on corresponding points in the two hemispheres will therefore be able to produce one and the same perceptive image” (trans. in Neuburger 1981, p. 280).

Franz Joseph Gall and Johann Spurzheim had introduced the concept of cortical localization just before this time, calling it “organology,” although “phrenology” became Spurzheim preferred word (Finger 2000). Their primary method was to correlate overt skull features, such as bumps, with unusual behaviors (faculties of mind), although they also turned to developmental changes, cross-species differences, and occasional cases of brain damage to bolster their structure-function relationships. Although both Gall and Spurzheim were exceptionally skilled in dissection, they did not recognize structural or functional differences between the hemispheres. Gall paid no special attention to the fact that all of his aphasic cases had sustained left-hemispheric damage (Gall 1822). What was important to him was only that the damage was in the front of the brain, behind an eye, in those with severe speech difficulties.

The theory advanced to account for any defects following unilateral cerebral damage was that unilateral lesions must disrupt the balance between the two equal hemispheres. François Xavier Bichat (1805/1827), who taught anatomy, physiology, and surgery in Paris, had promoted this way of thinking, writing: “The Nerves, which transmit the impressions received by the senses, are evidently assembled in symmetrical pairs. The brain, the organ (on which the impressions of objects are received) is remarkable also for the regularity of its form. Its double parts are exactly alike...” (1827 trans., pp. 20–21). He then added that any change in this equality could disrupt one’s ability to meld the impressions coming from the two hemispheres into one.

Marie-Jean-Pierre Flourens (1824, 1842), the leading French experimentalist of the first half of the nineteenth century, was greatly influenced by Bichat and found no reason to question this type of thinking. Neither did Charles Bell (1811/1936, p. 112), who wrote: “Whatever we observe on one side has a corresponding part on the other; an exact resemblance and symmetry is preserved in all the lateral

divisions of the brain. And so, if we take the proof of anatomy, we must admit that as the nerves are double, so is the brain double.”

Nevertheless, the notion of perfect symmetry was beginning to be questioned, at least in humans. In 1805, Félix Vicq d’Azyr wrote that the pattern of convolutions is more variable on the two sides in humans than it is in lower forms (Vicq d’Azyr 1805). And in 1836, a contributor to *The Phrenological Journal and Miscellany* wrote that some inequality between the hemispheres allows them to perform antagonistic actions or to act jointly (Watson 1836). To Henry Holland (1852), the London physician and author of *On the brain as a double organ*, the ability of the two hemispheres to function cooperatively must be due to the commissures uniting the two sides.

By mid-century, the belief that the two hemispheres might not be functionally equivalent had more backers, with at least one writer analogizing that we have a take-charge male paired with a weaker female hemisphere (Anon. 1850, p. 528). In addition, some physicians and asylum directors were now attributing mental illness to cerebral pathology that could disrupt the normal harmony between the hemispheres (Harrington 1985, 1986, 1987). This idea can be found in the writings of Jean Esquirol (1838) in France and Henry Holland (1852) and Arthur Ladbroke Wigan (1844a, b) in England.

Holland specifically mentioned the “incongruous action” that could set the two hemispheres against each other. Wigan, the author of *A New View of Insanity: The Duality of Mind*, maintained that although each hemisphere is a perfect and distinct whole, capable of independent thinking and action, one hemisphere is normally superior to the other, taking the lead so there is minimal conflict. He reasoned the left hemisphere is normally be superior to the right, since most people prefer to use the right hand for writing and other manual functions. The normal control is lost, he opined, in cases of insanity, resulting in internal conflicts. Since the functional harmony that would constitute normalcy is a learned skill, he reasoned, it follows that better education could prevent this from happening and also serve as a treatment for mental derangements.

Neither Esquirol, Holland, Wigan, nor any of the others writing at this time had been aware of the fact

that a paper showing just how different the two hemispheres really are had just been written in the south of France. Its physician-author claimed that speech is much more likely to be disrupted following left-hemispheric damage than right-hemispheric damage, and he backed up this statement with a large number of clinical cases.

Notably, another Frenchman, Jean-Baptiste Bouillaud (1825), who agreed with Gall that speech is an anterior lobe function, had not made this claim, even though he had published findings on 25 cases with lesions confined to a single hemisphere. Had he analyzed his data for right–left differences, instead of just for front–back differences, he would have seen that 73% of the cases with left hemisphere damage had what we would now call aphasias, whereas only 29% of those with right-hemispheric damage were aphasic (Benton 1984; this author points out that Morgagni and Andral had also sufficient case studies to begin to link the aphasias to left-hemispheric damage and right-sided paralyzes).

Marc Dax's 1836 Memoir

Details of the Marc Dax manuscript of 1836, including its history, can be found in several publications (Souques 1928; Ravoire 1933; Joynt and Benton 1964; Critchley 1964; Schiller 1979; Cubelli and Montagna 1994; Finger and Roe 1996, 1999; Roe and Finger 1996). Marc Dax was a physician who worked at a home for the elderly in Sommières, France, and he recorded his first case of *alalie*, or what would later be called *aphémie* or aphemia, and then *aphasie* or aphasia, in 1800. At the time, he thought little of the fact that the left hemisphere was damaged, but supposedly after a second case of his own and reading about another, he began to wonder whether damage to the left cerebral hemisphere was more likely to impair speech than damage to the right. By 1811, he was collecting cases in earnest, ultimately amassing 40 of his own and an equal number from the literature.

Dax then wrote a short paper on the topic and called it *Lésions de la moitié gauche de l'encéphale coïncidant avec l'oubli des signes de la pensée* ("Lesions of the left half of the brain coincident with the forgetting of the signs of thought"; for an English translation, see Joynt and Benton 1964). His thesis was that lasting speech disorders are always due to lesions of the left

cerebral hemisphere. In his words: "I believe it possible to conclude not that all diseases of the left hemisphere necessarily impair verbal memory but that, when this form of memory is impaired by disease of the brain, it is necessary to look for the cause of the disorder in the left hemisphere, and to look for it there even if both hemispheres are diseased" (trans. in Joynt and Benton 1964, p. 852).

Dax did not distinguish among the various types of speech defects, mixing various aphasic disorders together when coming to his landmark conclusion. Further, he did not conduct autopsies on his patients, but instead judged the side of the damage from what he observed (e.g., sword wounds, cranial defects) or from the fact that there was a paralysis affecting the right side of the body. Still, he had it right and he even recognized that slow growing tumors might not produce the same signs as acute brain damage, such as would accompany a stroke or a saber wound.

Marc Dax's chose the 1836 *Congrès Méridional* in nearby Montpellier, where achievements from the south of France were to be presented, as his platform. Although Gustave Dax, his son, maintained repeatedly that his father presented his material there, no hard evidence has been found to support this contention. Paul Broca (1865) even went so far as to check the local newspapers and with the Montpellier librarian, Monsieur Gordon. The librarian interviewed 20 physicians who had been present at the time, but not one remembered anything about Marc Dax or a presentation on language or the brain.

In this context, we must remember that things were different in the first half of the nineteenth century than they are today. A "presentation" did not necessarily mean that a paper was read out loud. The presenter might have done little more than place the paper on a table for a set amount of time for any interested party to read it, and there might not have been interested parties at the *Congrès Méridional*, since it was not a medical meeting, but rather one that dealt more with farming and technological innovations.

Along with this information, some more facts must be added. One is that Marc Dax died a year later, in 1837, and this could be why his paper was not published at the time. He was also a devout Catholic and might have concluded that his findings challenged the belief that an immaterial vital spirit can account for

higher-order behaviors, the very issue on which Gall had been attacked in Vienna just a few decades earlier.

There has been considerably less controversy about whether the paper had been written in 1836. Marc Dax, with his son's help, made copies of the paper at the time, and one copy was discovered among the possessions of a deceased Dean of the Faculty of Medicine at the University of Montpellier. This copy showed that Marc Dax had attempted to get feedback from at least one member of the medical establishment and might have been trying to spread the word before he died. In 1879, a note was published with this discovery to dispel doubts about the document's authenticity and to help set the record straight (Caizergues 1879; trans. in Roe and Finger 1996).

Gustave Dax and the 1865 Publications

Gustave Dax was born in Sommières 21 years before the *Congrès Méridional* and he too studied medicine at Montpellier. He completed his medical dissertation in 1843, 6 years after his father's death, and then went to work in the town of his birth. He was described as a short, combative man, who was intelligent and cared deeply for his patients. In between seeing his patients, he found the time to continue his father's work on aphasia.

In 1858, he finished a lengthy paper of his own confirming the importance of the left side of the brain for speech. Although Gustave's paper was not published at this time, it was handed to several other physicians whose names were made public in 1866, when the dates of what he and his father had previously written were being questioned in Paris (Roe and Finger 1996). It remained shelved until 1863, during which time Paul Broca (1861a, b) had become famous for localizing fluent speech in the frontal lobes.

In March 1863, Gustave sent a manuscript to Paris titled *Observations tendant à prouver la coïncidence constante des dérangements de la parole avec une lésion de l'hémisphère gauche du cerveau* ("Observations seeming to prove the constant coincidence of speech disorders with a lesion of the left hemisphere of the brain"). It was comprised of his father's memoir and his own material, actually 140 additional case studies, which supported and extended his father's case for a left-hemispheric specialization for speech (see Dax

1877). The material was registered with the *Académie des Sciences* on March 23, 1863, and with the *Académie de Médecine* one day later.

The *Académie des Sciences* sent it to a committee (Serres, Flourens, and Andral) for review, but this committee either did not comment on it or did not make their assessment public. As for the *Académie de Médecine*, they assigned it to Jean-Baptiste Bouillaud, Jules-Augustin Béclard, and Louis François Lélut. After an 18-month delay, Lélut, the head of the committee, presented his own negative verdict (see Finger and Roe 1996 for a translation of Lélut's document). He called the Dax findings a return to the pseudoscience of phrenology. Bouillaud, who had not published his own evidence for cerebral dominance, and might now have realized that he had missed a golden opportunity, did more than distance himself from Lélut's pronouncement. He opposed it, arguing that the idea of speech being asymmetrical should not be brushed aside since, as we all know, at least one other function, namely handedness, is asymmetrical.

Gustave Dax, clearly enraged by the reception his paper received in Paris, was not one to remain silent. He submitted what he had to the *Gazette Hebdomadaire de Médecine et de Chirurgie*, which published the material as two separate submissions, one immediately after the other, on April 28, 1865 (G. Dax 1865; M. Dax 1865). His father's memoir appeared first. It retained its original title and was published in its entirety. His own contribution was now given the title *Sur le même sujet* ("On the same subject") and was presented in abridged form (see Finger and Roe 1996, for an English translation). Here and in his later publications (see below) we find the younger Dax pointing to the left temporal lobe as the site of the lesion most likely to impair speech (see Finger and Roe 1999).

Paul Broca on Dominance

Before the Dax manuscript arrived in Paris, cerebral dominance had not been discussed in Paul Broca's *Société d'Anthropologie*, or in the other scientific and medical societies, as can be judged from the notes of these organizations. Paul Broca did not publically raise the possibility that the left hemisphere might be special for speech production until after it arrived. About a week later, in his April 2, 1863, report to the *Société*

d'Anthropologie, Broca stated that all 8 of his cases with fluent speech difficulties, beginning with Monsieur Leborgne (“Tan”) and Monsieur Lelong in 1861, had damage in the left cerebral hemisphere. But still believing in Bichat’s prevailing theory of paired organ equivalence, and being cautious, Broca (1863) initially said nothing more than that the side difference was an unexpected finding in need of confirmation.

Clearly, Broca could well have been influenced by what Marc Dax had sent to Paris, even though it was reviewed behind closed doors. Not only might there have been leaks (Schiller 1979), but also the title of the submission was published for everyone to see, and it pretty much told the story. Notably, it appeared on the very same page where Broca’s own application for membership in the *Académie de Médecine* appeared. This information alone might have given Broca, who was cautious by nature, the confidence to make his first public statement about cerebral dominance, a perplexing finding he nonetheless claimed he had recognized before March 24, 1863, the date of the Dax submission.

Later in 1863, Jules Parrot presented the case of a patient who had a lesion of the right frontal lobe without an articulate language disturbance. Broca recognized that this finding also pointed to the special role of the left hemisphere in speech. A year later, Broca described a colleague’s two patients with traumatic head injuries on the left side and speech difficulties, and now referred to the rapidly mounting evidence for left-side involvement, writing: “Numerous observations gathered during the last three years have a tendency to indicate that lesions of the left hemisphere are solely susceptible for causing *aphémie*. This proposition is no doubt strange, but however perplexing it may be for physiology, it must be accepted if subsequent findings continue to indicate the same view point” (trans. in Berker, et al. 1986, p. 1066).

Broca published his thoughts linking the left hemisphere to speech production in 1865. His paper was titled *Du siège de la faculté du langage articulé* (“On the Site of the Faculty of Articulated Speech”) and it appeared in the *Bulletin de la Société d'Anthropologie* 6 weeks after the two Dax manuscripts had been published elsewhere (see Berker et al. 1986, for the English translation). In contrast to the Daxes, he concentrated on just one speech defect, a loss of speech production. Although he dealt with fewer cases, he,

unlike the Daxes, had autopsy reports to supplement his clinical findings. The post-mortems also allowed him to be anatomically more precise than the Daxes.

Although he now took a firm position about the left hemisphere being the leading hemisphere for articulate speech (and handedness), he was careful to add that fluent speech is not the exclusive function of the left hemisphere. His views were shaped by the sparing of function that could be witnessed after early brain damage or with congenital defects (“I am convinced that a lesion of the third left frontal convolution, which is enough to cause a definitive *aphémie* in an adult, will not prevent a young boy from learning to speak”; see Broca 1865; Berker et al. 1986, p. 1070). They were also influenced by the fact that some recovery can be seen with speech therapy in adults, provided the damage does not severely impair a patient’s intellect, which, unfortunately, it often does following large strokes. Additionally, aphasic patients (e.g., Tan) might still retain the ability to curse involuntarily and, as found by others before him, to sing familiar hymns when prompted.

Broca clearly wrestled with the basis of the left-hemispheric specialization. Not willing to reject Bichat’s “laws,” he concluded that the two hemispheres are intrinsically equal, but that the left hemisphere matures faster than the right in the great majority of people. Hence, the more precocious left hemisphere takes the lead and dominates in speech, the most human of all functions. His late colleague Pierre Gratiolet had studied the development of the cerebral convolutions, and his anatomical findings were fundamental to his thinking (Gratiolet and Leuret 1839–57, II, pp. 241–242; see Broca 1865). More data suggestive of small anatomical differences would now follow, including some collected by Broca himself (see below).

Broca also wrote that he believed the right hemisphere might mediate speech in left-handed people, although he did not tie handedness (a motor function) and speech (an intellectual function) tightly together (see Eling 1983, 1984; Harris 1991, 1993). During the twentieth century, researchers would recognize that the majority of left-handed people (most notably those with left-handedness running in their families) depend more on the left than the right hemisphere for speech. The matter is complex, however, because a fair percentage of left-handed people exhibit varying degrees of

“split dominance.” Fluent right-hemispheric speech, in contrast, seems to be fairly rare.

Revisionist History

After Broca’s 1865 paper appeared, people erroneously began to backdate the discovery of cerebral dominance to 1861 and his case of Monsieur Leborgne, even though Broca did not recognize the left hemisphere as special for speech at that time. Since Marc Dax died in 1837, it was left to Gustave Dax to protest, which is precisely what he did.

His first public comments about the backdating of Broca’s contribution date from 1865 and took the form of letters, which were then published as a part of a larger piece in the *Montpellier Médical* of 1866. In this piece, he presented precise dates and the names of witnesses. As for Broca, he had this to say:

- ▶ I read the two reports written by Mr. Broca [in 1861]. Indeed, I found them very valuable. One cannot describe with more accuracy, classify the symptoms and the lesions in a more systematic way, and analyze more consistently. These cases are valuable. Besides, in my memoir, I regretted that there were not more cases of this sort and pointed out that only a small number of them would be enough to shed some light on the truth.

As I read his studies, I realized I had a deep esteem for the philosophical mind of the author. With a few more cases studied in the same accurate way, in time he would have made the discovery. But where in these two works did Mr. Broca generalize and conclude that the speech faculty was localized in the left hemisphere? Nowhere.

His observations are very valuable for the doctrine, but he never formulated the law. (Dax 1866; Trans. in Roe and Finger 1996)

Gustave Dax came forth with another impassioned defense of his and his father’s work in 1875 (Dax 1875), also in the *Montpellier Médical*. Finally, in 1877, he published the complete and unedited manuscript that he said he had registered with the two French academies in 1863. This publication was preceded by a new preface detailing how the Daxes were the first to discover and confirm left-hemispheric specialization for speech.

During the nineteenth century, some people gave the Daxes the credit they deserved, others pointed to

Broca alone, and still others called the discovery the Dax-Broca or Broca-Dax “law” or principle (Finger and Roe 1999). But with the passage of more time, the Daxes seemed to fade into oblivion, at least until the hundredth anniversary of cerebral dominance in the 1960s, when some historians took a fresh look at the literature. Today, Marc Dax is being increasingly recognized for his achievement in 1836. As for Paul Broca, clearly the third person on this chain, there can be no doubt that he was the most influential advocate of the new doctrine in the 1860s – and the most precise. Thus, there are good reasons to continue to refer to the discovery with the combined eponym, i.e., as the “Dax-Broca doctrine.”

Wernicke’s Aphasia

The idea that the left hemisphere is special received a boost in 1874, when Carl Wernicke demonstrated that left-hemispheric injuries are also associated with a more “sensory” sort of aphasia – a variety in which speech is fluent but filled with word substitutions and neologisms that make it less meaningful. In contrast to Broca’s type of aphasia, which he tied to the left frontal lobe, Wernicke (1874) most closely associated this condition with damage to the temporal lobe.

Although cases of Wernicke’s sensory aphasia can be found in the older literature, a fluent speech disorder had not previously been singled out and linked with a lesion in just one lobe of one hemisphere. Wernicke did not mention Gustave Dax, who was not specific about the speech deficit when he pointed out that the left temporal lobe was in the center of the lesion sites he was mapping. Then again, he also did not mention Theodor von Meynert, with whom he had studied, or Johann Baptist Schmidt, two of his predecessors who had gone even farther and associated auditory comprehension deficits with left temporal lobe lesions (Meynert 1866; Boller 1977; Whitaker and Etlinger 1993).

At least with regard to language, the left hemisphere now looked even more like the leading hemisphere. Not surprisingly, it would be soon called the major or the dominant hemisphere, whereas the right hemisphere would be referred to as the minor or non-dominant hemisphere. The problem with this terminology, which is based on speech and is still very much with us, is that additional clinical observations from the nineteenth century would show that the so-called dominant

hemisphere is, in fact, not the dominant one for some functions, most notably spatial and constructional skills.

John Hughlings Jackson and the Right Hemisphere

John Hughlings Jackson's first reference to cerebral dominance appeared in 1864, when he endorsed the idea that aphasia is most likely to occur after damage to the left side of the brain (Jackson 1864a; Greenblatt 1970). Later that year, Jackson (1864b) published another report, this time writing that he had examined many patients with speech loss or defective speech, and that the hemiplegia was on the right side in all but one of them, indicating problems with the left side of the brain. Nevertheless, Jackson had trouble with Broca's concept of an actual center for spoken language, explaining that to locate the damage that destroys speech and to locate speech are two very different things. Jackson, unlike Broca, tended to look at the brain in terms of sensory-motor relationships, even with regard to "higher functions" such as language, and he shied away from what he called "abrupt geographical representations."

Jackson (1874a), a follower of Charles Darwin, contended that propositional speech might be the most voluntary activity we humans possess. But although the left hemisphere might predominate for voluntary speech activities, involuntary activities, such as cursing, are probably governed both sides. He would maintain that the right half of the brain is for the automatic use of words, whereas the left half is for both automatic and voluntary functions. This, in effect, is why aphasic patients can still curse, yet cannot repeat, the same oath when asked to do so. Jackson also believed that understanding speech is an automatic or involuntary function, and thus one that involves both hemispheres, although only the left seems capable of consciousness in words.

Jackson is better known today for drawing attention to the fact that spatial abilities are more likely to be impaired after damage to the right than the left hemisphere, and the special significance of the posterior part of the right hemisphere in this domain. A year before Broca even published his 1865 paper on laterality, he was writing: "If, then, it should be proved by wider evidence that the faculty of expression resides in one hemisphere, there is no absurdity in raising the question as to whether perception, its corresponding

opposite, may not be seated in the other" (Jackson 1864b, p. 604).

In 1868, Jackson elaborated further on cerebral differences. One of his major points was that left-hemispheric patients with aphasia often retain their perceptual abilities (Jackson 1868). But this was "negative" evidence, and he recognized that positive instances were required to strengthen his case for right-hemispheric specialization for perceptual abilities. These cases began to be documented in the 1870s (Zangwill and Wyke 1990).

In 1872 Jackson described a man with a left hemiplegia who could not recognize people, including his wife, places, and things, and who had trouble finding his way back home (Jackson 1872). He presented a comparable case 4 years later. Elisa P., 59 years old, had trouble dressing and had lost her directional sense.

- ▶ She was going from her own house to Victoria Park, a short distance and over roads that she knows quite well, as she has lived in the same house for 30 years, and has had frequent occasion to go to the park; on this occasion, however, she could not find her way there, and after making several mistakes she had to ask her way, although the park gates were just in front of her. When she wished to return she was utterly unable to find her way, and had to be taken home by a country relation to whom she was showing the Park for the first time. (Jackson 1876, p. 438)

Elisa P. deteriorated and died 3 weeks after the onset of her illness. William Gowers, who examined her brain, found a large glioma in the posterior part of the right temporal lobe.

Jackson (1874b, 1876) coined the term "imperception" to describe the "loss or defect of memory for persons, objects, and places" (others preferred visual agnosia, mind-blindness, etc.). He associated imperception with posterior right-hemispheric lesions and felt that this association was just as important as Broca's association of fluent language with damage to the frontal lobe of the left hemisphere. As for why this is the case, he had previously accepted Broca's contention that the left frontal lobe develops faster than the right frontal lobe. Jackson (1868) extended this reasoning to the right posterior region, which he thought must grow in advance of its counterpart on the left, taking the lead in object recognition and related spatial-perceptual functions.

There were, of course, new questions to be asked in this domain. For example, does the spatial deficit found in posterior right-hemispheric patients cut across sensory modalities? In this regard, Jules Badal (1888) presented a case in which he found that the visuo-spatial defects in a case with good visual acuity were, in fact, linked to problems with other sensory systems. His patient with higher-order visual problems also had difficulty identifying the location of sounds, had body schema defects (e.g., right vs. left part confusions), and exhibited finger agnosias, among other things. With time, specific spatial defects would be correlated with lesions of individual parts of the right hemisphere (Benton 1982).

Anatomy, Dominance, Madness, and Society

By this time, additional anatomical support could be cited for these contentions, although there were notable exceptions (Harrington 1985, 1987). For example, Hans Carl Barkow (1864) had reported that he had made an extensive study of human skulls and had found the left frontal region more pronounced than its corresponding member on the right side. Notably, he also observed a trend for the right posterior region to be larger than the left posterior region. A report soon followed showing that there was more gray matter in the left frontal region than in the right frontal region (Roques 1869). As for Broca's own anatomical findings, he found no meaningful differences between the hemispheres as a whole, although he noted that the left frontal region was four grams heavier than the right (Broca 1875).

In 1890, Oskar Eberstaller, a Viennese anatomist, examined 170 human brains and found the left sylvian fissure to be 12% longer than the right. Two years later, D. J. Cunningham (1892) confirmed Eberstaller's (1890) findings and showed that a longer left Sylvian fissure could also be seen in near-term fetuses and newborns, although the difference was not as marked. He added that a small difference between the Sylvian fissures also exists in chimps and some (but not all) monkeys.

The emerging literature on cerebral dominance had a profound impact on society. During the second half of the nineteenth century, many people, including Broca (1869) and Charlton Henry Bastian (1880), believed that the asymmetry was greater in the brains of Caucasians than in "inferior races" (e.g., "Negroids"), which in turn meant that some groups were more educable

than others (Thurnam 1866). Along similar lines, some scientists contended that male brains are more asymmetrical than female brains, and again, that adults show more asymmetry than children (Delaunay 1874; Harrington 1985, 1987; Finger 1994).

In Italy, Cesare Lombroso even maintained that "born" criminals are more likely than upstanding citizens to have more animal-like symmetrical nervous systems, which correlated with them being more ambidextrous (Marro and Lombroso 1883; Lombroso 1903). His ideas had much in common with the newer literature on insanity, which was based in part on changes in personality after damage to the different hemispheres; differences in the weights of the two sides of the brain disappearing or even reversing in the insane (e.g., Luys 1879, 1881); and the idea that the right hemisphere has more in common with the animals, since it is less involved with speech, the most human of all functions.

Evidence could be cited to show that auditory hallucinations are more likely to be associated with the left ear, and that hysterics are more likely to affect the left side of the body (for both, read right brain). Brown-Séquard (1874a, pp. 10,14), for instance, wrote: "We have collected cases of paralysis in one-half of the body, caused by hysteria . . . in 121 of these cases, there was disease of the brain on the right side 97 times and disease on the left 24 times."

If this state of affairs is reminiscent of Robert Louis Stevenson's (1886) *Strange Case of Dr. Jekyll and Mr. Hyde*, it should be. His Victorian shocker about two opposing personalities – one good and the other evil – that are locked in a single body appeared in 1886. To a large extent, Dr. Jekyll personifies the Victorian image of the left hemisphere, while Mr. Hyde represents what was then believed about the more primitive right hemisphere, which in its brutish form could even commit murder.

In 1895, 9 years after Stevenson's book appeared, Lewis Bruce, the director of an asylum in Scotland, published a paper on a real individual who seemed to have two distinct consciousnesses (Bruce 1895; Finger et al. 2001). One was "absolutely demented and did not understand a word that was said to him," and he frequently jabbered in a language that sounded like Welsh. When this personality predominated, the man used his left hand for writing. The second personality was fluent in English and understood what was said to him,

although it was “restless, destructive and thievish” – and had no memory for anything that had occurred when the other consciousness dominated. This personality was right handed. On the basis of the exhibited handedness and what he knew about brain physiology, Bruce thought the two consciousnesses related to the respective actions of the right (with “little power of mental action”) and left (“educated”) hemispheres. Nevertheless, it took 2 more years for Bruce to point to a physical mechanism to explain the switching back and forth (Bruce 1897). In 1897 he pointed to evidence of epilepsy in such patients, contending that when seizures “paralyze” the more intellectual or human left hemisphere, the right hemisphere is released and can show its more primitive mental self.

If one thing seemed clear in some Victorian circles, it was the need to suppress and even change the basic nature of the right hemisphere. To some reformers, including Brown-Séquard (1874a, b, 1890), this meant educating the right hemisphere to bring it up to the level of the left, since “the right side of the brain was a natural breeding ground for madness” (Harrington 1985, p. 623). The obvious and easiest solution was to stimulate the right hemisphere intellectually, such as by asking right-handed people to write letters with the left hand. These notions were put into practice in a few schools in Great Britain, in the United States, and elsewhere, before it was increasingly realized that tampering with Mother Nature was not such a good idea (Crichton-Browne 1907).

Conclusions

The idea of cerebral dominance emerged in the nineteenth century, when the theory of cortical localization of function was gaining traction. To many onlookers and participants, it was an even more profound idea than the thought different parts of a hemisphere might have different functions, because the hemispheres look so much alike. Along with Bichat’s thinking about paired organs being functionally equivalent, this sort of thinking hindered the acceptance of the new concept, although it eventually caught on. As to who should get the lion’s share of the credit for the discovery, Marc Dax clearly preceded Broca in recognizing it, and the two Dax manuscripts were submitted and published before Broca’s tentative statement of 1863 and his important paper of 1865. Yet at the same time, Broca’s precision

and prestige were also very important in disseminating the new concept and making it acceptable in the 1860s.

The idea of cerebral dominance initially pertained to speech production. But during the 1870s, John Hughlings Jackson showed that the right hemisphere is special in its own way, particularly with regard to spatial functions. Since finding one’s way home, even consciously, was not thought to be on the same level as speaking, the right hemisphere continued to be viewed as intellectually inferior to the left, the seemingly more human of the two hemispheres. This association had many significant ramifications, and it was used to “explain” differences between the genders, differences among the races, criminality, and mental illness. It also spawned societies and schools to educate the right hemisphere, which was viewed as dangerous when “released” following damage to the left hemisphere.

Clearly, the material presented here is not the whole story of what transpired in the nineteenth century, the formative years of the theory of cerebral dominance. As can be imagined, there were extensions to other functions, distinctions within a function, and attempts at finer and finer localizations. Differences of opinion led to many contentious debates, due partly to two important facts. One is that there are individual differences in cerebral dominance and in how tightly some of the investigated functions are linked to each other. The other is that there was a tendency to think too simplistically about the phenomenon – that is, to view the two sides of the brain and their functions as dichotomous, rather than as being on a continuum with shades of gray between the extremes of black and white.

Today, with our more sophisticated tools, we know much more about cerebral dominance and structure-function relationships in general. Still, there are many questions that remain unanswered. Prospectors will discover that there is still much to uncover in the earlier literature and, at the very least, that digging into the past will help to put even our newest ideas into better perspective.

Chapanis, Alphonse

JOHN F. (JEFF) KELLEY

IBM Global Business Services, Clarkesville, GA, USA
Georgia Tech, Atlanta, GA, USA

Biographical Information

Born: March 17, 1917, Meriden, CT, USA

Died: October 4, 2002, Baltimore, MD, USA

Alphonse Chapanis was born in Meriden, CT, USA, on March 17, 1917, and passed away on October 4, 2002, in Baltimore, MD, USA. Dr. Chapanis received his Ph.D. in psychology from Yale University in 1943. Aside from 22 years of consultancy in Human Factors and Ergonomics, Dr. Chapanis served as a 2nd Lieutenant at the US Army's Aero Medical Laboratory and was professor of experimental psychology at The Johns Hopkins University from 1946 through 1982.

Major Accomplishments/ Contributions

Alphonse Chapanis has been warmly described as the “Godfather of Human Factors and Ergonomics.” His contributions to the fields of applied experimental psychology, human factors, and ergonomics spanned a career of over 60 years.

The 95 books and articles cited in his memoir (Chapanis 2002) are only a portion of publications he has authored, many of them significant in the evolution of the fields of human factors and ergonomics. Much of his work displays his interest in merging the fields of basic psychological research (notably vision and perception) with the practical application of research to engineering design and led to his being recognized as a distinguished leader in the fields of human factors engineering and ergonomics.

Chapanis wrote the first ergonomics textbook (Chapanis et al. 1949) and wrote an award-winning *Scientific American* article on color blindness (Chapanis 1951). These were partially a result of some groundbreaking work he did for the US Army's Aero Medical Laboratory (AML) during World War II, as well as subsequent systems research conducted at a US Navy sponsored field laboratory at The Johns Hopkins University.

While completing his Ph.D. in psychology at Yale, Chapanis joined AML as a 2nd Lieutenant, and began training in aviation psychology. His early work involved the design of night-vision displays and the effects of anoxia and high g-forces on vision loss.

In one famous study, Chapanis was studying the high incidence of postlanding crashes of the B-17 “Flying Fortress” aircraft. Not satisfied with the common classification of “pilot error,” Chapanis studied the incidents and concluded that the problem was, instead, a matter of “designer error.” As the controls for the flaps and the landing gear were identical and placed side by side, tired pilots landing at night after a long flight could easily select the wrong control. Chapanis solved the problem by “shape-coding” the controls (one resembling a wheel, the other resembling a flap), and providing a fail-safe control connected to pressure sensors in the landing gear (preventing retraction if the aircraft's weight was on the gear).

From 1946 until 1982, Professor Chapanis was a prolific member of the psychology department faculty at The Johns Hopkins University, graduating, among others, 29 Ph.Ds. In the early years, Chapanis, working under contracts from the US Navy, made fundamental contributions to the emerging field of systems engineering. His book *Research Techniques in Human Engineering* (Chapanis 1965b) had a great impact on the field.

It was also during this time that Chapanis adapted a critical incident approach to safety issues (such as hospital medication errors) and wrote a widely cited paper entitled “Words, words, words” (Chapanis 1965a) in which he decried the prevalence of confusing and conflicting wording in signs and labels in contexts ranging from highways to instruction placards to elevators, often leading to errors and safety issues.

In 1953 and 1954, Chapanis consulted with Bell Labs, doing ergonomics design studies of new toll-operators’ keypads that eventually contributed to the design of the push-button telephone.

In 1970, Chapanis started the Communications Research Laboratory (CRL) at The Johns Hopkins University. In the 12 years that followed, he and his graduate students did seminal work in the nascent field of multimodal communication – technology-mediated human–human communications and human–computer communications using video, audio, handwriting, and keyboard. This work led to significant advances in telecommunications, teleconferencing, video conferencing, and the intelligibility of digitized speech. Among many significant advances to come out of CRL was the “Wizard of OZ” method for development and assessment of natural language recognition systems in wide use today.

From 1959 through 1995, Chapanis had a long-term consulting relationship with IBM. In addition to setting up training programs to educate executives, managers, engineers and programmers about man–machine interface considerations (human–computer interaction) in the design of computing technologies, he also received support from IBM (and later, from GTE) for various communications graduate student research projects.

In the 1960s, Chapanis was an active international proponent of human factors and ergonomics which included lectures, and publications about cross-cultural issues in human factors and ergonomics. He was elected to the Council of the International Ergonomics Association (IEA) in 1967 and became President of that organization in 1973. There are interesting anecdotes in his memoir concerning his role in reporting observations from his travels, especially behind the Iron Curtain, back to the Office of Naval Research and the US military.

Alphonse Chapanis was actively involved in professional organizations throughout his career. In addition to his role with the IEA, Alphonse Chapanis was the 1960 President of the Society of Engineering Psychologists (Division 21 of the American Psychological Association), and 1964 President of the Human Factors and Ergonomics Society (HFES). In 1982 he won the IEA’s Distinguished Service Award and, in 1987, the HFES President’s Distinguished Service Award. He was also an advocate for professional qualification standards, helping to establish the Board of Certification in Professional Ergonomics in the mid-1980s.

Professor Chapanis, always a fierce advocate of his students, is remembered with great fondness by the many graduate students he shepherded into successful careers, despite (or, perhaps, because of) his legendary attention to detail and insistence on clear writing style. In recognition of his contributions in education, the Human Factors and Ergonomics Society, in 1983, renamed its prestigious Best Student Paper Award the “Alphonse Chapanis Award.”

All the more poignant the closing words in his memoir:

- ▶ There is one thing I have never regretted – and that is my choice of profession. Human factors has always been challenging, frustrating at times, rewarding at others, but never dull. I can honestly say in retrospect that I have had a full life – an exciting life –and that I have enjoyed telling people about human factors, educating students and others to take over where I have had to leave off, and grappling with problems of trying to make our material world safer, more comfortable, and easier to cope with. In fact, there is only one thing I truly regret -
- I’m sorry I’ve come to the end.

Chiarugi, Vincenzo

MICHAEL M. DENUNZIO, JOHN D. HOGAN
St. John's University, Jamaica, NY, USA

Basic Biographical Information

Born: 1759; Died: 1820

Vincenzo Chiarugi was a pioneer in mental health care, one of the first to introduce humane treatment to institutions caring for the emotionally ill in Europe (Mora 1959). Trained as a physician in Italy, Chiarugi's contributions to mental health reform were frequently overshadowed by others, particularly the French physician, Philippe Pinel. Nonetheless, his contributions were innovative and substantial.

Chiarugi was born in the village of Empoli, near Florence, in 1759 (Mora 1959). It is significant that this was a period before the emergence of a modern, united Italy. He received his medical training in Pisa, graduating in 1780. After graduation, he worked in several hospitals, including the Santa Maria Novella hospital and the Santa Dorotea hospital, both in Florence. It was at Santa Dorotea that he first outlawed the use of chains as a means of controlling patients. In the instances where a patient might need some form of restraint, Chiarugi replaced the metal chains with restraints made of fabric and felt in order to reduce the number of sores and abrasions on patients.

Chiarugi was fortunate in that during his time in Florence, the state was governed by the Grand Duke Pietro Leopoldo (Gerard 1997). The Grand Duke was a social reformer who introduced a series of changes to Florence. (In 1790, he would become Leopold II, Holy Roman Emperor.) In 1774, he had enacted legislation requiring the mentally ill to be transferred to hospitals for treatment. Such legislation was a landmark in Europe – there had been nothing like it before (Mora 1959; Pallanti 1996). Among his other contributions, the Grand Duke directed the building of a new

facility, the Bonificio Hospital. In 1788, he made Chiarugi the “physician-director” of the Hospital. It was here that Chiarugi began to introduce some of his humane methods.

Major Accomplishments/Contributions

With the government behind him, Chiarugi implemented his *Regolamento dei Regi Spedali di Santa Maria e Bonifazio* (hospital regulations) in 1789 (Mora 1959). This precedes any action by Pinel and his colleagues by 8 years. The *Regolamento* covered areas of administration, treatment of patients, and maintenance of the hospital. The portion of the rules pertaining to the treatment of patients addressed such issues as respect for the patient, the limited use of restraints, the importance of hygienic practices, and the need for play and exercise. Also included was a statement discouraging visits by family and friends (Gerard 1997). All but the last item is consistent with present-day practices for the treatment of the mentally ill in hospitals.

Chiarugi's major book *On Madness* (Italian: *Della Pazzia*), was a three-volume set, written and organized much like a psychiatry textbook. It was initially translated into German, and only the first volume was translated. The second volume contained more of Chiarugi's clinical theories. It was not until Mora's English translation that Chiarugi's models and methods of treatment were made available for mainstream consumption (Mora 1959, 1989). Chiarugi placed little emphasis on his own humanitarian reforms in his writing (Gerard 1997); he was more interested in making known his approach to psychiatric care.

Chiarugi's main focus was on establishing a biological model of mental illness much of which is depicted in *On Madness*. His writings on melancholia (depression) and manic-depressive disorder (bipolar disorder) caught the attention of the famous psychiatrist Emil Kraepelin. However, it is worth noting that Chiarugi ran hospitals in which he was in charge of all patients, not just the mentally ill. His emphasis on a medical model should be understood in that context.

Chiarugi left no “successor” in his place after his death in 1820 to continue his tradition and make known his accomplishments beyond the Italian states. But there are other reasons for Chiarugi's lack of visibility, including his personal qualities, his difficult writing

style, his position outside of the mainstream, and the fact that he wrote in Italian. There were also major socio-political events happening elsewhere at the time in this age of major humane reform, such as the French Revolution (Fee and Brown 2006). Still, in recent years, Chiarugi's work has achieved substantially greater recognition (Mora 1989) and he has been given increasingly greater credit for his pioneering contributions.

Chomsky, Noam

NAVA R. SILTON¹, ARIEL BRANDWEIN²

¹Marymount Manhattan College, New York, NY, USA

²Long Island Jewish Medical Center, New York, NY, USA

Chomsky Noam (7 December 1928) was an American linguist most renowned for his extensive work in the area of language development.

Biographical Information

Noam Chomsky (full name Avram Noam Chomsky) was born on December 7, 1928, in Philadelphia, Pennsylvania, to William and Elsie Chomsky. His father, a professor of Hebrew, spoke Yiddish as his primary language. However, Chomsky was discouraged from speaking Yiddish in his house during childhood. Though the community he grew up in was described as being a “Jewish Ghetto” composed of mainly Hebrew speakers, Chomsky was surrounded by anti-Semitism both in the surrounding communities and in school.

Chomsky was highly influenced by his uncle. His uncle owned a newsstand, where professors and other intellectuals would gather and debate various topics which were great sources of stimulation for Chomsky. Chomsky also involved himself in a variety of Zionist organizations early on, though his later perspectives on Zionism would become controversial.

In 1945, Chomsky began studying philosophy and linguistics at the University of Pennsylvania under the direction of Professor Zellig Harris. He earned his bachelor's degree in 1949 and completed graduate courses in linguistics, philosophy, mathematics, and Hebrew. He continued to study linguistics at the University of Pennsylvania in pursuit of a Ph.D., which he completed in 1955. From 1951 to 1955 Chomsky was a Junior Fellow of the Harvard University Society of Fellows. His completed dissertation in 1955, entitled *Transformational Analysis*, began the process of converting linguistics from an abstract concept into a well-examined science.

Following his studies, Chomsky taught at the Massachusetts Institute of Technology (MIT) in the Department of Linguistics and Philosophy where he continues to teach to this day. He earned a full professorship in 1961, became the Ferrari Ward Professor of Linguistics in 1966, and was appointed Institute Professor in 1976.

In 1949 Chomsky married fellow linguist, Carol Schatz, with whom he has two daughters and a son. They remained married for 59 years until Schatz died of cancer.

Major Contributions

Chomsky, a linguist, political activist, and writer is arguably most well-known for his prolific writing and lecturing on topics as diverse as linguistics, philosophy,

intellectual history, contemporary issues, international affairs, and US foreign policy. Some of his principal works include: *Aspects of the Theory of Syntax*; *Cartesian Linguistics*; *Sound Pattern of English* (with Morris Halle); *Peace in the Middle East?*; *Reflections on Language*; *The Political Economy of Human Rights*, Vol. I and II (with E.S. Herman); *A New Generation Draws the Line*; 9–11; and *Understanding Power*. While much of his earlier work focused on linguistics, many of his more contemporary writings focused on a variety of political issues.

With respect to his theory of language development, Chomsky focuses on mentally represented grammar that delineates the native speaker's knowledge of his language and the biologically innate language faculty, or "universal grammar," that enables the developmentally typical language learner, as a child, to construct a grammar of the language to which he is exposed. For Chomsky, the primary purpose of linguistic science is to create a theory of universal grammar that offers a descriptively adequate grammar for any natural language given only the type of "primary linguistic data" available to children in their social environments. This goal has galvanized the gradual refinement of Chomskyan linguistic theory from the initial transformational grammar of the 1950s and 1960s to the Minimalist Program of the 1990s and beyond.

More specifically, Chomsky believes that humans are genetically endowed with mental structures that afford them a linguistic capacity. In contrast to kittens, for instance, humans will acquire an ability to produce and comprehend language after being exposed to a linguistic environment, while kittens will not. Chomsky labeled this relevant linguistic capacity of humans: the "language acquisition device" (LAD). He proposed that linguistics should help determine what LAD is and what constraints it places on the range of potential human languages. He called the universal features that result from these constraints, "Universal Grammar" (UG). Despite revision to his theories, his core premise suggests that humans possess a "language faculty that helps them acquire linguistic knowledge that entails various facets of language-use, including both the expression and reception of utterances.

Chomsky was primarily interested in how the initial stage of this faculty transforms with children's exposure

to linguistic information. Chomsky was more interested in grammar than semantics or phonology. In many ways, he believed that vocabulary needed to be directly learned (though the LAD proposes Operating Principles to speed up the process) while grammatical forms cannot be learned. In this sense, linguistic theory attempts to "sufficiently" characterize the grammars (and thus mental states) attained by native speakers and to delineate how grammatical competence is attained. Theories are "explanatorily adequate" if they can demonstrate how one can attain adequate grammar from "primary linguistic data" (what children are exposed to and glean from their native grammars) and on the detailed theory of the general principles and parameters that characterize the initial, biologically endowed mental structures of language. Put simply, linguistics must explain all the grammatical utterances native speakers produce as well as describe the rejection of ungrammatical utterances by such speakers.

Chomsky was also intrigued by the following areas of language development: knowledge of language and its general epistemological implications, indeterminacy and underdetermination in linguistic theory, person-specific "I-languages" versus socially constructed "E languages" as key areas of scientific inquiry. Chomsky also deliberated over "the logical problem of language acquisition" concerning how children achieve mastery of their native languages despite their rather sparse databases.

In addition to Chomsky's innovative approaches to language development and linguistic theory, Chomsky, a self-described libertarian socialist, has written prolifically on what he deems to be the antidemocratic character of American capitalism and its influence on the country's politics and foreign policy, mass media, and academic and intellectual culture. His strong political activism was instigated early on due to his outspoken critique of the Vietnam War. In his 1966 essay, "The Responsibility of Intellectuals," Chomsky encouraged intellectuals "to speak the truth and expose lies," and he carried his protests beyond his writings: he became a tax resister and was arrested in 1967 at the Pentagon while protesting military involvement in Southeast Asia. Chomsky continued his criticism of US governmental policies since then. For instance, in *Deterring Democracy* (1992) and in other writings, he has honed in on trade

and economic controversies and has criticized the government for being a “rogue superpower.” “I’m a citizen of the United States,” says Chomsky, “and I have a share of responsibility for what it does. I’d like to see it act in ways that meet decent moral standards. It’s back to moral truisms: it’s of little value to criticize the crimes of someone else – though you should do it, and tell the truth. I have no influence over the policies of [other countries] but a certain degree over the policies of the U.S. It’s not a matter of expectation but of aspiration.” He also writes and speaks extensively about controversial issues in the Middle East.

Over the course of his life, Chomsky delivered a variety of impressive lectures: He gave the John Locke Lectures at Oxford in 1969, the Bertrand Russell Memorial Lecture at Cambridge University in January 1970, the Nehru Memorial Lecture in New Delhi in 1972, and the Huizinga Lecture in Leiden in 1977. Chomsky has also received honorary doctorates from more than 25 reputable institutions including the University of Pennsylvania, Georgetown University, Harvard University, Scuola Normale Superiore, Pisa, and the Universidad Nacional De Colombia.

Chomsky served as a Fellow of the American Academy of Arts and Sciences and the National Academy of Science. Additionally, he is the recipient of the Distinguished Scientific Contribution Award of the American Psychological Association, the Kyoto Prize in Basic Sciences, the Helmholtz Medal, the Dorothy Eldridge Peacemaker Award, the Ben Franklin Medal in Computer and Cognitive Science, and others.

City University of New York, Doctoral Programs in Psychology at

HENRY SOLOMON, LINDA ZENER SOLOMON

Marymount Manhattan College, New York, NY, USA

The Psychology Doctoral Programs of the City University of New York (CUNY) have a short history compared to the doctoral programs at such well-known private colleges as Harvard and Yale. However, the public CUNY programs offer degrees in a remarkable breadth of topic areas, eleven as of this writing, taught by distinguished faculty who mentor a diverse and worthy group of students (see CUNY website for individual CUNY colleges).

Municipal colleges in New York City date back to 1947 with the creation of the College of the City of New York for men (later called City College or CCNY). A college for women, The Female Normal and High School for the Education of Teachers (later called

Hunter College), followed in 1870. By the 1960s, there were 11 senior colleges and a number of community colleges in New York City as well. Some of these schools granted masters degrees, but doctoral-level education began in 1961 when the State of New York and the Governor created the City University (CUNY). All of the colleges were combined into one system and a well-funded Graduate School and University Center (GSUC) was added – situated most appropriately across the street from the New York Public Library. The Funding and turf issues among the various departments and college presidents were among the arguments against the merger. Originally, faculty lines included both central and noncentral faculty positions. The noncentral faculty “belonged” to their individual CUNY college and received extra course credits as incentives under Dean Harold Proshansky, a feature eliminated by subsequent administrators.

The ability to tap into the rich resources of all the colleges, their faculty and programs, and labs, while providing advanced graduate education to the diverse population of New York City, offered significant potential benefits that motivated this ambitious venture. The establishment of the Graduate School and University Center provided some unique opportunities. Proshansky (then Executive Officer of the Psychology department) was known to be interested in establishing a Holocaust Studies Center; in 1967, he used the hook of a full professorship with tenure to lure the reluctant (and untenured) Stanley Milgram whose controversial work in obedience had been related to the holocaust, to the Personality and Social Psychology program at the GSUC.

By 1965, the CUNY graduate programs had graduated their first two Ph.D.s, one of whom was Daniel Robinson out of the psychology program. Forty-four years later in 2009, by then a distinguished professor in psychology and philosophy at Oxford, Robinson returned to hood the 10,000th graduate of the CUNY graduate school.

There were nine original doctoral “subprograms” in psychology. *Social Personality*, *Developmental Psychology*, and *Environmental Psychology* are based at the Graduate School and University Center, and the others remain centered at the CUNY college psychology departments where they originated. These others include *Clinical Psychology* at City College,

Experimental Psychology (now *Cognition, Brain and Behavior*) at Brooklyn College, *Biopsychology*, and *Behavioral Neuroscience* at Hunter College, and *Neuropsychology* and *Learning Processes and Behavior Analysis* at Queens College. *Industrial/Organizational Psychology*, at Baruch College, was added in 1981, and *Forensic Psychology* at John Jay College of Criminal Justice in 1999–2000. All of the doctoral degrees are granted by the CUNY Graduate Center. The 11 subprograms can draw on the faculty and resources of all of the CUNY psychology departments including laboratories and special programs at the College of Staten Island and Lehman College in the Bronx. This organization provides a unique opportunity for cross-disciplinary interweaving of psychology, hardly to be found elsewhere.

The CUNY psychology doctoral programs can boast of an array of eminent faculty, as well as a number of graduates who have gone on to distinguish themselves in psychology. While a complete listing of these notables would exceed the space available here, the representative sample that follows provides a picture of the breadth and depth of their contributions to psychology.

Distinguished faculty have included Harold Proshansky (pioneer in environmental psychology); Mort Bard (criminal justice) Stanley Milgram (best remembered for his studies in obedience to authority and urban psychology); Florence L. Denmark (one of the original researchers and writers in the field of gender issues; she has also served as president of the American Psychological Association (APA), and APA representative to the UN); David C. Glass (ground-breaking researcher in effects of noise, health, and stress); Ethel Tobach (eminent researcher in comparative and physiological psychology); Howard Ehrlichman (researcher in neuropsychology of emotion and memory); Peter Moller (researcher in animal behavior, specifically the interrelationships of organisms and environment); Michelle Fine (innovative researcher in social justice – encompassing issues of race, education, access, etc.); Maureen O’Connor (lawyer and psychologist – researcher in social issues in forensic psychology particularly sexual harassment and stalking); and Edwin P. Hollander (researcher known for classic studies in leadership and organizational behavior).

Doctoral program graduates have emerged to distinguish themselves by their research in many areas: for example, in *Developmental Psychology* – Richard M. Lerner (Tufts University – Theory of relations between life-span human development and social change, and research about the relations between adolescents and their peers, families, schools, and communities.); in *Urban Psychology* – Harold Takooshian (Fordham University – research in urban psychology, prosocial behavior, and active in work to internationalize psychology); in *Health Psychology* – Richard J. Contrada (Rutgers University – research on psychophysiologic mechanisms linking personality to cardiovascular disease); in *Program Evaluation and Public Health* – Leonard Bickman (Associate Dean for Research, Vanderbilt University – research in program evaluation and mental health services for children and adolescents); Beatrice J. Krauss (Hunter College CUNY – research on HIV Aids and adolescents); in *Social Psychology* – Samuel Gaertner (University of Delaware – research on intergroup relations, winner of the Allport Intergroup Relations Prize and Lewin Memorial Award from the Society for the Psychological Study of Social Issues); John Sabini (the University of Pennsylvania – research on morality, character, and emotion); in *Gender Issues* – Suzanne Kessler (State University of New York at Purchase – research in transgender issues, social influence, and women and prison); and in *Neuroscience* – Jeffrey Halperin (Queens College CUNY – research on experimental cognition); Catharine H. Rankin (University of British Columbia – research on behavioral, cellular, and molecular mechanisms involved in learning and memory); David Crockett (Robert Wood Johnson Medical School in New Jersey – research on spinal cord injury and repair in animals).

In summary, CUNY graduates have conducted significant research, taken leadership positions in universities, and have been honored by professional organizations. Thus, the CUNY psychology doctoral programs, through the work of their faculty and graduates, have had national and international influence as well as an impact on the field in general. The programs also continue to offer exemplary opportunities for development and accomplishment to new faculty and new students.

Acknowledgments

Personal communications with present and former CUNY faculty to whom we are deeply indebted.

Clark University, History of Psychology at

ERIC P. CHARLES

The Pennsylvania State University, Altoona, PA, USA

Basic History of the Department

A Bright Beginning

Clark University was, in a sense, created for psychology. G. Stanley Hall was anointed founding president in 1888, having previously earned the first psychology Ph.D. granted in the United States, and having founded the *American Journal of Psychology* (AJP). In addition to all his empirical and theoretical contributions to the field, while at Clark, Hall founded the Pedagogical Seminary (now the *Journal of Genetic Psychology*), the *Journal of Applied Psychology*, the *American Journal of Religious Psychology and Education* (later renamed the *Journal of Religious Psychology*), the American Psychological Association (APA), and the Association of American Universities (AAU). Hall began Clark University as the first dedicated graduate institution in the United States, and only the second to offer formalized Ph.D. programs (Johns Hopkins was first). Further, the University was dedicated to scientific pursuit first and foremost, a progressive idea at the time. While it is widely rumored that Jonas Clark, the University's namesake and initial financier, envisioned a purely undergraduate college for Worcester's needy orphans, evidence from the time suggests he envisioned a prestigious, full-service university following the recent models of Hopkins and Cornell. The rumor is understandable however. Jonas Clark wanted to start with an undergraduate college, which he intended as

“a blessing to the community,” and there were long struggles between the founder, the president, and the trustees over the destiny of the institution. Further, Hall continuously misled the faculty in the early years about available resources, and blamed any financial shortcomings on Jonas Clark.

Undergraduate education was forced in only with Mr. Clark’s death in 1900: He left gifts to the University and the campus library, but reserved half his estate to found an undergraduate college. Clark College opened in 1902 and was managed independently of Clark University, even having different presidents, until Hall’s retirement in 1920. While the College did not become co-educational until 1942, the University admitted women after Mr. Clark’s death, and the first female Ph.D. in psychology was awarded in 1908 (a few women had been allowed to work with faculty earlier, including Mary Calkins). It is also worth noting that early Ph.D. students in psychology were, as we would now phrase it, ethnically diverse, with several early graduates being Japanese, and in 1920 Francis Sumner became the first African American to earn a Ph.D. in Psychology (Koelsch 1987).

Clark University remained a nexus for the field of psychology during Hall’s tenure. In addition to the many articles and books produced, *AJP* published at least 33 articles dedicated to “Minor Studies” from the University’s psychology laboratory. Edmund Sanford authored the majority of those publications, typically reporting results gathered by use of a new apparatus, complementing his 1898 publication of the first laboratory manual for psychology (Koelsch 1987). Students’ reports of these years provide a vision of a faculty and student body passionately dedicated to theoretical and empirical mastery of psychology, broadly conceived (e.g., Sheldon 1946; Terman 1930). There was no formal registration process, nor formal enrollment in the lectures and seminars. Research was primary, and the ample research and library facilities, as well as the priorities of the faculty, encouraged and allowed for self-directed work. The widely agreed upon highlight of the educational experience was Hall’s Monday evening seminar, which lasted from 7:30 until after midnight, in which works in progress (either experimental results or literature reviews) were aggressively discussed.

The University’s role as a pioneer of research education could not endure on the grand scale Hall

envisioned. A series of debacles ensued, and by 1905 the University had only ten faculty members, five in psychology. However, even with a small faculty, the University managed to award a significant number of Ph.Ds in its different fields. For quite some time, they awarded the majority of the country’s psychology Ph.Ds, including the American pioneers of educational psychology and intelligence testing: Arnold Gesell, Henry Goddard, and Lewis Terman. Others graduates of note include Linus Ward Kline, who provided the first studies of rats running Y-mazes, and Willard Stanton Small, who provided the first studies with more complex mazes. In biology, Margret Morse Nice, the great ethologist, received her M.A. in 1915. The faculty also maintained its prestige, with more than half being members of the National Academy of Sciences (Koelsch 1987).

The most historically crucial event of that period was Clark’s twentieth anniversary celebration held in 1909. The event involved an extended celebration with academic talks on a wide variety of topics, most open to the public. Included were programs focused on Child Welfare and Psychology, including lectures on psychology by Boas, Burgerstein, Jennings, Meyer, Stern, Titchener, and, from across the seas, Freud and Jung. At the time Freud’s work was relatively unknown; he was not the first choice for a speaker at Clark, and the appearance added much to his reputation, garnering him extensive coverage in academic and lay media. Regarding the lectures, Freud wrote that: “In Europe I felt as though I were despised; but over there I found myself received by the foremost men as an equal. . . it seemed like the realization of some incredible day-dream: psychoanalysis was no longer a product of delusion, it had become a valuable part of reality.” This was Freud’s only appearance in the United States and these lectures were later published as *Five Lectures on Psychoanalysis* (original publication, Freud 1910). This event significantly affected the trajectory of psychology, and Western culture (Fancher 2000) and have been written about in great detail (Rosenzweig 1994, see also Evans and Koelsch 1985; Koelsch 1984; Roazen 1977; Simon 1967).

Departmental faculty from the Hall era included Sanford (who was also the first president of the undergraduate College), neurologists Henry Donaldson and Clifton Hodge, Titchener disciples Wallace Baird and

E. G. Boring (then still an experimentalist), pedagogist William Burnham, psychiatrists Adolph Meyer and Edward Cowles, and anthropologists Franz Boas and Alexander Chamberlain. The productivity of the psychology department during Hall's tenure was influential in convincing other institutions to create positions for the scientific study of psychology, which, ironically, diminished Clark's importance to the field (Koelsch 1987).

Seeking Direction

Following Hall's tenure, the psychology department dropped rapidly in esteem. Within 3 years, there were practically no faculty left, and President Atwood (who succeeded Hall and Sanford to head the combined University and College) actually got the board of trustees to vote to cancel the psychology Ph.D. program in 1923 (though the decision was quickly reversed after it became public). Atwood appointed Carl Murchison head of the department, and it slowly started to rebuild. Faculty of this period include behaviorist Walter Hunter as the first G. Stanley Hall Professor of Genetic Psychology. Perhaps most importantly in this era, Murchison and Atwood founded the Clark University Press in 1927 which published, among other things, the *International University Series in Psychology* and *History of Psychology in Autobiography* books series, as well as *Journal of Genetic Psychology*, *Genetic Psychology Monographs*, *Journal of General Psychology*, *Journal of Social Psychology*, and *Journal of Psychology*. However, Murchison's publishing acumen could not make up for his personal and professional style, which drove off many faculty members. When he finally left the department in 1936 Vernon Jones, the only remaining member of the psychology faculty, became chair of a joint Department of Psychology and Education, and turned the focus toward education. Meanwhile, in biology, Hudson Hoagland attempted to start a Ph.D. program in neurophysiology. Lacking University support, he ended up with a program in physiology, with staff limited to grant-funded researchers, operating out of a repurposed carriage house. Hoagland went on to perform pioneering studies of neural functioning, including some of the first electroencephalograms of mentally ill patients, though with no apparent connection to the psychology department. In psychology, the only events of interest for the next decade were a series

of big-name hires, who came and went rather quickly: Raymond Cattell spent a short time as the Hall chair, as did Karl Buehler, with his wife Charlotte Buehler as a lecturer. Just before retirement, President Atwood appointed Roger Baker to the Hall Chair, but seeing little hope of establishing his desired field station, he soon left for Kansas (Koelsch 1987). Cattell quipped that the problems at the University were largely explainable by the "ghosts of Hall and Clark continuing their deadly struggle for an elite university and a poor boy's college" (Cattell 1974).

In 1946, Howard Jefferson became Clark's new President, drawn by the remnants of the intellectual enthusiasm characteristic of the University's early years. His efforts to revitalize the University were bolstered by the increased resources resulting from the G.I. Bill and the steady increase in female enrollment. He prioritized the reinvigoration of psychology and when Baker left for Kansas in 1949, Jefferson separated psychology from education, and hired Heinz Werner to head the psychology department as Hall Chair. In the 1950s, when deficits returned, Jefferson helped defend the department against another push to shut down its Ph.D. program (Lane et al. 2005; Koelsch 1987).

A Second Wind

Clark once again rose to prominence after Werner's arrival. Werner arrived with an established international reputation. One of his first public acts was to host the 1950 meeting of the Eastern Psychological Association at Clark, in celebration of the University's sixtieth anniversary (Koelsch 1987). Among other speakers, Anna Freud delivered a series of lectures, including one in the symposium on Genetic Psychology (Freud 1950). Werner was given permission to build the department around himself. With Jefferson's support, and with his skills at securing external funds, Werner grew the department significantly and divided the Ph.D. program into developmental and clinical tracks (Koelsch 1987), though a rigid separation of the subjects was thoroughly rejected (Kaplan et al. 2005). A first priority was to hire his collaborator, Seymour Wapner. Other very prominent new faculty included Kurt Lewin's student, Tamar Dembo, who worked on rehabilitation psychology, and Richard Lazarus and Mort Weiner who made empirical contributions to clinical psychology. Werner established

collaborations with numerous community institutions and mental health centers around Worcester and Boston, greatly expanding the resources available to faculty and graduate students. The grant funds allowed for post-doc and graduate student funding, and improved facilities. Werner and Wapner also had an important role in orienting the departmental resources downward toward undergraduates in a way that had never occurred before, and the department grew until it represented over 20% of all undergraduates at Clark (Koelsch 1987; Lane et al. 2005).

Werner's research focused on psychological development, broadly conceived to require an understanding of comparative psychology, clinical psychology, and biological development, all guided by an eye toward the interface of philosophical thinking and empirical investigation. In the 1950s, psychology as a field prioritized developmental psychology, and Werner's work was seen as central to the field (Valsiner 2005b). Werner was offering the first courses in America to cover the work of Piaget and Vigotsky (Franklin 1990). His past research covered many topics, but always focused on development, and within that category it focused on changes in psychological processes, rather than sequences of outcomes. Werner's theoretical work continued to be process oriented, but the new empirical research, much carried out by his colleagues and students, consisted mostly of short, outcome-oriented experiments, amenable to statistical analysis. The primary lines of this research were work on sensory-tonic theory, continued by Wapner, and symbol formation, continued by Bernard Kaplan (Valsiner 2005b). These included extensive studies of the factors, internal and external, that effected space perception (Wapner 2005) and the learning of word and symbol meanings (Kaplan et al. 2005).

Times were good, and the department developed a characteristic style of combining empirical investigation with sophisticated theory. This was often seen as a "school of thought" from the outside, but not recognized as such from within (Lane et al. 2005; Morant 1966; Valsiner 2005a). Perhaps encouraging the outsider's view, several department graduates were hired as faculty members, including Kaplan, Robert Baker, Lenard Cirillo, and Roger Bibace. Thus, Werner's influence persisted in shaping the department long after his retirement, and even his death (Franklin 1990; Lane

et al. 2005). This also means that Werner's influence did not spread as much as it might have. Some have concluded that, as the field of psychology shifted its priorities, Werner's approach waned in perceived importance, and the program's reputation diminished (Koelsch 1987; Lane et al. 2005). It has also been suggested that the Werner's theory suffered because Werner was not inclined to repackage his ideas into contemporary jargon, and also because its openness and flexibility made it more difficult to adapt to straightforward hypothesis testing than, say, Piagetian theory (Franklin 1990). That said, Werner's thinking has a sizable legacy of influence on work in developmental and clinical psychology (Bibace 1966; Glick and Zigler 2005; Miller 2005).

In 1957, the Institute for Human Development was founded (later the Heinz Werner Institute of Developmental Analysis), and in 1966 it began hosting the prestigious Heinz Werner lecture series and published the monographs thereof. In 1960, Wapner followed Werner as department head and Hall Chair. In 1965, the Eastern Psychological Association and Massachusetts Psychological Association held memorial services in Werner's honor (Wapner and Kaplan 1966).

Wapner was a skilled academic politician, a ferocious advocate of psychology as a discipline, empirical research as an activity, and Clark's psychology department as an institution. He held many offices in the American Psychological Association (APA), founded the Council of Graduate Departments of Psychology (COGDOP), and had the record for the longest continuous grant funding of any psychologist. In 1970, Wapner engineered a substantial departmental developmental grant, which funded positions in the psychology department designed to cement research relations with sociology and biology, and to lend some of psychology's prestige to those departments (Koelsch 1987). This led to a long struggle in the department between the integrative Wernerian tradition and a more conventional understanding of psychology as a multi-perspective discipline.

During the 1970s and 1980s, the department continued to have faculty with strong reputations as individuals, and there was a general focus on development. The studies were eclectic: Roger Bibace worked on issues in clinical work with children, Nancy Budwig on linguistic development, Leonard Cirillo on

sensory-tonic theory, Hobb Crocket on social psychology, Rachel Falmagne studied logic, Bernard Kaplan continued developmental research in the Wernerian tradition, James Laird worked on self-perception of emotions, Joseph de Rivera combined Lewin's field theory with contemporary social and personality issues, David Stevens on operant conditioning and the psychometrics of smell and taste, Donald Stein on localization of brain functions, Nicholas Thompson worked on communication in animals and humans, Ina Uzgiris on the interaction of behavioral and cognitive development, Morton Wiener on verbal development, Marianne Wiser on conceptual development of children, and Jack Wohlwill on experimental approaches to Piagetian theory. One characteristic of the faculty at that time, having been hired predominantly during the Werner/Wapner era, was a drive toward empirical and conceptual integration of ideas. The department was still characterized by an interest in higher-level theorizing; while the faculty seemed highly specialized to each other, within their subdisciplines their interests often seemed unusually broad.

After Werner and Wapner

Wapner maintained chairmanship of the department until his retirement in 1986. The year before, he presided over a symposium on "Freud in Our Time" marking the seventy-fifth anniversary of Freud's trip to America (Koelsch and Wapner 1988). Though Wapner continued to inspire both graduate and undergraduate students, psychology as a field had grown cognitive, and the computer model of the mind rendered Clark's Wernerian tradition, both in its specialized subject matter and in its broad approach to any psychological problems, no longer central to the field. Also, the Wernerian tradition, of deep thinking, and searching for the "critical experiment" to test ideas, did not fit in well with the rapid-fire publication trends developing during these times.

The bright spot of this period came in 1989 when Jacob Hiatt, University graduate and longtime trustee, gave a large endowment to name the Frances L. Hiatt School of Psychology. During the early 2000s, the Clark University Press closed shop (following the national trend of small university presses), the Werner lecture series ended, and the Heinz Werner Institute ceased to be active. There still remains a small reading room

containing a collection of Werner's files and many of his books under the label The Heinz Werner Library. Since Wapner's retirement, the Hall Chair has remained empty, though there also remains a reading room bearing Hall's name and containing a large part of his personal library.

A Current Assessment

The psychology department is still one of the flagship programs at Clark University, offering Ph.Ds through the development and clinical programs, as well as the social, evolutionary, and cultural program. Despite the downturn in prestige and departmental coherence following the Werner/Wapner era, the situation in the department never became nearly as grim as it was during the post Hall years. Bolstered by Hiatt funds, the department remains the largest on campus in terms of faculty and students, and enjoys recently renovated facilities. It has been very successful in getting its undergraduate students into graduate programs and its graduate students into tenure-line positions.

The department's current state reflects its history. The ghosts of Clark and Hall continue to fight in its hallways, and many tensions in the department reflect the modern difficulties in trying to run a prestigious graduate school and a prestigious liberal arts college simultaneously. The faculty members as individuals maintain strong reputations, publishing well and maintaining prestigious roles in niche professional societies. Michael Addis and James Cordova, for example, bring a strong neo-behaviorist flavor to the clinical program. Nancy Budwig was recently president of the Jean Piaget Society, Rachel Falmagne was president of the International Society for Theoretical Psychology, Michael Addis was president of the Society for the Psychological Study of Men and Masculinity (Division 51 of the APA). Joseph de Rivera directs the peace studies program. Michael Bamberg edits the journal *Narrative Inquiry* and the book series *Studies in Narrative*. Jaan Valsiner edits the journals *Culture and Psychology* and *Integrative Psychological and Behavioral Science*, and the book series *History and Theory of Psychology*, *Advances in Cultural Psychology*, and *Cultural Psychology of Social Representation*. Behind these individual accomplishments, the department as a whole lacks clear focus. This can be seen at both the faculty and student levels, made worse by increased

strictures in gaining APA accreditation for the clinical program, as well as struggles over campus resources. The problem can be seen most clearly, perhaps, in the artificiality of the department's division structure: Separations that were once lamented, such as those between clinical and developmental psychology (Kaplan et al. 2005), or between developmental psychology and cultural psychology, are now used to categorize students and faculty in highly reified ways.

The most notable continuity with the department's past is Valsiner, who continues the developmental psychology legacy of Werner and Hall through both original research and historic scholarship on developmental theories. He holds a weekly international meeting comparable to Hall's seminar from a century before, but without the aggression. Department faculty (most notably Bamburg, Bibace, Kaplan, Thompson, Weiner, and topologist Lee Rudolph) are joined by several students (graduate and undergraduate), international visitors, and, by video link, colleagues in South America and Europe, to discuss research in progress.

In 2009, the University celebrated its 120 year anniversary, the centennial of Freud's visit, with a combination of public and private events. Another conference to mark the Freud centennial was held by the New York Academy of Medicine.

The Future

The ghosts of Clark and Hall are still present at the University: The goals of running a research University and a small College are difficult to balance. Clark is not well positioned to compete with the enormous, well-funded research universities that currently dominate mainstream psychology. That said, the school has the potential to continue as a place of innovation, a place where not-quite-mainstream approaches to psychology, especially integrative approaches, can grow and thrive. In that sense, it retains its ability to once again become central to the field. However, there is little way of knowing in what form it will next arise.

Significance

The significance of the department to the history of psychology has been great, particularly during the Hall and Werner/Wapner eras. As one of the first departments of psychology, it produced the majority of psychology Ph.Ds in the country, and was essential in

raising the field to a prominence that led other universities to create psychology departments. Hall's developmental perspective, his journals, and the societies he helped found still shape psychology. The Murchison era saw the creation of the Clark University Press, which published many important journals and book series. Werner brought back a developmental focus to the department, and in addition to his historic importance, there is a current resurgence of interest in his work, which Kaplan and Wapner continued. Throughout that time, Clark has provided a pulpit for many notable speakers through its anniversary celebrations, its Werner Lecture Series, and its professorships (visiting and permanent). Several graduate and undergraduate students have gone on to become important members of the field.

Clark, Kenneth B.

ERIC JAMES, JOHN D. HOGAN
St. John's University, Jamaica, NY, USA

Basic Biographical Information

Born: 1914; Died: 2005

Kenneth B. Clark was a social psychologist and educator, whose research, writing, and activism had

a significant impact on racial issues within the USA. Clark was born on July 14, 1914, in the Panama Canal Zone. His Jamaica-born parents, Arthur Bancroft Clark and Miriam Hanson Clark, had immigrated to the Panama Canal Zone because of employment opportunities there. However, Miriam desired a better life for her children and, in 1919, left her husband and moved to New York City with Kenneth and his younger sister, Beulah, ultimately settling in Harlem (Guthrie 1976).

While many young African-Americans of the period were strongly encouraged to attend vocational schools, Miriam insisted that her son, Kenneth, pursue an academic track. In 1931, Kenneth Clark graduated from George Washington High School and was admitted to Howard University where he earned a bachelor's and master's degree. While there, he met Mamie Phipps, a young mathematics student who would become his partner in life and in research. They married in 1938. Clark continued his studies at Columbia University with Otto Klineberg, a psychologist who conducted studies debunking racial and genetic myths concerning intelligence.

In 1940, Kenneth became the first Black American to receive a doctoral degree in psychology from Columbia University. His wife earned a doctorate in psychology from Columbia in 1943, the second Black American to do so. The work for which Kenneth Clark became best known early in his career was a continuation of his wife Mamie's master's thesis in which she had examined self-concept and self-esteem in Black children. His report on the individual impact of racial prejudice prepared for the 1950 Mid-Century White House Conference on Children and Youth was viewed as important evidence for the NAACP, which was preparing lawsuits to challenge legal racial segregation in public schools. Eventually, Clark's work would make a substantial contribution to the noted Supreme Court decision, *Brown vs. the Board of Education*, which outlawed racial segregation in public schools.

Kenneth Clark achieved many firsts. He was the first Black American to hold a permanent professorship at the City College of New York, the first Black educator to join the New York State Board of Regents and, in 1970, he became the first and only (to date) Black American to serve as president of the American Psychological Association (APA). During his 20 years as a member of the New York State Board of Regents, Clark was often

described as the conscience of the board. When he became president of the APA, he provided that organization with the same conscience through his pursuit of ethnic and social responsibility. This foresight and dedication earned Clark the APA's Gold Medal Award for his contributions to public interest in 1987 and, in 1994, the APA's Lifetime Achievement Award.

Kenneth and Mamie Clark raised two children, Kate (born in 1940) and Hilton (born in 1943). Kenneth Clark died in his home in Hastings, New York, on May 1, 2005, at age 90. His wife, Mamie, died in 1983 (Jones and Pettigrew 2005).

Basic Accomplishments/Contributions

The early studies by the Clarks (e.g., Clark and Clark 1940) employed picture coloring and dolls in order to evaluate the racial identifications of young African-American children. In 1952, one segment of their experiments was repeated for the National Association for the Advancement of Color People (NAACP) with 16 children (ages 6–9) in Clarendon County – a segregated and racially polarized region of central South Carolina. Of the 16 children tested, 11 said the Black doll looked “bad,” 9 said the White doll looked “nice,” and 7 of the 16 tested said that the White doll looked like them when asked “show me the doll that’s most like you.” Because this part of their experiment was the most dramatic, it came to be known as “the doll test” (Jackson 2006).

In 1953, Thurgood Marshall and the NAACP Legal Defense and Educational Fund used the doll test and Kenneth and Mamie Clark’s early research on self-identity of Black children to challenge the constitutionality of “separate-but-equal” educational opportunities for Black and White children. Kenneth Clark also coauthored the Social Science Statement, an appendix to the legal brief submitted to the Supreme Court in *Brown vs. the Board of Education*. This was the first time social science research was presented as evidence to the Supreme Court and was said to have played a key role in the decision.

Together Kenneth and Mamie Clark founded the Northside Center for Testing (renamed the Northside Center from Child Development in 1948), an organization that provided vocational counseling to adolescents, psychological testing and consultation of children with

behavior issues, and parental education in childcare. In 1962, they organized Harlem Youth Opportunities Unlimited (HARYOU), an organization that provided school-based services to Harlem youths. In addition to HARYOU, Kenneth and Mamie Clark also established a consulting firm designed to improve race relations within the business community (Phillips 2004). Kenneth Clark, often with the assistance of this wife, published more than 20 articles pertaining to the psychological study of ethnic and minority issues and authored/coauthored more than half a dozen books including *Prejudice and Your Child* (1955) and *Dark Ghetto* (1965).

Cole, Michael

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/Major Accomplishments

Michael Cole, the American psychologist, has been studying the development of human thinking from

a cultural historical perspective for more than 50 years. Only in the last decade, however, has worldwide psychology come to recognize that Cole is in fact one of the giants of cultural psychology. He is arguably the most influential cultural, developmental, child psychologist, and educator of his North American generation. His work is studied by eminent contemporary academics, psychologists, philosophers, and educators. His influence is international. He reached across the world to a generation of teacher educators who passed on his ideas to succeeding generations. The impact of Cole's ideas upon the present-day cultural psychology is becoming increasingly evident. He is a thoughtful and immensely erudite scholar whose deep understanding of cultural historical mediating activity and children's thought processes have been admired and discussed by eminent scholars. Cole synthesized the work of earlier Soviet, European, and American psychologists and educators into a particularly North American package, suited to the practical bent of American education and psychological science. And always, at the heart of his work lay the belief that deep observation and practical activity are the keys to understanding the complex and unique realities of human development.

A pioneering psychologist, Cole is also a highly prolific intellectual thinker. His major works span dozens of books and monographs and over 400 scientific articles, written over roughly 50 years, from his early works in the USA, USSR, South America, and Africa to the field of cultural psychology. Cole's interests in the areas of cultural psychology, developmental psychology, educational psychology, child development, epistemology, and methodology are extremely diverse and interdisciplinary. His creative work in cultural psychology includes several key concepts such as social interaction, mental tools, cooperation, collaboration, activity, mediation, internalization, distributed cognition, distributed collective activity, collective cognition and memory, microgenesis, zone of proximal development, oral word, written word, reading, and writing. His work covers such diverse topics as literacy, concept formation, cognitive development, cultural development, after school learning activity, relation between learning and teaching processes, and the origin and development of higher mental functions.

Cole's theoretical insights are reported to have influenced the development of a wide range of educational and psychological theories such as activity system theory, distributed cognition, apprenticeship, and cultural historical psychology. Cole has a strong influence on a number of thinkers such as Sylvia Scribner, James Wertsch, Vera John-Steiner, Barbara Rogoff, and Urjo Engeström among others. He is largely responsible for introducing Vygotsky, Luria, Leontiev, and Soviet psychology to the US. He was the first who stressed the need for international cooperation in advancing a new science of human development capable of contributing to theoretical and practical solutions. This new science must overcome not only the theoretical fragmentation and controversies that characterize the present-day human sciences, but also the geographic or national isolation within which most theoreticians and researchers operate.

Cole first developed the Fifth Dimension educational project in 1986; and since then it has been implemented in many countries throughout the world. It is based on Vygotsky's cultural historical theory. Cole developed a major field of research known as cultural historical activity theory (CHAT). He took to the test Vygotsky's zone of proximal of development, concept of mediation, and concept formation in the learning process. According to Cole, the goal of education is not the individual adjustment to society, but rather the deliberate cultivation of ability to think creatively, to reason critically, and to operate abstractly.

Columbia University, History of Psychology at

ROBIN L. CAUTIN¹, LUDY T. BENJAMIN, JR.²

¹Manhattanville College, Purchase, NY, USA

²Texas A&M University, College Station, TX, USA

Introduction

In November 1885, 5 months away from earning his doctorate in psychology at the University of Leipzig with Wilhelm Wundt (1832–1920), James McKeen Cattell (1860–1944) wrote to his parents extolling his latest accomplishment, one of his first published articles (Cattell 1886): “I received today both ‘Brain’ and the ‘Studien’ with my paper. . . . A paper like this gives me a very secure place in the scientific world, makes me equal with any American living” (Sokal 1981, p. 192). The grandiosity of this statement from the 25-year-old Cattell was not atypical of self-descriptions that Cattell relayed to his parents, for example, in an earlier letter commenting that Wundt seemed to appreciate his “phenomenal genius” (Sokal 1981, p. 160). Clinical psychologists reading Cattell’s letters today would find much evidence there to make a diagnosis of narcissistic personality disorder (NPD). Whether such a diagnosis is merited for Cattell we cannot know. NPD, however, is not a debilitating condition; indeed, many individuals with NPD prove to be extraordinarily accomplished. Historian Michael Sokal, the leading authority on Cattell has characterized Cattell’s personal style as “self-righteous egotism that led him to expect others to defer to his views. . . . To Cattell, all was black or white, and he always knew which was which” (Sokal 2009, p. 90).

Although Cattell’s high opinion of himself may not have served him well in his interpersonal relationships, it likely played a critical role in his considerable entrepreneurial accomplishments as a psychologist, accomplishments that made him equal to any psychologist living in his time. Among his many achievements was his founding of a doctoral psychology program that can be argued to have been the most significant training ground for American psychologists for a 60-year period – the psychology program at Columbia University. In this entry, we trace the

histories of the psychology departments at Columbia University, first in the graduate program on the main campus, then at Teachers College, and finally at Barnard College.

Founding the Psychology Laboratory

James McKeen Cattell graduated from Leipzig in 1886 and remained in Europe, in Leipzig for a while and then in Cambridge, England, where he studied with Francis Galton (1822–1911). He returned fulltime to the USA in January 1889 to accept a professorship at the University of Pennsylvania where he established his first psychology laboratory (Cattell 1890a, 1928). But 2 years later, he was lured away to initiate a second laboratory at Columbia College in New York City.

Nicholas Murray Butler (1862–1947) was chair of the philosophy department at Columbia in 1890. He was aware of the new experimental work in psychology and sought an instructor in the subject. In a collection of brief articles in an 1890 issue of the *American Journal of Psychology* that described the status of the new science of psychology at American Universities, Butler (1890) wrote that the department at Columbia hoped “to secure within a few months not only a specialist in Experimental Psychology, but a well arranged laboratory and a fair stock of apparatus” (p. 278).

When Cattell joined the Columbia faculty in 1891, the college was on East 49th Street. He was housed in the attic of the administration building where he set up his psychology laboratory. One of his first students was Margaret Floy Washburn (1871–1939) who worked on a problem given her by Cattell, an assessment of the validity of Weber’s law for two-point thresholds on the skin. Although Washburn was fully supported by Cattell, Columbia College policies allowed women to attend graduate classes only as a hearer. And so she transferred to Cornell University in 1892 where she would earn her doctorate with Edward B. Titchener (1867–1927) (Washburn 1930). Cattell’s first doctoral student, who was a classmate of Washburn, was Harold Griffing (? – 1900), who completed his degree in 1894 with a dissertation on tactile perception (Griffing 1895). Apparently, Griffing never held an academic position. He was responsible for the financial support of his mother and an invalid sister and thus was “unable to accept such university positions with small salary as were open to him” (Anonymous 1900,

p. 639). Instead, he practiced law for a few years before his untimely death in 1900. Both Cattell (1900) and Washburn (1930) wrote of him as a scholar of great promise.

In 1893, Columbia hired Livingston Farrand (1867–1939) to teach courses on the brain and nervous system and on abnormal psychology. His initial training was in medicine at Columbia and then experimental psychology with Cattell, but he later functioned primarily as a professor of anthropology after training with the eminent anthropologist Franz Boas (1858–1942). Farrand taught 20 years at Columbia, the first 10 in psychology and the next 10 in anthropology (Woodworth 1940a).

Boas, who is considered the founder of modern anthropology, was already a world famous anthropologist when he joined the faculty at Columbia in 1896 as part of the Department of Philosophy, Psychology, and Education. Not surprisingly he and Cattell clashed, the meeting of two exceptional talents and egos to match. Cattell continued to be in charge of psychology but in 1899 the administration renamed his department Psychology and Anthropology. Yet 3 years later, Boas had his own separate department, leaving Cattell in charge of the once again renamed Department of Philosophy and Psychology.

In 1896, the same year in which Boas joined the Columbia faculty, Cattell made another hire that was critical to the success of his psychology program: Charles Augustus Strong (1862–1940). After studying psychology and philosophy with William James (1842–1910) at Harvard University and Carl Stumpf (1848–1936) at the University of Berlin, Strong founded the psychology laboratory at the University of Chicago in 1893. He joined the Columbia faculty in a similar role and also taught courses in analytic psychology. By 1903, the year in which he published his first book – *Why the Mind Has a Body* – Strong had shifted his teaching almost entirely to courses in philosophy, a subject he taught for the last decade of his 18 years on the Columbia faculty (Woodworth 1940b). Strong had married Bessie Rockefeller, the daughter of John D. Rockefeller in 1889. This connection would lead to a gift of \$100,000 in 1899 from Rockefeller to endow Cattell's professorship.

Cattell would not produce his second doctoral student until after the college moved to its Morningside

Heights campus in 1896. The psychology laboratory occupied nine rooms on the fourth floor of Schermerhorn Hall, which included, in addition to office space and classrooms, four rooms for research plus a shop (Woodworth 1942). Those first few years in the new labs would be among Cattell's most productive, resulting in eight doctoral students in 1898–1899 including Edward L. Thorndike (1874–1949), Shepherd Ivory Franz (1874–1933), and Robert S. Woodworth (1869–1962), two of whom would have especially important roles in psychology's history at Columbia as will be discussed later. Ever the entrepreneur, Cattell greatly expanded his psychology laboratory, acquiring additional research space in 1899 that covered half of the fifth floor.

Mental Testing at Columbia

In his studies with Galton at Cambridge University in the late 1880s, Cattell was much taken with Galton's anthropometric tests, even participating as a subject in Galton's test battery. He would meld a version of Galton's testing program with the experimental procedures he had learned in graduate study at Johns Hopkins University and Leipzig to initiate the earliest form of intelligence testing in America, an activity whose outcome would become an obsession nationwide for parents and school teachers and the mainstay of psychological practice for those who worked under such labels as clinical psychologist or consulting psychologist in the first half of the twentieth century.

Cattell is credited with coining the term “mental test,” first used in an article in the journal *Mind* in 1890. In arguing for the importance of such tests, he wrote:

- ▶ Psychology cannot attain the certainty and exactness of the physical sciences, unless it rests on a foundation of experiment and measurement. A step in this direction could be made by applying a series of mental tests and measurements to a large number of individuals. The results would be of considerable scientific value in discovering the constancy of mental processes, their interdependence, and their variations under different circumstances. (Cattell 1890b, p. 373)

Galton's testing program was an outgrowth of the philosophy of British empiricism that emphasized the primacy of the senses as the means by which all knowledge is acquired, by his hereditarian views of the

determination of genius, and by his goals for the betterment of the human race as expressed in his program of eugenics. Galton's testing program had emphasized sensory measures such as acuity and discrimination; reaction time; and physical measurements, including measures of head size (Fancher 1997). If all knowledge comes to the mind via the senses as the empiricists had asserted, then those with superior sensory abilities should be more intelligent. Reaction time to sensory stimuli was also considered a measure of intelligence because it was a measure of the speed of neural processing in the brain, a subject that Cattell had investigated at Johns Hopkins and Leipzig (see Cattell 1885, 1886/1887). Further, because brain size was believed to be important for mental ability, such that bigger brains were better, head size was also assumed to be a valid component in a test battery to measure intelligence. For Galton, his intelligence tests provided the means to select those individuals who should be part of a eugenics program aimed at improvement of the human species (Galton 1865).

Cattell's (1890) tests included some of the same measures. He began his anthropometric testing program in his laboratory at the University of Pennsylvania and soon settled on a battery of ten tests that included sensory measures (weight discrimination, two-point thresholds, pain perception), motor measures (rate of arm movement), physical measures (strength of hand grip), reaction time measures (to a sound stimulus and in naming colors), and cognitive measures (memory for letters, time perception).

Cattell (1893) touted the value of his tests in an article for teachers in the journal *Educational Review*. He claimed that "such tests give a useful indication of the progress, condition, and aptitudes of the pupil" and that conducting such tests "might serve as a means of training and education" (p. 257). At the same time that Cattell was promoting the value of his tests to educators, he was making a similar pitch to Seth Low, the President of Columbia University, asking for permission to test Columbia students to determine their "condition and progress. . . [and] the relative value of different courses of study" (Sokal 1982, p. 324). He confessed that he was not sure how his tests would determine such educational efficiency, but argued that the "best way to obtain the knowledge we need is to make the tests, and determine from the results what

value they have" (p. 324). Cattell received the authorization he requested in 1894 and, with Farrand's help, they began testing every student upon their entering Columbia University (Cattell and Farrand 1896). That program continued throughout the 1890s, and Cattell and his graduate students regularly reported on the results at various scientific meetings and educational conferences (Sokal 1982).

By the end of the 1890s, Cattell had a mountain of data from Columbia students. And he had a new statistical way to assess the validity of his tests as measures of intelligence. Galton introduced the concept of correlation in 1888 as a means by which the relationship between things could be statistically determined. His student, Karl Pearson (1857–1936), developed a formula to measure correlation, and it was this new statistic that Cattell learned about in the late 1890s. Here was a means by which Cattell's tests could be compared to student performance in college classes. Cattell enlisted the services of a graduate student, Clark Wissler (1870–1947), to perform the correlational analyses. Wissler compared each of Cattell's tests to the grades students earned in their classes and found that the resulting correlations were all in the near-zero range indicating no relationship. Thus, as predictors of academic performance they had no validity. It was the death blow for Cattell's decade-long research program. Sokal (1982) wrote, "Wissler's analysis struck most psychologists as definitive and, with it, anthropometric mental testing, as a movement, died" (p. 340).

Cattell would work another 17 years at Columbia, but his career as an experimental psychologist largely ended with his anthropometric studies. Instead, he focused much of his energies on the journals that he owned and edited. He had purchased the journal *Science* in 1894 and would edit that until his death in 1944, having created perhaps the most important scientific journal in the world (Sokal 1980). He edited other journals as well such as *School and Society* and *The Popular Science Monthly*, as well the early years of *Psychological Review* which he cofounded with James Mark Baldwin (1861–1934) in 1894.

Robert Woodworth and the Columbia Psychology Department

Woodworth finished his doctorate in 1899 under Cattell with a dissertation on the accuracy of

voluntary movement. Woodworth was a close friend to E.L. Thorndike whom he had met when they were students at Harvard together. They finished their doctorates at Columbia within a year of each other and were, without a doubt, Cattell's two most successful doctoral students. For many years, they would be the senior voices in the two graduate psychology departments at Columbia: Woodworth in the psychology department and Thorndike in the educational psychology department at Columbia's Teachers College. After graduation, Woodworth worked part time at Columbia as a lecturer prior to a 2-year sojourn to Europe where he worked with physiologist Charles Sherrington (1857–1952). Cattell invited him back to Columbia in 1903 and he would remain there for the rest of his life teaching until almost the age of 90 and directing the psychology department during some of its most successful years (Woodworth 1932).

Cattell was listed as executive officer of the psychology department from 1891 to 1912. Woodworth succeeded him formally in 1912 and served in that role until 1926. But in fact Cattell relinquished his duties much earlier, meaning that Woodworth had the work without the title or the salary (Winston 2006). In fact Cattell, whose home was 50 miles from the university, had an agreement with the Columbia administration that he was required to be on campus only 2 days each week. That left most of the administrative duties and much of the contact with graduate students, including research supervision, on Woodworth's shoulders (Poffenberger 1962).

By 1906, Woodworth handled the bulk of doctoral student supervision. That year, he founded a new journal, *Archives of Psychology*, which he edited until 1945. This was a monograph series that principally published doctoral dissertations of Columbia's psychology students, although other contributions were occasionally made, often by Columbia faculty or former students. For example, the first monograph in the series was by Naomi Norsworthy (1877–1916) and her dissertation was on "The psychology of mentally deficient children." She was hired by Columbia's Teachers College. The second and third monographs in the series were published the following year by Shepherd Franz and E. L. Thorndike. By 1945 when Woodworth's editorship ended, the journal had published 300 monographs, a number of which would prove to be

particularly significant contributions to psychology, for example, monographs by Otto Klineberg (1899–1992) on the psychology of race, Rensis Likert (1903–1981) on the scaling technique that would eventually bear his name, and Muzafer Sherif (1906–1988) on social factors in perception. Klineberg was Woodworth's student and the other two were mentored by Gardner Murphy (1895–1979) who Woodworth recruited to the graduate program and later to the faculty. Gardner Murphy, who taught at Columbia from 1920 to 1940, is often considered the founder of experimental social psychology based on his 1931 book by the same name. His social psychology students at Columbia included Solomon Asch (1907–1996) and Theodore Newcomb (1903–1984), in addition to Likert and Sherif. Those four names would be on any Mount Rushmore of social psychologists and is testimony to the strength of social psychology at Columbia under the guidance of Murphy and Klineberg.

Woodworth was chiefly responsible for the instruction in experimental psychology at the graduate as well as undergraduate level. His lectures for that course would eventually be "published" in a mimeographed form in 1909 and later expanded with his student Albert T. Poffenberger (1885–1977) as a coauthor. The book was known to Columbia students as "The Bible" (Winston 1990). It was ultimately published commercially in 1938 as *Experimental Psychology*, with Woodworth as sole author.

As Andrew Winston has shown, this book produced a sea change in the language of experimental psychology and, indeed, in what was judged to be experimental and not just empirical research. Woodworth defined an experiment as the manipulation of an independent variable and the measurement of its effects on a dependent variable or variables. As Winston (1990) has noted, "Woodworth's 1938 definition of experiment became nearly universal in psychology textbooks" (p. 391). Woodworth distinguished between experimental studies and correlational studies, noting that discovering causes was possible only in the former. He drew a sharp distinction between empirical studies and experimental studies, noting that the latter involved active manipulation of an independent variable which the former did not. In making this distinction, he argued that mental testing was empirical work but it was not part of experimental psychology, a point

that was hotly debated within psychology, especially among those who were heavily invested in mental testing, for example, Lewis Terman (1877–1956).

Winston (1990) made a further claim for the remarkable influence of Woodworth's *Bible* in arguing that Woodworth's restricted definition of an experiment and his insistence that it was the only method to reveal causation provided a crucial rationale supporting animal research in psychology during the 1930s through the 1950s. He wrote:

- ▶ . . . Woodworth's view would support the following reasoning: *If we can find the "causes of behavior" only by manipulating an independent variable while holding all other variables constant, and to do so with humans will frequently be unethical, impractical, or impossible, then we must seek the causes of behavior with laboratory animals, specially bred and reared under controlled conditions.* (pp. 397–398)

Winston has asserted that E. C. Tolman (1886–1959), B. F. Skinner (1904–1990), and many other psychologists of that time adopted the language of the experiment as defined by Woodworth and pursued their animal research in search of causes. Animal researchers, essentially disciples of Skinner, would soon control the psychology department at Columbia. Even if Winston is correct that Woodworth's definition of experimental psychology abetted them, Woodworth would never have favored the narrow disciplinary focus that psychology at Columbia would acquire. He believed in an eclectic psychology and largely fostered that ideal in the many years that he chaired the department (Poffenberger 1962; Thorne 1976; Winston 2006). His eclecticism is perhaps best illustrated in Edna Hebbreder's (1890–1985) description of what it meant to be a doctoral student at Columbia University during his tenure.

- ▶ Psychology at Columbia is not easy to describe. It stands for no set body of doctrine, taught with the consistency and paternalism found in more closely organized schools. Yet it shows definite and recognizable characteristics. A graduate student in psychology cannot spend many weeks at Columbia without becoming aware of the immense importance in that atmosphere of curves of distribution, of individual differences, of the measurement of intelligence and other

human capacities, of experimental procedures and statistical devices, and of the undercurrent of physiological thought. . . . He encounters many different trends of thought, and he frequently comes upon the same ones from different angles. But the separate strands of teaching are not knit together for him into a firm and patterned fabric. No one cares how he arranges the threads that are placed in his hands; certainly there is no model which he is urged to copy. Columbia students are as definitely marked as those of any other group, but the mark itself is straggling and irregular. The same units – the same "identical elements" – tend to appear in each member of the group, but in arrangement they vary enormously from person to person, and only rarely do they form a true design. (1933, pp. 291–292)

Hebbreder felt so strongly about the existence of a separately identifiable brand of psychology at Columbia University that she listed it as one of seven distinctive psychologies in her book *Seven Psychologies* (1933). So in addition to chapters on structuralism, functionalism, behaviorism, Gestalt psychology, psychoanalysis, and the psychology of William James, Hebbreder described a separate school of psychology at Columbia, focusing on the dynamic psychology of Robert Woodworth.

Woodworth's eclecticism was evident in his dynamic psychology as well that sought to draw on the richness of multiple approaches to understanding the nature of mental life. For Woodworth (1918), dynamic psychology demanded a

- ▶ . . . clearer view of the mental side of vital activity, refusing to be contented with the fragmentary views offered us by the exclusive students of either consciousness or behavior, but endeavoring to utilize the results of both these parties and the results of brain physiology as well, for an understanding of the complete processes of mental activity and development. (p. 36)

Two concepts were key to Woodworth's dynamic psychology – mechanism and drive. The first is about how things are done; the second is about why we do them. Thus, the principal quest of this psychology was to understand motivation, an impetus that led to his system being labeled *motivology*. Woodworth felt constrained by the narrow boundaries of a stimulus-response (S-R) psychology which he believed

eliminated a role for motivation. Consequently, he sought to identify the organismic variables that intervened between stimulus and response, producing his S-O-R psychology.

A Baseball Interlude

In 1919, George Herman Ruth, age 24, better known as Babe Ruth, was playing in his final season with the Boston Red Sox. That year he hit a total of 29 home runs, a new major league record. Because the Red Sox ownership was in financial difficulties, they sold Ruth to the New York Yankees after the 1919 season. In his first season in pinstripes, the Babe broke his own home run record, hitting an amazing 54, a number that exceeded the home run totals for 14 of the 16 teams in major league baseball that year. How could one player's performance be so out of line with the rest of the league? Asking that question in the twenty-first century would generate an easy answer – performance-enhancing drugs. As best we know, however, such substances were not available to Ruth. So to answer the question, after playing a game in 1921, Ruth was taken to a psychology laboratory for testing, specifically, to the labs at Columbia University. There two doctoral students subjected him to a number of tests including a measure of the strength and speed of his swing, changes in breathing during his swing, manual dexterity, speed in tapping his finger, hand steadiness, visual recognition, and reaction time to a visual stimulus. The lab had normative data on all of these tests and in comparing Ruth's scores with those norms they discovered that his performance was significantly better on all measures, sometimes by a very large margin. Clearly Ruth's sensory and motor skills suggested that he might be the superhuman many fans thought him to be (Fuchs 2009). And he added to that image again in 1921, once more setting a new single season record with 59 home runs.

Cattell retired from the university in 1921; Woodworth was in charge of the department. Note that it was graduate students involved in the testing and not faculty. Even given Ruth's fame it is unlikely that faculty would have shown any interest in what some would have judged a publicity stunt. But Hugh Fullerton, the sportswriter who arranged the testing, was quite serious in his quest to learn the secrets of Ruth's extraordinary performances. He published the

results of the testing in Cattell's magazine, *The Popular Science Monthly* in 1921 (Fullerton 1921). The results of the testing were never published in any psychological journal. Instead, they lay essentially forgotten for 75 years until they were rediscovered by psychologist Alfred Fuchs and published in a psychology history journal in 1998. Although some of the tests used with Ruth were ones that Cattell had used in his test battery, most of the tests appeared more relevant as measures of the sensory and motor skills that might be involved in hitting a baseball. On a related note, when Ruth visited the campus in 1921 there was a young man who was in his first year at Columbia. His name was Lou Gehrig, and he and Ruth would play together for 12 seasons with the New York Yankees, arguably the best hitting duo in the history of baseball.

Psychology's Golden Age at Columbia

Albert Poffenberger succeeded Woodworth as executive officer of the department in 1926 and served in that role until 1941. Woodworth remained as the senior faculty member and continued to play a major role in the department supervising doctoral students, conducting research, and writing his textbooks. His introductory psychology textbook, *Psychology: A Study of Mental Life*, first appeared in 1921. By the time the second edition appeared in 1929, the growth of behaviorism mandated that the subtitle disappear. And so it was entitled simply, *Psychology*. This textbook went through five editions, the last one in 1947, and through most of its life, it was the leading selling psychology textbook in the USA.

Poffenberger's principal interest was applied psychology, broadly defined to include vocational guidance, medicine, education, law, and business and industry. He taught courses on applied psychology, most of his 16 doctoral students did dissertations on applied subjects, and his books were mostly in that field. One of his earliest books was a textbook on applied psychology coauthored with Harry Hollingworth (1880–1956), another Columbia faculty member (Hollingworth and Poffenberger 1917). In 1925, he published a book on the psychology of advertising and later wrote several editions of the applied text as sole author (Poffenberger 1927, 1942). He was especially interested in the application of psychology to business but also interested in the growing field of

clinical psychology. In the 1930s, he sought to establish several applied programs, including clinical psychology, in Columbia's psychology department but was unsuccessful, presumably because it was opposed by Woodworth (Thorne 1976).

In 1935, during his term as executive officer, Poffenberger was elected the 43rd president of the American Psychological Association (APA). In holding that office, he followed both of his predecessors who had been president of APA as well: Cattell as No. 4 in 1895 and Woodworth as No. 23 in 1914. Actually, Poffenberger was the sixth Columbia graduate elected to that office: Thorndike was president No. 21 in 1912, Franz No. 29 in 1920, and Hollingworth No. 36 in 1927. Thus, the leadership of all Columbia psychology departments had been elected to the highest APA post, including Thorndike of Teachers College and Hollingworth of Barnard College, Columbia's college for women. Poffenberger was also elected president of the American Association of Applied Psychology (AAAP) in 1943–1944, the last person to be president of AAAP. He was a leader in the merger of AAAP with APA at the end of World War II (Benjamin 1997; Wenzel 1979). The examples of association leadership are cited here to illustrate the national standing of Columbia's faculty.

In 1925, the last year of Woodworth's term as executive officer, the department moved out of Schermerhorn Hall into the Physics Building where they had 25 rooms spread across multiple floors from the basement to the 14th floor. But Woodworth (1942) reported that the elevator service was good. Psychology remained in the Physics Building for 5 years before returning to Schermerhorn Hall in the newly constructed extension. It marked the first time in psychology's history that the department had been able to plan the construction of its intended space. In 1930, the department moved into 54 rooms for offices, laboratories, and a shop. The department also received the sum of \$30,000 for purchase of new equipment (Woodworth 1942).

The period 1920–1940 has been referred to as Columbia's "golden age" in psychology, both because of the number of doctorates awarded but also by the subsequent accomplishments of many of those graduates. From 1894 to 1919, a total of 26 years, 58 doctorates were awarded. In the 21-year period from 1920 to

1940, that number increased dramatically to 207. By 1948, Columbia's psychology department had awarded 344 doctorates, 75 more than any other department in the USA (Harper 1949). And as an illustration of the leadership and, perhaps, scholarly reputations of the Columbia graduates, between 1946 and 1970, more psychology department heads across the USA had received their doctorates from Columbia than any other university (Heckel 1972).

Not only was there strength in numbers but there was star quality as well, such as Henry Garrett, Paul Achilles, Harold Jones, Gardner Murphy, Elizabeth Hurlock, Edna Heidebreder, Frederick Lund, David Wechsler, Mary Cover Jones, Otto Klineberg, Winthrop Kellogg, and Henry Nissen, in the 1920s. Graduates in the 1930s included Anne Anastasi, David Klein, Rensis Likert, Samuel Beck, Solomon Asch, Gregory Razran, Anne Roe, Arthur Benton, Meredith Crawford, Muzaffer Sherif, Robert Watson, Saul Sells, and Isidor Chein. Frederick Thorne (1976), who graduated from the program in 1934, gave all the credit to Woodworth for creating the "golden age" at Columbia.

- ▶ ...the key to its success was the capability of its guiding genius, Robert S. Woodworth, who gathered a remarkable group of scholars about him. Woodworth's objective eclectic orientation provided the broadest possible approach within a rigorous experimental-statistical orientation. Woodworth's scholarly approach pervaded the department so that many of his colleagues also wrote encyclopedic works in their particular fields of specialization. The writings of the Columbia psychologists truly shaped the field. (p. 159)

There is no doubt that Woodworth's presence, his quiet leadership, his eclectic view of psychology, and his personality that endeared him to colleagues and students alike were key parts of the formula for the success of Columbia's extraordinary output in the 1920s and 1930s. Yet Poffenberger served as department head during most of this period, from 1926 to 1941. So was his a titular headship or did he play a significant role in the doctoral production of this golden age? He retired in 1950, thus 15 of the final 24 years of his career were spent in departmental administration. His research productivity was low compared to that of his colleagues. And few of the

superstars of the 1920s and 1930s were his students. Instead, the scholarly production was largely in the hands of his colleagues – Murphy, Klineberg, Henry Garrett, and, yes, Robert Woodworth, who remained an active researcher, textbook writer, and doctoral mentor into his 80s. The fact that he was able to prevent the establishment of applied programs, presumably because he believed that they would weaken the scientific orientation of the department, is further evidence of his influence on the department even though he was no longer serving in the executive officer role.

Later, Columbia psychology graduates might dispute the label of “golden age” for the 1920s and 1930s, preferring instead to assign that label to the reign of the animal researchers, especially Skinnerians, who would come to dominate the department in the 1950s. But there is no denying the large number of graduates of those years who gained eminence in psychology, especially in the fields of social psychology and measurement.

Henry Garrett, Otto Klineberg, and the Psychology of Race

Henry E. Garrett (1894–1973), a native of Virginia, received his doctorate in psychology at Columbia in 1923 where he worked principally with Woodworth and Poffenberger. He soon joined the Columbia faculty where he worked until his retirement in 1955 at the age of 61. Garrett took over the role of department head from Poffenberger, serving in that capacity from 1941 to 1955. Given his activities in the 1950s, it is reasonable to suspect that the administration at Columbia encouraged him to retire early, but we have no direct evidence of that.

Garrett made his scholarly reputation as a statistician, principally based on the success of his textbook *Statistics in Psychology and Education* (1926), which went through six editions, the last one published in 1966. Garrett expressed strong hereditarian and racist views and had written on personality characteristics of Jews and racial differences in intelligence even before he was elected president of the American Psychological Association in 1946. In 1952, Garrett testified in his home state in one of the cases (*Davis v. County School Board of Prince Edward County*) that would become part of the *Brown v. Board of Education* lawsuit that went to the Supreme Court in that same year.

Columbia University graduates Kenneth B. Clark and Isidor Chein were instrumental in writing an amicus brief for the Court on behalf of the Society for the Psychological Study of Social Issues (SPSSI) and the National Association for the Advancement of Colored People (NAACP). That brief provided the social science evidence leading to the 1954 decision overturning the court’s earlier decision establishing the “separate but equal” doctrine that made segregation legal. In his testimony in the lower courts, Garrett argued that the research of Clark and Chein on the psychological effects of segregation was so flawed that their results were wholly unscientific (Benjamin and Crouse 2002; Jackson 2001). Winston (1998) wrote that in the 1950s, “Garrett helped organize an international group of scholars dedicated to preventing race mixing, preserving segregation, and promoting the principles of early 20th century eugenics and ‘race hygiene.’ Garrett became a leader in the fight against integration and collaborated with those who sought to revitalize the ideology of National Socialism” (p. 179).

Countering Garrett’s views at Columbia was Otto Klineberg, a fellow faculty member, who published two books in 1935 that addressed the controversy over IQ score differences between blacks and whites. In *Negro Intelligence and Selective Migration* (1935a), Klineberg presented convincing evidence to dispute the hypothesis that the reason for African Americans in the North scoring higher on intelligence tests than those in the South was due to the selective migration of more intelligent individuals. He wrote, “As far as intelligence goes. . . [the difference in scores] may be explained by the more favorable environment [in the North], rather than by selective migration” (p. 62). In *Race Differences* (1935b), Klineberg wrote that “there is no adequate proof of fundamental race differences in mentality, and that those differences which are found are in all probability due to culture and the social environment” (p. vii). By the 1940s, and especially so after World War II when Americans felt revulsion toward Adolf Hitler’s claims of a master race, many psychologists came to accept Klineberg’s views that racial differences in intelligence tests were due to a cultural environment of prejudice and discrimination (Samelson 1978).

As noted earlier, Columbia University graduates played a crucial role in what is often regarded as the most important Supreme Court decision of the

twentieth century, *Brown v. Board of Education* (1954). When the NAACP, under the leadership of Thurgood Marshall as their chief attorney, sought help from the social science community to demonstrate the devastating effects of segregation, their search led them to Otto Klineberg. Klineberg referred the NAACP attorneys to his former graduate student, Kenneth B. Clark (1914–2005). When the attorneys told Clark what kind of scientific evidence they needed to make their case, Clark suggested that they read a chapter he had written for the 1950 White House Conference on Children and Youth (Clark 1950). The chapter included research on the differential personality development of African American children in segregated and integrated schools, research done by Clark and his wife, Mamie Phipps Clark (1917–1983), who had earned her doctorate in psychology at Columbia with Garrett as her advisor. In fact, it was Mamie Clark who had initiated those studies when she was a student at Howard University. That research, and other work, formed the basis of the amicus brief filed with the Supreme Court in September, 1952 and authored by Kenneth Clark, Isidor Chein, and Stuart Cook (2004). That evidence proved to be a deciding factor in the Court's decision to end legalized racial segregation. The *Brown v. Board* decision, the first Supreme Court decision to cite psychological research, included seven references to that research in a footnote to the decision. In his history of that decision, Richard Kluger (1975) has written that the placement of Kenneth Clark's 1950 work as first in the listing of seven sources was perhaps not arbitrary but was a tribute to Clark for the considerable role he played in preparing the social science evidence for the case.

The 1954 Supreme Court decision was a serious blow to Garrett's America, but he was not ready to give up the fight. Winston (1998) wrote that "the Brown decision galvanized Garrett and a number of other social and biological scientists into action with a new sense that a scientific attack might prove effective in reversing secular trends" (p. 184). One strategy was to use their scientific standing to demonstrate that the social science underlying the decision was bogus. After retiring from Columbia in 1955, Garrett returned to his native Virginia. He sought a position within the psychology department at the University of Virginia but the psychology faculty blocked his efforts. He instead

acquired a position in the education department. Over the next decade, he wrote articles, gave interviews, and published and distributed pamphlets designed to spread his views on the dangers of integration, for example, a 1963 article in *U. S. News & World Report* entitled "Racial Mixing Could Be Catastrophic" (Winston 1978). Despite his earlier positions of leadership at Columbia University and the American Psychological Association, when he died in 1973, his passing was little noted. Not one of the many psychology journals published his obituary, a very rare omission for former presidents of APA. His obituary in the *New York Times* was a meager 24 lines, and it included no mention of his racist activities (Anonymous 1973). At the time of this writing, the web page for the Columbia University's psychology department includes a history page that does not mention Garrett, although he is included in a timeline listing key faculty. Whereas Garrett's role in the segregation debates is remembered by few, the contributions of Klineberg, the Clarks, Chein, and others are regularly acknowledged as the high water mark of the value of social science.

The End of Columbia's Eclecticism

As is evident in this account thus far, Robert Woodworth was the glue that held the Columbia department together. He had the academic credentials, the reputation as the dean of experimental psychology, and a broad acceptance of what could be done in the name of psychology, so long as it was good science. But in 1945, at the age of 75, he officially retired. In truth he remained active for another 15 years publishing a second edition of his classic experimental psychology book at age 85 (Woodworth and Schlosberg 1954) and a thorough revision of his dynamic psychology book when he was 89 (Woodworth 1958), and delivering his last lecture at age 90. But the tenor of the department began to change in the 1940s under Garrett's watch, culminating in open dissension in the 1950s. The eclecticism that Woodworth had modeled and supported for so many decades was about to end. Columbia's golden age that had produced so many important contributors to so many areas of psychology would give way to a psychology that some would label religious zealotry.

When Woodworth retired, he was replaced by Clarence H. Graham (1906–1971) who came to

Columbia from Brown University. Graham remained at Columbia for 26 years where he mentored more than 50 doctoral students in vision and visual perception. Throughout his tenure at Columbia, he was one of the most productive faculty members and one of the department's most prestigious scientists (Geldard 1972). Graham's writing on visual perception was known for the objectivity expressed in the language he used, an influence of B. F. Skinner (Riggs 1975).

Skinner's influence was felt elsewhere in the Columbia department, especially in the research, writings, and teachings of Fred S. Keller (1899–1996) and William Nathan Schoenfeld (1915–1996). Keller joined the Columbia faculty in 1938 and Schoenfeld, who earned his doctorate with Klineberg, remained at Columbia as a faculty member after finishing his degree in 1942. Together they played the principal role in establishing a strong animal research presence in the department, grounded in Skinnerian behaviorism. In 1946, they created a pioneering introductory psychology course in which students engaged in hands-on laboratory experiences instead of the usual lectures. A few years later, they developed a textbook (Keller and Schoenfeld 1950) to accompany the course that drew considerably on Skinner's writings (Hearst 1997). As part of the transformation, more and more of the laboratory space in the Schermerhorn Extension was devoted to animal studies, principally operant conditioning research, but also included the animal research of Carl J. Warden (1891–1961) who had been a member of the faculty since the mid-1930s. The program produced a number of outstanding graduates including Helmut Adler, Philip Bersh, James Dinsmoor, Charles Ferster, Joseph Notterman, and Murray Sidman. One of those graduates has labeled this operantly dominated period as Columbia's "Golden Age of research on the most elemental of behavioral processes" (Dinsmoor 1990, p. 147). Not surprisingly, there would be faculty and graduate students who would vehemently dispute that assertion, particularly those in social psychology.

The growth of the Skinnerian presence in the department led to a schism resulting in a splitting off of social psychology into a separate department in 1961, with Otto Klineberg as department chair. Stanley Schachter (1922–1997) joined the Department of Social Psychology in its inaugural year. In his

autobiography, he described the psychology department prior to its division as it had been portrayed to him:

- ▶ ...the Psychology Department was a shambles...[it] seemed to have fallen victim to religion. Somehow, I never learned how or why, the Skinnerians had obtained a foothold and, like Jesuits, had simply taken over. The department was a pigeon and eyeball department with not only no interest in, but an open antagonism to, personality, clinical, social – in fact any branch of human psychology that wasn't devoted to the demonstration that humans could be shaped as easily as pigeons. (Schachter 1989, p. 461)

The "eyeball" reference is most likely to Graham and his colleagues in vision.

The social psychology department was a small one, but a very talented one. In addition to Schachter and Klineberg, there was Richard Christie (1918–1992), William McGuire (1925–2007), and Bibb Latané (1937–). The doctoral students were a stellar group as well. Schachter's graduates included Richard Nisbett, Larry Gross, Lee Ross, Patty Pliner, and Judith Rodin.

Eventually, the animosities faded as faculty turnover in both departments reduced the tensions. The division lasted only 8 years before the two departments were joined as one under the leadership of Robert R. Bush (1920–1972) as the new department chair. Bush's doctorate was in physics but he had worked in experimental psychology for much of his career, principally as a mathematical learning theorist. He had chaired the psychology department at the University of Pennsylvania for about a decade before his move to Columbia, and he was brought in specifically to move the combined department forward (Galanter and Luce 1974). His term was short-lived due to his early death, but he added some distinguished faculty in his brief time as chair. At the end of the 1960s, the department was focused on research emphasizing biological, social, and cognitive factors, an amalgam of which Woodworth would have approved.

Psychology at Teachers College

Teachers College was founded in 1887 as the New York School for the Training of Teachers; its founding reflected sweeping changes in the intellectual, educational, and social climate of the 1880s in America. The

late nineteenth century brought waves of industrialization and urbanization to the USA, accompanied by increasing public school enrollments and compulsory attendance laws. The educational sphere was further characterized by an expansion of higher education, the growth of the industrial training movement, and an increasing demand for the professional training of teachers. To be sure, normal schools had for some time committed themselves to teacher training. Traditionally, however, they focused almost exclusively on instructing elementary school teachers, and varied tremendously in terms of content and quality. With increasing demand for greater evidence of professional competence, a few of the superior normal schools began to transform themselves into teachers' colleges, and universities and liberal arts colleges established formal departments and/or professorships in education, offering formal study in what became a new, distinct discipline. Abroad, educational theorists had been proposing new theories of pedagogy, and although these specific theories did not take root in America's education system, they stimulated innovative approaches that fostered a commitment to educational reform. Finally, in late nineteenth century America, there was a resurgence of philanthropy, which aided the founding of Teachers College and assured it would flourish (Cremin et al. 1954).

The founders of Teachers College, Grace Hoadley Dodge (1856–1914), Nicholas Murray Butler (1862–1947), and James Earl Russell (1864–1945), by dint of steadfast commitment and resourcefulness, created an institution that, according to its 1889 charter, would “give instruction in the history, philosophy and science of education, psychology, in the science and art of teaching, and also in manual training and the methods of teaching the various subjects included under that head” (Fackenthal 1915, as cited in Cremin et al. 1954, p. 22). Grace Hoadley Dodge was the “guiding hand and financial backer” of what became the Industrial Education Association (IEA), which provided a broad array of industrial training for men and women, and boys and girls, and would become the precursor to Teachers College (p. 14). Although philanthropy had been the dominant motivating force behind the IEA during its first 2 years, education increasingly became its central goal, as evidenced by its growing connection with various boards of

education, the establishment of a Board of Trustees, the dissolution of all IEA committees, the work of which was to be consigned to a newly established Executive Committee, and a set of carefully articulated principles, labeled “Articles of Faith,” which highlighted the primacy of education in its mission (p. 17).

Its new administrative structure notwithstanding, the Association continued to have difficulty meeting the ever-growing demand for schoolteacher training. Thus, in 1887, at Dodge's suggestion, Nicholas Murray Butler (1862–1947), Associate Professor of Philosophy in Columbia College, was named President of the IEA, for “[j]ust as Grace Dodge epitomized the philanthropic urge of the age from which Teachers College emerged, so did Nicholas Murray Butler symbolize the newer ideas of specialized training for teachers and of education as a subject of serious study” (Cremin et al. 1954, p. 19). Under Butler's leadership, 1887–1891, the College expanded the scope of its educational curriculum, contributing to “the general education of teachers beyond the normal school, as well as to the serious study of education within the College” (p. 27). Butler's long-held intention to make the College a part of a university system, however, would be left unrealized.

Butler resigned as president in 1891, and was succeeded by Walter L. Hervey, who served as Acting President for 2 years and then as President from 1893 until 1897. Under Hervey's leadership, the College's first formal alliance with Columbia College was authorized in 1893. In 1894, the College was relocated to a new building on 120th Street; during that time, the College's standards had been elevated, signifying “a distinct advance upon the usual standards of professional work,” and placing the College “in the front rank of professional schools” (Cremin et al. 1954, p. 32).

During the last few years of Hervey's presidency, however, tensions grew with respect to the College's curriculum, its financial circumstances, its competing objectives, philanthropic and educational, and its alliance with Columbia. This was the backdrop against which James Earl Russell (1864–1945) came to Teachers College in 1897, initially to head the central department of the College, the Department of Psychology and General Method. But Russell soon found himself in the role of Dean of the College just at the time the College was about to commence a search for a new President.

Russell immediately suggested that, were Teachers College connected to Columbia as a bona fide professional school, a search for a president would be superfluous. At the urging of others, Russell articulated a bold new agreement to replace the 1893 contract, one that would confer on Teachers College university status. With only minor changes to Russell's original proposal, both the Columbia and Teachers College Trustees ratified this new agreement in 1898 (Cremin et al. 1954).

In this way, Russell had achieved what previous administrators had not. But the remaining work necessary to transform the school into a bona fide college was sizable and challenging, for at that time there was no exemplar in professional education. Undaunted, Russell strategically constructed the Teachers College curriculum. Its basic philosophy consisted of four goals: (1) general culture, by which he meant a "training [that was] liberal enough to inspire respect for knowledge, broad enough to justify independent knowledge, [and] accurate enough to beget a love of truth"; (2) special scholarship, referring to continued specialization in the materials the student was to teach"; (3) professional knowledge, by which Russell was specifically referring to educational psychology, the history of education, and educational leadership; and, (4) technical skill, or the knowledge of various skills and the reasoned judgment of when to employ one course of action over another and why (Cremin et al. 1954, p. 36).

Russell proved an influential and effective leader. The breadth of Russell's overarching philosophical structure for the curriculum, along with his broad conception of education itself and its role in society – that is, to serve the common good – alleviated many of the existing tensions that were due to the institution's seemingly conflicting objectives of philanthropy and education. In Russell's conceptual framework, each of these aims fit comfortably. Russell was also an ardent supporter of education reform, embracing a liberal educational philosophy, and, as such, found himself at odds with the dictates of the Ten Articles of Faith of the IEA, which emphasized traditional education. To be sure, Russell did not conceive of the Teachers College faculty as a monolithic entity of professional-mindedness, but rather of one balanced in its proportion of faculty interested in experimental research and

those interested in "the real world' of education" (Clifford 1968, p. 214). Accordingly, Dean Russell endeavored to attract new faculty members who were studied in cutting-edge pedagogical concepts or at least "men of open minds not confined in the ruts of academic tradition" (as cited in Cremin et al. 1954, p. 39) so that the movement to professionalize pedagogy could come to fruition. Reflecting Russell's professional acumen, "these pioneers in turn built up a tradition and handed on a heritage which was destined in two decades to make the College one of the primary forces in American educational thought and practice" (p. 42). One of these innovators was Edward L. Thorndike (1874–1949), whom Dean Russell hired in 1899.

Edward L. Thorndike and a Scientific Psychology of Education

At the recommendation of Thorndike's mentors, William James of Harvard and James McKeen Cattell of Columbia, Dean Russell visited Thorndike's classroom at Western Reserve University in 1899, where Thorndike was an instructor for a year. "Although the Dean found him 'dealing with the investigations of mice and monkeys,' he came away 'satisfied that he was worth trying out on humans'" (Cremin et al. 1954, p. 43); Russell offered Thorndike the position of Instructor in Genetic Psychology at Teachers College.

Thorndike had earned his master's at Harvard in 1897, and in the following year took his Ph.D. at Columbia. The son of a Methodist minister, the young Thorndike chose science in place of religion, "describ[ing] intellectual agnostics like himself as 'conscientious objectors to immortality'" and embracing a staunch commitment to "an exclusively naturalistic view of man" (as cited in Clifford 1968, p. 63). In the words of his longtime friend and colleague, R. S. Woodworth (1954), "Thorndike was unwilling to recognize any limits to the scope of quantitative science" (p. 217). At his core, Thorndike was a positivist – an empiricist, an experimentalist, and a "tough-minded" scientist, holding little concern for grand theories, but preferring instead to assemble myriad empirical quantifiable facts (Beatty 1998; Thorndike 1991). "Yet Thorndike was saved from the reliquary of an outmoded positivism by his fantastic ingenuity and eclectic tolerances. As his long-time friend and

associate, R.S. Woodworth, described Thorndike: his was a ‘sane positivism’” (Clifford 1968, p. 4).

His early work in comparative psychology established Thorndike as a significant figure in this newly emerging field. His doctoral dissertation, *Animal Intelligence: An Experimental Study of the Associative Processes in Animals* (1898), is considered a milestone in the history of psychology, as it not only initiated the animal laboratory in psychology, but also produced a new law of learning, the law of effect, that would form the basis for Thorndike’s connectionist learning theory and quantitative theory of intelligence (Woodworth 1954). Although it was generally believed that animal learning was simply a consequence of repetition, mental imagery, or imitation, Thorndike demonstrated that *the effect*, or consequence, of a particular behavioral response influenced whether or not that response was likely to be repeated.

Largely owing to the rapid cultural changes in higher education and their concomitant employment opportunities (Beatty 1998; Clifford 1968), Thorndike accepted the position at Teachers College, determined to apply experimentation and measurement – “his two guiding stars throughout his career” – to the scientific study of education (Woodworth 1954, p. 211). Thorndike thus shifted his attention from mice, chicks, and cats to human beings, and within 5 years of his arrival, had advanced from instructor to full professor and head of the Department of Educational Psychology.

Early in his tenure at Teachers College, Thorndike engaged in a broad range of school-related research, the findings of which often ran counter to the conventional wisdom of the day. For example, in collaboration with R. S. Woodworth in 1901, he published data indicating that “improvement in any single mental function rarely brings about equal improvement in any other function, no matter how similar, for the working of every mental function-group is conditioned by the nature of the data in each particular case” (Thorndike and Woodworth 1901, p. 250). The scant evidence of “transfer of learning” contradicted the long-cherished notion of “formal discipline,” according to which training in a specific field would generalize to performance in a more generalized capacity. Similarly, addressing the question of whether boys and girls should be schooled differently, Thorndike employed rigorous statistical analyses of

individual differences in mental characteristics and skills, concluding that sex differences in ability “were not of sufficient amount to be important in arguments concerning differentiation of the curriculum or of methods in teaching with conformity of sex differences” (Thorndike 1903, p. 118), an argument that contradicted G. S. Hall’s position on the issue.

At Teachers College, Thorndike established educational psychology as a distinct academic discipline. The discipline’s *raison d’être* was to address real-life educational problems based on experimental, quantifiable facts, not on mere speculation: “We conquer the facts of nature when we observe and experiment upon them. When we measure them we have made them our servants” (Thorndike 1903, as cited in Clifford 1968, p. 282). In the inaugural issue of *The Journal of Educational Psychology*, founded by Thorndike in 1910, he delineated the ways in which psychology could contribute to education, and vice versa. Psychology could elucidate educational aims by making them more precise and refined; and it could help “to measure the probability that [these aims] are attainable” (Thorndike 1906, p. 5). And, above all, psychology, as a result of measurement, could contribute to an understanding of educational materials and to the evaluation of validity claims regarding various teaching methods. According to Thorndike (1906), “[t]esting the results of teaching and study is for the teacher what verification of theories is to the scientist, – the *sine qua non* of sure progress” (as cited in Beatty 1998, p. 1148). Thorndike also mentioned that the “science of education can and will itself contribute abundantly to psychology,” referring to the classroom itself as a “vast laboratory in which are made thousands of experiments of the utmost interest to ‘pure’ psychology” (Thorndike 1910, p. 12).

Prior to World War I, Thorndike contributed a significant number of books, monographs, and journal articles that pertained to the “improvement of instruction in the classroom and the measurement of both the learner and the products of learning” (Hilgard 1996, p. 424), including *Educational Psychology* (1903), *An Introduction to the Theory of Mental and Social Measurements* (1904), *Principles of Teaching* (1906), *Empirical Studies in the Theory of Measurement* (1907), and the three-volume *Educational Psychology* (1913–1914). During the war, like several of his

psychology colleagues, Thorndike, retaining his civilian status and serving as a member of the Committee on Classification of Personnel from 1917 to 1919, contributed to the war effort. He was charged with developing and evaluating various psychological measures to be used in the evaluation of recruits.

Applications of Thorndike's educational psychology to the military enterprise affirmed the discipline's utility, motivating Thorndike to market his products on a grander scale. Along with his colleagues Cattell and Woodworth, Thorndike established the Psychological Corporation in 1921, which "married the 'advancement of psychology' to the 'promotion of the useful applications of psychology'" (Clifford 1968, p. 385). Although some psychologists criticized the commercial nature of the Corporation, Thorndike clearly supported it, serving on its Executive Committee from 1921 to 1940. For as Clifford explained,

- ▶ To Thorndike science does not become 'less science' when it investigates problems which have already obvious relevance for application or when it does assigned work not purely of its own choosing or when it tests its hypotheses in the marketplace as well as in the laboratory. (Clifford 1968, p. 386)

In addition to several standardized and copyrighted educational and psychological tests and scales, Thorndike authored dozens of influential publications, including textbooks, manuals, and dictionaries, which served instructors and school administrators alike. The royalties of *The Teachers' Word Book* (1921) and *The Thorndike Arithmetics, Books 1–3* (1917, 1922) more than doubled his academic salary in its first year, and quadrupled it within the span of a few more.

At the same time, Teachers College, with the assistance of private funding, established the Institute for Educational Research in 1921, in which Thorndike focused on two lines of research: mental measurement and learning. In 1926, his *The Measurement of Intelligence* detailed his CAVD Examination, the name of which referred to the four types of content – sentence completion (C), arithmetic (A), vocabulary (V), and directions (D) – that he considered most indicative of intelligence (Thorndike 1926). By now, Thorndike was fully immersed in research, having essentially renounced his teaching and advising responsibilities. In 1925, he was awarded the Butler Medal, which was

established in 1914 to be awarded every 5 years "for the most distinguished contribution made during the preceding 5-year period anywhere in the world to philosophy or to educational theory, practice, or administration" (Clifford 1968, p. 487). During the 1930s, Thorndike revisited his investigations on the processes of learning, ultimately revising some of his earlier statements regarding punishment, which he considered a much less potent factor in behavior determination. The last phase of his research was dedicated to applying statistical methods to societal issues – Thorndike considered virtually no topic to be outside the purview of science (Beatty 1998; Clifford 1968).

There were several other notable members of the faculty, including Arthur I. Gates (1890 – 1972), renowned for his contributions to education psychology, including his *Psychology of Reading and Spelling with Special Reference to Disability* (1922/1929) and *Educational Psychology* (1942); Percival Symonds (1883–1960), who was Thorndike's assistant in the Institute for Education Research from 1921 to 1922, and who despite being trained in educational psychology later became well-known for his contributions to school psychology; Rudolph Pintner (1884–1942), known for his contributions to the field of mental measurement and the study of handicapped children, particularly the deaf; and Goodwin Watson (1889–1976). Watson made significant contributions to educational psychology, including his *Educational Problems for Psychological Study* (1930), which he coauthored with his Teachers College colleague Ralph B. Spence; Watson also played a prominent role in the development of the Society for the Psychological Study of Social Issues (SPSSI).

Notable Women Professors of Teachers College

By 1917, turn-of-the-century cultural factors notwithstanding, women constituted 13% of the APA's membership. This represented a significant female presence in the discipline, contrary to what early historical accounts of the field may have suggested (Scarborough and Furumoto 1987). The present account highlights a few notable women psychology professors at Teachers College: Naomi Norsworthy (1877–1916), Leta Stetter Hollingworth (1886–1939), and Helen Bradford Thompson Woolley (1874–1947).

According to Scarborough and Furumoto (1987), Naomi Norsworthy was the only one of “the first generation women psychologists” recruited by a mentor. Born in 1877 in New York City, Norsworthy entered a New Jersey public school at age 8. Intent on becoming a teacher, Norsworthy subsequently entered the New Jersey State Normal School in Trenton, NJ, where she completed her courses in 3 years, and taught the third grade for the following 3 years, during which time she “nurtured an ambition to earn a college degree from Columbia University’s Teachers College” (p. 192). Upon entering Teachers College in 1899, Norsworthy intended to become a chemistry teacher, but Thorndike, “at once singled her out as a young woman of unusual mentality, and it was under his encouragement that all ideas of being a teacher of chemistry vanished” (Higgins 1918, p. 67). She was made student-assistant in 1900, earned her BS degree from Teachers College in 1901 and with her thesis, “The Psychology of Mentally Deficient Children” took her doctorate 3 years later (Higgins 1918). That same year, Norsworthy was officially hired at a tutor’s rank, and was promoted to instructor in 1905. In 1908, Thorndike recommended her for promotion to Associate Professor, an endorsement that encountered Cattell’s firm disapproval. In response, Thorndike proffered an explanation to his mentor:

- ▶ [I]f you were in full acquaintance with our situation at Teachers College and with her work, I think you would include it in a wider point of view. Teachers College is in part a graduate school and in part a professional school. The most gifted people for training teachers... are at present and will for a long time be women... Dr. Norsworthy is beyond question enormously successful in training teachers. The thoughtful men at the College... have asked me in surprise why she had not yet been promoted. ... I should be sacrificing the interests of Teachers College to do anything that helped withhold from her the promotion that a man equally competent would be sure to have had. (as cited in Clifford 1968, p. 222)

Ultimately, the dean decided in favor of promotion, and Norsworthy became Associate Professor in 1909. Three years later, she was promoted to the rank of Professor of Educational Psychology.

There are numerous testimonies to Norsworthy’s competence as a teacher/scholar, including a few that reflect the additional challenges of being a woman professional at that time. For example, as described in Higgins (1918), a student once complained to Dean Russell because he had expected a male professor and was “chagrined when the professor presented herself, ‘a slip of a woman’” (p. 80). The dean listened calmly and respectfully to the student’s complaint, but ultimately told the student,

- ▶ that he was still laboring under some sort of false impression, – ‘You will find her one of the strongest men on our faculty. Go to her classes a few times and see if you do not think her so.’ This story, a true one, is rounded out by the man’s returning to the dean in the course of time to assure him that his opinion concerning Dr. Norsworthy as one of the ‘strongest men’ of the faculty was entirely true. (p. 80)

On Christmas Day in 1916, Naomi Norsworthy died, finally succumbing to her battle with cancer. Her most influential work was *The Psychology of Childhood* (Norsworthy and Whitley 1918), which was intended to be a normal school text, and was completed after her death by a colleague (Scarborough and Furumoto 1987). Norsworthy’s success at Teachers College, albeit short-lived, prepared the way for other women of equal competence and drive.

Born in Nebraska in 1886, Leta Stetter Hollingworth (née Stetter) was raised by her maternal grandparents, following the death of her mother, who died during the birth of Leta’s youngest sister in 1890 (Klein 2002). At the age of 12, Leta Hollingworth and her sisters were reunited with their father, enduring verbal and emotional abuse at the hands of their stepmother, whom their father had married in 1896. Hollingworth “felt as though she was living day by day in a ‘fiery furnace’” (Klein 2002, p. 25). And, despite her father’s own inadequacies, he did encourage Leta to pursue college, which she did (Klein 2002). After being graduated from the University of Nebraska with a Bachelor’s degree and a State Teacher’s Certificate, Hollingworth spent 2 years teaching in Nebraska. In 1909, she then moved to New York to be with her fiancé, who had just accepted a position at Barnard College. But Hollingworth grew frustrated as her applications for various scholarships and fellowships were

unsuccessful, and she found that “married women were not given appointments in the schools of New York.” (Hollingworth 1990, p. 73)

After the Hollingworths had established a more secure financial footing, however, she finally entered Teachers College as a graduate student in 1911, studying under Edward Thorndike, whom she would regard as her most influential mentor (Klein 2002). During the course of her graduate studies, Hollingworth also served as a psychometrician at The Clearing House for Mental Defectives, where she administered mental tests to clients referred there by the courts. As her expertise and clinical experience grew, she became a leading voice in the campaign for professional status in the then-inchoate field of clinical psychology (e.g., Hollingworth 1918). In 1916, she was offered to the position of chief of a psychological laboratory to be established in Bellevue Hospital (Hollingworth 1990), but declined accepting instead a faculty position at Teachers College, replacing Norsworthy after Norsworthy’s untimely death.

Aside from her professional accomplishments, Hollingworth made significant scientific contributions to the study of sex differences and to educational psychology. Throughout her career, she emphasized the primacy of objective empirical evidence, distinguishing between what she called the “literature of opinion” and the “literature of fact”:

- ▶ By the literature of fact is meant those written statements based on experimental data, which have been obtained under carefully controlled conditions, and which may be verified by anyone competent to understand and criticize them. . . . Before experimental data were sought, the hypothesis was accepted that human females are, by original nature, different from and inferior to human males, intellectually. The factor of sex determined everything; the way to discover whether a given individual was capable of any given intellectual task was not to let the individual undertake the task and to judge by the result, but to indicate the sex of the person in question. (Klein 2002, pp. 84–85)

Based on her own experimental data, Leta Hollingworth revealed the falsity of various then-common assumptions regarding sex differences and mental traits. She demonstrated, for example, that the variability hypothesis, which was taken as evidence for

the congenital intellectual inferiority of women, was simply a function of sociology, not biology. Her writings frequently invoked the social role of women, as child-rearer and housekeeper, along with the social, legal, and practical constraints placed on women’s education and employment, to account for the observation that more men as opposed to women have achieved eminence (Shields 1975). Indeed, Hollingworth “repeatedly emphasized that the true potential of woman could only be known when she began to receive social acceptance of her right to choose career, maternity, or both” (Shields 1975, p. 748). In addition to disputing assumptions related to the variability hypothesis, Leta Hollingworth’s empirical findings contradicted the long-held notion that women were rendered “incapacitated when they menstruated,” a putative condition known as “functional periodicity” (Klein 2002, p. 90). In her dissertation, entitled *Functional Periodicity: An Experimental Study of the Mental and Motor Abilities of Women During Menstruation* (1914), Hollingworth found no “feminine cycle impairment” (as cited in Klein 2002, p. 90). Her views on the variability hypothesis stood in stark opposition to those of Cattell and of her mentor, Thorndike, both of whom were champions of the variability hypothesis (Shields 1975). Yet Hollingworth was undeterred from publicly expressing her views; more interestingly, Thorndike himself never interfered with her doing so. Beginning in the early 1910s, Hollingworth was involved in various feminist organizations, including as a charter member of both the Heterodoxy Club and of the Feminist Alliance, and as an active member of the New York Woman Suffrage Party (Klein 2002).

In addition to her influential work on sex differences, Hollingworth made important scientific contributions to educational psychology: her work on children with below average intelligence culminated in *The Psychology of Subnormal Children* (1920b), which became the field’s standard text, and *Special Talents and Defects* (1923). Three years later, she published *The Psychology of the Adolescent* (1928), based on her recognition that some children who appeared “mentally defective” were simply suffering from what would now be termed “adjustment disorders” in adolescence. For the next 2 decades, this book would define the field (Hollingworth 1990). Perhaps her most pioneering and influential work was her study

of the education and psychology of gifted children. Largely based on her research at the Speyer School in New York City, an experimental school for gifted children founded jointly in 1936 by the New York City Board of Education and Teachers College (Klein 2002), Hollingworth's work on the gifted contradicted the prevailing notion that they are self-sufficient and therefore do not require any particular consideration. To the contrary, she recognized that many "rapid learners" suffered "adjustment problems because of inept treatment by adults and lack of intellectual challenge" (Hollingworth 1990, p. xv). In response, Hollingworth developed a specialized curriculum, one that inspired intellectual curiosity, creativity, and initiative and that was "relevant to the pupils' lives" (Klein 2002, p. 145). Her book *Children Above 180 I.Q.* (Hollingworth 1942), outlining her longitudinal research on 12 exceptionally gifted individuals, was completed by her husband following her untimely death from cancer in 1939.

Helen Bradford Thompson Woolley's tenure at Teachers College was relatively short, albeit noteworthy. Born and raised in Chicago, she was a stellar student who was graduated from the University of Chicago in 1897 and earned her Ph.D. in 1900. In 1905, she married Paul G. Woolley, and during the next several years the couple relocated several times, eventually settling in Cincinnati, where her husband was appointed to the University's medical school faculty. As director of the Bureau for the Investigation of Working Children, later the Cincinnati Vocation Bureau, Woolley directed the production of important research reports on the effects of child labor, and became a potent advocate of child welfare reform. In 1921, when the Woolleys moved to Detroit, Helen was appointed to the staff of the Merrill-Palmer School, where she organized one of the first nursery schools in the USA for the study of child development and teacher training, conducting research on child cognition (Scarborough and Furumoto 1987).

Helen Bradford Thompson Woolley came to Teachers College in 1925, at the age of 50, when she accepted the position of director of the Institute of Child Welfare Research and professor of education at Teachers College (Scarborough and Furumoto 1987). Her first year in New York was quite productive, despite myriad "personal traumas" (p. 201). However, by 1926,

she "became emotionally incapacitated" and was required to take a leave of absence (p. 201). Upon returning 2 years later, she remained incapable of working effectively and was forced to resign in 1930, spending the remainder of her life in her daughter's home (Scarborough and Furumoto 1987).

Psychology at Barnard College

The late 1800s were a time in New York when "a woman could obtain the gratification of every want, wish, or whim, save one – she could not get an education" (Miller 1939, p. 6). The 1889 founding of Barnard, a 4-year college for women at Columbia, represented the culmination of longtime efforts of the former president of Columbia College, Dr. Frederick Barnard; Mrs. Alfred Meyer, a vocal advocate of women's education; and a few sympathetic trustees of Columbia College.

At this time, psychology was still a part of the philosophy department, and Miller (1939) reported that the first psychology course at Barnard was offered in 1894 by Dr. James H. Hyslop (1854–1920): "No longer the 'metaphysics and moral philosophy' of an older generation... the students of this time had the advantage of studying their subject in a masterpiece of English prose – William James's *Principles of Psychology*" (p. 45). Harry L. Hollingworth, in contrast, cited 1906 as the year in which the first psychology courses were offered (Hollingworth 1950). It seems unlikely that Hollingworth was unaware of Hyslop, although he had retired from Barnard by the time Hollingworth had arrived at Columbia in 1907 as a graduate student. Hollingworth may have discounted Hyslop's courses because of the latter's steadfast commitment to and engagement in psychical research, which Hollingworth and others would likely have considered illegitimate science. More to the point, it seems that Hollingworth considered the first bona fide psychology courses to be those that incorporated a laboratory component and made use of such equipment as the Hipp chronoscope. By these criteria, and consistent with Hollingworth's report, the first experimental psychology courses were indeed not offered until 1906 (Hollingworth 1950).

Eventually, Harry Hollingworth would be the founding chair of the Barnard College psychology department. Born in DeWitt, Nebraska in 1880, Hollingworth completed 10 years of school by the age

of 16, graduating as valedictorian of his class (Benjamin 1991). While working in his father's carpentry business, something he had done from the age of 11, Hollingworth obtained his teaching certificate in 1898. After teaching for 2 years, he returned to school to complete his college preparatory work. Undeterred by scarce financial resources, and determined to engage in intellectual pursuits, Hollingworth enrolled at the University of Nebraska in Lincoln in 1903. Along with his fiancé, Leta Anne Stetter, Hollingworth graduated from the University in 1906. Harry Hollingworth was keen to pursue graduate study in psychology or philosophy (Benjamin 1991); but lacking a graduate assistantship, he and Leta both assumed teaching positions in Nebraska. His luck would change a few months later when he received a telegram from Cattell of Columbia offering him an assistantship to begin in January of 1907. The Hollingworths were married at the end of 1908, and in the following year, Harry accepted a position at Barnard College as Instructor of Psychology and Logic (Hollingworth 1940). The couple was under substantial financial pressure: New York law forbade married women from teaching and Harry's starting salary of \$1,000 was insufficient to sustain them both.

These financial concerns pushed Harry's career in a more "practical" direction: Hollingworth would come to be regarded as a pioneer in applied psychology, an appellation about which he likely felt, at best, ambivalent. "It has been my sad fate," he wrote in his unpublished autobiography, "to have established early in my career a reputation for interests that with me were only superficial" (Hollingworth 1940, p. 6). Indeed, financial necessity alone provided the impetus for his entry into the field of applied psychology:

- ▶ My real interest is now and has always been in the purely theoretical and descriptive problems of my science, and the books, among the twenty I have written, of which I am proudest, are the more recent ones which no one reads. I became an applied psychologist in order to earn a living for myself and for my wife, and in order for her to be able to undertake advanced graduate training, for which she was just as eager as I had been. (Hollingworth 1940, p. 56)

His ventures into the applied arena began when he lectured at Columbia and conducted research in

business psychology, which culminated in his *Advertising and Selling* (1913). Perhaps his most public undertaking was the set of studies he conducted under the auspices of the Coca-Cola Company, which was being sued by the federal government, under the Pure Food and Drug Act of 1906, for selling a beverage that contained the "harmful" ingredient caffeine. Despite the fact that "accept[ing] private funds for the prosecution of research seemed to be considered by my colleagues a somewhat shady business," Hollingworth's motives for undertaking this project were twofold. As he wrote, "I needed money, [a]nd here was a chance to accept employment at work for which I had been trained" (Hollingworth 1940, p. 65). Hollingworth saw to the meticulous crafting of a contract that, along with allowing him to publish the results, prevented Coca-Cola from either suppressing the findings or exploiting his or the College's participation in the studies. Based on his several systematic and highly controlled studies, Hollingworth testified that his studies yielded no evidence for the deleterious effects of caffeine on mental or motor performance (Benjamin 1991; Benjamin et al. 1991).

The Coca-Cola studies had an enormous effect on the Hollingworths' personal lives: Not only was Leta Hollingworth able to complete her doctoral studies, but they also were able to balance their family budget. Moreover, many more opportunities to work in applied psychology were forthcoming, owing in part to the positive publicity associated with his caffeine studies (the stipulations of the contract notwithstanding) and to the knowledge in the business community that Hollingworth was willing to do such work (Benjamin 1991). And, during WWI, Hollingworth served as a Captain in the US Army as chief psychologist of the Curative Workshop and School for Reconstruction and Study of War Neuroses (NYTIMES, Sept. 18, 1956). Based on his experiences with "shell-shock cases," he developed a theory of functional neuroses, which was published in his book, *The Psychology of Functional Neuroses* (1920). In 1922, this book was awarded the Butler Medal by Columbia University (Hollingworth 1940). His many applied activities notwithstanding, Hollingworth always remained interested and engaged in theoretical issues in the field.

Once Harry Hollingworth became a full-fledged member of the faculty, William P. Montague (1873–1953), the head of the philosophy department,

- ▶ recommended the formation of a separate department of psychology, and I was it. Students increased in number; I dropped my teaching of Logic and devoted full time to the department. We were given then the suite of six rooms in the main building... which remained ever after the Psychological Laboratory. (Hollingworth 1940, p. 182)

Following WWI, Hollingworth began to hire instructors to assist him, some of whom would become well-known in the field, but were evidently not promoted to professorial rank, at least while at Barnard (Sargent 1987). This pattern evidently continued under Hollingworth's successor, Richard P. Youtz (1910–1986), who would chair the Barnard psychology department from 1946 to 1974. Two noteworthy examples of such instructors are Anne Anastasi (1908–2001) and Georgene H. Seward (1902–1992) (Sargent 1987). Anne Anastasi entered Barnard College as an undergraduate in 1924 at the age of 15. She received her BA at the age of 19, and her doctorate from Columbia University 2 years later. In 1930, Anastasi returned to Barnard as an instructor, but left in 1939 to become assistant professor of psychology at Queens College. In 1947, she assumed the position of associate professor of psychology at Fordham University, where she remained until her retirement in 1979, when she became Professor Emerita. Her most enduring scientific contributions are in the areas of psychological testing and differential psychology. Her resultant classic texts, *Differential Psychology* (1937) and *Psychological Testing* (1976), both of which remain internationally known, have appeared in multiples editions, and have been translated into nine languages. She earned numerous awards, including the APA Distinguished Scientific Award for the applications of psychology and the National Medal of Science. She also held numerous leadership positions within the field, including the APA Presidency in 1972; she was the third woman ever to hold the office (Reznikoff and Procidano 2001).

Georgene Seward took her BA at Barnard in 1922 and her PhD from Columbia University in 1928. She then taught at Barnard from 1930 to 1937. Seward's most enduring scientific contributions are her research

on sex differences, published in her *Sex and the Social Order* (1946), and her investigations of psychological stresses related to minority group membership, which culminated in *Psychotherapy and Culture Conflict* (1956) and *Clinical Studies in Culture Conflict* (1958). In 1987, Seward received the Distinguished Psychologist Award of the California State Psychological Association (Sargent and Williamson 1993).

In relation to the pattern of non-promotion within the Barnard psychology department, Sargent (1987) wrote: “the passing over of so many females [for promotion] led to some criticism of Barnard and of Prof. Hollingworth.” That most instructors, including Anastasi and Seward, were never promoted to professorial rank while at Barnard, however, may also reflect on some more general aspects of the institution's culture:

- ▶ First, the Barnard junior faculty were often graduates of the Columbia PhD program and there was a bias against keeping them around permanently. Second, Barnard faculty undergo separate college and university evaluations with respect to tenure recommendations... During that era, Youtz (and most of the Barnard faculty and administration) viewed Barnard's primary mission as the teaching of undergraduates. During Youtz's time as chair, junior faculty were not given the time or resources to have much chance of reaching the level of research productivity required for tenure in the university. And, third, the whole Columbia (and Ivy League) culture did not value ‘promotion from within.’ There were very few junior faculty in any Columbia department, including psychology, who moved up through the ranks. Most tenured faculty were brought in as appointments from outside the institution. (P. Balsam, personal communication, December 6, 2010)

Richard Youtz was the first to defy this pattern, as he would become a full-fledged member of Barnard's faculty in 1940 and would remain there until his retirement in 1974. Born in South Dakota, Youtz graduated from Carleton College in 1933 and began his graduate training in psychology under Clark Hull's tutelage at Yale University. After earning his doctorate in experimental psychology in 1937, Youtz served as an instructor at Barnard from 1937 to 1939, departing for an appointment as an assistant professor at Oberlin College for the 1939–1940 academic year. In February

of 1940, however, Dean Gildersleeve of Barnard College invited Youtz to return as “Professor Hollingworth’s first lieutenant,” since the budget allowed for a new assistant professorship in psychology (Gildersleeve 1940). The dean explained that the appointment was “at first an annual one, but [that] we should look forward to your remaining indefinitely if the plan worked out satisfactorily on both sides” (Gildersleeve 1940). Youtz accepted the dean’s invitation gladly: “I’m sure I shall never regret returning to Barnard. I liked it when I was there and was sorry to leave. Things seemed to have worked out just right” (Youtz 1940). Beginning in 1942, Youtz served the US Army Air Force as a Psychology Research Officer, returning to Barnard as chairperson of the department in 1946.

Richard Youtz valued strongly the scientific method and believed that there were no limits to the phenomena to which it could meaningfully be applied. He once “presented [a] paper in which he speculated that some reports of flying saucers might be due to visual afterimages” (Balsam 1988, p. 595). During the 1960s, in a separate line of research, Youtz studied experimentally the putative phenomenon known as dermo-optical perception, or the ability to perceive colors through the skin. Based on a series of experiments, Youtz demonstrated that such perception was attributable to thermal properties of the stimuli: “Youtz’s was a rational voice in the sometimes wild discussion of dermo-optical sensitivity that was taking place” (Balsam 1988, p. 595).

Although in many ways the Barnard psychology department remained in the embryonic stage of development, under Youtz’s leadership it developed a strong undergraduate curriculum that emphasized “hands-on experiences in experimental psychology” (Balsam 1988, p. 595), and was responsible for a significant number of Barnard psychology majors pursuing graduate training and careers in the field. In addition, plans were developed in the early 1950s, and were underway by 1953, to establish the Hollingworth Laboratories of Experimental Psychology at Barnard College. In July of 1953, Youtz wrote Harry Hollingworth, relating that the construction for the new laboratories was

- ▶ underway and [the labs] are approaching realization – i.e. the walls are going up, and they look as if they will really happen. As nearly as I can figure it means about

a 55% increase in space which will include: individual offices for each staff member, separate space for the three assistants, an olfactory lab with air-conditioning. . . , rat room, shop, observers’ room and subject room separated by one-way vision screen, 4 store-rooms, and two specialized rooms for Experimental Psych. . . ., each with 8 booths for pairs of students, and 17 experimental cubicles (6’ x 9’) for use of staff and students. (Youtz 1953)

Upon completion of the construction, a “gala opening” was held to commemorate the event. Afterward, Hollingworth expressed his gratitude in a letter to Youtz:

- ▶ It was right good of you and all the department staff to give the old man such a send-off. The naming of the laboratory after him was much appreciated tribute and will not be forgotten. All my days at Barnard were pleasant and high among the things I am proudest of is the group of people I was able to leave in charge, to build up a real modern department. You have done a first class job. . . The new laboratories are really splendid and seem well planned for effective work. (Hollingworth 1954)

Youtz’s own tenure and promotion broke the department’s long-standing pattern in which faculty members typically did not receive tenure and subsequently left. And while the structural and curricular changes that took place in the department under Youtz were important, he evidently perpetuated the pattern of non-promotion once in a position of authority. Simply attributing this pattern to cultural and structural factors of the Ivy League seems insufficient, because although such factors may have militated against the tenure and promotion of Barnard faculty, other departments at Barnard did tenure some faculty (Lila G. Braine, personal communication, December 17, 2010). In fact, Lila Ghent Braine, who was hired as professor and chair of the Barnard psychology department in 1974, relates that the College had been displeased with the way Youtz ran the department, particularly with respect to the non-promotion trend. Youtz was not asked to serve on the search committee to find his replacement, indicating the College’s desire for a change in course (Lila G. Braine, personal communication, December 17, 2010). The search

committee approached Braine, who had studied under Donald Hebb (1904–1985) at McGill University in the 1950s, because she had a strong record of scholarship and “was a feminist” (Lila G. Braine, personal communication, December 17, 2010). Under Braine’s leadership, the Barnard psychology department established roots, as qualified professors were tenured and promoted, contravening the pattern that had begun under Hollingworth in the 1910s. In fact, two of Braine’s early two hires – Peter Balsam and Rae Silver – remain active contributors to the Columbia University community (Lila G. Braine, personal communication, December 17, 2010).

Conclusion

This history of psychology at Columbia University is necessarily selective given the abbreviated length of this account. Nevertheless, it is clear that from the earliest days of the New Psychology in America, that the psychology departments of Columbia University, including those of Teacher’s College and Barnard College, played an influential role in establishing the legitimacy of the new science, providing leadership for a burgeoning discipline and profession, and nurturing future generations of psychologists, many of whom went on to have distinguished careers in the field. Columbia produced a research culture in psychology that was at the forefront of the new laboratory psychology. The several psychology departments not only produced many individuals of prominence but proved to be a defining entity for fields such as psychological assessment, educational psychology, social psychology, comparative psychology, visual perception, and operant psychology (Norsworthy 1906). It can be argued that for several decades, Columbia was indeed the gem of American psychology’s ocean.

Anticipations of “Comparative Psychology”

In the early days of experimental psychology, Hermann Ebbinghaus (1850–1909) said that psychology had a long past but a short history. Certainly that is true of comparative psychology; its prescientific phase traces back to the very origin of the human species, when we needed to distinguish between animal species that we could eat and those that could eat us. This very practical “comparative” study continued through the domestication and selective breeding of species including horses, dogs, cats, camels, and elephants.

Evolutionary Theory Stimulates Comparative Studies

Comparative psychology underwent a true sea change as a result of Charles Darwin’s (1823–1913) development of evolutionary theory, first published in his *Origin of Species* (Darwin 1859). Darwin was far from the first person to propose an evolutionary theory – his own grandfather, Erasmus Darwin, proposed a speculative evolutionary theory, and ancient Greek philosophers postulated the selective survival of various combinations of body parts, a primitive evolutionary theory.

However, Darwin *was* the first to propose an evolutionary theory based on careful comparative observation of hosts of species, living and dead. The essential feature of evolutionary theory is that organisms change over time, with favorable changes preserved, and unfavorable changes eliminated. These changes will be revealed in the fossil record and in the relationships between living species. Living species with common ancestors will resemble each other and their predecessors in the fossil record.

Comparative psychology can be defined as the search for patterns of similarities and differences in the

adaptation of animal species to changing ecological niches. Comparative psychology is closely related to ethology, but is more experimentally oriented, while ethology focuses more on studies in the natural environment. Traditionally, any study of the behavior of nonhuman animals is treated as belonging to comparative psychology.

Darwin’s theory of evolution greatly stimulated the study of the relationships between all animal species, but also was criticized by those who believed that God created all species in their present form. Indeed, while Darwin was writing his book on the evolution of species, his own wife took umbrage at the idea that species were not entirely direct and unique creations by God.

Even before Darwin published his seminal work on evolution in 1859, Herbert Spencer (1820–1903) argued (Spencer 1855) for an absolute continuity between humans and other animals, and even between animals and plants, and between conscious and unconscious, and living and nonliving matter.

George John Romanes (1848–1894), inspired by evolutionary theory, published *Animal Intelligence* in 1886; he was apparently eager to contribute to the evolutionary perspective by claiming that animals sometimes exhibited a human-like intelligence. C. Lloyd Morgan (1852–1936) was more cautious; he thought (Morgan 1891) that one should never attribute a higher intellectual faculty to an animal if a lower faculty was adequate to account for its behavior. A great example of this is the horse, Clever Hans, who, his owner and many observers believed, could count and answer questions about numbers, much as a human would do. He indicated the answer by tapping his hoof the correct number of times. However, a careful study by Oskar Pfungst (cf. Hillix and Rumbaugh 2004, pp. 50–51) showed that Hans had only learned to stop when he detected subtle movements from the audience when the number of taps was correct – one of Morgan’s “lower faculties.” It is tempting to attribute human attributes to animals (be anthropomorphic), but, as Morgan pointed out, one should do so only after careful study.

Darwin’s Theory of Evolution and the assumption of between-species continuity led to an interest in learning and intelligence in animals, which was to become the main focus of comparative psychology during a large part of the twentieth century. One early

assumption was that the most fundamental laws of learning were similar across species, despite some variation resulting from species-specific adaptations.

As the nineteenth century drew to a close, experimental psychology was born; the official dogma is that Wilhelm Wundt (1832–1920) established the first psychology laboratory in 1879 in Leipzig, Germany. Although Wundt was no comparative psychologist, he did publish briefly on animal psychology (Wundt 1894). However, despite being an experimentalist, he did not experiment on animals.

Theories of Reinforcement Become the Dominant Concern

Soon after Wundt established his laboratory, other experimentalists began extensive work with animals; in most cases the goal was to discover the fundamental laws of learning, with the implicit assumption that the laws would apply across a broad spectrum of animals, including human animals. This approach became strongly identified with E. L. Thorndike (1874–1949), who used a variety of species in his classic research (1898) with mazes and puzzle boxes, and with I.P. Pavlov (1849–1936) and his studies on conditioning.

Thorndike proposed a law of effect, which became a fundamental component of subsequent theoretical explanations of animal learning. To quote Thorndike:

- ▶ Any act which in a given situation produces satisfaction becomes associated with that situation, so that when the situation recurs the act is more likely than before to recur also. Conversely, any act which in a given situation produces discomfort becomes disassociated from the situation, so that when the situation recurs the act is less likely than before to recur. (Thorndike 1905, p. 203)

The law of effect and the associated concept of reinforcement are among the most durable concepts in psychology. Precursors of the law of effect and the concept of reinforcement can be traced back to the writings of Herbert Spencer and Alexander Bain in the nineteenth century, and arguably all the way back to Epicurus, who said in around 300 BC that the goal of life was to seek pleasure and avoid pain.

One of the obvious and best-known problems with the law of effect is its circularity. The “satisfier” is an event that is identified by noting that the animal does

things that lead to it, and the law of effect says that satisfiers strengthen the responses that precede them. Thus if an event did not strengthen a response, it was not a satisfier. As stated, the “law” becomes a mere tautology, and cannot be falsified.

However, Paul Meehl published a classic article in 1950 in defense of the law. He pointed out that an event that strengthened a response in one situation generally reinforced other responses in other situations. Thus, he stated a “weak law of effect,” that all reinforcers are trans-situational. A companion law was the strong law of effect, which held that all instances of learning involved a trans-situational reinforcer.

These two versions of the law of effect were clearly testable and quickly falsified. The best known of the exceptions to the weak law of effect were described in Keller Breland’s classic article, “The misbehavior of organisms” (Breland and Breland 1961). Raccoons given fish reinforcements for putting coins in a “bank” stopped doing this and instead displayed a stereotyped “hand-washing” behavior related to food preparation. Pigs stopped using coins and instead rooted them, as they had rooted the food reward.

These and many other failures of reinforcers to generalize across situations occur when the reinforcer elicits a strong reflex-like response that attaches to the preceding stimuli, thereby producing a version of the unconditioned response to the reinforcer, instead of the intended instrumental response. Animals generally have a repertoire of responses, some of which occur more frequently than others in anticipation of food. Those that occur frequently are easily reinforced by food, and those that decrease in frequency when food is anticipated are difficult to teach (Shettleworth 1975). Thus an important and clear conclusion reached by comparative study is that the success of operant conditioning depends upon the relationship between an animal’s existing behavioral preferences and the reinforcing circumstances.

Other findings also appeared to contradict the law of effect. Tolman (1886–1959) and his students showed that rats learned about a maze when they were allowed access to it in the absence of reinforcement, and demonstrated that they had learned when a reward was introduced. Kenneth Spence incorporated this finding into his theory that strength of stimulus–response association depended only on the number of times stimulus

and response had been contiguous, with the reinforcer acting only to activate already learned associations (Spence 1956).

Spence also performed work on eyelid conditioning that had striking comparative implications. Earlier work had demonstrated that humans usually extinguished conditioned eye blinks within one or two trials, while other animals continued to make the conditioned response for up to hundreds of trials. Spence and his students masked the true nature of the experiment for human subjects by telling them that their task was to learn verbal materials while being “distracted” by the conditioned and unconditioned stimuli of the eye blink experiment. With their cognitive apparatus occupied elsewhere, human behavior paralleled that of animals! (Spence 1956) This result suggests that cognitive factors may account for widespread qualitative differences between the controls of animal and human behaviors.

Another experimental surprise was delivered by John Garcia and his colleagues (1966). They discovered two important facts about conditioning: (1) that rats, and presumably other animals, are more “prepared” to associate some kinds of stimuli (tastes) than others (lights and sounds) to illness; and (2) that the association to the prepared stimuli may occur over much longer lags between the conditioned and unconditioned stimuli (hours rather than seconds or minutes) than had previously been thought. The adaptive function of this mechanism is presumably that it allows animals to avoid eating poisonous food.

New conceptions of what constitutes a reinforcing relationship have been suggested. First was Premack’s (1959) suggestion that reinforcement involves a higher-rate response that follows a lower-rate response; food reinforces bar-pressing because the independent rate of food-eating exceeds that of bar-pressing. Other suggested modifications followed: That reinforcement occurred when the reinforcer produced a higher *momentary probability* (not necessarily rate) of response, or when the organism was deprived of the reinforcing response (see Timberlake 1980, for a discussion of “equilibrium theory”).

What are we to conclude from this motley assortment of results? Clearly, in many situations learned behavior has been decoupled or emancipated from strict control by reinforcers. However, none of these

phenomena are viewed as particularly mysterious – and all have been explained with one or more theories.

An Alternative to Traditional Views of Reinforcement

The real question is why the term reinforcement has been retained. Is there a better alternative? One clue is the fact that all reinforcers seem to have one thing in common: They attract attention, they often elicit orientation responses – they are salient. This was the basis for an alternative theory based on amalgams (Rumbaugh et al. 2007). Amalgam formation is an evolutionarily old, primitive, and relatively simple process. It occurs when a strong, relevant-to-adaptation, evolutionarily important, informative, otherwise dramatic stimulus is brought into reliable temporal or spatial contiguity with a weaker, less interesting stimulus as in sensory preconditioning or Pavlov’s (1929) classical conditioning or in Skinner’s (1938) operant conditioning. The pairing causes the weaker stimulus to acquire some of the response-producing characteristics of the stronger stimulus, and the stronger stimulus to acquire some of the response-producing characteristics of the weaker stimulus. The stronger stimulus is said to have high salience, and the association of the two stimuli can produce an amalgam, as discussed above.

Amalgam formation is similar to the first learning stages of sensory preconditioning and classical conditioning. One advantage of the salience approach is that there is just one fundamental process: amalgam formation. Amalgam formation underlies sensory preconditioning, classical conditioning, and, most importantly, instrumental conditioning.

Therefore, perhaps there is just one process that underlies all learning, not two. This unitary approach is both clearly basic to conditioning and learning and simple to understand (see Rumbaugh et al. 2007, for an elaboration of this perspective).

The Practical Side of the Law of Effect

Although the law of effect has been disproven as a universal law, reinforcement of responses remains a useful technique, one upon which trainers and teachers rely, using aftereffects as disparate as gold stars and candy bars. Skinnerian operant conditioning techniques rest squarely upon the shoulders of reinforcement and its scheduling.

The Search for Fundamental Laws of Animal Behavior

In much of the twentieth century, especially its first half, researchers were preoccupied with discovering universal laws of behavior that applied to all species. The search was for similarities, not differences, between species. Comparative psychology was out of balance. Tolman (1948), Hull (1943), and Skinner (1938), probably the three most prominent theorists of that period, were searching for general laws. Their differences were in the laws they proposed, not in the species to which the laws were presumed to apply.

The Ethological Connection

Although experimental searches for the fundamental laws of behavior in both classical, Pavlovian, and instrumental (Thorndikian and Skinnerian) conditioning dominated psychology throughout the twentieth century, there was a parallel development of naturalistic approaches. We have already seen that Romanes and Lloyd Morgan observed, collected, and interpreted nonhuman animal behaviors. And, early in the twentieth century, Wolfgang Köhler (1887–1967) found that chimpanzees could demonstrate insight learning that manifested without previous reinforcement of the successful response (Köhler 1925; Rumbaugh et al. 1996; Yerkes 1943).

William James in his 1890 *Principles of Psychology* had a chapter on instinct that prefigured, to a remarkable degree, later developments in comparative psychology. For example, he described the phenomena of imprinting in considerable detail, as it had been observed by Romanes and Spalding. Although we usually think of Konrad Lorenz as the discoverer of imprinting, Romanes and Spalding observed both imprinting (the tendency of very young chickens and some other animals to follow and fixate on the first moving object they see) and the critical period (after a few days, if the young animal has not fixated on a moving object, the reaction to moving objects is fear and avoidance, rather than following).

James also presents a perceptive picture of the interaction between instinct and habit, which could well have inspired work like that of the Brelands, if they were aware of it. James says that sometimes instincts are dominant; the raccoons washing the tokens rather than making the rewarded response of depositing them is an

example of the triumph of instinct. Often habits are dominant, as when an animal imprints on the first moving object it sees, and afterward will follow nothing else.

Comparative psychology and ethology were greatly advanced by biologist Nikolas Tinbergen (1907–1988). He was justly famous for his work with supernormal stimuli; one of several examples is that birds often chose to sit on eggs that were larger, or more brightly colored, than their own eggs. Some female human breasts might also be supernormal stimuli.

Tinbergen (1963) argued that four questions should be answered in order to understand the behavior of animals. First, what was its proximate cause – the stimuli or situation that elicited the behavior? Second, how did the behavior develop over time – what was the interaction between instinct and experience? Third, how had the behavior evolved? Fourth, what was its role in adaptation? One of several prominent Tinbergen students at Oxford was Richard Dawkins (1941–), a contemporary evolutionist who stresses the importance of genes in the behavioral economy of both animals and humans.

Konrad Lorenz (1903–1989), a contemporary and sometimes friend of Tinbergen, rediscovered and very carefully studied imprinting (Lorenz 1952), apparently unaware of Spalding or Romanes, or of James's second-hand description of his predecessors. Together with Tinbergen, Lorenz described innate releasing mechanisms that elicited instinctual fixed action patterns.

Other biologists, ethologists, and psychologists observed animals in completely naturalistic situations, interfering as little as possible with animals' normal behaviors. Two of the most famous observers were George Schaller (1933–) and Jane Goodall (1934–), the former an observer of mountain gorillas, and the latter of chimpanzees. They dispelled myths of primate behavior in opposite directions: Schaller (1963) found that gorillas were gentle, social animals, when they had been mistakenly portrayed as vicious brutes. Goodall (1986), among others, found that chimpanzees in the wild were contentious carnivores who hunted and ate monkeys, but also that they used tools and were very social and intelligent. Schaller, Goodall, and many other students of animal behavior have been lifetime conservationist leaders.

Animal Language Studies: A New Era in Comparative Psychology

Studies of Captive Animals

Myths about talking animals are nearly as old as human history. Ancient Egyptians believed that some baboons had the gift of language, and revered those that did (Hillix and Rumbaugh 2004; Rumbaugh and Washburn 2003). Early investigators reared chimpanzees in human households in the hope that they would assimilate language, as human children do; among them were Kelloggs (1933), Nadezhda Ladygina-Kohts (1935), and Catherine Hayes (1951). Although the home-reared animals appeared to comprehend a significant amount of language, they manifested almost no ability to *produce* language. The abyss between animals and humans seemed to be unbridgeable.

Gardner and Gardner (1971) ushered in a new era of animal language study when they shifted the medium of communication from vocal language to sign language with their chimpanzee, Washoe. Washoe was named for the county in Nevada in which she and the Gardners resided, and her name in the language of the Washoe Indians meant “the people.” She was reared from an early age in a trailer next to the Gardners’ home, and taught a simple version of American Sign Language (ASL). Washoe eventually acquired a vocabulary of 170 signs while under the tutelage of Roger Fouts, one of the Gardners’ students, and his wife, Deborah Fouts.

Other investigators, like the Gardners, found new ways to communicate with primates. Ann and David Premack first tried to use a joystick that would let chimpanzees produce phonemes (it was not practical), and then used a pictorial language in the form of plastic symbols; their star pupil, Sarah, acquired a vocabulary of about the same size as Washoe’s (Premack 1970).

Duane Rumbaugh wanted to avoid the subjectivity that was involved in interpreting sign language, so he and his colleagues developed a language of “lexigrams.” The symbols of the language could be presented via computers or lexigram boards to which animals or humans could point to indicate words. His first chimpanzee pupil, Lana, learned both to comprehend and to produce combinations of symbols to obtain food, drink, other favors, and to answer

questions regarding the names and colors of 36 objects (Rumbaugh 1977).

Sue Savage-Rumbaugh extended the lexigram work to other chimpanzees, notably Sherman and Austin (Savage-Rumbaugh 1986), and to several bonobos, most prominently Kanzi, Panbanisha, and Nyota (Savage-Rumbaugh and Lewin 1994). Kanzi was reared in a combination of bonobo and human cultures, and demonstrably learned to comprehend hundreds of human sentences that he had never heard before (although he necessarily had learned the meanings of the words used in the sentences).

Other investigators extended the language work to other animals. Francine (Penny) Patterson obtained impressive results with her gorilla, Koko, using sign language similar to the language used by the Gardners (Patterson and Linden 1981). Similarly, Lyn Miles showed that her orangutan, Chantek, had both significant ability to learn sign language and impressive ability to make tools (Miles 1993). And Louis Herman demonstrated that dolphins have an amazing ability to imitate human actions and to comprehend a visual language presented with global movements of the arms and body (Herman 1986). The dolphins were trained after being socialized by swimming and interacting with them. A concept like “in” was taught by placing an object in a dolphin’s mouth and then encouraging her to place the object in a basket, in the presence of the sign for “in.”

Irene Pepperberg returned to the vocal channel with her African grey parrots, the most famous of whom was Alex (Pepperberg 1999). Alex learned to use over 80 words, an incredible feat for an animal with such a tiny brain, and a feat comparable to the accomplishments of the great apes (excluding human great apes).

Studies of Animals in Their Natural Habitats

Paralleling the studies discussed above are studies of animal communication in species literally ranging from ants to zebras, in their natural settings. Among them are striking studies by Von Frisch (1886–1982) and many others of the ability of bees to communicate roughly the distance and direction of food sources through the direction and intensity of their “dances” in the hive. Although Von Frisch’s work elicited a long-

standing controversy about the legitimacy of bee communication, his work has won widespread acceptance.

Animal Language and Comparative Psychology

What is one to conclude from the results of the work on animal language? If one accepts all or most of the results, one must conclude that, once again, the evolutionary generalization that there are gradations of differences – and similarities – between species is confirmed. That is not to deny that there is a huge difference, one that could be called qualitative, between human language and cognition and that of other animals. Future studies will continue to throw light on the basis of this, and other, difference between humans and other animals, and between different species of nonhuman animals.

The advent of animal language studies produces an entirely new set of possibilities: We are no longer entirely limited to observing animals from the outside. In some cases we can communicate directly with them, and our ability to do so is certain to increase, especially in the case of animals like dolphins, whose magnificent brains suggest rich possibilities not yet realized. The future of comparative psychology looks more exciting than ever before.

Some Tentative Generalizations from Comparative Studies

Humans seem to share with other animals the effects of contiguity and reinforcement on behavior. Instinct and the aftereffects of responses interact to determine patterns of behavior. Nothing in animal or human behavior contradicts the basic tenets of evolutionary theory (King et al. 2005; Schick et al. 1999). Learning is not based wholly on reinforcement and punishment, but aftereffects are an important determiner of animal behavior. Different species exhibit different instinctual behaviors that appear to have arisen in response to the requirements of adaptation to their individual environments. The more we learn about behavior, the more continuity we see between behaviors of related species (Schrier et al. 1965; Suomi 2005). Animals can even be taught some language-like behaviors and skills, although the gap in linguistic ability remains large. Comparative psychology and ethology have amassed a huge corpus of data on animal behavior, but have

probably realized only a small percentage of the possibilities.

True to its rich history, comparative psychology will continue to contribute to our understanding of behavior at all levels.

Consciousness and Embodiment

J. SCOTT JORDAN

Illinois State University, Normal, IL, USA

When scholars of consciousness utilize the concept “embodiment,” they are trying to express the idea that consciousness itself, or “what it feels like,” is heavily contextualized and constrained by the fact that brain is nested within a body, which, in turn, is nested within a particular environmental context. As a result, they argue the very nature of consciousness is best explained in terms of “being in the world” at a particular time, in a particular place. In short, consciousness is considered a contextually dependent phenomenon, with the degree of contextual-dependence varying across different theorists.

This “embodied” approach to consciousness has entered the scholarly debate on consciousness as a reaction to the idea that consciousness and mind are *informational* in nature, versus physical. What this means is that the nature of consciousness and mind are actually independent of the particular physical context in which they are instantiated. This informational view emerged during the years surrounding World War II, with the advent of both information-technology and cognitive psychology. During this time, scholars began to conceptualize the mind in terms of its functional properties; that is, in terms of the causal connections entailed in the dynamics of cognition. For example, while solving a math problem in your head, certain “operations” have to be run on specific “contents” in order to find the correct answer. The idea behind this *functionalist* approach to mind was that the series of operations, as well as the contents upon which they operated, were ultimately comprised of “causal relations,” much like the formal relations expressed in a mathematical equation or a computer program.

Given these operations could be substantiated in media other than neural tissue (i.e., silicon computer chips) scholars conceptualized them as informational properties that were independent of the particular physical properties of the medium in which they were instantiated.

Contemporary Approaches to Consciousness and Embodiment

The impetus for the move away from this informational view toward a more embodied view came from many different disciplines, for different reasons. For some, it had to do with explaining the causal properties of mind, while for others it had more to do with explaining the mind's phenomenal properties (i.e., consciousness). As regards the former, scientists of mind working to develop a third-person, objective explanation of what the mind is, began to challenge the informational notion the mind functions like a computer program and instead, focused on generating explanations based more on detailed, biological analysis of cognitive functioning. As regards the latter, some philosophers began to move away from conceptualizing the mind as an internal, symbol-processing system, and to model it, instead, as housed within a body whose real-time dynamics play a major role in the real-time dynamics of cognition. For these philosophers, the task was to explain how and why consciousness accompanies these brain, body, and world dynamics.

While at first glance, these two endeavors may seem independent, they have, in fact, informed each other. Thus, in order to understand embodiment and consciousness, it is important to understand the scientific discoveries that have led to its emergence as a leading scientific framework, as well as the philosophical conceptualizations that have coevolved with these scientific discoveries.

The Science of Consciousness and Embodiment

In cognitive psychology, researchers began to argue that the basis for higher-level cognitive abilities such as language is to be found in lower-level sensory-motor skills, versus formal, propositional structures. Such claims were based on findings that indicated that access to words seemed to be constrained by body dynamics (e.g., whether or not one was smiling or frowning while trying to identify a word – Glenberg 1997) as well as the extent

to which words referred to actions versus static events. These findings led researchers to propose that language is coded in terms of visual representations and/or action–perception contingencies (Barsalou 1999) versus computer-like programs. As a result, instead of language being conceptualized as a computer program instantiated in the brain as an informational system, it began to be conceptualized as a developmentally dependent recursion on the neural dynamics involved in actually getting the body to move around (i.e., sensory-motor skills).

Further arguments in support of a more embodied view on language came from attacks on Noam Chomsky's famous nativist account of language, known as universal grammar, or generative grammar. Chomsky (1959), along with others, claimed that language was an innate human skill. When initially presented in the 1950s, this position placed Chomsky squarely at odds with the then dominant behavioral view of language, which claimed language to be a learned form of behavior. Since the 1950s, Chomsky's view has undergone many revisions, and it is not clear to what extent he now believes language in total is innate, or whether there are certain parameters of language that are fine-tuned via learning. Chomsky's move toward lived experience as an enabler of language is also apparent in current embodiment attacks on the notion of innate language. These challenges stem from the recent discovery of language systems in South America that seem to defy certain properties of innate language asserted by Chomsky's theory of universal grammar. Given this lack of universality in grammar structures, these researchers assert language is not innate, and is, rather, contextually bound to one's culture (Everett 2005). While these researchers appeal to culture more than to embodiment, *per se*, they share the embodiment scholar's commitment to accounting for higher-level cognitive abilities in terms of the systems we use to manage ourselves in daily living. In other words, mental phenomena arise naturally and spontaneously out of lived life. From this perspective, all psychological phenomena are first and foremost, lived phenomena. Theories that ignore this lived quality and, instead, conceptualize cognitive phenomena as being independent of lived experience (i.e., medium-independent information structures, or innate skill) do so at the risk of completely missing the phenomenon they set out to understand.

Embodiment theories have also begun to appear in robotics as researchers move away from Strong AI and the notion of a disembodied, informational mind, to a more situational, embodied view in which the natural properties of the body are conceptualized as part of the computational problem solving necessary to the robot's production of complex behavioral sequences. Examples (Clark 2001) include robots designed to model mate-selection behavior in crickets. Instead of modeling mate-selection as a logical sequence of operations that requires a brain program capable of (1) discriminating between different sounds, (2) determining the directional source of the selected sound, and (3) activating the appropriate motor program needed to locomote toward the source, robots were designed that reflected the manner in which crickets actually solve the problem. Specifically, the cricket's "ears" are located on its forelegs, and the inner tube that connects them is structured such that only particular frequencies are able to influence the cricket's movements. In short, the actual bodily composition of the cricket solves what, from a functionalist perspective, may have been thought of as "cognitive" problems.

Further support for the embodiment view derived from neuroscientific discoveries that indicated brain dynamics do not reflect the neat functional divisions between perception, action, and cognitive typically posed by the informational/computational view. Specifically, it was discovered that neurons in the prefrontal, motor-planning areas of the monkey brain also seem to be involved in perception (Rizzolatti et al. 1996; Rizzolatti et al. 2002). The first discovery was that certain of these prefrontal, motor-planning neurons, what were labeled "canonical" neurons, became active when the monkey was presented an object that afforded grasping behaviors. In short, the simple sight of the object generated motor-planning, as if part of "seeing" the object was the planning of the actions needed to grasp it. The second discovery occurred serendipitously as the researchers reached out to change the objects being presented to the monkey. To their surprise, these neurons responded to the researcher's reach for the object in the same way they reacted if the monkey itself had reached. In short, these neurons, which were labeled "mirror" neurons, responded to both the *planning* and the *perception* of goal-directed activity. These findings did much to

dismantle the notion that cognition works according to clearly separated processing stages, for if perceiving and planning share overlapping neurodynamics, the two are not clearly discernable functions.

Since the discovery of mirror neurons in premotor cortex, additional mirror neurons have been discovered in parietal cortex. Instead of mirroring goal-related activity, however, these neurons mirror the kinematics of movement (Decety 2002). What this means is as one observes another engage in a goal-directed action, prefrontal systems mirror the goal, while parietal systems mirror the movements made to produce the goal. Kinsbourne and Jordan (2009) recently used these findings to claim that human interaction is dominated by multi-scale entrainment. Entrainment, in this sense, refers to what happens to one's prefrontal and parietal mirroring systems while observing another. Specifically, the dynamics of one's planning and movement trajectories are directly influenced, via mirroring, by the goal states and movements the other generates. In turn, one's own goal states and movements do the same to the other. This gives rise to the types of reciprocal mirroring episode that previous researchers have referred to via terms such a mimicry, imitation, and synchrony. Given that both goals and movements become entrained, the entrainment can be said to be multi-scale.

Using this notion of multi-scale entrainment, Kinsbourne and Jordan describe how spontaneous entrainment episodes between caregivers and infants lead to the infant embodying the dynamics of reciprocity in its neuromuscular system. Specifically, the smile given to an infant by a caregiver, entrains the child to smile. This then recursively entrains the caregiver to smile again. Such episodes entail spontaneous turn taking. Participation in many such episodes allows the infant to embody the dynamics of reciprocity into its neuromuscular architecture and, as a result, anticipate reciprocity. Once this medium of entrained trust is in place, caregivers can then direct the infant's attention to events in the environment. In essence, multi-scale entrainment affords individuals the ability to spontaneously entrain with others in ways that afford cognitive development and enculturation.

The Philosophy of Consciousness and Embodiment

Collectively, these findings support the notion the mind derives its properties from the functioning of

the body and from “being in the world.” As a result, such findings have had a profound impact on philosophical approaches to mind and consciousness. Some philosophers have echoed these advances in cognitive science and argued the content of consciousness derives from the “sensory-motor” knowledge embodied in our neuromuscular architecture. From this perspective, the conscious experience of seeing “red” is not simply a neural reaction to a particular frequency of electromagnetic radiation. Rather, it is the experience of a behavioral possibility, what ecological psychologists have referred to as an *affordance*.

Other philosophical reactions to embodiment have gone even further and attempted to equate consciousness with life. From this perspective, consciousness is not explained in terms of sensory-motor knowledge, but rather, in terms of the dynamics that distinguish living systems from nonliving systems. Common to many different versions of this approach is the conceptualization of living systems as open systems that are able to keep themselves far from thermodynamic equilibrium. What this means is that living systems are systems that sustain their integrity by taking in, transforming, and dissipating energy, and doing so in a way that leaves them with energy stores available for work (i.e., energy transformation).

One take on this view proposes that the distinguishing property of living systems is their ability to give rise to all the processes necessary to both sustain and replicate the living system. Such systems are referred to as *autopoietic* (Maturana and Varela 1980). From this perspective, consciousness, the phenomenology of “what it feels like,” is a *relational* property between an autopoietic system and the processes in which it sustains and replicates itself. This view leads to consciousness being a natural property of autopoietic systems. And the reason these scholars need the notion of “relational” properties is because they still conceptualize the autopoietic system’s body in terms of physiology. Thus, in order to avoid the reductionist position that consciousness is identical with the physiological body, autopoietic theorists assert consciousness does not reduce to physiological properties because, as stated above, it is a relational property.

While the theory of autopoietic systems and the notion of relational properties seems to perhaps solve the issue of embodiment and consciousness, there are those who challenge its distinction between physiological

and relational properties. These scholars propose that physiology itself is relational, in that, the dynamics of all living systems are naturally and necessarily “about” the contexts in which they have evolved and sustained themselves (Jordan and Ghin 2006). As a result, there is no need to divide the body into its physiological properties and its relational properties. Instead, the body is conceptualized as a self-sustaining embodiment of the multi-scale contexts (i.e., phylogenetic, cultural, social, and developmental) in which it has sustained itself. From this perspective, the natural world is conceptualized as a self-organizing energy-transformation hierarchy. What this means is that living systems form a hierarchy of systems (i.e., plants, herbivores, and carnivores) that sustain themselves on available energy. In the case of plants, sunlight constitutes the available energy. In the case of herbivores, it is plants, and for carnivores, it is herbivores that constitute the energy. As systems emerge within this hierarchy, their “bodies” must be “embodiments” of the constraints they must address in order to capture available energy. From this perspective, a lion can be conceptualized as a self-sustaining embodiment of the constraints that need to be addressed to sustain a system on the energy entailed in a zebra. Given such self-sustaining embodiments are naturally and necessarily “about” the contexts they embody, “aboutness” (i.e., meaning) is constitutive of what they are. And consciousness, our phenomenology of “what it feels like” is an evolved form of embodied “aboutness.” Conceptualizing consciousness as a form of “aboutness” prevents one from dividing the body into physical and phenomenal properties, and later trying to find a way to put the phenomenal properties back into the fully described physical system.

The History of Consciousness and Embodiment

While the attempt to conceptualize consciousness in terms of embodiment might seem unique, one could argue it is really nothing more than yet another manifestation of the age-old struggle to understand the relationship between mind and body. On the unique side, the notion that consciousness constitutes a necessarily embodied phenomenon seems progressive because it derives much of its support from recent advances in cognitive science and neuroscience. On the same-old side, the fact that recent scientific findings lead to the

notion of consciousness being embodied is, in and of itself, not a unique phenomenon. Many philosophers in the past have taken advantage of scientific discoveries as a way of reconceptualizing the relationship between mind and body. Thus, while the move toward embodiment seems an achievement in relation to the last 4 or 5 decades, it comes across as another recursion on the mind–body problem from a larger perspective.

Perhaps it is from this larger-scale perspective that we can garner a clearer perspective on the long-term contribution of the notion of embodiment to our understanding of consciousness. For what is clearly at stake for embodiment scholars is the need to conceptualize consciousness in a way that renders it *constitutive* of what we, or at least our brains, are. Doing so is critical to consciousness studies because ever since the twentieth-century turn toward naturalism in philosophy, reality has come to be conceptualized in scientific terms. Thus, it has come to be assumed that all ontological statements regarding the constituents of reality must be stated in terms of physics, chemistry, and biology. This is why many scholars now propose accounts of consciousness that basically equate it with the brain. Having accepted a physics-based naturalism, consciousness must somehow “emerge” as it were, via the interactions of physical systems. This poses a major problem for the reality of consciousness because once a phenomenon has been accounted for in terms of the conceptual frameworks of physics, chemistry, and biology, there seems to be no real causal work left for consciousness to do. Having no role to play in the nature of reality, consciousness is either discarded as constituting a real phenomenon (i.e., eliminative reductionism), is treated as a real phenomenon that entails no causal properties (i.e., epiphenomenalism), is conceptualized as a fundamental property of reality that is distinct from the physical and not yet understood (i.e., natural dualism), or is conceptualized as an informational property that is ultimately independent of the medium in which it exists (i.e., functionalism). Regardless of which naturalist-inspired version one selects, consciousness is not considered a necessary aspect of a scientific description of what we are and how we do what we do.

While on the one hand, one could accept the physicalist argument and assume that the persistent philosophical tension between mind and body is simply how it is, and that one of the above-mentioned strategies will eventually prove out scientifically, it might also be the

case that the emergence of embodiment into the current debate on consciousness will lead scholars to simply see the “mind–body” problem as the very problem. That is, what might be needed in the scholarship of consciousness is not a way to fit the phenomenal into the physical, but rather, to develop a description of reality and what we are that transcends the mind–body dialectic. To be sure, such an endeavor has been attempted many times in the past. Baruch de Spinoza, a seventeenth-century philosopher, rejected the mind–body dialectic at the root of Descartes’ mind–body dualism by arguing against Descartes’ notion of substance and the idea that the mind and the body were constituted of different types of substance. Spinoza argued that in order for something to constitute substance, it: (1) could not rely on anything else for its existence, (2) could not be caused by anything else, (3) could not be reduced to anything else. And the only thing he believed met all three conditions was *everything in total*.

While Spinoza’s attack on substance might seem strange to modern ears, what seems to really lie at its core is a staunch commitment to *holism*: the belief that all of reality constitutes a unity. From this perspective, all things are inherently interrelated. And it is within this dense web of interrelations that consciousness resides: not as a by-product of independent physical systems, but as the natural “aboutness” of reality in general. Again, modern talk of holism and dense interrelations may sound strange, but this is only because of philosophy’s twentieth-century commitment to naturalism. This alignment of science and philosophy was ushered in via strong attacks on the notion of internal relations that was central to a holistic, philosophical movement known as idealism, most well-known via the writings of Georg Wilhelm Friedrich Hegel. Early twentieth-century analytic philosophers such as Bertrand Russell wanted philosophy and our notions regarding reality to be based on science and mathematics. A necessary step in this campaign was to establish the nominal status of objects whose properties could be described by mathematics via the scientific method. As philosophers moved from idealism to naturalism, ontology came to be dominated by property-philosophy, and physics, chemistry, and biology came to be the conceptual schemes that drove the conversation.

Over the course of the twentieth century, there were those who worked within the confines of naturalism

and the scientific method while simultaneously harboring strong dissatisfaction with its implicit commitment to reductionism and nominalism (i.e., the idea that reality ultimately reduces to context-independent, individual “things” known as matter). Gregory Bateson, for example (Bateson and Rieber 1989), believed that “mind” and “matter” were unnecessary in cognitive science because the two represent conceptual distinctions that separate what was originally a unity (i.e., reality). That is, the two refer to different aspects of a unified reality (i.e., aspects of reality that *feel* as though they depend on an observer – mind, versus aspects that *feel* as though they do not depend on an observer – matter). When one then takes these two aspects of lived experience and reifies them into ontological categories, as opposed to conceptual categories, one then assumes that ontology must be committed to discovering the bridging principles at work between these two types of stuff. Conceptualizing the “mind–body” problem as conceptual, versus ontological, however, leaves one with a single reality in which it is incoherent to assume the existence of context-independent nominal essences. As a result, all “things” are context dependent and inherently interrelated.

The point here is not to call for a revitalization of idealism. Rather, the point is to place the modern interjection of embodiment into scholarship on consciousness in its proper historical context. Philosophy is currently caught in a large-scale struggle between holism and nominalism. Thus, the current debate over embodiment and consciousness can be seen as a modern recursion on this holism–nominalism theme. If the current embodiment movement leads to the emergence of an ontology that transcends the mind-body problem, it will have secured its status as a truly unique philosophical movement.

Corsini, Raymond J.

RIVKA BERTISCH MEIR

Mental Health Counselor, New York, NY, USA

Basic Biographical Information

Raymond J. Corsini was born on June 1, 1914, in Rutland, Vermont, the child of recent immigrants

from Italy. His father, Giuseppe Corsini, worked as a marble cutter, but his participation in a high-profile labor strike left him unemployable on the Atlantic coast. Forced to move, the Corsinis settled in Marble, Colorado.

Giuseppe was an uneducated, angry man. He abused Raymond with such violence that his wife, Evelina, feared for their son's life. Even so, Evelina continued to discipline Raymond with physical force after Giuseppe's death, when Raymond was 5. Evelina soon moved Raymond and his younger brother Harold to New York City, where they settled in a tough Irish neighborhood. Raymond attended St. Columbia, a Catholic elementary school, in which defiance of authority was punished with verbal and physical abuse. Raymond was also targeted by his classmates, as a pattern of animosity between children of Irish and Italian immigrants was well established.

While Corsini was at the bottom of his class at St. Columbia, he earned the highest score on the New York State Regents test, a prerequisite for entering public high school. The tension between his iconoclastic personality and his sharp intelligence and deep love of learning continued to define his education, as his grades were consistently low and his test scores high. At the City University of New York (CUNY), Corsini was counseled by the dean to quit after several months because of his low grades. After working briefly in the Civilian Conservation Corps, he returned to earn a BA 7 years later. The Great Depression prevented him from finding a job, so he stayed at CUNY and earned an MA in psychology. Once again his grades placed him at the bottom of his class, yet his score on the New York State examination for psychology was the highest among his 26 peers. This success earned him a job at Auburn Prison in New York in 1942. His personal suffering gave him a deep compassion for others' pain along with both the desire and the ability to help them heal.

Corsini did his doctoral work at Syracuse University, Cornell University, the University of California, and the University of Wisconsin, receiving his Ph.D. in 1954 from the University of Chicago, where he worked under Carl Rogers. During his training, Corsini met and interacted with J. L. Moreno, Fritz Perls, Victor Frankl, and Albert Ellis, among others, but his main teacher was Rudolf Dreikurs, an Adlerian.

In the course of his professional life, Corsini had three separate careers: as a prison psychologist for 15 years, including chief psychologist at San Quentin State Prison in California; as an industrial psychologist for 10 years; and as a psychotherapist and counselor in private practice for 30 years. He taught courses at more than a dozen universities, including full time at the University of Chicago, Illinois Institute of Technology, and University of California at Berkeley.

In 1966, Corsini created the Family Education Center of Hawaii (FECH) to help people with parenting and family skills and to provide a training facility for Adlerian family counselors. FECH, which was rechartered in 2003 by three of Corsini's former students, now partners with the University of Hawaii at Manoa in running a family education training center and in offering course curricula focused on Adlerian parenting. Corsini was the first recipient of the Hawaii Psychological Association's Significant Professional Achievement Award, and received the association's Lifetime Achievement Award in 2003.

Although Corsini was considered a late starter in psychology, the last 30 years of his life were undoubtedly the most productive. The majority of his books were published after he turned 70, and at the time of his death on November 8, 2008, he was working on a book about comparative religions.

Major Accomplishments/ Contributions

Raymond J. Corsini was a prison psychologist, clinical psychologist, teacher, author, and community organizer, and one of the most important Adlerian psychologists of his time. His early experiences of violence and clashes with authority shaped his character and decidedly influenced his adulthood and professional life. He was difficult and rebellious, remaining a target for criticism and abuse throughout his life. As a strategy to prevent painful, humiliating rejections like those he endured from his parents, Corsini would readily provoke and criticize others, sabotaging the possibility of human connection and reinforcing his isolation. He remained in the grip of this self-defeating cycle throughout his life.

What equally defined Corsini's character, however, was a powerful resilience. Despite a horrific childhood that left him largely unable to form healthy

attachments, he was self-aware, innately compassionate and optimistic, and ferociously determined and persistent. His relentlessness, ambition, and intelligence ultimately drove him to the top of his profession, even as his education was slowed by his defiance of authority and weak relationships.

Throughout his life, Corsini upheld Alfred Adler's concept of *Gemeinschaftsgefühl*, or social interest. His contributions to the larger community were consistent with this Adlerian conviction that the individual's primary responsibility is to contribute actively to the health, integrity, and well-being of the community. Thus Corsini worked as a community organizer and developed an innovative, progressive educational system rooted in the principles of democracy and social responsibility. The Corsini 4R (C4R) approach – based on responsibility, respect, resourcefulness, and responsiveness – is used by schools in various parts of the world.

Corsini's troubled upbringing proved both a blessing and curse. While providing a first-hand window into the suffering of others, enabling him to understand their pain and anger and imbuing in him a strong sense to heal, it also made him wildly critical of others when he perceived unacknowledged flaws. His lack of sensitivity, decorum, and respect earned him many rejections, to which he did not take kindly. Some say that his second wife, Kleo, was responsible for curtailing his excesses and teaching him about civility. In addition, this close relationship undoubtedly spurred him on to a lifetime of public service in which he devoted his energies to the caring of others.

The *Biographical Dictionary of Psychology* lists Corsini as one of the most important psychologists of the past 150 years. He is unarguably one of the key psychologists of his time, perhaps best known to scholars and students in counseling and psychotherapy as the first editor, with Daniel Wedding, of *Current Psychotherapies* (Thomson/Brooks Cole), a text that has sold more copies than any other in this field and is now in its 9th edition. Corsini published more than 100 articles and 60 books, including *The Dictionary of Psychology* (Brunner-Routledge), the most complete in the English language, and *The Corsini Encyclopedia of Psychology* (John Wiley & Sons), widely acclaimed as one of the best in the field. The publication of *The Dictionary of Psychology* alone provides insight into

the man. Despite the book's having been rejected by 60 publishers before it was finally accepted, at a time when Corsini was in his late 80s, his perseverance clearly shows a remarkable faith in his own ideas, values, and abilities.

Raymond J. Corsini will be remembered for many contributions to the field of psychology. First, as an encyclopedia author, lexicographer, and editor, he has given psychology students and budding psychologists a set of treatises to help them develop an overview of the field and provide specific references to different subjects. Second, as an Adlerian advocate, Corsini shows through case studies, critical discussion, and analysis how to apply Adlerian principles to diverse client situations. Third, through his service to education and to specific communities, Corsini has demonstrated how to utilize his Individual Education Model within family settings, so that young people can benefit from an Adlerian approach to parenting, as well as providing the framework through which future counselors can continue his work.

Cosmopolitanism in Psychology, Theories of

ERI PARK

Utrecht University, Middelburg, The Netherlands

Introduction

The word “cosmopolitan” derives from the Greek words *cosmos* (the universe) and *polis* (the city) and means literally translated “citizen of the world.” Cosmopolitanism is an umbrella term which has been used to describe a variety of different concepts.

These concepts, which find their origins in moral and sociopolitical philosophy, share a vague political common ground with an emancipatory claim. The core of the idea is that all human beings regardless of their race, sexuality, gender, religion, physical abilities or political affiliation, belong to – or at least could belong to – a single community which ought to be cultivated. And psychological contributions to this field of research are concerned with questions of how this cultivation can be fostered, and the exploration of phenomena which obstruct it.

Theories of cosmopolitanism have a long history in psychology although in the majority of psychological research they are not referred to by this hypernym. Explicit references are a rather recent phenomenon, which are also due to the contemporary political conditions and phenomena, for example, due to the processes which are commonly referred to as globalization, the organizational architecture of the global institutional order, and the fact that in today's world humankind encounters more and more problems which require concerted action on a global scale, such as environmental and health issues.

Definition

Depending on different foci in the concepts of cosmopolitanism psychologists refer to, both research approaches and the criteria for the definition of dispositions and psychological characteristics for a cosmopolitan person may vary. In the following, first a psychological definition of a cosmopolitan will be given which can be found in the *quantitative* paradigm. Here, cosmopolitanism is theorized as a measurable attitude. According to a second definition, which is grounded in a *qualitative* paradigm of discourse analytical principles, cosmopolitanism expresses a certain positioning in the world (Davies and Harré 1990), including a person's worldview, and corresponding emotions and actions.

Adherents to the concept of cosmopolitan democracy (e.g., Archibugi 1998; Held 2003; Kaldor 1996), the most popular form of cosmopolitanism in contemporary political theory, envision for the future a reinvention of democratic practices. Their aim is a political system in which democratic norms and values are applied with regard to global but also local institutions. One of the key questions is how the

concept of global governance, governance of the people, by the people, for the people, can be put into practice. Decisions are supposed to be made by those who will be affected by them, for example, via elected representatives or direct participation, and a single hierarchical form of authority is categorically avoided. A crucial part of this model is the aim of global governance without striving for a global government.

Psychologists operating with the concept of cosmopolitan democracy define cosmopolitanism as a worldview which is characterized by (1) holding the capacity to mediate between different cultures, (2) the recognition of increasing interconnectedness of political communities, and (3) the approval of political responsibility at the supranational and global levels. Researchers follow the quantitative paradigm and conceptualize cosmopolitanism as finding its expression in a measurable attitude manifesting itself in one's opinions, attitudes, and values. It is stressed here that actions and behavior are not part of the concept of cosmopolitanism. These are theorized under the key expression "transnational experience" (Cheah 1998; Roudometof 2005). In this version of cosmopolitanism, three interconnected dimensions can be identified:

1. The recognition of the increasing interconnectedness of political communities in diverse domains, including the social, economic, and environmental
2. The development of an understanding of overlapping collective fortunes that require collective solutions locally, regionally, and globally
3. The celebration of difference, diversity, and hybridity while being able to reason from the point of view of others and mediate traditions (Held 2003, p. 58)

In a nutshell: Characteristic of people with a cosmopolitan attitude is the recognition of people as, and the valuing of their integrity as that of, equal human beings, regardless of their national or cultural background. They are tolerant, open, and willing to engage with other people, and are also intellectually and aesthetically open, searching for differences rather than uniformity. Being aware of the increase in economic, political, and cultural interrelatedness, they embrace rather than oppose these contrasts. Hence, they are not only aware of global problems but also in favor of forms of global governance and supranational political regulation (Mau et al. 2008).

Adherents of the concept of intermediate cosmopolitanism (e.g., Pogge 2002b), the most popular concept in Global Justice Theory, choose a very different approach. Global Justice Theory is an interdisciplinary field of research dominated by political philosophers. Here one finds a whole gamut of variations between mild cosmopolitanism, the nebulous view that all human beings are of equal worth, and robust cosmopolitanism, the view that all human agents ought to treat each other equally and, in particular, have no reason to help any one needy person more than any other (Singer 1972, 2004). This is discounted by many critics as not viable because it is grounded on such abstract principles that it neglects the human condition. Thomas Pogge's (2010), the leading figure in the field of global justice theory, offers the concept of so-called intermediate cosmopolitanism. The strengths of his concept are that it is based on generally acknowledged norms, rules, and rights.

People distinguish in everyday life between duties to assist, help, give aid, and so on, which philosophers call positive duties, and the ethically weightier duty to ensure that innocent people are not unduly harmed for insignificant reasons through one's own conduct, which philosophers refer to as negative duty. Pogge's concept is based exclusively on negative duties. According to him, all citizens in high-income countries (but also the majority of rich people in low-income countries) violate this negative duty by participating in and imposing an unjust global institutional order on people living in low-income countries and by depriving them of their human rights. At the Vienna Human Rights Conference in June 1993, it was stressed by representatives from 171 nations that all the classical liberal rights and the social human rights are universal and interrelated. The articles most relevant for the concept of intermediate cosmopolitanism are Articles 25 and 28 of the Universal Declaration of Human Rights: "Everyone has the right to a standard of living adequate for the health and well-being of oneself and one's family, including food, clothing, housing and medical care." "Everyone is entitled to a social and international order in which the rights and freedoms set forth in this Declaration can be fully realised."

While it is important to remember that the foundation for the global institutional order was laid in

a long process of, for example, slavery and exploitation, any person striving to live according to cosmopolitan criteria is immediately responsible only for the present global institutional order. One is considered to be morally responsible for it if the following four conditions are fulfilled:

- ▶ 1) The affluent persons must *cooperate* in imposing an institutional order on those whose human rights are unfulfilled. 2) This institutional order must be designed so that it *foreseeably* gives rise to substantial human rights deficits. 3) These human rights deficits must be *reasonably avoidable* in the sense that an alternative design of the relevant institutional order would not produce comparable human rights deficits or other ills of comparable magnitude. 4) The availability of such an alternative design also must be *foreseeable*. (Pogge 2002a, p. 60)

According to this global justice theoretical approach of intermediate cosmopolitanism criteria from a psychological perspective to define a person taking the cosmopolitan position is (1) the acknowledgement of violation of negative duties in a transnational setting under conditions of a global institutional order which is judged to be unjust, (2) the performance of action based on the identified causes of the problem, and (3) the experience of corresponding moral emotions with regard to the harm and deaths resulting from this global institutional order, for example, shame, guilt, anger, outrage (Park 2011b).

This approach follows the *qualitative* research paradigm and is based on a concept of cosmopolitanism which explicitly includes action and behavior. For radical proponents of Postcolonial Theory, in contemporary times barely any catastrophes are classified as "natural" ones; instead, catastrophes on a global scale are considered to be human-made phenomena. Even when it comes to the impact of the weather, for example, El Niños or droughts, which are then followed by hunger and famine, or lack of access to safe drinking water with cholera epidemics, this is interpreted as a phenomenon that is interwoven in the web of the unjust global institutional order (Davis 2001), to which one has to position oneself. And it is in this positioning, including corresponding action (or lack thereof), that a cosmopolitan identity expresses itself (Park 2011a).

Historical Background

The first unambiguous expression of a cosmopolitan stance goes back to the fourth century BC. It was the Cynic Diogenes who, when asked where he came from, replied “I am a citizen of the world” (Kleingeld and Brown 2006). The contemporary debate on cosmopolitanism ties in with ideas of eighteenth century philosophers, who have attributed different thought and aspect to the concept of cosmopolitanism. Immanuel Kant (1724–1804), Johann Fichte (1762–1814), and Karl Schlegel (1772–1829) defined cosmopolitanism in terms of political institutions which are supposed to unite all people globally. This would have as a consequence the abolition of the nation states and the establishment of a single global state valid for all humans. So-called economic cosmopolitans (also referred to as market cosmopolitans), for example, Dietrich Hegewisch (1746–1812), envisioned cosmopolitanism as expressed in the economy, and aimed for an open market in which market tariffs and other controls over foreign trade should be abolished. As a result, a free market would flourish that would take care of peoples’ needs while the government’s control would diminish. They also argued that it would be to everyone’s advantage if the state emphasized the import of supplies that are expensive to produce domestically and did not prevent other states from their export. Once an ideal global market was established, war would be in no one’s interest. Nevertheless, this view of cosmopolitanism was the most questioned since it has been realized that it was precisely this kind of thought which has brought about the intensification of inequality in the national but also international realm, especially following the end of the Cold War. In opposition to this stance, moral cosmopolitans such as Christoph Wieland (1733–1813) but also Immanuel Kant, argued for a single world community whose members would help other people by respecting their value as human beings. Their argument was that people are fundamentally equal, which in turn rules out all forms of exploitation, subordination, slavery, and racial and gender inequalities. Similar views were also shared by cultural cosmopolitans, for example, Georg Forster (1754–1794), who rejected the idea of a strong attachment to a single culture. They visualized a community that would elude the strong bonding with

a national identity and instead value the importance of diversity and multiculturalism.

The unifying element of these different approaches is that all concepts are based on the idea of fostering some kind of global community providing the grounds for relations of mutual respect, recognition of, and respect for social, cultural and political affiliations. These differences with regard to a distinctive emphasis on certain characteristics can also be found in the contemporary debate on aims and criteria, which are summarized under the key words political, moral, and cultural cosmopolitanism. Some political cosmopolitans envision a world with a single world government (Keane 2002), whereas others argue for a system of nations without nationalism (Kristeva 1993). They address issues that require urgent attention and their solutions, for example, racism, multiethnicity, tolerance, integration, and cohabitation. Part of their vision is a community or a transitional society distinguished by social harmony in which differences with regard to religion, ethnicity, and sexuality are acknowledged. They argue for a reconstruction of the international order that takes into account new, more hospitable methods of acceptance toward strangers, fair economic laws, and firm and collective agreement on dealing with global phenomena, for example, environmental issues.

Moral cosmopolitans put the emphasis on an alternative to politics based on reason, in which society is united by solidarity, affiliation, acknowledgment of human finitude, and not by principle, reason, and progress (Nussbaum 1997). This cosmopolitan society should be characterized by the fact that all members would feel a fundamental connection to the entire humankind, and would also make personal and political decisions considering the well-being of all species. Postcolonial cosmopolitan thinkers with a moral outlook describe it in terms of respecting another person’s dignity (Appiah 2006). Individuals with a cosmopolitan stance would show not only respect and concern for family, compatriots, and local traditions, but also for foreigners. Here, firstly, the focus is on the encouragement of the avoidance of moral relativism, and instead on showing respect for differences. Secondly, a balance between universalism and nationalism is suggested. And finally, a “conversation” is aimed for in the sense that an exchange of ideas is considered to be the key to

coexistence, since humanity would never reach consensus on universal values.

Cultural cosmopolitans define cosmopolitanism as the ability to recognize the particularity of different cultures; this is also due to the fact that successful attempts to achieve cultural uniformity are deemed to be leading to cultural impoverishment (Kleingeld 1999). Contemporary cultural cosmopolitanism rests on the ideas of eighteenth century cultural cosmopolitanism, which was neither relativist nor ethnocentrist. Thus, on the one hand, they maintain tolerant and open-minded contact with other cultures, and on the other, they deny relativism. A further point supporting this argument is that although people find fundamental meaning and purpose in the local traditions, they are still able to mediate between the local and the hybrid culture-in-the-making. However, this appreciation and celebration of the hybridity of cultures should not go along with the continual borrowing, mindless absorption and “cultural shopping” that go on via modern media, internet technology and improved mobility. Instead, appreciation of hybridity presupposes that people should recognize and take seriously the particularity and uniqueness of every culture, as well as understand the difficulty of taking on new perspectives and customs (Hansen 2009).

Not only can cosmopolitanism be distinguished in various types, but there are also differences regarding “demands and degrees” of cosmopolitanism, such as “thin,” which is also referred to as moderate or weak demands, or “thick” cosmopolitanism including strong and extreme responsibilities. Furthermore, different combinations are also promoted, such as a combination of a strong moral cosmopolitanism with cultural cosmopolitanism (Nussbaum 2000). Here, it is argued that attachment and affiliation toward the local can only be justified by taking into account the well-being of all humans that are regarded as equals. Thin moral cosmopolitanism, on the other hand, claims that allegiance to and preference for the local have to be balanced out and be constrained by consideration of the interests of other people. Therefore, one can argue that cosmopolitanisms would be a more accurate use of the term. Furthermore, they stress that despite these various forms of political, economic, moral, and cultural cosmopolitanisms it would be wrong to assume that

they are mutually exclusive. The differences between them are a matter of emphasis, where, for example, in a given context it is more functional to emphasize political rather than cultural aspects (Skrbis et al. 2004). In fact, most cosmopolitan theories combine aspects of the various forms.

The crucial point with regard to theorizing on cosmopolitan ideas in the twenty-first century is that it is already a fact that humankind undeniably lives in global community due to three factors. Firstly, people live under a global institutional order which on the one hand comprises institutions such as the World Trade Organization, and the International Monetary Fund, and on the other hand a growing civil society with numerous nongovernmental and grassroots organizations (Park 2007b). Secondly, humankind encounters more and more problems which require a concerted action on a global and transnational scale to be successfully tackled, for example, disease, environmental issues, and poverty. These phenomena impose themselves and put humankind even involuntarily in the situation of representing one group facing a common goal (or adversary). And finally, it is claimed that for the first time the financial and technical means to solve these problems exist, which means that in a very ordinary sense the material prerequisites exist to deliver concerted action as a community (Pogge 2002a).

What becomes salient in this history is that concepts of cosmopolitanism are built on implicit assumptions about processes and phenomena which are in psychology referred to under keywords such as processes of identity building and questions of positioning, Postcolonial Psychology, Critical Whiteness Studies, race and racism, and the notion of justice (Park 2009).

Key Issues

Postcolonial Psychology: Unequal social systems are inherently conservative and have built-in economic and psychological mechanisms to perpetuate themselves; and in the social field of the symbolic order there are inscribed which practices are considered normal or abnormal, and many of them exist on the borderline between the known and the unknown (Leonard 1984). In other words, the clandestine power of dominant representations in a society is to create an *invisible normality*. And the main concern

of postcolonial psychology, a relatively young subdiscipline in the field of theoretical psychology, is to uncover the discursive mechanisms which help to sustain and perpetuate this normality on a global scale.

Postcolonial psychology rests on the conviction, and here one can find strong overlaps with Global Justice Theory, that the foundation for the contemporary global institutional order was laid in a long history of colonialism and exploitation. During the Imperial Era (1875–1914), a quarter of the land surface area of the globe was divided or redivided among half a dozen states, so that after World War I roughly two-fifths of the world's population were living under colonial rule: more than 600 million people. Of these, roughly 440 million lived in Asia, 120 million in Africa, 60 million in Oceania, and 14 million in the Americas. The peak of the development of modern colonization was reached in the 1930s. Only parts of Arabia, Persia, Afghanistan, Mongolia, Tibet, China, Siam, Nepal, and Japan have never been under formal foreign rule (Hobsbawm 1994).

These economic developments were enabled by a hegemonic discourse in which a relationship of “master and servants” was established, accompanied by a discourse on race and racism. Race is considered to be a social construction and racism as a process of ideological production which finds its socioeconomic reification via institutions (Miles 2003). But despite the institutional nature of the global institutional order, it is people who design, support, and maintain this system, and individual constructions of the world and structural inequalities reinforce one another. Hence, a theoretical starting point for postcolonial psychological questions is that just as global phenomena such as global poverty and discourses of dominance intersect historically and geopolitically, so they also intersect within an individual's mind and in a collective. This is why questions of identity construction and positioning are thoroughly analyzed (Park 2008).

Postcolonial psychology provides the analytical tools to show how the construction of an individual's identity but also identities on a wider level are based on an interplay of similarities and differences (Hall 1996; Bhabha 1994); for example, the formerly colonizing nations have a long tradition which can be summarized under the expression “developing countries”: dealing

with colonized countries in a manner which constitutes them as a particular place; not in an imaginary form, but rather as a contrasting image, as an integral part of a material culture and identity (Chakrabarty 2000). This helps “the self” to define itself through differentiation from the poor “other” as a surrogate and a subliminal ego. Defined as the “other,” the developing countries can be ascribed all the negative characteristics such as primitive, backward, poor, traditional, etc., which are considered as having been transcended in the supposedly modern societies (Said 1978; Mohanty 1991). These analyses are based on a deconstructed idea of the idea of a nation state. Nations are not interpreted as homogeneous, natural entities, but as collective identities created in a historical process. It was only when specific cultural conditions, such as novels and newspapers, had allowed a fundamental change in the social perception of space and time that the idea of the unity of an imagined community came up (Anderson 1991). Also, the sense of cultural connectedness among members of a nation did not precede the formation of nation states; rather, the creation of cultural norms first formed part of the basis for the formation of a national identity, but also vice versa: Various and sometimes even conflicting cultural forms were co-opted by different groups in order to declare them to be representative of a homogeneous national culture. The overarching element that unites various political and social groupings that attempt on different levels to homogenize their particular reading of the national culture and to exploit it for their own interests is the construction and simultaneous exclusion of an “external other” (Bhabha 1994).

These analyses are necessary for a cosmopolitan project in order to analyze the mechanisms which sustain global inequalities, for example, how differently people of color and white populations are affected by poverty. The dividing line which separates people in high-income countries and people in low-income countries on a global scale also runs through so-called multiracial societies, such as the USA, South Africa, and Brazil (Shields 1995).

Critical Whiteness Studies: Therefore, Critical Whiteness theorists consider it of major importance to adhere to the concept of race. This is due to the fact that for a long time, white was considered to be a neutral skin color, as colorless, invisible, normal;

being white was considered to be the norm, “anything” else than white was considered to be part of the multicultural discourse. Hitherto, the white standpoint has been represented as neutral in mainstream Western psychological discourses on “race” and “culture,” in other words: without reference to one’s own race and without culture. From this ethnocentric perspective, only “the others” appear as bearers of culture; they are different, and this difference is usually constructed as a deficiency of black people and people of color (Tissberger 2005).

Critical Whiteness studies, which use whiteness not in a naturalistic or essentialistic way but as an analytical category, seek to unveil how white identities are constructed, how these discourses expounded on by postcolonial theorists intersect in an asymmetrical web of racial relations and what kind of consequences and material effects this has: how a white self is created. It raises questions on the historical production of becoming white and how certain groups and/or individuals are in- or excluded; how legal, social, and political issues of a white collective inscribe themselves in a white individual. It targets questions of material as well as immaterial privileges and how these are maintained and their existence disavowed or legitimized and justified. Critical Whiteness studies are not so much concerned about the question of how others are marked as “others” but how white people construct themselves by the construction of a non-white “other”: It investigates what a certain construction of the “other” says about oneself/a “white self” and how even a racist construction of the “other” can peacefully coexist with the self-image to believe that one considers black people and people of color to be of equal value; how it is that people with a white identity (often) do not mark themselves; how certain rights are defined and claimed that these are or ought to be universalized on a broader level in a global sphere but denied to certain groups of people at the same time. In a nutshell: it targets the “myths of denial” and identifies these myths to be not more innocuous than those of racist confessions (Arndt 2008).

Different theorists stress different aspects in their understanding of the concept of whiteness but they share a common ground. Whiteness is used not as a natural but as an analytical category to name a discourse which is not tangible and whose power

lies in creating an invisible normality: whiteness is based on a racialized order of the world and at the same time, whiteness is considered to be the initiating force for this very order. It is a discourse which is in itself normative, but disavows this very fact; it guarantees a subject status to people who are in a position to consider themselves as whites (Kiesel 2006). One reason why the discourse is so powerful and difficult to grasp is due to the flexibility of the category: as it is not a natural category but evolved with a political motivation, which means that it did not develop randomly but due to an intention; and although this intention cannot directly be attributed to a single person, it is a discourse which follows a clear direction. Hence, whiteness carries the notion of becoming; it has to be reconstructed, and can be gained but also be lost – and sometimes be bought (Wollrad 2005).

A further aspect of the definition of whiteness is that it is considered to be a flexible and relational dimension of racism, which changes and is transformed according to time and space. While Frankenberg (1993) claims that there is no essential and transhistorical feature of whiteness but a magnitude of “local whitenesses” which have to be analyzed in their specific contexts and when they come into being in relation to others, Dyer (1997) explicitly problematizes that whiteness is usually focused on in relation to non-whites. According to him, whiteness reproduces itself at any time in all texts. Wollrad (2005) takes an even more radical approach than Frankenberg; for her, whiteness is not only a flexible dimension of racism but must be considered as being more than one of a multitude of different racially constructed variables. According to her, it is rather the core of racial hegemony. It is the drive of processes of racialization and the principle to order social relations and distribute economic and cultural resources; an idea which can be better understood by taking a glance at a historiography of the evolution of whiteness.

The myth of racial superiority helps to adhere to the discourse of power evasion, which has two dimensions. Firstly, an evasion that whites are privileged and secondly, a denial of the existence of racism and the rejection of the belief that social politics are needed in order to eradicate the negative consequences of institutional forms of racism (Neville et al. 2000; Federico and Sidanius 2002). On average, whites judged relief

efforts for current human refugee and health crises in nonindustrialized countries less favorably than non-whites. A color-blind racial discourse goes hand in hand with greater levels of racial prejudice and a belief that one's society is just and fair (Reed and Aquino 2003; Pratto et al. 2006). For whites this denial not only fosters inaction, which in turn helps to preserve the privileges many whites gain from the current system, it also leads to the consequence that the belief in in-group values, for example, equality, is supported: for whites, whiteness and the belief in the superiority of the white race especially works as a kit in societies with big social inequalities against the ones who are constructed to be racially inferior (Rabinowitz et al. 2009). Whiteness is identified to function as a sociopolitical positioning, which puts whites as much as people of color in their specific positions in society (Frankenberg 1997; Tissberger 2006).

Whiteness is a discourse which comes with decisive power effects. It provides a wide range of material as well as immaterial advantages and gives privileges also to whites who are less affluent and not highly educated. To explain the aspect how whiteness has to be considered as relational, one can compare the effects of whiteness to some degree to the multiplicity of masculinities: although not all men fit into the category of hegemonic masculinity, they still enjoy material and immaterial privileges of the patriarchal system; comparably there is a hierarchical social stratification within the category white, with hegemonic, subordinated, marginal, and complicit whitenesses.

The Notion of Justice: Justice concerns are argued to be an important aspect of our human nature, without being universal; which means that not all individuals judge fairness as their most important moral virtue (Ketelaar and Koenig 2007). Characteristic for a cosmopolitan is that principles of justice are ranked as (one of) the highest virtues, and it is this ascribed notion which motivates the person to act. From a cosmopolitan perspective, the global institutional order is deemed to be asymmetrical, so that it foreseeably and avoidably produces socioeconomic injustices which dominate the lives of certain groups of people; for example, people living in absolute or relative poverty, so that they have only limited means of representing themselves in their local community or do not have any means of representing their interests

on the world stage, for example, with regard to the World Trade Organization, or they have fewer means of protecting themselves against natural catastrophes or of even meeting their basic needs. The concept of justice plays a preeminent role, regardless of whether it is about one's own situation which is deemed to be unjust, but equally importantly if it is about the lives of other people who become the victim of injustice. This is especially important if the unjust situation takes place in a setting which can be evaluated in a way, such that one may become (involuntarily) a perpetrator and a beneficiary of this injustice, for example, as one can find with regard to global economic differences between citizens of high- and low-GDP countries.

Principles of justice have prominent social and psychological functions. Justice has been called "the first virtue of social institutions" (Rawls 1971), "the first requisite of civilization" (Freud 1933), and "the uniting function in the individual man and in the social group" (Tillich 1954), and requires, according to Aristotle, the acknowledgment of equality. Conceptions of justice provide a sense of meaning and control by stipulating the guidelines by which the individual orders her or his world, conducts life and predicts as well as evaluates outcomes.

Not only as individuals but also as members of a social group the sense of what is just or not is used to assess what oneself and others deserve materially and psychologically. Just behavior is interpreted as a means of gaining approval and respect from oneself and others. Violations of conceptions of justice present a threat and bring into question the evaluative framework that provides a foundation for individual and social action (Deutsch and Steil 1988) (see also: ► [Deutsch, Morton](#)).

According to the theory of the belief in a just world (Rubin and Peplau 1975), one assumes that one lives in a world where everybody gets what he or she deserves and deserves what he or she gets. Experiences perceived as unjust can even strengthen this belief, since the results are reinterpreted such that the consequences appear just, by blaming victims for their misfortune, so that at the end it seems reasonable to argue that they do not deserve any better. Or more compactly, the evaluation of conduct is projected into the result without causal coherence. The belief in a just world helps to reject the idea that something similar could happen to

oneself and also gives a feeling of security and immunity. And a lot is done to avoid any disruption of this belief. It is the belief that the world is not a just place which drives toward action, in other words: the more extreme the belief in a just world, the stronger the tendency to accept extreme injustices not only for oneself but also for others (Lerner 1998; Lerner and Miller 1978).

If someone becomes the victim of injustice not only the person himself or herself is affected, but also the group or community whose norms of justice are being violated. The crucial characteristic of a cosmopolitan position is that their concern about people living in other countries becoming victimized does not differ from their concern toward their fellows. Members of a group who accept common norms also share common obligations to protect those norms and to respond to their violation, meaning that the occurrence of an injustice which is not acknowledged and responded to is apt to generate feelings of alienation (Hafer 2000). What becomes salient at this point is the notion of emotions in the discourse of justice. Because emotions are considered to be epistemic, moral, social, and last but not least physical positions. They stand in a systematic relation to social conditions and are not only indicators but must also be interpreted as direct means of domination. Domination is not only in the outside but it transgresses the border to the bodies and inscribes itself, for example, in the form of constant emotional dispositions. Because these emotions represent a holistic unity of psychological representations and social action, they entail emotions of cognitive assessments and evaluative judgments (see also: History of Emotions).

Unjust events are associated with emotions such as anger, outrage, and resentment (Hafer and Olson 1998). The belief that a group is unfairly advantaged is threatening. Significantly, this is not so much about the issue of inequality in general or that the other group has less than it should, but that one's own group has more than it should and must therefore be considered to be unfairly advantaged (Chow et al. 2008). People have a general tendency to construct themselves as victims rather than as perpetrators of injustices (Mikula et al. 1998). Characteristic for cosmopolitans is that they can acknowledge their role as perpetrators in the global sphere and do not even try to construct themselves as ethical beings in a transnational setting

but experience existential guilt (Park 2007a). Existential guilt is a likely emotion if (1) people believe that their privileged position in the world results from controllable distributions that are unjustifiable, (2) they assume a causal relationship between their own privileges and the unfavorable situation of others, (3) they consider the discrepancies between their own and others' situation the result of an injustice, and (4) they feel solidarity with, and responsibility for, the disadvantaged (Montada et al. 1986), whom they would have to consider to be equal to themselves. Here, the main function of action is the reaffirmation of this principle, because even if one cannot expect that one's activity could stop an ongoing injustice or prevent killing, but what one does have power over is to ensure that the principle is upheld as long as there are people who are willing to keep it alive (Oliner and Oliner 1988).

Future Directions

Although the tradition of cosmopolitan theories is in its fledgling stage, its flourishing is unavoidable. Due to the global nature of the most pressing problems humankind encounters in the twenty-first century, it is unavoidable that psychology too considers questions to help tackle these problems. Global asymmetries and the unjust global institutional order are for many laypersons a paradox. The majority of people feel guilty for actively and knowingly doing harm and the world is considered to be a neutral background before/against which one acts. The crucial point is that with regard to global injustices this phenomenon presents itself contrariwise. The global economic order is already tailored in a way that merely existing for people living in high-income countries already means that other people suffer harm and may not even be able to fulfill their basic needs. And this harm is done without "the perpetrators" intentionally wanting to do so or even necessarily knowingly doing so.

For decisive reforms of the global institutional order to the extent required to tackle, for example, severe poverty, the support of citizens in rich countries is essential. Therefore, it is necessary to develop an understanding of people who are involved as much as an understanding of people who are not concerned about severe poverty, in order to convince opponents and to make alliances. Cosmopolitan theories in psychology

contribute to the development of a theoretical framework which is sensitive to the ways in which ethical, racial, and ideological factors frame the individual psyche but also intergroup processes and how these contribute to sustaining the contemporary global economic order. It is argued that until more attention is given to the social-psychological processes which make the rich-poor divide so acceptable, one's understanding of this situation will remain in its present semi-developed state, and attempts to alter the situation will fail.

Cox, C. M.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: May 20, 1890; Died: October 11, 1984

Born Catherine Cox in San Jose, CA, Miles obtained her B.A. from Stanford in 1911 and M.A. 2 years later in German language and literature. Thereafter, she was at the College of the Pacific and moved upward through the academic ranks there through 1920. During the First World War, Miles, a devout Quaker, contributed to the humanitarian efforts of the American Friends Service and was involved in distributing food in Germany after the war.

Major Accomplishments/Contributions

She returned to Stanford in 1920 to pursue a doctorate with Lewis S. Terman, who at that time was beginning his longitudinal studies of genius. These did not offer sufficient material at the time for her dissertation, so Cox chose a problem based on Terman's procedure for estimating intelligence from historical data. She conducted a meticulous historiographic study of the personal characteristics related to intelligence of over 300 eminent historical figures, including political and social leaders such as Washington and Luther, and scientific and artistic creators such as Goethe and Beethoven, and correlated these with their estimated intelligence. This study (Cox 1925) was published as the second volume of Terman's *Genetic Studies of Genius* in 1926. For a short time afterward, Cox worked as a clinical psychologist in the Mental Hygiene Clinic of the Cincinnati General Hospital, and then returned to Stanford, where she resumed her work with Terman which resulted in the development of a pioneering femininity–masculinity test, the Terman–Miles Attitude–Interest Analysis test, commonly known as the M–F Test. The culmination of her work with Terman was the book *Sex and Personality* (Terman and Miles 1936), which established the conceptual basis for much later work on sex differences in attitudes, object choices, and stereotypes. In 1927, she married the recently widowed Walter S. Miles (1885–1978) and, in conjunction with his growing interest in the nascent psychology of aging, collaborated with him over the next two decades on several studies of intellectual changes during the human lifespan. During the 1930s she also made forays into ► [social psychology](#), providing a succinct defense of the necessity of taking individual differences into account in social psychological theory and analysis (Miles 1937). After the Miles's move to Yale in 1932, she became, through 1953, professor of clinical psychology in the Department of Psychiatry and Mental Hygiene of the Yale School of Medicine and wrote on subjects in developmental psychopathology including sexual identity. She also contributed several overview articles in textbooks and handbooks, including chapters on individual differences in personality (Miles 1939) and gifted children (Miles 1946). While she is most often remembered for her early study on eminence and geniuses, her

work in her other areas of interest was an impetus to the development of both the psychology of sex roles and the psychology of aging, and her continuing influence is apparent today in recent historical and statistical studies on the psychological roots of eminence.

Craik, Fergus

KAREN M. ZABRUCKY, REBECCA BROOKE BAYS
Georgia State University, Atlanta, GA, USA

Basic Biographical Information

Fergus Craik was born on April 17, 1935, in Edinburgh Scotland. Craik went to school at the Locerbie Academy and his parents sent him to an excellent high school at the age of 12. By age 18, Craik was enrolled in a medical school at the University of Edinburgh but did not enjoy his classes (except for neurology) and so decided to study psychology instead. He received his Bachelor's degree in psychology from the University of Edinburgh and was accepted into graduate school at the University of Liverpool in 1960. He received his Ph.D. from the University of Liverpool in 1965, went on to a position at Birkbeck College in London, and, during this time, spent 1 year as a visiting professor at

the University of Toronto. The University of Toronto offered him a permanent position in 1971, which he accepted and held until he retired from the university. He is currently a University Professor Emeritus in the Department of Psychology at The University of Toronto and a senior research scientist with the Rotman Research Institute at Baycrest Centre for Geriatric Care in Toronto.

Major Accomplishments/Contributions

Before coming to Toronto, Craik was fascinated with basic memory processes as well as memory across the adult life span. He has examined those two primary research topics throughout his career. He spent his early years at Toronto laying the groundwork for what would turn out to be an extremely influential paper written with Robert Lockhart. In this paper Craik and Lockhart (1972) outlined a new approach to studying memory called levels of processing (LOP). The LOP approach suggested an alternative way of examining memory than the memory stages approaches popular at the time. Rather than examining different memory stages (i.e., sensory, short-term, and long-term memory), Craik and Lockhart felt that it was more advantageous to focus on the quality of an individual's processing of information. They argued that "shallow" processing of information (e.g., analysis of the physical features of a stimulus) would be more likely to lead to fleeting memories while "deeper" and, hence, more semantic approaches (thinking of the meaning of an item) would likely lead to longer lasting memories. This emphasis on quality rather than quantity of processing had a major impact on the study of memory that continues today. Craik went on to investigate the LOP model with Lockhart and other investigators (e.g., Craik and Tulving 1975) in a series of experiments. He returned to studying memory during the aging process as well. His contributions in the area of memory and aging have been enormously influential by providing a framework for investigating the conditions under which memory deficits will or will not occur in older adults as a function of the role of the demands of the processing task and environmental support.

Craik's contributions to the study of memory and memory and aging are impressive and consist of many major articles, books, and edited books. The number of

awards he has received is beyond the scope of this entry but a few noteworthy ones are the Distinguished Scientific Contribution Award from the Canadian Psychological Association (1987), the William James Fellow Award from the American Psychological Society (1993), the Hebb Award from the Canadian Society for Brain, Behavior and Cognitive Science (1998), and the Killam Prize for Science (2000). In May 2008, Craik was elected a Fellow of the Royal Society, the national science academy of the United Kingdom and Commonwealth.

Critical Psychology

THOMAS TEO

York University, Toronto, ON, Canada

Introduction

Critical psychology (better: critical psychologies) has emerged using multifaceted approaches in theory and practice outside of the mainstream of psychology in many countries around the globe. Although critical-psychological ideas can be found prior to the 1960s, the most important developments were made since that period on the background of the rise of social epistemologies and social movements. A core goal of critical psychologists was to transform psychology into an emancipatory, radical, social-justice seeking, or status-quo-resisting approach that understands psychological issues as taking place in specific political-economic or cultural-historical contexts. The term *critical psychology* was originally claimed for a German school of thought, but was soon self-applied by psychologists from the English-speaking world and from

other linguistic regions who gave the term their own meanings. Critical psychology has an even longer history if one considers critiques of mainstream psychology as belonging to critical psychology (Teo 2005).

Definition

Critical psychology can be divided into historical and current critiques of psychology (general meaning) and into theoretical and practical frameworks that are identified as such (specific meaning). In the latter sense, critical psychology is whatever self-identifying critical psychologists do or whatever is published in journals and books that use the title critical psychology. Beyond an empty “operational definition,” theories and practices that are based on social epistemologies and that have an emancipatory practical intent, in the widest meaning, should be subsumed under critical psychology. The term social epistemology refers to approaches that examine knowledge production and knowledge biases and limitations from the perspective of social categories (e.g., class, gender, ethnicity, sexual orientation, ability–disability) or in terms of power.

The first philosopher to systematically take social knowledge biases into account, from the perspective of class, was Karl Marx (1818–1883). Following his program, the critical theorist Horkheimer (1895–1973) proposed that critical theory should challenge the separation of individual and society, values and research, and knowledge and action. These three issues also form the historical core of critical psychological assumptions: The individual is embedded with in society, progressive sociopolitical values should guide psychological research, and what has been gained in critical theory should be put into practice. In all three areas, significant tensions exist, especially between approaches that focus on theory-development and others that focus on practice (e.g., armchair critical psychologists versus social activists), and in articulating these principles, which themselves have undergone significant changes in the last few decades.

Historical Background

The critique of psychological ideas has a long history. Aristotle (384–322 BCE) challenged Plato’s (427–347 BCE) conceptualization of the psyche. During the Middle Ages, there were extensive discussions on psychological topics such as the primacy of will or reason.

In modern times, René Descartes’ (1596–1650) thoughts on innate ideas were criticized by John Locke (1632–1704), who in turn was criticized by Gottfried Wilhelm Leibniz (1646–1716). Despite the importance of these critiques and controversies, they did not systematically challenge an entire field of research. Immanuel Kant (1724–1804) provided the first systematic critique of the dominant psychologies of his time. *Rational* and *empirical* psychology, a system division introduced by Christian Wolff (1679–1754), became the twofold target of Kant’s critique. Kant (1781/1998, 1786/1970) suggested that rational psychology was trapped in paralogisms, and that empirical psychology could not become a genuine natural science.

Other critics of psychology included the Neo-Kantian philosopher Friedrich A. Lange (1828–1875), who, in a book section originally intended as the *Critique of Psychology*, challenged the foundations of philosophical psychology from the perspective of the rising natural sciences. Lange (1866/1950) criticized philosophical psychology’s subject matter and methodology while outlining a program for an “objective” psychology nearly half a century before John B. Watson did (1878–1958). Auguste Comte (1798–1857) also developed a critique of the philosophical psychology of his time and suggested that psychology should be excluded from the positive sciences. Comte (1896) identified philosophical psychology as the last phase of theology and suggested that mental phenomena could be studied sufficiently within anatomy, physiology, and his own program of a positive philosophy.

The critique of psychology has also been advanced in the many *crisis* discussions regarding the discipline and its subfields. The first systematic book on the crisis of psychology was published by Willy (1899), who challenged the dominant research programs of his time. He identified speculative theory building and an inadequate methodology as sources of psychology’s crisis. The crisis literature was on the rise in the 1920–1930s and again since the 1960s and 1970s, some of it written by critical psychologists (e.g., Parker 1989). A critique of psychology’s lack of political relevance can already be found in the nineteenth century, when Beneke (1845) suggested that psychology should aid in solving political, social, and religious tumults while he critiqued psychology’s lack of understanding of social reality.

Wilhelm Dilthey (1833–1911) inaugurated a long tradition of the critique of natural-scientific psychology from the perspective of human-scientific approaches. Dilthey (1894/1957) argued that due to the specific subject matter of psychology, it would be wrong to emulate the natural sciences and that causal explanations as provided in those sciences could not be used satisfactorily in the domain of mental life. In his program for a *human-scientific hermeneutic* psychology, Dilthey understood the subject matter of psychology as experience in its totality, which could not be dealt with adequately by experimentation and measurement, and not by focusing on the elements or isolated parts of mental life. Eduard Spranger (1882–1963) developed a hermeneutically based psychology of personality and adolescence that contained a critique of natural-scientific approaches to the same issues. Edmund Husserl (1859–1938) critiqued the *naturalization* of the psyche, by which he meant the unwarranted emulation of the natural sciences in psychology.

In the English-speaking context, psychologists such as Gordon W. Allport (1897–1967), Abraham H. Maslow (1908–1970), and Carl Rogers (1902–1987) articulated the shortcomings of a natural-scientific oriented psychology. Beginning in the 1960s, Giorgi (1970) expressed the idea that psychology should not be part of the natural sciences, while at the same time he suggested that a human-scientific psychology could be scientific in character. He identified a lack of unity in psychology, the inability to investigate psychological phenomena in a meaningful way (doing justice to the human person), and a lack of lifeworld-relevance as sources for the inadequacy of the natural-scientific viewpoint in psychology. More recently, Slife et al. (2005) have applied, embedded in hermeneutic perspectives, critical thinking to psychology.

Although the natural-scientific critique of philosophical psychology and the human-scientific critique of natural-scientific psychology provided important arguments that have been taken up by some critical psychologists, these critiques cannot be seen as critical psychology in a specific meaning. Kant's (1781/1998) *Critique of Pure Reason* is not the historical starting point for critical psychology; rather it is Marx's (1845/1958) *Critique of the Latest German Philosophy* (subtitle of the book *The German Ideology*) and

Critique of Political Economy (Marx and Engel 1845/1958; Marx 1859/1961) (also the subtitle of *Das Kapital*) that drew up the program for a critique of the status quo as well as a framework for critical social inquiries and practices. Marx advanced the idea that humans may have false understandings of social reality because they belong or align themselves with a social category that benefits from misrepresentations.

For Marx, central was the notion that the dominant, most influential ideas in society are also the ideas of the ruling class. Critical approaches in the tradition of this stream of thought (e.g., feminist standpoint studies) analyze the role of social interest in knowledge production and dissemination and reflect on the knowledge producer's social existence and the potential ideological and practical biases that it might produce. Admittedly, the historical genesis of critical psychology is not undisputed and other researchers have claimed different sources. Billig (2008) analyzed the third Earl of Shaftesbury (1671–1713) as a hidden root of critical psychology because he suggested that humans establish understanding through conversation, that truth is a social and dialogical matter, and that the self is divided, and because of the demand for continuous self-reflection. These topics are central to critical psychologies following the linguistic turn in intellectual history.

Marx's ideas also inspired *critical theory*, a research program developed by German philosophers and social scientists in the 1920s at the Institute for Social Research in Frankfurt am Main (*Frankfurt School*). Some of the important first-generation figures include Max Horkheimer (1895–1973), Erich Fromm (1900–1980), Theodor Wiesengrund Adorno (1903–1969), and Herbert Marcuse (1898–1979), whereas Jürgen Habermas (born 1929) belongs to the second generation of critical theorists. In his groundbreaking article, *Traditional and critical theory* Horkheimer (1937/1992) argued that traditional theory (positivist theory that applied logic, mathematics, and deduction for the assessment of its ideas) hides the social function of science, the social formation of facts, and the historical character of research objects. In contrast, Horkheimer recommended the reasonable organization of society that would meet the needs of the whole society. Such a critical practice would include the struggle for the abolition of social injustice.

Critical theorists were also drawing extensively on Sigmund Freud's (1856–1939) work and combined psychoanalysis with Marxist theory. Freud's ideas contain implicit and explicit criticisms of mainstream psychology, while they also provided the most influential alternative approach regarding human subjectivity. However, critical psychoanalysts often self-identify as analysts rather than as critical psychologists. The materialization of the critical potential of psychoanalysis, which historically has also been used for oppressive purposes, depends, in part, on national contingencies. In Latin America, for example, psychoanalysis was well received in a counterculture that understood it as a liberating force against the oppressive structures in military-dominated states. More recently, in Britain, Lacanian-influenced critical approaches have achieved more recognition (see the special issue on *Lacan and Critical psychology* in the 2009 *Annual Review of Critical Psychology*).

Many psychologists, especially in the German-speaking context, still associate the term *Critical Psychology* with the approach taken by Klaus Holzkamp (1927–1995). This is misleading for Germany because there was a second group of *critical psychologists* (lowercase) that opposed *Critical Psychology* (uppercase; the group around Holzkamp). The former emerged mainly from the student movement, challenging the psychological mainstream or even wishing to abolish psychology. They agreed that mainstream psychology did not address the burning issues of the time (Rexilius 1988), whereas others focused on a critical history of psychology (Jaeger and Staeuble 1978).

The group surrounding Holzkamp evolved in the context of radical political and social movements. The concept of a group must be emphasized because the usual focus on Holzkamp as the mastermind of Critical Psychology and as its most important writer is misleading. Holzkamp was the editor of the journal *Forum Kritische Psychologie* [*Forum Critical Psychology*] and was the established professor at the Psychological Institute of the Free University of Berlin, as well as its most visible political and academic target, but the focus on Holzkamp neglects the major role of an interdisciplinary working group that built *Critical Psychology* collaboratively.

In the critical-theoretical phase (1968–1972), Holzkamp (1972) attempted to formulate solutions to

problems of psychology by finding compromises between critical-theoretical reflection and traditional psychology, a middle ground that was intended to lead to an emancipatory psychology. During this period, to be critical meant for Holzkamp to question the relevance of psychology for practice, to identify problems of traditional psychological methodology, and to disclose psychology's hidden, ideological assumptions. In the critical-conceptual period (1973–1983), Holzkamp held that psychology's problems could not be solved within the framework of traditional psychology, or in compromise between critical and mainstream thinking, but rather that psychology required a radically different outlook. Thus, he and his colleagues attempted to develop a better conceptualization of psychological objects.

Holzkamp (1973) laid out the basic methodology for conceptual studies in German *Critical Psychology*, according to which a real understanding of, for instance, perception would only be possible through the inclusion of the natural history, the prehistory, and the history of humanity. To accomplish these goals, critical psychology needed to include interdisciplinary material. The work during this phase was integrated within what Holzkamp (1983) considered a foundation for psychology, which he deemed a new paradigm, able to compete on a level playing field with mainstream psychology. Based on this framework, Holzkamp worked in his later years on establishing psychology as a science of the subject (Tolman 1994).

In the English-speaking world, or specifically in North America, Marx and associated categories such as class did not have the same impact in psychology (this might be a case of denial or repression as Harris 1997, shows). Categories such as gender, race, power, or community played a more important role in the development of critical approaches in psychology. Feminist psychologists were critical of either the content of a mainstream psychology that was perceived as biased or its methods (Gilligan 1977). Yet, most feminist psychologists, who understand gender as a significant social category in order to understand the knowledge and practices of the mainstream, identify first with feminism rather than with critical psychology. However, there exist leading critical psychologists that combine class and gender in their analyses (Walkerline et al. 2001).

The obvious biases of race research in psychology and the social sciences lent themselves to an easy critique (see Kamin 1974). In the context of postcolonial writings, this critique was extended to psychology in general, in asking questions about the global character of mainstream, especially American, psychology (Owusu-Bempah and Howitt 2000). Based on the assumption that social sciences are inherently cultural, the theories, concepts, and even the methods of psychology were assumed to reflect a *Western* bias. Consequently, so the argument goes, psychology cannot be globalized and exported from Europe or North America to the rest of the world in a meaningful way but is rather dependent on recognition, dialogue, or mutual exchange (see Brock 2006). Many writings in this area are critical of dominant theories without belonging to critical psychology in a specific sense (e.g., Winston 2004).

Postmodern or social-constructionist approaches pose a special problem in a historical and theoretical reconstruction. Many of these programs are critical of the mainstream (Gergen 1985), but have not grown out of social categories such as class, gender, or race but are based on the notion that modernity itself produces biases in theory and practice. Such an assessment would include a critique of grand modern programs such as Marxism or German *Critical Psychology*. Social constructionist approaches have been very influential in many strands of critical psychology in the last few decades (Kvale 1992). In particular, Foucault-inspired studies have had significant impact in critical psychology, and critical discourse analyses have been very productive (Parker 2002). Thus, following Foucault, Hook (2004) grounds his vision of critical psychology in an orientation that interrogates power in general. Indeed, critical plurality is endorsed, and instead of advocating for one social category, recent interdisciplinary developments in critical psychology focus on power and on new social categories (e.g., immigrants) (see Papadopoulos et al. 2008).

Certain subdisciplines in psychology – due to their particular subject matter – offer themselves for practical interventions. In North America, influential critical-psychological projects have been grounded in community psychology (Prilleltensky and Nelson 2002). For Prilleltensky (1994), the integration of theory and practice should be based on the ethical

point of view of social justice. Fox (2008) expressed concerns regarding the status-quo-stabilizing effect of existing research, while calling for action in critical psychology (Fox 2003), which could draw on radical programs such as anarchism. Fox et al. (2009) as well as Sloan (2000) provide good overviews of the diversity of ideas and practices of critical psychology. Sloan (1996) also shows how critical theory (Habermas) can be applied to psychological problems, and how critical activity can be materialized, outside of professional associations, in organizations such as *Psychologists for Social Responsibility*.

Finally, a few other critical programs should be mentioned. Critical historians of psychology may be critical of the mainstream without being critical psychologists in a narrow sense. These historians perform critical research, in pointing to some of the blind spots of traditional historiography as well as of mainstream psychology, while at the same time they do not need to compete with traditional psychology for “better” theories, methods, and practices. Thus, their primary identity is that of historians of psychology (Danziger 1990; Richards 1996; Scarborough and Furumoto 1987). Critical movements such as anti-psychiatry have had an influential history in the human sciences with well-known psychiatrists, such as Franco Basaglia (1924–1980), Thomas Szasz (born 1920), or Ronald D. Laing (1927–1989), spearheading ideas and practices, but they are less visible in the discipline of psychology. The same applies to critical disability studies, critical race theory, and queer studies.

Key Issues

Subject matter of psychology: One line of critique suggests that the most important models and metaphors representing human subjectivity or the human mind, with implications for an understanding of human nature, the relationship between mind and body, methodology and practice, are *technological* ones, and that the history of mainstream psychology parallels the development of technology (see Tolman and Maiers 1991). Machine models are embedded within a network of ontological assumptions, such as that a person reacts toward an external stimulus like a mechanism. The machine model excludes notions of agency, or the ability to reflect, choose, and act. Psychology’s mainstream operates with a *mechanistic*

and hence an *atomistic* and *reductionistic* model of human mental life (see also Teo 2009).

The *mechanistic* model is even maintained in biological traditions. Despite a commitment to an evolutionary perspective, the machine model is dominant in behaviorism because it is assumed that the individual responds to stimuli. Dividing psychological life into stimulus and response (behaviorism) or into independent and dependent variables (mainstream psychology in general) is problematic because it neglects subjectivity and action embedded in concrete cultural-historical contexts. More recent models in psychology that are based on evolutionary metaphors often neglect an understanding of how human mental life differs from various forms of animal mental life, particularly in terms of an understanding of the societal nature of human subjectivity.

The selection of variables and the focus on isolated aspects of human mental life (*atomism*) does not do justice to the integrated character of human mental life in concrete individuals. Instead of looking at the complexity of human life, which is the source of human subjectivity, the mainstream in psychology assumes that it is sufficient to study parts. It is *reductionistic* to assume that the parts sufficiently explain the complexity of human subjectivity, another consequence of the machine model. In reality, human subjectivity is experienced in its totality. Critics have argued, following Dilthey, that a psychology that does justice to human mental life should begin with the nexus of human experiences in order to understand the parts and not vice versa (see also Martin et al. 2003).

The machine model of human mental life has another consequence: Because it conceptualizes the person as individualistic and society as an external variable, the individual and society are seen as separate, yet reflecting bourgeois ideology and practices (see also Parker and Spears 1996). Accordingly, it is insufficient to conceptualize the sociohistorical reality as a stimulus environment to which one reacts; the individual is not independent of the environment and vice versa. In contrast, critical psychologists would agree that the individual is embedded in society, an insight that has several consequences: it allows for a critique of mainstream psychology; it implies that psychology must draw on other disciplines for an understanding of the subject matter of psychology; and yet, the concrete

conceptualization of what this idea means exactly is part of ongoing research in critical psychology.

Marx promoted an understanding of the nature of human beings and of human mental life as active and societal. *Cultural-historical approaches* in the tradition of dialectical materialism have argued that the environment, culture, and history are not just other variables. Contexts are interwoven with the very fabric of subjectivity. Vygotsky (1978) and his followers have challenged psychology's intrapsychological nature when it comes to understanding the individual mind, individual language, and individual activities, and have derived new theories and practices. Holzkamp (1983) conceptualized the person as part of a larger sociohistorical and economic web, which did not imply that the subject should not be taken into account in critical psychology. Indeed, Holzkamp envisioned a psychology from, literally, the *standpoint of the subject* (a first-person psychology) (see Tolman 2009). More recently, the problem of subjectivity has been advanced in English-speaking critical psychology (Walkerline 2002), and the critical-psychological journal *Subjectivity* focuses on this very topic.

Within a phenomenological tradition, it was argued that a focus on the mental life implies a neglect of the *body* (Stam 1998). This idea had a large impact on the feminist literature that had already recognized the nexus of person and society, and emphasized the concept of subjectivity in context. In addition, feminist psychologists have emphasized embodied theories of subjectivity, theories that do not exclude the body from the subject matter of psychology (Bayer and Malone 1998). Some of these theories draw also on arguments developed by social constructionists who understand the individual as nested in society and community (Gergen 1985). Gergen (2009) rejects the individualism of psychology and locates mental life as embedded in relations. Such ideas have led to an interest in the dialogical nature of personhood by hermeneutically oriented psychologists (Richardson et al. 1998) but also by critical psychologists who pay attention to key figures such as Mikhail Bakhtin (1895–1975) (see Billig 2008).

The postcolonial critique argues that the mainstream's psychological subject matter is part of a wider historical and cultural context and that the theories that try to capture this subject matter are

part of Western theorizing. Thus, the subject matter of psychology must be understood as part of Western ideology (Teo and Febraro 2003). Thus, psychologists and social scientists outside of the presumed center of psychology face the task of finding psychological theories, concepts, and practices that work in their lifeworlds rather than importing or exporting American ideas. For instance, Freire (1997), who emphasized that learners should be treated as subjects and not as objects, and Martín-Baró (1994), who applied Freirean ideas to psychology, have developed categories to deal specifically with psychological issues in Latin America.

In order to capture the subject matter of psychology, psychologists use concepts, and it is through those concepts or categories that they perceive sociopsychological reality. The nature of concepts has been studied, most notably by the critical historian Danziger (1997), who emphasized the social construction of psychological ideas and practices. Mainstream psychologists often pretend that concepts are natural kinds because they have empirical support. Yet, historical studies have shown that psychological concepts (human kinds) have a different status from natural-scientific concepts (natural kinds) and are constructed in specific cultural contexts for specific purposes. Moreover, constructed concepts can become a social reality and part of human identity (for instance, "race" or IQ). At the same time, culturally embedded concepts used in psychological theories can be understood as sources of power and oppression when they express a certain worldview and are *ideological* (see Foucault 1966/1970; Rose 1996).

Methodological issues: Mainstream psychology is committed to a natural-scientific, experimental-statistical, or empirical-statistical methodology. The mainstream operationalizes, in empirical research, concepts as variables (independent, dependent, moderating, mediating), so that traditional psychology can be characterized as a *psychology of variables* (Holzkamp 1991). This methodology provides an understanding of the functional or correlational relationship between variables but not the *why* of psychological phenomena, which is more relevant if one intends to derive social activism. For instance, of interest in traditional psychology is not the *why* of unemployment (which would include cultural-historical and political-economic analyses), but rather the relationship between the variable of unemployment and other

variables such as well-being, depression, self-esteem, personality, and so on.

Critical psychologists argue that problems of subject matter and methodology as well as practice are intertwined. In contrast, the mainstream promotes the idea that a natural-scientific methodology can and must be applied unquestionably to all research areas. The focus on methodology rather than on the subject matter has led to an epistemological attitude that can be called *methodologism* (Teo 2005). Others have used the terms *methodolatry* (Bakan 1967), the *cult of empiricism* (Toulmin and Leary 1985), and the *methodological imperative* (Danziger 1985). Holzkamp (1991) even argued that adequacy of the methodology with regard to the subject matter should be a central scientific criterion: As long as the adequacy of a methodology is not known, the scientific value and all other objectification criteria are worthless.

Based on the assumption that the psychological subject matter (i.e., active human mental life embedded in cultural-historical contexts) demands appropriate methodologies, critical psychologists, although not *a priori* opposed to quantitative methods (see Martín-Baró 1994, who demonstrated that quantitative methods can be critical of the status quo), favor a variety of *qualitative* methods that tend to focus on the content of human subjectivity as well as on the possibility of social action. Critical psychologists favor studies that have practical relevance, or *emancipatory* relevance, which means that research should contribute to overturning oppressive social situations. Critical researchers emphasize the transformative potential of research that not only addresses the status quo but also provides knowledge on how to change it.

Feminist researchers have identified the ideology of mainstream scientific methodology as *male biased*. In her classic studies, Keller (1985), using psychoanalytic concepts, explored the association between objectivity and masculinity and defended the thesis that scientific research is based on masculine discourses, ideals, metaphors, and practices. Instead, she advocated for research that emphasizes a connection with the participant and that does not exclude the participant's authentic experiences. In cultural-historical approaches, it has been argued that all involved parties should co-construct all parts of a study, which allows for a grounding of theories in praxis (see Roth and Lee 2007). According to German

critical psychology, research should be able to capture the *standpoint of the subject*. This means, for instance, that in psychotherapy research, it is less relevant how psychotherapy shapes a person than how a person contributes to his or her own change (Dreier 2007).

Social-constructionist or postmodern thinkers (a problematic label) such as Michel Foucault have inaugurated various methods of *discourse analysis*. Critical discourse analysis, a method that focuses on the analysis of written or spoken language, understands language as a social practice that is infused with biases because language is embedded in ideological, oppressive, or exploitative practices. Discourse analysis allows, for example, historical reconstructions of how multiple personality was made into an object of academic discussion (Hacking 1995) as well as an analysis of discourses's dependence on context (Dijk 2008). Foucault (1977) also provided suggestions for an analysis of nondiscursive practices: An analysis of architecture allows for insight into the workings of power in the context of human subjectivity and interpersonal relations.

In Martín-Baró's (1994) approach, methodology is intertwined with critical praxis. He suggested that psychology must base its knowledge production on the liberation needs of the oppressed people of Latin America. This means that knowledge must be generated by learning from the oppressed: Research should look at psychosocial processes from the perspective of the dominated; educational psychology should learn from the perspective of the illiterate; industrial psychology should begin with the perspective of the unemployed; clinical psychology should start with the perspective of the marginalized; mental health psychology should take as its point of departure the perspective of someone who lives in a town dump. Martín-Baró suggested an epistemological change from the powerful to the oppressed and recommends *participatory action research* (see below). It could be argued that feminist, sociohistorical, postmodern, and postcolonial ideas can be integrated into a meaningful *methodology of the oppressed* (Sandoval 2000).

Some critical researchers focus on meta-psychological issues that generate critical awareness without having a direct societal-practical impact. Historical studies and self-reflexive studies look at the discipline of psychology and at its participants. Not

only is human subjectivity embedded in society; psychology as a discipline and psychologists are also located in the same contexts. Science is then understood as a social enterprise embedded in power, money, and prestige. As Ward (2002) has shown, the reason for adopting a natural-scientific identity has more to do with the advantages of being accepted, and of being able to profit within academia and the larger public, than with internal progress. Historical and social studies of psychology allow critical questions about the purpose of research, about the personal, social, and political-economic interests involved in developing psychological studies, and about the groups and individuals that benefit from research results. In contrast, critical researchers have asked for more self-reflexivity in psychology (Morawski 2005).

It should be pointed out that so-called objective methods can and have been used for oppressive purposes. The hermeneutic deficit in psychology, despite a sophisticated methodological apparatus, appears in the context of the interpretation of group differences (e.g., gender or "race" differences). *Epistemological violence* is committed when the interpretation of data (not data themselves) lead to statements that construct marginalized groups as inferior, restrict the opportunities of marginalized groups, and lead to aversive recommendations for marginalized groups. For instance, if a researcher suggests that group differences are due to the lower ability of the *Other*, then this researcher has committed epistemological violence – because the data do not determine this interpretation, because alternative interpretations are available, and because this interpretation has negative consequences for the *Other* (see Teo 2008).

Ethical-practical issues: The mainstream's emphasis on control and adaptation neglects psychology's *emancipatory* potential. Psychology has been an extremely successful discipline in Europe and North America in terms of academic and professional expansion. However, such success does not necessarily imply the ethical-political quality of its practice. Psychological practice has often involved abuses perpetrated by the powerful, from intelligence testing as a means to control immigration into the United States (Gould 1996), to the application of psychological techniques to extract information from prisoners.

Many mainstream psychologists in the past and present have emphasized that *fact* (what is) and *value* (what

ought to be) are two different domains that should be kept apart. The problem is that, in any social science, these two domains are inherently intertwined. Critical psychologists (see Fox et al. 2009) challenge the idea that one cannot derive *ought* from *is*, and that science should remain neutral on political issues and concerns. Instead, most ethical-political critical psychologists emphasize the issues of social injustice and inequality (when it comes to class, ethnicity, gender, sexual orientation, disability, globalization, etc.) and make them a practical research concern. Obviously, values come into play when doing psychology and a lack of reflection on the values that guide one's research maintains the status quo (see Prilleltensky 1994).

The issue of praxis relates to Marx's famous notion of the primacy of praxis over theory: Intellectual reflection should not be about interpreting the world so much as changing it. For Marx, the final goal of all praxis was to change society's fundamental economic foundations, which he perceived as the source of inequality. Critical social research should be guided by progressive ethical-political ideas and should generate knowledge that has relevance. Critical psychologists have analyzed psychology's role in maintaining capitalism, patriarchy, colonialism, and Western ideology (Hook 2004). In not challenging the mainstream, psychology reinforces the status quo, which also means performing psychology in the interest of the powerful. The embeddedness of psychology in the market economy has made it difficult to promote psychology as a critical science. Even social psychology, which has a history of contributing to emancipation, has largely been transformed into a field that produces large amounts of socially irrelevant data.

It should be mentioned that cultural-historical, Neo-Marxist, and other critical approaches in the West have acknowledged the primacy of praxis but have often remained in the comparably safe environment of academia. Thus, instead of becoming politically active outside the political mainstream, many critical theorists have suggested that research, if not emancipatory itself, should at least have an emancipatory intention (Habermas 1972). In fact, in critical thought, one can find ethical-political orientations that range from left-liberal, progressive to radical. Many ivory tower critical psychologists also justify theoretical research as a legitimate option, because the production of

knowledge is considered a form of praxis (as is teaching) that is not inferior to concrete community-based interventions in the abolition of social injustice.

The most obvious consequences of praxis can be seen in economically less developed contexts where theorizing for the sake of theorizing and research for the sake of research must be considered indulgent practices. Martín-Baró (1942–1989) gave his own life in the political struggle for progress. He pointed out that an ethical-political stance, practice, and objectivity do not conflict with each other. For example, when it comes to torture, it would be possible to be ethical-practical (thus, rejecting and working against torture) while at the same time maintaining objectivity (understanding the objective consequences of torture on human mental life). Martín-Baró (1994) argued that it would be insufficient to put oneself in the shoes of oppressed people. Instead, he pleaded for a new praxis, which he defined as an activity that transforms social reality and lets humans know not only about *what is* but also about *what is not*, and by which means they may try to orient themselves toward *what ought to be*.

In consequence, for Martín-Baró, the psychologist is less a traditional clinician and more a resource for the community regarding intervention and support in the fields of disability, mental health, and drug use but also in terms of economic development and antipoverty programs. Martín-Baró worked with victims of state oppression, assumed active social roles, and worked with marginalized groups. It allowed him to understand suffering as a shared issue rather than an individualized problem. His *preferential option for the poor* was influential in shaping his political-ethical ideas. His concrete praxis-method is labeled *participatory action research*, originally introduced to psychology by Lewin (1946), who believed in the transformative power of research in social psychology. Concrete critical psychological praxis has also been addressed in the context of AIDS in Africa (Hook 2004).

International Perspectives

The *Annual Review of Critical Psychology* of 2006 provides an overview of critical psychology in several countries in Europe, North and South America, Asia, Oceania, and Africa. Critical psychologies have developed many branches, and thus, only a selective and limited account can be provided here. In Germany,

the (West) Berlin group that formed around Klaus Holzkamp founded its own school while other critical psychologists organized around the journal *Psychologie und Gesellschaftskritik* (*Psychology and Critique of Society*). Both groups have struggled in recent years to keep their theories and practices alive at universities and especially in psychology departments. In Austria, a *Society for Critical Psychology* has achieved official professional status recognized by mainstream associations and offers continuing education credits.

English-speaking accounts of critical psychology are internationally the most visible ones, as they are in many areas of the social and natural sciences. Yet, English-speaking approaches to critical psychology show large variations, depending on intellectual and practical traditions as well as on the national context. The United Kingdom has emerged as a center of critical psychology in providing training, education, and research programs of critical psychology (Manchester Metropolitan University, Cardiff University, the University of the West of England in Bristol, the University of East London, Loughborough University, and other institutions). In Britain, a critical social psychology has also been maintained (e.g., Gough and McFadden 2001). Some of the programs, journals, book series, research centers, and so on have sometimes short turnovers, and may lack continuity. For instance, the *International Journal of Critical Psychology* was relaunched as the journal *Subjectivity*. In addition, research stemming from the English-speaking context also demonstrates that successful critical studies on subjectivity need to be achieved in an interdisciplinary context, and might even require abandoning the traditional discipline of psychology.

In English-speaking North America, there exist no formal programs that offer an education or graduate training in critical psychology in its specific meaning, but there are departments where critical topics can be studied from theoretical, historical, social-constructionist, hermeneutic, or community-psychology perspectives. In Canada, the social and theoretical psychology program at the University of Calgary, the history and theory of psychology program at York University, and the community psychology program at Wilfrid Laurier University should be mentioned. In the United States, critical ideas can be studied at smaller institutions such as the University of West Georgia or Duquesne University. Interdisciplinary programs have been realized at the

Graduate Center of the City University of New York (e.g., Fine 2006) and at the University of Miami.

Oceania has significant enclaves of critically oriented psychologists at several universities, particularly in Australia and New Zealand, with degree opportunities and research centers (e.g., University of Adelaide, University of Auckland). South Africa has become more visible on the international scene of critical psychology since the publication of an extensive textbook (Hook 2004) that provides ideas on transforming psychology, combining Western and indigenous psychologies, introducing conceptual developments within an African perspective, and outlining an African-based critical psychology. Perspectives outside of the so-called center also emphasize the need to combine critical psychology with practical health matters – an international trend that has led to various critical health psychology approaches around the world.

Spanish-speaking initiatives promoting critical psychology in Latin America draw on the potential of Martín-Baró's liberation psychology. But they also include a critique of critical psychology, which has been perceived as a project from the North (Montero and Christlieb 2003). Spain also provides several approaches to critical social psychology. France, usually less known for critical psychology and more for critical approaches in philosophy or for psychoanalytic innovations, has an important history of the critique of psychology, beginning with Politzer (1928/1994) and also advanced by Sève (1978). In East Asia as well as in India, critical psychology programs are not located in psychology departments, but critical approaches focusing on subjectivity are found in cultural studies programs with opportunities for publishing journals and books and for presenting at conferences.

Future Directions

Habermas (1968/1972) articulated the relationship between knowledge and interest and identified critical social sciences as one basic category of science, besides the natural and the human sciences. After decades of critical inquiry, the question remains as to whether a critical interest is indeed necessary for human development. Posing the question also raises issues of legitimacy, because critical psychologies developed out of particular cultural-historical climates themselves. The partial institutionalization of critical psychology (e.g., academics

working at universities) raises issues regarding the value of theoretical and practical renewal that does justice to changing social realities on national and international levels. Problems of legitimacy are also raised on an ethical-practical level when, in the saturated countries of the globe, resistance is often envisioned on a subjective level as reactionary rather than as progressive or radical.

Ironically, the development of critical psychology is also contingent on the development of psychology as a discipline. Yet, the discipline of psychology is fragmented, and what is perceived as the academic core has moved to brain physiology and neuroscience. Although a critique appears necessary for such developments, many critical psychologists do not consider these developments relevant to their own research vision. Thus, they leave psychology for other social or cultural sciences; nevertheless, new approaches outside of critical psychology need to be advanced, such as *critical neuroscience*, for a better understanding of the opportunities and limitations of the latest developments. However, these critical developments, where they exist, have emerged often without a connection to the field of critical psychology (Choudhury et al. 2009).

Critical psychologists' move away from psychology may make them even more marginal within the mainstream. Still, this development allows for interdisciplinary and international exchange on matters such as subjectivity and for new theoretical and practical alliances and connections to occur. Certainly, such a trend will lead to more heterogeneity of sources and more theoretical and practical confusion about the core features and traditions of critical psychology. Instead of one critical psychology there will be many, indeed as there already are, because human subjectivity, and the intellectual and practical possibilities and limitations of the subject, are inherently dynamic, global, contextual, and historical, and any critical psychology needs to attempt to do justice to that reality.

was 4 years old. According to his sister, Lee was overheard then calculating the unit price of potatoes. He came to the conclusion that the market his mother shopped charged more than the market he was in with a babysitter. This feat was then reported to Blanche Cummings, a school psychologist and disciple of Lewis Terman. After Terman gave Lee an IQ test and found his score was 200, he enrolled Lee into his gifted program. With the push from his mother, he graduated from Fresno High School at the age of 14 and Fresno State College at 18 (Shavelson and Gleser 2002).

In 1938, he earned a master's degree at the University of California-Berkeley while teaching mathematics and chemistry at Fresno High School. Then he went on to obtain a doctor's degree in educational psychology from the University of Chicago. He became an associate professor of psychology at State College of Washington, and then moved to teach at the University of Chicago and University of Illinois. In 1964, he went to Stanford's School of Education and continued his career until he retired in 1980. After his retirement, he continued to focus on the debates on educational and psychological testing. He completed a book on a new theory of aptitude (Corno et al. 2001) and went on to work on a paper discussing the uses, misuses, and misunderstanding of the Cronbach alpha.

Major Contributions

His research can be divided into three major areas: measurement theory, program evaluation, and instruction, among which his contribution to measurement issues were undoubtedly of greatest help to all educational psychologists. The most impressive and popular of Cronbach's research is the Coefficient Alpha, currently known as Cronbach's alpha. His experience of teaching his first courses in evaluation and measurement and writing the first edition of *Essentials of Psychological Testing* (1949) contributed to the birth of this coefficient alpha. Most researchers in the field, whether they are educators, psychologists, and other social scientists, have had the experience of using it to provide a measurement of reliability from a single test. Although the Coefficient Alpha first appeared in 1951 (Cronbach 1951), however, it is still widely used today because it is easily calculated and could be applied to dichotomously-scored multiple-choice items or polytomous attitude scales.

Cronbach, Lee J.

JUN LI

Fordham University, New York, NY, USA

Early Life, Education, and Professional Development

Lee Joseph Cronbach was born in 1916 in Fresno, California. His talent in testing was revealed when he

His next greatest contribution is the Generalizability Theory. As Cronbach continued on his study during 1950s and 1960s, he was dissatisfied with reliability theory, realizing that different methods of calculating a reliability coefficient define the “true score” and measurement error differently. That dissatisfaction led to his work on a handbook on measurement, which recapitulated the reliability in the form of Generalizability Theory. The Generalizability is concerned with the relationship between the “true score” and measurement errors such as the unwanted main effect, interaction, or random error variances. He applied Fisher ANOVA to raw scores to estimate variance components and so compute reliability coefficients. The introduction of the Generalizability Theory first appeared in *The British Journal of Statistical Psychology* (Cronbach et al. 1963). The Generalizability theory combined the psychology with the mathematics to produce a comprehensive framework which identified sources of measurement error. It examines the influence of different aspects of a test on the test performance, which makes it possible for educators to address more realistic educational problems.

Cronbach’s contribution on validity theory is almost as significant as his work on reliability. He put construct validation in the center of psychological, educational, and social testing. Validation was a process that never ends. What was validity was not the test, but rather a proposed interpretation because a test may be used for many different purposes. The paper “Construct Validity in Psychological Tests” by Cronbach and Meehl (1955) laid the foundation for 50 years of work on validity.

Cronbach’s research also included his work on evaluation and instruction. In the 1970s, he directed the Stanford Evaluation Consortium, a research, service, and training organization. He recognized the merits and limitations of randomized field trials, the importance of local contexts on performance, the social and political aspect of program evaluation. The evaluation research resulted in two influential books *Toward Reform of Program Evaluation* and *Designing Educational Evaluations*. The latter was chosen as one of the top one hundred education-related Books of the Century by the Museum of Education, University of South Carolina in 2000.

Cronbach’s instructional research began with the work on personnel placement. He found that the

different characteristics of the individuals may make them suitable to one type of job instead of another type of job. The optimal decision to match a person to a suitable job was to find the job for an individual who could perform well. His instructional research focused on matching learning environments with students’ ability. He concluded that individual differences may be highly predictive of performance in one type of instruction and less in another. Thus the potential benefits for the students may be maximized by matching the type of instruction to students’ abilities, motivations, and interests.

Cronbach had a great impact on his field in educational psychology. His legacy includes, to name just a few, Cronbach’s alpha, the Generalizability theory, his validity study, his formative approach in program evaluation, and so on, each of which made him the indispensable person in Education psychology. Besides, his authoritative textbooks on educational psychology and psychological testing, his empirical experiments had profound influence on the development of the field. As Kupermintz (2003) summarized in Zimmerman’s *Educational Psychology: A Century of Contribution*, educational psychology is better off because of Lee Joseph Cronbach. He was president of the American Educational Research Association, the American Psychological Association and the Psychometric Society. He was also a member of the National Academy of Sciences, the National Academy of Education, the American Philosophical Society, and the American Academy of Arts and Sciences. He was honored by the Educational Testing Service, the American Psychological Society, the American Educational Research Association, and the Evaluation Research Society.

Cultural Psychology (General)

CARL RATNER

Institute for Cultural Research and Education,
Trinidad, CA, USA

Definition

Cultural psychology emerged on the contemporary academic scene in the 1980s as a transdisciplinary field that studies the relation between culture and psychology. It arose as a corrective to mainstream psychology – which minimizes the cultural organization of human psychology – and also to cross-cultural psychology – which employs positivistic methodology to reduce culture and psychology to abstract, fragmented variables.

Cultural psychology itself contains several strands that derive from different intellectual traditions (Ratner 1999; Ratner 2011a, b, c). In the space here, it is impossible to survey all of them. Instead, I shall articulate certain select principles that have proven useful for understanding culture, psychology, and their relation.

These may be summarized as follows: Culture and psychology are internally integrated and continuous. They are on the same plane; two sides of the same coin; they are interdependent. Psychology is part of culture, it is a cultural element. It is necessary and functional for constructing/maintaining culture; and it takes on the characteristics of the culture that it constructs. Psychology is the subjective side of culture, while cultural factors are the operating mechanisms of psychology. Psychology is not simply in culture in the sense that it is surrounded by a cultural context. Rather psychology is the subjectivity of culture; it is cultural psychology, or cultural subjectivity

that incarnates and promulgates the features of cultural factors as its content and operating mechanism.

Since psychology embodies features of culture, where culture is stratified into unequal classes, and dominated by a wealthy, powerful upper class, psychology takes on these characteristics. The politics that drive culture are similarly embedded in psychological phenomena. Vygotsky stated this clearly in the case of psychology in class society:

- ▶ Since we know that each person's individual experience is conditioned by the role he plays in his environment, and that it is the class membership which also defines this role, it is clear that class membership defines man's psychology and man's behavior.

Social stimuli that have been established in the course of historical development... are permeated through and through with the class structure of society that generated them and serve as the class organization of production. *They are responsible for all of human behavior, and in this sense we are justified in speaking of man's class behavior* (Vygotsky 1997a, pp. 211–212).

This is what the discipline of cultural psychology studies. It requires a serious, systematic understanding of social conditions, social factors, social structure, and politics. It looks for these in the genesis and content of psychological phenomena (Ratner 2011a, b, c).

Cultural psychology adopts a structural-functional standpoint. It regards culture that forms psychology as a concrete system of interdependent, interpenetrating factors – specifically social institutions, cultural artifacts, and cultural concepts. Each factor affects the others and expresses them through itself. The concrete character of these systemic cultural factors is imparted to psychological phenomena. Cultural psychology utilizes a methodology of cultural hermeneutics to elucidate the full cultural system that is implicated in a particular cultural element.

Historical Background

Cultural psychology springs from four main sources.

1. Eighteenth and nineteenth century human sciences (e.g., Herder's work; the study of language and society). These scholars emphasized the distinctiveness of human culture. They said that social life, language, and its symbolic and cognitive properties make

humans qualitatively different from (superior to) animals. Herder wrote: “The difference lies not in quantity nor in the enhancement of powers but in a completely different orientation and evolution of all powers.” This historical tradition has been carried on by historians who focus on psychological issues such as self, gender, emotions, senses. It has also been carried on by sociologists who study emotions, childhood, and other psychological topics. The history of “mentalities” by the French Annales historical school in the 1920s was a major force in pioneering this line of historical-psychological research (Burguiere 2009). This tradition has also been carried on by sociologists who study emotions, childhood, and other psychological topics. The first cultural psychologist was probably Al-Biruni (973–1048), who has also been called the first anthropologist. He was a Persian scholar (natural scientist and social scientist) who wrote a thorough ethnography of Indian mentality (published in English as Albiruni’s India, 1993) using phenomenological methodology. (I am indebted to Mohamed Elhammoumi for this reference, and many others.)

2. Sociocultural psychology of Vygotsky, Luria, Leontiev, which became popular in the 1980s after publication of Vygotsky’s *Mind in Society* in 1978. Bronfenbrenner’s (1979) ecological psychology drew on and contributed to this source.
3. Psychological anthropology of Shweder, Geertz, D’Andrade, Levine, Super and Harkness, Catherine Lutz, M. Rosaldo, and Kleinman that emerged during the 1980s (Kleinman and Good 1985; Shweder and LeVine 1984).
4. The sociology of Durkheim, Marx, and Bourdieu. Durkheim and Levy-Bruhl argued that socially formed “collective representations” of things act as filters which structure our thinking, perceptions, and sensations. Collective representations define the nature of things; they comprise the categories into which we place things; they form our expectations of how things will act; they guide our behavior. They are generated in social practice, vary with it, and are man-made. Yet they are emergent collective products which transcend individual beliefs and acts.

Marx and Engels developed a social philosophy of the individual. They argued that humans are essentially

social. They are not primarily (primordially) individuals first and then aggregate into groups, as Adam Smith maintained (Sayers 2007).

Cultural psychology flourished briefly for a decade, with an impressive outpouring of theoretical and empirical research. However, it was undercut in the 1990s by an alternative perspective. Ratner (1993, 1999, 2008, 2011a, b, c) designates this alternative perspective as microcultural psychology. Microcultural psychology reframed the definition of culture, the manner in which culture influences psychology, the nature of agency, and the use of qualitative methodologies to study cultural psychology.

It did so under the name of cultural psychology. However, microcultural psychology diverted and diminished the realization of the fruitful cultural psychology that showed promise in the 1980s.

After explaining cultural psychology, I shall introduce its differences with microcultural psychology and cross-cultural psychology.

Key Issues in Cultural Psychology

Psychological Theory

Cultural psychology is a psychological theory. It is also a cultural theory. It explains what culture is, what its predominant factors are, how it is structured, who controls culture, why it came into existence (i.e., its function for humans), why humans need to maintain culture in their behavior and psychological activity, how psychology is generated and organized by culture, and how psychology is vital for culture.

Cultural psychological theory goes beyond mere empiricism of correlating social factors and psychological phenomena. Such empiricism – as practiced by cross-cultural psychologists – has no theory of culture or of psychology. This is true even of interesting and important empiricist research that establishes the association of culture and IQ. As valuable as this finding is for refuting nativistic explanations of IQ, it does not explicate the cultural basis, character, and function of human IQ.

An indication of cultural psychological theory is Shweder’s (1990, p. 1) statement, “Cultural psychology is the study of the way cultural traditions and social practices regulate, express, transform, and permute the human psyche.”

A Darwinian Argument for Cultural Psychology: Cultural Psychology is Darwinian Psychology

To explain why culture is central to our psychology, cultural psychological theory employs Darwinian principles. Simply put, culture is our environment, our adaptive organ, our survival mechanism. Culture is collective, coordinated behavior and thinking. According to Darwin, an organism's features are selected by its environment. Features that help the organism survive in the particular environment are supported, while those that are incompatible with environmental requirements are unsustainable. Applying Darwinism to psychology, it follows that psychology must have features that are congruent with the cultural environment. This means that psychology must be collectively formed and coordinated. It cannot be rooted in individual, natural mechanisms that are independent of culture.

Attributing psychology to non-cultural processes and having non-cultural features violates Darwinian environmental selection/determination. Ironically, Darwinian psychology is cultural psychology – because culture is the human environment – it is not evolutionary psychology. Evolutionary psychology contradicts the fundamental premise of Darwin's argument, that organisms develop attributes which are congruent with their environment (Penn et al. 2008). If our behavioral mechanisms were not cultural and did not generate distinctly cultural behavior, culture would collapse and we would forego its benefits.

It is consistent with Darwinian adaptationism-functionalism that human beings have different kinds of mental and behavioral processes from animals, and that the mechanism which generates these features is also different from those in animals – because our environment is different from theirs. It is anti-Darwinian for evolutionary psychologists to insist that animal mechanisms of genetic mutation by which animals adapt to the natural environment are the only mechanism by which all organisms survive in all environments. Such a view ignores the specific character and influence of the organisms' environment, which is the essence of Darwinism. Evolutionary psychologists are pretenders to the throne of Darwinism; they are illegitimate heirs of Darwinism; they are imposters (*poseurs*) of Darwinism (Ratner 2006, pp. 201–209).

Culture is not simply one variable that psychologists can add to their arsenal of other variables. Culture is the human way of life. Consequently, our behavior and its mechanisms must be fundamentally and thoroughly cultural. They cannot be marginally, partially, and superficially cultural, for that would render them insufficient to meet the vast, profound needs of cultural life. They would be insufficiently adaptable to the cultural environment, which, in Darwinian terms, would be fatal.

The discipline of cultural psychology investigates the ways in which psychology, subjectivity, mentality, and consciousness are cultural, depend on culture, are required by culture, are generated by culture, construct and maintain culture, and embody the characteristics of culture. Cultural psychology is a reconceptualization of human psychology in light of our distinctive cultural existence. We construe human psychology as an emergent phenomenon, a new creation, that is designed to construct and utilize distinctively cultural things (artifacts, rules, symbols, structures). Gordon explained this with regard to emotions earlier.

Human psychology is not analogous to animal behavior. It is not an extension of animal behavior applied to new situations. Human psychology is a distinctively new kind of behavioral mechanism that is required by cultural life.

Even human biology is cultural in accordance with Darwinian environmentalism. Our biology must adapt to our unique cultural environment. In fact, the social brain hypothesis argues that the unique structure and functioning of the human cortex evolved to master social tasks demanded by the cultural environment. (Humana biology is non-determining with respect to behavior/psychology, and also with respect to disease. Contrary to popular and medical opinion, genes do not determine or predispose to physical disease. For the vast majority of diseases, one's genome has very little affect on whether one will contract a disease: <http://www.biosciencesource.org/commentaries/article.php?id=46>).

Cultural Factors and Psychology

A major principle of cultural psychology is that the cultural form of environment requires, stimulates, supports, and organizes uniquely human capacities and mechanisms that generate cultural behavior and cultural

products. These unique behavioral capacities and mechanisms are psychological phenomena. Psychology is the new operating mechanism for a new kind of organism in a new kind of environment. The new environment is culture and the new kind of organism is a social organism; psychology must be a social behavioral mechanism that generates social behavior in a social environment. Since psychology is selected – generated – by culture, it is important to understand the specific nature of culture in order to understand psychology.

The cultural environment is essentially one that consists of shared, coordinated, supportive behavior which combines the strengths of individuals into a supra-individual structure (institution) which is far more powerful than a sequence of separate individuals primarily acting on their own. A group of people working to lift a heavy load is capable of lifting far more than separate individuals working on their own, on their own behalf. A group of hunters that shares information about the behavior and location of some prey can catch far more prey than single individuals can.

Coordinating behavior in accordance with a common objective requires shared knowledge, common concepts, symbols, language, and behavioral norms.

Coordinating behavior and speaking a common language require shared intentions and also the ability to comprehend intentions. I must grasp that you are trying to catch that animal in order to work with you on catching it. I must know that you are trying to lift that load in order to work with you.

Culture is not reified social entities, it is active, coordinated, intentional, symbolic behavior.

Cultural behavior is structured in enduring forms such as institutions, artifacts, and cultural concepts. This makes it objective, regular, predictable, and enduring. These attributes are necessary for coordinated, cooperative behavior. It cannot be free-floating, amorphous, transient, personal/idiosyncratic, or spontaneous. These attributes would subvert the cohesion necessary for coordination, and cooperation.

Cultural behavior is structured without being reified. It is structured through common subjectivity, or *socius*, or *habitus* which are objectified in institutions, artifacts, and concepts but are not reified. Subjectivity/psychology designs and maintains cultural factors and always has the potential to revise cultural them.

This integral system of capacities, activities, and objectified cultural factors makes us social beings. To be social is to be linked to other individuals in an integral fashion that constitutes a new type of being. Sociality is not simply individuals interacting; it is a new kind of individual in new forms of relationships with others. To be social is to be linked with other individuals in and through a social system/institution/process; it is not an interaction of one independent individual with another. Sociality is a complex, “higher,” emergent social process that supersedes the individual and configures him within a social process that is greater than himself. Sociality is not reducible to individual processes. Tribal councils, unions, governments, corporate structures are ways that people are linked together through superordinate administrative bodies and social policies which set the parameters of social interaction. (Sociality is mediated through objective social structures: e.g., the quality of your neighborhood school depends upon educational budgets which depend upon income taxes which depend upon employment trends which depend upon investment decisions by corporate executives. Consequently, the decision by a CEO to cut jobs in Southern California affects the quality of your school in Northern California through this complex social structure.) Interpersonal, one-on-one interaction is not the model of sociality – the CEO, for example, does not directly interact with the administrator of the local school to affect its quality. Interpersonal interaction does not rise to the level of complexity that sociality has. (In fact, as I have argued in Ratner (2011a, b, c), interpersonal interactions derive from complex macro processes.) Nor would interpersonal interaction provide the benefits, requirements, and stimulation that complex, institutionalized sociality provides. The more complex the social relations that link individuals, the stronger and more supportive they are for participants, and the greater are the demands for complex subjective/psychological functions to perceive, understand, remember, and feel the social relations that comprise the cultural environment.

This new social creature in new modes of interaction is called a *socius* by James Baldwin, an American psychologist/philosopher, in 1895. The *socius* connotes a social self, a self of personal values, sanctions, and duties, in which all individuals by their very nature

participate. Being social is a new order of life that goes beyond the individual to create a new kind of body, a social body. Our social body adds a new quality to our existence. It transforms us from a physical being to a conscious, thinking, symbolizing, creative, willful being (Ratner 1991, Chaps. 1, 4). As Vygotsky said: “A human being as a specific biotype is transformed into a human being as a sociotype; an animal organism becomes a human personality.” “The biological, by means of social factors, melds into the social; the biological and organic into the personal; the ‘natural,’ ‘absolute,’ and unconditioned into the conditioned. This is the true material of psychology” (Vygotsky 1993, pp. 160, 155).

All the richness and advance of human civilization depends upon people having a social body that reconstitutes them as social organisms. Indeed, the *socius* is the foundation of individuality. Individual capacities derive from our social existence. This social psychology was developed by Baldwin later by scholars such as Vygotsky and Janet (Valsiner and Van der Veer 2000). Janet said that higher mental processes such as memory are first carried out externally and only subsequently become available as internal, private mental functions: “all social psychological laws have two aspects: an exterior part concerning other people, an interior part concerning ourselves. Almost always... the second form is posterior to the first one.” Vygotsky similarly said “The social moment in consciousness is primary in time as well as in fact. The individual aspect is constructed as a derived and secondary aspect on the basis of the social aspect and exactly according to its model” (Vygotsky 1997b, p. 77). “Essential is not that the social role can be deduced from the character, but that the social role creates a number of characterological connections” (Vygotsky 1997b, p. 106).

Culturally derived psychology/subjectivity is cultural not only in being stimulated by culture, but in being a cultural phenomenon. In other words, culture does not simply stimulate some innate psychological tendency that pre-exists culture as an individual phenomenon. Culture constitutes psychology as a cultural phenomenon in form and content. Baldwin (1913, p. 140) emphasized this in stating that “the character, ends, and objects of thought and life are collective.”

Consistent with Darwin’s thinking, human cultural environment requires a compatible cultural organism

equipped with a compatible behavioral mechanism. The mechanism of human (cultural) behavior must be a cultural phenomenon. It cannot be a natural mechanism that simply responds to a cultural environment. Human behavioral mechanisms match their environment just as animal mechanisms match their natural environment. If would not work, and would be anti-Darwinian, if humans in their cultural environment utilized natural behavioral mechanisms which animals use to function in their natural environments.

With coordinated, cooperative cultural activity being the basis of human psychology, it is imperative to maintain cohesive, organized, integral, structured cultural factors in order to enhance the development of our subjectivity and psychology. It is not just the common content of culture that draws people together in mutual support, it is also the act of forming and participating in common, coordinated, cooperative, structured, enduring, complex activity that makes people work together as *sociuses* with joint subjectivities. This kind of social activity is what stimulates and elicits advanced psychological functions such as thinking, remembering, perceiving, emoting.

Gordon (1981, pp. 563, 562) explains that “Social life produces emergent dimensions of emotion that resist reduction to properties inherent in the human organism. Socially emergent dimensions of emotion transcend psychological and physiological levels of analysis in terms of (1) origin, (2) temporal framework, (3) structure, and (4) change.” “Although each person’s experience of emotion has idiosyncratic features, culture shapes the occasion, meaning, and expression of affective experience. Love, pity, indignation, and other sentiments are socially shared patterns of feeling, gesture, and meaning.”

Culture must be maintained in order to enhance society and psychology. (I am speaking here of culture in general, not any particular historical culture. Many particular cultures degrade society and psychology.) Fragmentation, divisiveness, egoism, ethnocentrism, and similar anti-group practices degrade culture and deprive individuals of its social and psychological benefits.

A good example of a specific common culture is French public education from 1881 which defined the school as the place where national unity would be forged, where the children of peasants (who spoke

a variety of regional dialects and usually followed religious dictates) would become citizens/patriots. The school was to be the agent of acculturating children into a shared culture in which they could all participate. The goal of its pedagogy was to instill a common republican political identity in children from a diversity of backgrounds. The school was to effect a transition from private to public, from the world of the locality and the family to that of the nation. Teachers were the “missionaries” charged with converting their pupils to the wonders of science and reason and the reasonableness of republican principles. A shared language, culture, ideological formation, and nation was to be the outcome of the educational process. Uniforms were often used as a way of facilitating common culture and overcoming class differences in clothing.

This kind of cultural solidarity is crucial for obtaining the benefits of cultural sharing, stimulation, and support. Outsiders who lacked the common language, identity, purpose could not coordinate with those that did, and would not receive the stimulation and support that culture brings. Of course, common culture can be refined to incorporate new elements; however, the refinements would constitute a new solidarity that was shared by the members. New elements would not be compartmentalized into their own, separate spheres because this would isolate those members and fragment the culture, thus weakening it.

The foregoing description indicates that culture includes subjectivity, intentionality, individual activity, and psychology. This integration is emphasized by sociologists who study social institutions: “An institution links together different orders and realms of social life, notably the agentic with the structural, the symbolic with the material, and the micro with the meso and the macro structures of social organization” (Mohr and White 2008, p. 486).

The *socius* is our subjectivity, it is not simply our external environment. Our psychology does not simply exist within culture; psychology is informed by culture, it is cultural psychology; culture exists within psychology. Similarly, we are not simply animals who live in a cultural environment; we are cultural animals in the sense that our animal being has been acculturated and transformed.

Pred (1984) provides a more specific model of culture and psychology from the standpoint of

geography. He begins with a thorough description of culture as emergent sociality that configures individual psychology:

- ▶ Social structure is comprised of those generative rules and power relations - including the control over material, symbolic or authoritative resources - that are already built into a specific historical and human geographical situation, or into an historically and geographically specific social system. The rules and power relations of social structure do not only constrain and enable human agency and practice. They also emerge out of human agency and practice. A social structure's component rules may be formal or informal. Whatever their nature, these learned and humanly produced rules form the underlying grammar of activity and behavior in particular contexts. The power relations of a social structure may exist among different individuals, among different groups or classes, among different institutions, and among individuals or groups on the one hand, and institutions on the other. Insofar as power relations may differ in their geographical extent, structuration processes may simultaneously occur at multiple spatial levels, interpenetrating with one another through the practices associated with mediating institutions or individuals. (Pred 1984, p. 281)

Pred's description of culture is more thorough and specific than the typical notion of culture as shared customs that are historically transmitted. Pred identifies power relations in organized social structures. Moreover, the power relations that define a society permeate individuals and groups at all different levels of society, e.g., macro institutional, micro interpersonal levels, in various social spaces. Pred emphasizes that features of cultural factors form the grammar of individuals' activity in particular situations. “Power relations cannot be separated from the realm of action and everyday practice [manifested in]...the indirect control of who does what, when, and where;” and “what people know (and are able to say), and how they perceive and think” (pp. 290, 289). Even “independent” activities bear the imprint and limitations of cultural factors: “There are always culturally arbitrary dispositions or elements of practical knowledge associated with the creation and definition of ‘independent’ projects that can be acquired only via socialization, or

path intersections with institutional projects (Pred 1984, p. 286).” Pred perceptively observes that power relations always contain an “underside” of subjectivity that accords with positions of power.

Pred (p. 285) makes the important point that structured, political-cultural factors structure action, not only by encouraging it, but also negatively by limiting alternatives to given forms. This takes the form of limiting knowledge and competencies that can envision alternatives. (I have called this the psychology of oppression; Ratner 2011b). Pred identifies five types of culturally shaped “unknowing” that serve this political function.

1. The unknown, and not possible to know, in terms of being totally unknown to all or some local inhabitants.
2. The not understood in terms of not being within the frame of meaning of all or certain local inhabitants.
3. The hidden in terms of being hidden from certain local inhabitants.
4. The undiscussed, in terms of being taken for granted as true or natural by all or some local groups.
5. The distorted, in terms of being known only in a distorted fashion by all or certain members of the local population.

Of course, the status quo is not monolithic or immune to critique and challenge. “These daily-path experiences, interactions, and encounters occasionally result in the discovery of other long-term institutional role possibilities that, depending on the basis of a person’s biographical history and competition from other individuals, one may or may not have a realistic chance of entering into. Moreover, these daily-path encounters help one to define and redefine oneself, to renew and initiate strengths and weaknesses, and to form intentions” (p. 287). However, discovering viable alternatives to the status quo is difficult given the positive and negative mechanisms the status quo has at its disposal to enforce conformity. (The absence of viable proposals to solve current economic, ecological, and psychological crises – and the ease with which people fall victim to false, superficial solutions – testifies to this point.)

Pred makes the important point that social structure determines human’s interaction with nature. Consequently, living in a balanced relationship with nature requires transforming the social structure, it cannot be accomplished through technical means alone – such as green energy and organic food production: “Because the transformation of nature is inseparable from the local expression of structuration, from the historically contingent becoming of place, it cannot be understood unless the prevailing power relations at the core of local social structure are identified” (p. 289) (Note 1).

Case Studies of Cultural Psychology

The general principles of cultural psychology we have been discussing are meant to elucidate the specific cultural origins, characteristics, and function of particular psychological phenomena. These observations explain, describe, and predict particular psychological phenomena. These cultural observations also lead to effective strategies for enhancing psychological phenomena and solving psychological problems. We shall demonstrate these uses of cultural psychology in three “in vivo” case studies.

Racial Psychology

An excellent case study comes from historian Jennifer Ritterhouse’s account of how White psychology was generated by the slave system (its laws, values, institutionalized power and wealth and control over property) in the USA. After blacks had been legally freed and made citizens, Southern whites sought to maintain their rule over blacks through informal cultural rules known as racial etiquette (Ritterhouse 2006). Racial etiquette included demeanor on sidewalks (blacks were to defer to whites), sexual behavior, play, names (“Sir” vs. “boy”), and eating behavior. Violations of racial etiquette were met by beatings and lynchings. Indeed, “as many as a quarter of the 4,715 lynchings known to have taken place in the South between 1882 and 1946 resulted from breaches of racial etiquette that were seldom crimes” (Ritterhouse 2006, p. 36). A particular psychology was generated by racial etiquette, and it exemplifies how cultural factors are the origins, operating system, characteristics, and function of psychological phenomena.

One example of the cultural psychology of Southern whites was their acceptance of lynching blacks as just punishment for violating the cultural codes. Whites eagerly attended lynchings and derived pleasure from watching black men hanged from a tree. In Fort Lauderdale, Fla. in 1935 a white woman, Marian Jones, claimed that Reuben Stacey had attacked her. A mob of 30 armed men took Stacey to be lynched. Word of this spread and brought thousands of curious spectators, including women and children, to watch him be shot and hanged. Excitement was rife among the crowd and photographs showed smug, satisfied looks on the faces of some observers. Ritterhouse (2006, p. 74–75) describes the perceptions, emotions, and cognition displayed at these events.

- ▶ Some white southerners not only failed to regard lynchings negatively as horrors from which innocent children ought to be sheltered, but instead regarded them positively as exciting events that neither they nor their children should miss. The mob execution of a black man, woman, or family was not only a public spectacle but also public theater, often a festive affair, a participatory ritual of torture and death that many whites preferred to witness rather than read about. Special excursion trains transported spectators to the scene, employers sometimes released their workers to attend, parents sent notes to school asking teachers to excuse their children for the event, and entire families attended, the children hoisted on their parents shoulders to miss none of the action and accompanying festivities. Children's responses to what they saw included an eleven-year old North Carolina boy who injured a white playmate during a make-believe lynching, and that of a nine-year-old who returned from a lynching unsatisfied, telling his mother, "I have seen a man hanged, now I wish I could see one burned.

This is a culturally based, culturally formed, culturally specific, culturally functional, culturally shared psychology that was generated by the cultural practices and values of racial etiquette. People without these practices and values would not have the same perceptions, emotions, motivations, desires, and reasoning processes.

A white Southern woman recounted a childhood incident that further expresses the cultural basis,

character, and function of perceptions, reasoning, and emotions. When she was 8 years old, around the turn of the century, she and a playmate were walking on a sidewalk and an 8-year old Negro girl did not get out of their way. "We did not give ground – we were whites!" When the black girl's arm brushed against her, she turned on her furiously saying, "Move over there, you dirty black Nigger" (p. 129).

The white girl's perceptions and emotions were informed by the racial etiquette that included investing the sidewalk (a cultural artifact) with cultural (i.e., racial and social) significance – sidewalks were symbolic of white people's authority and superiority, and blacks were supposed to yield even if it meant they had to walk in the gutter. These cultural facts generated (a) the white girl's perception that the black girl's behavior was wrong, immoral, and disrespectful, (b) her reasoning that she had a right to correct this problem, and (c) her emotion of outrage and aggression. Without the symbolic significance attached to the sidewalk and the sense of white privilege, the psychological reasoning, perception, and emotion would not have been elicited.

Another white boy of 10 reacted on the same basis of white privilege. A larger, older black girl did not give way to him on a sidewalk and he hit her hard in the stomach. He declared in his memoir "I wasn't ashamed." (p. 131). He wasn't ashamed because his racial status entitled him to hit blacks and encouraged him to do so in order to preserve the racial status. His lack of shame was culturally based and formed.

These examples testify to central tenets of cultural psychology: the fact that cultural practices and values determine the situations in which emotions are elicited, the kinds of emotions that are elicited, and the concrete quality of these emotions.

An interesting cultural quality of the racist anger was that it was directed at violations of the racial code (i.e., social status of whites and blacks); it was not a personal animosity directed at the black individual. Whites actually felt close to blacks in their everyday lives, allowing them to hold, feed, clothe, and play with their children, as well as cook the food for the adults. However, whites felt angry if a black momentarily brushed their arm on a sidewalk, or sat next to them on the bus for a few minutes! Clearly, this anger was not a personal animosity that felt blacks were dangerous,

diseased, or reprehensible individuals who should be always shunned. The discomfort and anger at blacks violating social rules was a kind of *social outrage*, a *structural racism* that treated the offender in terms of his impact on the social order, not his immediate impact on the white person which imperiled her personal safety. Nor was this anger a feeling of animosity directed at black personhood or individuality that would impede future close personal encounters between the black individual and the white person's family in other situations. It was a situational anger confined to the particular social situation that was challenged by the black's behavior.

Another example of the culturally specific quality of White psychology was the fact that most, if not all, of their perceptions, emotions, and cognitions about Negroes were informed by a superior, paternalistic, patronizing, snobbish attitude that they were inferior to whites in intelligence, morals, civilization, and emotional control. The anger of the 8-year white girl who became furious at the black girl on the sidewalk was a specific kind of anger that was tinged with white superiority and the expectation of privilege. Superiority was in the anger. Her anger was neither abstract, nor was it similar to other concrete forms of anger such as anger at a spouse for arriving home late, forgetting a birthday, or having an affair. These forms of anger are tinged with disappointment, sadness, betrayal, or a sense of being unloved, not with superiority that was manifested in the girl's anger. Conversely, the girl's anger had no elements of sadness, disappointment, betrayal, or sense of being unloved.

This psychology is nuanced by cultural values, rules, and practices. It demonstrates how psychology is organized by and permeated by cultural issues. It is fair to say that these cultural values, rules, and practices were the operating mechanisms of White psychology. They generated the perceptions and emotions in particular situations with particular culturally nuanced qualities.

The attitude of white superiority sometimes led whites to not become angry at certain black "misbehavior" and to tolerate it as normal, typical expected, unavoidable, even charming, and amusing – as long as it did not challenge the racial etiquette of white superiority. Having children out of wedlock, and even stealing things elicited no outrage or

disappointment from whites because (a) they didn't harm whites to any significant extent and did not challenge racial etiquette, (b) they were regarded as natural for such inferior creatures. Indeed, whites enjoyed seeing blacks "misbehave" because it provided vivid testament to white superiority, and it justified whites' domination of blacks.

This patronizing tolerance of black "misbehavior" was an ingredient in whites' self-concept. It generated a sense of self-pride, benevolence, tolerance, and altruism because they did not punish blacks in these cases. This benevolent, tolerant self-concept was based on a sense, and a power relation, of superiority, not on a sense of genuine caring and helpfulness. White sense of benevolence depended on the malevolence of enslaving blacks and patronizing them; however, this escaped the attention of whites. White self-concept thus had a distinctive quality, or content. It was not an abstract, pride, benevolence, tolerance, and altruism, nor was it a genuine benevolence, tolerance, and altruism that whites practiced toward other whites of their status.

The affection that whites felt for blacks was also permeated with racial superiority. It was a paternalistic, patronizing, arrogant affection that was generated by the behavior of blacks as dutifully deferential, minding their place. "We loved 'our Negroes' downward but expected them to love us upward." "My sense of fellowship with Negroes had an odd tie-in with my snobbery." Within these hierarchical limits, these whites felt their relationships with blacks were beautiful and that a special love and understanding existed between them and blacks. As soon as blacks became too familiar or uppity, this special love and understanding unraveled and the ruling class men and women quickly used force to restore their class dominance. This affection that embodied racial etiquette was a specific, concrete emotion quite unlike the affection that whites felt for other whites. This other kind of affection was more egalitarian and personal and did not incorporate the quality of hierarchical distancing that characterized affection for blacks.

The psychology of white-black affection was governed by the operating system of racial ideology. Their ideology structured their caring in a particular – superior – form; this same ideology blinded them from accurately perceiving the form their own caring took;

their ideology blinded them from accurately perceiving the social and psychological effects their racist caring had on black recipients; and this same ideology blinded them from perceiving its own existence as the operating system that was behind all of this – i.e., behind the structuring, and behind the blinding of them to the structure and to the structuring. Instead, the ideology made them believe that their caring was a natural, empathic response to the blacks.

A striking example of how cultural values and practices comprise the operating mechanism of psychological phenomena is an incident that occurred in the early 1950s in North Carolina. A white boy and his friends were playing basketball with some blacks, all around 12 years old. One of the white boys tried to inflate the basketball using a needle he took from a black boy named Bobo. The white boy put the needle in his mouth to wet it before inserting into the ball. As he put it in his mouth, he realized that Bobo had wet the needle a moment before. The racial element of this situation generated a powerful emotional and sensory reaction: “The realization that the needle I still held in mouth had come directly from Bobo’s mouth, that it carried on it Bobo’s saliva, transformed my prejudices into a physically painful experience. The basketball needle had become the ultimate unclean object, carrier of the human degeneracy that black skin represented. It transmitted to me Bobo’s black essence, an essence that degraded me and made me, like him, less than human” (Ritterhouse 2006, p. 128).

The boy delicately explains how his racial prejudice generated a physically painful sensation and emotion in him. His cultural thought about blacks became a sickening sensation in his body. The cultural concept became a psychological phenomenon. The psychology was continuous with the concept, it was a transformation of the concept into a psychological form. The two were two sides of the same coin. His prejudice was the operating mechanism of his sensation and emotion in that it generated their qualities in response to this particular situation.

His emotion and sensation were stimulated by the symbolic significance he attached to the basketball needle. The needle incarnated racist prejudice about black bodies and people, and the needle transferred this prejudice about black malevolence into phenomenological sensations and emotions.

A white woman, Sarah Boyle, recounts similar powerful, body-wrenching emotions that were generated by the racial code: “When a Negro didn’t ‘keep his place’ I felt outraged. My indignation was triggered by a sense of guilt. I had learned that equality with Negroes was WRONG, and that it was my fault if a Negro attempted them. Therefore, I was immediately on the defensive at the first hint of familiarity.” When a cleaning lady who had conversed with Sarah on numerous occasions called her Patty instead of Miss Patton, “I felt my entire interior congeal! A Negro had failed to call me Miss! *And I was a[s] guilty as she.* How unseemly my attitude must have been to invite to such a thing! I experienced a terrible wave of depression, mixed with a kind of horror of *myself.*”

The cultural-emotional dynamic consisted of first learning a cultural concept (code) that equality was wrong and was her fault for allowing it. This cultural instruction that it was her fault became a feeling of guilt. Guilt is the feeling that an action is one’s own fault, and this feeling is simply the other side of the coin of the cultural instruction that equality was Sarah’s fault.

Boyle’s narrative, like the previous one, is exceptional in indicating the essential equivalence of cultural prescription and emotion (akin to the essential equivalence of mass and energy). The cultural prescription was the operating system of guilt; it made guilt happen in response to particular situations. Culture is in the mind, subjectivity, mentality, consciousness, agency, psychology.

Furthermore, guilt is continuous with defensiveness, for if one feels guilty, one seeks to defend oneself from blame. Negroes’ “misbehavior” made her look bad and feel bad, so she became angry at the immediate situation that generated this discomfort. (She overlooked the real cause of her discomfort which is the cultural prohibition against equal behavior. It was more convenient and socially acceptable to blame the black behavior than the cultural prohibition. Prejudice may be said to result from ignoring macro cultural influences on behavior. Macro cultural psychology is thus an important way to overcome prejudice.)

Each of these slides into the other like the levels of a spiral seamlessly slide into one another and become new levels of the original. The cultural prescription slides into guilt which slides into defensiveness which slides into anger.

Anger is not an independent thing that simply becomes conditioned to (associated with) blacks acting uppity. According to conditioning theory, culture functions like a kind of switch that simply links anger (as a given thing with natural, intrinsic, universal qualities) to black behavior. However, this psychological theory is wrong. Culture is not a switch that connects natural psychological processes to particular situations. On the contrary, cultural conditioning molds psychological phenomena to cultural factors. Culture makes psychology (anger) cultural, and imbues it with a specific cultural quality. Anger is converted into culture, it is not simply associated with culture.

Whites' anger at black people was the result of a net of assumptions and understandings about black peoples' psychology, nature, and cultural level which were internalized from the cultural code. These cultural assumptions became located within Sarah's "psychological infrastructure," forming it. Furthermore, white anger was not an immediate, quasi-physiological reaction to black misbehavior; it was the result of a string of spiraling transformations of a cultural prescription from guilt to defensiveness to anger. The prescription was therefore the operating system of anger that made it happen in response to a particular kind of situation. The situation itself, i.e., black behavior, did not mechanically generate anger by being moved into a proximate connection with anger. It only generated anger via the cultural prescription against equal behavior.

Behavioral theories, such as conditioning, which are drawn from simple animal behavior do not suffice to apprehend cultural psychological phenomena and must be replaced by a new cultural psychological theory. Whites' fury at black infractions was not an extension of a natural anger that all animals have. It was not a natural anger associated with a particular situation. The anger was a social anger, formed by social processes and incorporating social characteristics.

The cultural code of etiquette was also the operating system of Sarah's perception. The code oriented her to look inward at her behavior for the cause of blacks violating racial etiquette; it oriented her away from perceiving the oppressive Jim Crow system as the cause of blacks' resentment and resistance. The code also led her to regard "misbehaviors" of blacks as natural deficiencies on their part.

These examples reveal that the cultural code determines (a) the kind of situation in which an emotion (or perception or self-concept) is elicited, (b) the strength of the emotion, (c) kind of emotion – anger, guilt, or depression, (d) the concrete quality of the emotion – tinged with superiority or egalitarian, (e) the dynamic of the emotion – how it is generated through concepts and related psychological phenomena (e.g., surprise, looking inward, feeling guilty, hating oneself, feeling defensive, feeling angry).

The cultural code is thus not an external, secondary "influence" on some inner "basic" processes of emotion. The cultural code is the mechanism of emotions and perception. It is central to them, inside them, and constitutes their basic processes.

Another cultural feature of the psychology implicated in racial etiquette was the manner in which it was socialized. Interpersonal socialization practices reflected macro cultural factors. Mothers were the primary agents of racist socialization because they were the primary caretakers. Since the social system was racist, the female socializers of children inevitably socialized racism in their children.

A searing example of maternal socialization of racism occurred when Sarah Boyle's mother responded to Sarah's unhappiness over a servant's telling a lie. Her mother said, "We never do [lie]. Rosemary is a Negro. They aren't like us. Promises don't mean anything to them." Her mother's statement socialized Sarah into the Jim Crow belief system: "I don't think I ever again – that is, never until I became integrated at the age of about 45 – expected the truth of a Negro, or held one fully accountable as I would a white person, for telling me a lie. Another stone in my inner segregation wall had been cemented firmly in place."

Micro level interpersonal interactions should not be idealized as a purely personal realm beyond macro cultural forces. Quite the contrary, macro forces are implemented in interpersonal relations. White domination was implemented in small, mundane ways such as a calculated bump with a shoulder, or calling blacks "boy," or demanding blacks tip their hats, or requiring them to use the back door to enter a white house.

Micro level interpersonal interactions must recapitulate macro practices in order to inscribe subtle habits which will be conducive to accepting and participating in macro cultural practices. If micro level interactions

contradicted the macro level, people would question, resent, and deviate from macro norms. Psychogenesis can never be free of, or contradictory to, macro cultural factors.

The socialization of racist psychology and behavior was a two-step process. White parents allowed their children to play with certain black children and to treat their black nannies as surrogate mothers. However, as adolescence approached, parents indicated to their children that they must distance themselves socially and emotionally. This was a specific cultural pattern of socialization that led to a specific emotional outcome vis a vis certain groups of people but not others.

Importantly, the adult structure of life overrode the innocent, playful interactions of childhood. These positive experiences of childhood did not immunize white youth from falling into the adult molds of segregation and discrimination. “For the vast majority, the ‘forgotten alternatives’ of childhood interactions remained forgotten” (Ritterhouse 2006, p. 163). As Boyle said, “These incidents were little centers of genuine truth and experience which remained sealed off by my indoctrination and training, unable to permeate and purify my overall conception of the Negro people and their situation in the South” (Ritterhouse 2006, p. 43).

This is a powerful statement about the power of culture to shape one’s cognition, perception, and agency, and to override direct positive experience with individuals.

Accounts of socialization during the Reconstruction period reveal an additional interesting cultural pattern. Psychological socialization was generally implicit in the sense that parents simply acted out racial etiquette and children imitated them without any particular instructions or explanation. Social life was structured to enforce racism, and explicit, verbal instructions were generally unnecessary. This made it difficult to identify racism because it was rarely explicit. “We were given no formal instruction in these difficult matters but we learned our lessons well. We learned the intricate system of taboos, of manners, voice modulations, words, feelings, along with our prayers, our toilet habits, and our games” (Ritterhouse 2006, p. 131).

Instructions were only given to children when they breached the etiquette, e.g., by being too friendly with blacks and not manifesting sufficient distance and superiority. One case was Lewis Killian’s experience in

Georgia in the 1920s. When a black woman came begging at his front door, he rushed to tell his mother “There’s a lady at the door.” His mother spoke with the woman and afterward she rebuked Lewis: “You should have told me that was a colored woman. Ladies are white!” (Ritterhouse 2006, p. 80).

The fact that interracial play was tolerated among children testifies to variability in the racist system. It was not monolithic and absolute. Alternatives were present. However, these alternatives were circumscribed physically and temporally. They were closed off in adolescence as whites and blacks settled into their adult positions in the racist social structure.

Moreover, after the informal interactions were closed off in adolescence, it was necessary that they be overlooked and repressed or forgotten so as not to contradict adult norms and raise questions about them. Perception became desensitized to discrimination as it became normalized. “I went along,” one white woman recalled, “I wasn’t very interested in race at all. I didn’t see any segregation or discrimination or anything else” (Ritterhouse 2006, p. 161).

This demonstrates that memory/forgetting is also a cultural phenomenon. It has a cultural origin, character, operating system, and function. Its cultural character (content) was forgetting non-racist alternatives from childhood. Forgetting selectively forgot according to cultural rules. Cultural rules made selective forgetting happen.

Forgetting’s cultural origin lies in racist etiquette that demands alternatives be foreclosed. Parents insisted on terminating interracial play and relegating it to an insignificant episode of childhood unreality. In addition, the entire structure of white society drew whites apart from blacks and made earlier play psychologically insignificant.

- After a certain amount of confusion, frustration, and even defiance, most children accept ‘the way we do things’ without question, especially when ‘the way we do things’ works to their advantage, as white supremacy worked to the advantage of whites. Interracial play and other forms of childhood racial contact did offer alternatives to a social pattern scripted by racial etiquette, but because they were stacked against the incentives of parental love and white peer-group acceptance, not to mention personal pride and other

possible gains in status, the emotional attachments of childhood were fairly easy to “forget.” (Ritterhouse 2006, p. 164)

Forgetting’s cultural function was to promote racism as the only conceivable life style (Ritterhouse 2006, p. 9).

- ▶ It was easiest to repress and ‘forget’ one’s fear or guilt or even one’s unacceptable affection for a black nurse or playmate. That was what most white adults counseled, usually implicitly rather than explicitly and often by invoking racial etiquette. In a society in which adult white southerners energetically repressed any political alternatives to white supremacy, despite their own stated beliefs in Christian and democratic values, forgetting was also what made the rest of a white child’s world comprehensible, his or her most important relationships with family and friends sustainable. (Ritterhouse 2006, p. 178)

In other words, forgetting early positive interactions with blacks, and also forgetting guilt over abandoning them in adolescence under the pressure of racial etiquette, enabled white children to accept the exclusiveness of their white adult social world. Memory thus had, and has, a cultural function of sustaining (acceptance of) social norms.

Agency was also constrained by racial etiquette and functioned to uphold it. As one white man recollected, “At the age of ten I understood full well that the Negro had to be kept in his place, and I was resigned to my part in that general responsibility” (Ritterhouse 2006, p. 167). Lillian Smith recounts how she used her agency to serve Jim Crow by actively adjusting her psyche to participate in the racial code that framed her life: “I learned to believe in freedom, to glow when the word democracy was used, and to practice slavery from morning to night. I learned it the way all of my southern people learn it: by closing door after door until one’s mind and heart and conscience are blocked off from each other and from reality.”

All psychological phenomena have this social function. Racial etiquette could not have been maintained if blacks and whites had not developed appropriate perceptions, cognitions, motivations, emotions, and self-concepts to participate in it. If whites had developed an egalitarian, personal affection for blacks, they would

not have treated them in a patronizing, dominating manner. Their emotional affection had to contain the paternalism of racist social relations in order for those social relations to be maintained. Whites’ sexuality had to embody racist overtones in order distance them from blacks. Whites’ perceptions and cognitions of blacks had to incarnate a sense of their inferiority in order to justify discriminating against them. Whites’ memory had to selectively forget alternatives to racial etiquette.

This vivid historical example demonstrates that psychology is generated by cultural factors, its character/quality/content is cultural, it is formulated within cultural factors to construct cultural factors, its locus is in cultural factors, it is permeated by the class structure and politics of cultural factors, and it functions to maintain cultural factors (social institutions, cultural artifacts, and cultural concepts). Psychology is not a separate, internal, natural, or individual phenomenon.

Psychology has distinctive, subjective qualities that differ from objective qualities of macro cultural factors. Psychology is different from a classroom, it is different from a gun, it is different from the CIA and World Bank, it is different from the concept of family honor. This is why psychology deserves to be studied as a distinctive phenomenon. However, this study must emphasize the concrete cultural origins, character, and function of psychology which all permeate its subjective quality. This is what Ritterhouse does so masterfully, and what psychologists should imitate.

Neoliberalism

The elements of cultural psychology that are evidenced in racial psychology may be extended to a contemporary cultural phenomenon, neoliberalism. Neoliberalism is a central cultural force of our times. Its impact on psychology must be powerful, since psychology is an element of cultural factors. To understand the psychology of contemporary people, the manner in which it is organized by the pervasive neoliberal culture must become an important focus of study. This section will explore the objectives and content of neoliberalism and how it is institutionalized in our society. This in-depth analysis of its character and scope is necessary for generating constructs that can apprehend (explain, describe, predict, and improve upon) psychology in a neoliberal environment.

Neoliberalism is the brainchild of the Mont Pelerin Society, which was founded in 1947. The Society was formed with business funding to counteract liberal economic and political ideas of Keynes, Laski, and others. It sought to create a transnational network of academics and professionals to promote their image of the market as the central agent in human society, and thus shift government focus from public welfare to market creation and protection. Its first President (1948–1960) was the Austrian economist Friedrich von Hayek. Other early members were Karl Popper and Milton Friedman who was president of the Mont Pelerin Society from 1970 to 1972.

- ▶ Neoliberalism brings together the classical liberal economic faith in the ability of properly functioning markets to improve social welfare with a new political commitment to expand market relations into traditionally public arenas such as healthcare, education, and environmental management. As it developed after World War II, neoliberalism diverged from classical political liberalism by renouncing the passive notion of a *laissez-faire* economy in favor of an activist approach to the spread and promotion of ‘free markets’. Contrary to classical liberalism, neoliberals have consistently argued that their political program will only triumph if it becomes reconciled to the fact that the conditions for its success must be *constructed*, and will not come about ‘naturally’ in the absence of concerted effort. This had direct implications for the neoliberal attitude towards the state, as well as towards political parties and other corporate entities that were the result of deliberate organization, and not simply unexplained ‘organic’ growths. ‘The Market’ could not be depended upon to naturally conjure up the conditions for its own continued flourishing. It needed a strong state (divested of its unnecessary social welfare encumbrances) and the backing of international institutions such as the World Bank and the IMF to take its proper place in the neoliberal order. (Lave et al. 2010, pp. 660–661)

Neoliberalism was and is a concerted, coordinated, sweeping effort (culture) to expand capitalist economic principles to every sector of society (Mirowski and Plehwe 2009; Schulman and Zelizer 2008). This expansionist sweep extended to governmental institutions (including the judiciary), education, medicine, news

media, sports, scientific research, religion, national security, and exploring outer space. All of these sectors have been privatized, or turned over to capitalist enterprises which run them for their own profit, and to further their of privatization class hegemony over society. This occurred by depleting the country. A representative of the conservative American Enterprise Institute acknowledged that this corporate looting exploits working people and hamstring the economy: “Corporations are taking huge advantage of the slack in the labor market – they are in a very strong position and workers are in a very weak position,” he said. “They are using that bargaining power to cut benefits and wages, and to shorten hours.” That strategy serves corporate and shareholder imperatives, but “very much jeopardizes our chances of experiencing a real recovery” (New York Times, Jan. 9, 2011, p. WK4).

There has been a staggering rise in income inequality that is skewed toward the rich. In 1977, an elite chief executive working at one of America’s top 100 companies earned about 50 times the wage of its average worker. Three decades later, the nation’s best-paid C.E.O.’s made about 1,100 times the pay of a worker on the production line. (Similarly, the share of national income accruing to the top 1 percent of the Chinese population more than doubled from 1986 to 2003.) Inequality has even increased among the very rich. A study of pay in the 1970s found that executives in the top 10 percent made about twice as much as those in the middle of the pack. By the early 2000s, the top earners made more than four times the pay of the executives in the middle. This hegemonic domination of the ruling class makes it difficult for the lower classes to challenge the ruling class economically and politically. Neoliberal dominance is associated with low economic mobility. There is a 42 percent chance that the son of an American man in the bottom fifth of the income distribution will be stuck in the same economic slot. The equivalent odds for a British man are 30 percent, and only 25 percent for a Swede.

The hardening and widening of class division that neoliberalism institutionalized in the 1970s was abetted by mass incarceration that targeted the lower class. Thus, incarceration rates of white and black college-educated males did not increase, however, the rate for black and white men (combined) who did not finish high school increased three times from the 1970s to the

year 2000. The importance of social class is revealed in the statistic that whites with a high school education are imprisoned 20 times as often as those with a college degree. Mass incarceration causes poverty, because it deprives families of potential wage earners, it decimates family life which increases the odds of children's social failure, and it prevents ex-convicts from obtaining well-paying jobs. Mass incarceration also obscures poverty because inmates are excluded from unemployment figures. Mass incarceration also facilitates conservative, neoliberal political victories because it disenfranchises poor and minorities who usually vote for Democratic politicians (New York Review of Books, April 12, 2007, pp. 33–36).

The increasing hegemony of the ruling class also stifles economic growth. Every decade since the 1960s has witnessed a decline in the rate of GDP growth (4.4% in 1960s, 3.3%, 3.1%, 1.9% from 2000–2009), a decline in the share of national wealth that goes toward people's wages, and an increase in the unemployment rate. Since 1980, the country's gross domestic product per person has increased about 69 percent, as the share of income accruing to the richest 1 percent of the population jumped to 36 percent from 22 percent. But the economy grew much faster – 83 percent per capita – from 1951 to 1980, when inequality declined. Stagnation of the capitalist system is further revealed in the slowness of recovery from recessions: After the 1990–91 recession, it took 23 months to add back the jobs lost. After the 2001 recession, it took 38 months. (And this recovery was fueled by one of the great housing and credit bubbles in American history which is unavailable any longer).

At the current rate, the economy will need 72 to 90 months to recapture the jobs lost during the Great Recession (New York Times, Jan. 9, 2011, p. WK4).

Neoliberal policies such as NAFTA eliminated around 1 million American jobs according to the report “NAFTA at Seven,” from the Economic Policy Institute. Economic stagnation of capitalism is what led to massive borrowing to finance projects (mostly financial speculation rather than fixed investments), and living standards. From the 1970s to 2005, total outstanding debt in the United States leapt from 1.5 times the GDP to 3.5 times the U.S. GDP, close to the \$44 trillion world GDP. These facts reveal the lie of neoliberalism that it enhances economic growth and

the freedom of the individual (New York Times, Dec. 27, 2010, p. BU1).

One telling example is research laboratories at major universities being funded and controlled by big oil and pharmaceutical companies. An examination of ten contracts between leading oil companies and major universities, worth \$883 million over 10 years, revealed the following details of corporate dominance over scientific research.

- In nine of the ten energy-research agreements, the university partners failed to retain majority academic control over the central governing body charged with directing the university-industry alliance. Four of the ten alliances actually give the industry sponsors full governance control.
- Eight of the ten agreements permit the corporate sponsor or sponsors to fully control both the evaluation and selection of faculty research proposals in each new grant cycle.
- None of the ten agreements requires faculty research proposals to be evaluated and awarded funding based on independent expert peer review, the traditional method for awarding academic and scientific research grants fairly and impartially based on scientific merit.
- Eight of the ten alliance agreements fail to specify transparently, in advance, how faculty may apply for alliance funding, and what the specific evaluation and selection criteria will be.
- Nine of the ten agreements call for no specific management of financial conflicts of interest related to the alliance and its research functions. None of these agreements, for example, specifies that committee members charged with evaluating and selecting faculty research proposals must be impartial, and may not award corporate funding to themselves. (see Jennifer Washburn, “Big Oil Goes To College,” Center for American Progress, http://www.americanprogress.org/issues/2010/10/big_oil.html; see also G. Bowley “The Academic-Industrial Complex, *New York Times*, Aug. 1, 2010: <http://www.nytimes.com/2010/08/01/business/01prez.html?scp=1&sq=university%20industrial%20complex&st=cse>).

Neoliberalism has been as aggressive, expansionist, and hegemonic a social force as the Roman Empire and

Catholicism were. It is a top-down movement that is directed by wealthy capitalists through a maze of private and governmental organizations which influence policy and propagandize the populace (Lazzarato 2009; Stack 2009; Mayer 2010). It is not an accretion of individual behaviors, as classical free market economists, and individualistic psychologists, propose (Note 2).

The culture of neoliberalism entails a psychology – which Foucault called pragmatics of subjectivity, or technology of self that is formed by subjects under cultural pressure (Dean 2009; Miller and Rose 2008). One element of “neoliberal psychology” is violence. More than 30,000 people die from gunfire every year. Another 66,000 or so are wounded, which means that nearly 100,000 men, women and children are shot in the United States annually. Another one element of “neoliberal psychology” is insecurity. “Contemporary policies regarding employment, for example, ‘workfare,’ which forces those in receipt of assistance to work, are *policies that introduce degrees of insecurity, instability, uncertainty, economic, and existential precarity into the lives of individuals*. They make insecure both individual lives and their relation to the institutions that used to protect them. It is not the same insecurity for everyone, whatever the level and conditions of employment, yet a differential of fear runs along the whole continuum.” “Neoliberal politics operate a reversal of institutions of protection into apparatuses that produce insecurity” (Lazzarato 2009, pp. 119–120, 128, my emphasis). Work in capitalism is increasingly insecure in the sense that it is less protected by extended contracts, is less permanent, and more contingent. Employees (except for key personnel) become interchangeable, disposable, recallable, and transferable. Workers in high-paid, high-skilled jobs such as factory work have been terminated in droves and forced to accept unskilled, low-paid employment. The new neoliberal social organization consists of a “micro politics of insecurity” which is simultaneously a cultural psychology of insecurity.

The winner-take-all paradigm of neoliberalism, which enriches and empowers dominant members of the ruling class, generates a psychology of resignation, resentment, and cheating among the losers who have little hope of success (New York Times, Dec. 26, 2010, p. BU 1). This psychology would be inexplicable

without knowledge of neoliberalism’s structure described above.

Neoliberal culture also requires and fosters a new kind of commodified self. Foucault took up this topic with his usual perceptiveness. Lazzarato (2009, p. 121) explains it as follows:

- ▶ Foucault’s analysis allows us to understand the role of capitalization as one of the techniques in the transformation of the worker into ‘human capital’ in charge of his/her own efforts to manage him/herself according to the logic of the market. The individual is an “enterprising self.” The individual becomes a ‘capital-competence’, a ‘machine-competence’; he or she cannot become the new *homo oeconomicus* without being ‘a lifestyle’, a ‘way of being’, a moral choice, a ‘mode of relating to oneself, to time, to one’s environment, to the future, the group, the family.’

Foucault observed that the individual becomes an entrepreneur not simply of businesses, but of herself. As ‘entrepreneur of herself, the individual maximizes herself as ‘human capital’ in competition with all other individuals (Lazzarato 2009, p. 111). This is a pregnant statement because it states that people have internalized the commodification of people (labor) and treat themselves in the same way employers treat them, namely as human capital that is instrumentally used in economic relations to generate profit. People develop themselves into human capital so as to become profitable in that system. People do not passively suffer being commodified; they practice/institute commodification on themselves; they are agents of commodification. Commodification is the *habitus*, or *dispositif*, of individuals. Agency has thus become commodified. Agency does not stand outside society and resists it so as to express an autonomous individual. On the contrary, agency acquires cultural forms. In this case, it takes the form of entrepreneurship toward oneself.

The neoliberal, individualistic self-concept structures one’s emotions, actions, worldview, and politics. In the year 2,000, 137 people who had been affected by neoliberal cutbacks were interviewed. Most of the subjects accepted individualistic neoliberal ideology and held themselves responsible for their plights. Accordingly, few expressed outrage, i.e., at the political economy. Nor did they engage in political action to improve the political economy. Even individuals who had gone

to school to train for a job, and had worked hard getting and holding a job, reacted to displacement with doubt about their own decisions and motivation rather than anger at the power elite. Few of the displaced individuals emphasized structural factors and politics as responsible for their plights. Conversely, successful individuals prided themselves on their foresight and motivation. The never acknowledged social factors that contributed to their success. This is an important example of how psychology (of self) depoliticizes behavior by ignoring macro cultural factors, and by generating emotions that blame the individual (e.g., self-doubt) rather than blaming cultural factors (e.g., anger).

These individuals did not resist, negotiate, modify, or transcend prevailing neoliberal ideology and psychology (Braedley and Luxton 2010, chap. 8).

This neoliberal individualistic self-concept, with its notion of personal choice and responsibility, has permeated the notion of agency. Social scientists embrace individualistic agency because they construe it as peoples' liberatory capacity to resist, negotiate, and modify cultural factors. Ironically, individualistic agency/self impedes understanding, critiquing, and modifying cultural factors, because they are perceived as outside the individual realm where they neither affect the individual nor are affected by him. Consequently, Interviewees who espouse the individualistic self concept manifest significant helplessness, fatalism, and resignation. Individualism breeds a sense of reification and fatalism. Individualism, i.e., agency, cannot resist and transcend capitalism because it is a product of capitalism. One can only imagine that the individualistic self/agency transcends capitalism if one ignores the (capitalist) social basis of the self and agency and misconstrues it as being a personal or natural construct.

Neoliberal cultural psychology is organized and socialized by the various elements of the social system. Education is a major socializer of neoliberalism through its central role of teaching children how to think and learn and conceptualize things. Neoliberalist political economy has transformed higher education in line with capitalist principles: "the commercialization of education is a 'global' phenomenon, driven by international policy concerns through international institutions such as the World Trade Organization." "Within the UK, this trend toward higher educational reform

has been developed through a number of government policy initiatives and commissioned reports." Within the USA, Obama has reinforced Bush's neoliberal agenda to privatize schools (along with the military, space exploration, health care, the media, etc.). Specifically, "the neoliberal. commercial model is an 'instrumental' education, in the sense that it is about the development of human resources and economic prosperity much more than notions of personal achievement, growth and fulfillment and the promotion of education for the social good." (Lambert et al. 2007, pp. 526–527).

This economistic, sense of education is reflected in the reduction of education to preparing for quantitative, rote memory tests. Neoliberals use the procedure of testing for knowledge as an insidious means to re-engineer the entire pedagogical process in accordance with the capitalist political economy. Pedagogy becomes narrowed to simple, formulaic concepts that can be regurgitated on standardized tests. Testing-oriented pedagogy reduces critical, conceptual reasoning and explanation that cannot be readily measured. It reduces education and knowledge to a quantitatively measurable commodity. In this way, knowledge and thinking become compatible with neoliberal capitalism. A key link in this synchrony is the industrialization of grading standardized school tests. Standardized testing across school districts, cities, or states is scored and graded by a few multinational corporations. One of them, Pearson, owns the Financial Times, The Economist, Penguin Books, and Prentice hall publishers. These corporations employ thousands of part time employees to work in centers. Employees receive the tests electronically and score them individually in cubicles. There is no social interaction or communication at work. Employees are former security guards, office workers, anyone with a bachelor's degree. When work slows down, they are given two hours' notice that the work will end and they are terminated. Even the offices and computers are leased temporarily. Scorers earn 30–70 cents per paper; at 30 cents they must score 40 papers an hour to earn \$12 per hour. This piece rate incentive system encourages scorers to score rapidly with little involvement in order to maximize pay. Scoring standards are passed onto scorers by company leaders, and if scores deviate from a pre-determined scoring curve, the scorers are instructed to increase

or decrease the grades. With test scoring made into a for-profit industry, the tests must be congruent with this process. In other words, the test scoring industry is synchronous with the test format. The “MacDonalidization” of test scoring reaches back to affect test construction. Only a superficial, quantitative test can be scored profitably in the scoring combine. Test construction and test scoring are commodified industries which complement each other. And this entire corporatized, standardized testing industry acts back to structure teaching pedagogy. It thereby structures the educational psychology of students. A common response to the question “What is one of your life goals?” is “to talk less in class” and “listen to the teacher” (DiMaggio 2010). Culturally formed thinking, learning, and motivation then find comfort with commodified products and relations; they function smoothly within capitalist products and relations, and they desire them as well. They find non-commodified phenomena too demanding, complicated, and dull.

Neoliberal policies are restructuring education in line with the needs of contemporary capitalism (Ravitch 2010; Packer 2001). As work becomes increasingly deskilled under the domination of technology and management, sophisticated education is less necessary. Today in Britain, well over 80% of work is in service sector jobs that are dominated by low-grade and poorly paid occupations in the healthcare, hospitality, cleaning, fast food, catering and retail sectors. Sophisticated education is dysfunctional for this economy. It would lead to “unrealistic” aspirations among the populace and cause them to feel resentful and rebellious about their low social position. Neoliberal policies are curtailing education to conform to the political economy. The conservative government in Britain, in 2010, has drastically cut funding for higher education. Neoliberalism exacerbates inequality, exploitation, and consumerism (Braedley and Luxton 2010). All the sentimental waxing by the capitalist class about the need to strengthen education to remain competitive in the world economy is sheer rhetoric. Nowadays, educated individuals cannot find jobs at their level and are forced to take unskilled jobs for which they are overqualified. At the very moment that capitalists are curtailing the need for high-skilled, high-paid employment, and are promoting policies that reduce

government spending on education, they pretend that they are creating jobs that require a well-educated work force. This shifts the problem from their neoliberal policies to deficiencies in the populace who do not educate themselves, or to deficiencies in teachers who are not educating students to take advantages of the high skilled that the capitalists are supposedly creating. But if these jobs exist, why are educated people taking unskilled, low-paid jobs? In fact, the limited need for educated employees can be met with a few elite universities in the home country, and supplemented by importing educated employees from abroad. Even educational expenses are outsourced in this manner, as foreign countries (India, Iran) expend their resources to educate employees that eventually work for capitalists in the first world countries (Note 3).

The neoliberal form of education entails a corresponding psychology of self, cognition, and conceptualizing things. Other people, the self, and natural objects and animals tend to be conceptualized as commodified resources to be used instrumentally for exchange and profit. The “use-value” of people, animals, and things is subordinated to their exchange value. Neoliberal education also has profound implications for the motivation, attention, dedication, and understanding of material by students in school. Students tend to treat education as an instrumental means for their own social status and material income. They will focus more on superficial ways that knowledge and educational resources can be exploited rather than on deeply understanding them. They will try to maximize their educational outcome (measured in grades) and minimize their psychological input, in keeping with the neoliberal business model. Students will favor simple, quantitative evaluation of their work because the criteria are easy to understand and meet. In contrast, more conceptual demands for comprehending material are difficult to achieve and less clear-cut to evaluate. All that complexity is anathema to neoliberal efficiency and productivity which students come to embrace.

“Neoliberal cultural psychology” is organized by neoliberal political economy, and it reciprocally enacts neoliberal culture. Students’ educational psychology reinforces neoliberal education and neoliberal culture in general. Armed with neoliberal psychology makes students into agents of neoliberalism, just as consumer psychology makes consumers into agents of

consumerism. This is the reason that psychology is culturally organized. Culture needs psychology to enact cultural behavior that sustains a particular social system.

The cultural psychology of the instrumental, commodified self, instrumental-commodified cognition, and insecurity is built into the social organization of our dominant macro cultural factors. At the same time, this cultural psychology is often obfuscated by official pronouncements that claim to be ensuring our security, personal growth, fulfillment, and social interactions. The culture thus mystifies people about itself. Mystification is built into cultural praxis (Note 4).

The case study of neoliberal psychology illuminates and verifies the principles of cultural psychology. Like the example of racial psychology, it shows that psychology is part of cultural factors. It is the subjective side of cultural factors that animates them. Psychology is contained in cultural factors such as neoliberal policies and practices. This psychology is objectified and objective, as well as objectifying of experience. It is formed by cultural factors and takes on their features. For instance, insecurity is a social condition of neoliberal political economy in the sense that people objectively have little security in their jobs, pensions, investment; they are thrown into perpetual competition where they can always lose, and they are pawns in the movement of capital to more lucrative returns (Note 5). This social insecurity takes a psychological form. People subjectively feel insecure. They are anxious and uncertain about their future. One symptom of this is that young adults are postponing marriage and commitment because they are uncertain about their geographical, social, and financial future. For the first time, more Americans aged 25–34 are unmarried than married. This subjective sense of insecurity is the subjective side of social insecurity. (Of course, mainstream psychologists and psychotherapists ignore this and concentrate on identifying personal or biological causes of insecurity and anxiety.)

Psychological insecurity is both generated by the social state of insecurity and it is a way of coping with this state. Psychological insecurity and uncertainty has become normalized as “that’s how life is,” and a lifestyle has been created around it: “I don’t know what I’ll do after I graduate; I’m just looking forward to what life will bring me.” “I’m not sure if I can hang out with you

tomorrow since something might come up, but I’ll text you if I can.” Adapting to, and enacting, psychological insecurity is culturally functional (and conformist) in that it prepares people for expecting, accepting, and participating in social insecurity and the cultural factors that underlie it.

Cultural practices are utilized as templates of normal behavior. The precariousness of neoliberalism is recapitulated in personality attributes such as being “flexible,” “adaptable,” “tolerant of ambiguity,” and “multitasking.” These are a cultural technology of the self (as Foucault would call it) that is the subjective accommodation (acquiescence) to neoliberal political economy. Normalized psychology normalizes (facilitates) its social basis. Extolling uncertainty and uncommitment as “cool” is to extol neoliberalism as “cool” because uncertainty – in our time – is a symptom and a prop of neoliberalism.

Mental Disturbance

Cultural practices and psychology of society may be debilitating. This is certainly true in neoliberal society. Insecurity, competition, alienation, continual acquisitiveness and materialism, impulsiveness, and continual distraction by competing products take their toll on people (as research demonstrates). This toll consists of impeding other behaviors that are socially and psychologically desirable. The foregoing cultural practices impede generosity and altruism, accepting advice from others, thoughtfulness, and concentrating on a particular task. For instance, consumerism constantly distracts us by prodding us with myriad ads and products that vie for our attention and money. We are supposed to continually look for new products and be attracted by superficial features to forsake older products and impulsively buy new ones. Internet search engines such as Yahoo, and sites such as MySpace and The Huffington Post, distract concentration by providing hyperlinks that draw attention away from what one is reading to numerous extraneous web pages – the reason for this is that the sites receive advertising revenue for every click that viewers make on the hyperlinks. Many web users report a drop in their ability to finish reading a single work because of being attuned to distracting hyperlinks. This distraction is compounded by multitasking at work so that every moment and space is constantly productive (i.e., generating capital).

Workers are required to shift between several tasks at a time in order to be as productive/profitable as possible and never “waste” a moment. People conduct business using cell phones while going to the bathroom! Profit-generated multi-tasking at work and in consumerism has become a cultural icon and is carried over into personal time where people feel excited talking to one set of friends on the phone while having dinner with another set of friends. Deep involvement (attention to) in one activity is diluted through this transient involvement (attention) in multiple activities. Yet, culture also insists that we concentrate and follow through on tasks – pay attention in school, avoid distractions, keep to commitments.

Similarly, the individualism and materialism of consumer capitalism impedes social solidarity, altruism, concern with personal issues, and social support. (Milton Friedman said, “So the question is, do corporate executives, provided they stay within the law, have responsibilities in their business activities other than to make as much money for their stockholders as possible?” And my answer to that is, “no they do not.” In fact, the “corporate system,” say analysts, “has no room for beneficence toward employees, communities, or the environment.”) Yet people are expected to be benevolent, caring, and supportive.

This contradiction between competing social values is epitomized in the contradiction between cultural aesthetic ideals of a slim body and the ubiquitous plying of junk food to people.

The contradiction between competing social values places people in untenable situations. Accepting one of these values makes it difficult to achieve the other. Dieting to achieve a slim body fails because it is contradicted by the ubiquitous presence of junk food temptations.

This untenable state of affairs that tears people in conflicting directions and makes success difficult, is a pathological feature of the society; a social pathology. Eric Fromm (2010) calls it “a socially patterned defect” or “the pathology of normalcy.” Rieber calls it “psychopathy of everyday life.” I call it “the psychology of oppression.”

As oppressive practices and psychology become more intense and extensive, and as they impede achieving more positive cultural ideals which formerly mitigated them, more people become more seriously

impaired. Insecurity, distraction, impulsiveness, hyperactivity, competitiveness, egoism, acquisitiveness, and materialism become uncontrollable and dysfunctional as people become increasingly bereft of social support, solidarity, commitment, coherence, and the concentration necessary to master skills. Psychological disorder reigns in accordance with social disorder. Today, as much as one-third of the American population takes (legal) psychotropic drugs to palliate its social-psychological stresses.

Forty-six percent of college students said they felt “things were hopeless” at least once in the previous 12 months, and nearly a third had been so depressed that it was difficult to function, according to a 2009 survey by the American College Health Association. In recent years, more than 1,000 depression screenings were given to students, with 22 percent indicating signs of major depression. (New York Times, Dec. 20, 2010, p. A1).

Perversely, psychological disturbances are treated at the individual level by punishing and controlling individual behavior. The social pathology at the heart of psychological problems is ignored. In addition, false claims of biological etiology deny social causes. This, of course, makes treatment inadequate.

For example, hyperactive people are treated so that they can concentrate on tasks, while still participating in consumer culture with all of its distractions. Hyperactive people are expected to concentrate their attention in school and work while simultaneously attending to myriad advertisements, shifting their attention among competing products, superficially skimming magazines for whatever strikes their fancy, feeling bored when not stimulated by novel sensations, waiting passively for new external stimulation and sensations to energize behavior, shifting tastes to accommodate external stimulation (from marketers and also peers), and impulsively buying whatever they feel like at a moment’s notice. Hyperactives are never directed to understand or renounce these cultural demands which are the root of their hyperactivity. There is no concern about forming new cultural factors that would stimulate and support virtuous practices. Consequently, the roots of pathological behavior persist and undermine individual efforts to practice virtuous behavior.

In the standard approach of treatment, individuals are supposed to find inner strength within themselves,

in the form of psychological strategies of concentration, dieting, anger management, or emotional expression, to act in fulfilling ways. Yet pathological practices are institutionalized in neoliberal cultural factors. In this struggle between administered, funded, organized institutions, and isolated individuals, it is clear which side will be victorious and which will lose.

People are not treated so as to be free of impulsive-ness, fickleness, insecurity, alienation, competitiveness, egoism, materialism, and other debilitating values and actions – for that would require a social consciousness and social activism that would challenge the debilitating, neoliberal status quo. People are encouraged to use psychological strategies to manage themselves to endure (cope with) normal social and psychological life with all its debilitating features.

This trend of psychiatric treatment demonstrates that normal world of social practices determines how people are treated by the helping professions. “Help” is not a generic abstraction. It is informed by concrete cultural qualities that reflect and reinforce the social system. The helping professions may be as corrupted by the broad culture (political economy) as any sector is.

Psychological treatment takes the form of pep talks that extol the virtues of the status quo and encourage compliance to it. Treatment also takes the form of teaching coping skills to manage taken-for-granted, “normal” insecurity, alienation, egoism, competition, materialism, and distraction, so that one can concentrate on mastering tasks, having close personal relations, honoring commitments, and being well informed and socially active.

A more common tactic is to desensitize people to the conditions which generate their disease. Medication is the prime means of doing this. Psychotropic drugs desensitize people to their environment and dampen their reactions to it. This is the real meaning of curing psychological disease.

(Medication does not treat specific biochemical mental illnesses, because these are not an issue in the context which we are discussing. Of course, there are cases of biochemical disorders and brain injuries which incapacitate people psychologically. But these are irrelevant to the widespread social-psychological disorders we are discussing. Mental illness as a social problem is first and foremost due to oppressive cultural factors. This is overlooked in most psychological

accounts. Even cross-cultural and cultural psychologists confine their attention to describing distinctive cultural features of symptoms while neglecting the oppression that generates them. In our context of mental disorder as a widespread social phenomenon, there are no discrete biochemical mental diseases; rather there are diverse symptomatic behavioral/psychological responses to cultural stressors. Medication tranquilizes this broad variety of responses. Psychotropic drugs have general desensitizing effects (on perception and reaction) and this is why medications are interchangeable; they are not specific to specific mental illnesses).

Psychiatric cure includes desensitizing people to their injurious normal environment, rather than expanding awareness of it and changing its injurious features. The refusal to challenge debilitating cultural factors inexorably leads to accommodating the individual to them. Psychiatric treatment insidiously cripples the individual to enable her to function in a debilitating environment. Rather than eliminating cultural stressors materially and objectively, they are eliminated from view through distorting the perception (consciousness, subjectivity) of individuals. (This social and political conservatism is rationalized by subjectivistic epistemology that claims reality is reducible to subjective perception. Social problems are figuratively disappeared by adopting new views of them, rather than by changing objective social structures).

Despite its inadequacy, psychiatric treatment occasionally enables individuals to achieve success in business, politics, or school. However, this success still comes at a psychological price of curtailed sensitivity and reactivity imposed by the facilitating treatment. It is analogous to wearing gas masks during periods of lethal air pollution: The masks enable people to function in that adverse condition by greatly restricting their sensitivity and freedom of movement.

Neglect of Culture by Cultural Psychologists

Cultural psychologists could fruitfully use this analysis of neoliberalism to further study the extent to which its features are actually recapitulated and embedded in psychological phenomena. For example, to what extent is the social contradiction and mystification among cultural factors reflected in people’s consciousness; to

what extent do people experience and understand insecurity in their lives, and in what ways is it obscured, disguised, sublimated, or misunderstood because of obscurantist political propaganda and other practices? Other fertile questions for cultural psychologists to explore include the extent to which commodification, mystification, individualism, instrumentalism, and other aspects of neoliberal culture are embodied in people's self-concept, motivation, reasoning, emotions, learning, and understanding. Another question is how neoliberal psychology is learned/acquired/socialized. Another cultural psychological question is the extent to which individuals are aware of their role as social agents whose psychology serves to reinforce cultural factors.

Unfortunately, cultural psychologists ordinarily aver this kind of concrete study of culture and psychology. For instance, cultural psychologists who study educational psychology typically ignore the neoliberal political-economic character of education and its impact on students' psychology. Proposals to improve education and educational psychology do not challenge the neoliberal basis, characteristics, and function of educational issues.

In an article entitled "Construction of Boundaries in Teacher Education: Analyzing Student Teachers' Accounts," in *Mind, Culture, and Activity*, 17: 212–234, 2010, two authors used "cultural historical activity theory" (CHAT) to analyze the interaction of two activity systems: student teachers' learning trajectories and the learning by pupils. The authors analyze student teachers' accounts of their teaching "to explore how boundaries are constructed in interaction and how this creates limitations and opportunities for the student teachers' learning trajectories. In our study, boundaries are defined through the relations within and between activity systems; they are dynamic and evolving, constructed in the situated negotiation of the tools, rules, and divisions of labor of each of the interacting activity systems" (p. 215). The authors assume that activity systems are interpersonally constructed. Institutional rules are selected and utilized by participants, they do not structure behavior. Given these assumptions, it is not surprising that the authors fail to describe the sedimented history, structural and coercive aspects of institutional factors. They say they are interested in these, however they do not address them

in the way we have identified neoliberal cultural and political features of pedagogy, testing, privatized education. Their individualistic theory of activity leads them to regard institutional issues as mere opportunities for participants to utilize according to their own purposes. History, culture, and politics are thereby dissolved into individual constructs and "goal-oriented activity." "We analyze how the participants produce accounts for maintaining, challenging, or transforming the prevailing boundaries" (p. 220). This renders unnecessary any detailed description of history, culture, and politics because they are always recreated by individuals. The eliding of culture, politics, and history by individualistic reconstructions as personal goals is exemplified in the authors' statement that, "Positioning reflects cultural and historical distributions of power, legitimacy, and authority but is enacted in situated actions. In other words, positioning is collectively accomplished in a discursive process where one positions oneself and the other participants. In an utterance one makes available a subject position, which other speakers may or may not take up" (p. 220). Culture, politics, and history are mentioned but immediately displaced by voluntary choices in word use. If positions are voluntarily (may or may not be) taken up by individuals through their discourse, and thus readily changed by changing one's words, then power, legitimacy, and authority play no significant role in positioning. The individualistic, subjectivistic focus inexorably leads to stripping out cultural, political, and historical content from psychology and behavior and describing them in mundane, abstract ways. Thus, formulations about neoliberal, oppressive, class-based, profit-oriented, stupefying school testing are replaced by homilies such as: "In the two learning spheres, the student teachers work on the object by asking questions, bringing up dilemmas and problems, and making suggestions that are supported and elaborated by the others" (p. 226).

Additional examples of how culture is ignored under the rubric of cultural historical activity theory are found in Chaiklin (2001). Chapter 9 has the stated aim "to analyze instructional interactions in which one participant structures the overall solving of the task so that the other participant internalizes the skills and abilities that were accomplished jointly" (p. 148). This chapter concerns interpersonal interactions, not

history or culture. It focuses on micro interactions such as whether instruction is direct or indirect. Broader culture and history are never mentioned as descriptive constructs to deepen the description of the interactions (which I did with the example of school testing), or as explanatory constructs to help understand why the interactions occurred. This approach de-culturalizes, de-historicizes, and depoliticizes interpersonal interactions. It ignores the powerful cultural shaping of behavior – e.g., by neoliberal politicians and business people who relentlessly restructure educational activities and their boundaries – to create an imaginary sense of personal, subjective freedom apart from culture.

Chapter 10 would appear to include more culture and history in relation to psychology based on its title “Intersubjectivity in models of learning and teaching: Reflections from a study of teaching and learning in a Mexican Mazahua community.” However, the chapter exclusively concerns individual interactions which are never related to the culture. A typical statement is, “In Mazahua parent-child pairs, parents would initiate the activity by undertaking actions themselves while at the same time activating the child, mostly by giving the child an assignment” (ibid., p. 186). Mazahua culture is never described or implicated in psychology/behavior. It is simply mentioned as the name of the locale where the interactions occurred. Mazahua culture is never invoked as a descriptive or explanatory construct. Yet this analysis is called cultural-historical activity theory.

Using wrong words to describe action creates misimpressions as George Orwell observed. In this case it creates the misimpression that culture is reducible to voluntary interpersonal interactions, and that to study culture is to study these abstract, non-cultural, non-historical, non-political behaviors.

The ignoring of culture in cultural psychology is demonstrated by the fact that the word neoliberalism.

The word neoliberalism only appears once in 16 years of articles in the journal *Culture & Psychology*. It is never mentioned in the 17-year history of *Mind, Culture, Activity*. The word neoliberalism never appears in any article in *The Journal of Cross-Cultural Psychology*, which has been publishing for 30 years. The most dominant cultural force in the world over the past three decades is never mentioned (much less discussed) in the leading journals on culture and psychology. While the editors and editorial boards of these journals have

failed to mention cultural and psychological aspects of neoliberalism in their publications, other journals in anthropology, geography, sociology, cultural studies, education, and social studies of science have devoted special issues to these central cultural and psychological issues. In view of this disparity, editors and editorial boards of psychological publications are negligent (Ratner 2011a) (Note 6).

Sense of Time

Our third in vivo example of cultural psychology is sense of time. Time sense is a psychological phenomenon and a cultural factor.

Time is a cultural concept that is culturally specific and culturally variable. Time sense is a cultural factor that is objectified in clocks, parking meters, calendars, timed buzzers in school and at basketball games. It is required for specific forms of life activity. Socially inappropriate senses of time can undermine a particular cultural system, or way of life. A precise, punctual, quantitative sense of time is necessary for modern social life, and a person who lacks this cannot function in this kind of social system. If too many people lack this modern cultural time sense, the system will be jeopardized.

Time sense is also a subjective, psychological phenomenon. The cultural concept of time carries a psychological/subjective side which people experience as a clock inside their mind. One understands the importance of punctuality, one strives to be punctual by keeping track of time, one feels anxious about being late, and sorry when one misses a deadline. People feel annoyed (and suspicious) when someone misses an appointment with them. Our subjective sense of time reflects the social concept of time, just as personal insecurity reflects cultural insecurity, and racial psychological attributes reflected the socioeconomic position of blacks and whites. We have repeatedly emphasized that psychology must reflect and recapitulate cultural factors if the latter are to be maintained and if individuals are to succeed in cultural activities. This is why society rewards and punishes people for the kind of psychology they manifest. Society has a vested interest in inculcating psychology. It is not a personal choice. If psychology were personal and idiosyncratic, society would not inculcate it through rewards and punishments.

The historian E.P. Thompson (1967) has illuminated the connections between people's inward sense of time and the restructuring of industrial working habits and changes. He asked, "If the transition to mature industrial society entailed a severe restructuring of working habits - new disciplines, new incentives, and a new human nature upon which these incentives could bite effectively - how far is this related to changes in the inward notation of time?" (p. 57). This is a pregnant question that poses issues in terms of cultural psychology. For Thompson suggests that cultural incentives to work in a new fashion require a new psychology, or human nature, which will be receptive to them. (Just as incentives for consumerism require new needs, perceptions, and motives that will accept the incentives and act appropriately toward them.) A new subjective sense of time is thus an integral part of external work organization.

Thompson challenged the popular view that changes in time-discipline were simply by-products of new manufacturing techniques. He argues that time-discipline involved much broader, systemic cultural changes: a transformation in work ethic and orientation to labor. Time incarnated and reinforced a new social system of labor and capital. Time became treated as currency. It took on the features of money, it becomes monetized. This is why time was regularized/standardized, quantified, mastered, saved, wasted, calculated, and used up ("time is up, stop the game, hand in your exam"). Time was not simply "emphasized" in capitalist production; it was socially reorganized to include a new social character.

Time orientation replaced task orientation. Pre-capitalist time derives from working on a task; tasks defined time, e.g., planting required X days. This became reorganized by managerial demands of time – "produce a task in 15 s." Rather than the task determining time, time comes to define the task (how it is accomplished). Natural, irregular time became replaced by unnatural, regularized time. This culminates in changing nature itself to follow imposed time frames rather than natural rhythms. This is the basis of genetically modifying plants and animals – to make them grow quickly to maximize turnover, productivity, and profit. Time/speed determine the organism (how it will grow), rather than the quality of the organism determining the time to harvest it.

Capitalist time becomes abstracted from work/task, so it may become the parameter of work/task rather than the result of work/task (Note 7). The new time orientation clearly represents capital; it generates capital. Earning capital thus requires a new sense of time in which capital is incarnated. "We are concerned simultaneously with time-sense in its technological conditioning, and with time-measurement as a means of labour exploitation" (Thompson 1967, p. 80).

Capital exerted enormous pressure on the populace to adopt its time orientation (Note 8).

Thompson (1967, p. 69) notes the interdependence of the expanding time orientation throughout the populace and the increasing standardization of labor: "a general diffusion of clocks and watches is occurring at the exact moment when the industrial revolution demanded a greater synchronization of labour."

Time orientation was the subjectivity that drove capitalist productivity. Time orientation was not simply associated with productivity, and was not mechanically caused by it as a dependent variable is caused by an independent variable. Thompson explains how the need for clocks was a culturally created need that drove people to work for capitalism. "The small instrument which regulated the new rhythms of industrial life was at the same time one of the more urgent of the new needs which industrial capitalism called forth to energize its advance" (Thompson 1967, p. 69). The artifact of the clock embodied and promoted a need for monetized time, which drew people into capitalist production and labor.

Because time sense represented and reinforced a particular political economy, it was contested by the same parties who struggled over the political economy. It was supported by the commercial elite who dominated the capitalist political economy, and it was resisted by the working class who was exploited by the elite.

- ▶ Throughout the whole medieval period, there was a conflict between the cyclic and linear concepts of time. The scientists and scholars, influenced by astronomy and astrology, tended to emphasize the cyclic concept. The linear concept was fostered by the mercantile class and the rise of a money economy. For as long as power was concentrated in the ownership of land, time was felt to be plentiful and was associated

with the unchanging cycle of the soil. With the circulation of money, however, the emphasis was on mobility. In other words, men were beginning to believe that “time is money” and that one must try to use it economically and thus time came to be associated with the idea of linear progress. (Whitrow 1973, p. 402)

Accepting the modern time sense was tantamount to accepting its capitalist basis. This struggle over time is recapitulated in contemporary health care. Insurance companies pay physicians for 15-min appointments with patients. They utilize time as a labor enforcement tool, just as factory managers did. Calculating physician–patient interactions in terms of time is not simply technical record keeping, it is a means of labor exploitation as Thompson said. Standardizing interactions in terms of time is a proxy for the capitalist political economy (which demands and promotes this). Physicians correctly resist this kind of temporal standardization of medicine because they recognize it as a mechanism of control over their work, not simply an efficient form of record keeping and allocating their time. (Under a different political economy, the technical and exploitive aspects of standardized time could be differentiated. Standardized time could serve as information for efficiently allocating work to better serve people, as opposed to subjecting them to control by capital.) Physicians also recognize standardized, commodified time as a mechanism that subordinates human interaction and quality medicine to profit for the insurance companies – who are the new owners and bosses of medical labor. Because standardized time embodies, represents, and promotes capitalist political economy, resisting the imposition of standardized time in medical, educational, and other settings requires resisting its political-economic foundation. Short of this, resistance to time itself is futile.

Glennie, and Thrift (1996, p. 277) explain how the new cultural time sense was introduced externally but then became internalized:

- ▶ New time-disciplines were initially externally imposed through official timepieces and systems of communicating time to the workforce an enforcing continuous work during the working day. But these disciplines became internally realized in quite new every day time-senses among the labor force, and came to dominate society as a whole, not least through the school

system. This process of internalization was greatly facilitated by time ethics that had evolved from 17th-century Puritanism.

The new industrial time orientation was bolstered by educational and religious institutions. These applied the time orientation to subjective thinking processes (e.g., timing the speed of learning and regurgitating information). Time-discipline was a major emphasis of schools in the eighteenth century. Puritan religion also emphasized industrial time-discipline as valuable for good character and salvation. “Puritanism, in its marriage of convenience with industrial capitalism, was the agent which converted men to new valuations of time; which taught children even in their infancy to improve each shining hour; and which saturated men’s minds with the equation, time is money” (Thompson 1967, p. 95).

Thus Baxter, in his *Christian Directory* (1673) plays many variations on the theme of Redeeming the Time: “use every minute of it as a most precious thing, and spend it wholly in the way of duty”. The imagery of time as currency is strongly marked. “Remember how gainful the Redeeming of Time is in merchandize, or any trading; in husbandry or any gaining course, we use to say of a man that hath grown rich by it, that he hath made use of his Time” (Thompson 1967, p. 87). Evangelicals went so far as to condemn sloth as murderous, and sleep as felonious:

- ▶ Thou silent murderer, Sloth, no more
My mind imprison’d keep;
Nor let me waste another hour
With thee, thou felon Sleep.

Once consciousness itself had become re-engineered to operate according to monetized, abstract time, it would apply this capitalist orientation to everything it considered. Re-engineering consciousness is a more effective form of social control than conditioning single behaviors one by one.

Thompson observes how effective this coordinated network of institutional pressures were on generating a systemic psychology that centered on an internalized sense of time: “By the 1830s and 1840s it was commonly observed that the English industrial worker was marked off from his fellow Irish worker, not by a greater capacity for hard work, but by his regularity, his methodical

paying-out of energy, and perhaps also by a repression, not of enjoyments, but of the capacity to relax in the old, uninhibited ways” (Thompson 1967, p. 91).

This industrial cultural psychology of time is similarly revealed by contrasting it with the psychology of non-industrialized people:

- ▶ The Nuer have no expression equivalent to “time” in our language, and they cannot, therefore, as we can, speak of time as though it were something actual, which passes, can be wasted, can be saved, and so forth. I do not think that they ever experience the same feeling of fighting against time or of having to co-ordinate activities with an abstract passage of time because their points of reference are mainly the activities themselves, which are generally of a leisurely character. Events follow a logical order, but they are not controlled by an abstract system, there being no autonomous points of reference to which activities have to conform with precision. (Thompson 1967, p. 96)

Glennie and Thrift refine Thompson’s analysis by emphasizing that the industrial time sense was not monolithic, despite its cultural pervasiveness. Other senses of time persisted in the family and other domains. Some differences in experiencing time devolve around gender.

We must recognize that these alternatives are increasingly dominated by industrialized time. Time spent in hospital, or the doctor’s office, has become commercialized and abbreviated and depersonalized. Family interactions are increasingly gauged by how much time can be allotted to them from work time. Vacations and childbirth are bounded as time off from work and they are squeezed into (and haunted by) this boundary. Cultural factors, and psychological phenomena, tend toward coherence and hegemony because social coordination requires commonality. People must work for common ends using common means – including mental means – in order to pool their strengths and support each other. This is the advantage of culture.

The case study of time illustrates the principles of cultural psychology that the two previous case studies revealed. All three indicate that psychology is deeply rooted in cultural-historical processes. The examples indicate that psychology is a public, objective, cultural,

political phenomenon, designed in cultural factors, to promulgate/coordinate cultural factors, politicized by cultural factors, socialized by cultural factors, and struggled over in cultural factors. Understanding psychology requires understanding these cultural dimensions.

Cultural psychology emphasizes the importance of comprehending the concrete cultural features of psychology which stem from concrete cultural factors. In our case studies, we have emphasized that the emotions, perceptions, and memory of whites during Jim Crow had specific qualities that reflected particular features of the racial code. We emphasized how the self-concept and learning style of students in a neoliberal political economy and educational system have particular characteristics that reflect the system. Thompson similarly emphasizes that the modern time sense reflects concrete features of industrial capitalism, not more abstract aspects of culture: “Above all, the transition is not to ‘industrialism’ tout court but to industrial capitalism. What we are examining here are not only changes in manufacturing technique which demand greater synchronization of labour and a greater exactitude in time-routines in any society; but also these changes as they were lived through in the society of nascent industrial capitalism” (Thompson 1967, p. 80). All too often we overlook the concrete cultural-political basis and character of cultural factors and psychological phenomena. We concentrate on their technical, or abstract, aspects. Cultural psychology brings us back to concrete cultural-political aspects of cultural-psychological phenomena – including time, school tests, love, childhood, sex, and mental illness.

Methodology and Cultural Psychology

Objectivity and Cultural Psychology

Cultural psychology is an objective, universal theory. It says that all psychology of all people is part of culture and embodies cultural features. Cultural psychology explores the particular cultural factors in different societies to understand how they generate culturally specific psychological phenomena. Thus, the universal theory of cultural psychology accounts for cultural variations in psychology. Cultural psychology is thus

a paradoxical theory, for it posits a general, universal truth about psychology that paradoxically emphasizes cultural variations in psychology.

Equally, paradoxical is the fact that indigenous theories of psychology, proposed by a specific culture, may not acknowledge cultural factors as central to psychological phenomena. Mainstream Western psychology is a case in point. The psychological theories that have arisen in Western culture typically explain psychology in natural or personal terms such as genes, hormones, neurotransmitters, personal choices. Indigenous Western psychological theories are overwhelmingly non-cultural. They do not acknowledge the centrality of cultural factors to psychology. Indigenous psychological theories are not necessarily cultural psychological theories.

Indigenous explanations of psychology may postulate non-cultural explanatory constructs. In this case, a culture's own psychological theory may not be a cultural theory of psychology. The fact that a culture proposes a psychological theory must be distinguished from the kind of theory that it is, and it may not be a cultural theory of psychology.

Whereas a particular culture's theory of psychology may be non-cultural, the universal theory of psychology known as cultural psychology is a cultural account of psychology. Therefore, the universal theory of cultural psychology must supersede and correct culturally specific explanations that are non-cultural. The universal theory of cultural psychology may be more culturally oriented than indigenous cultural theories of psychology.

For instance, extensive research on the origins and character of the self, or personality, demonstrates that the self is dependent upon the stimulation, support, and structuring by cultural factors and cultural actors. Yet a number of cultural myths deny and obfuscate this objective, social character of the human self.

Many Western and Eastern cultural myths misrepresent the nature of the self. Western individualism misrepresents the self as individually formed by free will (personal choice), or as formed by biochemical processes such as genes, hormones, or neurotransmitters. Religious ideas claim that god gives people free will and intelligence. All these concepts ignore the profound impact that cultural factors have on the person. These concepts do not constitute a cultural

understanding of psychology. They impede understanding and changing the origins and features of self – which are social. Eastern myths such as reincarnation equally misrepresent the self. Reincarnation proposes that the self is transmitted from a former life into a present one. The self, or soul, can even be reborn in another species such as a spider or a carrot. The self is regarded as a disembodied spiritual entity that jumps from a dead organism to a living organism across species depending upon the acts that it has performed. This myth is not a cultural account of psychology.

Indigenous theories of psychological disturbance (“mental illness”) may be similarly flawed. “In current-day traditional Chinese medicine practice, depression is conceptualized as a disorder of qi (the life force that flows around and through the body). In traditional Chinese medical texts, depression is called *yuzheng*, which literally means a stagnation disorder. Within this model, depression is caused by qi stagnating in liver, spleen, and lung, and recovery is brought about by dispersing the stagnation of qi with herbal medicines or acupuncture” (Lee et al. 2007, p. 6). This indigenous theory is an interesting commentary on Chinese cultural concepts about depression, but it is not an accurate scientific account of it. Doctors cannot specify what qi is empirically, nor can they explain why or how it accumulates in the spleen, nor can they empirically locate any qi in the spleen – just as god and Jesus are not locatable in the sky. Lee, et al. conclude that the symptoms of their contemporary Chinese patients did not accord with the traditional account. “The centrality of sleeplessness in our informants’ narratives is in sharp contrast to the qi and mood conceptualizations of depression” (Lee et al. 2007, p. 6).

Moreover, the Chinese account of psychological disturbance does not make any reference to macro cultural factors that generate the causes or symptoms of mental illness. These have been identified by empirical research and by cogent psychological theories. Herbal medicine may help patients feel better, just as pharmaceutical medication may help patients to relax or become less reactive. But in neither of these cases do the medications eliminate the cause of the problem in a way that resembles an antibiotic killing the cause of an infection.

Unscientific cultural myths about self offer no insight into the real origins, features, and function of

psychology. On the contrary, these cultural myths only reveal that people can be wrong about their own psychology.

Cultural myths about psychology may comprise a psychology of mass delusion. This consists of suspending rational, logical, empirical thinking, and accepting on faith ideas about the self that are unintelligible. In the case of reincarnation, there is no conceivable way to explain how a human self becomes detached from its body, floats around intact in space, and then enters another body of a human or a spider or carrot and persists intact. The whole concept defies rationality, or empirical evidence (Note 9). The psychology of delusion also includes compartmentalizing thinking into a sphere of irrational, illogical faith that co-exists alongside a sphere of logical, rational, empirical thinking.

Uncritically accepting indigenous psychological constructs as true insights into psychological phenomena

- Prevents understanding how psychology truly works
- Prevents detecting erroneous concepts about psychology
- Traps people in ignorance
- Prevents people from knowing how to create fulfilling selves
- Denies the psychology of delusion
- Prevents studying the psychology of delusion

An objective critique of subjective errors does not demonize or persecute the individual, nor does it leave one bereft of identity. The point is scientific and educational: To help people understand the social character and social bases of their psychology so that they can better understand who they truly are and why they are that way. This enables them to realistically evaluate their identity and improve it by improving its social basis (Note 10). An objective psychological critique thus leads to improving society and freeing people from mystifying cultural factors. Cultural psychological science has political value.

If we did not have an objective psychological analysis, we would never know that indigenous understandings of self were erroneous; we would never know to search for malevolent cultural factors that mystify people about their psychology; nor would we

attempt to improve cultural factors in ways that would enlighten people about their psychology (we would deem them to be already enlightened, or we would use indigenous treatments such as psychotropic drugs or herbs, or we would place an article of clothing on a stick and wave it around to call home a wayward spirit).

Abandoning critical psychological science superficially appears to validate people by accepting their indigenous psychological understanding; however, it actually traps people within mystified understanding and mystifying cultural factors (Ratner 2011a, b). If people believe that their unfortunate social position and psychological state are due to their former lives as spiders, this prevents them from effectively analyzing and challenging the true causes of their misfortune. And if you treat mental illness with medicine instead of analyzing and altering distressing social factors, this distracts from real treatment and prevention.

Denying Universal Science

Multiculturalists generally denounce external, scientific critiques of culture and psychology as being elitist, patronizing, and dismissive of indigenous culture. The very attempt to evaluate another culture is denounced in principle. However, this is a misguided criticism. Expert, objective, scientific analysis is beneficial to help people understand and control events that affect them. When you go to a doctor to treat your cough, which you believe is caused by a cold, and he tests you and tells you that your cough is caused by lung cancer, he is providing an expert, scientific diagnosis that contradicts your own limited, incorrect knowledge. Yet this is beneficial to you; it is not dismissive, patronizing, or elitist. The same is true of psychological scientific analysis of psychological phenomena. The fact that it contradicts a people's indigenous opinion about the origins and characteristics of psychology does not make it dismissive, patronizing, or elitist. On the contrary, it provides useful information to people about the origins and characteristics of their psychology (Note 11).

Of course, psychological science is not as advanced as medical science; however, the principle of using objective scientific methods to arrive at conclusions which dispute people's common sense about psychology is constructive, salutary, and empowering in both

cases. This viewpoint leads to improving psychological science whereas the multicultural adulating of indigenous psychological constructs leads to rejecting psychological science that could critique these.

Nowadays, it is fashionable to disparage science as a fantasy about illusory objectivity and truth. Skeptics of science claim that all observation is ultimately subjective interpretation, constantly changing, and devoid of independent objectivity or truth (see Sokal 2008; Koertge 1998, chaps. 1–3 for a critique of this claim). This claim misunderstands subjectivity and objectivity. It is true that science involves subjectivity and interpretation, and scientific truths are struggled over and revised in line with new knowledge. However, science is based upon ontological and epistemological principles, including experimental controls and rigorous examination of empirical evidence and rigorous logical reasoning. This is far different from subjective opinion. Science does discover enduring facts about things. Even refinements in scientific knowledge reach greater truth about things; they do not testify to the impossibility of objectivity. We certainly know more about more things than in previous times. New scientific concepts are not random fluctuations in subjective opinion which disregard and disprove objectivity.

This is true in social science as in natural science. Cultural psychological science discovers facts and principles concerning the origins, characteristics, and function of psychological phenomena. This is what gives it value. Although social and psychological phenomena are human constructions, they are real constructions. The President has real power despite the fact that it is socially bestowed power. Money too has real power although it is socially bestowed. A person's anger is real and has devastating consequences, despite the fact that it is a humanly generated subjective state. These real facts have objective existence that can and must be accurately comprehended. One can be wrong in one's understanding of these phenomena. One can even be confused about one's own subjective state. Mistakes in this area have devastating consequences. Therefore, objective science is possible and necessary to apprehend humanly constructed phenomena.

Science skeptics falsely dichotomize subjectivity and objectivity. They believe that subjectivity and objectivity are antithetical. In their view, subjectivity prevents and refutes objectivity, and objectivity is mechanical, naïve

realism that displaces subjectivity. This dichotomy is false. Subjectivity and objectivity are dialectically complementary. The whole point of subjectivity is to comprehend the world. Human subjectivity comprehends things far more thoroughly than simple, sensory, animal processes do. It is indisputable that humans have more advanced subjectivity than animals and that we understand things far better than animals do. Our understanding of electrons, enzymes, and entropy is accomplished by subjectivity, it is not clouded by subjectivity. Conversely, objectivity requires and stimulates subjectivity, it does not contravene it. We must develop our subjectivity to comprehend the marvels of nature. They do not mechanically impose themselves upon our sense receptors without active subjectivity.

Subjectivity reaches beyond itself to the world; it is not absorbed in itself. Science skeptics reduce subjectivity to self-absorption. They reduce it to a personal process, located inside the person, colored by the person's individuality, and oriented toward the person. For them, subjectivity expresses and validates the person. Any attempt at apprehending a world beyond the person is not only impossible (because it is always refracted through personal attributes), it is depersonalizing in that it orients subjectivity away from the person. This desire to prioritize and affirm the individual in every act (and the fear of losing the individual in a larger world) is what stokes the passionate denial of a real, objective world beyond the individual that can be apprehended by science. The denial of science is essentially a political, social position (to affirm the individual), as most intellectual issues are.

Affirming science is equally social-political. It affirms worlds (natural and social) beyond the individual that can be known by directing subjectivity away from the individual to the greater worlds of which he is a part. Science is world-centric, while denying science is ego-centric. Affirming science brings the individual out of himself to vast worlds beyond him which he can and must understand and enhance. This growth requires subjecting his ideas to critical scrutiny from others and from nature. He cannot construe nature and society as he wishes, as his personal construction, within his own subjectivity. He relies on other people and natural phenomena to refine his own constructs. He has to work with them and through them to enrich his own life. All of this is implicit in the scientific outlook.

Science is a zone of proximal development in Vygotsky's sense. It is a good thing to subject the individual to social scrutiny and correction, as any teacher, parent, or friend does. This expands and enriches the person, it does not diminish him. This social view of people is implicit in the collaborative nature of science. Science skeptics have an individualistic view of the person.

Qualitative Methodology

An important methodology for arriving at a comprehensive, objective, scientific explanation and description and prediction of psychological phenomena is qualitative methodology. Qualitative methodology probes deeply into the quality of psychological phenomena which contains cultural and personal constituents. While psychologists prioritize positivistic methodology as scientific, and reject qualitative methodology out of hand, without knowing anything about it, this is a gross error. This issue has been explained in the book, *Cultural Psychology and Qualitative Methodology*. The flaws in positivistic methodology are discussed in the next section on cross-cultural psychology. Here the advantages of qualitative methodology for cultural psychology are indicated through the use of one example.

The example is a qualitative study on Chinese mental illness by Lee et al. (2007). They examined depressive experiences of participants by open-ended, in-depth, ethnographic interviews which were content-analyzed. These methods revealed six categories of affective experiences among the participants: Indigenous affective lexicons, embodied emotional experiences, implicit sadness, preverbal pain, distress of social disharmony, and centrality of sleeplessness. For instance, embodied emotional experiences combined affective distress with bodily experiences.

- The compound terms nearly always involved the heart—*xinhuang* (heart panic), *xinjing* (heart dread/frightened), *xinfan* (heart vexed), *xintong* (heart pain), and *xinyi* (heart dysphoric/depressed/clutched/compressed). Some informants were adamant that emotional distress could be felt right inside or over the heart. Other compound terms showed that *xin* (heart) could be both the anatomical heart and the metaphysical mind, as *xinxing* (heart wakeful) and *xinlei* (heart exhausted) indicated. It has been suggested that

“heart-mind” is the best formulation of *xin* as an embodied term.

“I felt my head swelling, very distressed and painful in the heart [*xin hen xinku*], my heart felt pressed . . . So . . . [sighing] . . . I felt my heart very irritated [*xin hen fan*], very upset . . . I felt my heart clutched and dysphoric [*xinyi*] . . . My brain swollen, so swollen inside. It is heart pressed and brain swollen [*xinyi naozhang*].” (Lee et al. 2007, p. 4)

Qualitative methods revealed the cultural-psychological quality of depression in a rich way that is important to cultural psychology and to an adequate understanding and treatment of psychology in general. No other methodology can reveal the nuanced quality of psychological phenomena that is necessary for understanding and treating them.

The cultural quality of psychological depression is real and essential.

- “Bodily complaints” are not best thought of as figurative or disguised symptoms. Rather they are bona fide experiences, as true as any other symptoms of depression, that deserve the same level of recognition and attention. Instead of regarding embodied symptoms, such as head swelling or chest pain, as atypical, metaphorical, or rudimentary, clinicians should view these expressions as windows that cast light on the deep sensibilities, personal and cultural, of being depressed. The failure to respect embodied affect can lead to therapeutic non-engagement. The failure of conventional diagnostic instruments to detect and capture embodied affective experience, as well as other ethnocultural expressions of depression, may explain the unusually low prevalence of depression reported in lay interviewer-administered epidemiological surveys among urban Chinese and in other societies.

We would like to emphasize that we are not presenting a critique of the DSM per se, but rather of psychiatry in general. We want to point out that contemporary psychiatric knowledge – as captured in the textbooks and diagnostic criteria – more accurately depicts depression in the West than in China. This result is unsurprising, given that the criteria and textbooks are based on Western patients. Nonetheless, we hope that the readers are aware that the phenomenology of depression is different in China and doubtless other non-Western societies. Hence, psychiatrists and

researchers working with non-Western patients need to ask different questions in order to elicit the depressive symptoms and illness experience. (Lee et al. 2007, p. 7)

It can be said that not only do conventional Western diagnostics fail to adequately apprehend the experience of contemporary Chinese mental illness, but traditional Chinese accounts, such as qi stagnating in the spleen, do not apprehend it either – as Lee, et al. mentioned in our discussion of objectivity.

Shweder et al. (2008) employ qualitative methodology to elucidate the cultural qualities of emotions. The authors usefully identify eight dimensions of emotions which are axis for comparing analogous emotions in different cultures. The authors employ qualitative methodology to identify the features of each axis. This yields a comprehensive qualitative portrait of all the dimensions of a particular emotion in different cultures. For instance, American anger is compared with its analog *lung lang* in Tibet. On the dimension of somatic experience, research reveals considerable overlap or similarity. Feelings of tension, anxiety, and heat were common to both cultures. However, affective phenomenology manifested significant qualitative differences. Americans were far more likely to experience anger lingering after the provocative event, whereas Tibetans were likely to have dissipated *lung lang* and replaced it with dysphoric feelings such as shame, regret, and unhappiness. This undoubtedly stems from differences in another emotional dimension, “normative social appraisal”: Tibetans regard *lung lang* as morally bad and leading to bad karma, whereas Americans regard their anger as morally ambivalent, neutral, or natural. Americans frequently emphasized the positive aspects of anger such as giving people energy to respond to problems or injustice. The different social appraisals of anger and *lung lang* also were the likely root of differences in another dimension, “self-management.” Tibetans were likely to believe that anger could be controlled and prevented; Americans did not believe this was possible or desirable. Americans felt that anger is natural and should be expressed for the benefits it yields. Tibetans felt their emotion is harmful and so it can and should be controlled and prevented. This also explains why Tibetans were quick to forget about anger while Americans continued to experience and recall it.

This qualitative research reveals how an emotion is an integral complex of qualitatively congruent dimensions that have an internal logic.

These examples demonstrate how qualitative methods apprehend the rich cultural-psychological quality of psychological experience/states. Since the objective of psychological science is to thoroughly comprehend the full complexity of psychological phenomena, qualitative methods may be said to be objective. They are clearly useful for elucidating subtle, nuanced cultural qualities of psychological phenomena. Positivistic methods are far less objective in this sense. They limit responses to simplistic, superficial, fragmentary responses to ambiguous, truncated test materials. This is evident in the shortcomings of cross-cultural research which rely upon these methods.

Cross-cultural Psychology from the Perspective of Cultural Psychology

To fully appreciate the distinctive emphasis of cultural psychology, it is useful to compare it to cross-cultural psychology. Cultural psychology arose out of dissatisfaction with cross-cultural psychology (Shweder 1990). This dissatisfaction must be elucidated in order to capture the genesis, motive, and telos that informs cultural psychology. There still remains a tension although cross-cultural psychologists have recently sought to downplay the differences and declare a “big tent” in which everyone concerned with culture and psychology can join hands. Several cross-cultural psychologists have written pieces and edited books on cultural psychology. However, differences in principle remain unresolved. “The big tent” is wishful thinking that papers over, rather than resolves, principled differences. This is harmful because it allows the weaknesses in cross-cultural psychology (that provoked cultural psychology to arise as a corrective) to persist. Eclecticism is regressive not progressive because it allows weaknesses to persist in “the big tent” and it blunts the critical effort to correct them. The controversy that existed in the 1980s and 1990s was healthy because it exposed the errors and fleshed out more valid directions in cultural psychology. However, eclecticism stifles controversy and criticism, and it embraces errors as just another viewpoint that has something to offer.

Because cultural psychology strives to avoid weaknesses of cross-cultural psychology, it is important to

know what these are in order to understand the thrust of cultural psychology. Cultural psychology, like any discipline, is defined in part by what it avers, because its aversions determine its direction along new lines.

We shall examine a representative example to illustrate the characteristics of cross-cultural research. The characteristics we shall encounter are the following: The authors rely on the positivistic ontology and epistemology that dominates mainstream, general psychology. This undercuts their efforts to identify and compare psychological content in particular cultures. The positivistic framework reduces complex, concrete factors that are interrelated in a specific social system, to fragmented variables which are abstracted from real systems and thus lose the nuanced, concrete content that they have in real life. Additionally, positivists' operational definitions of psychological and cultural variables are simplistic, superficial, and oftentimes irrelevant to the topic being investigated. They are usually developed to elicit expedient, easily quantifiable responses rather than to probe the psychological content/quality of an issue. The tests and measures thus provide little information about the topic of research. Oftentimes, detailed knowledge of cultural-historical factors is lacking, and is replaced by superficial, abstract, notions. Finally, statistical procedures supersede sensitivity to psychological issues. Statistical tests, which only indicate statistical probabilities, are used as criteria for whether research is significant. No psychological criteria are developed to assess whether empirical results are psychologically significant. This is a surreal situation that prevents psychologists from having any idea about the psychological significance of their research on psychological issues. Moreover, they do not see this as a problem that warrants correction. Instead, they blithely continue to use psychologically irrelevant criteria for assessing psychological research. This is as absurd as using psychological criteria for assessing research in physics – e.g., using the results of personality tests on physicists as criteria for whether their research on subatomic particles was significant (see Ratner (2002, 2006, pp. 26–30) for a comparison of cross-cultural psychology and cultural psychology).

Emotional Complexity

Our representative case study of these characteristics is Spencer-Rodgers et al. (2010) research on emotional

complexity (EC) – the co-occurrence of pleasant and unpleasant emotions. The authors assert that EC is more prevalent in East Asian than Western cultures. Euro-Americans traditionally show an inverse relationship between good and bad feelings; individuals who report experiencing positive affect frequently or intensely also report experiencing negative affect less often or intensely. In contrast, “In East Asian representations, constructs such as happy/sad are viewed as mutually dependent, coevolving, and existing in a state of balance. East Asians conceptualize the self in a dualistic manner and are more tolerant of contradiction. Consequently, they may have more complex emotional reactions to self-relevant experiences” (p. 110).

This description presents Asians as complex, balanced, and tolerant of contradiction and nuance. In contrast, Westerners are simple, one-sided, and crude.

This characterization of the populations is politically laden. The labels are implicitly demeaning to Westerners and congratulatory of Asians. Emotionally complex-balanced-tolerant is regarded by most people as more positive than simple, one-sided, crude emotionality.

In addition, applying the positive label of emotional complexity to experiencing multiple emotions simultaneously is a political act. This experience could just as well be labeled emotional confusion, or emotional inconsistency. Conversely, the Western separation of positive and negative emotions could be labeled as emotional consistency or emotional clarity. This choice of labels would reverse the positive and negative connotation of Easterners' and Westerners' psychology. Thus, the authors are engaging in a political act of degradation or glorification in their choice of psychological labels. Their choice is arbitrary because it could just as well have been reversed. (In the old days, Western male psychologists used labels in similarly political ways. They labeled the psychology of women and minorities with pejorative terms, which women and minorities objected to. Spencer-Rodgers, Peng, and Wang simply reverse this psychological imperialism and direct it against Westerners – just as it is now fashionable to label men as less emotionally sensitive, expressive, and complex than women.)

Indeed, the authors' measure of emotional complexity did formerly carry an opposite designation. The authors acknowledge that “In this study,

complexity scores are used to measure the extent to which participants reported experiencing both good and bad feelings over the past few weeks. Originally developed to measure ambivalence, these scores index the extent to which individuals hold *both* positive and negative attitudes or emotions” (p. 110). Thus, the correlation of positive and negative emotions was originally deemed to have a pejorative connotation of ambivalence; however, the authors arbitrarily reversed this connotation into a positive one of emotional complexity. This is a political act posing as social science.

Equally problematical is the validity of the conclusion that emotional complexity (EC) – the co-occurrence of pleasant and unpleasant emotions – is more prevalent in East Asian than Western cultures. Common knowledge about social life in China and the USA refutes the authors’ generalizations. Americans readily experience the complexity of emotions and the co-presence of sadness and happiness. Americans frequently experience a mixture of sadness and happiness when an infirm elder relative dies. Although we are sad at the departure of the loved one, we also feel relieved and happy that her (and our) suffering has ended. Upon marriage, almost all Americans feel a nuanced happiness that contains elements of worry about whether the marriage will end in divorce as 50% do. Most couples feel a mixture of love and disappointment for their partners. Hardly any Americans are deliriously happy about every aspect of their partner and have no grievances. Even losing a job can provoke a mixed sense of loss but also excitement at a new opportunity for a different kind of life. Graduation from high school or college typically provokes a nuanced sense of loss and excitement. Catholicism, which is believed by millions of Westerners, construes death as bittersweet because it is a passage to salvation at the same time it is a loss.

Conversely, Chinese often experience single, overriding emotions. During the Nanking Massacre, Chinese people felt overwhelming, single-minded hatred of the Japanese perpetrators. They did not feel a balance of fury and love for them. When a Chinese student is rejected from an elite university, his emotion is overwhelmingly sad; there is little tinge of elation. Conversely, when Chinese gymnasts win a gold medal, Chinese citizens feel elated; they do not feel a mixture of elation and depression.

The authors will say that they are only comparing degrees of emotional complexity; so of course some contrary cases will be expected in both populations. However, the counter examples that are enumerated are widespread, and not notably different in the two countries.

The authors do not assess these kinds of real life emotions in their study. Their measures do not tap real life practice/experience.

Emotional complexity was assessed using 20 items adapted from the PANAS. Participants indicated “the extent to which you have felt this way during the past few weeks” on a unipolar scale ranging from one (not at all) to nine (very much). They rated ten positive emotions (confident, content, calm, proud, bold, satisfied, pleased, energetic, happy, and interested) and ten negative emotions (sad, tired, bored, upset, disappointed, nervous, insecure, ashamed, angry, and embarrassed). EC scores were computed using the negative acceleration model by applying the formula, $([2 \times S] + 1)/(S + L + 2)$, where S is the smaller and L is the larger mean affect rating. Higher scores indicate greater EC.

This measure actually contradicts the sense of emotional complexity the authors present. Emotional complexity only exists when a given experience includes both positive and negative emotions, as in the aphorism which the authors cite: “For misery, happiness is leaning against it; for happiness, misery is hiding in it. Happiness and misery are interdependent and interpenetrating.” However, the authors’ positivistic measure of EC asks Ss to recall positive and negative emotions that were experienced separately during several weeks. Ss who experienced a positive emotion in one event and a negative emotion in a separate event would receive a score of 9 and be defined as emotionally complex. However, each emotional experience would have been simple and one-sided. The authors mistakenly equate a sum of separate emotions with an integrated, complex emotional experience. Their measure of EC violates the psychological meaning of emotional complexity which is an integrated, complex, nuanced emotional experience. Designating the measure as “emotional complexity” is a misnomer.

In addition, the operational definition relied on Ss’ memory of their emotions, it did not tap emotions that were actually experienced. Presenting, and entitling, the research as involving emotions is not quite accurate.

Statistical Significance

Another methodological problem with the research is that it subordinates psychological significance of the findings to statistical significance. For instance, the difference between Chinese and American students on EC was .06 ($M = .76$ for Chinese and $.70$ for Americans) which is miniscule and psychologically insignificant. Nobody would conclude that two people (or groups) whose score on a crude questionnaire about memory of events over a 2-week period differs by 0.06, are psychologically different, in a significant, meaningful way. (Of course, a more thorough psychological assessment of the data needs to be accomplished. However, positivists have resisted developing this kind of psychological assessment, so their study does not report any. We are forced to infer the lack of psychological difference from the minuteness of the score differences and from the crudeness of the measure of EC.) However, this difference in scores was statistically significant at the 0.05 level which the authors take as indicating their hypothesis.

But, statistical significance has nothing to do with psychological significance. The authors use a non-psychological criterion of statistical significance to produce a finding of significance, when a psychological assessment of the results indicates no significance (i.e., data indicate no significant psychological difference). They can only pretend their results are significant by using an irrelevant measure of significance. A true (psychological) assessment falsifies their results, so they use a false (statistical) assessment to validate their results. The false assessment converts the false results into significant results. The right assessment produces the wrong conclusion (no difference), for them, so they use a wrong assessment to produce a right conclusion, for them. They use an unscientific criterion to generate a socially acceptable conclusion because a scientific criterion generates a socially unacceptable conclusion (of no difference). They subjugate science to serve their social purpose of generating significant data (that will be socially rewarded by publications, social prestige and positions, and monetary rewards).

The authors, and all positivists, take the statistical finding of “significant” and transpose it to the psychological arena where it does not apply. This is nominalism. It uses a word to imply a reality that does not exist.

Dialectical Thinking

Another problem with this study is the authors’ ignorance of cultural factors in China and the USA.

The authors attribute emotional complexity to dialectical philosophy in Asian cultures. Yet it is not clear why the authors presume that dialectical thinking is an Asian attribute. For dialectics was developed by Western philosophers such as Plato, Hegel, Marx, Adorno, and Marcuse. Dialectics is an important element in Western philosophy. Vygotsky, for example, utilized dialectical thinking in many of his formulations. The word dialectics was coined in Ancient Greece, not in Asia. (Ratner and Hui (2003) have pointed out the error of identifying dialectics as Asian thinking.) So why do the authors presume that dialectics is the basis of Asian emotional complexity, rather than Western psychology? This is as unwarranted as presuming that emotional complexity is an attribute of Asian emotionality.

In addition, the authors do not understand dialectical philosophy. They operationally define it in a Dialectical Self Scale whose items include: “My outward behaviors reflect my true thoughts and feelings.” (reversed) This has nothing to do with dialectics. It would make lying the epitome of dialectics.

“I am constantly changing and am different from one time to the next.” This makes an unstable personality into the epitome of dialectics.

“My core beliefs don’t change much over time.” (reversed) This means that one is a dialectician if one changes a core belief that racial discrimination is bad to believing it is good.

Another item is: “When two sides disagree, the truth is always somewhere in the middle.” Thus, if one side says the Holocaust occurred, and the other side denies it, then believing something in the middle is dialectical! Another item: “When I hear two sides of an argument, I often agree with both.” That would mean that someone who believed humans co-existed with dinosaurs, and also believed humans did not co-exist with dinosaurs was a dialectician! Dialecticians such as Plato, Hegel, and Marx were a bit more sophisticated than this.

The DSS is a misnomer that reflects a profound ignorance of dialectics.

Dialectics does not accept two sides of an argument. Quite the opposite, it strives to identify inconsistencies in an argument which refute it as it stands. Socrates, for example, cross-examines his interlocutor’s claims and

premises in order to draw out inconsistency among them that warrants abandoning them.

For instance, in *The Republic* he argued that justice is antithetical to harming someone: “It is not then the function of the just man to harm either friend or anyone else, but of his opposite, the unjust. . . . If anyone affirms that it is just to render to each his due and he means by this that injury and harm is what is due to his enemies. . . . he was no truly wise man who said it. For what he meant was not true. For it has been made clear to us that in no case is it just to harm anyone.” Socrates’ dialectical argument culminates in a decisive, absolute position – in no case is it just to harm anyone – which refutes the opposite argument as unwise and untrue. Nothing could be more false than to claim that dialectical argumentation accepts both sides, a middle ground, or no truth.

Hegel’s *Phenomenology of Spirit* follows Socrates’ dialectical procedure of detecting inadequacies in philosophical positions (i.e., “untrue consciousness”) and correcting them to discover truth. The Introduction to the *Phenomenology of Spirit* announces the subject of dialectical philosophy as “the actual knowledge of what truly is.” This is achieved by “The dialectic process which consciousness executes on itself, in the sense that out of it the new and *true object arises*. . . .” The authors misunderstand dialectics to be the opposite of what Hegel says, i.e., to be compromising and denying truth. One of the measures of dialecticism on the Dialectical Self Scale is: “When I am solving a problem, I focus on finding the truth. (reversed)”

Marx condemned errors and distortions committed by bourgeois economists. He never accepted them along with his dialectical materialism. Mao explained dialectics in his essay “On Contradiction.” He recognized that “Hegel made most important contributions to dialectics,” and he embraced Marx’s dialectical thinking which he distinguished from Asian philosophy that he dubbed “metaphysical,” static, and reactionary (cf. Ratner and Hui 2003). He used it to denounce and correct erroneous thinking (including Chinese philosophical beliefs). He did not use dialectics to embrace all perspectives as equally true.

Confucianism

One might suggest that the measure of dialecticism is simply mistakenly labeled and is rather an indicator of

Asian philosophy such as Confucianism – which includes The Golden Mean and other modest concepts. Perhaps the operationalization should simply be retitled as Confucian thinking and then re-word the conclusion: Confucian thinking generates emotional complexity. However, the superficial, simplistic scale items are as divorced from Asian Confucian principles as they are Western dialectics. The study cannot be accepted as researching Confucian thinking.

Items such as “My outward behaviors reflect my true thoughts and feelings,” (reversed) “I am constantly changing and am different from one time to the next,” “I sometimes find that I am a different person by the evening than I was in the morning,” “I have a hard time making up my mind about controversial issues” do not represent Confucian thinking.

Confucius was a conservative thinker who emphasized the stability of kingdoms ruled by an aristocracy. Citizens must abide by social rules in order to maintain the system. Stability, order, commitment, obedience were the core values of Confucianism. Capricious individual behavior and uncertain, indefinite, unstable values (that are denoted by the study’s test items) would undercut the stability of the kingdom. They are as inconsistent with Confucianism as they are with dialectics.

This is clear from a number of Confucius’s statements: “The man who in view of gain thinks of righteousness; who in the view of danger is prepared to give up his life; and who does not forget an old agreement however far back it extends - such a man may be reckoned a complete man.” This is a definite, principled code of action that emphasizes adhering to old agreements. There is no hint here of constantly changing one’s behavior in different situations, or being uncertain or compromising about what is virtuous and true. Confronting gain and righteousness, the complete man definitely chooses the latter over the former. “The firm, the enduring, the simple, and the modest are near to virtue.” This is another clear statement about the value of the firm and the enduring. There is no celebration of change, unpredictability, and uncertainty. “To be able to practice five things *everywhere under heaven* constitutes perfect virtue...[They are] gravity, generosity of soul, sincerity, earnestness, and kindness.” Again, Confucius espouses consistent perfect virtue everywhere, in all action. Of course, virtue is rarely achieved, and is

always a state of striving, however, Confucius makes it crystal clear that virtue consists of particular, definite, universal attributes. He says, "Wisdom, compassion, and courage are the three universally recognized moral qualities of men." His statements are completely at odds with the authors' test items: "I often change the way I am, depending on who I am with." "I have a definite set of beliefs, which guide my behavior at all times." (reversed) "I prefer to compromise than to hold on to a set of beliefs."

Confucius clearly believed in right and wrong and in consistently upholding the former. He believed in absolutes such as virtue. He went so far as to espouse one word which serves as a rule of practice for all one's life: "Tsze-Kung asked, 'Is there one word which may serve as a rule of practice for all one's life?' The Master said, "Is not Reciprocity such a word? What you do not want done to yourself, do not do to others." This is clearly not open to change depending on circumstance and who I am with.

Finally, Confucius said, "When you know a thing, to hold that you know it, and when you do not know a thing, to allow that you do not know it - this is knowledge." In other words, knowledge is holding to what you know. The authors invent an opposite notion that "I often find that my beliefs and attitudes will change under different contexts."

The authors have concocted a set of measures that correspond neither to dialectics nor to Asian Confucianism.

Agreeing with two sides of an argument, or with a middle ground, is akin to postmodern relativism and eclecticism, and plain old lazy-mindedness, not dialectics or Confucianism. It is quite prevalent in American culture. Americans commonly say that many belief systems contain truth, they believe truth is a compromise among positions, and they accept multiculturalism that embraces all cultures as valuable. This contradicts the authors' claim that Americans think in either-or absolutes, and eschew nuance, balance, and complexity.

The authors do not understand the cultures they study or the psychology of emotional complexity that they study. They erroneously attribute dialectical philosophy to China, and they completely misrepresent dialectical philosophy in their operational definition of it. Plus, they rely on crude positivistic quantitative

measures and tests of significance which do not apprehend psychological issues.

Comparing Cross-cultural Psychological Research to Cultural Psychological Research

This cross-cultural psychological research pales in comparison with Lee, Kleinman, and Kleinman's qualitative study of Chinese depression. Qualitative methodology elucidated the felt experience of depression, while cross-cultural research blocks out experience by imposing simplistic, superficial, fragmented tests that reduce responses to similarly simplistic, superficial, fragmented, overt answers.

The cross-cultural research also pales in comparison with Ritterhouse's cultural psychological research on racial etiquette and psychology. That research was informed by a deep historical understanding of the topic. The cross-cultural psychologists were ignorant and confused about the historical character of their topic.

In addition, Ritterhouse dealt with a historically concrete, rich cultural factor – the code of racial etiquette – and elucidated its psychological elements that were internalized by southern whites. It elucidated the internal relationship between psychological phenomena such as emotions, memory, perception, self, and reasoning, and the cultural complex of values, strictures, power relations, property ownership, and legitimating-mystifying ideology. The mutual dependence and support of psychology and the cultural complex in which it was embedded were made clear. The richness of the cultural complex clarified and concretized the specific details of psychological phenomena, including the situations that provoked them and did not provoke them, their quality, their contradictions (e.g., violently attacking a black person who touched them on the street, or called them by their first name, but then allowing them to care for their children), their dynamics and organization.

In contrast, the cross-cultural research studied an ambiguous psychological issue, emotional complexity, that had no ostensible social importance. There was certainly no ostensible real life difference in EC between Americans and Chinese (as noted) that could have provoked the authors' interest in studying it. The lack of social significance made EC socially and

psychologically ambiguous and poorly defined. This contrasts with the glaring social significance and definiteness of white behavior toward blacks that Ritterhouse studied.

Our cross-cultural psychologists further deprived EC of social and psychological significance (reality and definiteness) by operationalizing it as a few superficial, simplistic questions that violate any meaningful sense of emotional complexity. Furthermore, the questions inquired about their recollection of their experience, which is clouded by all the distortions of long-term memory. Emotional complexity, per se, was not even studied.

Inadequate operationalizations similarly distorted the independent variable, “dialecticism.” The test items that operationalized it represent no recognizable cultural or historical phenomenon. The items are a self-contained invention that have no cultural basis or significance. They do not represent dialectics; nor do they represent Asian philosophy such as Confucianism. Taken at face value, they indicate a deceitful, vacillating, uncertain, lazy-minded, conformist, unprincipled, uncontrollable person. How this could be equated with dialectical or Confucian thinking is not clear.

It seems that every aspect of the cross-cultural study contorted real issues into unreal caricatures and misnomers. The authors concocted a realm of surreal constructs, tests, measures, and indicators that have no connection to the real issues these were said to denote. They create an Alice in Wonderland inverted world where nothing is as it seems. For example, the wrong test/criteria generates the wrong empirical conclusion (e.g., significant differences), yet these are presented as the right test that generates the right conclusion. The wrong operational definitions are used; yet, they are presented as objectively measuring psychological and cultural phenomena.

Consequently, conclusions based on the study’s methodology are phantoms. They are uninformative, and misleading about, actual cultural psychological issues such as dialectics, emotional complexity, and significance. The authors violate Confucius’s dictum: “The whole end of speech is to be understood.” Violating this dictum has serious consequences which Confucius pointed out: “If names are not right, words are misused. When words are misused, affairs go wrong. When affairs go wrong, courtesy and music droop, law

and justice fail. And when law and justice fail them, a people can move neither hand nor foot.”

This study pales in comparison with Ritterhouse’s cultural psychology in that it fails to elucidate any psychological connection between “dialecticism” and “emotional complexity.” There is no indication of why “dialecticism” fosters “emotional complexity” or how it does so. Cross-cultural psychology has no broader psychological theory of why culture affects psychology. What is the internal relation between the two? Why does psychology have a cultural genesis, character, and function? More specifically, what is the relation between cognition (a belief system, a way of thinking) and emotion?

In contrast, cultural psychology develops a psychological and cultural theory that explain these relationships, and refines the explanation through empirical research (Ratner 1991, 2006).

Spencer-Rodgers, Peng, and Wang’s research was conducted by prominent psychologists and was published in a prominent journal after being peer reviewed by prominent psychologists. Moreover, it continues a series of similar research that the authors have published over the years in other venues approved by diverse peer reviewers and editors. It is therefore representative of cross-cultural psychology.

Not all cross-cultural research is this flawed. However, positivistic methodology generates errors which are never completely avoided by cross-cultural psychologists. Positivistic methodology is a flawed, limiting methodology that dominates the best intentions of researchers. Even when positivists have a historical understanding of significant cultural and psychological factors, their methodology renders these unrecognizable by contorting them into simplistic, superficial, abstract, contrived, misbegotten definitions-measures (e.g., collectivism, parental control, responsiveness, and expressiveness that are devoid of cultural content) which are treated with statistical procedures having no bearing on psychological significance (Ratner 1997).

This is why cultural psychologists such as Shweder developed cultural psychology in opposition to cross-cultural psychology.

Positivistic methodology should not be confused with rigorous, quantitative, experimental, scientific methodology in general. Popper correctly designated

positivism as pseudo science, which he termed “scientism.” Quantitative, analytical, experimental methodology does not have to commit the errors that scientific positivism commits. Quantitative, analytical methodology has been usefully employed to pinpoint cultural factors that generate various physical disorders. These factors are difficult to perceive without quantitative, analytical methodology. Obesity and HIV are two illustrative examples.

In the case of obesity, there is a “social gradient of obesity” in which “the incidence of obesity is greater among the least privileged and most economically insecure in society; people with the least control over their lives and critical sources of self-worth; e.g., African-American and Mexican-American women” (Wisman and Capehart 2010, pp. 939, 945; Raphael 2009). Obesity prevalence was stable from 1960 to 1980, after which it has doubled to where 1/3 of the population is obese. The prevailing view of obesity continues to construe it as a disorder of individual behavior, rather than highly conditioned by the socio-economic environment. Other explanations that blame obesity on sedentary activities are also faulty. Television watching, automobile driving, and household labor saving devices became far more prevalent between 1960 and 1980, yet no corresponding increase in obesity was observed until after 1980. “Calories expended have not changed significantly since 1980 when the epidemic began” (Raphael 2009).

Wisman and Capehart explain the relation between insecurity/stress and consuming fatty and sweet foods as follows. Such foods appear to act as calming opiates to relieve stress. In animals and human infants, the ingestion of sweet and fatty foods, including milk, alleviates crying and other behavioral signs of distress. Eating high-fat and other “comfort” foods helps in reducing biological stress system activities and negative emotions resulting from stress (Wisman and Capehart 2010, p. 947).

Quantitative, analytical methodology also reveals that poverty is the primary cause of HIV. The US Centers for Disease Control studied 9,000 heterosexual men and women living in poor neighborhoods who were not at high risk for HIV (e.g., excluding gay and bisexual men). 2.1% of them were HIV positive. This figure is 20 higher than the prevalence of HIV among heterosexuals in the general US population. 2.1% prevalence is also double

the threshold for a generalized epidemic. Therefore, poverty alone (without personal factors such as homosexuality) is sufficient to generate an HIV epidemic. HIV is at least as much a function of where you live as who you are. The report’s author concluded that reducing HIV requires a structural approach that addresses housing, education, access to health care, and jobs (*Wall St. Journal*, July 19, 2010, p. A2).

Quantitative, analytical methodology can be profitably employed without positivistic errors to ferret out cultural causes of behavior that are not immediately apparent.

Microcultural Psychology

A recent development in cultural psychology has been the emphasis on individual factors which mediate culture. This approach champions individual creativity in selectively assimilating culture. Advocates of this approach reject the idea that culture has the power to organize psychological functions. Instead, culture is regarded as an external context which the individual utilizes and reconstructs as she sees fit. This approach defines culture as the outcome of a negotiated interaction between an individual, other individuals, and social institutions-conditions. In their negotiations, interpretations, selections, and modifications of institutions-conditions, each individual constructs a personal culture out of her own experience. Social life is like a tool kit which provides individuals with the means for constructing what they like.

I call this approach “microcultural psychology” because it construes culture and psychology as primarily organized by small, informal, interpersonal relationships which are continually negotiated to express each individual’s needs and interests.

Microcultural psychology denotes the level of analysis a researcher employs to explain culture and psychology. What is key is that the micro level of interactions is used to explain the origin of culture and psychology. Microcultural psychologists are not unique in trying to explain micro level social-psychological processes. This chapter has presented numerous attempts to explain micro processes in terms of broader, macro cultural factors such as racial honor codes and capitalist industry. Microcultural psychologists are distinctive in regarding the micro level as the basis of the macro level and of psychology.

The emphasis on individuals constructing culture out of a social environment has been a central theme of recent psychological anthropology (cf. Ratner 1993). For example, in her analysis of Balinese emotions, Wikan rejected trying to understand Balinese emotions as reflections of social categories. She sought instead to elucidate the personal experience of emotions. She said, “were we to make sense of Suriati’s endeavor by appealing to a Balinese ‘culture’ endorsing ‘grace’ we would come close to reducing her to an automaton: a mere embodiment of ‘her culture.’” “People do not live and embody culture. That would be too much of a reification” (Wikan 1990, pp. 13, 14). Wikan goes so far as to say “In my account, people occupy center stage, while my concern with ‘culture’ is incidental” (Wikan 1990, p. 19).

Wikan espouses the individualistic orientation in a later ethnography about poor people in Egypt. She explicitly disregards the socioeconomic context of her subjects, saying “I do not attempt to analyze the macroforces that determine the economic and social inequities that create poverty. Instead, I am trying to show how the particular forms of poverty and misery are experienced, and how they are actively shaped and transformed by the people who suffer them” (Wikan 1996, p. 3).

Wikan’s statement expresses the essence of the individualistic orientation to cultural psychology – namely, that individuals create their own cultural psychology out of conditions, and that their cultural psychology can be comprehended through the self-expressions of subjects without any additional analysis of the socio-cultural system. Wikan acknowledges that external obstacles constrain people, thwart their opportunities, and corrode their social relationships (Wikan 1996, p. 15). However, she paradoxically believes that individual actions transcend this context. She repeatedly states that her subjects are resilient, energetic, resourceful, and successful. She glorifies individual transcendence of social conditions to such an extent that she sub-titled her book *Self-Made Destinies in Cairo*.

The individualistic, micro approach to cultural psychology also finds expression in the work of Jaan Valsiner. He recognizes that there is a collective culture of socially shared meanings. However, “belief systems that exist within a collective culture do not have an effect in the sense of being copied directly (or

appropriated) by individuals. Instead, they constitute resources from which active persons construct their own (personal) belief structures” (Lightfoot and Valsiner 1992, p. 395). “Individuals construct their idiosyncratic (personally meaningful) system of signs, practices and personal objects, all of which constitute the personal culture” (Valsiner et al. 1997, p. 284). Valsiner’s co-construction of culture combines two entirely distinct and separate processes: an impersonal, social component plus a non-social, personal component. The collective part is “alien” while the personal part is “one’s own” (Valsiner et al. 1997, p. 285).

As an example of this personal construction of culture and psychology, Lightfoot and Valsiner discuss how a parent might react to an advertisement. She may comply with the message and buy the product. However, she may just as likely re-interpret portions of the advertisement and purchase other kinds of products; or she may reject the message completely and buy nothing. Her reaction is her choice, it is not shaped by external social situations. Social situations are grist for the individual’s mill, they are not the mill which structures the individual’s work. Lightfoot and Valsiner (1992, p. 411) state that “the particular hierarchy of beliefs constructed from media suggestions may vary from individual to individual.”

In other words, individual processes determine the effect that social life has on a particular person. Social life only affects someone to the extent that he allows it to.

In contrast to cultural psychology which construes the individual as profoundly affected by culture, the new viewpoint, called co-constructionism, grants primacy to the individual’s decision about how to deal with culture. Valsiner states, “The logic of the argument supporting the relevance of the social environment in human development is reversed in the co-constructionist paradigm” (Branco and Valsiner 1997, p. 37). According to the new paradigm, “most of human development takes place through *active ignoring and neutralization of most of the social suggestions* to which the person is subjected in everyday life” (Valsiner 1998, p. 393, emphasis in original).

In this model, social influences are regarded as “collective cultural viruses” which are “affect-laden meanings [symbolic concepts] meant to infect or penetrate personal belief systems (systems of personal

sense). Their success, however, depends on whether the individual's personal culture in its present state is susceptible to such influence, or whether it contains psychological 'antibodies' or conflicting beliefs (that had emerged during previous experiences), that block or neutralize the 'attack'" (Lightfoot and Valsiner 1992, p. 396).

These comments reveal that microcultural psychology is a statement of cultural phobia, not cultural psychology. Culture is construed as an infectious disease that injures people. People must resist culture by bending it to their individual will which they exercise in mundane acts. Cultural phobia leads these social scientists to displace cultural influences by subjective constructions of meaning.

Microcultural psychology is inspired by cultural phobia; it is a symptom of cultural phobia; it promulgates social phobia. Where you find an emphasis on individual, subjective construction of meaning, you will generally find a fear of culture, an animosity toward it, an aversion of it, a denigration of it (e.g., by calling it reified), an ignoring of it, a denial of it, a neutralizing and minimizing of it.

This cultural phobia is reflected in the characterization of social structures as reified. This implies that social structures are inherently dehumanized, depersonalizing, and immune to transformation. As such, the best and only way to achieve psychological fulfillment is to rebuff social structures and emphasize individual processes of social and psychological construction.

For example, in Lightfoot and Valsiner's discussion of individual interpretations, selections, negotiations, and modifications of advertisements, they fail to consider societal influences on the individuals' subjectivity activity. The authors never indicate societal factors which lead certain parents to comply with advertisements and others to resist in various ways; they are unconcerned with how many parents manage to reject the ads; they never pin point the extent to which individual acts differ from cultural norms, i.e., whether the acts are superficial, incomplete challenges. Any parental reaction is deemed to be an individual choice.

The authors do not want to perceive social influence on behavior because they construe it as reified and implacable.

However, the social model of microcultural psychologists is faulty. Their view of social structures and institutions as reified is wrong. And their alternative social model – of society as the sum of individual, micro level actions – is necessarily also wrong. Creating and attacking a straw man leads to erecting another straw man in its place.

I have demonstrated in the early part of this chapter that structures are humanly constructed and depend upon subjective processes. Neoliberalism, and social change in China, have been sweeping, coordinated, coherent, systemic, structural changes in society that were actively designed and implemented by human social agency. This is why structures are changeable. One of the greatest structuralist sociologists, Emile Durkheim, clearly recognized this: "sociology in no way imposes upon man a passively conservative attitude." On the contrary, "sociology, by discovering the laws of social reality, will permit us to direct historical evolution with greater reflection than in the past" (Durkheim 1909/1978, p. 75).

The correct way to understand society and psychology is to recognize that social structures contain and organize behavior/psychology. This is just how role theorists included subjectivity in social roles. Bourdieu includes subjectivity in his concept of the habitus which is organized by social structures.

The Contrast Between Cultural Psychology and Microcultural Psychology

Empirical evidence demonstrates that psychology is shaped by cultural factors. Ritterhouse amply shows that individual differences in the behavior of southern whites occurred within the parameters of the cultural codes, embodied these parameters (though in certain idiosyncratic ways), and never challenged them. "Although many white parents went beyond the core curriculum of racial etiquette to encourage moderation, almost none taught racial equality" (Ritterhouse 2006, p. 81). The basic core of behavior persisted despite marginal, ineffective efforts to transcend it.

Even when certain whites felt twinges of guilt over the way they and others treated blacks, these disruptive feelings were generated by the contradiction between the conflicting social values that all whites lived with:

democracy and Christianity vs. slavery. Clearly, the former would lead sensitive people to doubt their participation in slavery. This doubt is not some personal, non-cultural construction. It is the subjective reflection of an objective social contradiction. As Leontiev (1978, Sect. 4.4) said, “If the individual in given life circumstances is forced to make a choice, then that choice is not between meanings but between colliding social positions that are expressed and recognized through these meanings.”

Smith (1961, p. 39) expresses the pathos of cultural contradictions for the individual: “Something was wrong with a world that tells you that love is good and people are important and then forces you to deny love and to humiliate people. . . What cruelly shapes and cripples the personality of the Negro is as cruelly shaping and crippling the personality of the white. Though we may, as we acquire new knowledge, live through new experiences, examine old memories, gain the strength to tear the frame from us, yet we are stunted and warped and in our lifetime cannot grow straight again any more than can a tree, put in a steel-like twisting frame when young, grow tall and straight when the frame is torn away at maturity.”

Valsiner would deny and ignore this. He would facetly proclaim that people can simply ignore and neutralize social contradictions and endorse any aspect of culture one wishes to.

Microcultural psychologists also deny social trends which can be predicted and directed. For the free choices individuals make in constructing personal culture are unconditioned, unpredictable, and uncontrollable. Valsiner says that “the actual course of development is not predictable” (Valsiner et al. 1997, p. 284). This negates social science which strives to detect order, relationships, and principles of social life.

However, real life refutes Valsiner’s opinion. The actual course of development is predictable from knowledge of an individual’s race and class.

Research on racial demographics testifies to the structural shaping of behavior and the denial of individuals to freely shape their behaviors. Blacks are many times more likely than whites to experience poverty while never achieving affluence, less likely to purchase a home at an early age and build up significant levels of home equity, and more likely to experience asset poverty across the stages of the life course. Moreover, the

economic trajectories of whites and blacks across the American life course widen over an individual’s life. Blacks do not catch up to whites, hard as they wish to, and should be able to if they could negotiate and construct their behavior repertoires as microcultural psychologists believe. The increased racial disparities are striking.

A representative, longitudinal sample of 18,000 individuals over 40 years yielded striking increasing racial disparities:

Cumulative percentages of encountering at least 1 year of affluence for whites and blacks across adulthood			
Age	Whites	Blacks	Difference
25	2.2%	0.3%	1.9%
75	54.8%	13.1%	41.7%
Cumulative percentages of encountering at least 1 year of poverty for whites and blacks across adulthood			
25	3.3%	19.9%	16.6%
75	45.5%	88.2%	42.7%

Percentage of group achieving at least 1 year of affluence with no poverty during lifetime	
Whites	Blacks
33%	3.7%
Percentage of group achieving at least 1 year of poverty with no affluence during lifetime	
Whites	Blacks
25%	80%

For blacks, the American experience is captured by a staggering likelihood of encountering poverty during adulthood with little chance of attaining significant economic affluence. Only 3.7% of blacks will encounter 1 year of affluence without experiencing poverty during their entire adulthood. On the other hand, nearly 80% of black Americans will encounter poverty in their lives with no chance of ever achieving affluence (Rank 2009, pp. 60, 62).

Since blacks obviously do not relish these trajectories, structural forces are constraining them and preventing individuals from realizing their aspirations.

These structural forces override cognitive skills. In a longitudinal study of 9,000 individuals, children who

scored in the top quartile on cognitive competence when they were five, had a 65% chance of remaining at that level when they were 10, if they were from the upper socioeconomic class. Only 10% of these high SES children fell below the median at 10 years. For low SES children, on the other hand, only 27% of the top quartile at 5 years of age remained at that level at 10 years. 37% of high-scoring low-SES children fell below the mean by 10 years of age. More of these children fell below the mean than remained at their original high cognitive level.

For children who score in the bottom quartile of cognitive competence when they are 5, only 34% remain there when they are 10, if they are from high SES. However, 67% remain at the bottom if they are from the lower class. In addition, only 3% of low cognitive achievers at 5 reach the top quartile at 10 years of age; however, 14% of high SES children reach the top (Ratner 2006, pp. 125–126).

A high-ability student coming from a family of high SES is approximately 3.5 times more likely to obtain a graduate degree or professional education than a student with similar cognitive ability who comes from a family with low SES.

These facts refute the tenets of microcultural psychology. They refute the notion that individuals stand apart from society and imperiously select from it whatever they please, and use it any way they wish to fulfill any desire they spontaneously effervesce. The facts decisively demonstrate that individuals are bound by cultural factors in powerful and profound ways. Their cognitive levels are more affected by their class position than by their own cognitive competence.

Contrary to the wish that personal meanings are the individual's own, the reality is that "ideological themes make their way into the individual consciousness (which as we know, is ideological through and through) and there take on *the semblance* of individual accents, since the individual consciousness assimilates them *as its own*" (Volosinov 1973, p. 22, my emphasis). Individual consciousness erroneously takes the presence of meanings in subjectivity to have been created by subjectivity, when, in fact, they are cultural phenomena. This subjectivistic illusion, to which microcultural psychologists subscribe, is akin to regarding the moon as the origin of moonlight when it merely reflects light that originates in the sun.

Leontiev stated the opposition between the macro psychological approach and the micro psychological approach:

- ▶ The individual does not simply "stand" before a certain "window" displaying meanings among which he has but to make a choice; these meanings - representations, concepts, ideas - do not passively wait for his choice but energetically dig themselves into his connections with people forming the circle of his real contacts. (Leontiev 1978, Sect. 4.4)

Psychological phenomena are structured in and by cultural factors. They are not personal constructs. They have cultural origins, characteristics, and functions. Even the manner in which people regard and construct knowledge is institutionalized and administered. Different epistemologies are institutionalized in organizations which socialize and justify them, and condemn competing epistemologies. One's view of what counts as knowledge and how knowledge should be acquired is not a personal construct. Epistemology is institutionalized and objectified in organizations, and organizations have epistemological (mental, subjective) functions along with their other functions. Whooley (2010, p. 495) explains the epistemological function of organizations, specifically the adjudication of knowledge claims and the delineation of the universe of possible knowers through organizational formation and practices, which promote or demote epistemologies through the allocation of resources. If we think of epistemic commitments in terms of "dwelling in" an intellectual system, then organizations serve as the formal dwellings that shape the epistemological terrain for actors. Insofar as organizations validate certain epistemological standards over others, they set the parameters of intellectual debate, shaping the content of possible knowledge. Given these functions, actors attempt to harness the power of organizations to promote their epistemological agenda and to alter the epistemological terrain through organizational practices.

For example, journals in cultural psychology and cross-cultural psychology take principled stances on epistemological questions, accepting only articles that conform to their standards, and rejecting those that employ competing epistemologies and methodologies.

Other philosophical and scientific organizations promote rigorous, objective, independent epistemology

that is not biased by political or economic directives. Scientific thought/research is institutionalized in socially and spatially differentiated organizations which insulate epistemological standards from economic and political interests. It is not protected through the mental fortitude of individual scientists alone.

This objectification/institutionalization of epistemology even takes the form of enshrining independent, objective scientific thought in ethical principles. It is unethical for scientists to tailor their research processes and conclusions to political and economic ends. This is regarded as corruption. This ethical dimension of scientific objectivity and independence is crucial for generating the psychological desire of scientists to remain independent of political and economic interests.

These varied, mutually reinforcing objectifications of epistemology/cognition make it a cultural phenomenon – like most all psychological, mental phenomena are – far beyond the realm of personal constructs.

When neoliberal political and economic interests seek to influence scientific research for their own gain, they alter the epistemology and thinking of scientists by breaching the institutional and ethical walls that exclude these interests. Important strategies in this regard include (a) engaging in political and economic work to deprive scientific institutes of public funding, so that they will become dependent upon the private resources of political and economic interests; (b) promoting proprietary intellectual property rights that justify keeping scientific results and procedures private and secret (c) promoting the commodification of knowledge as a commodity to sell and buy, (d) altering the ethics of scientific research so that accepting political and economic direction is no longer unethical. This massive institutional, legal, and conceptual activity is necessary for altering scientific thinking, or consciousness. It proves that epistemology is not a personal construct that is individually decided for personal reasons.

Elucidating Culture in Psychological Research on Chinese Psychology

The different emphases between cultural psychology and microcultural psychology appear in research. Reflecting microcultural psychology, Goh and Kuczynski (2009), researched ways that Chinese parents are becoming more child-centered, and children

are consequently becoming more demanding and assertive. They vaguely mention that there have been macro changes that have affected the family; however, they do not mention one specific example except for the one-child policy that led parents to spoil their single child, in contrast to having to spread their largesse among several children as in the past. The language is revealing: “As the number of children in each household has decreased, traditional children as old age insurance, i.e., economic value, has been replaced by the emotional and psychological value of children” (Goh and Kuczynski 2009, p. 507). This statement implies that the number of children has an intrinsic affect on child rearing. The authors never mention consumerism, corporations, media (e.g., Western), advertising, government policies, private property ownership and the free market in labor that requires people to secure their own jobs and domiciles and be prepared to make decisions, instead of accepting assigned housing and jobs.

The authors assume that the number of children has an intrinsic, natural affect on child rearing apart from cultural institutions, concepts, and artifacts. “Children are few in number—in contrast to the larger families of previous generations—allowing the child to have one-on-one personal relationships with caregivers. Each adult caregiver has an emotional stake with the child” (p. 525). It is akin to an animal instinct that drives parents of a single child to develop strong emotional ties with her, which, in turn, naturally leads to being receptive to her demands and spoiling her, and even naturally, by itself, displaces the authority of grandparents. For instance, “Some parents were even resigned to the fact that the position of the grandparents has declined as compared to the single children, recognizing this as an inevitable consequence of the one-child policy” (p. 509). Of course, none of the parts of the sequence are naturally related. Single childhood does not necessarily generate strong emotional ties with a child, nor does a strong emotional tie necessarily lead to spoiling a child and being permissive with her, nor does any of this necessarily lead to reducing the authority of elders in the family. Omitting any cultural factors that might contribute to parents’ permissive child rearing of single children makes it appear to be a natural impulse that would lead even hunter-gather

parents to have the same psychology if they were left with only one child.

The authors' decontextualized thinking about childhood also leads to positing natural tendencies to children. The emotional ties that parents have with single children "means that the child's relationships with multiple caregivers *increase the child's relational resources*, which can be exploited to meet the child's goals" (p. 525, my emphasis). No reasons are given for children's desire to exploit their parents' emotional tie to them. Evidently, all children do this, even hunter-gatherer children. It is natural; akin to evolutionary psychology's notion of naturalistic expenditure of resources which govern behavior – e.g., the evolutionary account of male jealousy I mentioned in the introduction which is based on males conserving their resources by refusing to raise another male's child. Attributing child-centered socialization to having only one child is a naturalistic explanation, not a cultural one.

The authors obtained reports from family members about obedience, e.g., which adult the child obeyed more. From these mundane accounts, the authors conclude that "the little emperor was found to be an agentic child" (p. 504). "Agency was displayed in sometimes subtle and creative ways, in overt resistance that exploited weaknesses in each of their different relationships, in behavioral compliance accompanied by private rejection of parental messages, in creative attempts at evasion and delay, and in strategically using relationships with some adults to offset the influence of others" (p. 525).

This conclusion is taken to confirm "social relational theory" which claims: "Bidirectional influence comes about as parents and young or adult children acting as agents interpret or construct meanings from each other's behaviors and anticipate, resist, negotiate and accommodate each other's perspectives during interactions" (p. 508). This is the familiar mantra of individualistic cultural psychology. It glorifies individual, personal agency as creative, fulfilling, and self-expressive. It insists on bilateral negotiation among individuals, no matter what, as an inherent principle of human sociality.

However, this theory contradicts any cultural explanation of psychology. For if individuals freely negotiate their personal interests in a mutual give and take, how

can there be any cultural organization of behavior? Free negotiation of personal interests is antithetical to cultural organization. This is clear from free market ideology – which is the basis of microcultural psychology – that denounces social regulation of the "free market." Microcultural psychologists give lip service to "contextual embeddedness" of interactions; however, they never explain how this is compatible with free, bilateral negotiation among agents. Nor do they include cultural issues within the negotiation process. Cultural issues remain extraneous and indefinite, as in the authors' conclusion that children are agentic and creative. The authors vacillate between claiming some indefinite cultural influence that generates agency, and natural subjectivist individualistic agency which exists regardless of culture and in opposition to culture. Because microcultural psychologists seek to promote absolute, universal free agency, they rarely mention cultural factors in relation to agency, and when they do, they construe culture in vague, superficial ways which cannot interfere with free agency. Goh and Kuczinsky manifest both of these errors.

Social relational theory, like all microcultural psychology, is an absolute, ahistorical universal of human nature. This makes all people the same everywhere. All children are agentic in the sense of constructing meanings, negotiating, and resisting. It doesn't matter what social system they live in; they will always be this way. This eliminates, marginalizes, or trivializes cultural features and variations in agency and psychology. Microcultural psychology presumes that agency already exists in people, it requires no particular social organization. This is the whole point of microcultural psychology – to emphasize individual freedom from culture.

When cultural issues are mentioned, they contradict the notion of agentic negotiation. For instance, when the authors mention that the traditional Chinese family exercised authority over children, this countervenes the absolute insistence that children and parents engage in bilateral negotiation, and children resist parental authority. Social relational theory even contradicts the authors' claim that the one-child policy allowed for more childhood agency than previous customs had allowed. According to the theory, children have always been agents; consequently, no policies affect this.

The thrust of microcultural psychology is to reject and marginalize substantive culture in an effort to free the individual as an independent agent. Notice that the description of agency by Goh and Kuczinsky uses terms such as resist, avoid, and offset social influence. They never construe agency as embracing, benefitting from, and contributing to culture. This echoes Valsiner's characterization of culture as a set of viruses which must be resisted.

The increased individualism in China, as in the USA, is rooted in and promoted by top-down decisions by leaders of social institutions such as the government. (This does not deny that sentiments and struggles for these changes were present among the populace. It argues that the changes were only realized through coordinated, concerted leadership of social organizations. In this historical period, that leadership is undemocratic and coercive. In future periods, social leadership will hopefully be democratically controlled by and representative of the populace who can realize their sentiments through their own institutions. Footnote 13 discusses this point.) Yan's research documents the decline of organized sociality such as mass rallies, collective parties, and volunteer work for the public good; and the dissolution of the social safety net that guaranteed jobs and housing for all. This individualization of social policy fostered a popular sense of individualism in a wide range of social activities – from finding a job to a house to a spouse.

For instance, the Chinese Sports Federation used to pay for athletes' training and therefore set the rules for training, arranged their travel, and also kept most of athletes' monetary winnings. The Federation recently changed its official policy and now allows athletes such as tennis players to keep 88% of their earnings, hire their own coaches, train on their own, and plan their own trips to international competitions. This official policy changes the collective sense of personhood into an individualistic sense.

Far from individualized sense of self being a personal construct, Yan (2010, p. 489) demonstrates that "the rise of the individual and the consequential individualization of society should be viewed as a reflexive part of China's state-sponsored quest for modernity." "China and Western Europe were both forced into the current round of individualization through the impact of globalization, especially due to

the global triumph of neoliberalism and the capitalist mode of production." (p. 507).

- ▶ whenever individualization and privatization became necessary, the party-state did not hesitate to use its power to launch institutional changes. . . the three major reform projects since the late 1990s, namely, the privatization of housing, the marketization of education, and the marketization of medical care, are all institutional changes launched by the state to force individuals to shoulder more responsibility, to more actively engage in market-based competition, and to assume more risks and to become more reflexive. [One blunt way that the State forced individualization was to fire millions of State employees and force them to fend for themselves in market activities.] Chinese official data recognize that between 1998 and 2003 more than 30 million workers were laid off from the SOEs, representing a 40% cut in the state owned enterprise workforce. [Foreign data double this figure.] The life-style of the laid-off workers changed immediately once they lost both their jobs and their sense of security. (Yan 2010, pp. 498, 499)

In keeping with Bourdieu and macro cultural psychology, Yan illustrates Vygotsky's statement that psychology is a product of historical forces:

- ▶ While experiencing the radical changes in her/his life situation and biographic pattern over the last three decades, the Chinese individual has also gone through an equally radical breakthrough in the subjective domain, that is, a re-formation of the self and a search for individual identity. The institutionalized changes in the labour market, education, and career development, for example, have led to the rise of what Nicolas Rose calls the 'enterprising self', meaning the calculating, proactive, and self-disciplined self that is commonly found among the younger generations of Chinese labourers. (p. 504)

This culturally induced change in self-concept brings the same psychological pressures as in the West:

- ▶ The pressure to remake the self in one way or another created not only an additional responsibility but also a new psychological burden for the Chinese individual. Squeezed between the increasing market competition on the one hand and the decreasing support from

family, kinship, and state institutions on the other, many Chinese individuals suffer from various degrees of mental illness. According to a recent report, doctors at the National Center for Mental Health quote the startling figure of 100 million Chinese suffering from mental illness. Another noteworthy trend is that many individuals have turned to telephone hotlines, talk therapies, and psychological counseling for professional help instead of seeking support from relatives, friends, and family members as most people did in the past. (505–506)

In addition, consumerism has fostered a strong sense of individualism. Individuals were encouraged to consume by government policy as a way of stimulating the economy, fostering social content, and distracting people from social injustice and autocracy. Government policy encouraged banks to make consumer loans at low interests with low down payments. The media praised consumerism. “Chinese consumers’ enthusiastic embrace of commercial opportunities and products has accentuated the role of individual choice and diversified the venues in which individuals from a broad spectrum of urban society socialize.” “The ideology of consumerism, which simply encourages people to indulge themselves in the pursuit of personal happiness, effectively dilutes the influence of communist ideology.” (Yan 2000, p. 185).

Individualism did not spring out of spontaneous personal wishes, which magically coincided throughout the urban areas of China. Nor did it spring out of one child in the family. It was rooted in concrete cultural institutions (banking, media, ideology, advertising, employment practices) and normative activities which were encouraged by social leaders for political and economic purposes. It is these concrete cultural institutions and norms that are the crucible for particular psychological phenomena: “Mundane and commercialized activities of consumption provide the concrete content, the specific form, and the particular space that make this new kind of [individuality] possible” (Yan 2000, p. 185). All of this was deliberately cultivated by the government to regain social stability after the Tiananmen uprising in 1989: “The triumph of consumerism has drawn the public’s attention away from the political and ideological issues, overshadowed the increased social inequality and widespread

corruption, and eased the legitimacy crisis of the CCP after 1989” (Yan 2000, p. 188).

Ng (2009, pp. 424–425, my emphasis) amplifies the macro cultural-political changes that replaced Chinese style collectivism with modern individualism.

- In Maoist China, personal problems were moralized and politicized rather than medicalized and psychologized as in the West. Time outside of work became highly regulated. Leisure took place in group settings, and failure to participate in state-sanctioned leisure activities provided grounds to criticize individuals for “cutting themselves off from the masses” and “lacking collective spirit”

In the 1980s, the new leadership under Deng loosened state control over most domains of social, cultural and personal life. New urban sites including billiard parlors, bars and beauty shops have shaped patterns of consumption and city culture. *Economic and socio-political decentralization have opened new physical and social spaces for personal autonomy and subjective experience.* Parallel changes in the socioemotional landscape have also been documented in rural areas in China Broadly speaking, social life in both urban and rural areas has become increasingly depoliticized, and public discourse on mood and emotion has become less dangerous and more commonplace. Ordinary citizens could now openly express opinions, hopes and fears on an individual level. Popular media and professional literature have begun to utilize terms such as psychological (xinli), stress (yali), mood (xinqing) and depression (youyu) more regularly.

An important macro cultural factor in the individualizing of Chinese psychology has been the psychobiologizing of experience such as depression under the direction of capitalist pharmaceutical corporations: “With the influence of foreign pharmaceutical companies, availability of glossy psychology magazines at newsstands, popularization of psychology talk shows on television and radio, increased mental health education campaigns by the government and easy access to pirated foreign films and soap operas, many Chinese in Shenzhen are well aware of the concept of depression” (Ng 2009, p. 426).

Goh & Kuczynski know about some of these cultural developments (historical forces), yet they refrain from mentioning these in their study of family

relations. Rather than explaining how economic and sociopolitical decentralization and depoliticization, and corporatization (supported by the media) have organized new physical and social spaces for personal autonomy and subjective experience – which cultural psychologists should do – the authors extirpate them from analysis and zoom in on the family unto itself in order to create the impression that Chinese parents and children are active agents. The notion of free agency drives the authors – and the journal’s editor and reviewers – to decontextualize, deculture, and depoliticize family and personal relations (see Kurki and Sinclair 2010 for a similar critique of constructivism in international politics).

Contextualizing family changes within broader, political macro factors would reveal that Chinese individuals are conforming to imposed cultural parameters which they do not create through negotiation with the powers that be, and rarely resist, ignore, or prune effectively. Ng (2009, pp. 438–439) refers to this macro cultural forming of psychology, as a way of comprehending the psychology expressed in psychiatric narratives. Her macro cultural psychological discourse analysis is as follows:

- ▶ To better understand the four interviewees’ narratives of distress, it might be helpful to note the changing relationships between individuals and work in China across the decades. Major structural changes to the workplace in the reform era have led to increased flexibility and mobility for both employers and employees, in contrast with the stability and rigidity of Maoist-era work units (*danwei*). For workers of the Maoist era, one’s work unit was not individually chosen, and it defined one’s identity for all legal and bureaucratic purposes, as well as many aspects of one’s social life. Although some may not have been too satisfied with their allocations, the posts were seen as “iron rice bowls” one could count on, usually for life. Thus, the relationship to the workplace was one of restraint, yet also one of reliability and support. The obligation was mutual.

The transition toward a market economy in the reform era has seen the dismantling of this model.

While the work unit still exists, its influence has been diminished due to the increasing influence of privatization. Workers and employers can now

“negotiate” employment, particularly in the private sector. Fewer promises are made from both ends. “This has led to a related shift of attitude in younger workers, who prioritize the well-being of their personal and (often nuclear) family lives over that of the greater community and workplace. In this context, Mr. Tian’s narrative of frustration toward national policies and younger employees can be seen as a response to the changes in both workplace structure and worker psychology in the post-Mao era.” (Ng 2009)

Shifts since the 1990s toward a neoliberal model of funding have led to many reductions or outright termination of pension benefits, leaving some older workers and retirees nostalgic and bitter about promises made in the Maoist past. Across the country, workers and retirees have organized public protests over the depletion or denial of benefits. “Lacking reliable safety nets in the socioeconomic domain, many younger workers and students such as Mr. Zhong and Mr. Lu feel that they must indeed ‘rely on themselves’ for their own welfare and livelihood, as the availability of employment and benefits remains in constant flux, particularly for migrant laborers like Mr. Zhong. Thus, in experience of bipolar disorder, “the contents of complaints are very much in step with the socioeconomic atmosphere of their times.” (Ng 2009).

This research flatly contradicts the insistence of micro cultural psychologists that culture and psychology are individual constructs. Zhang’s (2010) superb ethnography of middle class life in China adds more evidence that “The emergence of the new middle class in China is fundamentally linked to the post-Mao market reforms and economic liberalization that set the conditions for the growth of private businesses and the accumulation of private wealth” (*ibid.*, pp. 5–6). “Privatization was a deliberate shift in China’s governing strategy to set citizens free to be entrepreneurs of the self” (Zhang & Ong 2008, p. 2; see also Hansen & Svarverud 2009). The emergence of the middle class was clearly not a product of interpersonal negotiations among individual agents as micro cultural psychologists insist.

Zhang brilliantly demonstrates that psychology (of the Chinese middle class, in this case) is objectified in, structured by, and functional for public, objective, cultural factors such as housing. “Privatization is a set of techniques that optimize economic gains by priming

the powers of the private self...This subjectivizing aspect of privatization as a mode of thinking, managing, and actualizing the self is a central element of the neoliberal doctrine” (Zhang & Ong 2008, p. 3). Newly formed private housing, that was promoted by and institutionalized in governmental laws, was a new spatial artifact that “provides the physical and social ground on which the making of the new middle classes becomes possible...Such emerging places offer a tangible location for a new class to materialize itself through spatial exclusion, cultural differentiation, and lifestyle practices” (Zhang 2010, p. 3). Such objective, public cultural factors are indispensable for the formation of middle class social identity and psychology.

This key cultural artifact of private housing was not interpersonally negotiated by individuals, it was an element of the new Chinese social system. It embodied the autocratic politics of the system: “The rapid expansion of the real estate industry and the rise of the new middle classes is not simply a matter of successful entrepreneurial endeavors or innocent [individual] consumption practices. It is also a matter of remaking urban spatial order and cultural distinctions between the relatively affluent and the less affluent through massive displacement. The glamorous new central financial district and private residential paradise for the new middle classes is built on the ruins of millions of demolished homes of long-term ordinary residents who have been forced out of the urban core [through forced evictions].” In Kunming in the 1990s, “In the three years before the Horticultural Expo, over 90% of the old neighborhoods were destroyed; tens of thousands of residents were forced out of the city. This was a major government-orchestrated event and individual families had little chance to resist” (p. 138, 139–140). Thus, the cultural artifact – housing – that was the locus and support system of middle class identity and psychology, was instituted by other cultural factors, namely political-economic institutions. Middle class identity and psychology rest upon this complex, massive, administered social system.

Zhang (2010, chap. 6) explains that among urban dwellers, self-concept now hinges on owning one’s own house, in contrast to the previous period (pre-1980s) when the men’s and women’s identities hinged on living in the husband’s parents’ abode. Social pressure falls heavily on men to define themselves as adequate

males in terms of acquiring wealth and owning a house. Failing in these material aspects directly causes men to feel insecure about themselves. It affects their virility as well. Most men feel threatened by women who are wealthy and own houses.

For women, self-worth is intertwined with conforming to social ideals of physical beauty and demeanor. There is a proliferation of clinics devoted to breast enlargement, eye lifts, face lifts, and other procedures. Women feel inadequate when they do not measure up to cultural standards of feminine beauty. They spend time, money, and psychological energy to measure up. Self-concept and sexuality are clearly organized by cultural values and practices.

Zhang & Ong (2008, pp. 1–19) construct a detailed, complex, nuanced, rich understanding of contemporary Chinese social structure and politics and they explain how this concrete culture fosters a culturally concrete self-concept. They first point out that neoliberal economic reforms are limited to certain social domains of personal lifestyle and consumption which co-exist with state control of the political economy. This makes Chinese neoliberalism distinctive from Western forms which are not dominated by state control of enterprises. The individualism associated with neoliberalism is thus more limited and personal than the individualism of Western market economies. And this means that the individualistic self that is associated with socio-economic-political individualism is more limited and has a distinctive character in China compared with the West. The individualistic self in China is contradictory to the state-controlled cultural practices, whereas it is more congruent with unrestricted market cultural practices in the West. There is consequently more tension built into Chinese individualism than in Western individualism because it is relegated to a pocket within State control of the political economy. The authors call this “an uneasy marriage” (p. 17).

Zhang & Ong concretize neoliberalism, individualism, and the individualistic self by observing their cultural formation. The authors dispel universalistic, generic notions of these constructs. These are not the same in all countries: “Privatizing needs, desires, and practices can be enhanced, deflected, or subverted by whatever else is going on under or around them” (ibid., p. 10).

This thorough, detailed analysis of culture and psychology contrasts with Goh and Kuczynski who only mention the one-child policy in relation to culture, and only mention children's "assertiveness," and "agency" (with no cultural or psychological detail) with regard to psychology.

The detailed social science research on China additionally corrects the misunderstanding of Chinese culture and psychology by cross-cultural psychologists. They misconstrue these in abstract notions such as collectivist or individualistic. And cross-cultural psychologists render China as collectivistic, oblivious to the rising individualism since the 1980s. This line of research that reduces culture to simplistic variables such as individualism/collectivism has been roundly criticized in numerous journals: *Asian Journal of Social Psychology*, vol. 2, issue 3, 1999; *Psychological Bulletin*, Jan. 2002.

As I observed in footnote #1, non-psychologists, such as Ng, Yan, Zhang, Pred, Thompson, Foucault, and Ritterhouse, have keener insights into cultural psychology than psychologists do (Note 12).

Agency

Agency is a microcultural psychological construct. Agency is regarded as a personal ability to initiate action that expresses the individual. This conception of agency is supposed to protect the individual from social determinism. Agency is what enables us to keep our bearings in the world, to make sense of the world, to resist undue social pressure, and negotiate with the world to express ourselves in the world. Agency is construed as an intrinsically liberatory force within each of us. This kind of agency has nothing to do with culture, except to counterpoise the self to culture. But it is not a cultural phenomenon in the sense of originating in culture, embodying culture, or having a cultural function. It is an individual attribute that counterbalances culture.

However, such a conception of agency is abstract, asocial, naïve, and false. It contradicts the principles of cultural psychology. Cultural psychology emphasizes that agency is a cultural phenomenon that derives its character from the kind of society in which it functions. Agency has no intrinsic, personal, liberatory character. In oppressive society, agency is stunted. It is an obstacle to liberation. It must be overcome through a social analysis of self and society. I have discussed this under

the rubric of the psychology of oppression (Ratner 2011a, b). Volosinov states the point accurately: "The content of the individual psyche is by its very nature just as social as is ideology, and the very degree of consciousness of one's individuality and its inner rights and privileges is ideological, historical, and wholly conditioned by sociological factors" (Ratner 2011a, b, p. 34).

Consequently, agency has no intrinsic capacity to liberate the people from oppression. Liberation requires looking outward toward society to understand its workings, the reasons for social problems, and how to construct viable transformations in the social organization of cultural factors. Agency is nothing more than the subjective activity that must carry out this social praxis. Agency does not have a built-in character that guides our praxis. One cannot find a way out of social problems by looking inward toward properties of agency. For our inner agency has been shaped by our social milieu such as racial honor codes, neoliberal political economy, and industrial concepts of time. Given this cultural form of agency, liberatory subjective activity must be developed. Agency must take on the content of a specific kind of social praxis. Agency must be trained to understand cultural factors and to transform them.

Liberation cannot be predicated on agency. On the contrary, achieving true agency (that initiates fulfilling behavior) depends on living in humanized cultural factors that are conducive to fulfilling behavior and authentic agency. Agency must develop its capacity to bring about more democratic and cooperative social institutions in order to realize itself as authentic agency. Agency must construct the material basis necessary to realize itself. It must construct a social environment that will stimulate and support authentic agency. Agency must "get beyond itself" in order to create the conditions for itself. (If agency wishes to become educated, it must construct an educational institution in which it can become educated; an educational institution that will provide the resources for its education.) This is the dialectical spiral of culture and consciousness enriching each other that is the cornerstone of cultural psychology.

Individualistic agency was itself developed through conducive cultural factors; it was not a natural, universal tendency. Our previous discussion of individualism in China testifies to this point. Yan and Ng demonstrate

that dramatic changes in state policy led to the blossoming of individualistic agency throughout China from the 1990s onward. “Villagers, after they were untied from the collective regime [by the government’s privatizing land and housing in the 1980s], began to make independent decisions and to engage in various self-chosen activities. . . . These traits of individual agency continued to develop in the subsequent 20 years” under pressure from social policy. “Modern social structures compel people to become proactive and self-determining individuals who must take full responsibility for their own problems and who develop a reflexive self.” This is “compulsive and obligatory self-determinism,” not the natural eruption of endogenous self-determining agency (Yan 2009, pp. xxi, p. 275).

An interesting and important way that individualistic identify was fashioned at the cultural level was through the issuance of personal identity cards by order of the National People’s Congress in 1985. Prior to this, only families received identity cards which identified people as members of families or work units. There were no cards identifying people as individuals (Yan 2009, p. 277–278). The personal identity cards bestowed an official, public, objective, objectified individual identity on people. This is a telling example of a public creation of a psychological phenomenon. The society defined people in new terms. This was reflected in the way people referred to themselves linguistically. For four decades,

- ▶ Self-identity did not exist in public life, and therefore the individual could never be an unit in public discourse. Consequently, people tended to use the plural term to substitute for the singular “I”, such as “we,” “our work unit,” etc., instead of saying “I,” “my work unit,” or “my family.” This customary usage of the plural “we” gradually disappeared in the 1990s and, by the late 1990s, a new Chinese phrase, “wo yi dai” (the I-generation or the me-generation), was coined to describe those were born in the 1970s and who had grown up during the reform era because of their proud usage of the first person.” (Yan 2009, p. 280)

This generation expresses its culturally formed individualistic agency in culturally appropriate individualistic behavior. Not only do young adults take to the free market in labor and business opportunities, they also live in their own dwellings after marriage,

instead of living with in-laws as in former times. Filial piety in the family is being replaced by individualism.

If individualistic agency is the product of macro cultural factors (rather than the product of human nature or spontaneous choice), then other forms of agency can be achieved through constructing other cultural factors to elicit and support them.

This requires exposing the individualistic politics that are implied by the popular use of “agency,” and emphasizing that agency can take other forms. We must do the same with related terms such as self-actualization. This term implies that humans actualize themselves as individuals, on their own. It assumes that social support, social concern, and social transformation are irrelevant to actualizing a person. This is a definite politics that legitimates the capitalist status quo. However, actualizing human potential requires social support, social concern, and social transformation. Thus, the individualistic politics inherent in “self-actualization” must be exposed and replaced by social politics.

Politics and Cultural Psychology: Psychological and Social Change

All social science is political because it carries assumptions about behavior, psychology, and society that either support or challenge the political interests which govern the status quo. The psychological theory that territoriality, violence, patriarchy, monogamy, racial inferiority, gender inferiority, jealousy, and exchange are innate psychological tendencies, supports the politics of the status quo. Conversely, a psychological assumption (and finding) that cooperation, collaboration, gender equality in psychological capacities, and racial equality in psychological capacities are psychological attributes necessary for mental health and development, challenges the competitive, privatized politics of the status quo, as well as gender and racial hierarchy. A conception of human nature as a general potential for all kinds of behavior is political insofar as it allows for the social possibility of erecting a social system based on equality and cooperation and altruism. No innate psychobiological forces are working to preclude these.

This chapter has observed that time sense is political in the sense of embodying a social system of work relations, exploitation, profit, etc. It is also observed

that emotional tones expressed by whites toward blacks during Jim Crow were political in the sense of representing the Jim Crow system. Self-concept also reflects and supports particular political-cultural systems. Fairclough (2001) explains how sociolinguistic conventions incorporate and reinforce particular relations of power in society. For instance, "The social dialectic which developed into standard English was the East Midland dialect associated with the merchant class in London at the end of the medieval period" (p. 47). Other dialectics spoken by the working class were designated as vulgar, and were marginalized. (Fairclough appropriately criticizes conversation analysis that "has been resistant to making connections between 'micro' structures of conversation and 'macro' structures of social institutions and societies." p. 9). Indigenous psychology and skepticism toward science are political in validating bourgeois individualism.

Psychological questions are political. The typical psychological question is "which individual will manifest a particular psychological phenomenon?" E.g., who will become violent, suicidal, hyperactive, genius in math? The focus is on individuals and individual explanatory factors: genes, hormones, neurotransmitters. The environment is construed as generally homogenous, with individual processes determining different individual responses to it. For instance, modernity is considered to be generally stressful, yet some people break down while others excel, depending upon constitutional factors. Constitutional factors determine the specific response that individuals make to the general environment. The questions which typical psychologists ask lead to addressing individual factors and circumventing cultural factors. Looking for individual causes and variations of psychological phenomena leads to redressing them through individual factors, not cultural ones.

In contrast, the cultural psychological question is "what are the cultural reasons this particular kind of psychological phenomenon exists in this culture/subculture?" "what is the social demographic of a particular psychological phenomenon? What groups manifest these phenomena in highest frequency?" "Why do so many people commit suicide, crime, violence in this society? Why are so many people in this subculture good students?" We look for social explanatory factors,

not individual ones. The cultural environment is specific and it constitutes the specificity of peoples' behavior. Understanding and altering the specificity of behavior requires changing its formative culture, not constitutional factors.

For cultural psychologists, It doesn't matter which particular individuals (John Doe or Mary Jones) manifest deleterious psychology. We do not try to predict this. That is the task of clinical psychologists. We try to predict the prevalence and the social distribution of the phenomenon. We try to improve cultural factors so as to enhance the prevalence of beneficial psychological phenomena, and reduce the prevalence of deleterious psychological phenomena. These cultural efforts will have the greatest impact on the most people. In contrast, identifying and treating individuals impacts small numbers of people. Indeed, the individualistic approach assumes that few people need treatment. If issues were regarded as widespread/social it would make no sense to treat them on the individual level.

We can see that politics is built into the questions psychologists ask about the nature of psychological phenomena. In fact, these political issues are what drive psychological science. The reason that psychologists look for individual causes of psychological phenomena is that solving psychological problems can justifiably be directed at individual factors, not cultural ones. Psychological science justifies political practice, it is not the primary instigator of political practice. It seems to academic psychologists that their theories are intellectual products which precede and generate practical solutions to psychological problems. It seems that scientific theory occurs in a rarefied realm of intellectual activity and that practitioners utilize this theory for practical means. However, the reality is opposite this appearance. It is practical approaches to solving problems that generate the development of psychological theory and methodology. It is the political need to find individual solutions to problems, which do not challenge the social system, that generates individualistic approaches to psychological science and theory.

Cultural psychology is equally animated by political considerations. In this case, the need to improve the broad culture leads to considering cultural aspects of psychological phenomena in the science of psychology. We would argue that this approach to psychological science is valid on scientific grounds. Empirical

evidence verifies cultural psychology as a science. The humane politics of striving to improve our culture and civilization generates a valid science of psychology. Psychological science is political, but it is not merely political ideology. It is valid science as well as being progressive politics.

Microcultural psychologists are driven to their view of society and psychology for social-political reasons. They seek to protect the individual from oppressive social conditions. They do this by adopting the concept of political freedom as rooted in inviolable individual autonomy and choice. This ideal leads to viewing culture as determined by individuals at the microcultural level, through negotiation as free agents with other agentive individuals. Valsiner and Litvinovic (1996, p. 61) claim that individuals continuously change culture in the simple act of dialoguing with it. Wikan (1996) similarly insists that individuals resist and transform culture in their everyday actions.

The political ideal of personal freedom also leads to endowing the individual the freedom to decide how he will react to culture and how he will construct his personal world of psychological meanings. The political ideal of personal freedom also leads microcultural psychologists to characterize social structure, social regulation, and social influence as toxic and reified.

The individualistic political ideal and ensuing conception of culture and psychology conform to the free market concept of neoliberalism, which we have described above.

Microcultural psychology is politically supportive of the free market/neoliberal status quo in glorifying individual action, individual agency, and renouncing the need for structural, political change in social institutions. Microcultural psychology postulates that people are already authentic agents who can express themselves through fulfilling acts. There is thus no reason to consider or transform social institutions in order to improve life. All that is needed to be done is to exercise its existing agency within existing society. (Of course, microcultural psychologists may contradict their psychological theory in real life, and may work for political change outside their professional activity. The chapter describes the political ramifications of their psychological theory, whether they follow these themselves or not. Inconsistency does not invalidate the real implications of academic work.)

For instance, Valsiner et al. (1997, pp. 287–292) complain that the asymmetry of parents directing children's behavior gives too much authority to parents and limits the child's self-actualization. However, a facile solution is at hand – children can mentally distance themselves from parental guidance, they can co-construct their culture by imagining their own goals which they may implement at a later time. Social asymmetry, and associated social problems, is dissolved by individual imaginary thought!

This formulation appears to be apolitical in disregarding politics and cultural factors. However, this very oversight is political on a deeper level. It exempts macro cultural factors from confrontation and therefore enables them to persist with impunity and immunity.

Although it presents itself as a radical alternative to social determinism, microcultural psychology is a counterrevolution against substantive social reform (Note 13).

In addition to being politically conservative, microcultural psychology is scientifically erroneous about the nature of society and the nature of psychology. Social systems are not reified as microcultural psychologists claim. Nor are they created bottom-up by individuals in interpersonal negotiations.

We have seen that neoliberalism is an organized, coherent political-economic-ideological system that structures virtually all areas of individual people's social life (Braedley and Luxton 2010). Yet neoliberalism is not reified because it is a movement initiated and implemented by active individuals. Neoliberalism was “a counter revolution from above” (Schulman and Zelizer 2008, p. 154; Pierson and Hacker 2010), instituted by people who transformed the structure of macro cultural factors. All systemic, structural changes are human (and all substantive, extensive, enduring human changes require transformations in social structure); they are neither reified nor reducible to personal interactions and reconstructions of meaning.

The individualistic political ideal of freedom, society, and psychology, eliminate the advantage of culture. Culture is a superorganic, emergent, collective entity that unifies individuals in supra-individual enduring, objectified, stable, predictable, dependable, historically sedimented, administered, institutionalized structures of joint intentionality and cooperation, objectified in

artifacts. These cultural factors are organized into differentiated systems which support and strengthen individuals materially, socially, and psychologically. Culture is not simply shared behaviors among individuals. It is massive, weighty structures. Indeed, the more massive and weighty, the more supportive they are. A factory exemplifies a beneficial, massive, weighty character of a cultural factor. It is productive of goods far beyond what casual, “light,” easily undone/renegeated, “shared practices” can provide. Destroying such cultural structures by reducing them to casual, personal, subjective (unobjectified), renegotiable interactions deprives us of culture’s benefits.

Micro cultural psychologists seek to circumvent alienation and exploitation, for example, by eviscerating the substance of cultural factors – their coherence, extensiveness, weight, strength, and supportiveness. They seek to solve concrete social problems on the abstract level, by destroying culture in general. They destroy culture in order to protect us from it. They cannot see the way to transform culture into a humane social system that preserves the advantages of culture.

Microcultural psychology misconstrues the individual, psychology, and freedom in anti-cultural terms, and it misconstrues cultural factors and systems in anti-human, anti-subjective terms. This undialectical thinking results in bad social science and bad politics.

The political weaknesses of microcultural dovetail its scientific errors. Both stem from denying cultural structures as influences on psychology. The science and politics of the discipline of psychology go hand in hand. Good science and good politics require addressing the cultural basis, character, and function of psychology. Denying this results in bad science and bad politics.

Cultural psychology is scientifically correct about society and psychology, and it provides effective avenues to improve social and psychological life.

Since psychology is fostered by cultural factors, occurs as part of them, is objectified in them, objectifies them in subjective processes, and reinforces cultural factors via galvanizing specific cultural behavior, it follows that new forms of psychology require a new cultural structure. Cultural psychology thus utilizes psychological phenomena to challenge the system, whereas microcultural psychology uses psychological

phenomena to engage in illusory escapes from the system which never threaten it.

Cultural psychology (at its best) identifies concrete cultural factors that are alterable; it does not get lost in abstractions about culture and psychology which are not amenable to change. To improve educational psychology, one could identify ways that educational administration, pedagogy, and educational psychology reflect deleterious neoliberal and consumerist characteristics, and would work to transform these within and also outside the field of education. We would not speak abstractly about helping students to become interested in their studies, nor would we speak abstractly about honoring students’ human rights (Note 14).

Furthermore, cultural psychology’s detailed conception of culture leads to the broadest and deepest social change, and therefore the fullest liberation from problems of the status quo. Cultural psychology appreciates culture as a system in which all the factors/elements are interdependent. From this structural notion of culture, it follows that changing one factor requires changing the network of related factors on which the one depends. A powerful example is that non-school factors such as family income determine 60% of students’ success in primary and secondary school. In-school factors such as teaching pedagogy accounts for about 10%. Thus, improving educational success requires changing the system in which school is embedded, more than it does changing school-specific conditions (Ravitch 2010, p. 23; New York Times, Dec. 27, 2010, p. A1). The fact that any cultural factor is deeply ingrained in other factors makes it weighty, entrenched, and obdurate. It is not a simple, single, free-standing element that is easily changed. The dialectical opposite of this obdurateness is that it draws us to transform many factors simultaneously in order to change any one. Thompson (1967, p. 80) expressed this with regard to the changing sense of time in the eighteenth century: “The stress of the transition falls upon the whole culture: resistance to change and assent to change arise from the whole culture. And this culture includes the systems of power, property-relations, religious institutions, etc., inattention to which merely flattens phenomena and trivializes analysis (Note 15).

Solidity, coherence, systematicity, and obdurateness of culture dialectically lead to broader and deeper social change. And structural change retains the advantages of

culture such as support and stimulation from large numbers of individuals. Of course, structural change is difficult, but as with all difficult work, its payoff is great. Studying a difficult subject matter in school is difficult to master; however, it pays greater dividends (in the knowledge you acquire) than superficially studying a simple subject does.

Approaches to culture, politics, and psychology which overlook macro cultural factors as the cause of problems and the solution to problems propose superficial, incomplete, or false causes and solutions. These include scapegoating, fear mongering, militarism, speculation, superstition, supernaturalism, myth-making, fundamentalism, suppression of dissent, and heightened security – all of which are abetted by the social elite to protect the status quo (Schulman and Zelizer 2008). These can only be avoided by identifying macro cultural factors as the source of problems and working collectively to humanize our culture.

Anti-structural approaches to culture pride themselves on circumventing the obdurateness of culture and making change viable. One gambit is to escape into subjectivity. Microcultural psychology does this, as does postmodernism. They claim that subjectivity defines culture; so we can easily change culture by simply changing a thought or behavior. Another way to circumvent social structure is to reduce it to single, discrete factors. Each one is addressed separately in an effort to improve it. Proposals are offered for improving education, or health care, or family interactions separately.

While both these anti-structural approaches appear to make social change manageable, they actually limit it. For they are based on myths. They simply ignore and deny the structured reality of society and psychology. This reality acts behind the backs of those who refuse to perceive it. The only real way to improve society and psychology is to address their reality. (Realism is the only path toward liberation.) Realism in social science and politics means comprehending and challenging the structured social system of cultural factors, including their subjective which is psychology. Vygotsky stated this with his characteristic aplomb: “Life becomes creation only when it is finally freed of all the social forms that distort and disfigure it. . . Not in the narrow confines of his own personal life and his own personal affairs will one become a true creator in the future” (Vygotsky 1997a, p. 350).

Notes

1. Pred’s insights into culture, psychology/subjectivity, and their interrelationship are complemented by research from geographers, anthropologists, historians, and sociologists. Historian Lucien Febvre (1933) called for a historical psychology that emphasized “mentalities.” (See Plamper (2010) for interesting interviews with historians about their work in cultural psychology of emotion.) This research into cultural psychology by non-psychologists is deeper than cultural psychological research by psychologists – as we shall demonstrate with additional examples. Evidently, training in social science attunes scholars to the richness of culture that is absent from training in psychology. Perhaps this explains the general failure of psychologists to engage with social science research in cultural psychology.

2. The point of neoliberalism is to free natural resources and labor to be exploited by capitalists to maximize their private profit. Natural resources and labor are to be freed from protective social policies and organizations – e.g., regulation, unions – and humane concerns that counter their exploitation by capital. Freedom is a devious term that really connotes freeing natural resources and labor from community regulation so they can be exploited by the free, unrestricted activity of capitalists. Freedom for neoliberalism does not connote autonomy, self-fulfillment, and freedom from exploitation, but rather freedom to be exploited.

Neoliberalist freedom is an Orwellian term that means the opposite of what it claims for the populace. It is the freedom for the capitalist class to exercise and extend its hegemony over society. Neoliberalism is not freedom for the populace to develop itself. This is proven by the vast enrichment and empowerment of the capitalist class in the societies where neoliberalism is dominant. It is well known that the American superrich has greatly increased its wealth and power while the subaltern classes have lost wealth and power since the 1970s when neoliberalism was unleashed. In addition, social mobility has stagnated as public programs to enhance the educational and occupational opportunities of the underprivileged have been decimated (by Democrats and Republicans alike) and individuals rely more on private, family assets. Privatization makes people more dependent upon the resources at their disposal, which keeps the

wealthy rich and the disadvantaged poor. This is proven by the fact that Intergenerational income mobility – the difference between the wealth of parents and their children – has decreased in the dominant neoliberal economies. England has the lowest level of intergenerational income mobility in the world, with the USA the second lowest in the entire world (*New York Times*, October 16, 2010, p. B6). This means that American and British children are less free (have less opportunity) to deviate from the conditions of their birth, whether rich or poor. In contrast, children have more freedom to rise out of poverty and to fall from privilege in other countries with less neoliberal freedom.

Neoliberalism restricts personal freedom to be independent of socioeconomic conditions! That is its *raison d'être*: to maintain the class structure of society with all of its exploitation, inequality, and insecurity for the masses. This is why neoliberalism is endorsed and funded by the capitalists. They would never fund a movement that could reduce their class power by granting empowerment and freedom to the populace.

Neoliberal freedom is class-based. It is freedom for the ruling class but not for the subaltern classes. However, it is used as a general term devoid of class, and applicable to all individuals. Neoliberal ideology semiotically obscures the class basis and class limits to freedom. It overgeneralizes freedom to subaltern classes that are unfree. Neoliberal ideology thus semiotically inverts the unfreedom of lower classes into freedom. Whenever we hear the word freedom applied abstractly to all individuals, we must remember its concrete class character and class limits. We must remember that these do not extend to subaltern classes. When referring to the populace, we must reinvert the meaning of freedom into unfreedom to correct the rhetorical inversion of unfreedom into freedom. Semiotic terms cannot be accepted at face value. They must be compared to social reality to determine how accurate, or objective, they are.

Abstract terms such as freedom, people, agency, opportunity, individual are misleading in class society. Abstract terms strip away concrete distinctions among exemplars and promote the appearance of equality or identify. However, class society rests upon inequality. In class society, freedom, people, agency, opportunity, and individual exist in grossly different conditions with grossly different features. Rhetorically equalizing them

through abstract terminology obfuscates their concrete inequality. Abstract terminology serves the political function of smoothing over inequality, injustice, exploitation, and social class, without explicitly denying them. Denial would entail acknowledging their possible existence; it would also risk counterargument. It is safer to erase these features through utilizing the abstractness of language which simply has no place for them, and renders them inconceivable. The reality of social class is symbolically eradicated through the silence of abstraction, not through the vocalization of argument about class, or noisy political struggle to eradicate it.

3. Modern capitalism has brought about new forms of work which are brought within the orbit of neoliberal practices and policies. Capitalism now depends largely upon immaterial labor power such as affective labor of care providers, personal relations, and information networks. The relations, networks, affect, and technology that bring labor together are central to surplus value generation and they are infused with capitalist social relations such as commodification. The networking, communication, and psychological output of capitalist work is recapitulated in social networking technology such as internet sites. The new commodified forms of networking, communication, and psychological expression must be researched by cultural psychologists to discover the ways they are embedded in psychological phenomena. Cultural psychologists would do well to follow Arlie Hochschild's research into the emotional commodification of service workers who "employ" emotions as they are employed at work.

4. These "security" measures are really designed to surveil and suppress people from challenging the insecurity of the market political economy (Wacquant 2009; Melossi 2008). Security measures thus actually reinforce their opposite – insecurity.

5. To wit: one out of every seven applicants for private health insurance was refused coverage by American insurance companies in 2009 because the applicants had a prior medical condition that made them liable for expensive care which the insurance companies did not want to pay. One of the medical conditions that disqualified an applicant from health insurance was pregnancy, or attempting to adopt a child! (*Wall Street Journal*, October 13, 2010, p. A2).

6. Lave et al. (2010) describe how neoliberalism also affects science. This is an important aspect of cultural psychology. For cultural psychology analyzes the cultural origins and nature of psychological science as well as psychological phenomena.

Understanding the politics of social science approaches is explored in the academic discipline known as science, and technology studies (STS). It studies how social, political, and cultural values affect scientific research and how the latter affect society, politics, and culture. A leading journal in the field is *Social Studies of Science*.

7. Using time as the parameter of work increases productivity and profitability by cramming more work within the fixed parameters of time and wages. In the old task orientation, increasing production output would lead to expanding the time required, and this would maintain productivity (work per unit of time) and profitability at constant levels.

8. In England,

- ▶ the preliminaries to the industrial revolution were so long that, in the manufacturing districts in the early eighteenth century, a vigorous and licensed popular culture had evolved, which the propagandists of discipline regarded with dismay. Josiah Tucker, the dean of Gloucester, declared in 1745 that "the lower class of people" were utterly degenerated. Foreigners (he sermonized) found "the common people of our populous cities to be the most abandoned, and licentious wretches on earth." "Such brutality and insolence, such debauchery and extravagance, such idleness, irreligion, cursing and swearing, and contempt of all rule and authority. Our people are drunk with the cup of liberty." The irregular labour rhythms [of this socioeconomic activity] help us to understand the severity of mercantilist doctrines as to the necessity for holding down wages as a preventative against idleness... (Thompson 1967, pp. 80–81)

Time orientation and time discipline thus served to carry out broad social change in the life activity of the lower classes so as to subjugate them to industrial labor and capitalist class rule. This was reinforced by a corresponding new sense of character that was elevated by punctual, consistent work, and was compromised by idleness and indolence. Being a good person was defined in capitalist terms just as time was.

Former pleasurable, social activities such as wakes and holidays and the annual feasts of friendly societies, and "the slothful spending the morning in bed" were denounced as "shameful devourers of time and money."

9. It demonstrates that religion's role is not to enlighten people about unfathomable mysteries. Religion only provides a subjective comfort of feeling protected by a higher being, feeling a higher purpose or order to life, feeling connected with people, nature, and the universe, or a sense of justice – reincarnation contains this sense since the soul is connected to individual bodies and even species, and rebirth justly rewards or punishes one depending upon previous actions. But this sense of purpose, order, connectedness, justice, and protection are wishful metaphors. Real life is divisive, disconnected, unfair, exploitive, chaotic. Most religion posits a spirituality that is opposite to these and which exists alongside material life. Most religion does not improve material life, and this is why it never deals with material issues. It abandons them and retreats to a metaphorical, metaphysical realm of spirituality that supposedly exists outside (alongside) real, material, social life. It allows people to suffer all the slings and arrows of real social life, but then believe in a better spiritual world apart from this. But this gambit accepts the evils of material, social life. (Of course, people are expected to be kind in their interpersonal interactions, but without any alteration in the social institutions and artifacts in which they conduct their lives.) This is why exploitive societies endorse religion: it allows them to exploit people with impunity and to look to nonsocial spiritual solutions to social problems. The most conservative, exploitive rulers embrace religion because it allows them to claim to be sympathetic to justice, order, connectedness, and protection on a spiritual level; while they simultaneously exploit people in the real, material, social realm. Exploiters know that most religion will not challenge their material, social practices because it has accepted social life as it is, and escapes into an unreal, metaphorical, metaphysical realm to explain and solve problems. This explains why the Catholic Church never officially condemned fascism, and actually condoned it in many instances.

Religion's disengagement from understanding and reforming social reality leads it to adopt a spiritual,

metaphysical outlook that is similarly disengaged from physical, scientific reality. Abandoning social reality (to the exploiters and the sufferers) and retreating to an unreal realm, the constructs that are relied on to provide social protection, purpose, justice, and connectedness are devoid of any intelligible, specific, or empirical properties. There is no specification of what god is, how “he” created the earth. Nor is there any specification of how a soul becomes reborn in another body and even species. Nor is there any interest in such real questions. By definition, religion cannot posit real, intelligible, empirical phenomena because it has abdicated real, material, social life and retreated to a metaphorical, metaphysical realm. It is fruitless to challenge religious devotees to explain their constructs in terms of real mechanisms (e.g., in relation to scientific knowledge) because they are not designed to deal with real things. They are designed to simply give people a metaphorical sense of order, connection, protection, and justice without any reality to these. Irreality is accepted as part of the metaphysical, metaphorical, spiritual realm. It can never lead devotees to renounce their constructs.

Religion does not enlighten people about the mystery of things; on the contrary it compounds the mystery by introducing explanatory constructs – e.g., a higher being, or reincarnation – that is unintelligible. Not only is the origin of the earth difficult to fathom, but the god that is supposed to explain it is unintelligible. We now have two mysteries instead of one. (See Belzen 2010 for a cultural psychological analysis of religion.)

10. An objective analysis of psychology not only enables us to identify and refute fallacious concepts about psychology, it also enables us to trace them to their cultural roots. We can explain the features of society that generate false concepts about psychology. We can critique capitalism for organizing an oppressive content to our psychology – e.g., egocentric, consumerist – and also for obscuring the full character and origins of our psychology, thus making it difficult to alter.

11. The politics of the external, critical perspective and the indigenous, multicultural perspective that validates diverse cultures “for who they are,” is revealed in the dispute over the Nobel Peace Prize that was awarded to a Chinese dissident, in prison, on October

8, 2010. The dissident, Liu Xiao Bo, was serving an 11 year prison sentence for his writings urging democracy, an independent judiciary, and multi-party elections in China. The Nobel Commission awarded him the Peace Prize as a way of supporting the cause of democracy, despite the fact that Liu’s activities were judged to be illegal by the Chinese system. The Commission challenged indigenous Chinese practice on the basis of a higher standard of human rights. The Chinese denounced this external social critique as not respecting Chinese law and culture. They accused the Nobel Committee of imposing “Western” values on China and showing contempt for its legal system. They used the indigenous cultural argument that a culture’s practices are immune from external critique.

The Chinese government threatened to punish Norway economically and diplomatically for granting the award to a dissident criminal. The government also blocked announcement of the Peace prize from its news media and from internet sites that carried it. Anyone typing the words “Nobel Peace Prize” or “Liu Xiaobo” into Google found themselves facing a blank screen. And the police raided a private party in a Peking restaurant where a few Chinese who learned of the Prize were celebrating. The police imprisoned several of the group on charges of disturbing the peace. The police did not even know who Liu was. The government also placed Liu’s wife under house arrest and cut off her cell phone – because her husband had received the Nobel prize!

This case illustrates the politics of the two positions we have been discussing. If you support the indigenous, multicultural viewpoint, you would endorse China’s defensiveness and nationalistic pride. If you support the external social critique argument, you would endorse the Nobel Commission’s actions. That is, if you were consistent in your thinking. Of course, many multiculturalists in the domain of social science would be aghast at the Chinese’s actions, even though their dismay contradicts their indigenous, multicultural position in social science.

12. A related example of cultural psychological research that minimizes real culture is Gladkova’s (2010) comparison of linguistic connotations in Russian and English. She concluded that words such as “sympathy” are used differentially toward in-groups but not toward members of out-groups in Russian,

however, these words are used equally toward both groups in English. A cultural explanation was proposed: “These differences in meanings can be attributed to the prevalence of different models of social interaction in these two cultures” (p. 280). Specifically, Americans do not distinguish in-group and out-group as dramatically as Russians do. This cultural explanation is faulty in several ways.

First, it is dubious. Americans segregate in-group from out-group quite strongly. Every American child is taught “do not talk to strangers;” cliques are rampant in school, and the cause of considerable anxiety among outsiders who cannot break into an in-group; American residences are protected against outsiders by gates and guards; employees treat supervisors at work completely differently from a friend or spouse.

Secondly, Gladkova offers not a single example of these purported cultural models. She particularly fails to mention examples in public, objectified laws, moral precepts, historical records, philosophical concepts, entertainment programs, and child-rearing literature, where they would be true cultural factors, subject to politics and other features of cultural factors I have enumerated throughout this book. These features are necessary for models to be shared, intelligible across a society, and useful for achieving cultural purposes. To casually mention some vague “cultural model” as the cultural explanatory construct of semantic meaning, without any specification or documentation is alarming – especially for an article which is entitled “A Cultural Analysis” and which is published in a journal named *Culture & Psychology*.

A third weakness in the author’s treatment of the social model as cultural explanation, is that it is isolated from any other cultural factors. The model of social interaction is ungrounded in cultural factors, structures, conditions, ideology, politics. It ignores the horizontal and vertical “hermeneutic circles” that comprise the social structure. Gladkova’s “social model” is suspended in time and space, it is deculturated and depoliticized. (This abstractness is what makes it vague.) This is again alarming for a “cultural analysis.” In fact, it is insidious. For it pretends to be a cultural analysis when it is not. The unwary reader will be led to believe that casual, abbreviated mention of some vague, undocumented, ungrounded – and dubious – cultural phenomenon

suffices as a cultural analysis. This is a dangerous model of cultural analysis which impedes serious interest in culture as a substantial, organized, administered, meaningful, concrete, consequential influence on psychology.

13. Joseph de Maistre described counter-revolution in the following poetic terms: “La Contre-Révolution ne sera pas une révolution contraire, mais le contraire de la Révolution.”

14. The concrete struggle to identify and humanize cultural factors is a topic in its own right. That struggle certainly begins among individuals. However, even at this stage, it is always a struggle that is directed at macro cultural factors. It is not a discussion in which individuals negotiate their personal desires for self-expression, which microcultural psychologists focus on. Furthermore, struggles for social and psychological change always expand beyond the initial small group of individuals who foment them. They are realized in organized campaigns that strive to alter macro cultural factors via broad dissemination of social propaganda through social media outlets that reach masses of people simultaneously. Social change is not a sequential movement of interpersonal interactions.

15. For instance, the development of the individualistic self/agency in China required state policies regarding employment, land ownership, and allocating housing, along with corresponding changes in family relations, dowries, sexuality, youth culture. Similar grand societal changes are necessary to construct or transform any cultural factor (e.g., education) and its psychology (educational psychology, time sense, prejudice).

Cultural Psychology and the Cinema

ROBERT W. RIEBER

Fordham University, New York, NY, USA

- Dreams hang in fragments at the end of the (screening) room, suffered analysis, passed – to be dreamed in crowds, or discarded.

F. Scott Fitzgerald, *The Last Tycoon*

If the cinema is not made to translate dreams or all that which, in conscious life, resembles dreams, then the cinema does not exist.

Antonin Artaud, *Cinema and Reality*

Introduction

Cinema may be considered a form of mass communication. Nevertheless, there is much more to this medium that makes it even more complex and interesting. If there is one word that has been associated

with the motion picture since its inception, it would have to be entertainment. There are serious movies and edifying movies and movies that teach and promote ideologies or beliefs. But generally speaking, we go to the movies to be entertained. And it is that very capacity to effectively deliver entertainment – bypassing our critical faculties – that make movies so powerfully influential for better and for worse in ways that we may not even be aware of. Consider what Shakespeare taught us in what is widely regarded as his best play – *Hamlet*. Here, Shakespeare helps us to gain insight into the process of what is actually involved in the entertaining us. Hamlet's dialogue with the players highlights three possible forms of entertainment: as history, comedy, and tragedy. In the play within the play, he famously makes his intentions clear, asserting, "The play's the thing/wherein I'll capture the conscience of the King." But the theater and film also have the capacity to capture consciousness as well as conscience, and I believe Shakespeare would consider it an agreeable addition. Both conscience and consciousness are essential factors because they constitute the foundation of what we call Cultural Psychology of the Cinema – or what I call the Social Dream – which constitutes the major subject matter of this discussion. How entertainment can reach our conscience and affect our consciousness will become the "light motif" (the cinematic techniques) and "heavy motifs" (the impact of the content conveyed by means of those techniques) throughout. I will begin by tackling the question as to how cinema's evolution allowed movies to create an ever more palpable illusion of "reality" for viewers, holding them captive in the artificial worlds they create. After all, our conception of reality is not based exclusively on what our senses tell us, it is also what goes on in our heads – specifically in our imagination and the associations that surface in our memory. And if there is one thing that movies have shown themselves successful at, it is getting into our heads. As Richard Eberwein put it in his book on film and dreams: "Film gives us the dreams we never had, the dreams we yet await. . . . Film's overwhelming images invite a return to that state in which the ego dissolves" (Eberwein 1984).

By the canny (or uncanny) use of such techniques as flashbacks and flash-forwards, jump cuts and montages, the technicians of cinema have been able to evoke to some extent the way in which memory works and

how emotion colors the way we perceive the external world. But movies have also proven to be remarkably efficient vehicles in duplicating dreams. Indeed, surrealists like Salvador Dali and Luis Brunel were among the first to exploit the possibility of using film to create dreams on the screen (think of the iconic image of a razor slitting an eyeball in *Un Chien Andalou*). Brunel has stated that film seems expressly designed for exploring the subconscious, noting that the images, as in dreams, can appear and disappear through "dissolves" and fade-outs while the laws of time and space are routinely violated.

Movie mavens and students of psychology alike have long observed the similarity between the state of dreaming and the state of the viewer's mind watching a movie. "An analogy between cinema and dreaming has long been drawn, film appearing to us as dreamlike, while our dreams are experienced – at least to our waking minds – like movies," observes Elizabeth Cowie, a British film scholar. Even though we are conscious when we sit in a theater, she says, we are still in a passive position – "immobile, silent and . . . attuned to only those stimuli arising from the film performance. . . . oblivious to other events around us, while the exigencies of reality, and the demand to test for reality, are placed in abeyance" (Cowie 2003).

But I will also look at the ways in which film has become a means of recording and transmitting the collective dreams of culture and society – what Roland Barthes called "collective representations" – whether or not the filmmakers understand what those dreams are. I will then proceed to examine a sampling of the cinematic dreams that have haunted our collective unconscious over the last several decades and focus on three of the principle types of characters or archetypes that have figured prominently in these dreams, indeed, have effectively defined what the dreams are really about (My use of the terms 'collective unconscious' is not meant to imply that I am a Jungian. However, for the purpose of this discussion it is a convenient and apt description of the kind of social dream that films can embody).

Pinpointing the origin of cinema is more difficult than might be imagined. It depends largely on which invention you identify as the first moviemaking device. Some scholars choose the camera obscura used by Renaissance painters. Others favor a device known as

a phenakistoscope, a spindle viewer invented by a Belgian physicist in 1832 or opt for the zoetrope invented a year later by a British mathematician. More weight probably should be given to Edison's kinoscope, which was introduced at the Chicago Exposition of 1893. To operate the device you dropped a nickel into a slot, triggering a small motor that allowed you to peer through a magnifying glass and watch a girl dancing or boys fighting. Your nickel bought you half a minute of entertainment. However rudimentary these devices, all had one thing in common: the capacity to create the illusion of movement out of a sped-up sequence of still images.

Early Psychological Views of Cinema

Just exactly how films can operate on our minds was a question that psychologists were already grappling with in the early part of the twentieth century notwithstanding Freud's belief that it was impossible to "graphically represent the abstract nature of our thinking in a respectable form." (Freud rebuffed offers to write a photoplay on several occasions, even turning down an offer of \$100,000 from Samuel Goldwyn, a fortune at the time.) Modern cinema and psychoanalysis both emerged around the same time. Freud and Joseph Breuer's pioneering *Studies on Hysteria* was published in the same year (1895) that the Lumière brothers were screening films they had produced using their new "cinematograph." The two explorations had a great deal in common. Freud and Breuer were investigating the phenomena of hysterical fits among patients at Salprière hospital, examining behavior that they characterized as "automatism" – spontaneous verbal or motor behavior or acts performed unconsciously. Meanwhile, the Lumières were bringing the inanimate to life on screen – or at least the representation of life – in a jerky, uncoordinated manner that recalled the uncoordinated movements of the patients Freud and Breuer were observing. The new medium illustrated what Freud called the uncanny – a juxtaposition of the familiar and the strange, the animated and the lifeless.

It appears likely that the first experiment to assess the impact of film on the spectator was conducted in 1916 by the eminent Harvard psychologist Edwin Boring. In his "picture-test," viewers composed of children and adults of both sexes were presented with

a 1-min scene from an Edison film entitled *Van Bibber's Experiment*. The clip depicted a confrontation between a "gentleman and a burglar." The test was designed to measure the accuracy of reporting by the viewers – what they retained of what they saw. A sex difference in suggestibility emerged from the study especially among the adults: "The men exceed the women in range of report, range of knowledge, accuracy of report, assurance (and) reliability of assurance. . ." The results led Boring to conclude that "in general the men appear to be superior as witnesses to both women and boys, whereas between women and girls and between girls and boys there is a much less striking difference." He did not hazard a guess as to why men were so much superior reporters; perhaps men were more susceptible to the new medium than women or responded to the subject matter more enthusiastically. It would have been interesting to learn whether a similar "picture-test" showing two women in a domestic situation would have yielded the same results (Boring 1916).

Munsterberg on Film

If Boring was in the vanguard of psychologists examining the influence of film, it is safe to say that the German philosopher Hugo Munsterberg is the medium's first significant critic and analyst. Munsterberg's seminal contribution is found in an almost forgotten monograph published in 1916 called simply *The Photoplay: A Psychological Study*. Not content with being a critic, Munsterberg flirted with filmmaking himself. In 1916, he approached Paramount Pictures with "material for a series of psychological test demonstrations in moving-picture form," noting that movies "have stirred up a very considerable interest for mental life in many cities." As an example of what he meant, he proposed to present the Montessori educational system in a cinematic form. If he were in charge of film studios, he wrote, they would specialize in particular categories because otherwise how were audiences to know what they were getting when they walked into a movie theater? "I think the greatest trouble in the moving-picture world today is the lack of discrimination and differentiation," he wrote, attributing "the crude state of the moving-picture industry" to this inconsistency. Instead he favored "a clean division of labor" among production companies (Munsterberg 1922, p. 125). History has shown that he proved more

prescient in his role as critic than he did at postulating a viable business model for Hollywood.

It should be pointed out that Munsterberg had no interest in the way in which cinema might embody a social dream. In what is arguably his most famous statement he declared: “The story of the subconscious mind can be told in three words: there is none.” (Munsterberg 1909, p. 125). Munsterberg’s inner philosopher, his daughter Margaret wrote, never allowed the inner scientist the final say on any problem of real life (Munsterberg 1922, p. 283). If the philosopher did not believe in the existence of a subconscious, no scientific data to the contrary was going to cause him to change his mind. So it follows that in his consideration of the cinema he did not take any interest in the way in which it affected a part of the mind that was not immediately accessible to our awareness. According to the critic Giuliana Bruno, Munsterberg conceived of psychic life “as a mechanism to be unraveled – a technology of sorts” that led him to recognize “the psychic function of the film apparatus.” Bruno writes that he regarded cinema as an “actual ‘projection’ of the mind.” Our minds, he believed, acted like screens in which a motion picture was rolling whether the subject was awake or asleep (Bruno 2009, pp. 190–191).

All the same, his pioneering study on the nascent medium provides us with valuable insights about the ways in which films do in fact infiltrate and embody our individual and collective dreams. He foresaw – correctly – that film had the potential of uniting the sensibilities of both the highbrow and the lowbrow and characterized the directors and screenwriters as photopoets who “recognize the special demands of the art.” (Munsterberg 1922, p. 283) It is a tribute to Munsterberg that he was willing to credit cinema as an art, not as a mere novelty. “What we need for this study is evidently, first, an insight into the means by which the moving pictures impress us and appeal to us,” he wrote. “Not the physical means and technical devices are in question, but the mental means. What psychological factors are involved when we watch the happenings on the screen? But secondly, we must ask what characterizes the independence of an art, what constitutes the conditions under which the works of a special art stand. The first inquiry is psychological, the second esthetic; the two belong intimately together” (Munsterberg 1916, p. 21).

In his monograph, the philosopher tackles the subject of film in two basic ways. First, he considers the influence of film through its technology and cinematic techniques – what he terms “processes of perception and attention” – developed by early masters like D.W. Griffith. Second, he examines the impact of these processes on the spectator in terms of his or her “interest, memory, imagination, suggestion, and emotion.” (Munsterberg 1916, p. 40) Whatever the limitations of Munsterberg’s outlook – we are all constrained by our time and place, after all – his views stand up to scrutiny even now. He is similarly perceptive when it comes to the impact these technologies and techniques have on the viewers.

Emotion was central to Munsterberg’s theory of film. It represented an “inner venture” and “an intimate voyage – a tour of the emotions.” Motion pictures were composed of “emotion pictures” and provided the psychic terrain in which feeling could be navigated “and charged cinema with the ‘moving’ power of emotion.” (Bruno 2009, p. 191) Depending on the context, Bruno writes, the audience will interpret the same shot of a facial expression with different emotional responses. One might, for example, “project” onto the same expression sadness or joy, love or hate, hunger or satisfaction. The test of a filmmaker’s ability to reach his audience was the effective use cinematic techniques as “a form of empathy” (Bruno 2009, p. 102).

How do Movies Operate on the Consciousness?

In Munsterberg’s view, the success of the motion picture is directly related to the processes of the mind. The objective world, he maintains, shapes and molds the mind; the mind in turn uses the stuff of the external world to develop “memory, ideas and imaginative ideas” and then “in the moving pictures they become reality.” He goes on to say: “The mind concentrates itself on a special detail in its act of attention; and in the close-up of the moving pictures this inner state is objectified. The mind is filled with emotions; and by means of the camera the whole scenery echoes them” (Munsterberg 1916, p. 21). The mind perceives the world on the screen in a different manner than it does the external world. “We perceive the movement; and yet we perceive it as something which has not its independent character as an outer world process, because

our mind has built it up from single pictures rapidly following one another. We perceive things in their plastic depth; and yet again the depth is not that of the outer world. We are aware of its unreality and of the pictorial flatness of the impressions” (Munsterberg 1916, p. 21). In other words, the spectator becomes a collaborator of the filmmaker. We understand that what we are seeing on the screen is not objective reality but “a product of our own mind which binds the pictures together.” The illusion of movement results from a dynamic between our perceptions and the deployment of the technical repertoire of the filmmaker. Consider, for example, the close-up. “The attention turns to detailed points in the outer world and ignores everything else: the photoplay is doing exactly this when in the close-up a detail is enlarged and everything else disappears.” His assessment remained valid even as films developed over the years. Roger Manvell, a noted British critic, said almost the same thing in the 1950s long after film was a nascent art form: “One of the first tests of filmmaking is the degree to which the camera is used to assist the spectator to select what there is to see, that is, when the camera is used to help interpret the action” (Manvell 1955, p. 23).

The ways in which the camera is used to shape the spectator’s movie-going experience, as described by Munsterberg, informs the next part of our discussion.

The Techniques

In Munsterberg’s scheme there are five principal techniques that filmmakers make use of to produce their movie magic: depth, composition, movement, the close-up, and what he calls the cutback. To this list we also need to add sound, an innovation that did not come about until several years after the monograph was published.

Depth, or rather its illusion, provided cinema with much of its effectiveness – so much so that “some minds are struck by it as the chief power in the impressions from the screen.” Munsterberg compares the impact of depth as conveyed by film with depth as perceived by theater audiences. (The theater, for obvious reasons, was the medium closest to the film.) He cites the poet Vachel Lindsay who wrote that “the little far off people on the old-fashioned speaking stage do not appeal to the plastic sense” with anywhere the same impact as the “dumb giants in high sculptural relief”

on the screen. Of course, the “dumb giants” on the screen would find their voice soon enough with the introduction of the talkies, a development that Munsterberg did not live to see. All the same, viewers were not deceived; they certainly did not mistake the depth of a scene they were watching on the screen with “true depth and fullness,” but on the other hand, they were perfectly content to be taken in. This illusory reality “brings our mind into a peculiar complex state; and we shall see that this plays a not unimportant part in the mental makeup of the whole photoplay” (Munsterberg 1916, p. 40). (When Munsterberg refers to the photoplay, he means the film as a whole and not just the screenplay.)

Depth is only an attribute of space; how it is used by the filmmaker to evoke a mood, establish character, and advance the plot is another matter entirely. (I am using the term filmmaker as a convenient term to refer to the director, cinematographer, and film editor, all of whom play a role in determining the shots that wind up in the final footage.) This brings up the “problem” of pictorial composition. As Marvell observes: “Composition can, consciously or unconsciously, greatly affect the attitude of the audience to what is going on in the story” (Manvell 1955, p. 31).

Unlike the problem of depth, which can be easily ignored by audiences, Munsterberg wrote, movement “forces itself on every spectator.” Explaining motion in film is “the chief task which the psychologist must meet” – essentially resting on his ability to account for the complex mental process that creates the impression of movement from a series of still images. The mind is fooled into perceiving motion, a happy illusion. At the same time, the philosopher points out, the spectator also realizes that the actors’ movements are not continuous; we see a hand reach for a gun and then the gun is in his hand and yet the interruption does not trouble us at all.

Filmmakers have other tricks up their sleeves in addition to the use of depth and movement to make audiences sit up and pay attention. They also know how to employ the close-up to optimal effect. “An unusual face, a queer dress, a gorgeous costume or a surprising lack of costume, a quaint piece of decoration, may attract our mind and even hold it spellbound for a while.” What was a small detail on the screen, easily overlooked, can be made to fill the entire screen, obliterating everything else,

so that we have no choice but to focus on it. In underscoring the importance of the technique, Munsterberg once again uses the theater as a basis for comparison: “The close-up has objectified in our world of perception our mental act of attention and by it has furnished art with a means which far transcends the power of any theater stage” (Munsterberg 1916, p. 56).

The last technique that Munsterberg examines in his discussion of the power of the film is what he calls the cutback and what we now refer to as a flashback. Noting that the cutback may have “many variations and serve many purposes,” he is mainly concerned with the flashback as “an objectivation of our memory function.” He believes that the cutback and the close-up are complementary or parallel functions. “In the one we recognize the mental act of attending, in the other we must recognize the mental act of remembering.” Here again, the film has an advantage over the theater where mental states can be suggested but seldom shown. “*It is as if reality has lost its own continuous connection and become shaped by the demands of our soul.*” The film has reversed the natural order: the external world has become “molded in accordance with our fleeting turns of attention or with our passing memory ideas” (Munsterberg 1916, p. 89).

The introduction of sound revolutionized the development of the new medium. The first commercial film with fully synchronized sound was shown in New York in 1923. “The film owes its power to the mobility of its images combined with the selective use of sound, and its aesthetic derives from this,” Manvell writes. “Its poetry lies in the richest use of these potentialities by the artist, as the power of literary poetry derives from the potentialities of words used in the service of emotional experience” (Manvell 1955, pp. 91–92). Sound – excuse the pun – amplified the illusion of reality on the screen, making it in Manvell’s words “an extension of our own world,” something the silent film could never be. (The strength of silent film was principally found in its depiction of fantasy, its other-worldliness.) While sound can represent reality, the British critic goes on to say, it is also “a highly artificial form of expression which the artist can control at every point” (Manvell 1955, p. 35).

Psychological Component

As I stated earlier, the spectator is a silent, but not necessarily passive, collaborator of the filmmaker. If

the spectator is not engaged nothing on the screen is going to have much of an impact. In Munsterberg’s theory, the filmmaker is deliberately trying to fool the audience, but the audience is in on the game, indeed, would not have it any other way. As Gregory Bateson puts it in his essay “Steps to an Ecology of the Mind,” “Conjurors and painters of the trompe d’oeil could concentrate on acquiring a virtuosity whose only reward is reached after the viewer detects that he has been deceived and is forced to smile or marvel at the skill of the deceiver. Hollywood filmmakers spend millions of dollars to increase the reality of a shadow” (Bateson, p. 182).

So “depth and movement alike come to us in the moving picture world, not as hard facts but as a mixture. . . . They are present and yet they are not in the things. We invest the impressions with them” (Munsterberg 1916, p. 4).

If we consider both the “outcome of esthetic analysis” and “psychological research,” Munsterberg writes, than it is possible to combine the results of both into what he calls a unified principle that he defines thusly: “the photoplay tells us the human story by overcoming the forms of the outer world, namely, space, time, and causality, and by adjusting the events to the forms of the inner world, namely, attention, memory, imagination, and emotion.”

We will now turn to the ways in which the actions of the inner world can enhance the effectiveness of a representation of the outer one.

Munsterberg is like a visionary who has seen the future, and the future is cinema. Here he is extolling the power of the medium in almost ecstatic terms: “The massive outer world has lost its weight, it has been freed from space, time, and causality, and it has been clothed in the forms of our own consciousness. The mind has triumphed over matter and the pictures. It is a superb enjoyment which no other art can furnish us” (Munsterberg 1916, p. 173).

How does our mind achieve this remarkable triumph over matter and the pictures when it is the pictures that are the very source of that triumph? Consider: Even though we may suspend our disbelief when we walk into a movie theater, that does not mean that we relinquish our identities. We come to each film armed with our memories and our imagination. The film has the capacity to stir *our* memories (sometimes

of a previous film we have seen no less than memories of our own experiences). And, as Richard Eberwein points out, it also has a capacity to bring us into “greater contact with a character’s mental life” because of the way that film resembles individual dreams while simultaneously having the ability to evoke a social dream. “To this screen we bring memories of how we experience the rapid jumps, incoherent connections, and ambiguities of our own dreams. They serve as constitutive psychic coordinates helping us to follow through the dreamer’s experience. . . In this sense, our involvement in the filmic dream seems to be part of a collective dream experience” (Eberwein, p. 54).

At the same time through its use of flashbacks (cutbacks in Munsterberg’s parlance) a film can also evoke the memories of the *characters*. “Memory breaks into present events by bringing up pictures of the past. . .” Similarly, film goads and provokes the imagination, heightening expectations or even imposing a narrative on the film that might not be what the director originally intended. For the characters, however, “the imagination anticipates the future or overcomes reality by fancies and dreams.” Film is uniquely able to mimic the mental processes – the way in which “our mind is drawn hither and thither” – by showing “intertwined scenes everything which our mind embraces” (Munsterberg 1916, p. 171).

Munsterberg argues that filmmakers have managed to abolish time or at least manipulate it so that it can be attenuated, compressed or chopped up into bits and pieces, served up on screen at intervals when they are likely to pack the most punch. “The temporal element has disappeared, the one action irradiates in all directions,” Munsterberg avers although he is quick to add a qualification, noting that the technique can be overdone, especially “if the scene changes too often and no movement is carried on without a break.” As an example, he notes that at the end of *Carmen*, starring the legendary Theda Bara, the scene changes no less than 170 times in 10 min, an average of a little more than 3 s for each scene, which, he admits introduces “an element of nervousness.” When Munsterberg talks about time, he is really talking about cause and effect or more simply, the concept of causality. The film makes a mockery of causality by interrupting one series of events on screen with another series of events that do not immediately lead to the consequences they would have in the real world. “A

movement is started, but before the cause brings results another scene has taken its place. What this new scene brings may be an effect for which we saw no causes.” As a result, different objects can fill the same space, a physical impossibility in the world we have left behind when we entered the theater. “It is as if the resistance of the material world had disappeared and the substances could penetrate one another.” You are unlikely to find someone who buys a ticket to a movie because he wants to “experience this superiority to all physical laws.” But that, says Munsterberg, is what he is really doing (Munsterberg 1916, p. 185).

Munsterberg seems to understand that the movies do not quite cause time to disappear as much as they play havoc with our sense of time by speeding it up or slowing it down. Films have a particular rhythm; in that respect they are similar to music, a point made by the director Ingmar Bergman (who pointed out that the film has more in common with music than it does with the novel in spite of the fact that both usually rely on narrative). “The melody and rhythms belong together,” Munsterberg writes, observing that “as in painting not every color combination suits every subject. . . so the photoplay must bring action and pictorial expression into perfect harmony.” The images “roll on with the ease of musical tones” (Munsterberg 1916, p. 176).

Manvell agrees: “Because the film as a whole takes the form of a succession of many different shots, the timing as well as the order of the shots must be considered. Just as variation of rhythm in music has a great effect on the listener, so the tempo of the cutting of a film affects the audience.” The rhythm of the film depends largely on the film editor. Indeed, in his study *The Technique of Film Editing* the director Karl Reisz contends that the development of a true principle of editing helped the medium discover its real powers (Manvell 1955, p. 26).

That films are free to leave the “world of space and time” behind and dispense with causality, Munsterberg writes, does not mean that films are not bound by certain laws in much the same way that music is governed by rules of harmony, melody, and rhythm. These rules are established by rigid esthetic criteria, he argues. In music “everything is completely controlled by esthetic necessities.” Even a creative genius cannot get away from “the iron rule that his work must show complete unity in itself.” Film, too, for all freedom it

permits filmmaker to play with “the physical forms of space, time, and causality,” if not escape them completely, “does not mean any liberation from this esthetic bondage. . .” (Munsterberg 1916, p. 184).

Anticipating the current argument about multitasking – whether it is possible to attend to or effectively carry out several different tasks simultaneously – Munsterberg notes that the psychologists of his day were debating the question. Could the mind “devote itself to several groups of ideas at the same time” or was it a “rapid alteration” of attention? In either case, he maintains that “this awareness of contrasting situations, this interchange of diverging experiences in the soul, can never be embodied except in the photoplay.” This brings him to the idea of association. The scenes on the screen trigger a mental process by means of suggestion. A suggested idea, he says, takes root in our mind in much the same way that ideas do that are inspired by memory or the imagination. When we see a landscape depicted on the screen, for example, it can evoke any number of associated ideas based on the memories and fantasies that already exist in our minds. While the filmmaker controls what we see on the screen, we are in control of how we perceive and react to the images and sequences. The suggestion, he writes, is “forced on us,” but what we do with that suggestion is another matter entirely. The “outer perception” is not just a starting point but “a controlling influence” so that we never mistake the associated idea “as our creation but as something to which we have to submit.” Taken to an extreme, the film acts as a hypnotizer, keeping us spellbound in the theater or at the very least keeping us in a “in a state of heightened suggestibility.” Once again we are straying in the direction of the dream and the idea that film is a medium which invites its audience to share the dream it presents. “*It is as if reality has lost its own continuous connection and become shaped by the demands of our soul*” (Munsterberg 1916, p. 95).

What really excites Munsterberg – and spurs him to make such impassioned declarations – is the film’s capacity to connect a variety of “parallel currents” on the screen and in the minds of the spectators. (With its multitude of links the Internet has a similar property.) We may be confined in a single room, he writes, but every phone call we receive in that room brings news of the outside world. Film provides us with that same

sense of interplay and connection. “There is no limit to the number of threads which may be interwoven. A complex intrigue may demand coöperation at half a dozen spots, and we look now into one, now into another, and never have the impression that they come one after another.” Once again he is eager to show us how the film can abolish the temporal element and sabotage our traditional conception of causality.

The juxtaposition of images or the rapid succession of images and scenes that Munsterberg is talking about is now referred to as a montage. The foremost proponent of the montage was the great Russian director Sergei Eisenstein. “At its simplest,” says Manvell, the theory of montage boiled down to “the axiom that, in editing, one plus one equals not two, but two plus; in other words, that the total effect of a series of shots purposefully placed in sequence is the creation in the audience of an entirely new train of thought and feeling, different from anything that could arise out of those shots seen as a number of separate units.” (Manvell 1955, pp. 191–192) Montage, as opposed to mere representation, Eisenstein contended, “obliges spectators themselves to create” and arouses emotions in a way that a film that simply conveyed information cannot (Eisenstein 1943). In effect, Eisenstein is advancing the same argument that Munsterberg does when he refers to “emotion pictures.” (Eisenstein propagated his theory in a 1923 essay called *The Montage of Attractions*.) But credit for the use of montage (or free association if you will) belongs to the pioneering French filmmaker George Melies who believed that every image on the screen “possessed the element of magic.” (And he should know; he was also a magician by trade.) By splicing in parts of different films, clever editing, and altering scenes to create “illusion of magical transformation, appearance, and disappearance,” he was able to turn a human into an animal or separate a man from his head and track them as they went on their separate ways. “He could make anything happen at all so long as it didn’t violate the laws of everyday life.” So at the end of the film, man and head would be reunited. “Melies sensed or knew that fantasy and magic, like dreams and nonsense language, have a structure and logic of their own, and to deviate from them is a sure way to lose an audience.” (Sklar 1994, p. 137) Here again we can see the resemblance between film and dreams. The unconscious seems to

make liberal use of montages – it is possible that every dream *is* a montage – and the filmmaker is simply tapping into the same emotions and associations that fuel our dreams.

In the final chapters of the monograph, Munsterberg turns his attention to the emotional impact of the medium. It is safe to say that today's audiences, growing up with TV and accustomed to watching video on the Web, are not quite so strongly affected by the film as the audiences of Munsterberg's time. He notes that "neurasthenic" spectators were known to experience hallucinations and "illusions" after watching a movie and remarks on the "strange fascination" of film that could induce audiences – especially among the "rural population" – to applaud "a happy turn of the melodramatic pictures." Movies also had "a profound effect on fantasy life," writes Robert Sklar in his book *Movie-Made America*. These cinematic fantasies "provided rich materials for dreams about sexual partners, settings and passions far removed from the reality of one's environment" (Sklar 1994, p. 307). Sklar is not quite as alarmed by the potentially pernicious effect of film on audiences as Munsterberg who warns: "...it is evident that such a penetrating influence must be fraught with dangers." When one thinks of the impact of Nazi propaganda films like Leni Riefenstahl's *Triumph of the Will* (1935) it is hard to say that Munsterberg was exaggerating. The Nazi propaganda machine was run by a great film admirer, Joseph Goebbels, who was especially impressed by Hollywood films and adopted many of their techniques for his own malign ends. (Color films enthralled him even though most politicians of the time who used film to disseminate their messages found them too unreliable.) Although he disdained detective movies and comedy reviews, he was fascinated by documentaries, appropriating their cinematic vocabulary to create the illusion of veracity, most notably in the notorious anti-Semitic film *Jud Süß* (1940), a box office sensation across Germany and Europe, based on a novel by Lion Feuchtwanger.

In spite of these "dangers," Munsterberg insists that the depiction of emotions (and by extension, the evocation of emotions in the spectators) "must be the central aim of the photoplay" (Munsterberg 1916, p. 66). Words are not necessary for film to achieve its effect (recall that he is writing before the advent of

talkies) since "the actor whom we see on the screen can hold our attention only by what he is doing and his actions gain meaning and unity for us through the feelings and emotions which control them." The film sets in motion a kind of feedback loop in which the actors display emotions on the screen, stirring emotions in the audience which may, of course, be entirely different. By the same token, the emotions evoked in the spectator may color how he or she reacts to the film. Here is how the author puts it: "If we start from the emotions of the audience, we can say that the pain and the joy which the spectator feels are really projected to the screen, projected both into the portraits of the persons and into the pictures of the scenery and background into which the personal emotions radiate" (Munsterberg 1916, p. 83).

Dream Language

We have seen that the "language" of film is very similar to and may have borrowed from dreams. This language consists of montages, flashbacks, and close-ups, and it is characterized by the abolition of the temporal element and the subversion of causality. Let us now try to examine more closely what the language of dreams consists of and how it differs from the languages of logic, mathematics, and software programs. Leave aside for the time being the controversy as to whether dreams have a psychological function. (I suspect, though, that dreaming performs a very useful psychological function by helping us understand and resolve our problems.) The languages we use in our waking life and that we rely on to keep our computers running require rules. These rules allow users to produce statements in a limitless number of variations that can be understood on one or more levels, literally or implied. Such languages rely on symbols whose meanings transcend the symbol that represents them. The word "chair" stands for a real chair even though it does not convey anything particularly chair-like in terms of its appearance or sound. (In computers, the symbols consist of two numbers – 1 and 0). We call these languages discursive languages. By contrast, in the privacy of our minds, when we tell ourselves stories or engage in reveries or dream, we are using a distinctly different kind of language which we call nondiscursive. That is not to say that nondiscursive languages do not have a given set of rules or a lexicon of sorts – they do – but

they do not use symbols in such an abstract manner. Nondiscursive languages tend to favor metaphors, similes, and analogies. But where we are most likely to find the use of nondiscursive languages is in myths, folklore, fairy tales – and dreams. Symbols in nondiscursive languages may be pan-cultural insofar as they are found in many different cultures (Not surprisingly, the sun and moon have been deified by any number of cultures.) But symbols can also be culturally specific like flags and logos; the cross, the swastika, and hammer and sickle are cases in point. Finally, symbols can be accidental or idiosyncratic in that they are more personal. Individual dreams tend to be filled with accidental and deeply personal symbols (Rieber 1997, pp. 110–111).

Some film theorists believe that our way of perceiving and absorbing the images we see up on the screen and those we see in our dreams at night both have their origin in the way that we as young children navigated the world, relying on visual and sensory experiences without regard for logic of space or time – which is to say, in a nondiscursive language. Cinema, in their reading, can lead the viewer “into a dreamlike world where regression is possible and where one senses a unity with the external world” (Eberwein 1984, pp. 24–25). In other words, we are reverting to a childhood state of consciousness, if not unconsciousness, when we sit in a movie theater: “Given the replication of the dreamlike state in the viewing process, our sense of ego differentiation is at first heightened: those characters up there on the screen are ‘not-me.’ . . . That is, the dreamlike film, the film as sensed and perceived as being like a dream, brings us back to a state. . . in which we are more susceptible to the loss of ego, and, hence, to identification with those characters who are ‘not-me’” (Eberwein 1984, p. 41).

The use of discursive and nondiscursive languages is not discreet nor is there a firewall between their domains. Sleeping and waking are bipolar elements that the human organism needs in order to develop an ability to exist cognitively, affectively, and volitionally as well as to assimilate diverse sensory experiences. Communication between these two polar states – being asleep and being awake – takes place in both nondiscursive and discursive dialects. Human knowledge is a continuum that moves between these two states, while daydreaming represents an

intermediate state which shares attributes of both poles (Rieber 1997, p. 111).

What I call “knowledge” is not exclusively confined to the intellect. In addition to cognition, minds also are a crucible of emotions and instincts. Dreams share these components to varying degrees so that one dream might be influenced by an individual’s emotional problems whereas another might yield a solution to a vexing work-related problem. A society also responds both affectively as well as cognitively to sensory input. Scientific and technological knowledge is the domain of cognition, transmitted by means of documentaries, nonfiction, and academic papers. (Mathematics is a good example; the same equation or algorithm can be understood by a mathematician anywhere in the world.) But society also dreams, so to speak, through its artistic expression. That expression takes the form of intrasocietal nondiscursive communication. And like individual dreams, society’s can be used – intentionally or unconsciously – to present and resolve conflicts (Rieber 1997, p. 111).

The act of dreaming functions as a kind of symbolic process, revealing not only an individual’s intellectual and emotional development, but also involving the play of imagination and the state of his or her physical and mental health. Dreams can often be serious experiments whose outcome depends on an understanding of the dream language – for example, its symbols and images. There are seldom one-to-one correspondences where each symbol has an easily identifiable counterpart in real life. Instead, a symbol’s meaning usually involves a dynamic complex rather than a simple entity. It is a part of a Gestalt pattern. Human nature attempts to transcend culture and actualize itself by self-examination and criticism, a dialectic process developed in the waking state by means of objective discursive introspection. In the sleeping state, however, this process takes place when we dream – using nondiscursive images (Rieber 1997, pp. 111–112).

Films and dreams have something else in common: their evanescence. “Like dreams, the screen resists physical scrutiny; touch it and it breaks,” writes Robert T. Eberwein in his book *Film & the Dream Screen A Sleep and a Forgetting*, “If we want to retrieve the images from dreams or cinema, we must rely on memory. In both cases, we must be content with fragments – the images left in our minds of what we experienced”

(Eberwein 1984, p. 23). While they may offer “us a momentary triumph over our isolation from the world,” films also exert a spell that is difficult to break when the movie is over, as he points out: “. . . reentry into reality after we awake from the dream or conclude our viewing of the film plunges us back into our alienation from our perceptions” (Eberwein 1984, p. 23).

The types of social dreams can vary widely and almost invariably depend on the cultural context. Social dreams certainly do not require film to express them. For instance, the dramas of Sophocles and Euripides represented the social dreams of ancient Greece and B.F. Skinner in *Walden Two* represents the social dream of a psychologist as realized in a fictional ideal community. Myths and dreams expose ideas by means of images. Because social dreams express anxieties, prejudices, and desires that often are not articulated – or cannot find adequate expression in words (e.g., discursive language) – film may prove the best medium for exposing the dreams to the light of day (Rieber 1997, p. 108).

“Film language” is something of an oxymoron since language is antithetical to film. The spectator receives images on the screen, watches the actors, observes their behavior and facial expressions, registers the background music, and understands what is happening. Movie going is an act of inference. (Dialogue may or may not be necessary to comprehension.) It is in that sense that films are illiterate events. But if we consider film language as a kind of dream language, we can draw some valuable insights about these social dreams.

The Dreams That Money Can Buy

I have stated that films can function as social dreams that express the dilemmas and anxieties of a culture; by the same token interaction with the culture can affect the dreams of the individual filmmaker. We can think of the culture as a dream machine or factory. Those creators who are able to benefit from the fruits of this machine can produce works with the power and the resonance to bring unconscious longings and fears of their audiences to the surface.

Film factories are most closely associated with Hollywood. The major production studios were interested in two things: entertainment and the bottom line. Exploration of the psyche was largely left to the avant garde films – what film critic Philip Sitney in his

seminal history of the genre *Visionary Films* called “trance films” – that enjoyed something of a golden age in the 1940s and 1950s. According to Sitney, trance films were “an erotic quest,” and its quest figure was “either a dreamer or in a mad or a visionary state.” In their investigation of the unconscious, these films broke taboos that the big studios would never address – homosexuality in Kenneth Anger’s *Fireworks* (1947), masturbation in Stan Brackhage’s *Flesh of the Morning* (1966), and the premonition of and desire for death in Maya Deran and Alexander Hammid’s *Meshes of the Afternoon* in which the end of the dream also represents the end of the life of the dreamer (Sklar 1994, p. 307).

Perhaps no trance film exemplifies the interaction between the artist and the dream machine than the aptly titled *Dreams That Money Can Buy*, a 1947 film which is both about dreams and is in its own way a dream itself. It is difficult to think of any dream that relies so much on the nondiscursive language of a dream. The film is the creation of the German modernist artist Hans Richter. He did not start out as a filmmaker, but rather as a painter strongly influenced by surrealism and Dada. However, many of the same preoccupations and themes that informed his painting found their way into his moviemaking as well. “But even if I recognized film as a form of expression independent of painting, I still felt how closely related these two arts were,” Richter wrote, “Problems of the one seemed to touch on the other. . . Roads lead from painting to film and from film back to art. . . Film was not only a region for a painter’s experiments, but a part of modern art, the expression of a new total experience” (Richter 1965, p. 35).

In service of his vision, Richter marshaled new photographic and technical skills such as extreme boom shots, zoom shots, enlargements, photo montage, extreme angles, transparency, and negative and multiple exposures (von Hofsker 1998, p. 129). Richter was not just trying to be a virtuoso with the camera. Here is how Richter put it: “The technical liberation of the camera is intimately interrelated with psychological, social, economic and aesthetic problems” (Richter 1965, p. 46).

Richter was particularly interested in the effects of juxtaposing elements that did not logically fit together – just as dreams do. “Richter’s method was to establish relationships between similar and similar actions by

improbable association,” noted critic Marion von Hofsker. “Movement from frame to frame is continuous and their associations are surprising.” In one of his earlier films, for example, a scene showing two men shaking hands abruptly changes into two boxers shaking hands. In another sequence, the moon’s surface is transformed into a man’s bald head. In a series of rapid cuts, we are shown legs pedaling a bike, a child kicking, a small plane flying, a high diver, and a pigeon in flight – a series of associations that are meant to duplicate the kind of phenomenon we experience in our dreams every night (von Hofsker 1998, p. 138). In his 1927–1928 film *Inflation*, Richter limited his imagery to depicting two objects: paper money (German marks) and the owner of that money. The German mark expands in size as the number of zeroes increase until there are more zeroes than can fit on the screen. It is a simple but biting comment on the out of control inflation that destroyed the economy in Weimer Germany earlier in the decade. It is also a salient example of a social dream (von Hofsker 1998, p. 127). Richter employed a similar montage technique in his use of sound which he believed ought to enjoy a role equal to that of the visual images. One soundtrack featured music from a barrel organ, spoken words, and unintelligible phrases played in short intervals and in rapid succession (von Hofsker 1998, p. 139).

What Richter was hoping to do in film was break away from, even revolt against, traditional narrative forms of theater and the nineteenth Century novel. “We expect stories from film, not only because we are so conditioned by experience; we even ‘invent’ stories if none are offered. The flow of images will always ‘make’ a story, because our perception and imagination work that way, even if abstract form follows on abstract form” (Richter 1965, p. 114). The process Richter is describing is similar to the way in which we try to make stories (sense) out of our dreams.

Richter realized that the film was a medium uniquely capable of duplicating the form and feeling of a dream, noting that “the use of the magic qualities of the film to create the original state of the dream, – the complete liberation from the conventional story and its chronology. . .in which the object is taken out of its conventional context and is put into new relationships, creating in that way a new content altogether” (Richter 1965, p. 47).

Dreams That Money Can Buy is the result of an extraordinary collaboration; actually, it is composed of several “dreams” conceived of and realized by some of the twentieth century’s most celebrated artists (Fig. 1). “Since 1925 I had had many discussions with (Ferdinand) Leger about a film-project,” Richter wrote regarding the film’s genesis. During a stroll through lower Manhattan, Leger suggested a film which would be entitled *Folklore d l’Americaine*. “In Grand street we found what we had in mind: miles of bridal gowns on both sides of the street. A lovestory between 2 wax-mannequins! . . .and so my film *Dreams that Money can buy* began.” He rounded up old friends from “beloved but bereaved Europe” – Leger, Max Ernst, Alexander Calder, Yves Tanguay, Marc el Duchamp, Jean Cocteau, Man Ray, and Jean Arp. “And so a very un-warlike document grew in the midst of war through the cooperation of 2 Americans, 2 Frenchmen and 2 Germans, – in the then cultural center of the free world.” They shot the film on a shoestring budget, using a condemned building in Manhattan’s garment center as their studio. They could only work on weekends or at nights since

Cultural Psychology and the Cinema. Fig. 1 Wax mannequins from *The Dreams that Money Can Buy*

Richter was otherwise occupied in his day job as Professor of City College (Richter 1965, p. 114).

On one level, *The Dreams That Money Can Buy* bears a resemblance to a detective story. (Ever since Freud, of course, psychiatrists and therapists have been acting in the role of detectives trying to unravel the meaning of their patients' fantasies and dreams.) But any attempt on the spectator's part to find a traditional narrative is doomed to failure. That is not the point. The protagonist (to use the word loosely) is memorably named Joe Narcissus, an utterly unmemorable man, who has to figure out how to pay for the rent on a room he has just leased. But when he looks in the mirror (as Narcissus is wont to do) he discovers that he can visualize the images and thoughts running through his mind – voila! He now knows how he will pay the rent. “If you can look inside yourself,” he tells himself, “you can look inside anyone!” He will put his unique talent to use in the service of others by selling them dreams. This is the setup for the seven dream sequences that follow: *Desire* (directed by Max Ernst); *The Girl with the Prefabricated Heart* (directed and written by Fernand Léger); *Ruth, Roses and Revolvers* (directed and written by Man Ray); *Discs* (written by Marcel Duchamp); *Ballet* (written and directed by Alexander Calder); *Circus* (written by Calder); and *Narcissus* (written and directed by Richter). The sequences make little or no effort to hook the viewer with a traditional narrative. In *Desire*, for example, a couple Mr. and Mrs. A. come into Joe's office. Mr. A. is an accountant – and that is the problem says his wife. His mind is like “a double entry column; no virtues, no vices.” And no dreams she could have added. He is desperately in need of a dream, one “with practical values to widen his horizons, heighten ambitions, maybe a raise in salary.” Joe finds a dream for Mr. A. using a collection of art images cut out of magazines – a woman reclining in bed; a woman sitting on an old man's lap; a woman being shot by an animal-headed man; a red liquid passing through water, and a melting wax figure of a woman – as the source material for the accountant's dream. These images are transformed into the sort of dream that Mr. A. could only dream about. Leaves fall to the ground beside a red curtain. As a woman in white reclines on a red-curtained four-poster bed a small golden ball rises into her mouth and drops down from it with every breath she takes. Finally she swallows one of the balls

and falls asleep. Bars suddenly separate her bed from the viewer. A man watches from behind the bars as if he can visualize her dream in which both nightingales and calves' hooves have an important part to play. But it turns out that the man is not watching her dream; he is a part of it – but that does not mean that he has any idea of what he is doing there and so he “telephones” her to discover what is going on. In a voiceover, she informs him that “they talked about love and pleasure” – and who could ask for a better dream than that? Then her telephone falls to the floor. A misty smoke enshrouds her and Mr. A's dream is over.

In the second dream that Joe sells, two store window mannequins – inspired by Richter and Léger's sighting on Grand Street – conduct a kind of mechanical romance accompanied by a song written by John Latouche and sung by Libby Holman and Josh White, called “The Girl with the Pre-Fabricated Heart.” Subsequent dreams become even more abstract with contributions from Man Ray and Duchamp. One dream consists of a “ballet” of billiard balls on wires conceived of and realized by Calder. The final dream appropriately enough takes the form of a psychoanalytical session as seen through the disturbing – and distorting – lens of the unconscious. *The Dreams that Money Can Buy* is actually a dream within a dream within a dream. The first dream belongs to Joe Narcissus, the purveyor of dreams. The second dream is the dreams of the customer who buys them from Joe. The third dream is the “dream” of the audience watching it (Fig. 2).

As the distinguished film critic Siegfried Kracauer observed, “Modern art, as it appears in this film, intertwines the region of pure forms with the virgin forest of the human soul. What lies between – the vast middle sphere of conventional life – is tacitly omitted or overtly attacked. Both the Léger and Richter episodes are very explicit in defiance of our mechanical civilization.” In this respect, this movie, which is predicated on dreams and presents the bewildering, acausal nature of dreams, is also, at least in part, a social dream insofar as it is a critique of a mechanistic society, in Kracauer's words, “which smothers the expression of love and creative spontaneity.” That, he says, explains why modern artists like those recruited for the film are so preoccupied with “unconscious urges,” and why dream imagery comported so well with their surrealist and Dada roots. Kracauer cites the superimposition of the female

Cultural Psychology and the Cinema. Fig. 2 Image from *The Dreams That Money Can Buy*

nudes and Duchamp’s “rarified movements” and the juxtaposition of a primitive mask and “a sort of ram’s horn” with Calder’s mobiles. “And in the Max Ernst sequence the turmoil of sex so radically upsets the nineteenth century interiors that they seem on the point of disintegrating-scattered elements predestined to be reborn with non-objective textures” (Richter 1965, pp. 118–119). The power of *The Dreams That Money Can Buy* lies principally in its canny use of associations. Even a philosopher with an aversion to the subconscious would understand why Richter’s work represents a breakthrough – but also a dead end. Dreams can also be a bore except for the dreamer. Films are most successful at embodying and transmitting social dreams when they tell a compelling story. In other words, they almost go out of their way not to entertain. Trance films were solipsistic “expressions of psychic interiors” which like dreams, required audiences to interpret rather than to enjoy them (Sklar 1994, p. 307).

The Social Dream

Psychological phenomena – self, agency, emotions, sexuality, perception, cognition, memory – do not

arise exclusively within the individual. They also need to be considered within the context of the larger culture. We all operate in an environment that consists of various institutions, artifacts, and cultural concepts. Psychological processes are always at work as people conduct their activities or respond to these institutions and concepts. These psychological processes assume particular form and content. In other words, people mold their psychology in congruence with or reaction to certain macro-cultural factors. A struggle is constantly taking place among groups to direct (control) macro-cultural factors in their interest. Whoever dominates this struggle dominates the form that cultural factors take, and by extension the corresponding form that psychological processes take. Consequently, it would be a mistake to think of psychology only in personal terms when it is also a cultural and political phenomenon. So what we see happening is a kind of feedback loop in which psychological phenomena are then objectified in the culture and transmitted to individuals as they participate in the culture. The ways in which the sense of self, romantic love, and pathologies like schizophrenia become objectified cultural phenomena help define society. Individuals draw upon these cultural-psychological factors to define and understand themselves – just as they draw upon standards of beauty, dress, and status.

What is less clear is whether a social or collective dream is still capable of embodying or representing a nation or a region, the way that German cinema did, for instance, in the 1920s and 1930s. That films could be distinctively “French” or “Italian” or “British” was probably true to some extent through the 1950s, as Martha Leites and Nathan Wolfenstein tried to argue in their 1950 book *Movies: A Psychological Study*, but globalization has made such generalizations and stereotypes a more problematic exercise as Sklar explains in his own book about American films: “American movie presented American myths and American dreams, homegrown for native audiences, yet only man-made borders, kept them from conquering the world” (Sklar 1994, p. 212). Those borders have been disappearing ever since.

So how is this interaction between the culture and the individual expressed in a social dream – a social dream that takes the particular form of a film? Like psychoanalysis, film has long been preoccupied with

identity and the fragile sense of self. Jean Cocteau's *Orpheus* (1950), for instance, explores the tenuous border between reality and imagination. In Ingmar Bergman's *Persona* (1966), a nurse played by Bibi Andersson becomes one with her patient played by Liv Ullmann. The viewer is drawn into Bergman's dream so that it becomes our dream to an extent as well. In one interview, Bergman has called all of his films his "dreams." "The reality we experience today is in fact as absurd, as horrible, and as obtrusive as our dreams," he told an interviewer, "We are as defenseless before it as we are in our dreams. And one is strongly aware, I think, that there are no boundaries between dream and reality today" (Peter Cowie, *Sweden 2*, cited by John Simon, *Ingmar Bergman Directs* (NY: Harcourt Brace, Jovanovich, 1972) 239). In another context, the director declared, "When film is not a document, it is a dream. . . .No form of art goes beyond ordinary consciousness as film does, straight to our emotions, deep in the twilight room of the soul" (Bergman 1960, p. 73).

But while a filmmaker's work might tap into his dreams for inspiration or even be conceived as equivalent to a "dream," it does not invariably follow that the filmmaker is aware what the dream is, on an individual level and certainly not on a collective level. Artists working in any medium usually do not consciously try to represent a social dream in their work and often do not realize that they have done so except in retrospect. More often, other people can recognize that a work has greater resonance than its creator. And that is probably for the best: if the artist were aware that he was trying to convey a social dream, he would probably be paralyzed or else produce a work that was attenuated or polemical.

In some cases, the social dream as projected by film (literally and metaphorically) can have a beneficial effect. During the bleak days of the Depression, for instance, films were able to knit society together "by their capacity to create unifying myths and dreams." In spite of clergymen in backwater towns who railed against "sin on the silver screen," the academic, media, and literary elites of their day regarded filmmakers "with considerably more respect, awe and envy" since they were in "the possession of the power to create the nation's myths and dreams" (Sklar 1994, p. 159).

The question of identity has always made for a powerful social dream, especially during periods

characterized by upheaval, social, economic, and cultural. A case in point is *Sybil*, the purportedly true life story of a woman with multiple personality, which appeared first in book form in 1973 and then as a TV movie of the week in 1975 with Sally Field as the title character and Joanne Woodward as her psychiatrist. The authors Flora Schrieber and Cornelia Wilbur, *Sybil*'s psychiatrist, maintained that *Sybil*'s condition was a result of early childhood trauma, although the evidence was shaky at best and fabricated at worst (*Sybil*'s real name was Shirley Mason). A psychological oddity, so bizarre and rare that it was barely mentioned in most textbooks before 1973, multiple personality disorder suddenly acquired respectability and acceptance in the aftermath of *Sybil* in her various incarnations, eventually making its debut in the 1980 Diagnostic and Statistical Manual of Mental Health which classified it as an important disorder. The number of cases and therapists specializing in the treatment of MPD escalated quickly and so did the number of personalities that victims claimed. (One therapist identified over 1,000 personalities in one patient, not all of them human). With its emphasis on childhood sexual abuse, it also spawned two other related obsessive phenomena: one was the belief that people were being adversely affected by buried memories and the other was that only by reawakening those memories through hypnosis was recovery possible. Together, the three phenomena constitute what I term "a trinity of affinity." It is hardly surprising that these phenomena arose in the wake of the 1960s (a time of intense tumult) and the early 1970s, when in the aftermath of Vietnam and Watergate, all authority and institutions were being challenged. America's own sense of identity was being shaken like never before. In the decades that followed, the *Sybil* myth lost much (but not all) of its appeal, supplanted by other social dreams. It is true that several memoirs have appeared whose authors claim to have suffered from MPD, but they have not sparked the kind of media publicity or spawned a similarly ersatz therapeutic movement as the original *Sybil* did. (For a more detailed discussion of the *Sybil* case please see my book *The Bifurcation of the Self* published by Springer in 2006.) A remake of the TV movie in 2007 barely caused a blip on the media's radar screen. However, with the economic downturn that the US began to suffer in 2008, we can reasonably expect to see more films that

are centered about problems of identity. So many Americans, after all, especially men, have identified their lives so closely with their work that when they lose their jobs, they often find themselves at a loss, unable any longer to figure out their place or purpose as husband, father, or as a productive member of society.

Sybil was not a horror film per se, but it had a lot in common with the genre in suggesting the possibility of monsters lurking within us. Horror films work even when we know that what we are seeing on the screen is not “real.” Gregory Bateson, for instance, observed that there are two types of messages or signals – those that are untrue or not meant and those that denote signals that do not exist. In his essay “Steps to the Ecology of the Mind,” he cites the example of a viewer struck by terror as he cringes from a spear thrown in his direction in a 3-D film or feels that he is plunging from a cliff to his death in a nightmare. Neither spear nor cliff exist, Bateson points out, and the viewer and the dreamer (at least on waking) understands as much, recognizing that the images do not denote what they signify, but nonetheless the fear is real (Bateson 1972, p. 118). Otherwise, horror films would not have the impact they do. And if a horror film did not produce thrills and terror (much like a roller-coaster ride), what would be the point of making it?

Certainly horror and thriller films have had a field day excavating the recesses of the mind for things we would rather not acknowledge. The monster elicits a “visceral response of revulsion and disgust,” observes Donald Campbell in his essay on the Italian horror filmmaker Dario Argento. Campbell contends that this revulsion can be traced to adolescence, observing that adolescence is characterized by a pull-push relationship in which hormonal and psychological changes are pushing the adolescent toward adulthood while he or she is being pulled in a regressive direction toward childhood in which infantile fears and anxieties about survival and omnipotent fantasies of triumph over loss, death, and castration predominate (Campbell 2003). Campbell focuses on what he calls “body horror” – those horror films in which monsters emerge out of normal human beings. Think of all the “normal” people in movies who, having been bit by vampires and savored the taste of blood, turn into vampires themselves. Or consider Brian DePalma’s *Carrie*

(1976) which depicts in an exaggerated manner the fear and disgust that menstruation arouses. Rouben Mamoulian’s *Dr. Jekyll and Mr. Hyde* (1931) is another example of body horror where the protagonist by means of a drug turns into a monster. At the same time, these body horror films also evoke social dreams that touch on issues related to the stability of identity. It is not the monster outside of us that we are so afraid of, but the monster that we fear we could become.

Hitchcock’s *Psycho* (1960) and Jonathan Demme’s *The Silence of the Lambs* (1991) succeeded in terrifying their audiences and are no doubt responsible for countless troubling dreams. Each in its own way expresses a social dream, albeit a terrifying one. The *Stepford Wives* (1975) and its tepid sequel *Return of the Stepford Wives* (2004) are horror films of a different kind, exemplifying not so much the inequalities between the sexes as the actual struggle and conflict. The social dream in these films warns of disintegration of the family as well as of the blurring of male and female roles (Rieber 1997, p. 128).

The Western is a genre where the social dream is often explicit, tapping into myths that still resonate in the USA – the myth of self-reliance, the myth of an undiscovered natural paradise, and the myth of boundless freedom. “Since Birth of a Nation American films have returned again and again to the basic problem of human conduct and the establishment of law and order in a new and widely scattered society,” Manvell writes in his consideration of the Western classic *The Oxbow Incident* (1943), “These have often proved wonderful subjects for films – the westering of the pioneers, the dawn of the concept of justice in remote regions, and the outbreak of gang or mob violence in the rural and urban areas” (Manvell 1955, p. 146). The Western exerted such an influence over the popular imagination that some directors who had grown up far from America tried their hand at it, most notably the Italians who invented a subgenre all of their own – the spaghetti Western. Its most famous exponent, Sergio Leone, was attracted to the Western because, he said, “the west was made by violent, uncomplicated men, and it is this strength and simplicity that I try to recapture in my pictures.” In *Once Upon a Time in the West* (1968), Leone cast Henry Fonda against type as the villainous enforcer for a railroad tycoon. The story is a scathing take on capitalist exploitation which takes the form of

a struggle over water, in this case a piece of land near Flagstone, Arizona called – appropriately – Sweetwater. It is the only source of water in a region where a railroad will be constructed. Water suddenly becomes valuable because it will be needed for the steam engines that empower locomotives. Leone's film was only one of a slew of Westerns about the epic struggle over resources (often pitting ranchers against cattlemen). The director also earned worldwide box office success for his Dollar trilogy: *A Fistful of Dollars* (1964), *For a Few Dollars More* a year later, and most famously, *The Good, the Bad and the Ugly*, which followed in 1966. The plot of *The Good, the Bad and the Ugly*, set during the Civil War, focused on three gunslingers who are after a cache of hidden Confederate gold and featured a young Clint Eastwood as a mysterious lone gunman with a lightning fast draw. It embodied two dreams at once, both of them integral to Americans' mythical – and mystical – association with the land and its resources. The first is the belief that if one looks hard enough there are always riches waiting to be found (in whatever form or currency) and the second is the conviction of being rescued by the savior who comes from out of nowhere, a hero who has integrity, a gun, and a good aim. Probably no film illustrated the obsessive and illusory – and finally tragic – quest for hidden wealth than *The Treasure of Sierra Madre* (1948) which starred Humphrey Bogart. In that film a savior never appears.

If Westerns harken back to the social dreams that have shaped America, science fiction often plays on the fears and anxieties of the present (usually dressed up as the future.) Superman emerged as a comic book hero in 1938 on the verge of World War II (before being incarnated in a TV series and in movies beginning in 1978). However, the quest for an *Übermensch* – the superior individual of Nietzsche who has the rational and emotional capacity and volitional need to transcend the problems of society – has been a social dream of any number of societies (Rieber 1997). It can be argued that Superman reveals a major flaw in the American national character because it relies on magical thinking, a hope for the superman magic and the belief that we have license to do something without taking full responsibility for our actions. Americans seem to be looking for the hero who will save them, and they are ready to pay any amount of money for the gimmick,

the product or the shortcut to get it without a full-hearted effort. The social dreams of our times seem to be screaming out, proclaiming this problem to us, but whether anyone is listening is another question (Rieber 1997, pp. 130–131). If anything, that old superman magic is more prevalent than ever given the increasing number of super heroes that recent films have appropriated from graphic novels: Spiderman, Batman, and Ironman to name just three of the cinematic saviors to have made their appearance on the big screen. If they have not achieved superman magic exactly, there is no disputing that they are responsible for creating box office magic, which says something about how deeply entrenched this particular social dream remains.

The recent resurgence of the vampire on TV, film, and in books (along with zombies) suggests that another form of social dream is emerging. The meaning of this particular dream, however, is not quite as easily interpreted as one might assume. Vampires have never gone away, of course; they have surfaced in any number of cultures since Vlad the Impaler, and vampires have been making regular appearances on American and international screens. The film adaptation of *Interview with a Vampire*, based on Anne Rice's novel, was a big hit in 1994. But why are they experiencing such a huge comeback now? 2008 was a banner year for vampires. That year saw the publication of *Breaking Dawn*, the final installment of Stephanie Meyer's *Twilight* series; it sold 1.3 million copies in the first 24 h. That was followed by the launch of HBO's wildly successful new series *True Blood*, the Swedish film *Let the Right One In* (whose plot revolved around preadolescent vampires), and finally the release of the film adaptation of *Twilight*. Both the HBO the *Twilight* series have attracted huge numbers of ardent young fans, especially prepubescent and teenage girls. These vampires are sanitized; the vampire who falls in love with the human girl is too nice to bite. Desire is suppressed in favor of a dreamy romanticism, which undoubtedly explains its exceptional popularity for its target demographic. A year later, the sequel *New Moon* broke box office records – and still no sex. The conventional explanation for the hold that vampires have on the imagination can be found in *Soul of a Popular Culture* by Mary Kittleson. “Symbolically, we can imagine vampires as unconscious energy that sucks us dry of the will essential to

desire life. . . At the same time, predatory impulses are an integral part of our human biological history” (Kittleson 1998). Unlike humans, vampires cast no shadows, she points out. Formulating her argument in Jungian terms, she argues that the culture has to do its “collective shadow work” in order to evolve. “Culturally, the vampire’s presence may be beckoning our society to kill off the adolescent conception of ourselves as innocent heroes and heroines who desire only the best for the world” (Kittleson 1998). But is this really the social dream that the vampire resurrection embodies? Most of the vampires who are enjoying popularity these days depart from the traditional conception of the vampire; far from being monstrous or evil, they are increasingly depicted as young, strong, and sensual beings. Even the vampires in *True Blood* are a different breed. To be sure, in contrast to the vampires in *Twilight* and *New Moon* who show such extraordinary, these Bayou vampires have no compunction about indulging in either sex with humans or slaking their thirst on human blood (although they often rely on a synthetic substitute). Nonetheless, they are presented as a kind of ethnic minority, stigmatized and subject to prejudice, but nonetheless are tolerated to some degree by the humans they live among. These examples suggest that it might be possible to give a more optimistic reading of the vampire’s new incarnations. Maybe the social dream that vampires represent indicate a greater tolerance for diversity, especially among the young, where ethnic, cultural, and religious differences or sexual orientation are no longer seen as threatening in sharp contrast to the attitudes of older generations.

The question as to whether horror films (or programs on TV) can cause nightmares (infiltrating our actual dreams in other words) has not been well studied. But, as Margaret Talbot points out in an article on nightmares for *The New Yorker*, movies do have an influence on “our sense of what nightmares generally look and feel like. . . from the surreal dreamscape that Salvador Dali designed for Alfred Hitchcock’s ‘Spell-bound’ to the twisted fantasies of David Lynch.” She goes on to say, “Such cinematic sequences succeed better than most nightmare studies do in re-creating what it feels like to be transfixed by frightening images that are screened in the projection room of one’s mind.” The relationship can work in reverse, too: “if

filmmakers draw on nightmares, their films, in turn, sometimes give us bad dreams.” In a study published in 2000, children who had nightmares frequently cited a program they had seen on TV. Some studies have tracked the types of nightmares people have experienced over the last century “and found that dreams of the bogeyman were common in the twenties; dreams of ghosts, devils, and witches reigned in the fifties and sixties, and those of movie villains predominated in the nineties.” Both Freddy Krueger of the *Friday the 13th* series of movies and the evil Voldemort from the Harry Potter novels and movies have made regular appearances in the nightmares of children interviewed for a study conducted by the Dream and Nightmare Laboratory at Sacre-Coeur Hospital in Montreal, but whether they have any lasting or negative influence is unknown (Talbot 2009).

Nightmares are by no means confined to horror films. Apocalyptic scenarios are also commonly found in science fiction films. Although 2008 may have been a banner year for vampire flicks, it was also the year that saw the remake of *The Day the Earth Stood Still*, which was originally released in 1951. But the remake was a dud, whereas the earlier version was powerfully evocative. The social dream that the 1951 film expressed has been superseded by other more resonant dreams in the intervening years. The original version was simultaneously reassuring and terrifying – reassuring because it seemed to offer a possible resolution to the conflict between the USA and the USSR that had the potential of blowing humanity to smithereens and terrifying because it suggested that we needed extraterrestrial intervention to keep us from doing so. Godzilla represented a similar social dream. The Japanese monster made his initial appearance in 1954 in the first of dozens of films and remakes. A fearsome prehistoric creature, Godzilla is the result of a mutation caused by radiation from the atomic bombs dropped on Hiroshima and Nagasaki. He can even deliver a powerful thermonuclear death ray from his mouth.

In dreams, we often envision and “try out” future scenarios. They are a way of exploring best and worst case possibilities. Science fiction films have a similar role to play when they offer visions or versions of future societies, more often than not dystopian ones. *Rollerball* (1975), for instance, is a film reminiscent both in theme and content of 1984 and *Brave New*

World in that it presents an alternative world order; it is set in 2018 where the world is controlled by six corporations. The authorities promote a game called Rollerball which is intended to allow the population to let out its aggressions. The fear of technology run amok, a variation of the Frankenstein myth, is also a recurrent social dream, one that has probably never been more dramatically illustrated than by the malevolent computer Hal in Kubrick's *2001: A Space Odyssey* (1968) (Rieber 1997, p. 127).

Logan's Run (1976) plays upon America's obsession with youth and beauty; the inhabitants of a high-tech Edenic cocoon (established in the aftermath of some worldwide catastrophe, possibly nuclear war) enjoy a hedonistic existence until they reach the age of thirty at which point they are exterminated in an elaborate ritual. Old age is not only stigmatized, it is abolished. The *Handmaid's Tale* (1990), based on Margaret Atwood's novel, offers another dystopian vision set in the near future, but in this case the world has been devastated by pollution as well as war with the result that 99% of the female population has been rendered sterile and the surviving population has fallen under the rule of barren misogynistic couples who use ritualized violence to impose their will. The handmaids of the title are concubines who are recruited to serve them. A similar social dream – inspired by the fear that humans will be reduced to eking out a living in a despoiled environment – manifests itself in *Children of Men* (2006) in which all women have apparently become sterile and the human race is poised on the brink of disappearing forever until one African immigrant turns up pregnant. The gnawing fear that humans will drive themselves to the brink by their own negligence and greed finds grim expression in the 1973 *Soylent Green* in which overpopulation is to blame for depleting the planet's resources, resulting in widespread impoverishment and such a scarcity of food that fruit and vegetables become rare and highly prized. The storyline hinges on the mysterious green wafers that the majority of people rely on for sustenance. The wafers turn out to be made out of humans: here the tools of mass production are marshaled in service of cannibalism. The persistence of the dystopian social dream can also be seen in the 2009 film *The Road* (based on a novel by Cormic McCarthy) which recounts the odyssey of a father and his son to survive

in a world that has been laid waste by some catastrophe. What kind of catastrophe – whether a nuclear war or environmental disaster – is never specified. It probably does not matter: the message is that as much as you may fear impending catastrophe, maybe you would do better to worry about what comes afterward. An ancient calendar – in this case the Mayan – also provided the inspiration for another 2009 disaster film *2012*, which left audiences a mere 3 years to prepare for the world's end.

Impending catastrophe has often served as a catalyst for filmmakers to produce some of the most powerful social dreams on celluloid. Take, for example, the German films that appeared after the cataclysm of the First World War. The national trauma “led to the haunted film, preoccupied with masochism, sadism and death,” writes Manvell. These films also reduced the role of the individual, no doubt reflecting the sense of powerlessness that people felt after defeat. “The Cabinet of Doctor Caligari was of this kind; the medieval, the Gothic, the corpse-laden, dream-laden world of legend and fantasy gave the designer rather than the actor his chance” (Manvell 1955, p. 44). In his groundbreaking study of German expressionist films *From Caligari to Hitler*, Siegfried Kracauer declared, “It is my contention that through an analysis of the German films deep psychological dispositions predominant in Germany from 1918 to 1933 can be exposed – dispositions which influenced the course of events during that time and which will have to be redeemed with in the post-Hitler era” (Kracauer 1947, p. 154).

The Cabinet of Caligari (1919) is a horror story which plays on the delusions of its narrator Francis who relates his investigation of the seemingly unhinged Dr. Caligari. The story is told through a series of flashbacks. In Francis' account, Caligari is the orchestrator of a traveling act featuring his somnambulist slave Cesare. He promises that Cesare will answer any question. When Francis' friend Alan asks him how long he will have to live, the slave tells him he will die by dawn – as he does. It turns out that Caligari and Cesare have been implicated in several murders in the German countryside. Eventually Cesare is killed and Caligari – revealed as the director of an insane asylum – is unmasked as a pathological murderer. But we learn that what we have been shown is not what happened; Francis is an unreliable narrator; indeed, he is a patient

and Dr. Caligari is no madman but the physician who is trying to cure him. Here we see an exemplary example of a social dream – and a precognitive one at that, as Kracauer has pointed out, since it would not be long before Germany itself became a virtual insane asylum whose insane director, far from treating delusions, propagated them.

(*The Cabinet of Dr. Caligari* was one of a string of pioneering expressionist films released by the UFA Film AG under the Weimer government. The company began in 1917. It boasted such seminal directors as Fritz Lang and F.W. Murnau. Aside from *Caligari*, its fame rests on such films as *Dr. Mabuse* (1922), *Metropolis* (1927), and *The Blue Angel* (1930) starring the incomparable Marlene Dietrich in her first talkie. By the end of the 1920s, however, the studio had come under the control of an industrialist sympathetic to the Nazis (UFA became a propaganda machine, churning out anti-Semitic films that helped pave the way for Hitler's rise to power in 1932).

One further example may be cited to indicate the cultural reality of the fictional world. In motion pictures, Wernher von Braun, the German engineer who was largely responsible for the early work on rocketry and space travel, has indicated that his interest in these matters was directly precipitated by the seeing of Fritz Lang's movie on space travel *Frau im Mond* (1928). Von Braun was the person largely responsible for the development of the V-2, about 1,000 of which were fired against London subsequent to their becoming operational in September of 1944. Wernher von Braun's testimony about the effect of the film on him leaves little doubt, but that had he not seen the film it is not likely that his interest in rocketry would have been awakened. Certainly, the film by Lang, or rather which was indicated by the film, has to be considered as part of the "cause" of the destruction wreaked by the V-2 bombing of London.

Film Versions of Psychologists

Dr. Caligari is only one of a long line of cinematic shrinks. Psychiatrists have been appearing as characters in film for almost as long as film has been around as a popular medium. How they have been portrayed over the years says a great deal about how the society of the day regarded (or disregarded) them. (The first film about psychoanalysis – G.W. Pabst's 1926 *Secrets of*

a Soul – was written by Karl Abraham, an associate of Freud's, and used a variety of superimpositions and distortions of images to hint at the confusion in the protagonist's mind.) A Maryland psychiatrist named Irving Schneider has come up with a classification system of celluloid psychiatrists based on three types: Dr. Dippy, Dr. Evil, and Dr. Wonderful. Schneider begins his study with the 1906 film *Dr. Dippy's Sanitarium* in which four patients chase an attendant out of a sanitarium. The harried patients eventually return to the hospital where they are soothed by the eponymous Dr. Dippy who eschews drugs in favor of pies. Dr. Dippy obviously is the buffoon, an innocuously comic character and an easy mark. A psychiatrist of a distinctly different sort emerges in D.W. Griffith's 1908 *The Criminal Hypnotist* in which an evil doctor puts a woman under a trance so that he can steal her father's money, a plot thwarted a "mind specialist" – the heroic kind of psychiatrist Schneider categorizes as Dr. Wonderful. Caligari is, of course, Dr. Evil. His successors include the homicidal psychiatrist in Alfred Hitchcock's *Spellbound* (1945), the staff of the asylum (especially Nurse Ratched) in *One Flew Over the Cuckoo's Nest* (1962), and the transvestite psychiatrist played by Michael Caine in *Dressed to Kill* (1980). *Spellbound* represents a shift toward a more sophisticated (if still sensationalized) portrayal of the profession. Its famous dream sequences were designed by Salvador Dalí, the dean of surrealists. The titles serve as a kind of tutorial for viewers. "Our story deals with psychoanalysis," the prefatory titles declare, which is described as "the method by which modern science treats the emotional problems of the sane. The analyst seeks only to induce the patient to talk about his hidden problems, to open the locked doors of his mind. Once the complexes that have been disturbing the patient are uncovered and interpreted, the illness and confusion disappear. . . and the devils of unreason are driven from the human soul" (Bower 1987, p. 188).

Dr. Wonderful shows up as the compassionate Dr. Berger in *Ordinary People* (1980). Of the 200 or so films Schneider surveyed, he found a greater number of Dr. Dippy's (35%), followed by Dr. Wonderful's (22%), with Dr. Evil trailing behind (15%). Schneider admitted, though, that had he included exploitation and horror films Dr. Evil would have racked up a greater tally (Bower 1987, p. 189). Here we can see the power

of the “emotion pictures” that Munsterberg wrote about. The capacity to project emotions is, of course, not limited to film (or any other medium). As a phenomenon, it is often (too often) seen in politics and represents what Psychology Professor Paul Bloom calls “emotional contagion” where people feed off of and influence the emotions of others. This happens frequently in darkened theaters. It also happened at Nazi rallies at Nuremberg.

Schneider is not alone in his attempt to categorize psychiatrists on screen. Krin Gabbard (a literature professor) and Glen O. Gabbard (a psychoanalyst) have also investigated the subject in their book *Psychiatry and the Cinema* (University of Chicago Press 1999). Elaborating on Schneider’s scheme, they divide psychiatric films into three historical periods. The first period extends from the Dr. Dippy’s of the one-reelers of the early 1900s to the escaped lunatics of the mid-1960s. For the most part, the authors contend, the profession was seldom treated seriously. Dr. Wonderful’s of this period, they write, “were little more than glorified guidance counselors” who helped achieve “a consoling resolution” to the plot (Bower 1987, p. 189). This period was followed by what they call the “Golden Age of psychiatry in the cinema,” beginning with *The Three Faces of Eve* (1957) and culminating in 1962 with several films, most significantly *David and Lisa*, which is considered one of the most realistic depictions of psychiatry. The third period, beginning in 1963, is a much darker one in which negative portrayals of shrinks predominate. They are “often associated with society’s false values and shown to be inept or malevolent” – a sharp break from the 1950s “fantasy of social harmony and better living through psychiatry” (an idealized conception to which psychiatry itself contributed). Undoubtedly, the anti-institutional, antiauthority fervor of the 1960s fueled the trend which, the Gabbards say, began to ebb only with the release of *Ordinary People*. The Gabbards reserve a special place in their universe of celluloid psychiatrists for the works of Woody Allen and Paul Mazursky, both of whom, while treating the profession with humor, nonetheless depict psychiatrists as generally humane and occasionally the source of valuable advice.

They argue that the depiction of the stereotype can be “double-edged in which “good” and “bad” psychiatrists are paired together. They also introduce another

type – the “faceless” psychiatrist who has “few, if any, identifying traits,” citing as examples the neutral psychiatrist of *Fear Strikes Out* (1957) about the baseball player Jim Piersall and the offscreen psychiatrist in *Diary of a Mad Housewife* (1970). If the portrayal of many male psychiatrists in films is less than flattering, female psychiatrists generally come off even worse. Beginning in the 1940s, the Gabbards maintain, female psychiatrists are either seen as corrupt or as “inadequate as women” and susceptible to seduction by their male patients (in a reversal of the classic transference).

The ambivalence of filmmakers toward psychiatrists is hardly surprising. Their audiences felt similarly conflicted. “Awe at their perceived ability to unscramble the mysterious workings of the mind is mixed with contempt for their limitations and disappointment with their failure to solve complex problems,” notes Bruce Bower in his 1987 Science article. Psychotherapists are perceived as superior on the one hand but also envied and feared on the other, which prompts people (and filmmakers) to ridicule them and try to “put them in their place” (Bower 1987, p. 189).

Psychiatrists offer only one example of the kinds of stereotypes that filmmakers have exploited, promoted, and foisted on their audiences. The same interchange of cultural-psychological factors that gave us Dr. Dippy, Dr. Evil, and Dr. Wonderful also found expression in a system of social archetypes, stereotypes, and role models who epitomized those standards of beauty, dress, and status. And there was no more powerful medium to dramatize these archetypes and stereotypes than the film. An elaborate production base was established in California to generate films that functioned as a means to show people social norms and customs, how they were to behave, and what things were desirable to buy and own – in general films showed forms of life to which audiences, sitting in dark, palatial theaters, must aspire. Each film becomes a lesson in how people were to define and understand themselves. Here the cultural dream machine is providing the dreams (in advertising as well as in the biological sense) for the audiences.

D

Dallenbach, Karl M.

RAND B. EVANS

East Carolina University, Greenville, NC, USA

Karl M. Dallenbach was an American experimental psychologist and editor of *The American Journal of Psychology* for almost 50 years. He was a student of Edward Bradford Titchener, receiving his Ph.D. degree in 1913, and was a member of the faculties of departments of psychology at Oregon State University, Ohio State University, Cornell University, and The University of Texas at Austin.

Basic Biographical Information

Dallenbach was born in Champaign, Illinois, on October 20, 1887, and died on December 23, 1971 (Dallenbach 1967; Boring 1958; Evans 1972; Evans 2006). He received his BA at the University of Illinois where he took classes in psychology from E. B. Titchener's student, John Wallace Baird. After graduating from the University of Illinois Dallenbach received a fellowship to the University of Pittsburg in psychology, receiving there an MA degree in 1910. He had plans for a medical degree but when he received the Sage Fellowship in Psychology to Cornell University to study under E. B. Titchener for the Ph.D. he changed his plans and went to Cornell in 1911. Dallenbach also took a minor in educational psychology from Guy M. Whipple. In the summer of 1912, Dallenbach went to Germany and spent the summer in the Bonn laboratory of Oswald Kuelpe, returning in the Fall to complete his dissertation. His doctoral dissertation was with Titchener and it was published as "The Measurement of Attention" (Dallenbach 1913). After gaining his Ph.D. Dallenbach married his college sweetheart, Ethel Douglas. He held positions at Oregon State

University and Ohio State University but was called back to Cornell by Titchener as an assistant professor in 1916. After World War I broke out, Dallenbach went into the Army and served in the Psychological Testing Corps. After the war he returned to Cornell and stayed on the faculty there until 1948, excepting during World War II when he went back into the Army to direct the Psychological Testing Corps.

Major Contributions

Dallenbach's primary research interest after returning to Cornell was in attention which, following Titchener's lead, treated attention as an attribute of sensory experience. His research demonstrated a clear distinction between that approach and that of attention as a cognitive process (Dallenbach 1920; Gill and Dallenbach 1926; Glanville and Dallenbach 1929). Unfortunately, attention as attributive clearness came to a dead end with the demise of Titchener's structuralism and introspective psychology.

Research on the psychology of touch proved to be more fruitful. His research on the experience of heat was particularly important (Burnett and Dallenbach 1927). For research on temperature sensations he invented a temperature stimulator for delivering punctate stimuli, a device that could maintain a calibrated, constant temperature rather than requiring the device to be reheated after every application (Dallenbach 1923). Another device, his heat grid, produced a burning experience when laid across the skin. It was made up of two tubes running closely together. One carried warm water and the other carried cold water. The heat grid became a standard demonstration piece in psychological laboratories (Burnett and Dallenbach 1927).

The first of Dallenbach's classic experiments on the role of interference versus trace decay in forgetting was published in 1924 (Jenkins and Dallenbach 1924). He found that activity after learning reduced retention

of the information significantly more than lack of activity over the same period of time. In 1946 he followed up the experiment with a similar one on the cockroach which demonstrated the same thing (Minami and Dallenbach 1946).

Perhaps Dallenbach's most significant studies had to do with localization of objects in space by the blind (Supa et al. 1944; Worchel and Dallenbach 1947; Cotzin and Dallenbach 1950; Ammons et al. 1953). The prevailing view since the time of Diderot (1749/1916, pp. 68–141) had been that the blind sense objects by sensations of pressure localized on their faces. Dallenbach's experiments demonstrated that the real basis for localization or objects in space was due to the auditory sensations of reflected sound produced by the footsteps of the blind person (Griffin 1958, pp. 303–309).

The American Journal of Psychology

Dallenbach believed his greatest contribution to psychology was through his ownership and editorship of the *American Journal of Psychology* (Dallenbach 1967). In 1921, thinking he was negotiating for a group of Cornell professors, including E. B. Titchener, Dallenbach arranged for the purchase of the *American Journal of Psychology*, then solely owned by G. Stanley Hall (Evans and Cohen 1987, pp. 339–353). Dallenbach negotiated a price and paid out of his own money, the good faith deposit pending the sale. On returning to Cornell, Dallenbach found that neither Titchener nor the other Cornell faculty had money to actually carry through on the purchase. By gaining a loan from his father, Dallenbach was able to carry through on the purchase. He became the business manager for the *American Journal of Psychology* and Titchener became the sole editor. There was no written agreement between the two men which proved to be problematic. Only 3 years later, in 1924, Titchener wanted the AJP given to Cornell or to some nonprofit group. Since Dallenbach had a large financial investment in the AJP he had to refuse to give it away. Titchener resigned and helped found the *Journal of General Psychology* as a competitor. This led to great stress between Dallenbach and Titchener until Titchener's sudden death from a brain tumor in 1927.

Dallenbach always looked at the ownership of the AJP as being a stewardship and never profited from it. He worked with a board of editors, including Margaret

Washburn, Madison Bentley, and Edwin G. Boring in the early years. The board changed over the years but Dallenbach, along with his editorial assistant Margaret McGrade, continued to do all the copy editing. In 1968, Dallenbach contributed the American Journal of Psychology with a sizable endowment to his *Alma Mater*, the University of Illinois where it still resides.

The University of Texas

Dallenbach left Cornell in 1948 for the University of Texas as distinguished professor of psychology. There he arranged to have the university construct a state-of-the-art building for the Department of Psychology and he designed the new laboratory (Dallenbach 1953). He chaired the Department of Psychology for 10 years while continuing to teach, work with graduate students, and edit the *American Journal of Psychology*. He was allowed to continue after the normal retirement age, primarily teaching the history of psychology and once in a while, classical psychophysics. One of his last experimental studies was one involving a study on single-trial learning in humans and the production of a stochastic mathematical model for the process (Evans and Dallenbach 1965).

He retired from academic life in 1968 at the age of 81.

Danziger, Kurt

ADRIAN C. BROCK
University College Dublin, Dublin, Ireland

Basic Biographical Information

Kurt Danziger’s innovative contributions to the history of psychology have received widespread international recognition. He was born in Germany in 1926 and emigrated to South Africa at the age of 11. After receiving degrees in Chemistry and Psychology from the

University of Cape Town, he continued his studies at the newly established Institute of Experimental Psychology at the University of Oxford in England. His work there involved standard 1940s psychology experiments using laboratory rats (e.g., Danziger 1953). On completing his doctorate, he joined the University of Melbourne in Australia where he did research in developmental psychology, studying children’s understanding of social relationships (e.g., Danziger 1957).

Major Accomplishments/Contributions

In 1954, Danziger moved back to South Africa where social psychology soon became his main area of research. Following a 2-year stay as Visiting Professor at Gadjah Mada University in Jogjakarta, Indonesia, Danziger returned to South Africa as Head of Psychology at the University of Cape Town. There, he conducted some groundbreaking studies inspired by the sociology of knowledge (e.g., Danziger 1963). This research is still cited and was continued by others for many years (e.g., Du Preez and Collins 1985; Finchilescu and Dawes 1999). Danziger’s time in Cape Town and his eventual departure from South Africa were marked by his opposition to the apartheid policies which were being enforced with increasing violence and brutality. This active opposition, both within and outside the academy, eventually led to threats and reprisals on the part of what was becoming a repressive police state. He left South Africa for Canada in 1965 and was prohibited from returning until the collapse of the old system after 1990.

Danziger took up an appointment as Professor of Psychology at York University, Toronto, where he continued to work in social psychology. His publications from this time include a textbook, *Socialization* (Danziger 1971) and a monograph, *Interpersonal Communication* (Danziger 1976), both of which were translated into several languages.

Danziger had a longstanding interest in the history of psychology and began intensive study of primary sources in the early 1970s. He became particularly interested in Wilhelm Wundt’s work. Around the time of psychology’s “centennial,” marking the establishment of Wundt’s laboratory in 1879, Danziger published a number of chapters and articles related to

this topic (e.g., Danziger 1979). However, during the 1980s, he became increasingly interested in the history of psychological research methods (e.g., Danziger 1985). This interest culminated in what is probably Danziger's best-known book, *Constructing the Subject: Historical Origins of Psychological Research* (Danziger 1990). Danziger was also interested in the history of psychological concepts and categories, and in a later book, *Naming the Mind: How Psychology Found Its Language* (Danziger 1997), he traced the historical origins of modern psychological concepts like "behavior," "intelligence," "attitude," "personality," and "motivation." He has continued this line of work in his most recent book, *Marking the Mind: A History of Memory* (Danziger 2008) with a detailed study of one of the oldest psychological concepts in existence.

Danziger has always been critical of historical accounts that celebrated currently fashionable disciplinary trends. He regards insights derived from work in the philosophy, history, and sociology of science as the indispensable foundation for a more critical approach to the history of psychology. In spite of this, he is committed to working from within psychology, largely because of the institutional separation that exists between the various fields which study science and science itself (Danziger 1994). It was this commitment that led him to play a central role in establishing the graduate program in history and theory of psychology at York University.

A symposium on Danziger's work was held at the annual meeting of the Canadian Psychological Association in 1995. The papers from this symposium were included, together with others, in a special issue of the *History and Philosophy of Psychology Bulletin* titled, "Tribute to Kurt Danziger" (Dzinas 1995). In 2000, the European Society for the History of the Human Sciences devoted a two-part symposium to Danziger's work in which nine papers were presented by scholars from Europe, North America, and South Africa. These papers formed the basis of an edited collection, *Rediscovering the history of psychology: Essays inspired by the work of Kurt Danziger* (Brock et al. 2004). Also noteworthy is an interview with Danziger, which appeared in the journal, *History of Psychology* (Brock 2006). More recently, he has published an autobiography (Danziger 2009) and there is now a website devoted to his work (www.kurtdanziger.com).

Darley, Frederic L.

HARRIS WINITZ

University of Missouri-Kansas City, Kansas City,
MO, USA

Frederic Darley had a distinguished career in several areas of communicative disorders. After receiving his Ph.D. in speech pathology and audiology from the

University of Iowa, he was honored by the departmental faculty by being given a faculty position and the opportunity to participate in its ongoing research programs. Later in his career he opted to head the speech pathology services of the Mayo Clinic in Rochester, Minnesota where he contributed his theoretical and clinical background to the treatment of patients with speech and language disorders. His contributions to the field of human communication and its disorders were twofold. First, Darley implemented the study and design of speech and language norms for the purpose of providing quantitative measure of the developmental delay of children with speech and language disorders. In this regard, Darley provided the impetus for the use of rigorous assessment procedures in the diagnosis and treatment of speech and language disorders. Today, the effect of Darley's innovative approach can be seen by the recognition of the clinical importance of speech and language norms in the testing and evaluation of patients. Second, Darley contributed to the clinical disorder of aphasia and associated disorders by reporting clinical findings and summarizing the diagnostic and treatment procedures in his well-recognized book *Aphasia*.

Dearborn, Walter F.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: July 19, 1878; Died: June 21, 1955

Dearborn was born in Marblehead, MA. He attended Wesleyan University in Connecticut, graduating with a B.A. in 1900 and attending as a graduate student in 1900–1901. He taught for a time in Connecticut schools and received an M.A. from Wesleyan in 1903. He then went to Columbia for his Ph.D. work under the direction of W. S. Woodworth and J. McK. Cattell. Dearborn was one of several researchers,

including C. H. Judd who also had Wesleyan connections, inducted into the study of eye movements by the technical advances in their measurement and photographic recording pioneered by Dodge and Erdmann between 1896 and 1898. Dearborn, in his 1905 thesis, *The Psychology of Reading: An Experimental Study of the Reading Pauses and Movements of the Eye*, wrote that he was “indebted to Professor Dodge for whatever knowledge I may have secured of the technique and methods of the experiments” (Dearborn 1906, p. 150).

Major Accomplishments/Contributions

Dearborn was one of the first to provide precise measurements of eye fixations during reading utilizing a variety of materials and type styles. He began his academic career at the University of Wisconsin between 1905 and 1909, and then moved to the University of Chicago. By apportioning study in Germany over several years between 1904 and 1911, he also obtained his M.D. from the University of Munich in 1913. In 1912, he started a 35-year career at Harvard. There he continued his work on reading which he expanded into a general theoretical consideration of reading disability. His most well-known student was Leonard Carmichael (Ph.D. 1924) who, though he became more well known for his researches on the development of complex behaviors in utero, also published a study of mirror writing in a monograph with Carmichael and Elizabeth Lord in 1925 on reading disabilities (Lord et al. 1925). Carmichael continued his association with Dearborn and they coauthored a book on fatigue and reading in 1947 (Carmichael and Dearborn 1947). Dearborn saw his studies of reading disability in the context of the importance of assessing individual differences, both in reading performance and generally: he was one of the contributors to Walter Miles's *Festschrift* for Raymond Dodge, a comprehensive contemporary survey of individual difference research (Dearborn 1936). Dearborn was also the founder in 1922 and director for over a dozen years after that of the Harvard Growth Study, a longitudinal study correlating physical and mental growth. Mental growth was charted through the use of intelligence tests Dearborn devised. Though it produced more raw data than conclusions at the time (Modell 2001), the Harvard Growth Study did eventually serve as a source of data for studies of the

adult lifespan, much like the Harvard Grant Study of college men which began soon afterward. Through the 1930s Dearborn continued to publish on dyslexia and reading difficulties (e.g., Dearborn 1931; Dearborn 1932). He retired from Harvard in 1947 and joined the faculty of Lesley College in Massachusetts: one of its laboratory schools was named after him. Dearborn also became a respected expert on the teaching of reading, like Miles Tinker and others who became well known in as consultants on the teaching of reading due to their expertise in its underlying psychology and physiology. His last published work was a textbook of some influence in that field (Anderson and Dearborn 1952). Recent evaluation of Dearborn's work suggests that he inaugurated or anticipated several methods in current reading instruction (Zimmer 2007).

Delabarre, E. B.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: September 25, 1863; Died: March 16, 1945

Edmund Burke Delabarre first studied psychology with Charles Edward Garman (1850–1907) at Amherst, graduating in 1883, and then over the next several years studied with William James at Harvard between 1888 and 1890 (contributing a short reminiscence of this time to the *Psychological Review's* commemoration of 50 years of the American Psychological Association in 1943), with Binet at the Sorbonne, and with Münsterberg at Freiburg, with whom he took his Ph.D. in 1891 with a thesis on sensations of movement.

Major Accomplishments/Contributions

He returned to America and founded Brown laboratory, twelfth in the US (Mitchell 1993). In 1896, he replaced Muensterberg at Harvard as director of the Psychological Laboratory for one year. He continued as director of the Brown Department and was succeeded by Leonard Carmichael. Delabarre's psychological interests and publications at the beginning of his career were consonant with those typical of the second generation of US psychologists. He was adept at building measuring instruments and employed these in the study of the relation of movement and consciousness, an extension of ideomotor theories current in his era and a foreshadowing of realist and behaviorist theories emphasizing movement.

He was comfortable in the community of eclectic philosopher-psychologists of his day: he is fairly represented, in terms of his immediate intellectual environment and community of influence, in the commemorative volume for Charles Garman by his students, *Studies in Philosophy and Psychology* (Garman et al. 1906) which contained, along with a chapter by Delabarre on the influence of surrounding objects on the direction of lines, contributions by Arthur Henry Pierce, Charles Edward Garman, F. J. E. Woodbridge, and R. S. Woodworth. While at the Harvard Laboratory,

he published several collaborative papers on the force of reaction movements, involuntary movements made to pleasant and unpleasant stimuli, and the effects of studying for examinations on the nervous condition of female students. He wrote on the plaster-cast method of fixing apparatus to the eye to record eye movements and reviewed Laura Steffens' early work on motor set, with Müller at Göttingen, in 1901 in the *Psychological Review*. Between 1911 and 1913, he contributed reviews to the *Psychological Bulletin* of theories of the will and its connection to motor consciousness, including those of Ach, Bergson, Wentscher, G. V. N. Dearborn (a former Harvard student), Kohnstamm, Pillsbury, and E. C. Rowe. However, most of Delabarre's work remained in unpublished manuscripts due to his intense perfectionism. On the other hand, he was, perhaps more than most psychologists, distinguished by his extensive amateur interests in things that did not appear specifically psychological, although in his synoptic view of the subject they were. On these, in distinction to his psychological work, he published freely. He was a member of the Brown-Harvard expedition to Labrador in 1900 with the geologist Reginald A. Daley and published about it on his return (Delabarre 1902), and also contributed a chapter on the flora of Labrador to Wilfred Thomason Grenfell's *Labrador, The Country and the People* (1909). After purchasing a summer home at Assonet Neck near Fall River in southeastern Massachusetts, he became fascinated with the inscriptions on Dighton Rock on the Taunton River, which had been known since at least 1680 for its multiple inscriptions and graffiti. Delabarre took great pains to photograph the rock, which is difficult to access and submerged most of the time, and concluded after years of study that the apparent writings on it were the work of the Portuguese explorer Miguel Cortereal, who, while searching for his lost brother Gaspar, traveled to the area and carved them in 1511, claiming to be "by the will of God leader of the Indians." Delabarre's efforts were well received by the Portuguese community in the area and he eventually received a decoration from the Portuguese government for his endeavors (Brennan 1975). His most well-known contribution to psychology is his experimental research, undertaken on himself, on the psychological effects of ingesting Cannabis Indica (or, in his terms, "Haschisch"). This forms part of a long trend of

psychological interest in the subject of substance-influenced consciousness stretching back to Benjamin Blood and William James and forward through the experiments on consciousness and LSD conducted by Timothy Leary at Harvard in the 1960s and their current vicissitudes. Like Dighton Rock, most of this work, conducted for more than thirty years, is submerged in Delabarre's unpublished manuscripts. John Poplestone, first director of the Archives of American Psychology, published a resume of Delabarre's 1931 summary of his experiments, which refract the texture of late nineteenth and early twentieth century theories of psychology including motor consciousness and rhythm through the lens of drugs: a noteworthy example of the value of a historical archive to the scientific record in this area (Delabarre and Poplestone 1974).

Delboeuf, Joseph-Rémi-Leopold

DAVID J. MURRAY
Queen's University, Kingston, ON, Canada

Basic Biographical Information

Joseph-Rémi-Leopold Delboeuf was born on October 1, 1831, in Liège, a large French-speaking industrial town

in Belgium, and died on August 13, 1896, in Bonn, Germany. Although he contributed toward many areas in science, his contemporaries considered him to be, first and foremost, a psychologist. For example, in discussing the latest views on the extent to which a person might be consciously aware of events intrinsic to his own active muscular movements, William James said that “no less a Psychologist than Prof. Delboeuf” indicated that the “muscular sense” should be considered as helping us to estimate spatial distances (James 1950/1890, Vol II, p. 189). During his career, Delboeuf participated in three of the most vociferous controversies in the history of psychology. First, there was the debate on whether sensations could be measured (this question is at the heart of Fechner’s psychophysics). Second, there was the debate as to whether and how Darwin’s theory of evolution could be integrated into experimental psychology. And, third, there was the debate as to the value of studies of hypnotism for our understanding of human psychopathology; this debate played a crucial role in Freud’s early career.

Delboeuf obtained a doctorate in philosophy and in physical and mathematical science from the University of Liège, then carried out postdoctoral research at the University of Bonn. In 1863, at the age of 32, he was appointed to the Chair of Philosophy at the University of Gand (Ghent, in Flemish), also in Belgium, some 70 miles west of Liège. Only 3 years later, he returned to the University of Liège, where he held the Chair in Philology. All his psychological writings were in French, and were published in the major French and Belgian scientific journals of his day.

Major Contributions

Both his first and final psychological publications were on optical illusions (Delboeuf 1865a, 1865b, 1892). Titchener (1905a) devoted considerable space in his teaching text on experimental psychology to this topic, partly because it was “fashionable” in the sense that numerous scientists competed to explain well-known illusions, such as the Müller-Lyer illusion, in as few words as they could; Delboeuf’s views on optical illusions were prominently discussed by Titchener, and have been summarized by Nicolas (1995a). Nicolas (1995b) has also summarized some early views on memory put forward by Delboeuf.

In 1865, Delboeuf began his psychophysical research, inspired by his reading of Wundt (1863) and of Fechner (1860/1964). His experimental findings were not published until 1873, but were disseminated to the English-speaking world by such authoritative figures as William James (1842–1910) and Edward B. Titchener (1867–1927). Basically, Delboeuf (1873) succeeded in actually constructing a rotatable disk on which was painted a set of eight concentric rings. Each ring was painted a shade of gray in such a way that inspection of the whole display in normal daylight showed the circles as differing from each other by equal-appearing steps of grayness from black at the center to white at the periphery. When revolved, the different levels of grayness on the wheel seemed to merge smoothly, from black to white, from the center to the periphery. It should be noted that illuminating the wheel (viewed in daylight) by bringing a candle close to it did not lead to an apparent preservation of equal-appearing levels of contrast between adjacent rings; brightening or dimming the whole by judiciously placed candles distorted the apparent evenness of the transition from black to white of the eight rings on the wheel.

But the most impressive theoretical achievement associated with Delboeuf’s disk was the fact that he had *calculated*, from first principles, the degree of grayness with which each ring ought to be painted if they were to appear equal-stepped in grayness levels from the center to the periphery. If we may plunge from here directly to 100 years further on, it was found that, in measuring the goodness-of-fit of each of Delboeuf’s eight painted graynesses to the grayness that would be predicted by each of three famous psychophysical laws relating sensation intensity to stimulus intensity, Delboeuf’s own law (to be given in a moment) yielded the best fit, with Fechner’s law and Stevens’s law tied for second and third places (Murray 1993, p. 136). Fechner’s law had asserted that sensation strength was a logarithmic function of stimulus strength. Stevens’s law had asserted that sensation strength was a power function of stimulus strength. Delboeuf’s law was that sensation strength was a logarithmic function of stimulus strength, where, however, the latter was measured by the degree by which the strength of the “external” stimulus exceeded the strength of the stimulation arising from a resting-level of physiological activity caused by spontaneous receptor activity, fatigue, and other

internal forces. More on the historical background of these psychophysical laws, including the role played by Helmholtz, will be found in Murray (1993), Norwich (1993), Nicolas et al. (1997), and Laming (1997). Stevens's power law had actually been anticipated in a review of Delboeuf's monograph that been written by his eminent Belgian colleague, Joseph Plateau (1801–1883); Plateau's review has been translated by Laming and Laming (1996).

Delboeuf's psychophysical contributions also included a quiet paving-of-the way toward an interpretation of the meaning of the expression "sensation strength" that would not get a firm foothold in psychophysical theory until well into the twentieth century. Fechner's aim had been to define a "scale" of sensation strength in which an increase in strength from one step on the scale to the next step would constitute an increase of one "unit" of sensation strength; this unit was assumed to be constant in subjective size no matter what the location of that first step on the scale. Fechner himself chose the "unit" to be the "just noticeable difference" between two sensations, but was soundly contested on this matter by Plateau and others. On Delboeuf's disk, the subjective grayness-strength, d_1 , of one ring was contended to differ from the subjective grayness-strength, d_2 , of an adjacent ring by an amount equal to the difference between the subjective grayness-strength of d_2 and that of the next ring, d_3 . But everyday English language usage allows us to say that the subjective "contrast" between d_1 and d_2 is therefore equal to the subjective "contrast" between d_2 and d_3 . Between 1873 (the year Delboeuf published his memoir about the disk) and 1905 (the year of Titchener's groundbreaking textbook on experimental psychology), the opinion slowly took root, influenced in part by a monograph by Delboeuf (1883) on psychophysical laws in general, that what psychophysicists are measuring is the "sense distance" between two stimuli, rather than the number of "units" of sensation strength by which the two stimuli are presumed to differ (Titchener 1905b). A monograph by Laming (1997) has lent strong support to this relativistic approach to psychophysical measurement; he failed to find evidence that "sensation strength" referred to a unidimensional variable that could be easily isolated in the way that one can isolate the variables of "length" and/or "duration," in the course of experimentation in physics.

It is only recently that Delboeuf's contributions to the dissemination of the theory of evolution have been acknowledged. In the course of the development of his theory of genome phenotyping, the microbiologist Donald Forsdyke (2001, p. 54) discovered that Delboeuf (1877) was able to prove, using probability theory, that if an anomalous or isolated phenotype were to be expressed by chance (e.g., a single antelope might have unusually shaped horns for its species), then that phenotype could probably be passed on to subsequent generations (rather than "die out"). Another forgotten contribution by Delboeuf to evolutionary theory was his assertion that, in the evolution of individual organs, it was the sensory receptors that most readily provided evidence of selective adaptations to new environments and were, therefore, the organs most likely to demonstrate the validity of Darwin's theory of evolution by natural selection (Delboeuf 1876). In particular, the evolution of sensitivity serves to mediate the acquisition of memory representations that can facilitate the development of the cognitive skill of comparison-making. The evolution of sensitivity also serves to maintain an instinct of self-preservation.

It was toward the end of his life that Delboeuf found himself more or less obliged to consider the importance for psychological theory of hypnotism and related phenomena. Binet and Féré (1887/1891) had written a short (and still useful) history of how hypnotism had gradually become scientifically acceptable after its rocky start in the near-quackery of Mesmer's "animal magnetism" theories. By 1886, when Delboeuf was 55, studies of hypnotism and its use in psychotherapy were concentrated in Paris, at the Salpêtrière hospital, ruled over by the eminent neurologist Jean-Martin Charcot (1835–1893), and at the town of Nancy, in eastern France, where family doctors H. Bernheim (1840–1919) and A. A. Liébault (1823–1904) were exploring hypnotic phenomena. Delboeuf visited both Paris and Nancy, and compared the various autobiographical accounts by Charcot and Bernheim, as well as accounts of the achievements of a stage hypnotist named Donato, concerning their methods of inducing a hypnotic state. In several short volumes, Delboeuf (1886, 1890) reported that the plethora of opinions on the optimal methods of hypnotic induction reflected the influences of the hypnotizer's preconceptions upon his interpretation of the patient's behavior

during hypnosis; the influences of the behavior of the first subject successfully hypnotized upon the subsequent choice of method to be used by the hypnotist with later patients; the multifarious influences of teachers upon their pupils; and biases set up by theories so amorphous that it was possible to explain any form of behavior induced under trance by reference to “suggestion,” to “unconscious” layers of personality, or even to the influence of magnets held near the head of the patient (it is hard to believe nowadays that even Binet himself subscribed to the opinion that magnets could induce hypnotic states; see Binet & Féré 1887/1891). Into these debates Delboeuf brought the steadying hand of a scientific skeptic, work for which he has only recently been given well-deserved credit (Duyckaerts 1992; Macmillan 1991/1996). Delboeuf’s contributions to the literature on hypnotism are referred to in various places in Ellenberger’s magisterial book on the history of dynamic psychiatry (Ellenberger 1970).

Denmark, Florence L.

NANCY FELIPE RUSSO
Arizona State University, Tempe, AZ, USA

Basic Biographical Information

Florence Harriet Levin was born on January 28, 1931, in Philadelphia, Pennsylvania. She described her mother as the driving force behind her accomplishments (Denmark 1988, p. 281). Her father, an attorney, supported Denmark's achievements. After graduating Phi Beta Kappa from the College for Women of the University of Pennsylvania in 1952, she married Stanley Denmark in 1953 and continued her graduate training at the University of Pennsylvania, earning an A.M. in psychology (1954) and a Ph.D. in social psychology (1958). After graduate school, Denmark lived in New York City, where she had three children, Valerie (1959), and twins, Pamela and Richard (1960), while holding an adjunct teaching position at Queens College of the City University of New York (CUNY) and working part-time in the college's counseling center. She divorced Stanley Denmark, and in 1973 married her second husband, Robert Wesner, a publisher with Aldine Publishing Company, who was also divorced with three children: Kathleen, Michael, and Wendy. He became an important source of encouragement and support throughout her career.

Major Accomplishments/Contributions

Florence L. Denmark is an internationally recognized scholar, researcher, mentor, and leader. She received her Ph.D. from the University of Pennsylvania in social

psychology and has six honorary degrees. As of this writing, Denmark is the Robert Scott Pace Distinguished Research Professor of Psychology at Pace University in New York.

Denmark's full-time academic career began in 1964, as an instructor at CUNY's Hunter College. For the next 26 years, Denmark remained at Hunter, becoming an assistant professor in 1967, an associate professor in 1970 (with an appointment to CUNY's Graduate Center faculty), and professor in 1974. She chaired Hunter's Department of Academic Skills (1968–1970) and served as the first director of the SEEK (Search for Education, Elevation, and Knowledge) program (1968–1970), created to help high school graduates from poverty areas to attend college. In 1972, as an associate professor, she became Executive Officer of the psychology doctoral program at CUNY's Graduate Center, a post she held until 1979. In 1984, she was named Thomas Hunter Professor in the Social Sciences. She later headed the doctoral program in personality and social psychology at the Graduate Center (1986–1987). In 1988, Denmark became the first Robert Scott Pace Distinguished Professor of Psychology at Pace University, an endowed chair, and also became chair of the Pace Department of Psychology.

Florence L. Denmark's career has had a significant impact on psychology through scholarly and professional contributions in research, education, teaching, and mentoring, and through her professional leadership and advocacy. Denmark's scholarship and professional leadership have played pioneering roles in establishing the psychology of women as a recognized and legitimate scholarly field, stimulating new research and curriculum change. Denmark taught the first ever doctoral course in the psychology of women in 1970. A charter member of the Association for Women in Psychology (AWP), founded in 1969, she helped found and develop APA's Division 35 (Psychology of Women) in 1973, serving as its third president from 1975 to 1976.

Denmark's numerous leadership positions include the presidency of the American Psychological Association (APA), three APA divisions (1-General, 35-Psychology of Women, 52-International Psychology), the International Council of Psychologists (ICP), Psi Chi, and the Eastern Psychological Association.

Denmark has also served as the main NGO representative to the United Nations for both the APA and the International Council of Psychologists. She also chaired the New York NGO Committee on Ageing and serves on the Executive Committee of the NGO Committee on Mental Health and the NGO Committee on the Families.

A prolific writer, her body of work includes more than 26 books and monographs, 109 journal articles and book chapters, and dozens of other works. Denmark's extensive publications and most significant research have emphasized women's leadership and leadership styles, the interaction of status and gender, ageing women in cross-cultural perspective, and the history of women in psychology. In addition, her work on the advances, growth indicators, and contributions of the field of the psychology of women, has validated and legitimized the field as well as individuals working in it.

Denmark's many awards include election to fellow status of the Association for Psychological Science, the APA, and 14 APA divisions. She is also a fellow of the Society for Experimental Social Psychology (SESP) and a Fellow of the New York Academy of Sciences. She has received numerous national and international awards for her contributions to psychology. She received the 2004 American Psychological Foundation Gold Medal for Lifetime Achievement in the Public Interest. In 2005, she received the Ernest R. Hilgard Award for her Career Contribution to General Psychology. She was the recipient in 2007 of the Raymond Fowler Award for Outstanding Service to APA. Also in 2007, Denmark was elected to the National Academies of Practice as a distinguished scholar member. She received the Elder Award at the APA National Multicultural Conference in 2009 (Paludi and Russo 1990).

Dessoir, Max

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: 1867; Died: 1947

Dessoir was born in Berlin, and though he suffered some early privation, his Gymnasium education brought him into contact with persons destined for eminence in German academic and commercial life, among them Walther Rathenau. He matriculated at the University of Berlin and obtained his Ph.D. with Wilhelm Dilthey in 1889, and also earned an M.D. from Würzburg in 1892. He joined the faculty of the University of Berlin where he remained for the rest of his career.

Major Accomplishments/Contributions

Dessoir's primary psychological interests were in hypnotism and states of consciousness. His theory of double consciousness found a hearing among those psychologists in the early twentieth century who were concerned with unusual mental states such as somnambulism and automatism, for instance Boris Sidis and Morton Prince (Sidis 1915). However, Dessoir, in this as in virtually every area in which he was active, played a supporting rather than a leading role. Dessoir, by virtue of his position at the University of Berlin, was a member of Germany's academic elite, but among the Mandarins of academic culture (Ringer 1969) he had peripheral status, overshadowed in philosophy and psychology by others of greater renown. He had his greatest influence as a teacher: Gordon Allport remembered him favorably and Dessoir also was the dissertation advisor for Abraham Joshua Heschel, one of his last students, who became a leading Jewish theologian in America.

Dessoir had an interest in magical and occult phenomena dating back to his teens. By the time he was 20, he had already formed an association with German Theosophists and in 1889 was a founding member, with Albert Baron von Schrenk-Notzing and Albert Moll, of the Gesellschaft für Experimentelle-Psychologie

which was devoted to the empirical study of occult phenomena (Bauer 2004). Also in 1889 Dessoir, in an article in the journal *Sphinx*, coined the term “parapsychology” which became the term of choice to denote the experimental wing of occultism. Dessoir continued to publish books on occult phenomena, for the most part limiting himself to reportage rather than to advocacy, and often was an acute critic. Dessoir was very active in aesthetics and founded the journal *Zeitschrift für Ästhetik und allgemeine Kunstwissenschaft* which he edited until 1937. His exposition of his aesthetic theory, *Ästhetik und Allgemeine Kunstwissenschaft* (Dessoir 1906) was a standard German source for philosophers. Regarding its influence on psychology, it appears it was minimal in English-speaking circles. For example, Herbert Langfeld did not cite either Dessoir’s book or journal in his book *The Aesthetic Attitude* in 1920, the most comprehensive American psychological work on aesthetics at that time, even though he had studied at Berlin. Likewise, Dessoir’s history of psychology, focused on the classical roots of the subject, found less favor in a community that sought its roots in science rather than philosophy. Translated into English in 1912, it was quickly superseded by Boring’s and Gardner Murphy’s 1929 works. However, Boring recommended Dessoir’s history after G. S. Brett’s as a history of classic philosophic sources in psychology, and credited Dessoir for a useful review of the history of the concept of specific nerve energies in 1892. Also, Dessoir’s 1888 bibliography on hypnotism was an important early contribution to scholarship in that area. As psychology in Germany became more applied, Dessoir became further marginalized, but apparently kept up with the times: one of the students he recommended to the Wehrmacht’s growing psychological staff, the philologist Gotthilf Flik, was accepted (Geuter 1992). Dessoir had the curious distinction of being selected to visit the Eastern Front in 1915 under the aegis of Field Marshal Hindenburg and the General Staff of the German Army to observe and interview troops in action. His report on his tour, *Kriegspsychologische Betrachtungen* (Dessoir 1916), is one of the few psychological studies of war conducted in the field during combat. However, this did not make his career any easier at the end of his life. In 1899, Dessoir married the famous singer Susanne Triepel, who had a long career in Germany, and whose Christian background

played an important role in Dessoir’s career after 1933. Dessoir terminated his relation with the University of Berlin in March 1934 and though he remained in Berlin, his distant Jewish heritage rendered him less and less welcome in the academic community and eventually he was subjected to a publication ban, partly due to a dispute with Nazi philosophers. His marriage and connections shielded him from physical annihilation, but, isolated and in limbo, he had to watch as the German academic community was decimated during the war and as his library and papers were destroyed in the bombing of Berlin in 1943. His memoirs, published as *Buch der Erinnerung* (1946), contain particularly poignant descriptions of various suicides that occurred in Dessoir’s circle during the early 1940s: Dessoir himself attended, with his wife, the last Christmas gathering at the home of the tragic Lutheran theologian and writer Jochen Klepper.

Deutsch, Helene

VLADIMIRA VARBANOVA, JOHN D. HOGAN
St. John’s University, Jamaica, NY, USA

Basic Biographical Information

Born: 1884; Died: 1982

Helene Deutsch, a student and patient of Sigmund Freud, was a key figure in the establishment of the first psychoanalytic training institute, and a pioneer author on women and sexuality. Rebellious and often uneasy, Deutsch drew upon personal experiences and insights to develop her theories, which were quite divergent from Freud's. She fled the Nazis in 1934, and spent the second half of her life in the USA, where she taught and authored a number of influential articles and books.

Helene Rosenbach was born on October 9, 1884, in the town of Przemysl, in Polish Galicia, at the time part of the Austro-Hungarian Empire. After graduation from the local school, she refused to accept the traditional role of the idle life of a debutante, and demanded the opportunity for further education. While still in school, Helene met Herman Lieberman, a prominent socialist leader, with children, and significantly older than Helene. Inspired and supported by Lieberman, Helene became very active in the socialist movement, organizing the first working women group and leading them to a strike in a shirt factory in town. In 1907, Helene became one of only seven female students to enter the University of Vienna Medical School. Not long after, she decided to specialize in psychiatry.

Helene eventually left Lieberman to finish her degree in Munich, and aborted the child she was expecting with him. In Munich, she met her future husband, Felix Deutsch. The same age as Helene, Felix was a Zionist and a fellow student in internal medicine. They married in the spring of 1912.

Upon the completion of Helene's medical degree, the couple returned to Vienna. Although interested in psychoanalysis, Helene decided to stay with a more traditional approach to psychiatry. She took on a few internships in mental hospitals, the most significant of which was at the Wagner-Jauregg's Clinic for Psychiatry and Nervous Diseases, the largest in Austria, where she stayed until 1918. She also sought admission into the Vienna Psychoanalytical Society's Wednesday evening meetings, which was granted to her in 1918.

Meanwhile, Deutsch was experiencing a recurrent personal drama. She was convinced that many spontaneous abortions, including hers, were due to psychogenic factors. The Deutsches' only child, Martin, was born in January 1917. Helene was haunted by anxiety and constant guilt that she was not devoting enough

time and energy to her son because of her work. It was because of the poor relationship with her son, as well as her strong interest in psychoanalysis, that she became a patient of Freud in August 1918.

Major Accomplishments/Contributions

Helene attended the Hague Congress in September 1920, presenting her first paper as an analyst. She was deeply intrigued by Karl Abraham's writings on the female castration complex, and in early 1923, she left for Berlin to start analysis with Abraham and continue her training.

The next period in Helene's life became her most productive. She published her first book *Psychoanalysis of the Sexual Functions of Women* (1925). In it, she depicted the stages of female sexual development – infantile sexuality, puberty, sexual intercourse, pregnancy, childbirth, menopause – as coming full circle from mothering (a woman's own mother) to mothering. She was also a key figure in the founding of the Vienna Psychoanalytic Training Institute, which she headed with Freud's support for the next 10 years. Deutsch remained the Institute's most prominent teacher. By the time she fled from Vienna in 1934, Helene had left a significant body of work, including clinical papers, a psychohistory of George Sand (1928), and her second book *Psychoanalysis of the Neurosis* (1930), which became a standard teaching text.

Due to escalating anti-Semitism in Europe, as well as for personal reasons, the Deutsches moved to Boston, despite Freud's initial disapproval. Helene established a successful practice, taught at the Boston Psychoanalytic Society-Institute, and held a position at Stanley Cobb's psychiatric clinic at the Massachusetts General Hospital.

Helene Deutsch's most famous work *The Psychology of Women* was published in two volumes – *Youth and Motherhood*, in 1944 and 1945, respectively. After long years of work on topics as diverse as phobias, obsessions, depression, narcissism, "as if" personality, masochism, lesbianism, and anorexia, Helene Deutsch retired in 1963, influenced by her husband's deteriorating health. A major figure in the study of psychosomatics, Felix Deutsch died in 1964. Not succumbing to grief, Helene continued to work and published two more books – *Neuroses and Character Types* (1965) and *Selected Problems of Adolescence* (1967).

Deutsch's voluminous and novel work was received at the time with not only admiration, but also quite some antagonism as well. As a response to the 1950s "stay home and raise kids" propaganda for women, in which Deutsch's work was cited, feminists harshly criticized Helene for her ideas. In fact, her theories support the ideal of a passive and submissive woman only on a superficial reading. Many feminists failed to recognize the deeper implications of her work. Most relevant is her main deviance from Freud's theorizing – the suggestion that it is in fact the mother who remains of utmost importance throughout a woman's life.

In 1973, she wrote an autobiography dedicated to her late husband called *Confrontations with Myself: An Epilogue*. The book is entirely written in psychoanalytical terms, and for Deutsch represented a natural supplement to her main work *The Psychology of Women*, since so many of her advances in psychoanalysis were based on personal experiences and introspection. Helene Deutsch died on March 29, 1982, at the age of 97.

Deutsch, Morton

LISA M. BROWN
Pace University, Brooklyn, NY, USA

Basic Biographical Information

Morton Deutsch was born prematurely on February 4th 1920 to Charles and Ida Deustch in Bronx, New York. He was the youngest son in this middle-class Jewish family. His parents had immigrated to America from Poland. Deutsch skipped several grades in both elementary and high school, graduating at fifteen and entering the City

College of New York in Fall of 1935. He was initially premed, wanting to become a psychiatrist; however, he switched his major to psychology. After graduating from City College, he earned his Masters at the University of Pennsylvania, graduating in 1940. He then stated a rotating clinical internship at Letchworth Village, Warwick and Rockland State hospital, all in New York (Deutsch 1999; Frydenberg 2005).

After the bombing of Pearl Harbor, Morton Deutsch enlisted in the Air Force in January of 1942. Initially assigned to the psychological unit, he performed psychological assessments of aviation. Deutsch then trained as a navigator and flew combat missions eventually earning the Distinguish Flying Cross. After the war, Deutsch headed off to MIT to earn his PhD under Kurt Lewin. While at MIT, Deutsch met Lydia Shapiro whom he married in June of 1947 and had two sons, Nick and Tony (Deutsch 1999; Frydenberg 2005).

Major Accomplishments/Contributions

After graduating in 1948, Deutsch joined the Research Center for Human Rights at The New School. When the center moved to New York University, he joined the faculty, teaching there from 1949 to 1956. During 1952 – 1954, Morton Deutsch was a member of the Society for the Psychological Study of Social Issues Committee on Civil Rights. His work on interracial housing was an important part of the research used in the historic Brown vs. the Board of Education. In 1954, Morton started training as a psychoanalyst. He would work as a practicing psychoanalyst for nearly 30 years. After working briefly at Bell Telephone Laboratories, Deutsch accepted a position with Columbia University's Teachers College where he would teach, influencing many future psychologists, until beyond his retirement in 1990. In 1982, Deutsch was named the E.L. Thorndike Professor of Psychology and Education (Deutsch 1999; Frydenberg 2005).

In 1986, Deutsch founded the International Center for Cooperation and Conflict Resolution at Teachers College. The center was focused on cooperative learning and conflict resolution in schools. Deutsch and his team were awarded a contract with the New York City Board of Education to train high school staff in conflict resolution. The ICCCR continues to do conflict resolution training in schools as well as in the United Nations (Frydenberg 2005).

Morton Deutsch is considered to be one of the foremost scholars of conflict resolution and one of the founders of conflict resolution theory. In 2005, Columbia University's Teachers College established the annual Morton Deutsch Awards for Social Justice to honor a distinguished scholar-practitioner and an exemplary student paper on social justice. Additionally, courses on conflict resolution and mediation have become a part of the curriculum (Frydenberg 2005).

Deutsch has been recognized for lifetime achievement by numerous associations including the American Psychological Association (APA) which awarded him both the APA Distinguished Scientific Contribution Award and the Distinguished Research Scientist Award. He has also received the Kurt Lewin Memorial Award, the G.W. Allport Prize, and the Carl Hovland Memorial Award. Deutsch has also been President of the Society for the Psychological Study of Social Issues, the International Society of Political Psychology, and several divisions of the APA. Now in his 1990s, Deutsch is still involved with the ICCCR and continues to write and think about conflict resolution in a post-9/11 world (Frydenberg 2005).

Dewey, John

DAVID PATTON BARONE
Illinois State University, Normal, IL, USA

Basic Biographical Information

John Dewey was an American philosopher, psychological and educational theorist, and public intellectual. He was born in Burlington, Vermont, on October 20, 1859,

and died in New York City on June 1, 1952. After receiving an A. B. from the University of Vermont, he taught high school for 2 years and then attended graduate school at Johns Hopkins University. He took courses from G. Stanley Hall, but his main interest was in German idealist philosophy. He subsequently wrote on Leibniz, Kant, Hegel, and Herbart, and retained a holistic perspective even after he abandoned idealism for experiential naturalism. Dewey was hired at the University of Michigan in 1884 and began teaching the basic psychology course. In 1887, he published *Psychology*, one of the first American textbooks on the subject.

Dewey became professor and chair of philosophy at the University of Minnesota in 1888 and returned to the University of Michigan as chair in 1889. He became chair at the University of Chicago in a philosophy department that included pedagogy and psychology. Among Dewey's colleagues were James Tufts, with whom he wrote on ethics, George Herbert Mead, with whom he shared an interest in social psychology, and James R. Angell, who became chair of the newly founded psychology department when Dewey left the University of Chicago in 1904. The department came to operate the university laboratory school and started a psychology laboratory, where the graduate student John B. Watson worked.

Major Accomplishments/Contributions

Dewey's influential 1897 paper, "The Concept of the Reflex Arc in Psychology," was a preemptive strike against reductionistic behaviorism. He advocated the concept of a circuit or coordination, later developed into a recursive feedback unit by George Miller. Dewey was recognized as a founder of functional psychology, whose early spokesperson was Angell. Dewey also became a founder, with Charles Pierce and William James, of pragmatism, a philosophy consistent with an evolutionary, scientific perspective.

Dewey was elected to leadership positions in psychology, philosophy, and pedagogy. He served as the eighth President of the American Psychological Association during 1899–1900. Dewey's (1900/1976) presidential address, "Psychology and Social Practice," remains a respected statement of psychology as an integrated science and profession. After Dewey moved to Columbia University in 1904, his direct involvement

in psychology declined, but he addressed APA on “The Need for Social Psychology” in 1917. Because Dewey had produced theories rather than positive facts, he had come to be viewed as one of philosophers that psychology had left behind.

Dewey’s (1922/1983) *Human Nature and Conduct: An Introduction to Social Psychology* provides the best overview of his mature psychology. It is more of a foundational text in personality than social psychology and offers a functionalist alternative to Freud’s psychodynamics. In it and his 1910 book for teachers, *How We Think*, he presented his theory of deliberation as mental simulation. Imagining possible actions and outcomes gives humans an adaptive advantage and moral responsibility for the future they help create. Dewey’s theory of inquiry as active reconstruction of knowledge was to influence Jean Piaget, Lev Vygotsky, and other constructivists. In his 1922 book, Dewey also presented his view of psychology as applied ethics, involving scientific knowledge about means-ends connections and development of interventions to change habits and character. His views influenced the personality theories and psychotherapies of Carl Rogers and George Kelley.

Later in life, Dewey increasingly became a public intellectual, honored on the cover of *Time* in 1928. He contributed regularly to *The New Republic*, supported progressive causes such as the depression-era People’s Lobby and the Committee for Cultural Freedom, which sought to keep religion out of public schools. He also was involved in founding the American Association for University Professors and the American Civil Liberties Union. Dewey was respected internationally for his educational theory and visited schools, lectured, and served as a consultant in Japan, China, Turkey, Mexico, and the Soviet Union. Despite his leftist position, he disavowed Stalinism and chaired the Commission in Mexico City investigating the assassination of Leon Trotsky.

There was renewed interest in Dewey’s ideas about progressive education and humanistic ethics in the 1960s and 1970s (for which televised fundamentalist preachers rail at him). A comprehensive biography of Dewey was published by Dykhuizen (1973). Likewise, his pragmatic philosophy, eclipsed by analytic philosophy in America, has been revived by Richard Rorty and others. Dewey’s role in the history of psychology has also received more attention (Barone 1996; Dalton 2002). His complete works have been published in

37 volumes by Southern Illinois University Press, and Southern Illinois University at Carbondale is the home of The Center for Dewey Studies. There are Dewey societies worldwide and Dewey international seminars in 1959 and 2009 commemorated the 100th and 150th anniversaries of his birth.

Dodge, Raymond

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: February 20, 1871; Died: April 8, 1942

Dodge attended Williams College (AB 1893) where he developed a deep interest in philosophical questions. He next went to Germany and, unlike most Americans who sought out either Wundt, Stumpf, or Müller, followed a recommendation of an American mentor and studied with Benno Erdmann at Halle. Erdmann came to the conclusion that Dodge, for various reasons, did not have the requisite skills to

become a distinguished philosopher. However, fortunately for psychology, Erdmann had other interests including the psychology of reading. He set Dodge, who had natural mechanical ability, the task of constructing apparatus to capture the process of eye movements during reading. Together Dodge and Erdmann developed an improved tachistoscope for isolating words in text, publishing the results of their studies in 1898 under the title *Psychologische Untersuchungen über das Lesen*, which incorporated the insight that, in reading, perception occurs only during fixations, not between them. Dodge continued to develop apparatus to measure eye movements, including a novel camera utilizing a falling photographic plate on which the eye movements were captured by a corneal reflection. This led to Dodge's most important scientific achievement: the exact measurement of saccadic eye movement (Dodge 1903). Thereafter, Dodge, over the next 30 years, studied all facets of eye movements and continued to construct sophisticated instrumentation which was essential to the development of eye tracking (Vicary 1999; Wade and Tatler 2005). Beyond this, Dodge developed, early in his career (e.g., Dodge 1902) a functional account of perception as a comprehensive set of relations between the eye, the organism, and the environment which anticipated later cognitive approaches to perception. Dodge, on his return to America, served briefly at Ursinus College in Pennsylvania and then moved to Wesleyan University in Connecticut, succeeding C. Hubbard Judd, who founded the laboratory there. Dodge was associated with Wesleyan for 26 years. There he was an effective teacher and mentor, and from that base he formed a wide network of contacts among the leaders of American experimental psychology. By 1903 he was counted, in Cattell's *American Men of Science*, as among the top 50 psychologists in the United States.

Major Achievements/Contributions

Dodge's scientific interests were broad and, beyond his pioneering work on vision during reading, on saccadic eye movements, and on compensatory eye movements and nystagmus, he also wrote on the philosophic and scientific underpinnings of the idea of human variability, whose sources he believed to lie in physiological processes ultimately occurring at the neural level (Dodge 1924; Dodge 1931). Dodge also collaborated with Francis

Gano Benedict on a series of studies of the psychological effects of alcohol (Dodge and Benedict 1915). While involved in this project Dodge had to absent himself from Wesleyan for a year between 1913 and 1914: his replacement, Walter Miles, became a close friend and emulated Dodge's precision and breadth of view. Dodge also was interested in the relation of psychology and psychopathology and contributed not only an early study of visual correlates of mental disease (Diefendorf and Dodge 1908) but also collaborated with the psychiatrist Eugen Kahn in an examination of the human craving for superiority (Dodge and Kahn 1931). Dodge, at heart a philosopher, wrote extensively on a comprehensive theory of psychology toward the end of his career. Mind, Dodge held, was the result of two incompatible elements, the external world of stimuli and the reactive, biological organism, engaged in a constant reciprocal reactive process which in his view never reached equilibrium during life. Analysis and synthesis are likewise incompatible but yet necessary for each other: as Dodge put it, "We know no wholes without parts – no parts without configuration" (Dodge 1934, p. 99). The organizing principle of the reactive interchange and part-whole relations, Dodge maintained, lies outside of these systems at a level best described as cosmic. Dodge was modest and preferred to let his scientific achievements speak for themselves. Nonetheless, he played an important role in the higher levels of leadership of nascent psychological science, serving as APA President in 1916 and then, in 1924, moving to Yale University where he contributed substantially to the establishment and structuring of the Yale Institute of Human Relations. At the end of his career, he revealed, in his autobiography (Dodge 1930) and in the last chapter of *Conditions and Consequences of Human Variability* (Dodge 1931), social meliorist and spiritual elements of his personality and thought which were ultimately his motivations toward science.

Donders, F. C.

PETER J. BEHRENS

The Pennsylvania State University, Lehigh Valley,
Center Valley, PA, USA

F. C. Donders (1818–1889). Used by permission from the Digital Library, Royal Netherlands Academy of Arts and Sciences

Basic Biographical Information

The work of Dutch physiologist Franciscus Cornelius Donders was of great significance to early experimental psychology. Born in Tilburg, the Netherlands, on May 27, 1818, to a modest working-class family and identified early as a bright, energetic student, endearing to his teachers, he entered the University of Utrecht at the age of 17 for the study of medicine. At the same time, he became a student at the military hospital. He was awarded a medical degree in 1840 and became a military surgeon and health officer, working on hospital wards, conducting autopsies, and contributing papers to medical journals. His reputation as a brilliant medical officer landed him a position at the Military Medical School in Utrecht to lecture on physiology, anatomy, and histology (Bowman 1969).

In 1847, recognized for his outstanding abilities, Donders was named Professor Extraordinary at the University of Utrecht, which gave him the opportunity to select his own subjects for lecture and engage intensively in physiological research, particularly ophthalmology (Bowman 1969). In May 1888, on attaining his 70th year, he was obliged, by the rules of the University of Utrecht, to retire. He died in Utrecht on March 24, 1889.

Major Accomplishments/Contributions

By the mid-1850s, Donders was deeply immersed in various aspects of physiological research, notably optics and color sense, but also investigations of muscle sense and the physiology of vocalizations, areas of study that occupied him for more than 20 years. In 1862, he became the chair of the Department of Physiology at Utrecht and intensified his efforts with laboratory research with the collaboration of able students.

Europe of the mid-nineteenth century saw an acceleration of interest into what were fundamentally psychological topics, such as sensation, movement, judgment, and perception, conducted by physiologists like Donders and others, such as Hermann von Helmholtz, Gustav Fechner, and A. Hirsch (van Strien 1997). All this occurred more than 10 years before Wilhelm Wundt opened the first psychological laboratory at Leipzig University in Germany in 1879.

Donders' thinking was critically influenced by the new evolutionary theory of Charles Darwin and the laws of nature that governed human activity. He developed a close professional relationship with

Darwin, enthused by his 1859 *Origin of Species*, which led him to see the relationship between his work and the certain laws of the harmony in human life. Donders was particularly taken with the laws he termed *habit*, *exercise*, and *inheritance* (Bowman 1969), which he viewed from the perspective of the physiologist, as opposed to the naturalist. He firmly grasped how all life is governed by the continuous operation of organization, adaptation, and renovation (Bowman 1969).

It was in the middle years of the 1860s that the attention of Donders and his students turned to the laboratory investigation of the measurement of activity known as reaction time (RT). The good physiologist could rightly propose that mental action, like physical action, not only occurred in the context of time, but that it also could be measured by the new instruments at their disposal. For this purpose, the noematachograph and phonautograph were designed by Donders to determine the duration of mental activity (van Strien 1997).

Donders and his students measured RT in various stimulus and response aspects of experiments and found that the RT could be lengthened as the requirements of the task were made more complex for the subject. For example, “simple RT” was the time it took a subject to respond to a single stimulus, such as a flash of light. However, RT was lengthened when the subject had to choose between two or more stimuli, each with a different response. Donders called this the “complex RT.” He inferred from this situation that RT increased because additional mental operations were involved to make a correct response. The way to measure the length of time of the mental operations was one of Donders’ most important contributions to psychological theory of his time. This was the method of subtraction: complex RT minus simple RT yielded the duration of mental activity involved in the complex task. Donders named his theory based on the subtractive method “mental chronometry.”

Donders presented the first experimental results of mental chronometry at the 1865 meeting of the Dutch Royal Academy of Sciences in Amsterdam and published his results that same year in a Dutch journal (Koster 1969). The measurements were carried out with the assistance of his graduate students at Utrecht, notably Johan Jacob de Jaager, who subsequently was awarded his doctoral degree on the basis of his work conducted in Donders’ laboratory (Brozek and Sibinga 1970). Three years later, a major publication on the

laboratory work appeared in Dutch, French, and the more accessible German (Koster 1969). This summarized the large amount of measurements collected over the years and provided the theoretical and methodological bases for his mental chronometry (Koster 1969; Brozek and Sibinga 1970).

Later researchers credited Donders for his important experimental work and established the RT experiment as a cornerstone of laboratory research in sensory psychology in Europe and America (Boring 1950). The theory Donders proposed, however, as well as RT theories proposed by Wilhelm Wundt and others, came under criticism toward the end of the nineteenth century for their inherent theoretical and methodological flaws. For example, Donders proposed that as many as 12 separate and distinct mental activities intervened between a stimulus and a response, and Wundt proposed at least seven (Boring 1950; Brozek and Sibinga 1970). Unfortunately, as with all theories based on propositions of intervening mental activity for a reaction, there was no way to independently verify the proposed processes or measure them empirically. Methodologically, too, RT experiments were not free from considerable variation from subject to subject and from one day to the next for an individual subject. Such variation presented the problem of the validity and reliability of a “true” RT for any subject, especially as it may be used in comparison to other subjects. Nevertheless, the work of Donders stands as a noble attempt to understand human choice and decision making, because of the central importance of reaction time to learning, memory, attention, perception, and many other aspects of human activity (Koster 1969).

Downey, J. E.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: July 13, 1875; Died: October 11, 1932

June Downey was the daughter of Evangeline and Col. Stephen Downey, a territorial delegate to the US Congress who was instrumental in the establishment of the University of Wyoming, from which she graduated in 1895 with a degree in Greek and Latin. Aesthetic and literary interests took her to the University of Chicago where, after publishing her first psychological article on group emotional impressions of piano music in the *American Journal of Psychology* in 1897, she obtained her A.M. in 1898 and returned to Wyoming to teach English and Philosophy (Hogan and Thompson 2003). She was drawn steadily toward experimental psychology, attending Cornell University for a summer session in 1901 and eventually, after publishing a volume of poems, *The Heavenly Dykes* (Downey 1904), returned to Chicago. There, sponsored by James Rowland Angell, she completed a thesis on control processes in handwriting for her Ph.D. in 1907. She then returned to Wyoming and, though she continued to maintain an interest in literature which resulted not only in further literary creations as well as several monographs on the psychology of poetry and the creative process, committed herself completely to a career in experimental psychology. In 1915, she became the head of a combined Department of Philosophy and Psychology: one of her undergraduate students from that time, John E. Anderson, became an eminent developmental psychologist and APA President in 1943.

Major Accomplishments/Contributions

Her experimental career consisted mainly in working out the relations of handwriting to two very typical period research subjects: motor behavior and individual differences. This culminated in her monograph *Graphology and the Psychology of Handwriting* (Downey 1919) and her creation, in the same year, of a test of personality based on handwriting, the Downey

Individual Will-Temperament Test. This test, later expanded into both individual and group versions (Downey 1922; Downey 1923), involved simple writing tasks (for instance, writing the phrase “United States of America”) under varying conditions. The trace evidence and timings of the process then were analyzed into several components which, Downey claimed, would reveal personality differences, especially as they related to processes of internal control (i.e., the will). These components were: speed of movement, freedom from load, flexibility, speed of decision, motor impulsion, self-confidence, noncompliance, finality of judgment, motor inhibition, interest in detail, coordination of impulses, and volitional preservation. Decision scores were calculated based on proofreading tasks involving searching and underlining materials in text. Self-confidence was based on emphatic double underlining, while “finality of judgment” was scored as a function of time taken in reconsideration of decisions. The Will-Temperament Test in both its original individual and later group versions was attractive in its simplicity but was criticized for its unreliability, which Downey acknowledged and which she was endeavoring to correct when she died. Her collaborator Richard Uhrbrock, at Wyoming for a short time in the 1920s, continued work both on the validation of the Will-Temperament Test and on other handwriting-related interests of Downey’s, including laterality of function, for a long time afterward. Downey wrote a book on basic psychology for schoolchildren, *The Kingdom of the Mind* (Downey 1927), which drew a favorable review from the British public health specialist G. A. Auden, W. H. Auden’s father. Her *Creative Imagination: Studies in the Psychology of Literature* (Downey 1929) is a good record of some little-known data relating to the measurement of aesthetic responses. One of her last contributions, to the first volume of the journal *Character and Personality* in 1932, was an inadvertently autobiographical comparison of her personal knowledge of her siblings – she was one of 10 children – and parents and their performances, estimated and actual, on a variety of personality measures (Downey 1932). All in all, her work was overshadowed by the many other competing approaches to personality that appeared during her later career and it has for the most part not survived, but her work should be of interest to those interested in psychological thinking which blended aesthetic as well as scientific interests.

Dreikurs, Rudolph

RIVKA BERTISCH MEIR

Mental Health Counselor, New York, NY, USA

Basic Biography

Rudolph Dreikurs, an American psychiatrist and educator, was born in Vienna, Austria, on February 8, 1897. He completed his medical training at the University of Vienna in 1923 and began his medical career in Austria, before immigrating to the United States in 1937. Five years later, during World War II, Dreikurs began a 30-year career at the Chicago Medical School as

a professor of psychiatry. He also lectured in psychiatry at Loyola College from 1957 onward, and was a visiting professor at several other American universities as well as at colleges in Brazil and Israel.

Dreikurs was a student of the Austrian-born social psychologist Alfred Adler, who also immigrated to the United States in the 1930s; the two became close professional colleagues. Adler based his theories of individual psychology on the premise that people as social beings are primarily motivated by the need to be part of a social context and accepted by others. For both Adler and Dreikurs, the key to improving individual behavior and social relationships was encouragement. If it is supposed that individuals are in control of their actions, then positive support ought to be the most effective strategy for helping people make appropriate decisions about how to conduct themselves. By the time of Adler's death in 1939, Dreikurs was a leader in Adlerian circles. He continued to promote and expand Adler's work in individual psychology through lectures in colleges, prisons, and healthcare settings.

Rudolf Dreikurs founded the Society of Individual Psychology of Rio de Janeiro in 1937, was a founding member of the American Psychological Society in 1952 and the International Association of Individual Psychology in 1954, and served as the editor of the *American Journal of Individual Psychology* from 1952 to 1956. As Viktor Frankl put it, "What Adler achieved and accomplished was no less than a Copernican switch." But just as Copernicus needed Galileo to convey the meaning and significance of his revolutionary discovery to the world, so Adler needed Dreikurs to carry out the same function.

In 1943, Dreikurs married Sadie Ellis Garland (1900–1996), an art therapist. The two worked together on Dreikurs's writing and teaching, as well as traveling together to open psychiatric clinics and conduct hospital-training programs. In her own work, Sadie "Tee" Dreikurs began to apply Adlerian principles to the practice of art therapy.

In 1952, Dreikurs founded the Alfred Adler Institute in Chicago, now called the Adler School of Professional Psychology. As part of the organization's mission, Adlerian training programs were established across the United States and Canada. At the Adler School, Sadie "Tee" Dreikurs created one of the first

art therapy training programs in the country, and her student, Judy Sutherland, became the director of the Adler School's Master of Arts in Counseling Psychology: Art Therapy program, which has become one of the school's most successful endeavors.

The Adler School curricula continue to apply Adler's theories and methods to developing social responsibility and solving social problems, including those of marginalized and underserved populations. In Chicago, Dreikurs also established the first Adlerian Child Guidance Center, where he trained counselors from many countries; these professionals have continued his work by creating Adlerian-Dreikursian Family Centers around the world. After Dreikurs died on May 25, 1972, the Adler School's Rudolf and Sadie "Tee" Dreikurs Psychological Services Center was established in 1973 to deliver comprehensive mental health services to the Chicago community through its clinics, and off-site in prisons, businesses, schools, and other settings.

Accomplishments

Among the 30-plus books and articles that Dreikurs published, the most famous were *Children: The Challenge* written with Vicki Soltz and first published in 1964, and *Parents' Guide to Child Discipline*, written with Loren Grey and first published in 1968. As a psychiatrist, educator, and theorist, Dreikurs primarily focused on the behavior of preadolescents. He strongly believed that children (as well as adults) choose how to behave in a given social situation based on their personal interpretation of that situation. Because such interpretation is subjective, it is readily influenced by biases or mistaken information, leading children to make inappropriate behavioral choices. Misbehavior, therefore, can be characterized as a child's mistaken assumptions about how to meet the needs for belonging, significance, and acceptance in a social setting. Dreikurs believed that, when children feel socially isolated or insignificant, they resort to behavior driven by four mistaken goals: attention, power, revenge, and avoidance. The misbehavior – attention-seeking in nature – begins when children do not receive the attention they need, regardless of whether their conduct is bad or good. When such children feel ignored, they look to gain power or take control by defying authority. If children lose a power

struggle, they seek revenge, and when revenge fails to bring about the desired outcome, they begin to feel inadequate and give up.

Dreikurs developed effective techniques for teachers and parents to respond to a child's behavior when it becomes subverted toward mistaken goals. First, adults identify the mistaken goal(s) by noting their own response to the misbehavior and observing the child. For example, attention-seeking children tend to annoy parents and teachers, while children vying for control leave adults feeling abused or embarrassed; revenge-seeking children tend to make others feel hurt; and children who give up and avoid the situation leave others feeling ineffective. The adult then explains the mistaken goal(s) to the child, because giving the child the chance to understand, assess, and adjust his or her conduct is effective, whereas discipline is not.

When children's misbehavior is aimed at the mistaken goal of control, Dreikurs recommended that adults avoid power struggles. Dreikurs also recommended thwarting a child's revenge-seeking behavior by setting up a situation in which the child could demonstrate his or her abilities and experience a sense of belonging and significance. Furthermore, he suggested that a child who presents a sense of inadequacy should be encouraged and supported for even the smallest effort.

Dreikurs understood that if children are made to feel like valuable contributors to the family – and to the classroom as an extension of the family – they will behave appropriately and cooperate without the need for discipline. Teachers and parents can shape social environments to foster good behavior, providing children through positive settings with the feeling of belonging that they need and the opportunity to display their knowledge and skills. Children then realize that contributing to the good of the group also contributes to their feelings of significance and acceptance. In the classroom, Dreikurs refers to this as “democratic teaching.”

Dreikurs did not believe in discipline, punishment, reinforcement, or praise. Rather, he felt that encouraging children unconditionally was the most effective way to prevent the feelings of discouragement from which misbehavior emerges and to provide children, as social beings, with the approval they seek regardless of their level of success. Dreikurs also considered that logical

and natural consequences are the most effective way for children to experience the effects of their behavioral choices. Logical consequences are reasonable requirements that follow a particular behavior and require children to correct what they did wrong. Thus, students who do not finish their work during class must finish the assignment for homework. Natural consequences are set in motion by the misbehavior itself. For instance, students who are not prepared to give an assigned oral report when the teacher calls on them suffer sufficient embarrassment without the need for further discipline or punishment.

As a close colleague of Alfred Adler, Dreikurs continued Adler's work on individual psychology by developing a practical methodology for evaluating misbehavior in preadolescents and using encouragement to foster appropriate behavior in the family and the classroom. Adlerian parent education aims to give children the skills and tools they need to approach life constructively and positively, as well as the means to avoid traps and manage the difficulties that life presents. The approach supports parents by providing them with practical tools to understand and manage children's behavior.

Dreikurs also built on Adler's work by developing strategies and techniques for applying the theory of individual psychology to counseling, psychotherapy, family education, and classroom settings. He is perhaps best known for simplifying Adler's theories so that parents and educators could use them in school and at home.

Dunlap, Knight

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: November 21, 1875; Died: August 14, 1949

Dunlap was a native Californian, born in Diamond Spring, El Dorado County, in placer country. His undergraduate education he gained at Berkeley: There he was inspired to a career in psychology by a person whose eclecticism Dunlap carried forward, George M. Stratton. After completing his graduate work at Harvard with Münsterberg in 1903, Dunlap – whose earliest publications were in philosophy – taught at California until 1906 and then moved to Johns Hopkins University, where he lasted through the time of James Mark Baldwin and John B. Watson until 1936, when he moved to the University of California at Los Angeles. There he chaired the Department until his retirement in 1946.

Major Accomplishments/Contributions

He played a visible and central role in the development of psychology as an academic and professional discipline: he was President of the American Psychological Association in 1922, contributed to the efforts of Howard C. Warren and others on terminological standardization, and established the *Journal of Comparative Psychology*, as well as devising an important modification to chronoscope design incorporating a synchronous electric motor instead of a spring (Perera 1999). Kate Gordon Moore, who held the chairpersonship at UCLA between the death of Shepard Ivory Franz in 1933 and Dunlap's appointment in 1936, reiterated. In her obituary of Dunlap (Moore 1949), his programmatic statement of his theoretical activity in psychology. This included attacking introspection, replacement of introspection with response and reaction (while accepting consciousness as a necessary correlate), attacking images and treating ideas as real objects, adoption of peripheralism rather than brain theory, elimination of "instinct" as a psychological concept, and revision of concepts of heredity. This gives more structure and direction to what was a ceaseless shifting

activity across all of these areas of psychology, in many of which Dunlap was a part of a larger chorus (for instance, in emphasizing response and motor-based theories of consciousness over old-fashioned introspection or in arguing against the instinct concept). What really distinguished Dunlap from his contemporaries who strove to establish a scientific psychology was his drive toward iconoclasm which led him into some blind alleys but also to several formulations that sometimes approximated or anticipated later more successful ones. In learning theory, for instance, he advanced a view that emphasized the importance of pattern recognition which presaged later views of perceptual learning (Dunlap 1926b). In the same field, his counterintuitive theory of negative practice contained the germ of other later formulations. Negative practice, as Dunlap described it (Dunlap 1942) involved performing an action that was to be removed from the repertoire in the same fashion and under the same conditions as it would ordinarily be performed, while substituting different thoughts and motivational content. This implication of consciousness in the learning process probably had some influence on later theories of learning emphasizing cognition or expectation, especially when translated into more conventional S-R terminology, for instance by Dunlap's student O. Hobart Mowrer. Dunlap had a complex relation with eugenics: he came close to the hereditarian fire but didn't get burned. On the one hand he published a theory relating personal beauty to racial betterment (Dunlap 1920b), delivering his first remarks on this at Lynchburg, Virginia at the beginning of the sterilization era, and carried forward the racial vocabulary of his time in his social psychology (Dunlap 1926a). On the other, he is credited (Zenderland 1998) for laying to rest the one-sided hereditarianism typified by Goddard's Kallikaks (Dunlap 1940) and was ahead of his time in considering the effects that population increases might have on social behavior. Bluff and mercurial and apparently as independent and contrarian a person as much of his written output suggests, he was ever ready with suggestions for anyone about everything from making coffee to women's skirt lengths (Dunlap 1928) to the role of athletics in academic life (Dunlap 1929b) to driving etiquette: his diary of his trip to Europe and the Levant in 1929 is worth reading not only for its insights into the fine texture of

a psychologist's life but also his character (Dunlap 1929a). At Hopkins, he took on the Quixotic task, as chair of a faculty task force in 1934, of trying to eliminate football (he succeeded in removing the admission charge to games.) Dunlap campaigned strenuously – remarkably he didn't include it in his programmatic statement – against “mysticism” in psychology (e.g., Dunlap 1920a). Yet he published, with Robert Gill, an editor at Williams and Wilkins publishers in Baltimore, *The Dramatic Personality of Jesus* (Dunlap and Gill 1933), a takeoff on the highly successful characterization of Jesus as salesman by Bruce Barton from 1925, *The Man Nobody Knows*. Dunlap later wrote a long treatise on the psychology of religion which incorporated his views on survival of bodily death (Dunlap 1946). One additional irony can be noted in the relation between Dunlap and Evelyn Hooker, a colleague at UCLA. Dunlap considered homosexuality a bad habit ripe for modification (Dunlap 1932). Yet it was Dunlap who accepted Hooker as a graduate student at Hopkins in 1930 when she had been rejected at Yale because of her gender. And, while he felt he could not appoint another woman to the UCLA faculty in 1939 as he already had three, he found her a position as a research assistant and an extension instructor which led to her long career there and ultimately to her pioneering work that made homosexuality a legitimate subject for scientific study and contributed substantially to its social acceptance.

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered

EUGENE I. TAYLOR

Harvard Medical School, Boston, MA, USA
 Saybrook University, San Francisco, CA, USA
 Massachusetts General Hospital, Boston, MA, USA

Dynamic theories of personality generally posit the reality of the unconscious, and are considered dynamic because they involve some explanation of how psychic energy is transformed as it passes back and forth between the waking rational everyday state of consciousness and the unconscious within the interior life of the individual (Taylor 2009). Laboratory experimentalists acknowledge only the reality of the rational waking state. This is the point where a person's inward reality interfaces with external material reality through pleasurable and painful attachment of the senses to objects or other people in the outer world. Historically, for the reductionists into operational definitions and

measurement, science is based on the rational ordering of sense data alone, excluding emotion and intuition in their methods, the product of which is then overgeneralized to all of reality. Consequently, scientific psychology has always been in crisis about phenomena that cannot be directly measured. To avoid this problem, experimentalists simply claim that there is no such thing as an unconscious. Behaviorists from Pavlov around 1900 to Watson commencing in 1913, followed by Skinner in 1938, all took this position. Investigators in the 1920s around John Sears, Saul Rosenzweig, and David Shakow, and then later figures such as John Dollard and Neal Miller, tried to launch various enterprises to measure psychoanalytic concepts. But they were the exception rather than the rule in the academy. Behaviorism, which had declared itself a reductionistic and positivistic science, had decreed that whatever it was, if could not be measured, it was not science. Freud was to remain to this day unscientific in the minds of such experimental purists.

Meanwhile, the clinical tradition was erroneously called applied psychology by the experimentalists who believed that only they represented pure science, dating from G. Stanley Hall's introduction of the term "applied" in the *American Journal of Psychology* in 1888. This view was further cemented by the experimentalists' claim that Lightner Witmer, a student of Wilhelm Wundt and James McKeen Cattell, was the Father of Clinical Psychology, by which Witmer only meant school psychology, as he had openly attacked James and the Emmanuel Movement for their psychodynamic fantasies (O'Donnell 1979). In reality, however, the clinical tradition in American psychology had its genesis in the French tradition of bedside teaching, which evolved into the French Experimental Psychology of the Subconscious (Taylor 2000a). This was the investigation of the interior life using hypnosis, suggestion, and dissociation theory as a way to understand fugue states, somnambulism, double consciousness, hysteria, and multiple personality.

Dissociation and Multiple Personality Along Charcot's Axis

Charcot rehabilitated hypnosis before the French Academy of Sciences in 1881, which ushered in an unprecedented era of depth psychology (Ellenberger 1970). He demonstrated that using suggestion on subjects

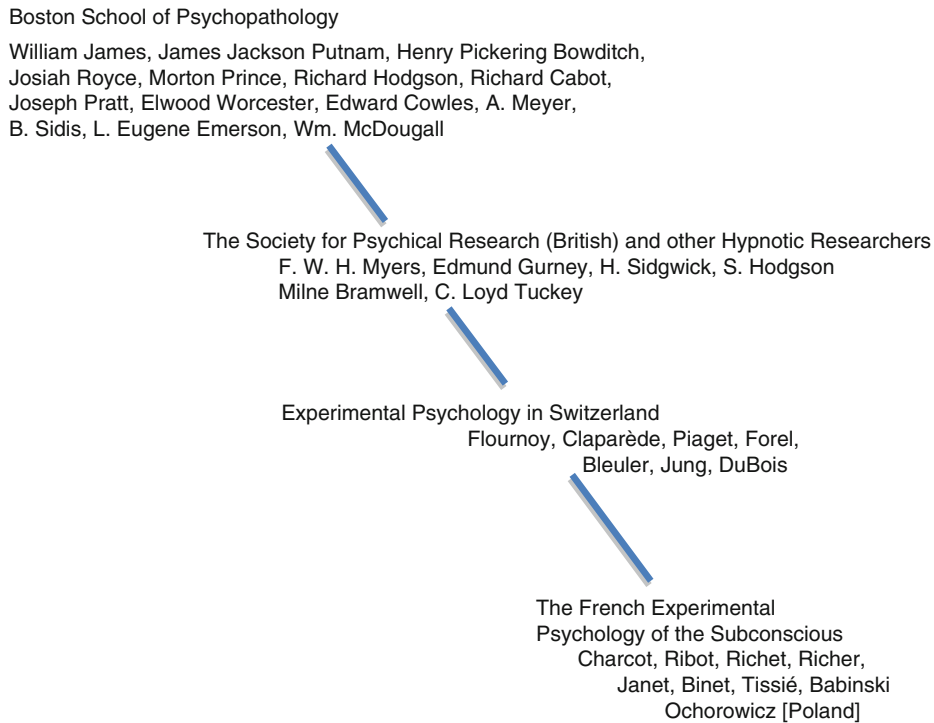

while entranced and by the implanting of post-hypnotic suggestion, he was able to induce the symptoms of hysteria such as paralysis, syncope, and choking in normal subjects. Meanwhile, in hysterics, while entranced, he could suggest the same symptoms away, though they would return on coming to. His disciple, Pierre Janet, would soon develop this into the psychogenic hypothesis – that both physical and psychological symptoms emanated from an idea buried in the subconscious. Psychogenesis could explain traumatic experiences that could not be assimilated into the waking life of the person that for various reasons were cast into the subconscious as dissociated phenomena. There, they would operate according to laws of their own, attracting other unassimilated experiences and appropriating their memory in the form of psychic energy, causing generalized states of anxiety. When this energy reached a critical mass, it could burst forth into the field of waking consciousness as a physical symptom or even appear in the form of an apparently independent personality.

Originally, Charcot claimed that hypnosis had identifiable physical stages of lethargy, catalepsy, and somnambulism, and that hypersuggestibility was an extreme symptom of psychopathology that ceased upon recovery. Hippolyte Bernheim, a young physician at the Nancy School of Medicine, objected, however, and maintained instead that these claims about the identifiable physical stages of hypnosis were not true and that suggestibility was not a pathological phenomenon but an extension of normal suggestion. Further, it was Burnheim who developed the idea that psychogenesis could be applied to the diagnosis and treatment of what came to be known as the ambulatory psychoneuroses in his work *Suggestive Therapeutics* (1880). As Henri Ellenberger (1970) has stated, the continued rift between the Salpetriere and the Nancy schools brought the issues of dynamic psychology to international attention, attracting psychopathologists in the USA, psychical researchers from England, experimental psychologists from Switzerland, and a raft of investigators from Europe, Scandanavia, the Netherlands, Russia, Italy, and Poland, including Josef Breuer and Sigmund Freud in Vienna.

It became an era of hysteria and multiple personality that was dominated by the dissociation model of

consciousness. Dissociation theory was the standard explanation in dynamic psychology that explained everything from the forgetting of memories from moment to moment to full blown cases of fugue, somnambulism, and multiple personality. The general tenor of these scientific investigations led to the conclusion that we do not live perpetually in just one state of consciousness – the normal everyday waking state – but that personality is actually made up of plurality of states of consciousness. F.W.H. Myers, eminent psychical researcher in England, even posited that these interior states arrange themselves in a spectrum ranging from the psychopathic, at the dissolutive end, to the transcendent, at the higher, evolutive end, with waking consciousness occurring somewhere in the middle, its function being the biological survival of the physical organism in the external material environment. This evolutionary development permits the person to experience all these other states, each of which, William James said, has its own field of application and adaptation.

Further, the era was dominated by the emergence of a cross-cultural comparative psychology of subconscious states. Insofar as the physiological psychologists of the previous era made their scientific advances by experimenting on the nervous system of the frog, and the behaviorists followed after 1913 with their experiments on the white rat, the most renowned of the dissociation theorists each focused on a single case study that was either a case of multiple personality or a medium. The case provided by William James was that of the clairvoyant Mrs. Lenora Piper; the case presented by Morton Prince was that of Sally Beachamp, an example of multiple personality; the case presented by Boris Sidis was that of Rev. Thomas Hannah, who had experienced a succession of fugue states leading to complete loss of memory as to his personal identity. The case presented by Theodore Flournoy in Geneva was that of the psychic Helene Smith. For F.W.H. Myers in England, it was the medium Stainton Moses and also the case of Lucy Goodrich-Freer. The case presented by the young psychiatrist Carl Jung in Zurich was that of the medium Helene Preiswerk; and from Pierre Janet in Paris, there was the case of Leonie, a hypersuggestible hysteric, among others (Fig. 1).

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 1 Charcot's Axis: A loose-knit consortium of French, Swiss, English, and American psychotherapeutic investigators (1882–1920)

Charcot's School

Emphasizing Charcot's view, the biologist Alfred Binet soon became Charcot's primary exponent for the idea that physiological symptoms of such disorders as hysteria had their origin not in a lesion in the brain but in an idea held in the subconscious. The energy accrued by "the buried idea" then often erupted into waking consciousness, expressed indirectly and symbolically as a physical or mental symptom. Through hypnosis one could then alter or banish the buried idea, which would have an effect on alleviating a symptom that appeared in waking consciousness. It was left to Charcot's pupil Pierre Janet to decide the activity of the buried idea, which had split off from waking rational consciousness to float around in the subconscious acting according to laws of its own (Janet 1899). The more energy that accrued to the primary image, the more energetic power built up into what became known as a subconscious complex, out of which symptoms might arise (Janet 1894). This was psychogenesis.

The Bernheim School

Following the earlier teaching of the country physician A.A. Liebeault, whose *Sleep and Analogous States* had awakened the attention of even William James back in 1868 (James 1868), as we have said, Bernheim took the position that the hypersuggestibility of the hysteric state was not a distinct pathological condition unto itself. Rather, it was an extension of normal suggestibility. Ellenberger (1970) notes that Charcot and Bernheim argued back and forth in a public debate that elevated dynamic psychotherapy to international attention. This drew adherents to both sides and further served to spread these new ideas widely among professionals, although, in the end, history suggests that the so-called Bernheim school more or less gained the upper hand in the argument and after 1889 Charcot's view began to fade. With it, reputations such as that of Alfred Binet, who had so ardently defended Charcot, followed.

Figure 2 is an overly simplistic rendering of the debate between Charcot and Bernheim, as it was taken up in Europe and elsewhere. The main point to

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 2 The Bernheim "school" of psychotherapy in Europe (1885–1899)

note is that there was more of an organized consortium of ideas around Charcot and Janet along the so-called French-Swiss-English-American psychotherapeutic axis than there was among European, Nordic, and Russian investigators such that, according to Ellenberger (1978), Janet probably found his greatest following in Boston. There certainly was communication going on between the investigators in Europe and elsewhere, but it does not appear as organized as what we have called the Axis of Charcot.

The Axis of Charcot had several defining characteristics depending on which theorist spoke to different aspects of the psychogenic hypothesis and what their own theoretical persuasion was regarding the nature and scope of consciousness. In general, several ideas prevailed. The first and most common was that all psychological phenomena were interpreted according to the model of dissociated states, from the common case of forgetting what you had for lunch on Tuesday of last week to the full blown identification.

A second characteristic, articulated most clearly by William James (1890) in his article "The Hidden Self," published in *Scribner's Magazine* and later developed into his metaphysical position of noetic pluralism, was that the basis of personality was that of a plurality of selves, not just one (Fig. 2).

Rationalist conceptions of the person are of necessity monistic, however, because the rationalist sees only from the vantage point of the single state in which they find themselves. Big science is a case in point. Big science defines itself by the rational ordering of sense data alone, and anything deviating from it is considered not science. In this case, the scientist is limited to experience in that one state only without knowledge and experience of other states. For the scientist, such states just do not exist. This turns out to be an extremely important point that William James made 100 years ago, when he said that experimental psychology was nothing more than a colossal elaboration of the ego, and as I point out here, the situation has remained fixed for almost a century. This situation was not the case within the context of the early dynamic theories of personality, which appear to have had conceptualizations that are just now entering the psychological lexicon around resilience, spirituality, mindfulness in psychotherapy, the mind/body effect, and, in the case of Existential-Humanistic and Transpersonal psychology, transcendent states of consciousness.

A third characteristic of the era, originally put forward by F.W.H. Myers and the British psychical researchers, was the idea that consciousness did not refer to waking rational consciousness alone, but also encompassed a spectrum of interior states ranging from the psychopathic to the transcendent, with waking consciousness being somewhere in the middle, its primary function being the survival of the physical organism in the external environment so that the person could experience these other state of consciousness, which somewhere had their own field of application and adaptation. The lower order condition enveloped dissolutive states, such as those seen in true personality disintegration, while the higher states above waking rational consciousness were evolutive in nature, expressed as states of higher and superior intelligence, representing the direction human evolution was heading for in the future. In this vein, psychic abilities would

naturally appear as guides of signposts along the way as a benchmark of progress toward higher states of spiritual self-realization.

Not everyone agreed with this model. Pierre Janet in France and Morton Prince in the USA did not posit any growth-oriented dimension in their own dynamic theories of personality. But William James clearly made that commitment in his 1896 Lowell lectures on *Exceptional Mental States* (Taylor 2010). In his chapter on “Multiple Personality,” he demonstrated that some of the cases of dual personality revealed the emergence of a superior person, who took on the primary identity for the rest of that individual’s life.

In any event, the dissociation model and its attendant sequelae persisted into the twentieth century, but were eventually displaced by dynamic models of the unconscious around the theories of psychoanalysis.

Freud and the Freudians

The late nineteenth century can be defined as the era of multiple personality against a backdrop of multiple states of consciousness, largely dominated by the so-called French Experimental Psychology of the Subconscious. Freud, who had already been introduced to hypnosis by Breuer and to “the talking cure” by Breuer’s patient Anna O., travelled to both Paris and to Nancy for a brief period and translated several of the volumes of Charcot and also Bernheim into German, thus appropriating all that was contained in the French theories, which he applied to his own purposes. Freud had broken with Breuer after publishing their “Preliminary Communication on the Nature of Hysterical Phenomena” in the *Neurologische Centralblatt* in 1893 and their coauthored book *Studies on Hysteria* in 1895. After Breuer, Freud took up a correspondence with Wilhelm Fleiss, an eye, ear, nose, and throat specialist, discussing cases and numerous theoretical points, such as the inherent bisexuality of all human beings and the erectile nature of nasal tissue. But Freud’s father died in 1896 and he descended into what Ellenberger called a period of creative illness, in which he struggled to define his own identity. He continued to write about the anxiety neuroses, only indirectly alluding to the French point of view. These were the years of some deep self-reflection and what he called his quiet isolation. Then in 1899, he emerged with a new method of free association, which he called

for the first time psychoanalysis. At the same time, he produced the *Interpretation of Dreams* (Freud 1900), the germ of his later full blown theory of personality. In that work, he presented a dynamic model of the unconscious, based upon the idea that dreams were a doorway into the unconscious, and their symbolism revealed that dream imagery was based on wish fulfillment, usually traced back to some sexually related episode from one’s childhood, mixed with immediate memories of the present day. He also introduced there his theory of the Oedipus Complex, where a young son of age 5 or 6, recognizing his own identity, wants to displace the father from the parents’ bed and become one with the mother. The father reasserts his position as the dominant figure in the relationship to the mother and ousts the boy from the marital bed by threatening to castrate him. The boy flees in abject fear but comes to accept that arrangement. The farther is then free to take the boy and introduce him to the world of the masculine. In this way, the proper psychosexual relations are established for the boy over the rest of his life, and he is free to go out and find a mate who is like his beloved mother. It was a monumental self-analysis on Freud’s part, based on an investigation of his own dreams.

Forming a Wednesday evening study group of devoted young Jewish followers, Freud closed out his correspondence with Fleiss and, in the context of presenting cases in this group, which later became known as the Vienna Psychoanalytic Society, he continued to see patients and to publish more books, first *The Psychopathology of Everyday Life* (1901), then *Jokes and Their Relation to the Unconscious* (1905), and then *Three Essays on the Theory of Sexuality* (1905). In these works, he elaborated on the dynamic principles of the unconscious as he interpreted that term, and also enumerated his theory of the psychosexual stages of development in young children – oral, anal, phallic, a latency period, and genital – as well as writing on the perversions. He invited such figures as Alfred Adler to join his group in 1903, and did likewise with Jung, after Jung first wrote to him in 1906 and paid a visit, accompanied by Ludwig Binswanger, to Vienna in 1907 (McGuire 1988).

Jung quickly became Freud’s heir apparent to the psychoanalytic throne, principally because he was a Swiss Protestant and a not a Viennese Jew as Freud’s

immediate disciples were. Jung's ascent, Freud did not attempt to hide, proved to the world that psychoanalysis was not just a Jewish science. But all was not right in Freud's circle, as defectors began to leave the fold, largely on theoretical grounds. First there was Wilhelm Stekel, then there was Adler, and then, by 1913, Jung himself. In 1914, Freud published *A History of the Psychoanalytic Movement*, writing Stekel, Adler, and Jung out of the picture. At the same time, behind the scenes to his disciples Freud began to convince them that Jung was an anti-Semite.

After 1914, Freud began to produce what he called his papers on metapsychology, meaning his speculations regarding the significance of psychoanalysis for understanding culture at large. His most important reformulation at this time was that, in addition to Eros as the basis personality and the sublimation of the sex instinct into the building of civilization, because of the carnage of World War I, he now posited the existence of Thanatos, the death instinct. This was quite disconcerting to his followers, as they had built their own formulations around the primacy of sexuality, now having to rewrite their understanding to more accurately reflect the new formulations of The Master. The important point was that up until then, Freud's formulations had been drawn directly from case studies, while these papers were metapsychological precisely because they were speculations not based on case histories. *Beyond the Pleasure Principle* (1920), *The Ego and the Id* (1923), *Civilization and Its Discontents* (1930), and *Moses and Monotheism* (1937) were such productions.

Though unscientific in a clinical sense, they created an international focus on Freud's writings to the point where psychoanalysis came to dominate public perceptions of psychology and psychiatry and for some 50 years it came to dominate the definition of clinical teaching in the helping professions, at least until the community psychiatry movement and the separate advent of psychedelics in the 1960s.

During the 1920s, Freud continued to elaborate on his model of personality in terms of the id, the ego, and the superego, while his emphasis had been more on the id in the early part of his career. He now began to pay more attention to the development and adaptation of the ego. His daughter Anna assisted him in this regard, as she began to write extensively on child

psychoanalysis and to also elaborate on her father's theory of defense mechanisms (Freud 1936). This was also a period that marked the founding of the various psychoanalytic institutes in Berlin, London, Budapest, and elsewhere, each one vying for the title of which was the most dedicated to preserving the purity of Freud's teachings. The New York Psychoanalytic Institute had been founded in 1913, but the Boston and Chicago institutes were not organized until the early 1930s. Each was created as an independent entity free from the controls of the local medical schools and universities. The institutes served to preserve the teachings and set the professional standards for training analysts, and they functioned under the aegis of national and international organizations that had all been launched central to Freud. At the same time three separate tributaries began to flow restructuring psychoanalysis as Freud aged and finally passed from the scene in 1939.

The Object Relations School

Freud fled Vienna for London when the Nazis arrested his daughter Anna in 1938, but then released her. He only lived a year longer, but Anna Freud succeeded him as an important carrier of the direct lineage. She was joined in this regard by Ernest Jones, Freud's later biographer and owner of Sigmund Freud's publishing business, and also James and Alex Strachy, who produced the Standard Edition of Freud's Collected Works in English. Marie Bonaparte, who had introduced psychoanalysis into France, was their constant visitor. At the same time, Anna Freud had to compete with Melanie Kline (1932), who had already established her own psychoanalytic school in England and attracted numerous followers. Around her constellated such figures as D.W. Winnicott (1958), R.D. Laing (1960), Wilfred Bion (1952), Masud Khan (1974), and John Bowlby (1969), who were influential in developing what came to be known as object relations theory. The focus was no longer on the id, but on the ego's extension to objects – the mother's breast, the favorite childhood toy, significant individuals toward whom the baby “cathected.” While it developed mainly in England, the British psychoanalytic scene was further complicated by such events as Jung's lectures to the Tavistock Clinic in 1935, which tended to produce hybrid kinds of psychoanalysis thereafter (Jung 1968).

The Psychoanalytic Ego Psychologists

The expansion of psychoanalysis beyond Freud's original writings produced a greater emphasis on the person in terms of both ego functioning in the external material world as well as social relationships. For Freud, the sexual instincts focused on the pleasure principle, while the ego instincts focused on the reality principle, a formulation Freud beached early in his writings but did not really develop until the late 1920s, in which he delineated a more robust ego carrying out the executive functions and able to control instead of merely reacting to the impulses of the id. Out of his writings during this period, psychoanalytic ego-psychology developed. Freud's chief interpreters in this regard were, of course, Anna Freud, but also Heinz Hartmann, whose formulations presented a psychoanalytic picture of the normal personality and characterized ways to apply the method in clinical as well as educational settings (Hartmann 1958); David Rapaport, Hungarian psychoanalyst who was director of research at the Menninger Foundation before moving on to the Austin Riggs Center (Rapaport 1951); Ernst Kris, Austrian psychoanalyst and art historian (Kris 1952); and Rudolph Loewenstein, Polish and French-American psychoanalyst influential in the International Psychoanalytic Association (1982). Most eminent among the ego-psychologists, however, was Erik Erikson (Erikson 1968), who extended psychoanalytic thinking out into culture and who had a particularly daunting influence on cultural anthropologists such as Ruth Benedict, Margaret Mead, and others.

The Post-modern Freudians

Post-modernism is inextricably bound up with modern definitions of human science and the method of hermeneutics, traditionally understood as originally a form of Biblical interpretation from the nineteenth century, which evolved as a more secular philosophy through writers such as William Dilthey and the then existential phenomenologists, but which has in our own time also become associated with European and Marxist social movements, particularly from the Frankfurt School (Messer et al. 1988)). Politically, the voices of the Frankfurt School were generally critical of the Western rational tradition and the control of institutions of culture by the bourgeois mentality and its

ruling elites, defined by the radical feminists as controlled mainly by men. Lately, it has come to be a vehicle for the proliferation of an ideology that fuses race, class, and gender, limited to a radical feminist interpretation of Freud. Personality is most often defined in this line of thinking, not by internal psychodynamics, but by external social forces.

Martin Heidegger, Jurgen Habermas, Jacques Lacan, Jacques Derrida, Simone de Beauvoir, Herbert Marcuse, and Michele Foucault are but a few names who became some of the most important voices of post-modernism emanating from the tradition of European social criticism, some of whom wrote specifically on depth psychology as a fulcrum for social revolution. The extent to which post-modernism has penetrated into traditional psychology can be seen in such works as Messer, Sass, and Woolfolk (1988).

Possibly the most influential post-modernist was Herbert Marcuse, German-Jewish socialist, philosopher, and social critic, called "The Father of the New Left," who fused Marx and Freud in his widely read text, *Eros and Civilization* (1955). Drawing heavily on Freud's *Civilization and Its Discontents*, Marcuse reviewed the struggle of the id, which represents the pleasure principle, to continually express itself in the face of repression demanded by the reality principle in order for civilization to progress. It is the battle between freedom and restraint, where freedom must be sacrificed in the name of the common good, a process that defines the person in modern society, each in an individual way. While a certain amount of sublimation is necessary, there is such an overabundance of it demanded of the person in the modern industrial age that mental psychopathology is the result, particularly with regard to gratification of the sexual impulses. Using Marxian social theory, Marcuse describes a Utopian society of the future in which civilization is allowed to progress while also promoting Eros, the sexual liberation of individuals and therefore of society, which would also transform the relation between men and women. While links between psychoanalysis and Marxism formed back in the 1920s, Marcuse's ideas had particular appeal to a segment of the counterculture revolutionaries of the 1960s, especially among the radical feminists. In this way depth psychology became a tool for the advancement of political ideology.

Another influential example of the post-modern criticism of psychology from the standpoint of Freudian psychoanalysis has been the controversial work of Jacques Lacan, French physician, psychoanalyst, linguist, and leader of the “Back to Freud” movement. Born in Paris in 1901 and raised in a Catholic environment, Lacan came to question the value of his religion by the time he attended a Jesuit college. He entered medical school at age 26 and also became interested in Hegel’s phenomenology and the existential phenomenology of Karl Jaspers and Martin Heidegger. He was also influenced by Rudolph Loewenstein, who later became one of the prime movers of psychoanalytic ego-psychology with Ernst Kris and David Rapaport. Lacan undertook a lengthy didactic analysis with Loewenstein, which likely accounts for the overemphasis on the ego in Lacan’s theories.

Lacan’s early contribution to the psychoanalytic literature outlined what he called the mirror phase in Freud’s theory of the psychosexual development of the child. The “mirror phase” was that moment when the child, from somewhere around 6 months onward, first recognizes that he or she is an independent entity from other human beings, whereas before, the child was an undifferentiated organism dependent on the mother. From then on, the person must contend with the socialization imposed upon the individual, which Lacan interprets more broadly than Freud, implying that the free expression of the instincts of the id must give way to socialization by the growing ego in light of pressure from the superego. Lacan interpreted this process as one of castration for both males and females, and as such was the inevitable outcome of resolving the Oedipus phase of psychosexual development.

Though he was a member of the International Psychoanalytic Association, and the prestigious *Société Psychoanalytique de Paris*, the more orthodox psychoanalysts largely ignored him, though his reputation grew in French circles particularly among the surrealists. Among his acquaintances were Andre Breton, Salvador Dali, and Pablo Picasso, thus reinforcing his subscription to a neo-Romantic view of psychopathology. He was a member of various psychoanalytic study groups, while he carried on his own weekly seminars at the teaching hospital where he first received his medical training. These seminars went on for over 60 years and became the platform from which he tested his

theoretical ideas. Here he declared that psychoanalysts needed to return to Freud’s original texts and undertake a more refined examination of the language of psychoanalysis, particularly with regard to symptomatology. All healing, he said, takes place in conversation with The Other. Within the person, this is a conversation between the person and his or her own unconscious. In therapy, it was the discourse between patient and therapist, and in the world at large it is the basis for the successful interaction of the individual with the society.

Though his ideas eventually had a profound influence on modern French culture, the majority of his career was spent in open disagreement with his more traditional psychoanalytic colleagues, finally to the point that he was dismissed from their various societies, his response to which was to form societies of his own. He advocated, for instance, deviating from the standard psychoanalytic hour of 55 min, arguing instead for however much time was needed in any particular session. He also maintained that penis envy was not just a female’s reaction to what she lacked as compared to the boy, lending supremacy of the boy and not the girl in Freud’s theories. Lacan widened the concept to include the larger domain of the phallus, that the original overidentification with the mother was more than just the boy’s desire for sexual gratification with the most loved one, but the masculine impulse writ large on the resolution of the Oedipus conflict and the establishment of the primal law according to the father, which was then enshrined in the sublimated products that define all of society. As a result, Lacan’s ideas came to appeal to the radical left, again particularly among the feminists. *Ecrits* (1966), a collection of his weekly seminars and conference presentations over the years, became his main works, only parts of which have been translated into English. A text particularly germane to the language of depth psychology has been Lacan’s *The Language of the Self: The Function of Language in Psychoanalysis*, originally published in 1966 (Lacan 1968).

The Neo-Freudians

Less orthodox than the purists who followed Freud’s writings exclusively, but certainly of tremendous historical influence, were the Neo-Freudians around Harry Stack Sullivan (1953), Clara Thompson (1950),

Karen Horney (1937; 1942), and Erich Fromm (1941; 1956). Their domain was primarily in the USA, where they analyzed each others' cases together in local speakeasys, and wrote books that became the first popular best sellers in the psychoanalytic literature. Sullivan worked primarily with schizophrenics, particularly adolescent boys, while his main lines of connection to psychoanalysis were through Clara Thompson, whom he sent abroad to be analyzed by Sandor Ferenczi. Horney had been associated with the Berlin Psychoanalytic Institute under Franz Alexander and involved in an amorous relationship with Erick Fromm, whom she invited to follow her when she immigrated to the USA. She became a primary spokesperson for a completely new psychoanalytic view of women quite different from Freud's original conceptions of penis envy and the Electra Complex, and for such liberties was eventually pushed out of traditional psychoanalytic circles. Undaunted, she started her own institute. Eventually, such lights as Rollo May were drawn into their neo-Freudian circle. Meanwhile, Fromm became a major interpreter of why mass population so easily falls under the sway of authoritarian personalities, which he captured in such best-selling works as *Escape from Freedom* (1941). His psychoanalytic interpretation of human relationships, *The Art of Loving* (1956), also another best seller, was on the bookshelf of nearly every modern American teenage girl whether she had read it or not (Fig. 3).

Horney's books, such as *The Neurotic Personality of Our Time* and *Self Analysis*, drew wide attention, as did Rollo May's *The Meaning of Anxiety*.

While psychoanalysis came to control clinical teaching in psychology and psychiatry for over a quarter of a century in the USA and contributed to major developments in psychosomatic medicine from the 1930s onward, by the 1960s it had played itself out as a major force due to the advent of the community psychiatry movement, the widespread use of psychedelics among artists and savants in the counterculture, and the explosive development of the pharmaceutical treatment of mental illness. Finally, in the 1980s, a class action suit was brought by Ph.D. psychologists against the psychoanalytic institutes that were controlled exclusively by physicians. The psychologists won the right to enter the training programs, and so they founded their own institutes, where psychoanalysis

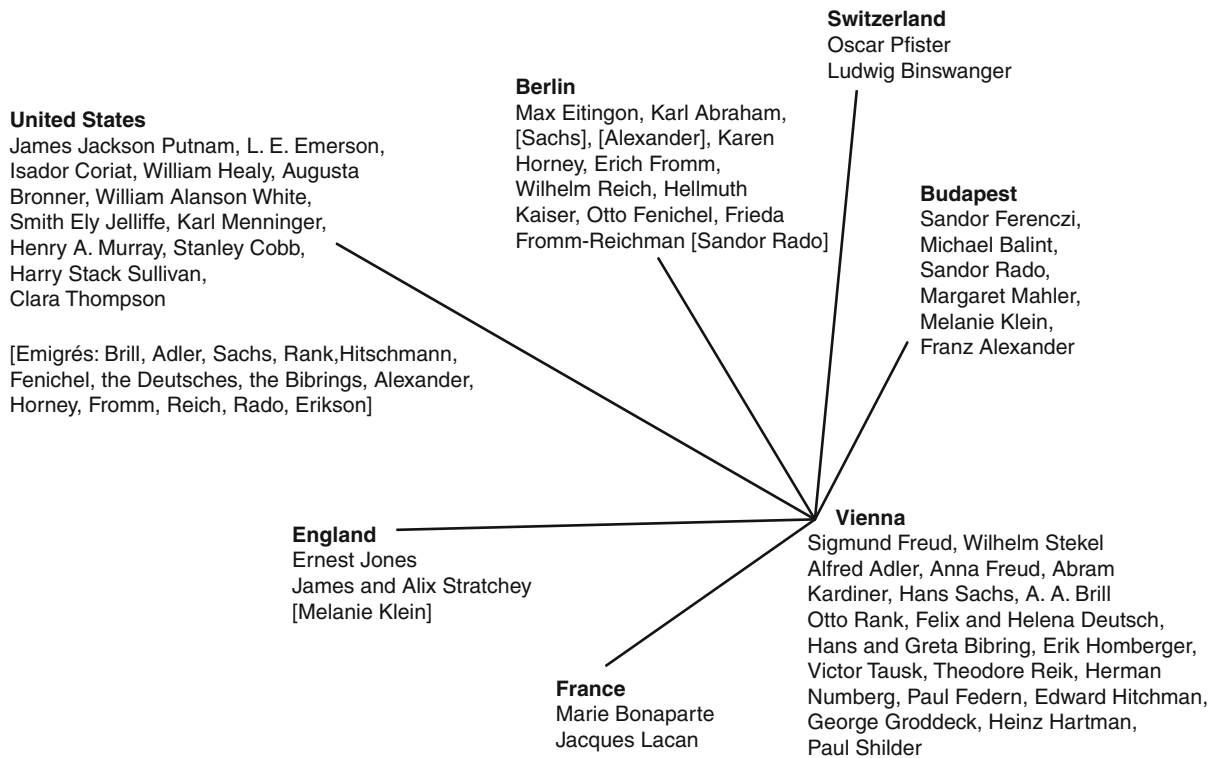

continues to proliferate today but with greatly diminished cultural influence. The core of the Freudian empire had been set by 1939, in any case (see Fig. 4).

Adler's *Menschenkenntnis*

Alfred Adler (1870–1937), Viennese physician and founder of Individual Psychology, proclaimed loudly to Abraham Maslow in 1934 that he had never been a student of Freud's. Jung said the same thing, but the *Encyclopedia Britannica*, Ernest Jones, and most of the Freudians who followed Freud have continued to say otherwise. There is no doubt, however, that Adler's Individual Psychology is nothing like Freud's psychoanalysis or Jung's complex psychology. For himself, Adler focused on *menschenkenntnis*, the intuitive, practical understanding of human beings in their natural and social context, and the ways in which the individual developed with regard to social feeling (*gemeinschaftsgefühl*). As a result, his theories had a completely different life of their own than any of the other depth psychologies.

Adler was born outside Vienna in 1870, the second child in a family of six children. He seems to have been closer to his father, a grain merchant, than to his mother. He also had an antagonistic relationship with his only older brother. Early schooling was unremarkable. His training in medical school taught him to pay attention to the patient as a whole, and that the emotional disposition of the physician had also to be taken into account. He joined the student socialist movement and became an advocate for reforms. In this circle, he met his future wife. Here he also absorbed a certain amount of Marxist philosophy that influenced his later work on the influence of environmental and economic factors on personality. He became interested in the common man. He received the MD in 1895, was married in 1897, and his first child arrived in 1898. The same year, his first book appeared, *Health Manual for the Tailoring Trade*. In 1902, he also began publishing in a newly launched medical journal, in which he was the main contributor.

He began his medical practice in a lower-middle-class section of Vienna, next to a well-known amusement park. There, he served a mixed clientele of professionals, waiters, acrobats, and artists, and there he first began to understand the weaknesses of apparently strong people – that their strengths often grew out

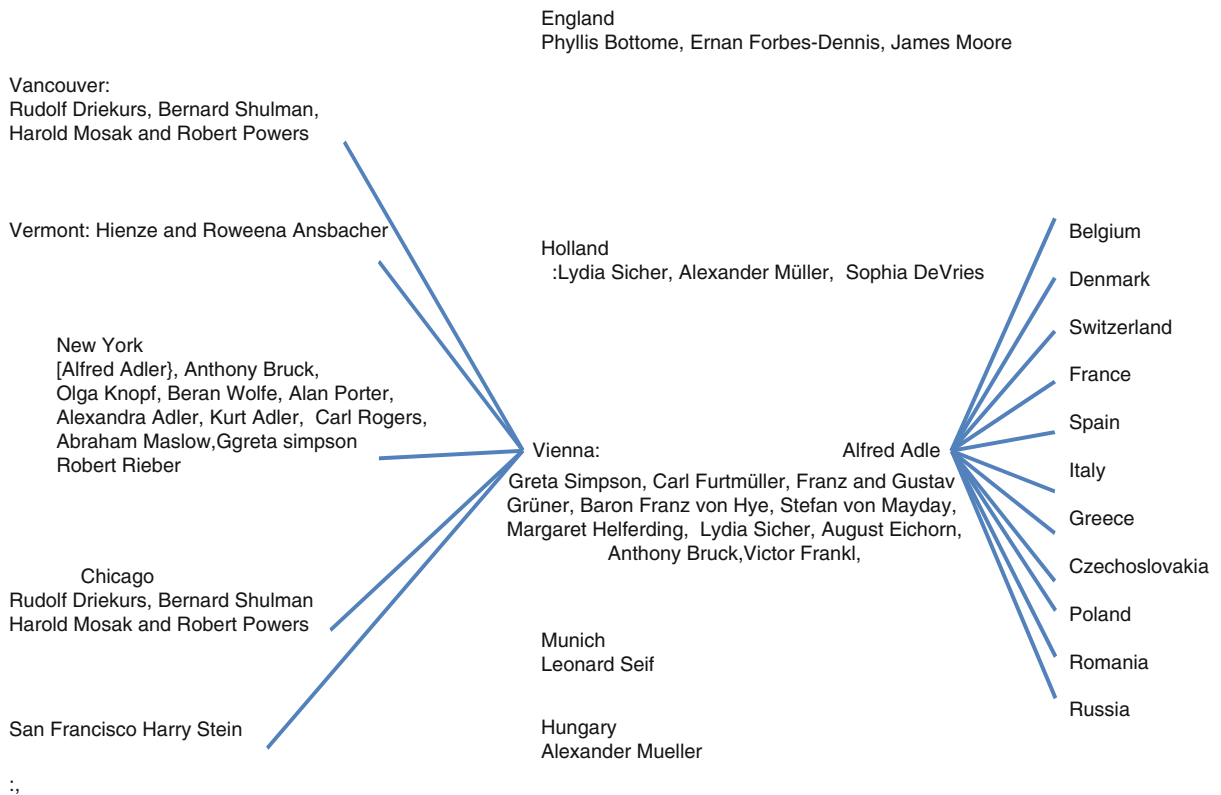

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 3 The Freudian empire: 1913–1939

of their compensation for their inferiorities. He became particularly adroit at both diagnosis and treatment. He also studied his own children and developed theories of education and child guidance.

Adler first encountered Freud in 1902 by reading his work, which had immediately engendered opposition from the established medical community. Without having actually met the author, Adler defended Freud's right to a fair hearing in print on two occasions, one of which was a response to *The Interpretation of Dreams*. Adler also adapted Freud's methods to his own independent ends, as he would do throughout the course of their relationship. He had already been reading Charcot and Janet when he heard Freud lecture for the first time in 1899. In 1901, Freud invited him to discuss his ideas before his Wednesday evening circle. Adler joined in 1902, but never saw himself as an acolyte or disciple. Freud nonetheless maneuvered things to make him stay, which he did for 9 years. Adler not only began to advocate for psychoanalysis, a term that meant something much more general at that time than today, he

also published several works on the subject. But these works were a continuation of his own ideas. In a break with the ethnic identification of psychoanalysis with Judaism, for instance, he converted to Protestantism in 1904, demonstrating ideological commitments beyond the Freudian circle. By then, in his writings he had already established the idea of organ inferiority, the ideas of the pampered child, self-confidence and courage, and a complete theory of education.

In 1907, Adler published an influential monograph, *Studie über Minderwertigkeit von Organen*, translated into English as *Studies of Organ Inferiority* (1917). In it, he put forth the idea that all mental inferiority stems from organ inferiority, which the individual deals with either through denial or compensation. Freud thought it an important contribution to psychoanalysis and hence began the idea of the inferiority complex, attributed to Freud, but originated by Adler. Despite the fact that Adler was 14 years younger than Freud, each absorbed much from the other, which Adler's followers later meticulously tried to catalog. Adler proposed

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 4 Adler and his world: 1910–1939+

a separate aggressive drive, for instance, which Freud rejected at the time, but later embraced after Adler had left the fold. Adler first defined the inferiority complex, which later authors attributed to Freud, and so on. The list is long. He was one of the original four who first constituted Freud's circle and was a member of the inner group until 1911.

At the same time, working on his own ideas, Adler turned out to be mainly a listener, which annoyed the Jewish analysts following Freud, and he often took contentious positions toward what was being discussed, so he was not popular to begin with. Thus, he could not identify with their general feelings of persecution, either as Jews or psychoanalysts. It was always Freud who was the bridge builder. Adler thought the drives to be very important, but he did not assign sexuality the valence that Freud did.

In 1927, *Menschenkenntnis* appeared, translated into English as *Understanding Human Nature*. It was a major summary of his dynamic theory, in that it was

not so much a preconceived theory as an intuitive characterization of personality, which could be reached by anyone putting any thought into the subject. The character of the individual in normal adult life, he said there, is already laid down within the first 4 years and changes very little from that time. The study of children is therefore recommended as the place to start in understanding human nature. If you want to change the behavior patterns in maturity, then start with those laid down in earliest childhood. From there we are led to pedagogy and the wider field of education if we want to understand the science of human nature.

Adler believed that empathy comes through having lived through psychic crises, not from reading books. What one should look for was the unique core of the person, the soul. From the very beginning, Adler made use of the soul as a referent to the individual. From this we see that the psychic organ is always goal oriented. It demonstrates purposiveness teleology. Life is

a preparation always for some future situation. In this way the soul is always associated with movement.

The soul that cannot withstand the pressures of survival on its own necessarily joins the herd for increased protection. This leads to the communal life because man, unlike other animals, cannot exist by himself in nature. Weak animals never live in solitude. Instead, one is surrounded by layers of protection, from help during childbirth, to protection in the first few days of life, to avoiding the vagaries that beset the survival of children in the early years. Inferiority and insecurity are thus built into the individual's constitution. Desire, will, understanding, and speech have all grown up to assist the person who is inferior in nature to adapt to the communal life. Legal codes, totems and taboos, education, and laws all then become necessary in regulating this relationship. Adaptation to the community is the most important function of the individual soul.

Every type has a meaning only when we understand its relationship to its environment. The soul is born in early childhood in those situations whose function is to make normal life possible. The different types of individuals begin in this early period. The goal is maximum satisfaction of the instincts with the least possible friction. Similarly, reflections of the environment are to be found in the behavior of every child. Creative education can always come out of striving to accommodate one's inferiorities. It begins with organ inferiority and proceeds to psychological, and then sociological weaknesses.

The sense organs are the first to show these tendencies to adaptation. Usually a child overemphasizes one or the other of them and through compensation develops a repertoire of identifiable traits to his or her personality. Sense organs lead to perceptions and to the creation of memory and imagination.

Fantasy is yet another creative activity of the soul, always concerned with the future. The striving for power often plays a dominant role. This also implies a goal, usually one involving social recognition and significance. It is well developed in the weak that use it to deprecate reality and elevate themselves to a fictional level in their own imagination.

Thus the main outlines of his theory were laid out. The unique expression of the soul begins to flourish in the recognition of organ inferiority, which generalizes

to psychological and sociological adjustments and the paramount importance of social striving.

Adler's influence as a physician who had his own unique theory of personality and educator of young children was considerable. Adlerian schools sprang up all over Europe, England, and the Netherlands while he lived in Vienna. His disciples, such as Lydia Sichar, Leonard Seif, Alexander Müller, Sophie DeVries, who remain to this day largely unknown pioneered in his methods and spread his teachings, which were more about the development of human nature as a whole rather than specifically focused all the time on the treatment of psychopathology. In the USA, his most ardent followers became Heinz and Rowena Ansbacher. His children, who became credentialed analysts in their own right, also participated in founding various Adlerian centers in the USA, particularly in New York and Chicago.

Adler's approach also had a large influence on the early founders of Existential and Humanistic psychology. Victor Frankl who was actually not a Freudian but an Adlerian, was inspired to develop logotherapy after his exposure to Adler's ideas and the terrible effects of his own concentration camp experiences. Rollo May, rather than exposure to Freud, took a seminar with Adler in Vienna at a particularly important period of self-formation in his life and only read Freud's works later under the influence of Paul Tillich. Maslow was a constant visitor to Adler's salons in New York City once Adler had moved there. Adler's ideas, much like Rank's, had an intuitive side to them that made such theorists sometimes sound almost existential in tone. In any case, their influence is consistently underrated by historians of psychology.

Jung's Complex Psychology

Carl Gustav Jung, Swiss psychiatrist who spent almost his entire career in Freud's shadow but who really came from a radically different tradition (Taylor 1996), was still possibly the second best well-known promulgator of a dynamic theory of personality in the Western world. He was born into a relatively well off family where the father was an ordained Protestant minister who was appointed by the Church to minister to the patients of a local insane asylum, so his library was full of books on theology and psychiatry. Jung's mother was from a well-to-do Swiss family and was a woman who

believed she had the gift of second sight. Indeed, the trait seemed to run through many of the women on her side of the family. She knew all about the world's religions and used to recite stories about them as Carl Jung grew up. Intelligent and well educated enough, he struggled personally with a range of philosophical conundrums that characterized the age – What was the relation of science to religion? Was there a God and if so what was his relation to the church? And what about ideas in the life of the mind that seemed to be foundational to getting along in the world, but could be easily overpowered by strange visions and dreams that periodically overwhelmed him? What was this alternative inner world? It seemed to divide him from himself, so that there were two Jungs, the one within, which he came to call the Spirit of the Depths, and the one without, which he called the Spirit of the Times, each vying for supremacy. He kept a record of these inner events, as they would subsequently shape the course of his own life work.

From then on, he lived as two distinct personalities. One was drawn to science and reason, while the other was deeply grounded in the emotional, the intuitive, the archaic, and the mythological. He thought there might be some way to unite the two, but he was not sure how. For his medical dissertation, he took up the scientific study of occult phenomena from a psychological point of view. Later, his *Red Book* (Jung 2009), constructed between 1913 and 1928, was a chronicle of a man who had lost his soul and who had set out to find it again, hidden somewhere in the realms of the heavens and the hells within. He was successful, and the text of that journey, *The Red Book* (Jung 2009), became the blueprint for the psychology that constituted his life work from then on. Out of it would come his central formulations of the archetypes, inherited brain stem structures that were mythopoetic and visionary in nature, and the collective unconscious, a substrate common to all human beings that linked the psyche of the individual to the primordial history of human consciousness.

But before all that, he attended medical school at the University of Zurich, specializing in psychiatry, and then became an assistant physician under Eugen Bleuler at the Bürgholzli Asylum. There he worked with psychotic patients, and among other accomplishments devised the association test, a psychophysiological

measure of a patient's unconscious complexes. For this, he established a budding international reputation and was introduced to American psychological and psychiatric audiences in 1905 to wide attention. Eventually, after publishing his psychiatric researches and a book on *The Psychology of Dementia Praecox* in 1907, Jung established a relationship with Sigmund Freud for a 13 year period in which Jung believed he was working as a younger collaborator, while Freud took Jung as his junior disciple. Their relationship was complicated as both switched roles often in a kind of *folie a deux*, soaring to the heights in which Jung was announced as Freud's heir apparent to the psychoanalytic throne, and then coming down for a crashing finale, in which Freud dismissed Jung for contradicting The Master in print on the basic nature of psychic energy. Freud could tolerate any kind of heretical debate in private among his followers, but publication of *Wandlungen und Symbole der Libido* (1911) in Freud's own psychoanalytic literature was just too much. Freud subsequently wrote Jung out of the history of the psychoanalytic movement, and circulated the idea among his followers that Jung was an anti-Semite.

Jung's response was to retreat within his own interior life in which he entered into a state of creative isolation for 6 years, during which he experienced dreams and visions that he privately recorded and which formed the blueprint for the entire system of his later psychology. He was a man who had lost his soul during the years with Freud, and in these tumultuous times that followed he struggled to find it again within his interior life. His success was reflected in the unique psychology he articulated, founded on narrative methods of comparative symbolism.

He employed dream interpretation in order to initiate a dialogue between consciousness and the unconscious within the person, the end product of which was individuation by means of the transcendent function – the coming to selfhood, where the ego cedes control of personality to the Self, which then is able to mature under the direction of emerging spiritual values. He also developed the technique of active imagination – the intentional evocation of trance images in the waking state – and employed such devices as the Oriental mandala and other artistic productions, believing that “often the hands know how to solve a riddle with which the intellect struggles in vain.”

Throughout, he continued to analyze his students and his patients and to write prolifically on the subject of personal transformation in world cultures. His quest after composing *The Red Book* was to link the primitive psyche to the psyche of modern men and women, which he felt he accomplished with his extensive studies on alchemical symbolism, the motifs of which he set out to chronicle in the world's religions and the mythologies unique to each culture.

Jung's Circle

Jung drew around himself a significant group of individuals who wrote about his ideas, many of whom became practicing analysts themselves, demonstrating his platform was radically different from that of Freud.

Aniela Jaffé (1903–1991) was Jung's longtime private secretary, who cowrote *Memories, Dreams, Reflections* (1963), Jung's alleged autobiography. From a German-Jewish family, she fled the Nazis in 1933 before she could complete her doctorate in psychology from the University of Hamburg. She immigrated to Switzerland, where she underwent an analysis with Liliame Frey and then Jung himself. She was first secretary of the Jung Institute when it opened in 1948, and she became Jung's private secretary in 1955 until his death in 1961. She carried on an active analytic practice, although not formally credentialed, edited several works of Jung's with others, wrote *The Myth of Meaning* (1970), and with C. G. Jung wrote *Word and Image* (1979).

Jolande Jacobi (1890–1973) of Hungarian-Jewish descent met Jung in the early 1920s when he came to one of her salons, held in her apartment, which was a meeting place for writers and artists in the early 1920s. Beginning in 1934, she studied psychology under Charlotte and Karl Bühler at the University of Vienna, where she eventually received her degree, commuting to Zurich in order to be analyzed by Jung. She was instrumental in the founding of the Jung Institute in Zurich and endowing a foundation that collected paintings from many analysts from around the world. She was a prodigious writer of articles and books, among them *The Psychology of C. G. Jung* (1942) and *Complex/Archetype/Symbol* (1959), and was one of the coauthors of *Man and His Symbols* (1964) with Jung.

Barbara Hannah (1891–1986) was born in Brighton, England. Her father was a bishop in the

Anglican Church. She was in different ways, according to Kirsch, sometimes as close to Jung as Jolande Jacobi. She was reserved and aloof, described as the archetypal English spinster, reminding one sometimes of the witch in *Hansel and Gretel*. Even she declared that Jung had softened her aggressive masculine impulses, says Kirsch. She went to Zurich to study with Jung after reading his essay "Women in Europe" (1927). Jung put her to work, which eventually turned into an analysis, and afterward she engaged in extensive writing and teaching. She wrote numerous books but is perhaps best known for her biography of Jung, a work lauded by some Jung scholars as still the best rendering of the maestro (Hannah 1976).

Franz Riklin (1909–1969) was a Swiss physician whose father was also a psychiatrist, while his mother was Jung's cousin. Riklin coauthored *Studies in Word Association* in 1904 with Jung, was analyzed by Jung, did his psychiatric training at the Bùrgholzli, and ran his own private analytic practice while he taught at the Jung Institute for 25 years. It was he who organized the *festschrift* on Jung's 80th birthday. He was also a leading figure in the founding of the International Association for Analytic Psychology.

Helton Goodwin "Peter" Baynes (1882–1943) was a British physician and an early analyst of Jung. He was Jung's assistant in Zurich and organized Jung's trip to Africa in 1925. He spent a year in Northern California in 1928, where he met Joseph Henderson and encouraged him into Jungian analysis. Before the *Collected Works*, Baynes translated various volumes of Jung's works into English, among them *Psychological Types* (1921a) and *Contributions to Analytical Psychology* (1928a), and in collaboration with his third wife, Cary Baynes, *Two Essays on Analytical Psychology* (1928). He also wrote two books of his own, *Mythology of the Soul* (1940) and *Germany Possessed* (1941). Cary Baynes, herself, also later translated the *I Ching* (1968) from German to English and was co-translator of Jung's *Modern Man in Search of a Soul* (1959b). In Kirsch's opinion (2000), Peter Baynes was known as an effective and dynamic interpreter of Jung's ideas.

Gerhard Adler (1904–1988), of German-Jewish origin, was analyzed by James Kirsch, Thomas Kirsch's father, in 1929 in Berlin, and from 1931 to 1934, by Jung. Adler earned the Ph.D. in psychology and afterward immigrated to England with his wife in 1935.

He was the author of *Studies in Analytical Psychology* (1948) and *The Living Symbol* (1961), a case study of a Jungian analysis. Adler was close with Jung for almost 30 years, coeditor with Aniela Jaffé of a two-volume set of Jung's published letters and member of the editorial board of Jung's *Collected Works*.

Michael Fordham (1905–1995) Kirsch (2000) dubbed one of the most creative first generation analysts after Jung and the undisputed leader of Analytical Psychology in England for over 50 years. He studied medicine and physiology at Cambridge University, was analyzed by H. G. Baynes, a family friend, and then went to Zurich, but was unable to arrange an analysis with Jung. He returned to England and resumed with Baynes, then, with Jung's permission, switched to Hilda Kirsch, Thomas Kirsch's mother, as her first analytic patient. When he developed an erotic transference toward her, she invited him to dinner to meet her husband, which immediately solved that problem. He was analyzed by her from 1936 to 1940, he said, to good effect, after which she abruptly had to terminate on immigrating to the USA in 1940.

Peter Baynes had used Fordham's analysis and artistic drawings in *Mythology of the Soul*, concluding erroneously there that he was a schizophrenic. As a child psychiatrist, Fordham was influenced by Melanie Kline. Jung, who did not see children in analysis himself, believed that one need only analyze the unconscious of the parent to cure the neuroses of the patient's child. Meanwhile, Fordham developed analytic theory around the nature of the child itself as a way to understand its psychic development in *The Life of Childhood* (1944). He was responsible for the mixing of Analytical Psychology with object relations theory in England, although he considered himself a Jungian to the end.

Carl Alfred Meier (1905–1995) was originally Jung's "crown prince." Born in 1905 in the same town where Emma Jung was from, Meier met Jung as a young boy. He graduated from the University of Zürich, interned at the Bùrgholzi, and then underwent an analysis with Jung in the late 1920s. He was secretary of the International Medical Society for Psychotherapy the last 6 months of Jung's tenure as president, trying to rescue psychotherapy from the Nazis. Kirsch thought he was the most important male figure around Jung, who was otherwise surrounded by women. He inherited Jung's

patients, succeeded him as professor at the Swiss Technical Institute in Zürich, and generally acted as his right-hand man for almost 30 years. Interested in the relation between quantum physics and Analytical Psychology, he was a close friend to Wolfgang Pauli and edited the Jung-Pauli correspondence. Meier wrote numerous books interpreting Jung's theories. They fell out with each other in 1957, however, and thereafter he withdrew from Analytical Psychology. He died in 1995.

There were numerous others. James and Hilde Kirsch founded the Analytical Psychology Club in Los Angeles. Sir Laurens van der Post was a friend and biographer of Jung's. Joseph Wheelright and his wife, Jane, founded the Jung Institute in San Francisco and shaped its early training program. Ann Ulanov teaches at the Union Theological Seminary and writes on Jung in the context of Christian spirituality. Edwin Eidinger, a Yale MD, who trained at the New York Institute, was known for his book *Ego and Archetype: Individuation and the Religious Function of the Psyche* (1972). Christopher Whitmont trained in New York, but was also a homeopathic physician.

Similarly, June Singer has written on Jung and William Blake and was instrumental in the transpersonal interpretation of Jung. Jean Shinoda Bolen and Clarissa Pinkola Estés have both written best sellers from a Jungian perspective. Joseph Cambrey, Linda Carter, Claire Douglas, John Beebe, Andrew Samuels, Murray Stein, A. Guggenbuhl-Craig, and Hester Solomon have been contemporary key figures in the International Association of Analytical Psychology, the official credentialing body of Jungian analysts (Cambrey et al.).

At the same time, local organizations have flourished even though in the beginning they had no official status. Among them, Ruth Thacker Frye launched the C. G. Jung Educational Center in Houston, Texas, in 1958 with Jung's blessing and influenced Carolyn Fay and others to support it. It is now a fully fledged society and an accredited training program in Analytical Psychology, most recently guided by James Hollis.

Eisendrath's Three Schools

The Cambridge Companion to Jung, edited by Polly Young-Eisendrath and Terrance Dawson (1997), identifies three schools of contemporary Jungian thought: the lineage around the Jung Institute in Zurich,

a breakaway line led by Marie Louise von Franz, and then those who are the followers of James Hillman.

The Jung Institute of Zürich was first founded in 1948 around those who were closest to Jung. After Jung died in 1961 and this generation themselves aged and began passing from the scene, new, younger personalities began to emerge. James Hillman was one, and Adolf Guggenbuhl-Craig another. Hillman, who had become director of training, had a falling out with the institute over an affair he had carried on that involved the civil courts. Half wanted him to go and the other half wanted him to stay. Guggenbuhl Craig, who held the key position on the Curatorium, which oversaw the institute, put changes in place that were not popular, such as the inauguration of training courses in Jungian group therapy that many of the older analysts, such as Marie-Louise von Franz, believed deviated too much from the process of individuation in the person, which was Jung's primary focus. As a result, several of the older analysts left the institute to form their own separate training group.

Marie Louise von Franz (1915–1998) was German born and later became a Swiss citizen. She met Jung when she was 18 on a class trip. In exchange for analytic sessions, which she could not then afford, she translated Latin and Greek alchemical texts for Jung, which he needed at the time. She completed her Ph.D. in classical philology in 1943 and wrote thereafter on fairy tales. She was active in founding the Jung Institute and attracted a large following to her lectures and seminars over the years. While remaining close to Jung, she moved in with Barbara Hannah and they lived together for decades, devoted to Jung's cause. She became Jung's primary interpreter internationally and opposed divergences such as those of Michael Fordham. She founded her own independent Jungian Institute in Zürich in the 1980s. At the time of her death, Thomas Kirsch mentions that she was working on the texts of a Shiite alchemical mystic.

James Hillman (1926–), an American from New Jersey, went to Zürich to study with Jung and ended up earning a Ph.D. from the University of Zürich as well as becoming a credentialed analyst. According to Kirsch, he entered private practice in Zürich and became director of studies at the Jung Institute there. He resigned in 1969 over the affair previously mentioned, which had by then developed into an

international incident. Hillman remained in Zürich until 1978 and then immigrated to Dallas, Texas, where he taught at the University of Dallas, which had a doctoral program at the time in phenomenological psychology under Robert Sardello and Robert Romanyshyn. Later, he (Fig. 5) settled in Thompson, Connecticut, as an internationally noted author and lecturer, affiliated at a distance with Pacifica, a doctoral program in Santa Barbara, California, which is devoted to training graduate students in depth psychology.

He was the main motivating force behind Spring Publications and launched *Spring*, a journal devoted to Analytical Psychology, now published by Nancy Kater. His main focus after leaving analytic practice has been to elaborate on the diseases of cultural consciousness, by way of what he calls archetypal psychology, a “therapy of ideas” (Hillman 2004).

Psychoanalysis at Harvard

Standard histories of personality theory tend to focus on the experimental analysis of the person, which, after the post-1900 era of character and temperament, commenced in the 1920s with the measurement of traits within the context of behavior (Allport 1922). No more prime example can be found than the early work of Gordon Allport, then under the direct influence of his brother Floyd at Harvard, although once Allport came in contact with Henry A. Murray an amazing transformation began to happen with regard to Allport's previous interest in Gestalt psychology and Murray's newer focus on a dynamic psychology of the unconscious. At Harvard, Allport (1937) would represent the normal personality, while Murray the abnormal (Murray et al. 1936), and they saw each other's theories as complementing each other. By then, contrary to the standard biographies of him accepted by the American Psychological Association, Allport had moved away from large-scale nomothetic designs where one variable was measured across a large number of subjects, and instead embraced the idiographic approach—the in-depth case study of the single individual. Allport even mellowed with regard to his initial rejection of Freud and actually incorporated concepts from the Freudian unconscious into his own theories of the person. More than that, toward the end he flirted with Humanistic, the existential psychiatry of Victor Frankl, and even the psychology of Vedanta. As such,

Allport, Murray, and others such as Gardner and Lois Murphy emerged as pioneers in the new approach to personality as well as social psychology. The Gestalt psychology of Kurt Lewin (1935) became as focus among them, as did topics in the psychology of religion. As for Murray, a detailed study of Herman Melville became his single case study for the reconstruction of his personological system, and the Thematic Apperception Test (Morgan and Murray 1938), coauthored with Christiana Morgan, the second best seller of anything Harvard University Press ever published (H.A. Murray, personal communication). Indeed, when Murray took over the Harvard Psychological Clinic on the death of Morton Prince in the 1930s, he created an environment in an otherwise experimentally oriented psychology department where, in his domain at least, Freudian and Jungian psychology flourished. Murray was deeply involved with Professor Stanley Cobb over in psychiatry at the Harvard Medical School introducing psychoanalysis into the curriculum in both psychology and psychiatry independent of decisions made in Vienna (White et al. 1984).

Collectively, these macro-personality theorists of the 1930s and 1940s would later become the godfathers and godmothers of the Humanistic movement in psychology, while their own students straddled the divide between normative trait theory of the mainstream and the counterculture psychotherapies of the 1950s and 1960s, where their own teachers had gone.

Humanistic, Existential, and Phenomenological Psychology

With regard to the Humanistic movement in psychology, two points are relevant to dynamic theories of the unconscious. First, when the Humanistic movement emerged around such figures as Abraham Maslow, Carl Rogers, and Rollo May in the late 1950s, it represented many different interests across numerous disciplines that all rushed to one point, creating numerous conceptual problems concerning what Humanistic psychology actually was and what it was about. In general, one could say that it inherited the personality theorists' march toward a science of the whole person, while over time the movement evolved in its own right into a person-centered science. Second,

Humanistic psychology was not merely a reaction against behaviorism and psychoanalysis so much as it was a critique of reductionistic positivism in experimental science using the methods of phenomenology. This underlying agenda, however, was never allowed to fully develop, once the Humanistic movement was embraced by the Human Potential Movement, where it fractionated into meditation and altered states of consciousness, group dynamics and bodywork, and radical political psychology after 1969.

The histories of traditional personality theory will often mention Maslow and Rogers as variants of more mainstream empirical developments but often omit to associate the two of them with Humanistic psychology. If Humanistic psychology is considered, what is usually revealed is the complete lack of understanding of the inner history of the movement on the part of the historians. In my analysis, the progression begins with William James, whose functional psychology championed the integration of mind and body that promoted a humanism informed by the transcendent experience. This legacy was inherited by the macro-personality theorists of the 1930s and 1940s, who also fostered the development of new expressions in psychology beyond even Maslow, Rogers, and May, such as that of Alan Watts and Aldous Huxley. Meanwhile, in the 1950s, Clark Moustakas, an existential psychologist at the Merrill Palmer Institute in Detroit, along with others, convened a gathering that included Carl Rogers, Abraham Maslow, and Rollo May. Their intent was to launch a new movement whose time had not quite come, although the papers from that conference were published in *The Self* (1956).

The significance of this event, however, was to broadcast the important historical link between the budding movement and the influence of the existential and phenomenological impulse on defining the rise of Humanistic psychology. Two years later, *Existence: A New Dimension in Psychology and Psychiatry* appeared, edited by Rollo May, Ernst Angel, and Henri Ellenberger (1958). It was the first major introduction of existential thought into American psychology, although it had been preceded by the English translation of Victor Frankl's *The Doctor and the Soul: An Introduction to Logotherapy* (1955) by 3 years.

That the leading lights of the Humanistic movement took this event seriously can be gauged by the fact

that a year later at the 59th annual meeting of the American Psychological Association, September 4, 1959, Abraham Maslow, Rollo May, and Herman Feifel were presenters at a symposium on Existential Psychology, and Carl Rogers and Gordon Allport were discussants. The event marked the dissemination of the existentialist impulse as central to the new definition of Humanistic psychology.

The symposium appeared in book form in 1961 as *Existential Psychology*, edited by Rollo May (1961). At that conference, a statement on the emergence onto the American scene of Existential psychology was given by Rollo May. The paper by Abraham Maslow was on the value of Existential psychology for American psychotherapists, while a discussion on the relevance of death in psychology was presented by Herman Feifel, and a chapter on the existential bases of psychotherapy was presented by Rollo May. Carl Rogers gave a delineation of the objective versus the existential view of psychology, and finally, a commentary on the papers was delivered by Gordon Allport. In the end, May had said of it "I believe that there is in this [existential] approach the demand for, and the guiding principles toward, a psychology that will be relevant to man's distinguishing characteristics as man" (May 1961, p. 48).

By 1961 a confluence of forces permitted Anthony Sutich and Abraham Maslow to launch the *Journal of Humanistic Psychology*, and a short time later the American Association for Humanistic Psychology was launched from their combined mailing lists to support the journal. James Bugental, the existential psychotherapist from Detroit, was elected its first president. Between the official launching of the journal and the association, Humanistic psychology was to represent a science of the person, promote human potential, study self-actualization, and foster an understanding of growth-oriented rather than deficiency-oriented motivation. By the end of the decade the movement had become international in scope, but it had also expanded out in all directions and significant problems of definition had emerged. Also in 1961, Michael Murphy and Richard Price cofounded the Esalen Institute, the premier growth center in the Human Potential Movement that was to become the model for a proliferation of other experiential programs across the USA. Their aim was self-actualization and the

expansion of consciousness but their primary focus became the cultivation of the body, the emotions, group work, and human relationships. This set up something of a tension between Humanistic psychology as an academic endeavor in which a person-centered science redefined the discipline as opposed to a counterculture movement outside the universities that appeared to be antiscientific, anti-intellectual, and almost entirely experiential. The experimental laboratory was abandoned in favor of the psychotherapeutic hour as the living laboratory of personality transformation until the psychotherapeutic hour itself became transformed with the radicalization of depth psychology. Therapy for the neuroses left the office and emerged as education for transcendence out in the world: Reichian body work, Gestalt therapy in the tradition of Fritz Perls, sex therapy, couples therapy, sensitivity training workshops, psychedelic drugs, psychotherapeutic massage, pure foods, martial arts such as tai chi and aikido, and also meditation and yoga. Such approaches sprang up in weekend hotel conferences on personal transformation and became the stock in trade of workshop leaders whose private practice expanded to the bursting point, especially with other therapists eager to work on themselves and also appropriate the newest training from whomever therapist knew more than they did.

The academics, theorists, and architects of the Humanistic movement, meanwhile, gathered in October of 1964 at Old Saybrook, Connecticut, for what was later called the First Old Saybrook Conference, cosponsored by the Association for Humanistic Psychology, Wesleyan University, and the Hazen Foundation (Taylor, Martinez, and Martin). Allport, Murray, the Murphys, and others such as David McClelland who argued for a science of the whole person met with May, Maslow, Rogers, Bugental, Sutich, and others, who championed psychology as a person-centered science and symbolically connected the generations, passing the torch to the new psychology. Deans and University Presidents were there, anticipating at that moment in the history of Western thought that the Humanistic movement would expand and take hold, answering the rift between C. P. Snow's Two Cultures, referring to science and the humanities. Henry A. Murray gave the keynote address, announcing the end of the Dark Ages in the history of American psychology (Taylor 2000).

Afterward, a spate of new books covered the landscape on the new Humanistic movement in psychology, most of them trade books, undergraduate and graduate programs in psychology sprang up around the USA fueled by the new movement, links were made to new experiments in progressive education, new definitions of the family began to evolve, people changed their sexuality going from men to women and women to men. The feminist movement cultivated relationships between women without men, growth groups proliferated, an entire generation began to experiment with consciousness expanding drugs supplied originally by the CIA. The result was that the lines between the academy and the counterculture began to blur more and more. Even Murray had lamented at the Old Saybrook Conference that the historical links between classical personality theory and Humanistic psychology did not show any direct descent but only a general one, in the sense that by the time of the conference, the humanistic psychologists had their philosophy already well formed. In fact, as history was soon to show, Maslow, Rogers, and others were about to leave the academy for more fruitful endeavors at that late point in their respective careers and within a decade would begin dying off, in any case.

As we have said, the Humanistic movement in general had by the end of the 1960s become more focused on the body, emotional development, and human relationships out in culture at large. No one was more aware of this than Anthony Sutich and Abraham Maslow. While attending a Humanistic Theology Conference at Esalen together, both had several disturbing experiences. In one instance, while conversing with a group of catholic priests, Sutich inquired about their personal experiences with mystical states of higher consciousness. The priests were perplexed and admitted that none of them had ever had such experiences. There was also the famous encounter with Fritz Perls, promulgator of Gestalt Therapy, and his minions. Perls moved into Esalen on his own and took the place over as if it were his own for some seven years. At one point he and some of his followers broke into one of the workshops that Maslow and Sutich were attending, dropped down and slithered across the floor, and attached himself to the speaker's leg, talking in baby talk. The meeting ended in chaos. The effect on Maslow and Sutich when they left was a resolve to leave

Humanistic psychology to its own devices and found a new movement, specifically devoted to the exploration and cultivation of human spirituality. As a result, in 1969, they launched the *Journal of Transpersonal Psychology*, and the Association for Transpersonal Psychology, which occurred a few years later. It was at this point that Humanistic psychology as an umbrella term that harbored under its wings existential and phenomenological psychology, biofeedback and the new psychophysiology, Transpersonal psychology, feminist psychology, Asian psychology, and the seeds of multiculturalism and human science broke up. When that happened Transpersonal was more self-consciously embraced by the Human Potential Movement, though in reality it remained the offspring of its proper parents, the Humanistic psychologists. Those who identified with Humanistic psychology proper went on to found Division 32 in the American Psychological Association, now called the Society for Humanistic Psychology, and to publish their own journal, *The Humanistic Psychologist*. At the same time, the Association for Humanistic Psychology continued its annual meetings as a professional organization. Eventually, however, its main publication, *The Journal of Humanistic Psychology*, spun off as an independent peer-reviewed publication, unaffiliated with any university setting.

At the same time these developments were taking place, the phenomenological psychologist Amedeo Giorgi published *Psychology as a Human Science* in 1970, one of the first clear statements that the Humanistic psychologists had something important to say, not just about psychoanalysis or behaviorism, but about a fundamental change in the way psychology as a science was being conducted in the West. From the phenomenologists' perspective, Giorgi went a step further than merely criticizing contemporary reductionistic positivism as the underlying foundation of present-day experimental psychology. He took a more prescriptive position, offering a new epistemology for the way experimental science ought to be conducted, namely, as a phenomenological, human science rather than a reductionistic and positivistic one. His solution to the problem of unity in psychological science was for psychology to become more descriptive and phenomenological, which would automatically take the relation between experimenter and subject and client and therapists and make them equal.

In this regard, Giorgi continued to expand his work, becoming well known in European circles, but generally ignored by the experimental psychologists in the USA. His work was, however, embraced by Humanistic psychology, not only as a pure phenomenological psychology of its own, but also as kin to the Existential-Phenomenological psychologies that had been flourishing under the banner of the Humanistic movement since the 1950s (Fig. 6).

Meanwhile, other expressions of a phenomenological critique of reductionistic science generating entirely new conceptions of the person also appeared. Clark Moustakas articulated his own understanding of phenomenological research methods for Humanistic psychology, as did Adrian van Kaam, whose *Existential Foundations of Humanistic Psychology* had a significant influence on bringing Christian ministers and pastoral counselors into both psychotherapy and research into the domain of Humanistic psychology. Irvin Child at Yale followed with his thoughtful work *Humanistic Psychology and the Research Tradition: Their Several Virtues*. The historical anomaly remains the same, however. Just as the epistemological critique of reductionistic positivism was getting underway, the most far-reaching contribution of Humanistic psychology to the research tradition, its platform disappeared when the Humanistic movement was absorbed almost completely into the Human Potential Movement. It remains to this day as a legacy to be actualized.

During this period, while he is remembered for his therapeutic and research innovations, Rogers also set forth his own conception of a dynamic theory of personality. It can be found in Sigmund Koch's monumental six-volume work, *Psychology: A Study of a Science* (1958–1963), which was a reassessment of experimental psychology at mid-century commissioned by the American Psychological Association. In it, 87 of the world's premier scientific psychologists assessed the rules linking quantification to theory construction against what they had actually accomplished over a lifetime of their own individual work. The result was a correlation so low that it became a massive indictment of psychologists' agenda to establish psychology as a reductionistic and positivistic science. The work also became a landmark symbolizing the era of deregulation in academic psychology that followed, thus opening the door to the further

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 6 The diffusion of existentialism and phenomenology as continental philosophies and their amalgamation as existential-phenomenological psychology under the umbrella of humanistic psychology in the USA

development of Humanistic psychology as a potential new leading movement that would reshape the discipline.

One of the more important comprehensive summaries solicited by Sigmund Koch for his massive reevaluation of the presuppositions of scientific psychology at mid-century was that presented by Carl Rogers (1959). Rogers's piece was entitled "A Theory of Therapy, Personality, and Interpersonal Relationships, as Developed in the Client-Centered Framework." Rogers found the original assignment quite forced, as he had never expressed his project in terms of dependent, independent, and intervening variables, so he presented instead the organic evolution of his work. He did, however, have a healthy respect for quantifiable studies, but the difference was that these were not primary; they were secondary to understanding the mystery of the person. They were ways to check one's self, to corroborate, to confirm or deny certain hypotheses, but these were not the purpose of the work. The purpose of the work was the person. It was the

person who was at the center of his scientific theory, not justification for psychology as a science.

Rogers's primary distinction was to show that the basic data of a scientific psychology could be generated out of the psychotherapeutic hour, not the laboratory. Its focus was the inward ordering of experience, not the measurement of behavior; his approach was scientific even if the first steps were crude and only suggestive. His science was dynamic and not static. Establishing the methods of the laboratory as the only legitimate standard for psychology produced a sterile pseudoscience "of no particular importance." Nor was advanced theoretical physics a correct model for psychology. He was certain psychology was nowhere near this same status. Every theory contains error and mistaken inference. The book is never finished and therefore never closed. Too many small caliber minds in psychology jump to accept a theory as the dogma of truth. While he was thinking of the behaviorists in this regard, he was also referring to the Freudians. Freud may have had some good ideas from an intuitive level, but they kept

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 7 Roger's theory of personality

changing. His disciples, meanwhile, had already cast his theory in stone.

Only a complete theory will show us what God and man are, Rogers said, but this is probably unattainable, even if a lofty goal to strive for. At the same time, every theory cannot cover everything. More realistically, "every theory deserves the greatest respect in the area from which it was drawn from the facts and a decreasing degree of respect as it makes its predictions in areas more and more remote from its origins" (Rogers 1959, p. 191.). Finally, he believed that subjective experience was primary in every endeavor, including that of objective science. Operational definitions, experimental method, and mathematical proof are the best way of avoiding self-deception, but they are not the purpose of the research. They do not provide us with the final truth, only the individual perceptions of what appears to each person to be such knowledge.

He then presented his theoretical model. In the center, beginning with the experience of the person, was his theory of therapy. Branching off from it in all four directions were its important developments. The first was a theory of personality. The second was a (Fig. 7) theory of interpersonal relationships. The third was a theory of the fully functioning person, while the fourth involved the theoretical implications for various human activities, including family life, education and learning, group leadership, and the resolution of group conflict.

With regard to the theory of therapy and personality change, the basic conditions for therapy to take place are several. Two people first must be in contact. The client will normally be in a state of incongruence, feeling vulnerable and anxious. The therapist should feel congruent in the relationship and also feel unconditional positive regard toward the client; the therapist should feel an empathetic understanding of the client's internal frame of reference, and finally, that the client should perceive this regard and this empathy from the therapist.

Assagioli and Psychosynthesis

Meanwhile, in Italy, the Italian psychiatrist Roberto Assagioli had launched psychosynthesis, which was to become a central teaching of the counterculture psychotherapeutic movement and the Transpersonal psychology, an offshoot of the Humanistic tradition that emphasized meditation and altered states of consciousness. Psychosynthesis was one of the more important examples of a dynamic theory of personality to appear on the American scene in the early 1960s because of its association with Michael Murphy and Esalen Institute.

Assagioli spent his entire professional career in Florence, founding there the Institute for Psychosynthesis. Because of the nature of his system, which paralleled Jung's to a remarkable degree, and his ready access to Eranos, the retreat and conference center on

Lake Lugano on the Swiss-Italian border, where Jung delivered some of his most important papers, Assagioli himself was a frequent guest and presenter. By the 1960s, when Assagioli was in his late 1970s, psychosynthesis emerged as a significant counterculture psychotherapy in the Western hemisphere, because of interest in Assagioli's work by Michael Murphy, cofounder of Esalen Institute in Big Sur, California. Murphy, himself, was versed in the models of personality and consciousness of the nineteenth century, being one of the few authors who had thoroughly read and absorbed the subliminal psychology of F.W.H. Myers and brought those historical insights forward under the framework of Humanistic and Transpersonal psychology. Assagioli published a number of books on his system, but the one to highlight here is *Psychosynthesis: A Manual of Principles and Techniques* (1964), second in the Esalen series brought out by Viking Press.

Assagioli opened his text by noting the similarities and dissimilarities between psychosynthesis and existential psychotherapy, referencing Adrian van Kaam and echoing Maslow's 1959 paper at the APA symposium on "Remarks on existentialism and psychology." The method of starting from within, with the self and its presence, is the same. We find the same emphasis, Assagioli said, in Gordon Allport, Kurt Goldstein, Erich Fromm, Clark Moustakas, and Erik Erikson and in such personalists as Tournier and Baudoin. This self is in a constant state of becoming, where meaning is central to life. Ethical, noetic, and religious values are central, as in the work of Victor Frankl. Choice and responsibility follow. Anxiety and suffering are taken fully into account. The role of the future in creating a dynamic present makes them similar, as does the centrality of the person, which he compared to Allport's theory of the idiographic personality. Each one requires a new method.

The various theories are different in many ways, however. Psychosynthesis emphasizes the will much more than most existential therapies. Psychosynthesis also emphasizes more the experience of the pure self in the immediate moment independent of the content of consciousness. Psychosynthesis emphasizes the positive joyous and peak experiences, some of which Maslow had written about. As such, self-realization is actively induced in psychosynthesis. Loneliness is neither ultimate nor essential. It is a temporary condition. The

goal is the harmony of the sexes and one's connection to humanity. Following Pitrim Sorokin, Fromm, and others, Assagioli said, its emphasis is ultimately on love and its many forms. Psychosynthesis uses active techniques to direct psychological energies to actualize one's potential and to achieve higher states of consciousness. He believed the personality could be recreated along entirely new lines. The necessary techniques are defined by the uniqueness of each person. At the same time, however, psychosynthesis is neither a religion nor a philosophical system. It is a psychological framework for the actualization of the person, which may incorporate religious and philosophical concerns, but is not meant as a replacement for them. Rather, it is a "scientific psychodynamic" (Assagioli, 1976, p. 8). It is appropriate in the treatment of the neurosis, but its real purpose is the spiritual transformation of the person into their highest and best form. It does this by reclaiming the will for the ego in a way that no other psychology has yet proposed.

He then rehearsed the history of dynamic psychology, from Janet and Breuer and Freud, to the Neo-Freudians and to Jung, and beyond his theories to that of the existentialists such as Binswanger and Frankl. He linked psychosynthesis to developments in psychosomatic medicine, the psychology of religion, investigation of mystical states, the work of the parapsychologists, and non-Western epistemologies, especially Hindu psychology. He reviewed the links to Allport, Angyal, Goldstein, Maslow, Murphy, Perls, Proffoff, and Stern. Social psychology and anthropology were noted, citing Sullivan, Lewin, Murray, Allport, and Sorokin at Harvard, and the work of Margaret Mead. He also included the techniques of the waking dream of Robert Desoille and Jacob Moreno's psychodrama as well as the work of Ruth Munroe and Gardner Murphy.

Assagioli then made the attempt to depict his model of consciousness. He acknowledged the spectrum from the lower-order domain of psychopathology and the primitive and instinctual – the centrality of the waking consciousness, the domain in which the ego functions – but then posited a superconscious state in the individual, all of which was surrounded by the collective unconscious of humanity. The superconscious condition, like the lowest domain, remains unconscious, but is nevertheless the source of artistic, scientific, and

aesthetic creativity and the spring of heroic, humanitarian, and altruistic action.

The ego, in contrast, exists in a state of conditioning, being attached to external objects through the senses and beset by habits, attitudes, and compulsions from within. It remains at the mercy of circumstances as long as the individual does not recognize that there is an internal life beyond external control, that there is a higher as well as the lower domain within, and that the higher domain is actualized by training of the will. This, however, takes knowledge of one's own personality, control of its various elements, discovery of one's true self as a unifying center, and a means to accomplish that goal, which is psychosynthesis.

While the majority of psychologists who refer to the term self-actualization usually have only had exposure to the writings of Abraham Maslow on the subject, Assagioli, relying partly on Maslow, developed it in more elaborate and refined detail, including its vicissitudes. Writing on the relationship of self-actualization to psychopathology, he presented the idea that much of what we consider psychopathic may be the result of thwarted spiritual growth. He enumerated four critical stages: crises preceding spiritual awakening, crises caused by spiritual awakening, reactions to spiritual awakening, and phases in the process of transmutation (p. 6) (Fig. 8). He recommended a twofold competence for practitioners, one that they be trained professionals, but also, two, that they be experienced travelers along the path of self-realization. Though rarely found in formal programs leading to clinical licensure, the need for such types may be even greater than before.

Classical Asian Conceptions of Personality and Consciousness

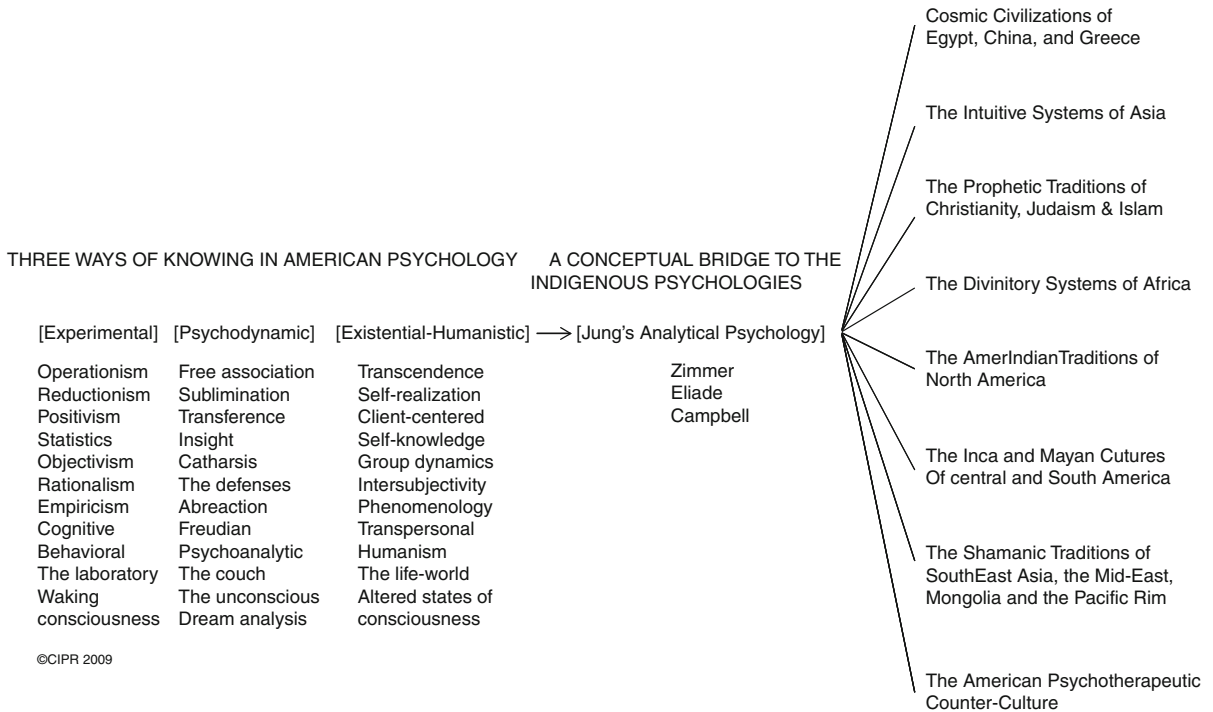

Dynamic theories of personality within the framework of a person-centered science also include, as we have previously said, the classical psychologies of Asia. By such means, a Humanistic, Existential-phenomenological, and Transpersonally-oriented depth psychology presents the larger discipline of psychology with an expanded definition of personality, a wider definition of consciousness, a more complete spectrum of methods for scientific inquiry, and an epistemology allowing psychology to dialogue with non-Western models of personality and consciousness.

A case in point is the Vedantic conception of personality in Hindu psychology. Reminding the reader of the religious, philosophical, and psychological roots commonly shared in these traditions, the person is expressed in terms of the individual human being, or *jiva*, and its relation to *Atman*, the Supreme Self. The consciousness of the individual is identical to the ultimate spiritual consciousness of Brahma. "That art thou, O Svetaketu" is declared in the *Upanishads*. But the normal individual does not realize this because of the veil of illusion, or *maya*, which keeps them in a state of *avidya*, or ignorance. Meditation (*dhyana*) causes one to break through this veil of illusion by detachment of the senses to their objects in the external material world and a turning within for purposes of self-realization. Achievement of this realization through intuitive insight produces the *jivanmukti*, one who is liberated while still in the body. Personality is transformed through the experience of transcendence. In that experience, the one who acts outwardly and the one who watches from within are then recognized as the same (Fig. 9).

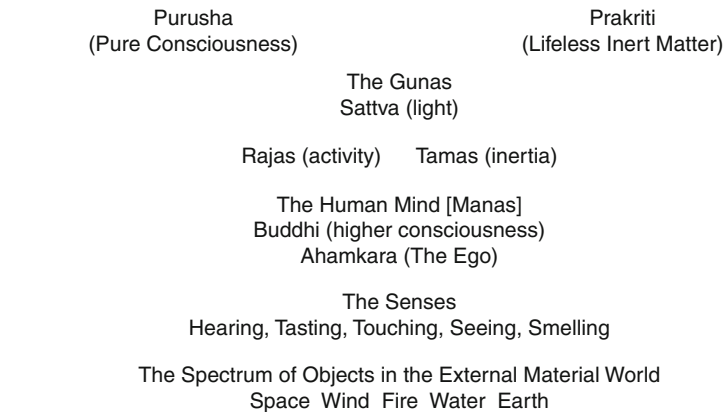

In Yoga psychology, transcendence is achieved by practice of *sadhana*, spiritual discipline, the purpose of which is to generate heat (*tapas*), equated with the fire of transformation. Under the instruction of a spiritual teacher, one follows the blueprint laid down in the *ashtanga-marga*, or eight limbs. These involve (1) *yama* and (2) *niyama*, bodily and mental cleansing as preparation for entering the higher states; (3) *asana*, the practice of physical postures; (4) *pranayama*, the science of breath control; (5) *pratyahara*, withdrawal of the senses from attachment through the senses in either a pleasurable or painful way to objects in the external material world; and then the threefold tool of *samyama*; (6) *dharana*, attention; (7) *dhyana*, meditation; and (8) *samadhi*, absorption. Successful application of the eight limbs causes a quieting of consciousness (*cittavrittinirodha*) and an elimination of states of mind that are scattered and unfocused (*kspita*), torpid (*mudha*), or obsessively attached to fixed ideas (*viksipta*). Application of the threefold tool of *samyama* leads to insight into whatever the particular object of meditation may be.

A series of more refined states of consciousness then follow focusing on absorption at the level of sense impressions, the ego, and the intellect, and the internal

Three different Epistemological streams in American psychology showing the existential-Humanistic Tradition as a portal through Jung to a spectrum on non-Western psychological anthropologies, which reflexively includes the American Psychotherapeutic Counter-Culture

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 8 The existential-humanistic tradition as a portal into non-western epistemologies

spiritual sense, until the person is experiencing a continuously flowing stream of insights into the world of all objects (*samprajnatasamadhi*). This occurs

at each level through generating more and more of the light of pure consciousness (*purusha*) through insight (*sattva*). The principles of energy (*rajas*), inertia

The Normal States of Consciousness

Ksipta, the restless state
Mudha, the torpid state
Viksipta, the distracted state

Yogic States of Consciousness [Samyama]

Ekagra, the focused state
Niruddha, a complete cessation of
all mental activity on the surface
of consciousness

Samyama Consists of:

Dharana –concentration on the object
Dhyana –meditation [sustained concentration] on the object
Samadhi –absorption into the object
 Samprajnata Samadhi –a continuously flowing stream of insights into the world of
 objects
 Savitarka Samadhi –gross objects as meditation
 Nirvitarka Samadhi –objectless concentration beyond gross objects
 Savichara Samadhi –subtle objects as meditation
 Nirvichara Samadhi –objectless concentration beyond subtle objects
 Sananda–Bliss as an object of meditation
 Nirananda –objectless concentration beyond bliss consciousness
 Asmita –the ego as an object of meditation
 Nirasmita –objectless concentration beyond the ego
 Asamprajnata Samadhi –isolation of pure consciousness from the objects of the
 continuously flowing stream of insights.

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 10 Stages of consciousness leading to samadhi in Samkhya-Yoga

(*tamas*), and light (*sattva*) go into equilibrium as one *samyama*; (6) *dharana*, attention; (7) *dhyana*, meditation; and (8) *samadhi*, absorption, and shift one's attention from the objects of insight themselves to their illumined quality. By so doing, pure consciousness (*purusha*) is separated from lifeless inert matter (*prakriti*), and the person goes into a state of complete isolation, immersed in pure consciousness. This is the highest state, or *asamprajnatasamadhi*. As a result of attaining such a state, the adept is called a *kaivalyn*, one who is now liberated while still in the body, similar to the idea of the *jivanmukta* in Vedanta psychology (Fig. 10).

While the methods of yoga are generally appropriated by all schools of thought in Hindu psychology (*darshana*), they have also been absorbed into Buddhist psychology, which aims to achieve release from suffering (*dukkha*). Buddhist psychology is based on the idea that all things are impermanent (*anicca*), have no underlying substantial self to support them (*anatta*), and that clinging to the notion of substantiality is the cause of suffering.

Normal personality is considered illusory, since there is no underlying permanent self to define it. The normal identity is constructed out of a mere heap or conglomeration of conditions (*skandha*). They are *nama-rupa*, name and form; *vedana*, feelings; *samjna*, perception; *samskaras*, the unconscious seeds of waking conscious impression; and *vijnana*, personal consciousness. The first is the physical body, while the last four, the aggregates, are considered the ego or personality – that which detaches itself from the body at death and transmigrates to another body in the process of rebirth according to one's *karma* (meaning thoughts, words, and deeds), until the final state of liberation (*moksha*) is achieved through good deeds and rebirth ends.

The ideal of the liberated personality differs from school to school in Buddhist psychology. In Hinayana Buddhism, it is the *arahat*, one who has “reached the farther shore,” by having achieved *nibanna* (Sanskrit: *nirvana*), “a burning out of the flame of desire.” In the Mahayana philosophy, the ideal is to achieve *sunyata*, the state of complete emptiness. The ideal personality is the *bodhisattva*, one who is liberated while still in the

body, who can step over into enlightenment at any time, but who has vowed to return to the world of suffering and assist all sentient beings down to the last blade of grass to pass over first.

Particularly relevant to the Tibetan Vajrayana Buddhist schools is the Tantric concept of the 84 *mahasiddhas* (Tibetan: *Grub thob chen*), shared also with the Shaivite tradition of Hinduism. These are a collection of profiles of enlightened beings with exceptional powers representing no particular tradition but who are skilled adepts and complete masters of the technologies of enlightenment. They are also called *hamsa*, or wild geese, suggesting that what we are actually dealing with is the generic experience of spirituality within each person regardless of lineage, independent of association with any one particular spiritual tradition.

Other Asian traditions also have conceptions of the liberated personality. In Chinese Confucianism we might point to the ideal of the *chuntze*, “gentlemanliness based on strength of character rather than on hereditary feudal acquisition,” or the master of *wu-wei* (non-doing) in popular Taoism. The point is that each culture has its conception of the ideal and expresses personality according to its own definition of human nature. As we have said, the Existential-Humanistic and Transpersonal traditions at least listen to these other cultures, instead of superimposing a preconceived set of categories or measurable traits of Western origin onto them and then claiming that we somehow understand the people of that culture.

This is but a limited attempt to summarize a dynamic theory of personality within the Humanistic tradition in terms of what I would call a Humanistic, Existential-Phenomenological, and Transpersonally-oriented depth psychology. Existential psychology, phenomenological psychology, and transcendent theories of personality are the only portal we have for entering into the Asian world view. All others superimpose Western categories of reductionistic science onto those cultures and ignore their indigenous systems, but at our peril. Regardless, this flaw is a clue to the change that is to come for psychology (Taylor 2010) (Fig. 11).

The Future of Dynamic Theories

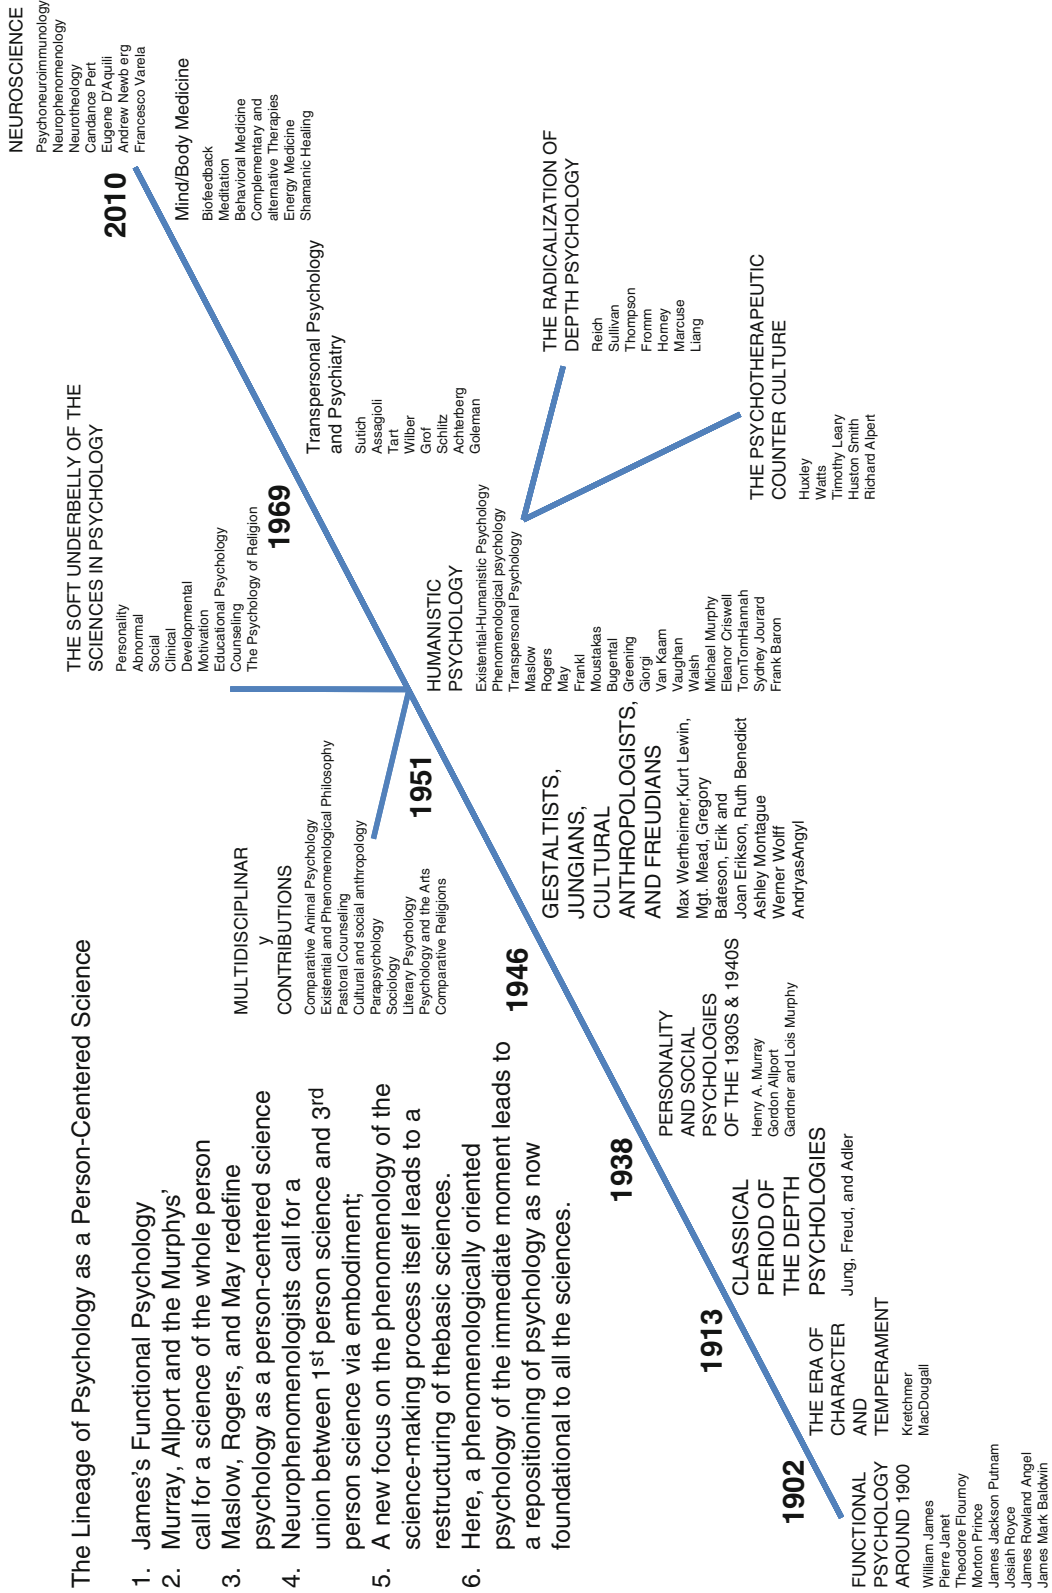

Toward the end of the first decade of the twenty-first century, dynamic theories of personality have been

relegated largely to clinical practice in psychology and psychiatry. Experimental research in personality theory has become largely dominated by trait theory, with some call for more narrative, psychobiographical methods from the periphery. Psychoanalysis has become colonized by Ph.D. psychologists and left by the wayside by psychiatrists, who in the medical school curriculum have integrated it into more general “psychodynamically assisted” approaches to psychotherapy. Cognitive psychology has become the new vogue. The new focus on neuroscience has barely any reference to personality and has substituted this construct for a more cognitive and behavioral definition of the self. Borrowing a phrase from Fernando Vidal, Sonu Shamdasani has referred to this new focus as the ascendancy of “brainhood.” The person is equal to the brain conceptions of mind. Between parallel distributive processing theories, neural plasticity, and string theory, the person has nearly disappeared off the computer screen in the current milieu, though historically this may only be a temporary state of affairs.

Dynamic theories of personality themselves might at first seem to be a thing of the past, although, given the spectrum of epistemologies represented in their history (see Fig. 11), four major forces are at work that may bring them forward in an entirely new way. Advances in trait theory have recently called for the marriage of the five (Fig. 12).

Factor Theory with the DSM, taken with the call for a globalization of both scientific psychology and psychiatry, would extend the DSM and Big Pharma to all cultures in the world. Reacting oppositely, this is enough to jump-start a kind of alternative psychological science on an international scale that takes seriously the way especially non-technological cultures have expressed their own definitions of the human ideal in their own terms.

Collectively these could be taken as the contribution that non-technological cultures have to make toward a definition of world mental health that would be quite eradicated by a global movement to instantiate the DSM and Big Pharma. At the same time, the psychotherapeutic counterculture has expanded considerably into alternative and complementary therapies, particularly from non-Western sources such as Traditional Chinese Medicine, and the lineage of Ayurvedic Medicine from India, and also such systems as homeopathy from the Western

The Lineage of Psychology as a Person-Centered Science

1. James's Functional Psychology
2. Murray, Allport and the Murphys' call for a science of the whole person
3. Maslow, Rogers, and May redefine psychology as a person-centered science
4. Neurophenomenologists call for a union between 1st person science and 3rd person science via embodiment;
5. A new focus on the phenomenology of the science-making process itself leads to a restructuring of the basic sciences.
6. Here, a phenomenologically oriented psychology of the immediate moment leads to a repositioning of psychology as now foundational to all the sciences.

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 11 The development of existential-humanistic, phenomenological, and transpersonal psychologies in the USA and their sequelae

The Positivistic Assumption:

Consciousness is defined as solely what is in the field of the everyday rational waking state, in contrast to states of coma, sleep, or hyperexcitability. Consciousness is equal to awareness. There is no such thing as an unconscious. The thinker is the thought. Manipulation of the person's articulated thoughts and observable behavior is believed to be all that is needed to change personality.

The Psychodynamic Assumption:

Consciousness is defined as a field of awareness in the everyday waking rational state, but is largely controlled by a vast interior and more primitive domain of the unconscious. Consciousness is also used to refer to the ability of consciousness to bring accessible parts of the unconscious into the field of waking rational awareness, thus leading to a change of personality, based on resolution of unconscious conflicts.

The Transcendent Assumption:

Consciousness is considered either a plurality of states or a single, universal and integral field. Waking consciousness is only one state of consciousness among many others, ranging from the psychopathic to the transcendent. The function of the waking rational state is preservation of the biological organism, which is the primary vehicle for the experience of these other states of consciousness. Awareness and consciousness are not considered the same, as inferior or superior states can control the waking condition without waking rational consciousness being aware of it. Waking consciousness can be transformed through the experience of higher, more expanded transcendent states of awareness and the development of intuitive insight.

Dynamic Theories of Personality, Classical, Post-Modern, and Person-Centered. Fig. 12 Epistemologies of consciousness underlying models of personality in the history of psychology

tradition. All of these alternatives can be better comprehended through the epistemology of depth psychology, not the rationalists' method of logical empiricism or cognitive behaviorism.

Regarding the future of dynamic theories of personality, there are also the humanistic implications of the neuroscience revolution in terms of the biology of consciousness, where the search for the solution to the mind/brain problem is likely to proceed through the phenomenology of the science-making process itself, especially in terms of the dynamic inner life of the scientist. Finally, there is a movement toward a more person-centered science, more so in medicine than in scientific psychology. In a person-centered science, the personality of the caregiver as well as the recipient, or experimenter and subject, becomes an integral part of defining the outcome of what is considered good science.

With these changes a transformation of basic science as we know is also likely to come about. The old Newtonian, Kantian, and Cartesian model of reductionistic empiricism from the nineteenth century still driving present-day psychological science may have to share the stage with a more sophisticated phenomenological model of human experience that may

eventually be seen as foundational to all the basic sciences. Big Pharma coupled with the DSM may not be driving world science at that time when it comes down to which culture has a more accurate grasp of human consciousness. The present reductionistic and positivistic model may have significant competitors from alternative and complementary therapies, indigenous psychologies, and world epistemologies different from our own. Meanwhile, the real impetus for transformation may come from the humanistic implications of the neuroscience revolution itself (Taylor 2009, 2010a). Such is the possible direction of a dynamic psychology to come.

E

Ebbinghaus, Herman

KAREN M. ZABRUCKY, REBECCA B. BAYS
Georgia State University, Atlanta, GA, USA

Basic Biographical Information

Herman Ebbinghaus was born on January 23, 1850, near Bonn, Germany. He studied languages and philosophy at the University of Bonn, although his studies were briefly interrupted in 1870, when he served in the army during the Franco-Prussian War. He obtained his Doctor of Philosophy degree in 1873.

Ebbinghaus began researching memory in 1878, and became a private lecturer at the University of Berlin in 1880. He is best known for a monograph published in 1885 (titled *Über das Gedächtnis* and translated as *On Memory*), which resulted in his appointment of Professor at the University of Berlin in 1886. He moved to the University of Breslau in 1894, and after 11 years he moved to the University of Halle. Ebbinghaus died of pneumonia on February 26, 1909.

Major Accomplishments and Contributions

Ebbinghaus's monograph, *On Memory*, documents his well-known research on memory. Ebbinghaus regarded memory as "ideas" and "mental states," and he was the first to look at memory using a system of methods rather than simply philosophical speculation. Today, he is regarded as one of the important pioneers of memory research, bringing phenomena such as free recall, serial learning, and the forgetting curve to psychological inquiry. Ten of his studies are cited in his monograph. In each study, he was his only participant and his materials consisted of a series of nonsense syllables, with each comprised of three letters, including one vowel.

Ebbinghaus recited the nonsense syllables until he considered them mastered. Mastery was attained when he could recite 150 syllables per minute (one syllable per 0.4 s) without any error or hesitation. According to Tulving (1985), no one is sure why Ebbinghaus chose this rate, but the purpose of his method was to eliminate the effects of prior knowledge on memory. He was primarily interested in forming new memories.

Ebbinghaus examined the speed at which he could memorize certain syllables and whether the length of the syllable had an impact on memorization. He also explored whether repetition affected his ability to memorize nonsense syllables, and more importantly, whether repetition affected forgetting them.

Some of Ebbinghaus's results on learning and forgetting are among the most famous in psychology. He studied the rate at which learning and forgetting occur (learning and forgetting curves) and documented the well-known serial position curve in recall. Ebbinghaus's research reveals the effects of fatigue and time of day on retention as well as the effects of list length and repetition on retention. He also examined the effects of distributed versus massed practice on recall and even short-term memory span, referenced in his work as around seven syllables after a single reading. Thus, much of Ebbinghaus's research and results remain of great interest today.

In addition to his contribution to experimental psychology and memory, Ebbinghaus is also known as a prominent lecturer. His teaching abilities were admired, so much that Cornell University offered him a position in an attempt to lure him to America. While *Über das Gedächtnis* (1885) is his most famous publication, he also published many journal articles in the areas of sensation and perception. Ebbinghaus cofounded the first journal of psychology in Germany, titled the *Zeitschrift für Psychologie und Physiologie der Sinnesorgane* (*Journal for the Psychology and Physiology of the Sense Organs*) with Arthur König and served as

editor for 22 years. Ebbinghaus was also contracted by the school board of Breslau during his last years of life to develop intelligence tests for schoolchildren that would help demonstrate the best distribution of study time for assessments.

In America, Ebbinghaus's research is largely praised for bringing informative methodologies to learning and memory research. He contributed an experimental model that is upheld today, allowing researchers to test alternate hypotheses. He also provided experimental psychology with a model of a research report, including an introduction, methods, results, and discussion section much like what is used today.

Edgeworth, F. Y.

DAVID L. SEIM

University of Wisconsin – Stout, Menomonie, WI, USA

Basic Biographical Information

Francis Ysidro Edgeworth was born February 8, 1845, in Edgeworthstown, Longford, Ireland. Edgeworth is recognized as a brilliant and eccentric economist, statistician, and social philosopher. He is especially known for his development of mathematical models of rational behavior, which he used to build models of mutually beneficial trade. Born the fifth son of a father who had been a sixth son, Edgeworth actually ended up inheriting the entire Edgeworthstown estate in 1911, when all other lines of the family died out or produced

no heirs. Edgeworth's education consisted of private tutoring followed by higher education at Trinity College, Dublin, and then at Exeter and Balliol Colleges, Oxford. His university studies were in ancient and modern languages, and during the 1870s he added a self-taught education in mathematics and economics. In 1881, Edgeworth earned a position teaching logic and political economy at King's College, London (Edgeworth 1881). Ten years later, he left King's College upon accepting the Drummond Chair of Political Economy at Oxford University. During his first year teaching at Oxford, Edgeworth assumed founding editorship of *The Economic Journal*, a responsibility he would keep for 35 years. Edgeworth did not marry, had no children, and died on February 13, 1926 (Newman 2001).

Major Accomplishments/Contributions

In 1877, Edgeworth published his first book, *New and Old Methods of Ethics*, a work in which he applied such mathematical forms as the calculus of variations and Lagrangian multipliers to problems of utilitarian philosophy. Edgeworth's main concern was what was then dubbed “exact utilitarianism,” which meant research into optimal allocations of resources to maximize the “happiness of society.” Edgeworth argued that any success of such allocation efforts ultimately depended upon the “capacity for pleasure” of the people of a society. While an “equal capacity” between all people ought to be generally assumed in most cases, Edgeworth nevertheless wondered if certain classes of people might have greater psychological capacities for pleasure than others; specifically, he believed men have more such capacity than women. These were capacities that were innate, mental, and capable of evolving over time (Newman 2003).

In 1881, Edgeworth published *Mathematical Psychics: An Essay on the Application of Mathematics to the Moral Sciences*. The book is a dense and notoriously difficult work that introduces connections between “utility functions” at the level of individual psychological wants and “equilibrium” outcomes from multiple persons trying simultaneously to maximize their individual well-being through trade. A new tool that Edgeworth introduced to help tie these two levels of analysis together was the “indifference curve,” designed to represent a whole series of different weightings of

goods and assets that can be of equivalent psychological value to a given person. In connection with his introduction of the first-ever description of an indifference curve, Edgeworth also introduced the generalized individual-level utility function $U(x, y, z)$, which it seems he developed partly by studying research in psychophysics, such as that done by Gustav Fechner and Wilhelm Wundt.

Also appearing in *Mathematical Psychics* is Edgeworth's analytical finding that under a system of free "recontracting" there will be many equilibrium solutions to a trade situation. This discovery led Edgeworth to the result of the "indeterminacy of contract," i.e., that all any economist can definitively declare is that there exists a "range of final settlements," any of which can be considered possible outcomes of aggregate activity in a market. Edgeworth culminated this line of argument with a long-term, large-numbers result, now known as "Edgeworth's conjecture" (or "Edgeworth's core"), which is that as the number of agents in an economy increases, the degree of indeterminacy is reduced. Edgeworth describes many exchange processes in the book, many within a simplified, bounded-world model, now known as an "Edgeworth box." Altogether, in a manner analogous to mathematical physics, Edgeworth applied his mathematical psychics to the measurements of utility, ethical value, and economic value.

Edgeworth also wrote on topics in many other fields in economics, statistics, and social philosophy. One area of contribution was in probability theory and statistics, for which, in 1885, Edgeworth introduced an interpretation of significance tests for the comparison of means; in fact, Edgeworth even is credited as the inventor of the very word "significance" in its statistical meaning (Edgeworth 1885). Edgeworth executed other studies over many years to look at facets of two-dimensional and multidimensional normal statistical distributions. He contributed advances to our understanding of the law of errors, estimation of correlation coefficients, and understanding of a particular statistical outcome now known as the "Edgeworth series" (FitzPatrick 1960).

Edgeworth studied trade theory and taxation too, treating both in a kind of philosophical fashion as he explored principles for equitable reallocations of economic wealth and well-being. In 1894, he published a series of papers that pioneered the use of "offer

curves" and "community indifference curves." In 1897, he published his "taxation paradox," which is that increased taxation of a good can, in theory, result in a decrease in price. Edgeworth's work on taxation policy also set some foundations for so-called progressive taxation based on his arguments that the optimal distribution of taxes should be such that "the marginal disutility incurred by each taxpayer should be the same"; this is recognized as Edgeworth's "Pure Theory of Taxation." Edgeworth also introduced theoretical breakthroughs on such subjects as monopolies, duopolies, and wartime production (Newman 2001).

When assessed overall, Edgeworth – despite the difficult and even obscure style of his writing – is a giant in the history of social and behavioral science.

Ekman, Paul

KEVIN RUSTAM

Pace University, New York, NY, USA

Basic Biography

Ekman is a pioneer and world-renowned expert in the study of emotional research and nonverbal communication, particularly on emotional micro-expression and the corresponding physiological activity of the face (Ekman n.d.).

Paul Ekman was born on February 5, 1934, in Washington, D.C., although he never lived there, Growing up, Ekman lived in Newark, New Jersey, Washington, Oregon, and Southern California (Ekman 2003).

Paul Ekman received his undergraduate education at the University of Chicago and New York University. He received his Ph.D. in clinical psychology at Adelphi University in 1958. During which, he completed his clinical internship at the Langley Porter Psychiatric Institute, part of the University of California, San Francisco (UCSF). While Ekman was still at University of Chicago, his classmates included Susan Sontag, Mike Nichols, and Elaine May. After receiving his Ph.D., he served as chief psychologist in the US Army, Fort Dix, New Jersey from 1958 to 1960. After 2 years as a Clinical Psychologist in the Army, he returned to UCSF (University of California at San Francisco), where he had a postdoctoral research fellowship for 3 years from 1960 to 2004.

Ekman's interests have focused on two separate but related topics. He originally focused on nonverbal behavior; however, by the mid-1960s, he shifted his concentration to the expression and physiology of emotion. In addition, to his research on emotion and its expression for the last 30 years, he has also been studying interpersonal deception (Richard and Ekman 1994). His research on facial expression and body movement began in 1954 and he published it in 1957. In his early work, his approach to nonverbal behavior showed his training in personality. However, over the next decade, a social psychological and cross-cultural emphasis characterized his work, with a growing interest in an evolutionary and semiotic frame of reference. Ekman's work on facial expressions had its starting point in the work of psychologist Silvan Tomkins. Ekman showed that contrary to the belief of some anthropologists, including Margaret Mead, facial expressions of emotion are not culturally determined, but are universal across human cultures and thus biological in origin. Expressions he found to be universal included those indicating anger, disgust, fear, joy, sadness, and surprise, or also known as the six universal emotions.

In 2000, Paul Ekman and his Holiness the Dalai Lama spent 39 h discussing the world of emotion. During their conversation, they found such synergy in their understanding of human emotions that the Dalai Lama gave Ekman \$50,000 in seed money to learn how

to improve emotional balance in schoolteachers and other people in high-pressure jobs (Ekman 2003).

Currently, Ekman is the Manager of the Paul Ekman Group, LLC (PEG), a small company that produces training devices relevant to emotional skills. One of these devices is the FACS, or Facial Action Coding System, for deciphering which of the 43 muscles in the face are working at any given moment, even when an emotion is so fleeting that the person experiencing it may not be conscious of it (Ekman and Rosenberg 1998). Ekman is also currently on the Editorial Board of *Greater Good* magazine, published by the Greater Good Science Center of the University of California, Berkeley. His contributions include the interpretation of scientific research into the roots of compassion, altruism, and peaceful human relationships. Ekman is also working with Computer Vision researcher Dimitris Metaxas on designing a visual lie-detector.

Due to Ekman's detailed knowledge of facial expression, he is much in demand these days. Movie producers from the movie animators such as Pixar and Industrial Light & Magic had sought him out as a consultant in giving lifelike expressions to cartoon characters. In 2009, Ekman was acting as a consultant on the FOX series "Lie to Me" starring British actor Tim Roth (Kreisler 2004).

The Federal Bureau of Investigation (FBI), the Central Intelligence Agency (CIA), Bureau of Alcohol Tobacco and Firearms (ATF), and state and local police forces have also turned to him for help learning to read subtle emotional cues from the faces, voices, and body language of potential terrorists and questionable visa applicants.

Accomplishments

In 1971, Paul Ekman received a Research Scientist Award from the National Institute of Mental Health, and that award that renewed in 1976, 1981, 1987, 1991, and 1997. For over 40 years, his research program was supported by: fellowships, grants and awards from the National Institute of Mental Health, the National Science Foundation, and the Advanced Research Projects Agency of the DOD. In 1972, Ekman was appointed as Professor of Psychology at UCSF, and he remained there for 32 years.

Ekman's many honors included: the Faculty Research Lecturer from University of California, San Francisco in 1983, Distinguished Scientific

Contribution Award of the American Psychological Association in 1991, an honorary doctor of humane letters from the University of Chicago in 1994, William James Fellow Award given by the American Psychological Society in 1998, Honorary Doctor of Humane Letters by Adelphi University in 2008 and Times Magazines Top 100 most influential people of 2009.

In 2001, Paul Ekman was named by the American Psychological Association as one of the most influential psychologists of the twentieth century based on publications, citations, and awards (Taylor 2009).

Elliott, Richard M.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: November 3, 1887; Died: May 6, 1969.

Elliott was born in Lowell, Massachusetts to Unitarian parents who encouraged his scholarly gifts. He matriculated at Dartmouth where he intended to study astronomy but concluded that his abilities in mathematics and physics precluded a career in physical science. He

found philosophic debate congenial and arrived at graduate school at Harvard in 1910, to his regret one month after the death of William James. He did his doctoral work with Munsterberg on handwriting, but his most significant mentors were E. B. Holt and R. M. Yerkes. He was attuned to Holt's balancing of aesthetic sensibility with a realistic epistemology. Elliott considered continuing as an experimentalist for a time after his Ph.D. in 1913 but found, while teaching at Harvard, that his heart was not in it. The First World War then intervened and Elliott found himself in a battalion of mental testers under the command of Donald G. Paterson. After the war, Yerkes, who had been at Minnesota in 1917 but rapidly moved to Washington D. C. and into the arena of national scientific affairs, employed Elliott to work on the summary of the war testing work and then recommended Elliott to Minnesota as his replacement. Elliott, along with William S. Foster and Mabel Fernald, arrived in Minnesota in 1919 where he began a career of more than 30 years as department chair.

Major Accomplishments/Contributions

He was the quintessential conductor harmonizing a group of superior psychologists, including Karl Lashley until 1925, B. F. Skinner between 1936 and 1945, Starke Hathaway, Paul Meehl, and Donald G. Paterson. With Paterson and several others, Elliott assisted in developing the Minnesota Mechanical Ability Tests (Paterson et al. 1930) and also contributed to the depression-era survey *Men, Women, and Jobs* (Paterson et al. 1936). Elliott said of himself that he created no psychology, but he made much psychology possible (Elliott 1952). He helped structure the introductory course at Minnesota which came to be a model of its type, and also taught for many years an innovative course in biographical psychology. He mentored Frank Barron, eminent scholar of creativity. He was a member of the planning subcommittee of the WWII-era NRC Emergency Committee in Psychology (Boring et al. 1942) which was an important formative influence on the modern structure of the psychological profession. And, in 1928, Elliott, on E. G. Boring's suggestion, became the editor of the Century Psychology Series for the publisher Appleton-Century-Crofts. In this capacity, he was responsible for bringing to print the essential texts of the systematic behaviorist era, including Tolman's

Purposive Behavior in Animals and Men, Skinner's *Behavior of Organisms*, and Clark Hull's *Principles of Behavior*, as well as many other works in applied psychology, social psychology, and developmental psychology, often by Minnesota colleagues. The Century Series, always recognizable with its red-banded spines, was particularly important in the development of the scholarly study of the history of psychology, publishing among other works Edna Heidebreder's *Seven Psychologies*, E. G. Boring's *A History of Experimental Psychology* and Wayne Dennis's *Readings in the History of Psychology*. Elliott married well to Mathilde Rice, and together they lived a life of cultivated culture and civic involvement in the Minneapolis area: Elliott owned one of the first Art Moderne homes in the University Park neighborhood and his wife was a docent and teacher at the Minneapolis Institute of Art. Fittingly, in light of his respect and support for natural science, Elliott and his wife are memorialized in the Richard M. and Mathilde Rice Elliott Prairie Scientific Natural Area, a habitat for endangered grassland birds near Rothsay, Minnesota.

Ellis, Albert

DEBBIE JOFFE ELLIS

Psychologist and Mental Health Counselor, New York, NY, USA

Basic Biographical Information

Albert Ellis, Ph.D., was born in Pittsburgh, Pennsylvania, on September 27, 1913. He is recognized

as one of the most influential figures in modern psychology. The contributions of Albert Ellis changed the course of the field of psychology in the twentieth century, and continue to be a dominant influence now in the twenty-first century. He pioneered the field of cognitive psychology and therapy with his specific approach of Rational Emotive Behavior Therapy (REBT).

His father was a businessman who often traveled, and his mother attended to raising him, his younger brother, and sister. Throughout his childhood he suffered from various illnesses and was often hospitalized. He was rarely visited in hospital by his parents, and as a result of sadness about this and other difficulties and adversities he faced in his life, along with an insatiable interest in reading and learning, he developed a philosophical attitude, smart strategies, and efficient tools to help him suffer less emotional pain.

In his later childhood, teen years, and early adulthood, he was an avid reader—particularly interested in the writings of classic, stoic, eastern, and contemporary philosophers, as well as all sorts of fiction, and he also read works by various psychologists, including the behaviorist John B. Watson, Sigmund Freud, and Alfred Adler.

As a young man he found ways to overcome his extreme shyness related to talking to women and speaking in public—and the means he applied for doing so are tools now found in the REBT approach, such as “in vivo desensitization”: pushing oneself to *do* whatever it is that one wants to feel comfortable doing while “anti-catastrophizing”: reminding oneself that no catastrophe or tragedy will result if one makes mistakes or if it takes one a while to achieve one’s goal.

He would also read hundreds of books and articles on issues of relationships, sex, and marriage, helping friends who came to him for advice, and in doing so discovered his talent for problem solving and helping others. As a result he studied psychology; helped many who were having relationship problems by giving them marriage, family, and sex therapy; founded the Love and Marriage Problem (LAMP) Institute for research and therapy in 1938; and continued his study, work, and research. He became a noted sexologist, and was the founder and first President of the Society for the Scientific Study of Sexuality.

Albert Ellis attained his degrees in clinical psychology from Columbia University, completing his M.A. in 1943 and his Ph.D. in 1947, and practiced the then-norm of psychoanalysis with clients—but quickly felt dissatisfied with this therapy as he observed that clients were not significantly getting better as a result of that approach.

He increasingly became more active-directive in the therapy he gave, continuing his researching and writing, and in August 1956, he presented his first paper on Rational Emotive Behavior Therapy (which at that time was named Rational Therapy) at the annual meeting of the American Psychological Association in Chicago. He was jeered and booed by conservative attendees, but persisted in presenting and writing about his empowering approach of Rational Emotive Behavior Therapy which became increasingly and greatly accepted.

Dr. Ellis held many important positions and roles, too many to mention here, which include Chief Psychologist in the state of New Jersey, and adjunct professorships at Rutgers and other universities. He was a consultant in Clinical Psychology to the New York City Board of Education, and to the Veterans Administration. He was a Fellow of the American Psychological Association and served as President of its Division of Consulting Psychology, Executive Member of its Divisions of Psychotherapy and Humanistic Psychology, and as a Member of its Council of Representatives. He was a Fellow of the American Association of Marriage and Family Therapists, the American Orthopsychiatric Association, the American Sociological Association, the American Association of Applied Anthropology, and the American Association for the Advancement of Science. He was a Diplomate in Clinical Psychology of the American Board of Professional Psychology, in Clinical Hypnosis of the American Board of Psychological Hypnosis, of the American Board of Medical Psychotherapists, and of the American Board of Sexology.

He received the Distinguished Alumni Award of Teacher's College, Columbia University, and of the City College of New York. Many professional societies honored him, and he was awarded the 1971 Humanist of the Year Award by the American Humanist Association; the Distinguished Psychologist Award of the Academy of Psychologists in Marital and Family

Therapy; and the Distinguished Practitioner Award of the American Association of Sex Educators, Counselors and Therapists. He achieved the highest awards for professional achievement from the American Psychological Association, the American Counseling Association, and the Association for the Advancement of Behavior Therapy.

Major Contributions

In 1959, Dr. Ellis founded the Albert Ellis Institute and dedicated himself to its work of training professionals, providing lectures, courses, and programs to educate members of the public, and seeing clients in its clinic which provided affordable counseling. His famous Friday Night Workshops for the public were conducted over there on a weekly basis for over four decades. For some years it sponsored an experimental school for children, The Living School, in which emotional education was incorporated into the academic curriculum.

He served as consulting or associate editor of many scientific, psychiatric, and psychological journals, and published more than 800 articles as well as over 80 books and monographs, including a number of best-selling popular and professional volumes. His autobiography *All Out!* was released in 2010, and one of the last books he worked on, *Rational Emotive Behavior Therapy*, was published in 2011 (Ellis 2010; Ellis and Ellis 2011).

He wrote and presented on subjects relevant to the times, and in his final years focused on topics such as Buddhism and REBT. He encouraged rational spirituality, in which one practices kindness, compassion, and tolerance (Ellis 1962). Throughout his career he used and expressed great humor, encouraged others to do so to help them take things less seriously, and wrote hundreds of rational humorous songs—some of which were often sung by delighted audiences in his workshops.

He was very well known throughout the United States and across the globe as a unique and charismatic speaker, and appeared on hundreds of radio and television shows. He wrote for, and was interviewed in, prestigious newspapers such as the New York Times and many popular magazines. His books have been translated into over 20 different languages.

Rational Emotive Behavior Therapy is a highly philosophical approach. It emphasizes the importance of

Unconditional Self-Acceptance, Unconditional Other Acceptance, and Unconditional Life Acceptance.

At its core it is a most humanistic and compassionate approach, while also most vigorous and dynamic in its encouragement to clients, lecture and seminar attendees, readers, and students to challenge their faulty thinking and to take the appropriate actions to enhance the quality of their lives and facilitate the achievement of their goals (Ellis and Joffe 2002). REBT is a holistic approach, recognizing that thoughts, feelings, and actions are intertwined. Cognitive attention and awareness are not enough to bring about change and emotional well-being in many cases—*action* is also required.

The REBT theory and therapy processes apply to issues within the spectrum of those coping with simple everyday problems, to those with neurotic tendencies, across to those with more severe psychoses. It applies to those suffering from addictive behaviors. REBT is applicable to people from all cultures. Its main principle is that it is not the events which happen to people that create their emotions, but their *perception of* and their *beliefs about* the events which happened that create their emotional destinies.

REBT teaches that healthy and appropriate emotions are created when people think in *rational* and healthy ways, which include: (a) keeping things in perspective, (b) wanting—*without demanding*—that things go the way they prefer, and (c) developing high frustration tolerance and ability to tolerate unpleasant circumstances and difficulties if they cannot change them (and changing them when they can).

When people think in unhealthy *irrational* ways—which include (a) *demanding* (instead of preferring) that they *should* or *must* or *ought* to have things the way they want them to be, (b) damning themselves and other individuals and the world when they do not act in the ways they insist they all should be acting, and (c) having low frustration tolerance—then they create debilitating and unhealthy emotions such as anxiety, depression, and rage, which can prevent them from living more fulfilling lives and attaining more of their goals (Ellis 2005).

REBT reminds people that they create their own emotional destinies by the ways in which they think; that they are responsible for doing so; and it urges them

to apply REBT principles and life-enhancing actions in an ongoing fashion throughout their lives, so that they do not create unnecessary suffering and experience greater joy.

Despite the various adversities and difficulties Albert Ellis faced throughout his lifetime, he continually applied his principles in his own life, practicing what he preached. He continued to help others till he was too ill to do so, even months before his passing away. This unique man contributed immeasurably to the well-being of millions of people, and through his great works his legacy will endure.

He died in New York City on July 24, 2007.

Erdmann, Benno

DAVID C. DEVONIS
Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: May 30, 1851 Died: January 7, 1921.

Erdmann was born in Guhren bei Glogau, Silesia, and seemed destined, due to his father's early death, to a nonacademic career. However, good fortune intervened and he was able, after graduating from the Realschule in 1868, to enter Gymnasium and ultimately to matriculate at the University of Berlin in 1870. There in 1873 he defended his doctoral thesis on the *Ding an*

sich in Kant's *Analytik* and *Ästhetik* and also habilitated in 1876 with a thesis on non-Euclidean geometry and its relation to the theory of knowledge. His first academic position was at Berlin as Privatdozent, and he then obtained professorships at Kiel (1879), Breslau (1884), and Halle, where he served between 1890 and 1898. After that he spent the next 11 years at Bonn and then returned to the University of Berlin in 1909 where he finished his career.

Major Accomplishments/Contributions

Erdmann established an early reputation as a Kant scholar and produced several critical editions and commentaries, including a much discussed introduction to the *Prolegomena to Every Future Metaphysic* in 1878, an edition of the *Critique of Pure Reason* (also 1878), and commentaries on the *Anthropologie* and the *Critique of Pure Reason*, *Reflections on the Critical Philosophy* (1882–1884). He is usually mentioned in connection with other psychologically oriented Kantians such as his Halle colleague Hans Vaihinger and Alois Riehl. Alongside this Erdmann also made forays into epistemology, psychology, and education, producing *Die Psychologie des Kindes und die Schule* (Erdmann 1901), *Über Inhalt und Geltung des Kausalgesetzes* (Erdmann 1905), and *Wissenschaftliche Hypothesen über Leib und Seele* (Erdmann 1907), and also edited the history of philosophy of his predecessor J. E. Erdmann, an important early influence on Neokantianism. Beneath his philosophical exterior, however, Erdmann was very much in the mold of other contemporary German philosophers who were intensely interested in the laboratory study of psychological processes and the development of a distinct discipline of scientific psychology. Between 1885 and 1893 he had contact with Franz Boas and James Rowland Angell. Boas studied with Erdmann for a time in the 1880s, and Erdmann would have been the dissertation advisor for James Rowland Angell who had prepared to defend his thesis on Kant but left to take a job at Minnesota that would facilitate his marriage. Thus it fell to Raymond Dodge to be the single conduit for Erdmann's blend of philosophy and psychology to modern American psychology. Dodge, by coincidence, became familiar with Erdmann's work through John

E. Russell, his advisor in philosophy at Williams, and decided to study philosophy at Halle with Erdmann. After Dodge arrived in 1894, Erdmann rated Dodge's chances for success as a philosopher low, and put him to work on a problem in epistemology which devolved into psychology at a fundamental sensory and physiological level, the question of the movement of the eyes relative to text while reading. Solution of this problem necessitated the concurrent solution of a specific mechanical problem, the creation of a tachistoscope with both monocular and binocular fields of view to present text sentences. Dodge solved the conceptual engineering problems and with the assistance of the resident equipment builder constructed a mirror tachistoscope which made possible exact observations of the eye's activity in reading, which led ultimately to the verification of the saccadic pauses characteristic of reading eye movements described earlier by Javal and others. Dodge and Erdmann published their empirical and theoretical account of reading as *Psychologische Untersuchungen über das Lesen auf Experimenteller Grundlage* (1898), a foundational document in the psychology of reading. It also marked a decisive moment of change in developing conceptions of cognition, as it introduced the concept of an active, scanning eye in place of a fixed and passive stimulus receptor, which, after many later elaborations by others, developed into the modern study of attention and into information pickup theories of perception. Erdmann was one of the many luminaries at the International Congress of Arts and Science at the St. Louis Exposition in 1904 where he addressed the Section for Methodology of Science. Dodge (1922) noted that Erdmann was not driven to system building and also not particularly defensive of his point of view, which made him the ideal colleague for Dodge but certainly diminished his influence in an era of great scholarly contention.

Erikson, Erik

KOURTNEY KEITT

Marymount Manhattan College, New York, NY, USA

Basic Biography

Erikson, H. Erik (June 15, 1902–May 12, 1994), was an artist turned psychoanalyst, and was best known for the initiation of the concept of an identity crisis and his influence on psychosocial aspects of stage-like development.

Erik Erikson was born in Frankfurt, Germany, to his mother Karla Abrahamsen. When Erik was about 3 years old his mother, Abrahamsen, married Dr. Theodore Homberger, Erik's pediatrician. Erikson never knew his biological father, who abandoned Abrahamsen before Erikson was born. Erikson had blonde hair and blue eyes and grew up getting teased in grade school due to his Nordic looks, and due to his Jewish roots. Erikson, originally named Erik Homberger, grew up in South Germany where he finished high school and lived a spontaneous young life of traveling through Europe, focusing on art, and visiting

museums. Around the age of 25, after a few years of traveling, Erikson was approached by a friend that was also an artist who told Erikson to apply to teach at a school for American students under the direction of Dorothy Burlingham, who was also friends with the Freud family. Over the next few years Erikson received a certificate from teaching at a Montessori school as well as a certificate from the Vienna Psychoanalytic Society. During the time when Erikson got his certificate he met his future wife Joan Serson, and they had a family with three children, Kai, Jon, and Sue (who also became a psychologist). Not long after raising his family, Erikson decided that he and his family should move to Copenhagen to escape the rising Nazi regime in Vienna. Thus after leaving Copenhagen, they came to settle in Boston.

When Erikson came to America he formally changed his name from Homberger to Erikson, the exact reason is unknown. In America, Erikson taught at the prestigious schools of Yale University and the University of California at Berkeley. Erikson also took some time to work on what would become some of the most famous research studies about modern life. In 1950, Erikson wrote his book on *Childhood and Society* which analyzed the lives of Hitler and Maxim Gorkiy. Erikson also won a Pulitzer Prize award for the book that he wrote on Mahatma Gandhi. During the time that Senator McCarthy was in office, Erikson decided to resign from University of California because educators were being pressured into signing loyalty oaths. After resigning, the fear of being “academically blacklisted” was prevalent, which may be what motivated Erikson to pursue a clinical career as opposed to an academic career. After parting ways from University of California, Erikson left the state and taught at a clinic in Massachusetts and then proceeded to work at Harvard for another 10 years.

Major Contributions

Erikson's most famous contribution to the field of Psychology is his theory on psychosocial development. His work is based on the idea that in every stage of life there is a conflict of interest or internal struggle that a person faces, this idea was known as Erikson's Eight Stages of Psychosocial Development. The general basis of his theory can relate loosely to that of Freud, but focuses more on development throughout the entire

lifespan. His theory is a cumulative process that takes places over one's life. Erikson identified eight stages of psychosocial development. Erikson's eight stages of psychosocial development include: Basic trust versus Mistrust, Autonomy versus Shame and Doubt, Initiative versus Guilt, Industry versus Inferiority, Identity versus Identity Confusion, Intimacy versus Isolation, Generativity versus Stagnation, and Integrity versus Despair. From creating these levels, Erikson creates an ideal level that every human being can approach and surpass throughout the span of their entire lifetime. These stages are obstacles that every person can identify with depending on their age and the period of life that they are facing.

The first stage (Basic trust vs. Mistrust) happens around the first year of life where the responsibility is on the caregiver to invoke a sense of trust in a young child, and to give him/her a sense of stability. The second stage (Autonomy vs. Shame and Doubt) occurs around age 1–3, and the child is starting to get potty-trained, and do little tasks on his/her own. The third stage (Initiative vs. Guilt) is during the preschool age, where children are learning to take responsibility for their own actions, feel guilt if they fail at a task, and ultimately gain a sense of morality. The fourth stage (Industry vs. Inferiority) is at an elementary school age where the person masters intellectual knowledge and gains confidence. The fifth stage (Identity vs. Identity Confusion) is during adolescence when the person is figuring out his/her identity, asking questions like: Who am I? Who do I want to be? They set vocational goals, and begin romantic relationships. The sixth stage (Intimacy vs. Isolation) is during young adulthood when a person is finding and losing him/herself in another person, and really breaking down the barriers and putting trust in their personal relationships. The seventh stage (Generativity vs. Stagnation) is during middle adulthood, when the person is leading a productive lifestyle and raising a family, or gaining success in their career. The final stage (Integrity vs. Despair) is during late adulthood near the end of a person's life when they reflect back and evaluate their life.

Erikson's contributions to the field of psychology were not solely in his theories on psychosocial development, but in his combination of various aspects of learning to psychology like psychohistory,

psycho-biographical, psychosocial, and more. Many of his most famous books were on his analyses of historical figures like Martin Luther King, Thomas Jefferson, Mahatma Gandhi, etc.

After his many contributions to the field, Erikson retired from teaching at Harvard in 1970. After moving around for a few years, Erikson and his wife Joan eventually moved back to Cambridge and founded the Erik Erikson Center, which was directly associated with Cambridge Hospital and Harvard Medical School. Throughout the rest of their lives Erikson and his wife continued to work together and conduct research, and on May 12, 1994, Erikson died.

²Queen's University, Kingston, ON, Canada

This entry has three sections. The first concerns the beginnings of evolutionary psychology in the late nineteenth century. The second briefly provides a historical background, set between 1900 and 1975, for the third section, which concerns evolutionary psychology from about 1975 to mid-2010.

Late Nineteenth-Century Evolutionary Psychology

Anaximander, a pre-Socratic philosopher of the sixth century BCE, was quoted by the Roman scholar Plutarch as having said that

- ▶ [At] the beginning man was generated from all sorts of animals, since all the rest can quickly get food for themselves, but man alone requires careful feeding for a long time; such a being at the beginning could not have preserved his existence. (Nahm 1964, pp. 42–43)

Moreover, Plato wrote that Anaximander declared

- ▶ [Not] that fish and men were generated at the same time, but that at first men were generated in the form of fishes, and that growing up as sharks do till they were able to help themselves, they then came forth on the dry ground. (Nahm 1964, p. 43)

Some 2,400 years later, Charles Darwin (1809–1882; see Dewsbury 2009, for a short biography) wrote, using the term “*Quadrumana*” to refer to animals with opposable thumbs, including apes, monkeys, and lemurs:

- ▶ The *Quadrumana* and all the higher mammals are probably derived from an ancient marsupial animal, and this through a long line of diversified forms, from some amphibian-like creature, and this again from some fish-like animal. In the dim obscurity of the past we can see that the early progenitor of all the Vertebrata must have been an aquatic animal, provided with branchiae [gills], with the two sexes united in the same individual, and with the most important organs of the body (such as the brain and heart) imperfectly or not at all developed. (Darwin 1871/1899, p. 609)

Anaximander, when he had focused on the long period of prepubertal growth of humans, may have carried out the thought-experiment of imagining that, if all species had been born at one and the same time, animals maturing faster than humans might have brought their own progeny to a level of population that threatened the survival of humans, probably by competing for food, or possibly by feeding on still immature humans who had not yet developed the fighting skills of faster-maturing species.

Darwin’s “Sexual Selection”

When Darwin wrote that the aquatic ancestors of humans had both male and female characteristics within the same individual, he was preparing the way for the amplification of his theory of evolution by natural selection (Darwin 1859/2004) to include an additional kind of selection, namely, sexual selection. Darwin’s thesis was that, starting at the level of the insects, males had evolved certain physical characteristics whose main purpose was to attract the female, with the outcome that those males naturally born to appear attractive would be more successful at breeding than would rival males who were less attractive. Hence, certain male characteristics, which Darwin called “secondary sexual characteristics” to contrast them with the “primary characteristics” of the organs of reproduction, would become enhanced over successive generations. These secondary sexual characteristics had the peculiarity that they only showed themselves relatively late in life, following puberty, and, as a consequence, females and young males would not possess these characteristics. These ideas were put forward in *The Descent of Man* (Darwin 1871/1899). The influence of Darwin’s ideas about sexual selection on twentieth-century evolutionary psychology was assessed by Ghiselin (1973).

Briefly listing several genres of what Darwin surmised to have been sexually selected characteristics, we can include the use of special sounds to attract females (as in grasshopper stridulation, bird song, and the roaring of sea elephants); the use of special scents (as in the musk of certain deer); the use of bright colors, as in fish and birds (one of Darwin’s many impressive achievements was his explanation of how eye-shaped decorations, ocelli, in the tails of peacocks and of argus pheasants could have evolved over aeons from chance variations in the shading of adjacent feathers); and the use of fierce-looking body-parts in males accustomed to fight in front of females in order to attract the latter (examples include the mane of the male lion, the tusks of male elephants, the horn of the male narwhal, the antlers of many male deer, and the fangs of the male baboon).

There was an additional reason, according to Darwin, why it should have been males, rather than females, in whom these secondary sexual characteristics had been developed. Bright colors, in a female bird,

might give away her position on an open nest to predators, thereby endangering both her life and the life of her nestlings. If so, it could be predicted that, in those rare instances where the female of a species was more brightly decorated than was the male, such females would occupy closed nests, or holes in trees, where they would not be visible to overhead predators. Darwin was able to confirm this prediction from his extensive knowledge of natural history.

However, the possession by male birds of accessories such as very long tails could encumber their flight; and the possession, by male deer, of widespread antlers could impede their forward progress when being pursued over heavily treed terrain. It might then be predicted that the possession of exceptionally well-developed secondary sexual characteristics might lead to a reduction in the survival prospects for highly endowed males. But competition from one or more weaker males might already have been eliminated by such a male, and this single winner in a male-to-male competition might be chosen not by just one, but by several females, to be their mating partner, thus ensuring that the effects of any premature demise of such males on the survival of the species could be compensated for. Møller (2008) has noted that

- Typically, male traits related to the presence of weaponry, or sheer size, have evolved and are being maintained by male-male competition, while visual and vocal displays are involved in mate choice, although exceptions occur . . . sexual size dimorphism in such diverse taxa as pinnipeds, ungulates, and primates increase from monogamous species over multimale polygyny to single-male polygyny. (Alexander et al. 1979; Møller 2008, pp. 78–79)

Darwin assumed that all of these features have their counterparts in humans, but to an extent that is relatively vestigial in comparison with the corresponding features of humans' more savage animal forebears. Recent researchers, however, have stressed that, in Darwin's time, social circumstances were such that Darwin himself might not have been aware of certain intergender issues that nowadays are having a considerable impact on our social mores in the modern industrial West; such issues can arise from situations of conflict between the sexes including deceptive practices, infidelities, and sexual coercion, not to mention

interfamilial conflicts such as arguments between step-parents and biological parents. Buss (2009) had good reason to write "the battle of the sexes, in short, defines one of the momentous struggles unknown to Darwin, a battleground that follows logically from the modern 'gene's eye' view of selection" (Buss 2009, p. 146). This gene's eye view, which contrasts with Darwin's "species' eye" view, will be discussed when we come to late twentieth-century evolutionary psychology.

But, to return to the problem of how humans differ from animals with respect to secondary sexual characteristics, Darwin (1871/1899, pp. 56–58) did contend that one characteristic that clearly distinguished humans from the anthropoid apes was the fact that humans are almost denuded of hair compared with the apes. After giving reasons against the supposition that the lack of hair in humans was associated with the greater ease of keeping cool in hot climates or with the greater ease of picking lice and similar pests from the body-surface, Darwin concluded that

- The view which seems to me the most probable is that man, or rather primarily woman, became divested of hair for ornamental purposes, as we shall see under Sexual Selection; and, according to this belief, it is not surprising that man should differ so greatly in hairiness from all other Primates, for characters, gained through sexual selection, often differ to an extraordinary degree in closely-related forms. (Darwin 1871/1899, pp. 57–58)

In a widely publicized book, Morris (1967) suggested that the evolutionary transition from a fruit-eating ape in the treetops to a meat-eating ape on the ground had led to a change in societal structure in which males hunted as a group while females stayed behind to tend the children. This suggestion revived the heat-reducing argument that had been dismissed by Darwin because Morris claimed that the hunters were forced sometimes to engage in the unaccustomed exertion of sprinting when chasing their prey; a naked skin would be more easily cooled than would hairy skin. If it be wondered whether the brief activity of sprinting could have a long-term effect on the adaptation of physical features, there is the evidence that "The cheetah is in a separate genus from the other cats, however, because it has blunt claws that can be only partly retracted" (Burton and Burton 1969/1974, p. 406). These changes would have been adaptive for

the cheetah because they would have facilitated the sprinting component of hunting, for which the cheetah is famous.

As a side-effect of increased nakedness, however, major changes were postulated by Morris to have occurred in hominid sexual activity, including front-to-front copulation (instead of the rear-mounted copulation associated with the apes), copulation extended over minutes (instead of the seconds associated with, for example, baboons), the invention of clothing for the control of antisocial urges by hiding the genitalia in both sexes (Morris speculated that this use of clothing preceded the adoption of clothing for the purpose of keeping warm), and the development of the female breast as a sexual entity (instead of serving solely as a device for feeding; Morris considered that many breast-feeding difficulties in humans were a byproduct of the fact that the human female breasts had become more globular than were those of their anthropoid ancestors). Morris also briefly discussed, but did not follow up on, yet another theory of why the human is naked; according to an “aquatic theory,” there was an age in which some land-dwelling animals returned to the water prior to resurfacing on land. A naked skin is better for swimming than is a hairy skin, as can be seen from the naked skin possessed by aquatic mammals such as whales and dolphins (Hardy 1960). This theory would later be dismissed, however, on the grounds that whales and dolphins also evolved subcutaneous layers of fat to keep them warm. Humans had exactly the opposite problem, namely, that of keeping cool (Foley 1995, pp. 142–143).

It will be noted that, if Morris is correct and the evolution of human nakedness was originally for cooling purposes, then nakedness has also become an incidental factor contributing to the evolution of human sexual behavior. Cases like this lead to the following question. If an adaptation has evolved for achieving a goal A, and it then turns out that the adaptation also has value in achieving a second goal B, should the second achievement also be labeled an “adaptation”? Gould and Lewontin (1979) and Gould and Vrba (1982) maintained that examples of the second kind should be called “exaptations.” A useful introduction to exaptation in the context of evolutionary psychology has been given by Alcock and Crawford (2008, pp. 37–40), who also discuss reasons for

thinking that sexual selection might be considered a subset of natural selection, even though tradition has favored their being considered conceptually distinct (pp. 30–31). Jablonski and Chaplin (2000) have suggested that, when nakedness first appeared, the skin coloration was black; white skin evolved when, following northward migration, there was an adaptive depletion of black pigment (melanin) to allow more vitamin D to be formed on exposure to the scant sunlight of northern climates.

Darwin was at pains to stress that sexual affinities between males and females were probably expressed very differently in archaic societies than is nowadays the case. He believed that promiscuity probably characterized a very early society, not omitting incest, and not ignoring the fact that the paternity of a child could be in doubt; but gradually, as people developed the social instincts of cooperation (working with other people, rather than against them) and of sympathy (learning how other people thought and felt, and working deliberately to encourage self-respect in others), so did the institution of marriage arise as a device for enhancing child care, for ensuring that a father knew that a certain child was his, and for facilitating fidelity between sexual partners. Darwin gave many examples of cases in the animal kingdom that would have reminded his readers of the tensions between polygamous and monogamous practices in humans. Morris (1967) distinguished between a courtship phase and a reproductive phase in human sexual relationships and considered that marriage was a special case of a more general phenomenon found in both animals and humans, namely, pair-bonding. As noted above, psychological issues relating to pair-bonding constitute a major topic in present-day evolutionary psychology (Buss 2009; Symons 1979; Williams 1975).

Darwin on the Evolution of Emotional Expressions

In his next book of direct relevance to evolutionary psychology, *The Expression of the Emotions in Man and Animals*, Darwin (1872/1904) zeroed in on one particular set of human behavior patterns that he thought exemplified his evolutionary theory of the origin of *Homo sapiens* particularly well, namely, the voluntary or involuntary expressions of emotional

feelings experienced by a person. Many of these expressions are easiest to understand if it is accepted that the progenitors of humans, be they anthropoid or subanthropoid, also experienced those emotional feelings and deliberately or involuntarily displayed those emotions using behavior patterns that would continue to persist, in increasingly diversified and modified forms, in the line of species that had evolved between those progenitors and present day *Homo sapiens*.

To take a simple example: When threatened or put into a situation where fighting might ensue, many dogs bare their teeth in such a way as to reveal their canines, and also depress their ears flat against their heads. Darwin postulated that the ear-depression was a movement designed to reduce the possibility that the ears would be bitten. Turning to humans, Darwin pointed out that we do not fight with our teeth, so our canines are not as large or as sharp relative to our other teeth as are those of dogs; and we have evolved the habit of turning our head, rather than our ears, toward the source of a novel sound, so that we have lost the ability voluntarily to move our ears in a variety of directions. Nevertheless, vestiges of our animal ancestry can be detected in the way we express certain human emotions that are more sophisticated than those possessed by dogs. One such emotion is that of disdain or contempt; one expression of this emotion is the so-called “sneer” or “snarl”; to reveal this feeling toward the person who has actually aroused our disdain or contempt, we turn back the lips at one side of the mouth only and slightly elevate the upper lip to reveal the canine tooth beneath it (Darwin 1872/1904, Plate IV). Darwin’s own account of this action is far more detailed in the exactitude with which he describes the facial muscles involved; and he noted that sometimes a dog, when pretending to fight, “draws up the lip on one side alone, namely, that facing his antagonist” (Darwin 1872/1904, p. 260). In his observations about human infants, Darwin had also noted that a “child does not sneer, because no young animal has [big] canine teeth” (Ghiselin 1973, p. 967).

Because it so well illustrated how the expression of an emotion by a human can reveal the multiple influences exerted by whether or not the muscles are moved voluntarily or involuntarily, and how each component of a set of movements can be shown to have originated at some point in the evolutionary sequence, we quote

in full Darwin’s summary of how it is that, following one or more experiences of loss, bereavement, or sadness, the so-called “grief” expression can come about in humans. In this expression, the transverse lines of the forehead are raised, but only in the region near the bridge of the nose, with the result that the inner parts of the eyebrows take on an oblique orientation near that location.

- ▶ Few points are more interesting in our present subject than the extraordinarily complex chain of events which lead to certain expressive movements. Take, for instance, the oblique eyebrows of a man suffering from grief or anxiety. When infants scream loudly from hunger or pain, the circulation is affected, and the eyes tend to become gorged with blood: consequently the muscles surrounding the eyes are strongly contracted as a protection: this action, in the course of many generations, has become firmly fixed and inherited: but when, with advancing years and culture, the habit of screaming is partially repressed, the muscles round the eyes still tend to contract, whenever even slight distress is felt: of these muscles, the pyramidalis of the nose are less under the control of the will than are the others, and their contraction can be checked only by that of the central fasciae of the frontal muscle: these latter fasciae draw up the inner ends of the eyebrows, and wrinkle the forehead in a peculiar manner, which we instantly recognize as the expression of grief or anxiety. Slight movements, such as those just described, or the scarcely perceptible drawing down of the corners of the mouth, are the last remnants or rudiments of strongly marked and intelligible movements. They are as full of significance to us in regard to expression, as are ordinary rudiments to the naturalist in the classification and genealogy of ordinary beings. (Darwin 1872/1904, p. 372)

The determinants of this expression of grief include the inhibition of habitual responses (the “partial repression” of screaming), the persistence into adulthood of the screaming of the infant, and the defensive contraction of the muscles surrounding the eyes in order to reduce an over-supply of blood to them. This last mechanism is described, elsewhere in the book, as playing a role in the development of weeping (the production of tears) as a response, not only to unhappiness, but also to elation (“he wept for joy”),

and in the course of laughter. Provine et al. (2009) have listed several reasons for why it might be that only humans weep, including the use of weeping as a signal. Darwin also noted that there were two emotional expressions that were peculiar to adult humans. One is the frown (expressing not only worry or disapproval, but also intellectual concentration). The other is blushing (when an act of self-attention is infused with a knowledge that other people are also attending to oneself at the same time; blushing is usually facial because the face is the body-part most obviously visible to onlookers).

Enough has been said to convince the reader that the human behavior patterns typical of the expression of the emotions can be seen to have evolved, often with surprising twists and turns, from the manners in which subhominid creatures express simple emotions such as fear, rage, and surprise. Characteristics that are giveaways concerning the antiquity of certain expressive movements are whether or not the infants of a given species share those movements, from the time of birth, with adults (for example, newborn and adult humans share screaming as a common response to pain, but not weeping); whether or not all, or only some, humans share those movements (for example, affection expressed by kissing, and agreement expressed by head-nodding, are not universal among humans, so are probably determined culturally rather than by inheritance); and whether or not a given set of movements can be controlled voluntarily by both ancient and modern varieties of a species (for example, Darwin speculated that the hominid ancestors of present-day humans could voluntarily vomit food that turned out to be unpleasant when eaten, whereas present-day humans become ill before involuntarily vomiting such food; Darwin thought that modern-day expressions of disgust might be vestiges of that ancestral habit). Incidentally, Sir Francis Darwin (1848–1925), the botanist son of Darwin who completed the editing of the posthumous second edition of Darwin's book, noted that Darwin himself may have queried this explanation after it had been published in the first edition (Darwin 1872/1904, p. 271, Footnote 12).

It is appropriate to mention here that Morris (1967) has surveyed a variety of human expressions of emotion from the same perspective as did Darwin,

but with the addition of more detail than is found in Darwin concerning the expression of emotions involved in human courtship and the human sex act. Morris made good use of the well-known evidence on human sexual responses provided by Masters and Johnson (1966). In discussing present-day social interactions, Morris stressed how the various expressions of aggression in animals (especially those of threatened animals) and of submission in animals (especially those adopted by animals low in a social hierarchy with a dominant male) have their modern counterparts in human behavior. A useful table showing that the social organization of different species of apes is surprisingly variable has been provided by Foley (1995, p. 185) and will be discussed again later.

The classification of the emotions had been a topic of discussion since antiquity; the writings of Hippocrates, Plato, Galen, and others were modified and crystallized into a theologically-based canon of Western psychology by St. Thomas Aquinas (1225–1273). Murray (1988, Chaps. 1 and 2) has summarized these characteristics and here it need only be stated that the emotions were divided into two major classes: those that were aroused in the originations of, and attempts to satisfy, particular desires (the so-called “concupiscent” passions) and those that were aroused when the execution of concupiscent-based actions were thwarted or frustrated (the so-called “irascible” passions). In their review of various modern attempts to classify the emotions, Nesse and Ellsworth (2009) give prominence to the view of Nesse (2004) to the effect that a phylogeny of emotions can be derived from a kind of arousal called “excitement” and another called “apprehension.” Excitement leads to desire and hope; apprehension leads to fear and anxiety. Other emotions fall naturally into place as the desires and/or fears are satisfied or blocked in the course of mating, kinship relations, alliance formation, and the preservation of social status (Nesse 2004, Fig. 2, p. 131). If Nesse's “excitement” is compared with Aquinas's “concupiscent,” and Nesse's “apprehension” is a counterpart to Aquinas's “irascibility” when a desire is thwarted, there is an unexpected convergence between the two.

As for the ways in which emotions are actually expressed by humans and animals, Hess and Thibault (2009) have shown how distinctions have been made

between a theory that stresses the communicative or “cultural” importance of expression of emotion (Darwin 1872/1904; Ekman et al. 1972), a theory that expressions of emotion are signals of behavioral intentions (Fridlund 1994), and a theory that stresses that expressions of emotions are signals of an animal’s appraisal of a situation (Frijda 2000; Scherer 1984). Darwin himself thought that “some expressions are what we might call signals, some are not, and that when they first originated, before they began to evolve, none were signals” (Ghiselin 1973, p. 965).

Darwin’s findings can be schematized as having been concerned with the *feelings* associated with emotions, with the *control* of those emotions, and with the *learning* of how to control both the intensity of the feelings and the unambiguousness of the expressions of those emotions. A brief digression is in order here. The idea of classifying mental characteristics under a few headings goes back to Greek and Roman times. For example, St. Augustine (354–430) argued that the three major faculties of the human mind were memory, understanding, and will; these were superimposed on a model of brain that stressed that inputs from the five senses were integrated there, elaborated using reason (humans) or inherited instincts (animals), and then stored as memories (Murray 1988, pp. 37–68). By the time of Immanuel Kant (1724–1804), St. Augustine’s division was being replaced by a more general scheme that still included inherited behavior patterns, but, with a few exceptions, excluded the idea that any kind of “knowledge” could be inherited. Kant, who was one of those exceptions (please see the section on Baldwin below), has been described by Murphy (1949, p. 404) as having concentrated on the distinctions between “feeling,” “willing,” and “knowing.” As academia slowly absorbed psychology into its curricula, this division became ingrained in the teaching of psychology; for example, Porter’s (1877) textbook entitled *The Elements of Intellectual Science* distinguished between three kinds of conscious state, namely, states of feeling, states of will, and states of knowledge, and so did many other late nineteenth-century textbooks of human psychology.

At the start of the twentieth century, the behaviorist movement, founded by J. B. Watson (1878–1958), emphasized the importance of learning in animal

and human behavior to such an extent that the possibility that behavior patterns could be inherited was more or less overlooked (except insofar as some simple muscular responses and glandular secretions were acknowledged to be “reflex”). The claims of McDougall (1908/1931, especially p. 333), who argued that feeling (“affective”) states, willing (“conative”) states, and knowing (“cognitive”) states had to be integrated into discussions of purposive and instinctive behavior, were widely known but under-appreciated. Tolman (1932), working within the same academic environment that had fostered the over-emphasis on learning theory, was eventually able to demonstrate experimentally that the behavior of rats in laboratory tasks showed evidence of purposiveness and of sophisticated forms of mental representation. This was among the first major breaches to be made in the behaviorist fortress.

The reason that this is mentioned here is that, in their histories of evolutionary thought in psychology, both Plotkin (2004, pp. 53–62) and Salmon and Crawford (2008, pp. 7–8) have asserted that evolutionary psychology almost vanished in Western universities during the behavioristic period covering roughly the years 1913–1950. Green (2009), however, has contended that this view of the history of evolutionary psychology is too black-and-white; the movement known as American “functionalism” maintained a pro-Darwinian position vis-à-vis the name and the nature of psychology over the first decade or so of the twentieth century. The fact that one of functionalism’s outcomes was Watson’s (1913) initial manifesto of the behaviorist ideology should not, according to Green, blind us to the importance with which evolutionary theory had been invested between about 1900 and 1913.

Romanes on the Evolution of Feeling, Willing, and Knowing in Animals and Humans

The division of the mind into compartments labeled feeling, willing, and knowing was an intrinsic feature of the first major attempt, following Darwin’s demise in 1882, to stipulate how natural and sexual selection could have combined, through geological time, to endow the various species of animals (including humans) with the abilities to feel, control, and amend

their emotions. Darwin had served as a mentor to a Canadian-born colleague, almost 40 years his junior, named George John Romanes (1848–1894); a new monograph about Romanes's life and letters is entitled *Darwin's Disciple* (Schwartz 2010). It was Romanes who undertook this enormous and challenging task. Romanes used the terms “the emotions,” “the will,” and “the intellect” for his tripartite classification of the mental abilities.

He drew a large chart showing how different species had evolved, from simple unicellular and multicellular organisms with very low levels of sensory discrimination and of neural mobility, to species whose diversity of emotions, whose level of control of the expression of those emotions, and whose increasing degrees of sophistication at habit-formation and at problem-solving would eventually attain the levels we associate with *Homo sapiens*. A special development in the realm of “intellect,” one that probably took place in the transition from early hominid species to present-day *Homo sapiens*, was the introduction of human language.

In order to have been able to construct this chart, Romanes had to collect reliable information about the behavior patterns associated with a large number of the known species of fauna; most of his evidence on insects could be drawn from the findings of experiments by entomologists, but most of his evidence on subhominid vertebrates had to be based on observations, made in zoo settings, household pet settings, farm settings, and natural outdoor settings, by authorities Romanes considered reliable, including missionaries, military personnel, professional breeders, and fellow naturalists. *Animal Intelligence* (Romanes 1882) documented these observations for species ranging from insects to dogs and apes. *Mental Evolution in Animals* (1883) drew from the observations reported in *Animal Intelligence* to construct those portions of the chart that applied to those subhominid animals. And *Mental Evolution in Man* (1888) filled in an empty portion of the chart, from the apes to humans, including separate discussions of the evolutionary origins of language and of self-consciousness. We may give a brief overview of the gist of this chart, which was published as a pullout in both *Mental Evolution in Animals* and in *Mental Evolution in Man*. The chart has been reproduced by Grinder (1967,

pullout facing p. 172), Boakes (1984, p. 29), and Murray (1988, pp. 266–267).

Romanes essentially reiterated Darwin's claim that the emotions experienced by humans were more influenced by experience and were more capable of being controlled than was the case for subhominid animals. Romanes contended that unicellular and multicellular marine animals (e.g., coelenterates, starfish) felt no emotions; the most primitive emotions, those of surprise and fear, first emerged in the larvae of insects and in the annelid worms; these, as well as the molluscs, probably also possessed sexual emotions, that were not, however, influenced by preferences based on sexual selection. Insects and spiders were the first to reveal parental affection, sexual feelings based on sexual selection, pugnacity, industry, and curiosity. Fish and batrachia showed jealousy, anger, and play, whereas “higher crustacea,” reptiles, cephalopods, moths, and butterflies were capable of affection and sympathy.

With birds, came the appearance of an aesthetic love of ornament, the use of imitation (called “emulation” by Romanes), and the emergence of pride; resentment and terror could also be experienced by birds. The carnivores, rodents, and ruminants are capable of feeling both benevolence and the “negative” emotions we call cruelty, hatred, and grief. Monkeys and elephants were claimed to add, to the above emotions, rage and revenge; and dogs and the anthropoid apes were claimed to add, to these emotions, shame, remorse, deceitfulness, and a sense of the ludicrous. It has now been confirmed that primates do indeed practice deception (Byrne and Corp 2004). On a psychological scale purporting to measure the level of attainment of the “products of emotional development,” Romanes judged dogs and anthropoid apes as having a rating of 28 on a scale of 1–50. Ancestral hominid species were rated as being between 31 and 37, while humans ran a gamut from 37 to 49.

No breakdowns in terms of separate words or names were given of the evolution of individual levels of voluntary control over movement, non-endocrine secretions, or expressions of emotions; the levels of control were simply presumed to be lower in invertebrates generally than they are in vertebrates, with humans having the highest rating.

Romanes's analysis of the evolution of intellect was prescient. Very broadly, the simplest unicellular and

protoplasmic organisms have “excitability,” that is, they are able to move (using non-neural mechanisms) in certain environments. Among the earliest appearances of sensory nerves, along with motor nerves, are those found in jellyfish (who respond to a sensory stimulus with their whole body) and in starfish (who respond to a sensory stimulus with only part of their body, such as an arm). Romanes’s experimental research on this topic led Lesch (1976) to consider him a pioneer in the discovery of the synapse. To Romanes’s heading of “sensation,” which Romanes thought was probably first found in extinct coelenterates, were added various products of learning and of cerebrosplinal elaboration. So, to “sensation” were added “perception” (first found in molluscs, then in insects and spiders), “imagination” (first found in fish and batrachia), and, first found in the other animals listed above, “abstraction,” “generalization,” and “reflection and self-conscious thought.” Romanes’s usages of these terms will now be described.

Along with “sensation” in the coelenterates and echinoderms appeared pleasure and pain. Along with “perception” appeared memory and association by contiguity; Romanes’s claim is in agreement with modern research on habituation and on classical conditioning in the marine mollusc *Aplysia* (Kandel 2006). Along with “imagination” appeared the recognition of offspring (insects and spiders), association by similarity (fish and batrachia), reason (higher crustacea), recognition of individuals (reptiles and cephalopods), and the communication of ideas (butterflies and moths). According to Romanes, birds can recognize pictures and respond to words of command. Carnivores, rodents, and ruminants can “understand mechanisms,” that is, manipulate objects in order to change the location of those objects, a pre-requisite for the solution of many problems in laboratory settings. Under the heading “abstraction” appears the use of tools by monkeys and elephants and an “indefinite morality” attained by dogs and anthropoid apes.

At the same time, Romanes suggested that the above stages of cognitive development in animals were recapitulated over the first 15 months of a human’s life. But older children can go on to develop what Romanes called “generalization” (which here refers to concepts of the kind often referred to by abstract nouns) and “reflection and self-conscious

thought” (the “self-attention” Darwin had referred to in his analysis of human blushing behavior).

In his third book, Romanes went on to show how language could have evolved in the course of speciation whereby *Homo sapiens* had evolved from hominids and subhominids. Romanes’s theory of language is here presented in oversimplified form; but it too incorporated the assumption of a recapitulation, during a human child’s growth from infancy to the age of about 5, of the stages by which language had evolved across subhominid and hominid species.

Romanes saw the evolution of human language as progressing in intimate association with the progression of two other intellectual capacities along the lineage leading from subhominid animals to *Homo sapiens*. One of these capacities concerned the ability to learn; the other concerned the ability to experience self-awareness. What we, as human adults, call “mental states” varies in clarity from sleep-states involving no conscious experiences (other than occasional dreams), through intermediate half-waking states which, with Romanes, we here deliberately call “vague” states of conscious awareness, to the full-blown clarity of those conscious states we describe variously as “waking,” “alert,” “aroused,” or “self-aware.” For Romanes, a complex human language is only available to organisms who are capable of memorizing a large number of words, whose vocal apparatus is capable of pronouncing a large number of phonemes, and whose consciousness is capable of taking on an immense variety of potential mental states, many of which can be communicated verbally to others who share most or all of that same kind of consciousness.

From the learning point of view, we have already seen how Romanes ascribed habituation and learning by contiguity to creatures as simple as molluscs, and learning by similarity to vertebrates such as fish and frogs. What the word “learning” means, at least in most of the animal literature, is that a stimulus that would normally elicit an unlearned response such as surprise or fear can, through repetition or even one-time experience, come to elicit no surprise or anxiety; on the other side of the coin, stimuli that normally elicit responses indicative of pleasure or of insouciant curiosity, can, through repetition or even one-time experience, come to elicit avoidance responses. Typical of the latter is the way in which

birds can learn to avoid pecking at caterpillars following just one unpleasant experience with a bitter-tasting morsel. Let us completely ignore the behaviorist advice that we can avoid the charge of anthropomorphism by not speculating about an animal's presumed feelings of "consciousness," and say that the bird *is* "aware" in what we deliberately describe as a "vague" way, that the particular sense-data associated with that particular species of caterpillar should be appropriately followed by behavioral responses that do not include pecking at that caterpillar. Then we can say that the stimulus that consists of the sight of that caterpillar has acquired the potential to lead to a range of responses none of which were subsumed under the range of neutral, or interest-aroused, responses associated with inexperience with that class of stimuli. But because the bird's "conscious" level of awareness is presumed to be "vague," the learned association between the caterpillar and "not pecking" was given, by Romanes, its own special name; it is a "receptual" association. Had a human learned that a particular brand of chocolate ought not to be purchased because the chocolate contained an allergen or was too hard-centered for the human's taste, the association between the brand and "not buying" would have been given, by Romanes, the special name of "conceptual" association. The human's presumed "conscious" level of awareness of this association is "clear" (as opposed to "vague"), and the association can be clearly communicated verbally to other humans who share his or her language.

For Romanes, the origins of language development proceeded phylogenetically in lockstep with a transition from animals and hominids capable of acquiring "receptual" associations to *Homo sapiens*, who, in infancy, can only acquire receptual associations, but, in early childhood, can grow to acquire conceptual associations as well. Communications between animals have been listed by Wilson (1975/2000, Chap. 10) as being chemical, tactile, surface-wave, visual, electrical, and auditory. The earliest auditory communications between animals were the emission of sounds, usually involuntary, but, as the brain grew in complexity, could have become voluntary, for example, a bird-call serving as a warning-signal to its young. Among hominids, warning-cries and other signals were probably complemented by communicative gestures, and by

sounds that imitated natural phenomena (such as the roar of a lion, or a clap of thunder) or consisted of rhythmic chanting for marching or other repetitive work. Knobloch (1988) has summarized the history of such ideas in Germany prior to Wundt's (1921/1973) exposition of his version of the gesture theory of the origins of human language; Murray (1990a) has reviewed Knobloch's book and summarized its contents.

Romanes, while not denying the usefulness of these theories, preferred to stress that individuals among *Homo sapiens*, who had evolved a throat- and tongue-musculature that was capable of enunciating many more sounds than could be produced by any other species of primate, started, when they were infants, by using the rudiments of verbal communication in contexts where receptual associations were acquired; for example, a child just beginning to learn to talk could ask for something present-in-the-here-and-now (for example, some milk visible on the table), not only by pointing to it but also by emitting a word such as "Mama" or "milk." After the child has developed the ability to mentally represent things-not-present-in-the-here-and-now, the child could use the word "milk" to ask for milk when none was visible; and the growth of conceptual association-forming would lead the child to construct multiword units such as "milk cold" and later to construct sentences such as "this milk is cold" if his request for milk had been satisfied. The final stage in the acquisition of language by conceptual association-forming is when the child has developed a self-concept, and so can say "I want you to bring me some milk." When the child has reached the conceptual level of mental representation, growth in linguistic skill does not have any parallels in subhominid animals, and is closely related to the growth of the child's degree of self-awareness.

Three points need to be made immediately about the foregoing account. First, in simplifying the argument for the purposes of this entry, many distinctions and subdivisions made by Romanes, in his theory of the evolution of language, have been omitted.

Second, Romanes's distinction between receptual and conceptual associations has an important present-day parallel in the distinction now being made by evolutionary psychologists between

“primary” and “secondary” mental representations. In most animals, and in very young children, any representations of events in the external world are based on the presence of those events in the here-and-now and are called “primary” representations. If a ball rolls under a sofa, the child behaves as if the ball had vanished (“out of sight, out of mind”). An older child, however, as well as many vertebrates with a high level of cerebral development, can behave as if they were aware that the ball still existed, but was merely hidden from view by the sofa. So a human child will scabble with her hands, or even with a stick, under the sofa, hoping to retrieve the ball. The child has a mental representation of the continued existence of the ball, even though the ball is absent from the visible contents of the here-and-now. Such a representation is called a “secondary” representation. In his pioneering work on how children acquire social skills and their versions of what is popularly called a “theory of mind,” Perner (1991) introduced the distinction between primary and secondary representations; and the degree to which the distinction has been adopted is exemplified by the following title of a journal article: “Mental evolution and development: Evidence for secondary representation in children, great apes, and other animals” (Suddendorf and Whiten 2001). This article summarizes findings by late twentieth-century evolutionary psychologists that essentially corroborate Romanes’s postulate that humans, hominids, and perhaps apes, monkeys, dogs, and elephants can mentally represent events not taking place in the here-and-now. According to Romanes, the evolution of this ability laid a foundation for the evolution of spoken language in *Homo sapiens*, who, alone among organisms, has a vocal apparatus capable of making the many sound-producing articulations necessary to support such a language.

Third, this theory of Romanes’s (1888) about the evolution of human language has been almost completely forgotten in the later literature. None of the late twentieth-century writers on the evolution of language mention it; these writers include Donald (1991, 2001), Kirby (2007), MacNeilage and Davis (2005), and Perner (1991). Corballis (1991, pp. 16–17) briefly mentioned Romanes’s (1883) chart but made no attempt to deal with Romanes’s (1888) theory of the evolution of language.

This completes our summary of theories about how human psychology, especially the psychology of emotional expression and of cognitive development, could be integrated into the new Darwinian formulation of the animal kingdom and how it had evolved. Central to that evaluation were the mechanisms of natural selection and sexual selection. But, before the nineteenth century came to a close, advances in child psychology led James Mark Baldwin (1861–1934) to speculate that children who were specially adept at acquiring new skills might have also have inherited that adeptness; and Romanes himself, who, like his contemporaries, knew little about the physiological transmission of heredity, contributed to the discussion of evolution a new form of selection based on some ideas about that little-known physiological transmission, ideas that have never received, till the twenty-first century, the attention they deserved. Baldwin (1896) postulated what he called “organic selection,” which had to do with the adaptive value of the degree of readiness-to-learn in given individuals within a species. Romanes (1886, 1897) postulated what he called “physiological selection,” which had to do with anomalous physiological characteristics possessed, by chance, by both conspecific parents at the time of conception.

Baldwin’s “Organic Selection”

Baldwin had a strong background in the non-Kantian empiricism of the Scottish “common sense” school (Murray 1988, pp. 121–124) and the British associationist school (Murray 1988, pp. 137–161). This was in part because one of his earliest instructors was James McCosh (1811–1894), who served as the President of Princeton University between 1869 and 1888 and who wrote a book about the Scottish school during his tenure there (McCosh 1875). Kant is mentioned here because, as O’Keefe and Nadel (1978) have suggested, he was a proto-evolutionist who believed that the brain/mind system of every animal was geared to mesh with its environment in order that the animal survive. For example, birds can fly, with little in the way of formal instruction, without collisions except in illusion-inducing circumstances. Baldwin, however, felt that this meshing of gears vis-à-vis an animal and its environment must necessarily have been acquired by an evolutionary process, one that had extended over

the previous generations of the animal's lineage (a "phylogenetic" process) but one that could also operate within an animal's own experience (an "ontogenetic" process).

A study of his own children convinced Baldwin (1895) that a child had to learn to acquire an understanding, not only of how his or her environment can be influenced by his or her voluntary actions (such as when a child reaches out to grasp an object), but also of how other humans, children or adults, would respond to his or her own voluntary actions (such as when the child asks a person for an object). Baldwin asserted that the acquisition of this understanding involved a series of ever-advancing feedback-loops. For example, the child would do action *A*, the environment would be changed, and the child's mental representation of the environment would be modified; next time the child did *A*, a modification of *A* would suit the child's changed representation of the environment. To illustrate this process using a concrete application: If action *A* consists of the child's moving a cup nearer to herself, the child would mentally represent the cup as being nearer, and the next time the child reached for the cup, the child would reach a shorter distance than had been the case when she first reached for it. Advancement in dealings with other people would follow a similar pattern, leading to the child's developing a theory of mind that facilitated the child's social development. An important component in these learning-by-results processes is the incorporation, into the child's repertory of behavior patterns, of certain acts that had been acquired by imitation; imitation would be especially important in language acquisition and in cooperative play with other children in which toys were interchanged. This theory of the development of child cognition is, of course, a historical antecedent of that associated with the name of Jean Piaget (1896–1980), a matter discussed by Cahan (1984). It also shares elements with the views of Perner (1991) mentioned above. As will be explained below, our modern understanding of learning by imitation is also being strongly influenced by the late twentieth-century discovery of "mirror neurons."

But, if Baldwin's approach were to be considered a plausible extension, to human behavior, of the evolutionary processes that had been applied, by Darwin and Romanes, to animal behavior, there would be

a need for a new mechanism of selection to be added to the categories of natural and sexual selection. This new kind of selection would have the adaptive consequence of favoring, in the breeding process, those individuals who could adjust most successfully to new situations, where, by "adjusting successfully," we can include the remembering and subsequent and modified performance of intended movements, such as reaching and grasping, and vocalizations such as requests (what Skinner 1957, called "mands") or verbal expressions concerning the infant's primary and secondary mental representations (what Skinner called "tacts"). Any infant (of any species) who was more efficient at adjusting his or her behavior in a world that responded to their movements and vocalizations (animals), or to their movements and utterances (humans), would, it was postulated, possess genetic characteristics that reflected this adjustability or readiness-to-learn; and so, in the course of evolution, those individuals who were most successful at responding to an always changing environment would be favored.

Baldwin (1896) called this "organic selection," although it later came also to be known as the "Baldwin effect" (Weber and Depew 2003). Gottlieb (1979) has placed organic selection into a context of evolutionary theory generally; Wozniak (1998) has traced in detail Baldwin's progression from child psychology to evolutionary psychology; Plotkin (2004, p. 83) has stated that Baldwin is the only psychologist to have exerted an influence on evolutionary theory in a specialist sense of that term; and Kirby (2007) has stressed that the Baldwin effect is consistent with complex dynamical systems each of which operates on a different time-scale, namely, individual learning, genetic selection (especially of language), cultural transmission, and biological evolution. Baldwin arranged for his collected papers on evolution to be published, conveniently, in book form (Baldwin 1902).

Baldwin was also among the first to discuss what is currently called "evolutionary epistemology" (Plotkin 2004, pp. 83–88; Wozniak 1998, pp. 449–451); it is a close relative of "genetic epistemology" (Inhelder 1998). The word "epistemology" refers to a theory of knowledge and, here, has a specialized connotation concerning the growth of knowledge within an individual's lifetime; Baldwin's theory of how a child

acquired her knowledge by a series of feedback-loops can be interpreted as a theory according to which successful actions persist in, and unsuccessful actions drop out of, the repertory of behavior patterns acquired as the child ages. This obvious analogy with evolutionary “successes” (adaptations leading to reproductive success) and “failures” (adaptations leading to reproductive failures) as geological time advances led Herbert Spencer (1820–1903), one of Darwin’s first adherents, to claim that the persistence or dropping out of habits, depending on the “success” or “failure” of those habits with respect to the individual’s well-being, could be described as an ongoing transition from a “homogeneity” of potential behavior patterns in the neonate to a “heterogeneity” of established behavior patterns in the elderly (Spencer 1855/1890).

Other examples of this approach in the recent literature on intraindividual development include the application of dynamic systems theory to cognitive development in the child (Lewis 1995) and the extension of a Darwinian approach to individual sequences of neural events that can persist or drop out depending on the benefits they can confer on normal neurophysiological processes (Edelman 1987). Murray and Farahmand (1998) have pointed out that the Gestalt psychologist Kurt Koffka (1886–1941) presented a view of child cognitive development that anticipated the dynamic systems approach (Koffka 1921/1925).

The behaviorist J. B. Watson presented a chart of the conditioned reflexes he presumed to be acquired by a typical child during the first 6 years of his or her life (Watson 1924/1930, p. 138); whether a given item of behavior was rewarded or punished determined its longevity within the hierarchy of habits attained by the child. This is as valid an example of “evolutionary epistemology” as are others in the above list; where Watson differed from those others, however, was in his downplaying of purposiveness in animals, and of mental imagery in humans, as contributors to the ontogenetic development of problem-solving ability. Also in the behaviorist tradition is the account given by Homans (1961), who provided a Skinnerian analysis of the development of human social behavior within a human’s lifetime in terms of what behavior patterns have been socially rewarded and therefore repeated. The sociobiologist E. O. Wilson has contended that

the word “reward” can be defined as the “set of all interactions defined by the emotive centers of the brain as desirable. According to evolutionary theory, desirability is measured in terms of genetic fitness, and the emotive centers have been programmed accordingly” (Wilson 1975/2000, p. 551).

Romanes’s “Physiological Selection”

Darwin, in discussing the use by humans of a shoulder-shrug to express a sense of powerlessness or inability to improve a situation, had referred to a case history communicated to him by a “medical professor” (Darwin 1872/1904, p. 277). According to Darwin, the low level of demonstrativeness displayed by English men and women as compared with that of other European people implied that shoulder-shrugging should be less common in England than on the Continent. In the case in question, a gentleman we here name X, for convenience, had a French father and a British mother. X married a lady, both of whose parents were British. Their two children were reared in Britain, with the assistance of a British nursemaid. Neither X’s wife nor the nursemaid showed any inclination to shrug their shoulders; X himself did so only occasionally, especially when arguing with somebody. But both of X’s children shrugged their shoulders as infants, with the habit dropping out when the children were about a year and a half old. Moreover, both children had a strong physical resemblance to their French grandfather. When that grandfather had wanted something immediately, he had indicated his impatience by rapidly rubbing his thumb against his index and middle fingers; neither X nor his wife used this gesture; but both of X’s children did display it, even though they had never met their grandfather.

This case demonstrated that there was more of a resemblance, with respect to this voluntary gesture, as well as to shoulder-shrugging, between the grandfather of X’s children and X’s children than there was between X and X’s children. For present-day evolutionists, the interesting feature of this case is that a behavior pattern, rather than an anatomical or physiological characteristic, appears to have been inherited; but, for Darwin’s generation, another interesting feature was that children could, in some cases, inherit a characteristic more typical of their grandparents than of their parents.

The explanation of this riddle we owe, of course, to Gregor Johann Mendel (1822–1884), who had studied sweet peas that he grew in his monastery garden in experiments that ultimately led to what we now call the “Mendelian laws of heredity.” These are most often taught to students using examples such as the inheritance of eye color, or Mendel’s own experiments. Using the latter method, Cock and Forsdyke (2008, pp. 205–206) show how Mendel’s experimentation had demonstrated that a characteristic that is not expressed by the first generation of offspring can nevertheless be expressed by the second generation. Mendel had reported this research in 1865, 6 years after the publication of *The Origin of Species* in 1859; but it lay, almost unread, until the work of H. M. de Vries (1848–1935) and others led to its rediscovery in 1900. In Britain, the mathematician W. F. R. Weldon (1860–1906) provided an accurate but critical account of the Mendelian laws of heredity (Weldon 1902), and William Bateson (1861–1926) proposed that the new specialization in science that included the study of heredity and of evolution be named “genetics” (Cock and Forsdyke 2008, p. 248). Moreover, according to these authors, “Bateson was the first to show that Mendel’s laws apply to animals as well as to plants” (Cock and Forsdyke 2008, p. xviii).

But a controversy over the scientific value to be attached to those observational and experimental situations that reported frequencies of genetic features that did not exactly match those predicted by Mendel’s laws led to a rift in the fledgling community of geneticists between a group consisting of Sir Francis Galton (1822–1911, a cousin of Darwin), Karl Pearson (1857–1936) and others, and a competing group consisting of Sir Ronald A. Fisher (1890–1962) and his supporters. This fascinating story is told by Cock and Forsdyke (2008, pp. 197–294), and Plotkin (2004, pp. 62–69) indicates that, because the Galton group were in favor of eugenic engineering to improve society, the resulting dislike, by many social scientists, of the Galton group led to a rather sudden loss of interest in the pursuit of the evolutionary psychology that had been set on such a firm foundation by Darwin, Romanes, and Baldwin. An account of the eugenics movement that relates it to the ongoing movements in genetics is given by Cock and Forsdyke (2008, pp. 419–438).

But we are ahead of ourselves. Back in the 1880s, around the time of Darwin’s death in 1882 and the appearance of Romanes’s books on the evolution of cognition, little was known about the physiological mechanism underlying intergenerational inheritance. Darwin had invented the word “gemmule” to refer to this hypothesized mechanism; Romanes had adopted the word “germ-plasm” from the biologist A. F. L. Weismann (1834–1914), who was among the first to demonstrate that physiological characteristics acquired by an individual prior to becoming a parent were not passed on to the offspring of that parent. For Romanes, the germ-plasm denotes the unknown carrier that took information from the parents and transmitted it, via the sperm and the ovum, to the offspring. One of the difficulties with both natural selection and sexual selection was that they both seemed too “slow” to produce new species (as opposed to varieties) very often in the course of geological time.

Romanes’s postulated “physiological selection” offered a partial solution to that problem. According to Romanes, it could be that an accidental (unpredictable) variation could arise in the germ-plasm of a male which could be matched by an identical, or highly similar, but equally accidental, variation in the germ-plasm of a conspecific female. If this male mated with that female, the offspring would be fertile (as opposed to sterile, which usually occurs when the male of one species mates with a female from a different species). Moreover, the first generation resulting from this mating could have physical and/or behavioral characteristics so different from the corresponding characteristics in the parents, that the first generation could not readily be classified as a normal “variation,” or even as a “variety” of the parents’ species, but instead might plausibly be classified as being the first generation of a new species. That even a minor variation in the first generation could actually persist (rather than be eliminated) in later generations had been proved, using probability theory, by Delboeuf (1877/2010).

Although Romanes’s speculation was ignored for some 100 years after he put it forward, Forsdyke (2006) has argued, in fine detail, that physiological selection can be considered to be a precursor of a new hypothesis about hereditary transmission, one that is currently being evaluated by experts in evolutionary bioinformatics. The hypothesis is that phenotypes

(those observable characteristics of a species that are inherited as opposed to acquired) are not restricted to the conventional kind that has evolved as a consequence of natural selection. They can also include “genome phenotypes” that have evolved as a consequence of the operation of physiological selection. Watson and Crick (1953) had reported that genetic information is coded by individual “base pairs” (adenine-bonded-by-hydrogen-with-thymine, cysteine-bonded-by-hydrogen-with-guanine) that join the two sides of the twisted “ladder” of the DNA molecule like individual rungs. Through a process too detailed to describe here, a sequential pattern of base pairs can be transcribed onto an RNA molecule, and that pattern can later serve as a code for the assemblage of a protein molecule. Protein molecules constitute the building blocks of many cells and also assist in many of the chemical processes involved in the total work of getting from the original DNA molecule to the cells of the offspring-organism that results from the uniting of the DNA from the mother with the DNA from the father.

There have been at least two surprising discoveries about the length of human DNA molecules, where the “length” of a DNA molecule is measured by the number of base pairs each DNA molecule contains. First, despite the fact that humans are cognitively very much more advanced than are amoebae or lungfish, human DNA molecules contain *fewer* base pairs than do the DNA molecules of some apparently simpler animals. The length of a DNA molecule seems to be determined by the properties of the environment in which the organism lives, especially if extremes of temperature or of humidity are present (Watson 2003, p. 204).

Second, it is not the case that *every* base pair on a DNA molecule carries information that will mediate the encoding and production of the conventional phenotypes of an offspring-organism; only a fraction of the total number of base pairs on a DNA molecule can be called “genic.” This means that a typical human DNA molecule may have only a small percentage of its total length that is genic, the remaining portion being apparently “non-genic.” In the nucleus of a typical human cell (of any kind), there are 23 pairs of chromosomes, with each member of each pair containing its own complement of DNA; and “From

measurements of the amount of DNA in a single cell, we have been able to estimate that the human genome – half the DNA contents of a single nucleus – contains some 3.1 billion base pairs” (Watson 2003, p. 165). Of these, just over 35,000 base pairs are genic.

The near-billion remaining base pairs have been called “junk” (Watson 2003, p. 197); on the other hand, they may be precursors of strands of DNA resembling viruses (Dawkins 1976/2006, pp. 245–248); and, very recently, Barash et al. (2010) have observed that very few genic base pairs might actually determine what happens to very many of the apparently non-genic base pairs. The genome phenotype theory outlined by Forsdyke (2001, 2006) and by Cock and Forsdyke (2008) is able to assign properties to those so-called non-genic base pairs, properties that turn out, in fact, to assist in the transmission of heritable information from the parents’ DNA to the offspring’s DNA. The theory can also explain how a new species can arise more rapidly than would be the case if natural selection were the only determinant of what gets transmitted.

1900–1975: A Theoretical Background for Evolutionary Psychology

As noted above, there was a hiatus between about 1910 and 1960 in the study of evolutionary psychology because of the fear of eugenics and because of the dominance of behaviorism. In the discipline of genetics, the period between about 1910 and 1920 was dominated by experimentation, led by T. H. Morgan (1866–1945), on the means whereby chromosomes could mediate the transmission of inherited characteristics from the two parents to their offspring.

Morgan had used the word “gene” to specify the unknown factors contained in a chromosome that mediated the transmission of phenotype from parent to offspring. The 1943 edition of *Chambers’s Twentieth Century Dictionary* defined a gene as “a material unit whose transmission determines (along with other conditions) the inheritance of a given quality” (Davidson 1901/1943, p. 1232). Dawkins (1976/2006) has expressed his preference for Williams’s (1966) definition of a gene as “any portion of chromosomal material that potentially lasts for enough generations to serve as a unit of natural selection” (as cited by Dawkins 1976/2006, p. 28). Morgan’s (1926) book entitled *The Theory of the Gene* described the findings

he had obtained by breeding fruit-flies over several generations; the fact that fruit-fly cells only had four chromosomes made it possible to establish that some inherited phenotypes were linked together as if the corresponding genes had been linked on the same chromosome. Morgan considered that “mutations” arose when the two *copies* of a chromosome break apart and recombine during the “crossover” phase of the manufacture of sperm cells and egg cells. We now understand that a mutation can arise when one base of a base pair is miscopied during the recombination process (Watson 2003, p. 54).

Mathematics had been introduced into evolutionary theory by Delboeuf (1877/2010) and into population genetics by Galton, Weldon, Karl Pearson, and others influenced by developments in inferential statistics and by Galton’s (1888) introduction of the basic concept of statistical correlation. The period from about 1920 to about 1960 introduced mathematics into population ecology. Sewall Wright (1922), having introduced a single number, a “coefficient of inbreeding” that indicated the extent to which individual cattle were purebred, also introduced a “coefficient of relatedness” that would later be popularized by Hamilton (1964a, b). Fisher (1930) explained why the ratio of males to females among the offspring of many vertebrate species that reproduced sexually was about 50/50. Darwin (1871/1899, pp. 242–260) himself had devoted much energy to confirming the 50/50 balance in various vertebrate species. Sewall Wright (1931) showed that, in animal populations, random factors operating during the “crossover” phase of the interaction between copies of the same chromosome during the manufacture of a sperm cell or ovum can have a much greater influence when the population is small than when it is large. Waddington (1957) emphasized how a radical change in environment can favor the presentation of phenotypes that had been genetically determined, but not yet expressed, in individuals who were unusually resistant to the negative effects of that change. If the change persists, the exceptional genic information possessed by that individual would eventually be propagated throughout most of the population. This process of “genetic assimilation” was asserted by Wilson (1975/2000, p. 72) to be consistent with the Baldwin effect.

The period from about 1960 to 1980 was also a period in which new mathematical approaches were introduced into population ecology, but now most of the innovations were inspired by studies of insect populations. When the explanatory value of these quantitative approaches to insect populations became apparent, those same approaches were applied to vertebrate, including human, populations.

The two copies of the chromosome that determines the development of the sperm cell and ovum (in humans, chromosome #23) are labeled XX if a female reproductive cell (the ovum) is to be produced, and XY if a male reproductive cell (the sperm cell) is to be produced. In some insects, notably ants, the two copies of the corresponding chromosome are labeled XO, meaning that there is no chromosome copy equivalent to the Y chromosome copy seen in vertebrates. Making use of this anomaly, Wilson (1971) was able to explain why it should be that, in ant societies, one outsize female “queen” and one or more fertile males (“drones”) could produce a large number of “worker” offspring who themselves would never become parents. Later, Trivers and Hare (1976) showed that, if a majority of males were sterile and, therefore, not competing for females, a pattern of altruistic cooperation between individuals could emerge in a colony, leading to a kind of society named “eusocial” by entomologists. Eusocial societies have three aspects: individuals cooperate in the caring of the young; there is a division of labor with respect to reproductive behavior (for example, sterile males work on behalf of fertile males); and there is an overlap of at least two generations of individuals capable of this kind of cooperation for the good of the colony. Some of these characteristics are also typical of vertebrate “bearing and caring.”

Wynne-Edwards (1962) had argued that many species display altruistic behavior. Because altruism by definition included interactions between individuals who belong to groups, it would follow that any adaptations consequent to changes in altruistic behavior could be thought of as natural selection operating, not just on individuals, but on groups. Wynne-Edwards’s theory of “group selection” was, however, criticized by Maynard Smith (1964) as being less applicable in Nature than was a theory that specified that altruism was preferentially shown toward

an individual's kin; and Williams (1966) integrated various criticisms of group selection theory into a book-length argument, and also collected many of the articles mentioned here into a book of readings entitled *Group Selection* (Williams 1971).

Hamilton (1964a, b) argued, on quantitative grounds, that there would be a genetic advantage for the species if altruism were more likely to be demonstrated by an individual toward a close relative rather than toward a non-related individual. He hypothesized that the probability of altruistic behavior would decrease, with a proviso now to be mentioned, as the proportion of genes shared between the two individuals decreased. The proviso is as follows: within any species, some 90% of genes are shared; so the proportion of genes shared that are uniquely concerned with kinship will be below some 10%. Hamilton utilized the coefficient of relatedness, r , that described the probability that two related individuals would share a gene for an individual trait, over and above the 90% already shared. The crucial point to be noted is that the value of r for any given degree of kinship is not the same for insects as it is for vertebrates. Wilson (1975/2000, p. 416) provided a table, based on findings by Hamilton (1964a, b) and Trivers and Hare (1976), showing that the value of r relating an insect-mother to her daughter is 1/2; it is also true that the value of r relating a human mother to her daughter is 1/2. But the value of r relating an insect-mother to her son is 1.0, whereas the value of r relating a human mother to her son is 1/2.

Hamilton (1964a, b) used the appropriate values of r to calculate what was called the "inclusive fitness" of a social interaction between two individuals. His hypothesis was that "A genetically based act of altruism, selfishness, or spite will evolve if the average inclusive fitness of individuals within networks displaying it is greater than the inclusive fitness of individuals in otherwise comparable networks that do not display it" (Wilson 1975/2000, p. 118). By "inclusive fitness" is meant a measure of how two individuals can both benefit from an altruistic act, and the measure incorporates r .

It was realized, however, that any given altruistic act might involve costs as well as benefits. For example, the vervet monkey has a pronounced alarm call which benefits others by warning them of danger but exposes

the monkey itself by revealing its whereabouts (Gazzaniga 2008, p. 61). A form of mathematical analysis that is especially appropriate for the calculation of costs and benefits to two interacting individuals is game theory, which had been first applied in a biological context by Lewontin (1961). Maynard Smith (1972) later applied this approach to conflicts in humans; Maynard Smith and Price (1973) demonstrated its value when applied to animal conflicts; and Maynard Smith (1977) applied game theory to a specific case of "reciprocal altruism," a name that had been fruitfully applied by Trivers (1971) to cases in which two individuals cooperate in such a way that the inclusive fitness of both is increased. The specific case was that of parent/infant nurturance, where there is little question as to the benefit obtained by the infant, but where there can be a cost to the parent in terms of the time and effort invested in the feeding. Zahavi (1975) applied game theory to the problem of mate selection, which involves costs and benefits to both partners.

Much later, Zahavi (1995) argued that theories of group selection, kin selection, and reciprocal altruism all had their limitations, and that a better alternative was a theory that emphasized that altruistic behavior, no matter to whom it was displayed, also had a benefit for the helper. In fact, the value of "doing good" for the reputation of the helper had been stressed by Darwin (1871/1899, Chaps. 4 and 5) himself, who, in the words of Ghiselin (1973), had affirmed "that a "moral sense" had evolved. But since it furthers the competitive ability of the individual and his family, an "altruistic" act is really a form of ultimate self-interest" (p. 967).

Other evidence obtained in experiments concerned with human social interactions, led to the surfacing, in studies both of human and of animal conflict situations, of evidence that, within a population, there might evolve a common "Evolutionarily Stable Strategy" (ESS) with a genetic basis. In more problematic situations, however, there might emerge, within a population, two or more competing strategies. Separate groups of individuals might each prefer their own strategy for dealing with a conflict situation. Mate selection, sibling rivalry, male desertion, and the division of foodstuffs and other assets between individuals are all examples of conflict situations in human

societies where different strategies of conflict resolution for different individuals may have evolved. Some of these conflicts and these strategies will be mentioned again.

Standing back, it can be seen that the study of social behavior in insects in particular has led to what was earlier called a “gene’s eye” view of evolution. This view was epitomized in two classic works: Wilson’s *Sociobiology: The New Synthesis* (1975/2000) and Dawkins’s *The Selfish Gene* (1976/2006). Many investigators believe that both books remain solid foundations for present-day evolutionary psychology as it applies to humans. In the first edition of *Sociobiology*, the chapter on animal communication paved the way for the study of human communication when Wilson showed that gesture communications could include a range of about 10–20 separate movement “signals” in insects (including the “waggle dance” of honeybees), about 16 in fish (including the “zigzag dance” of the ten-spined stickleback), about 21 in birds, about 25 in mammals, and from 150 to 200 in humans; but humans can also communicate verbally, using between 20 and 60 phonemes (Wilson 1975/2000, pp. 184–185). In the second edition of *The Selfish Gene*, it was shown that eusocial colonies are not restricted to insects, as had been thought in the 1970s; on the dry Uganda/Kenya/Ethiopia borderlands, a recently discovered species of mammal, named the naked mole rat, lives underground in huge colonies and, like colonies of social insects, each colony has a single queen mole rat who breeds only with two or three males. All the other males are sterile; and the work of the smallest males includes digging the burrows and feeding the young (Dawkins 1976/2006, pp. 313–316). It is probable that these animals became naked in order to keep cool (Foley 1995, p. 142).

A historical account of the events discussed in this section, covering the period from 1920s to the 1980s, has recently been provided by Harman (2010). In *The Price of Altruism*, Harman weaves his narrative around the life of George Robert Price (1922–1975), who contributed substantially to the mathematical treatment of kinship theory, before disappearing from academia. Price’s treatment posited that group selection was one possible, but not necessary, determinant of the persistence of altruistic behavior down generations.

1975–2010: Current Trends in Evolutionary Psychology

What began as the study of eusocial insect colonies has led, in roughly the manner described above, to the study of the evolution of human societies, in which cooperative activities, resolutions of conflicts, strategies for competitive survival, and devices for the detection of wrongdoing, are commonplace features. Any evolutionary account of human behavior must, of necessity, treat human beings as members of the group of primates; the primates evolved later than many other orders of mammals, around 60 million years ago (MYA). The first primates to evolve were the ancestors of the modern lemurs, lorises, and tarsiers; the New World monkeys and the earliest hominoids emerged around 40 MYA. The Old World monkeys and the gibbons arose about 25 MYA and the orangutans, gorillas, and chimpanzees emerged between 11 and 2 MYA. About 2.4 MYA, *Homo habilis* had evolved; he was succeeded by *Australopithecus sediba* and then by *Homo erectus* about 1.8 MYA. From *Homo erectus* emerged two lines, namely, Neanderthal man (now extinct) and modern man (*Homo sapiens*). The division of hominids into these two most recent species took place around 0.25 MYA. That they shared a common ancestor has been strongly suggested by analysis of the DNA found in the mitochondria of Neanderthal fossils (Watson 2003, Chap. 9). A chart of modern *Homo sapiens*, showing its African and non-African varieties as estimated from studies of mitochondrial DNA, will be found on page 237 of Watson’s book.

Probably because of the varying environments and climatological conditions, the different species of ape had different types of social organization. Old World monkeys, and gibbons, like chimpanzees, are divided into kin-bonded groups; but the monkey and gibbon groups consist of females rather than males. Orangutans tend to be more solitary, but retain kin-bonding of females. Gorillas are organized very hierarchically, with one male gorilla keeping a harem which will be inherited by his son. Chimpanzees have kin-bonded groups of males in communities, where both males and females help with the offspring. According to Foley (1995), the dropping out of kin-bonding by females, and its replacement by kin-bonding by males, in the sequence leading from gibbons to chimpanzees, was:

- [P]robably a key event in evolution. It provides the ancestral condition from which the patterns of later hominids would be derived, and established the strategies that would be available for modification in the face of the further ecological and environmental shifts of the last 5 million years, the period of hominid evolution. It also illustrates the way in which behaviour, and social behaviour in particular ... is pivotal to understanding evolutionary events. (pp. 184–187)

Taking this assertion broadly, we begin by reviewing recent ideas on how present-day human cognition may have evolved as a consequence of a brain that had grown larger among the predecessors of humans *because* those predecessors had developed societies in which increased levels of social sophistication were demanded. The best-known proponent of this view was Robin Dunbar, whose ideas were paralleled by the general suggestion, by Byrne and Whiten (1988), that any kind of social organization demands of its members a high degree of understanding of how to interact with others. It was in 1988 that Dunbar produced his book entitled *Primate Social Systems* (Dunbar 1988).

It was, however, also at about the same time that other major contributions to human evolutionary psychology were made. For example, Cosmides and Tooby (1987) contributed an article entitled “From Evolution to Behavior: Evolutionary Psychology as the Missing Link,” and thereby started a sequence of investigations that culminated in an authoritative discussion on the role of social exchange in human society (Cosmides and Tooby 1992a, b). Gigerenzer and Todd developed the idea that many problems could be solved by humans using a small number of “fast and frugal” strategies of thinking. The idea of altruism that had been explored by evolutionary biologists was extended to incorporate the study of empathy into evolutionary psychology by Frans de Waal. Simon Baron-Cohen had formulated a model of how children begin to form a “theory of mind”; his theory was later amended to include more about emotions and empathy. Our treatment of human evolutionary psychology from 1975 to 2010 will therefore first trace, in more detail, the approaches to the topic illustrated by the contributions of Byrne and Whiten, Dunbar, Cosmides and Tooby, Gigerenzer

and Todd, de Waal, and Baron-Cohen, in that order. Some remaining issues will then be briefly introduced.

Primate Mental Evolution: From Byrne and Whiten’s Machiavellian Intelligence to Dunbar’s Social Brain Hypothesis

Prior to the surge of field studies in the 1950s and 1960s, discussions concerning the evolution of primate mentality had typically focused on two aspects of interest. First, there were accounts based on discussions of the use of tools by primates. For example, with bipedalism came the freedom to use one’s hands, so a new sophistication in primate intelligence was presumed to have evolved alongside the increased ability to coordinate manual and related bodily activities with mental activities. Second, influenced by new research on ecological issues, the suggestion was made that changes in problems of the environment prompted changes in primate brains. In the 1980s, a synthesis of these two approaches with a number of new observations took place regarding the evolution of primate mentality. These observations included (a) the complexity of primate social groupings (e.g., both competition and cooperation were taking place in the same social groups), (b) an extraordinary enlargement of the neocortex, relative to their body size, in primates, and (c) the finding of a correlation between brain size and group size; sizes in social groupings corresponded to increases in the mean size of the neocortex in the members of those groupings.

Although the sociality of animals in general had been recognized, sociality had not been considered in terms of its implications for the development of primate intelligence in particular. The observation that nonhuman primates often needed to rely on others for support in gaining rank in their social group, as well as to compete with others in that social group in order to attain status therein, presented a standpoint for investigating the particular skills needed to survive in the complexities of a primate society. With the recognition of the social complexity of the social world of primates came a need to account for how this complexity would be processed in terms of intelligence. Primates had to deal with many social dilemmas in their conspecific social groups. So the

question became: what capacities had evolved for maintaining the tricky balance between competition and cooperation in these conspecific groups?

The “Machiavellian Intelligence Hypothesis” (Byrne and Whiten 1988) was initially proposed as a means of explaining why primates have a larger neocortex relative to their body size than do other vertebrates, and how this increased size may have evolved, given the selection pressures exerted by social complexity and group size. (A more detailed anatomical account of the expansion of the neocortex has been given by Miller 2007.) According to Byrne (1996), primates needed to evolve the capacity to use their “heads” in keeping track of the players in their social world. Therefore, solving social problems, planning social interactions, and retaining memories of previous engagements all became skills that necessarily had to be developed within the primates’ social world; activities such as “coalition formation,” and mentalities such as “tactical deception,” were invoked to describe some of those skills.

The main idea behind the Machiavellian intelligence hypothesis is that increased social complexity served to select for increased cognitive sophistication, and the most important social skill that evolved was the ability to predict the actions of others. Social intelligence involves being able to make decisions about when to compete or when to cooperate, in addition to knowing how to engage toward either end; all three types of decision are facilitated by skills at predicting the actions of other individuals. Competition or cooperative activities in the primates’ social group can ultimately be explained through the “gene’s eye” view, where genetic fitness is operating at the level of the group. Two reasons given for why these advanced cognitive adaptations emerged were ecological pressures and social pressures. However, Byrne and Whiten argued that social pressures, in the case of primates, outweighed ecological pressures. This was because any increase in the sociality of primates would make it necessary for individuals to develop social intelligence and the cognitive capacity to predict what their opponent’s next move would be; those were the individuals who were more apt to survive.

Machiavellian Intelligence was renamed the “Social Brain Hypothesis” (Barton and Dunbar 1997; Dunbar 1998), and new hypotheses were formulated about how social group size correlates with neocortex volume in

primates. According to Dunbar (1998), bigger brains are expensive energy-wise; therefore there must be a good reason why the primate brain has gotten so large. In particular, the enlarged size of the primate brain is primarily due to an increase in the size of neocortex (which is generally regarded as the seat of the brain associated with reasoning and consciousness). According to proponents of the social brain hypothesis, the more social the reality, the more intelligent one must be. Dunbar and colleagues have found that physiological indices of intelligence (such as the “neocortical ratio,” which is the volume of the neocortex relative to that of other basal brain structures) correlate positively and significantly with indices of social complexity (group size).

The general level of cognitive capacity associated with individuals also acts as a constraint on the number of individuals that can coexist in one social group. The demands of the social system require an ability, not just to remember, but also to manipulate information (for example, by computing risk levels). Therefore, the larger the group, the greater the computational demand. This constraint on group size, according to Dunbar, is not only evident in nonhuman primate relationships, but also in human relationships. Dunbar reported that the sizes of various human groups identified in any society seem to cluster tightly around a series of values (5, 12, 35, 150, 500, and 2,000); as these values increase, they represent decreasing degrees of familiarity. It was predicted by social brain theorists that the amount of cognitive effort demanded by participation in any group would increase directly with the size of the group. For example, Dunbar (2003) claimed that we can retain five individuals in a close-knit clique, we can keep 12–15 persons in a “sympathy group,” and there are 30–50 people we encounter at least once a month. It is assumed that there is an advantage to having only a limited number of trusted others (e.g., kin and friends) nearby; one does not have to expend inordinate amounts of cognitive energy in keeping score or accounting for who had done what for whom. According to this view, the larger the social group, the more cognitively sophisticated one has to be in order to survive.

Dunbar (1996) expanded his opinions on the social brain to include the suggestion that grooming behavior

between apes in the social group, which serves the purpose of indicating to any member of the group which other members can be relied on to perform this favor, has a parallel in human language. In human language, the imparting of information about who can be trusted to deliver a service is often conveyed by gossip. According to Byrne (1997), “Dunbar therefore argues that speech evolved as an efficient replacement for grooming: Speech does not require the use of hands, which can thus collect food concurrently” (p. 178). Kudo and Dunbar (2001) claimed that social complexity itself could be measured by grooming clique size.

Dunbar (2007) himself has provided a short but valuable summary of his current views on the social brain. According to Dunbar, the evolution of the social brain made it possible for animals to live in groups in which collaborative efforts to solve problems of day-to-day survival would be more efficient than would leaving those problems to be solved by individuals alone. Dunbar also emphasized that humans may have needed a highly developed neocortex in order to make the computations necessary in social interactions in which one individual attempts to read another individual’s mind. The part of the neocortex that is best adapted for this function are the frontal lobes.

If individual X can determine Y’s intention, this is known as a “first-order level” of intentionality. If X can determine that Y can determine what X is intending, this is known as a “second-order” level of intentionality. Evidence that there is a linear relationship between the level of intentionality understood by a species and the absolute frontal lobe volume of that species has been reported by Dunbar (2003), using monkeys, apes, and humans.

Cosmides and Tooby’s Account of the Human Brain: Psychological Adaptations and Cognitive Modules

According to contemporary evolutionary psychologists Leda Cosmides and John Tooby (1992a), the human brain contains a number of functional mechanisms known as “modules,” which had evolved through the process of natural selection. According to these writers, evolutionary psychology is founded on a computational theory of mind, that is, the brain has developed different adaptive mechanisms or cognitive modules designed to address *particular* problems that

our ancestors would have encountered. As a means of ensuring the maintenance of reciprocal altruism in an increasingly social world, for example, Cosmides and Tooby proposed that these modules include a cheater-detection mechanism designed to reveal the presence of cheaters when we are dealing with others in our social exchanges. The word “cheater” had originally been introduced in the context of reciprocal altruism in animal populations; the word “cheating” had been used “solely for convenience to describe a failure to reciprocate; no conscious intent or moral connotation is implied” (Trivers 1971, p. 36). But, when extended to humans, Trivers acknowledged that repeated acts of non-reciprocation could lead to retaliation by the other altruist in the form of “moralistic aggression.”

The experiment for which Cosmides and Tooby are best known is too complicated to describe in detail here, so only its gist will be given. If a difficult problem involving the application of logical “if . . . then . . .” thinking is presented, in which a violation of logic has to be detected, and in which the four propositions of the problem are P (or not-P) and Q (or not-Q), many fail to detect that the conjunction of P and not-Q violates the rules of logic. But if the problem is presented in such a way that activities and people are involved in a problem in which a violation of social rules has to be detected, then the task is performed much more efficiently. For example, the activities can be described as drinking beer (or Coke) and the persons can be described as aged 25 (or 16); a violation of the drinking rules would be demonstrated by a person drinking beer who is only 16 (this is analogous to the case of P and not-Q).

The explanation offered by Cosmides and Tooby (1992b, pp. 184–206) for this finding emphasized that it was not just a change from non-familiar (P and Q) to familiar (person age 16 and drinking beer) or any of several other plausible hypotheses that could have led to this finding. It was the authors’ opinion that the ease with which the problem was solved arose from the fact that humans had evolved a special facility for detecting behavior that did not match socially determined norms of what was acceptable. Most social situations involve reciprocal altruism; but there is always a danger that one of the participants has an ulterior, and not particularly benevolent, motive. In order to detect “cheaters” such as these people, it was postulated, as noted

above, that humans have evolved a “cheater-detection module” that facilitates normal social interactions.

Among the important theoretical contributions of this group was Cosmides and Tooby's (1992a, b) criticism of what they called the “Standard Social Science Model” (SSSM). This model seeks to provide rules that can be easily adapted to any situation that might arise when individuals are interacting socially; but these rules, being so general that they lack any kind of specificity of content or of context, can never be trusted to generate situation-specific hypotheses that can be disconfirmed. In place of the SSSM, Cosmides and Tooby (1992b) argued that “the human mind contains algorithms (specialized mechanisms) designed for reasoning about social exchange” (p. 164). In a later article Cosmides and Tooby (1994) refer to these modules as “functionally specialized computational devices” (p. 329). These devices could have evolved to answer the challenges faced by our hunter-gatherer forebears (for example, habitat selection, foraging, social exchange, competition from small armed groups, parental care, language acquisition, contagion avoidance, and social rivalry). On evolutionarily recurrent tasks such as object recognition, grammar acquisition, or speech comprehension, these devices can often perform better than general-purpose problem-solving methods do. To this list can be added predator avoidance, sexual attraction, mate choice, navigation, hunting, and coalitional cooperation (Ermer et al. 2007).

Humans were considered to have evolved these devices in the course of entering a “cognitive niche” that included an “improvisational” kind of intelligence (as opposed to a “dedicated” kind), and an efficiency at finding information about ways of obtaining needed objects when environmental circumstances are rapidly changing. The search for information can be made more efficient by acquiring the desired information from others, preferably by using linguistic utterances, by making use of the searcher's knowledge of how other humans represent the world, and by a remarkable variety of ways of representing “what would happen if...?” questions and answers. This improvisational intelligence rests on a foundation of “dedicated” modules, including modules for object mechanics, tool use, intuitive biology, social exchange (as outlined earlier), and others.

Barrett et al. (2007) argued that the advances in cognition needed for the acquisition of important information are unique to the human species. They maintained that differences between humans and animals include the extent to which human males help to care for women and children by provisioning them, and in the unprecedented extension of cooperation to large human groups, including those involved in collective aggression. Recent articles by Petersen et al. (2010) and by Tooby and Cosmides (2010) have respectively provided new evolutionary approaches to our understanding of how criminal justice systems should operate and of how coalitions can lead to declarations of war. Both articles incorporate a new variable, namely, a “Welfare Trade-off Ratio” (WTR), which is an index of the extent to which one is disposed to trade off one's own welfare against another person's welfare when one takes action.

In Cosmides and Tooby's (1992b) article, considerable space was devoted to game theory as applied to situations involving reciprocal altruism. It sometimes happens that, if A helps B, and B promises to help A, A does help B, but B then neglects to help A. The payoff to B for cheating can exceed the payoff to B if he helps A as promised. Trivers (1971) had claimed that cases like these were analogous to what game theorists called the “prisoner's dilemma,” a game in which each of the two players has a choice between cooperating or defecting. Because prisoners, in at least some justice systems, are not allowed to talk to each other and because many animals obviously cannot talk to each other, it is not surprising that this game theory approach has been applied to cases of reciprocal altruism between nonspeaking organisms (for example, symbiotic marine species), between individual cells, or even between chromosomes within cell nuclei. An optimum strategy in a game between two noncommunicating individuals who only meet once can be proven to be that in which both players defect (an all-defect strategy, ALLD). But if players meet more than once, a TIT FOR TAT strategy has been proven, both mathematically and experimentally, to be the optimum. A player cooperates on the first move and then does whatever the other player did on the preceding move (Axelrod and Hamilton 1981, p. 1393). Gat (2010) has pointed out that, although a TIT FOR TAT strategy seems superficially like what happens in

a war, war adds the possibility of physically eliminating an opponent in a way no TIT FOR TAT strategy provides for.

Other arguments have been made to the effect that the prisoner's dilemma need not be applied, without qualification, to games in which two players actually *do* communicate during a game. Cosmides and Tooby (1992b), having said that in simultaneous, face-to-face interactions, one can often recognize whether one is about to be cheated, go on to belittle the importance of this argument because the ability to recognize cheating in present-day contexts usually applies to monetary exchange, a historically recent form of interchange that was not built on the social exchanges under discussion here.

But the argument has not gone away. Zahavi (1995) wrote of the prisoner's dilemma:

- ▶ In the real world, individuals assess the qualities and the motivations of their potential partners and invest in advertising their own qualities and motivations – before they enter into any collaboration. ... In the prisoner's dilemma the collaboration is neither preceded by communication, nor are the prisoners able to talk to each other during the game. Hence, clever as the "dilemma" and its solutions are, they have very little, if any, relation with the world of biology and social behaviour. (p. 3)

Zahavi claimed that human players in a prisoner's dilemma game usually benefit from knowing, in advance, each other's propensities to cooperate or to defect. Ridley (2010) described an experiment by Frank in which volunteer participants were divided into groups of three, who then conversed within each group for 30 min. In a real prisoner's dilemma game, only 26% of players actually defected and 74% of the players actually cooperated. This result can be interpreted as being consistent with a penchant for reciprocal altruism in humans that coexists with a tendency *not* to defect (despite the logic-based advantage of an ALLD strategy).

Ridley (2010) has also asserted that the kind of reciprocity studied by Cosmides and Tooby (1992b) was:

- ▶ [A] habit inherited from the animal past that undoubtedly prepared human beings for exchange. But it is not

the same thing as exchange. Reciprocity means giving each other the same thing (usually) at different times. Exchange – call it barter or trade if you like – means giving each other different things (usually) at the same time: simultaneously swapping two different objects. (p. 57)

This argument by a distinguished evolutionary psychologist actually lends support to Cosmides and Tooby (1992b, p. 175) when they had stated that it is not appropriate to judge the merits of social exchange theory on the basis of behavior in a monetary exchange transaction. But later, Cosmides and Tooby (1994) themselves strongly urged that economists recognize that social exchange theory might be more valuable in economics than traditional logic of a "rational" kind has been. The use of specialized modules to make reasoned inferences has become so automatic (because genetically expressed) in human mental activity that the making of these inferences can plausibly be described as "reasoning instincts," which "... make certain kinds of inferences just as easy, effortless, and 'natural' to humans as spinning a web is to a spider or building a dam is to a beaver" (Cosmides and Tooby 1994, p. 330).

Gigerenzer and Todd's "Simple Heuristics" in Human Cognition

Gerd Gigerenzer started his career with a scholarly and rigorous treatment of how sensory abilities and cognitive preferences in humans can be scaled and measured (Gigerenzer 1981). A critical review on how inferential statistics had been applied in experimental psychology and another critical review on how it has been claimed that humans fall well short of computers in speed and accuracy when it comes to probabilistic reasoning (Kahneman et al. 1982) were included in a monograph on how mathematics had been applied in cognitive psychology up to the middle 1980s (Gigerenzer and Murray 1987, Chaps. 1 and 5). Gigerenzer and his colleagues went on to demonstrate that some of the "biases" associated with inappropriate human probabilistic thinking could be lessened in impact if probabilistic questions were rephrased in terms of relative frequencies. For example, Todd et al. (2005), pp. 793–796) reviewed evidence that when participants were asked to base a diagnosis of breast

cancer on the basis of mammograms, presenting the information about false alarms (false positives) and missed signals in terms of probabilities led to only 16% of diagnoses being based on a thinking process analogous to that made by a probability theorist. But when the same information was presented in terms of relative frequencies, this percentage rose to 46%. The actual number of answers close to that predicted by (Bayesian) probability theory was also greater when the question was framed in terms of relative frequencies than when it was phrased in terms of probabilities.

In the remainder of their article, Todd et al. (2005) claimed that humans will try to predict what will happen, given evidence from a small number of events that have happened recently, by reasoning in a rough-and-ready way from the evidence before them. They claimed that one of the reasons that humans have short-term retention capacities of only about four to seven randomly ordered digits or words (Cowan 2001) is that a small number of mental representations concurrently in consciousness can be shown to be as reliable as is a larger number when it comes to making predictions about what will happen next. The adaptive value of a less-than-perfect working memory had also been emphasized, in a mathematically rigorous manner, by Kareev (2000) and foreshadowed in the sequence of Adaptive Control of Thought (ACT) models presented by John R. Anderson and his coworkers (for example, Anderson 1990; Anderson and Milson 1989; see also Anderson et al. 2004).

By about 1995, the “fallacies” in human probabilistic thinking that had been emphasized by Kahneman et al. (1982) and the “fallacies” in human logical thinking that had been emphasized in the experiments on the Wason task described by Cosmides and Tooby (1992b) were being considered, not necessarily as evidence of the inefficiency of computation by humans as compared with computation by computers, but instead, as cognitively adaptive for humans in a world that had grown increasingly complex over the past 50,000 years. Gigerenzer, Todd, and others founded a research group at a Center for Adaptive Behavior and Cognition (the ABC group), located at the Max Planck Institute for Human Development at the University of Berlin; their first major publication was

entitled *Simple Heuristics That Make Us Smart* (Gigerenzer et al. 1999).

The members of the group argued that, in the course of the evolution of human cognition, mental strategies had evolved, some 50,000 years ago, that had been proven to be practically useful, especially in an environment where the prediction of potential danger was of paramount concern; these strategies, of necessity, had to be “fast and frugal.” Todd and Gigerenzer (2007) have gone on to characterize their system of “fast and frugal” heuristics as being an account of “ecological rationality.” Among the classes of simple heuristics are the preference, in a situation involving a choice of options both familiar and unfamiliar, for choosing familiar options; the selection of a particular criterion for choosing one of two options (for example, allowing price or geographical location to be the criterion for choosing at which of two restaurants to eat); a whittling down or elimination procedure (also postulated by Tversky 1972) that focuses on one of several possible criteria that might be used to choose between more than two options; and, in sequential choice situations, such as that of successive interviewing while searching for a secretary, or successive dating while searching for a mate, finding a “stopping rule” to limit the search.

The ABC research strategy can be illustrated by an example concerning the fourth class of heuristics. It was proven, by Todd and Miller (1999), using computer modeling, that the optimum present-day strategy for searching for a suitable employee or mate need not require the interviewing of as many as 37% of potential candidates (the number predicted by one application of probability theory), but between 10 and 20 candidates no matter how large the number of potential candidates in the particular environment being searched. In mate selection, the fact that a candidate himself or herself had to view the searcher as a potential candidate adds a new constraint on the efficiency of the search; and it had been Gigerenzer and Hug (1992) who had demonstrated that performance on the Wason task could be influenced by whether, for example, the task about underage drinking was viewed from the perspective of a law enforcer (the conventional perspective) or from that of a teenager who enjoyed beer. An important change in performance, from the teenager’s point of view, was that a violation

of the social rules now became “not-P and Q” instead of the usual “P and not-Q.” But this finding did not negate Cosmides and Tooby’s (1992b) claim that a “cheater-detecting module” was operative during the search for a violation.

Todd and Gigerenzer’s “fast and frugal” heuristics and Cosmides and Tooby’s “cognitively adaptive modules” are similar in that both avoid the temptation to make mathematically or logically exact predictions the standard against which all human prediction-making should be judged; this high standard is impossible to attain given the limitations of the evolved human brain; but evolution has ensured that a number of adaptive domain-specific cognitive strategies exist that have allowed humans to survive (some might say “muddle through”) successfully to the present day. Nevertheless, it is an opinion within members of the ABC group that:

- ▶ If a different heuristic were required for every slightly different decision-making environment, we would need an unworkable multitude of heuristics to reason with, and we would not be able to generalize to previously unencountered environments. Fast and frugal heuristics can avoid this trap by their very simplicity, which allows them to be robust in the face of environmental choice and enables them to generalize well to new situations. (Todd and Gigerenzer 2007, p. 208)

Frans de Waal, Empathy, and the Evolution of Morality

Aristotle (384–322 BCE) was among the first to report that whales, dolphins, and porpoises were mammals because, unlike fish, they breathed through blowholes instead of gills, were viviparous, and suckled their young. Accordingly, Linnaeus (1707–1778) placed whales and dolphins in the order *Mammalia* rather than in the order *Pisces*. Linnaeus also put humans (*Homo sapiens*) and orangutans (*Homo troglodites*) into a “human” order separate from a “pongid” order, which included the great apes; nowadays, these two orders are collapsed into a single “primate” order. Modern evidence that altruism was practiced by primates observed in their natural habitat, as opposed to zoos or research centers, was bolstered by the work of Diane Fossey (1984) on gorillas, Jane Goodall (1986)

on chimpanzees, and Biruté Galdikas (1995) on orangutans; it may not be an accident that all three researchers were women who “empathized” with their animal subjects to such an extent that discussion of primate behavior *without* reference to altruism would have seemed to them unacceptably impoverished. Unfortunately, Aristotle did not report any evidence of altruistic behavior in monkeys and apes; he only described apes in terms of their external appearance, emphasizing their hand-like use of their feet, their hairiness, and their lack of tails; monkeys were described as tailed apes; and baboons were characterized as having dog-like teeth. On the other hand, Aristotle did report the following example of altruism in dolphins:

- ▶ On one occasion, a shoal of dolphins, large and small, were seen, and two dolphins at a little distance appeared swimming in underneath a little dead dolphin when it was sinking, and supporting it on their backs, trying out of compassion to prevent its being devoured by some predaceous fish. (Aristotle, ca. 362 BCE/1910, p. 631)

This leads us directly to the work of Frans de Waal, who, in 1977, obtained his doctorate in biology at Utrecht University in the Netherlands with a dissertation on conflict behavior in Old World monkeys (macaques). He then carried out research on alliance formation among chimpanzees in a large colony at the Arnhem Zoo, and continued to study chimpanzees, and also bonobos, when he worked, first, at the National Primate Research Center in Wisconsin from 1981 to 1991 and, then, at the Yerkes National Primate Research Center at Atlanta. Here he extended his investigations to include the study of New World monkeys (capuchins). Between his first book, entitled *Chimpanzee Politics: Power and Sex Among Apes* (de Waal 1982/2007) and his latest book *The Age of Empathy: Nature’s Lessons for a Kinder Society* (de Waal 2009), there are seven other books about social behavior in primates; from his early interest in conflict resolution, he has moved to the adoption of an almost activist stance in his insistence that apes and monkeys are capable of disinterested altruistic behavior and that this behavior rests on a foundation of animal-to-animal empathy. The study of animal-to-animal empathy is itself part of a broader context that includes

animal-to-human, human-to-human, and human-to-animal empathy.

According to de Waal (2005), morality is not just a “vener” spread over the natural evil to which we humans are prone; it plays an intrinsic and central part in primates because empathy and reciprocity are the chief “pre-requisites” of morality (de Waal 1996); later he wrote that empathy and reciprocity constitute the “building blocks” of morality (Flack and de Waal 2000). The failure of academic psychologists to have recognized this in the twentieth century was, for de Waal (2009), yet another of behaviorism’s sad legacies.

In a recent review, de Waal (2010) contrasted “reconciliation,” which is an altruistic-seeming aftermath of fighting but is also easy to categorize as self-serving in the sense that it postpones any new and immediate outbreak of hostility between two competitors, with “empathy,” which is an internal feeling that reflects the emotional state of another conspecific individual who is in one’s presence; empathy can also be a feeling conducive to the carrying out of actions that is not just “altruistic seeming” but genuinely altruistic. Among altruistic actions shown by chimpanzees, and their less rambunctious primate relations, the bonobos, de Waal amassed evidence for “consolation” behavior, which he defined as “a friendly, reassuring contact directed by an uninvolved bystander at one of the combatants in a previous aggressive incident” (de Waal 2010, p. 39). These observations on reconciliation and consolation in chimpanzee social interactions had first been reported by de Waal and van Roosmalen (1979).

Consolation behavior has been demonstrated by chimpanzees and bonobos both with conspecific individuals (animal-to-animal empathy) and with their caregivers (animal-to-human empathy). But consolation behavior has not been demonstrated in rhesus macaques, even though these Old World monkeys do demonstrate reconciliation behavior (de Waal and Aureli 1996). This difference between apes and monkeys was claimed to be related to the fact that chimpanzees and bonobos can recognize “themselves” as being separate from other conspecific individuals. Self-recognition is attested to when chimpanzees and bonobos can pass a “mirror test,” in which they attempt to rid themselves of a spot of rouge that had been

painted onto their foreheads unbeknownst to them and then seen for the first time in a mirror. Macaques cannot pass this test.

Empathic feelings allied with altruistic intentions can also explain what de Waal called “targeted helping,” defined as “altruistic behavior tailored to the specific needs of the other even in novel situations” (de Waal 2010, p. 42). Aristotle’s example of targeted helping by “compassionate” dolphins has received support from modern research on dolphins (Caldwell and Caldwell 1966). Furthermore, dolphins can pass the mirror test (Reiss and Marino 2001). Examples of targeted helping abound in de Waal’s (2009) book, and those animals that can pass the mirror test (apes, cetaceans, elephants) are those most likely to show it. Nevertheless, some isolated anecdotes are reported of targeted helping by monkeys and baboons, neither of which usually pass the mirror test. A claim by Hauser et al. (1995), based on video-taped evidence, that cottontop tamarin monkeys were able to pass the mirror test, was, unfortunately, not supported by Anderson and Gallup (1997), who viewed the identical video-tapes; and a replication by Hauser et al. (2001) of the 1995 study indicated that this species of New World monkeys did indeed fail the mirror test. de Waal (2009, pp. 143–150) suggested that there might be different “levels of mirror understanding” attainable by different species; even though some species of monkey might not be able to pass the mirror test, they do know how to use mirrors to find food that is hidden round a corner.

Three other kinds of behavior were added by de Waal (2009) to targeted helping as evidence for the empathic induction of certain behavior patterns. Some animals can indicate, by hand gestures or by direction of gaze, that objects (such as food or predators) of interest to other individuals can be found at a certain location; chimpanzees were particularly good at this kind of communication (de Waal 2009, pp. 151–157). If two individuals known to each other, and seen by each other, receive unequal amounts of food or attention from a caregiver, the individual with the lesser share displays its discontent; capuchin monkeys provided experimental evidence for “inequity aversion” of this kind (pp. 189–193). Food sharing between two capuchin monkeys, well known to each other, can be shown to be increased if the two cooperate to obtain it (pp. 176–177).

These observations are consistent with the views expressed by Ridley (2010) to the effect that humans and apes both show evidence of cooperation; but humans differ from apes in so far as humans reveal more cooperation between strangers, for example, with respect to barter and exchange, while primates usually share only with kin or colony mates. Supporting de Waal's arguments is the following quotation: "Capuchin monkeys and chimpanzees are just as resentful of unfair treatment as human beings are and just as capable of helpful acts toward kin and group members" (Ridley 2010, pp. 96–97).

Targeted helping, consolation, and empathy have been integrated by de Waal into a single model he called the "Russian doll" model (de Waal 2004). In a later account of this model, empathy is defined as follows:

- ▶ Empathy is the capacity to (a) be affected by and share the emotional state of another, (b) assess the reasons for the other's state, and (c) identify with the other, adopting his or her perspective. This definition extends beyond what exists in many animals, but the term "empathy" in the present review applies even if only criterion (a) is met. (de Waal 2008, p. 281)

de Waal called it a Russian doll model because these three capacities, namely, targeted helping, consolation, and empathy, are considered to be nested within each other, with empathy the innermost "doll." According to de Waal, "Empathy engages brain areas that are more than a hundred million years old. The capacity arose long ago with motor mimicry and emotional contagion after which evolution added layer after layer, until our ancestors not only felt what others felt, but understood what others might want or need" (de Waal 2009, p. 208). de Waal considered emotional contagion to be an example of the most primitive form of empathy (the inner core of the doll). Over the course of evolution, two more kinds of capacity were added: first, a concern for others (as in the evidence for consolation behavior, both animal-to-animal and animal-to-human), and, second, the ability to understand the perspective with which others are viewing oneself and one's surrounding (as in targeted helping, both animal-to-animal and animal-to-human).

According to de Waal's (2010) summary of his ideas, the emotional contagion layer is presumed to

be linked up with the ability to mimic the movements of others, via a single hard-wired "Perception-Action Mechanism" (PAM). PAM had first been introduced by Preston and de Waal (2002). The consolation layer, now called a layer associated with "sympathetic concern," is linked via PAM with the ability to cooperate with others in efforts to achieve common goals. And the "targeted helping" layer is linked via PAM with the ability to emulate some of the more sophisticated behavior patterns displayed by others. PAM is postulated to be the mechanism responsible for the increasing complexity of empathy. What is unique about this approach is the way that empathic responses are considered to be centrally organized responses in the evolved brain; they are not the outcome of associative responses acting on mental representations acquired in social situations. Some of the evidence for the autonomicity of empathic responding has been provided in fMRI studies by Singer et al. (2006); but, for de Waal, the evidence from self-observation also counts; one tends to follow, with purely mental "footsteps," each successive step of an artiste on a high wire; a mother tends to copy the mouth movements made by her child as he is being spoon-fed.

Frans de Waal also espoused a "co-emergence hypothesis," according to which certain cognitive capacities could only be expected to emerge in species that pass the mirror test. Among these are advanced empathy abilities such as perspective taking. The way in which a human child has acquired a self-concept by the age of about 2 years is believed to parallel the way the self-concept appears to have evolved in animals whose brains are growing in size. Dolphins and elephants, whose good performance on mirror tests indicates that they also have evolved a self-concept, also happen to share, with apes and humans, certain brain cells known as von Economo neurons (VEN). This led de Waal (2009, p. 138) to wonder to what extent these cells, which may have evolved to ensure greater connectivity within large brains, might mediate the linkups between the development of a self-concept and the development of the ability to imagine what perspectives other individuals may have with respect to oneself. In their review of evidence concerning human children's behavior on mirror tests, Howe and Courage (1993) showed that the use of the pronouns

“me” and “you” is attained at just about the same age as the mirror test can be passed (between 18 and 25 months).

Simon Baron-Cohen and His “Theory of Mind Mechanism”

Simon Baron-Cohen is a psychiatrist based at the University of Cambridge in England; his research in the early 1980s was focused on autism. In the course of his career, he has developed two models, in both of which normal cognitive development in childhood is recounted in such a way as to show how autism can be a naturally occurring variant of normal development. In the first model, Baron-Cohen (1995) argued that, over the first 4 years of life, children learn how to predict the intentions and actions of others by developing a “Theory of Mind Mechanism” (ToMM). This final phase of competence, acquired between 2 and 4 years of age, is preceded by a “Shared Attention Mechanism” (SAM) acquired between 9 and 15 months of age; it was claimed that autistic children are delayed in acquiring SAM, and therefore ToMM. By “shared attention,” Baron-Cohen meant the ability of the child to combine information about (a) how the movements of another person can provide a signal as to that other person’s intention with (b) information about how the location toward which that other person’s gaze is directed can signal the extent to which that other person is paying special attention to that location. Under a shared attention mechanism, a child about a year old can have a “triadic representation” by combining two “dyadic representations,” for example, “Mother wants the cup” (based on the child’s observation of the mother’s movement toward the cup) and “Mother sees the cup” (based on the child’s observation of the mother’s direction of gaze). Putting the two together yields the relatively uninformative representation “Mother wants the cup she can see.” But if the child itself is also looking at the cup, the nontrivial triadic representation “Mother sees that I see the cup” can emerge; this is the beginning of the child’s developing a theory of his mother’s mind. It was suggested that children with autism perform at a level close to that of normal children on tasks involving Baron-Cohen’s “Intentionality Director” (IDD) and “Eye Direction Detector” (EDD).

But, some 10 years later, Baron-Cohen (2005a) realized that the above scheme left out the acquisition, by the child, of a theory of mind that incorporates an understanding of the emotions being experienced by another person; the earlier model had “focused on only volitional, perceptual, informational, and epistemic states” (Baron-Cohen 2008, p. 418). Accordingly, in the first 9 months, an “Emotion Detector” (TED) is added to the IDD and to the EDD; these three detectors combine in arriving at the shared attention model stage of 9–14 months; at approximately 14 months, an “Empathizing System” (TES) develops, and between 14 and 48 months, a modified ToMM has emerged. But this model was also transformed, in its range of applicability, because of the hypothesized existence of important differences between empathic reasoning and “systemizing” reasoning, the latter involving an algorithmic approach to the determination of cause and effect, particularly in the operation of machines and other engineering artifacts (Byrne 1997).

Both Baron-Cohen (2008) and Badcock (2008) have developed this theory in such a way as to lead to a contrasting between adult autism and adult psychosis. This contrast also involves a discussion of gender differences. Baron-Cohen (2005b) has also argued that testosterone levels in the fetus at midterm can affect behavior after birth. The reader is referred to the above articles, because they go into technical details that are difficult, for reasons of space, to convey here.

Some Remaining Issues

A full review of the history of evolutionary psychology would refer to far more literature than can be included here, including the recent publication of books written for a general audience in which have been highlighted the shortcomings of a human mind that evolved in the past for a hunter-gatherer environment and must now be deployed in an often urban environment (Chabris and Simons 2010; Marcus 2008). Here we elaborate briefly on the contention by Cosmides and Tooby (1989, p. 60) that, in order for social exchange to be possible in any species, but especially in humans, the individuals in a particular community should be able to recognize each other and to remember earlier interactions, to understand or guess what each other is intending, to communicate with each other in

language, and to provide approximate cost/benefit estimates of what future interactions with each other might bring.

Recognition Capacities

First, with respect to recognition and the remembering of prior interactions, it is appropriate to acknowledge, in this historical article, the contributions of T. Wesley Mills (1847–1915) to our knowledge of how newborn animals come to adapt to their new environment. As is described in more detail by Murray (1990b), Mills (1898, 1905) reported how he kept diaries of the development of newborn puppies, kittens, and the young of other domestic species. To take one example: A purebred St. Bernard puppy was studied over a period of several weeks after its birth. Its eyes first opened fully by about the 16th day; it could follow a moving object with its eyes on the 18th day; it could blink if a hand were moved before its face as if to strike, on the 19th day; it could follow behind a small object at a distance of 1 ft., or a larger object at a distance of 5 ft., on the 26th day; but it was not until the 31st day that Mills felt comfortable about asserting that the puppy was able to recognize its mother “by sight alone” (Mills 1898, p. 132). The cues of smell and hearing had been more important than had visual cues in the first month of this puppy’s life.

But even though the processing of visual information may come late in the experience of the young of many species, there is little doubt now of the usefulness of visual information for the survival of almost all vertebrate species except perhaps for cave-dwelling fish and burrowing mammals such as moles and naked mole rats. Allan Paivio, of the University of Western Ontario, has devoted his career to furnishing evidence that human beings have evolved a “dual-coding” mechanism for experiencing mental representations, one code being visual (often experienced as visual imagery) and one being verbal (often experienced as inner speech or as “talking to oneself”). Extensive evidence supporting the usefulness of dual coding for our understanding of human memory, including the invention of mnemonic systems, was reported in his first book (Paivio 1971). But this evidence has since been supplemented by his reporting of data concerning the processing and retention of visually presented information by animals (notably birds) and by human children prior to the

age of 5 years or so (Paivio 2007). Following the publications, already mentioned above, by Tolman (1932) of evidence that rats can use “cognitive maps” to facilitate their navigation of mazes in order to obtain food and by O’Keefe and Nadel (1978) on the role played by the hippocampus in mediating visual memory performance in animals and humans, it is now appreciated that Paivio has shown how important vision is, not only for the recognition of locations associated with shelter, food, predators, etc., but also for mediating the “secondary representations” that had been stressed as essential by Romanes (1888) for the evolution of language and by Perner (1991) for the development of a child’s theory of mind.

The ability by humans to recognize faces might even be an example of a specialized adaptation or “module” that has evolved for the purpose of facilitating a baby’s ability to respond preferentially to the faces of certain individuals, such as the baby’s mother, who are usually sources of affection and nurturance. But it was the geneticist team of Axelrod and Hamilton (1981, p. 1395) who suggested that face recognition might represent a specialized neural mechanism that appears to be associated, if brain damage occurs, not with a general deficit in visual recognition ability, but with a specific deficit in face recognition only (“prosopagnosia”).

Empathy Capacities

A number of studies have revealed that empathy might also be a capacity whose neural underpinnings might have been selected for genetically. It was discovered, by recording from individual brain cells, that certain cells in the ventral premotor cortex of a monkey A will respond if monkey A sees monkey B make movement M. These cells were named “mirror neurons” by their discoverers, who acknowledged from the start that the activity in these neurons might signal only that they mediated the visual recognition of movement-actions, carried out by B, that A had also seen performed in the past (Gallese et al. 1996). Accessible summaries of later research on mirror neurons have been provided by Rizzolatti et al. (2006) and by Iacoboni (2008/2009).

But mirror neurons have also been associated with empathy because a human volunteer A could watch a human volunteer B suffer a small amount of pain

administered to B's hand; when A's mirror neurons responded, their neural responses were synchronous with the neural emotional responses recorded for B, but there was no concomitant activation of the part of A's brain that would indicate sensations of pain in A's hand (Singer et al. 2004). Moreover, if A sees an emotional expression on B's face (say, of fear, sadness, anger, happiness, surprise, or disgust) and A then imitates that expression, not only are A's mirror neurons stimulated, but A also claims to feel what B was feeling; a brain region called the insula probably serves as a connection between the mirror neurons in A's ventral premotor cortex and the neurons in A's limbic system, a brain-region phylogenetically older than the cerebral hemispheres, that appears to mediate the feelings associated with strong emotions (Carr et al. 2003).

Later experiments along these lines have shown that individual differences in empathy can also depend on the opinion that person A holds of person B. If A and B had competed in a prisoner's dilemma game, and B had played fairly; and then A had to pay attention to B while a painful stimulus was administered to B; it was found that A's mirror neuron responses to B's suffering (as measured by fMRI) was suggestive of a high level of intensity of fellow feeling. But if B had played the game unfairly, and A knew it, the amount of apparent empathy felt by A because of B's suffering was low or even absent (Singer et al. 2006).

It is to be noted that de Waal (2009) has expressed doubt as to the validity of claims by some authors (e.g., Meltzoff and Moore 1977) that newborns can imitate actions performed by others without the newborns' having ever performed those actions beforehand. It is probably prudent to assume that, just as some neurological configurations appear to mediate face recognition, so mirror neurons are neurological configurations that mediate the recognition of movements (including facial movements) carried out by others. Just as the existence of specialized face-recognition systems of neurons was felt to be supported by the existence of prosopagnosia, so the existence of specialized movement-recognition systems of neurons has been felt to be supported by the existence of autism (Iacoboni 2008/2009, pp. 168–183).

Another contribution to our understanding of empathy has come from our appreciation of the fact

that if individual A intends to deceive individual B, A is materially helped if A understands "how B's mind works." The existence of deceptive behavior in chimpanzee colonies has now been well documented; a review of the relevant literature by Byrne and Corp (2004) precedes an account, by those authors, of how they collected evidence of the frequency of deceptive acts, carried out by various individuals, over the course of long periods of observations, and found a significant positive correlation between the frequency of those acts and the size of the neocortex in those individuals.

Language Capacities

In the nineteenth century, the eminent linguist F. Max Müller (1823–1900) of Oxford University had claimed that the main feature differentiating, say, chimpanzees from humans is the existence of language. He had written: "Man speaks, and no brute has ever uttered a word. Language is our Rubicon, and no brute will dare to cross it" (Müller 1866, p. 392). Most of the theories that have been put forward in the twentieth century, however, have followed the gradualist approach pioneered by Romanes (1888); humans, because they possess self-consciousness and the ability to use words to synthesize new propositions, had outpaced animals, who could only associate vocalized sound with what we now call "conditioned emotional responses" and Romanes had called "receptual associations."

A review of the twentieth-century literature on the evolution of language by MacNeilage and Davis (2005) began by centering on the work of Noam Chomsky, who, in at least one stage of his career as a psycholinguist, had argued that the study of the so-called "universal grammar," with which we all had been born, was unlikely to benefit from an evolutionary approach that emphasized individual differences. As a guide to clear thinking about language, MacNeilage and Davis reproduced two diagrams, one of language production, and one of language comprehension; the diagrams were taken from articles by Levelt (1999) and by Cutler and Clifton (1999), respectively, that had appeared in the same edited volume. MacNeilage and Davis then reviewed various theories of the ontogenetic, phylogenetic, and cultural determinants of language development, including Bickerton's (1995) postulate, to be illustrated below, that "protolanguages" of a very

simple kind evolved before languages useful to modern *Homo sapiens* had emerged. These useful languages included subtle syntactic and semantic specifications and lexicons that contained enormous numbers of words; according to Hoffer (2007), the approximate number of different human languages spoken in 2006 was 6,912.

Intriguingly, Skinner (1957, Appendix), in the same book on language that was so famously criticized by Chomsky (1959), also insisted that the study of evolution was unnecessary in psycholinguistics. The course of acquisition of speech by a child could be described entirely in terms of classical and instrumental conditioning, the stimulus-terms of which were determined entirely by the child's environment. For Skinner, there was no need to specify any part played by the theory of evolution in determining an underlying brain physiology that would mediate certain states of consciousness, in the growing child, that might be prerequisite, over and above the acquisition of vocabulary and syntax, for successful language performance.

It is accepted by many linguists, however, that certain states of consciousness can exist in prelinguistic children (and maybe in some nonlinguistic animals, according to Smith et al. 2003) that form the cognitive substrate whose contents are to be transformed, once the vocabulary, syntax, and articulatory movements associated with a language have been acquired, into linguistic utterances. It is difficult to find just the right words for this nonlinguistic state of consciousness, as has been attested to by O'Regan and Noë (2001) in their consideration of how far visual representations can form potential constituents of this particular state. The word "concept" (along with cognates such as "conceptual") was used by Romanes (1888) and is also in wide use among present-day psycholinguists. For example, Kirby (2007, Fig. 46.2) represented language as a device that bridged a gap between our "concepts and intentions" and our "articulations and perceptions." Levelt et al. (1999) asserted that, when we prepare a word utterance, the first stage is one of "conceptual preparation" for a lexical search; alternatives for "concept" have included the words "intention," "idea," and "notion."

Donald (1991, 2001) utilized the word "mimetic" to refer to a prelinguistic mode of thinking in which any

imagery that takes place is one in which the actor imagines himself, or perhaps even somebody else, carrying out a sequence of movements, mainly of the hands and arms, but also of the face, torso, or lower extremities. In modern humans, this histrionic kind of imagery has largely been added to by visual or verbal imagery, as mentioned above (Paivio 2007). Jaynes (1977) has even argued that in ancient times, at the dawn of writing, the cognitive states of individuals may have included hallucinatory states. Bickerton (1995) gave three examples of what he called protolingual "fossils," by which he meant small fragments of language that actually did convey a meaning, the associated cognitive state of which would necessarily be somewhat indeterminate. He gave examples of short utterances in Hawaiian Pidgin English of about 200 years ago, some two-word utterances of a 23-month-old Anglophone boy, and some equally short communications by apes trained to express their desires.

Corballis (1991) has also argued that gestures probably constituted the main form of communication among the precursors of modern humans, but added that, because hominids were now bipedal (probably from having shifted from forest-dwelling to savannah-dwelling), they used their hands in a variety of ways, including weapon-manufacture, weapon-throwing, and pottery-making (see also Wynn 2002). But hominids also appear to have developed hand preferences, mainly preferring the right hand for most of these tasks. At the same time, the left cerebral hemisphere appears to have become specialized for the production, as well as for the comprehension, of spoken utterances (Corballis 2003). Our understanding of how individual regions of the left temporal lobe mediate the production of linguistic utterances is still not well advanced (Grodzinsky 2000; Reilly 2002); but there is some agreement among researchers that the ability of humans to incorporate the recursive embedding of phrases "nested" within a sentence (for example, "The woman was eating, while reading the newspaper, a banana") illustrates a high level of flexibility in the *ordering* of mental representations, be they words (as in literature), visual elements (as in painting, sculpture, and architecture), or auditory elements (as in music). Corballis emphasized that this aspect of the human mind could be designated as

“generative”; its reordering propensities not only helped in the evolution of human language (which Reilly 2002, believed preceded the evolution of right-handedness), but also in the advances in technological innovation we typically associate with human progress.

Donald (1991, 2001) stressed the influence exerted by the evolution of human language upon the evolution of written culture in particular. He insisted that human culture was a “hybrid” of items stored in “internal memories” (our brains) and in “external memories” (libraries and databases). Included among the contents of our internal memories were what Dawkins (1976/2006) had called “memes,” which are stereotypes or icons of widely disseminated phrases or nuggets of knowledge that had been “picked up” from conversations, advertisements, magazines, and the like. These memes are probably stored neurologically in the same way as are other memories, although it is doubtful that the information they contain can be transmitted genetically (Aunger 2007).

Evolutionary changes also determined the present conformation of the human vocal tract; as described in detail by Lieberman (1984, 1991), the human laryngeal tract is more voluminous and lower down the throat than is that of chimpanzee, thereby permitting a much wider variety of sounds to be produced, from the larynx itself, than is the case for the chimpanzee. Variations in breathing force, tongue and lip movements, and the activation of the vocal cords are associated with the production of some 60 different phonemes.

At the start of the twenty-first century, a case-history was discovered that involved specific articulatory defects that spread over three generations within a single human family; a study of the family’s DNA led Lai et al. (2001) to postulate that the disorder was related to a mutation that may have taken place, between 100,000 and 200,000 years ago, on a particular gene known as the FOXP2 gene. This discovery acted as a magnet for drawing in persons who saw FOXP2 as a “language gene”; but the fact that FOXP2 also exists in songbirds and other kinds of animal, as well as the fact that FOXP2 can be expressed in the embryonic development of the alimentary canal and lungs, inspired several evolutionary biologists to write lengthy cautionary articles about not jumping to hasty conclusions, given the extraordinary

complexity of the events that determine *any* gene-to-phenotype expression (Balaban 2006; Fisher 2006). Ridley (2010) has noted that, when the FOXP2 gene is added to mice, its effect is to enhance “the rapid flicker of tongue and lung that is called speech” (p. 55). But he also noted that, although the FOXP2 gene has been detected in Neanderthals as well as in present-day humans, there is no record that Neanderthals were linguistically advanced enough to have left behind any evidence thereof.

Corballis (2004) has, however, combined the evidence for a language-facilitating FOXP2 gene with the evidence for a mirror-neuron movement-recognition system. He suggested that the acquisition of language, both phylogenetically and ontogenetically, may have been based on an ability to recognize and also to imitate the mouth and facial movements observed in others. Perhaps, auditory feedback and feedback via bone conduction could have helped individuals to connect the hearing of certain self-produced sounds with kinesthetic memories of the articulatory movements they had used to make those sounds. The relative recency of the gene suggests it may have occurred after gestural communication had first been made available to our hominid ancestors, perhaps 350,000 years ago. But “because FOXP2 is expressed in the embryonic development of structures other than the brain . . . it is possible that mutation of FOXP2 was the most recent in the incorporation of vocalization into the mirror system” (Corballis 2004, p. 96).

It was not only Corballis (2004) who saw the possible involvement of mirror neurons in language acquisition; if one combines a suggestion by Meltzoff and Moore (1977) that newborns could imitate gestures they had never seen before, with the new knowledge that mirror neurons could mediate the recognition of gestures performed by others, it is easy to hypothesize that human children might acquire language by imitating, in their own orofacial movements, what they see and hear other humans doing with *their* orofacial movements. A series of studies in various laboratories demonstrated that the mirror neurons of an individual A might be involved, not only in the observing of movements (such as grasping) made by individual B, but also in the execution, by A, of an imitation of B’s movement. These experiments were then extended to the study, using brain-imaging

techniques, of the execution, by A, of imitations of orofacial movements performed by B. These experiments have been reviewed by Iacoboni (2008/2009, Chaps. 2 and 3). Arbib (2005) has developed an argument that the evolution of mirror neurons helped to pave an evolutionary path between movement-recognition in monkeys and the evolution of spoken language in humans.

From a historical point of view, the fact that there may have been a sudden, genetic event, rather than a graduated series of cognitive and/or social events, that determined the ability of humans to produce many more sounds than can primates, means, paradoxically, that Max Müller may have been closer to the truth about the non-gradual origination of human language than Romanes would have cared to admit.

Cost-and-Benefit Estimations

As noted, Ridley (2010) has claimed that the literature on evolutionary psychology has tended to ignore the kind of financial interchanges that so dominate twenty-first-century urban society; the growing discipline of behavioral economics is remedying that oversight. But it has also been assumed, by evolutionary psychologists, that the decisions associated with mate selection (and mate retention, or mate desertion) are also based on cost/benefit analyses that include one's emotional, as well as financial, well being. The huge scientific literature on what is popularly known as "romance" is greatly indebted to David M. Buss of the University of Texas at Austin, and Buss's (2009) summary of what has been learned so far is an excellent starting point from which to search for more detailed information.

The first book whose title contained the term "evolutionary psychology" was actually a tract in a religion called theosophy, which had been founded at the turn of the twentieth century (Preston and Trew 1928). But the modern evolutionary psychologist is more often looking for affinities between the behavior patterns of infrahuman species and those of humans that might throw light on human, as opposed to divine, behavior. To throw some perspective on this topic, we now list differences between chimpanzee and human mating behavior patterns based on an account by Buss (2007).

First, chimpanzee females advertise their readiness for copulation by a swelling of their genitalia that is clearly visible to the males in their vicinity. In humans, our clothes hide these regions; but the curious fact that in animal societies, it is usually the male who displays his finery while the female remains rather drab, whereas in human societies, it is usually the females who dress more colorfully than do males, becomes more understandable historically when it is realized that Darwin himself originally postulated that it was the females of most species, rather than the males, who were the more selective and discriminatory as to whom copulatory privileges should be extended. Much is what is currently known about the role of physical attractiveness in human mating choices has been summarized by Sugiyama (2005) and Scheyd et al. (2008).

Second, in chimpanzees, copulation only normally takes place at propitious times in the ovulatory cycle of the females. But there are few limits, either within a monthly cycle or across the assemblage of cycles that span a large proportion of the lifetime of human females, on how often copulation might be permitted. Because many copulations will not end in pregnancy, the frequency of copulatory activity can be expected, by human males and females, to be far more variable than is the case for chimpanzees. A review of the behavioral consequences of the need to adapt to changes in ovulation has been provided by Gangestad et al. (2005).

Third, chimpanzees rarely form long-term relationships between males and females; humans form such relationships often. This means that human males are often faced with choices unknown to animals, for example, whether to prefer to copulate with the aim of having children or to have sex for its hedonic consequences only. It has been argued that changes in sexual habits down the ages are reflections of changing strategies vis-à-vis the desirability of reproductive, as opposed to recreational, sex; reviews of these historical changes have been presented by Westermarck (1891/1894), Buss (2003), and Shorter (2005). Among the more obvious changes have been the growing social acceptability of premarital, homosexual, and lesbian sex, as well as of common-law marriage. Reviews of the biological impact of these various kinds of human sexual behavior have been offered by Symons (1979) and Schmitt (2005). One of the perennial problems in reproductive behavior, both animal and human, has

been the tendency for males to apply sexual coercion to females. This topic has been reviewed by Thornhill and Thornhill (1992) and by Malamuth et al. (2005).

Fourth, chimpanzee males rarely invest much time or effort caring for their progeny, whereas human males often invest heavily in their children. Geary (2000) reviewed the scientific evidence concerning paternal investment, and, later, summarized his findings as follows:

- ▶ If the certainty of paternity is high, selection favors paternal investment if:
 - A. Investment improves offspring survival or quality, and
 - B. The opportunity costs of investment (i.e., reduced mating opportunities) are lower than the benefits associated with investment. (Geary 2005, p. 487)

It is doubtful whether a conscious process of cost/benefit analysis prefaces all human relationships by either or both partners; moreover, Geary's (2005) summary was based on evidence garnered not only from human communities, but also from primate colonies and insect societies.

Concluding Remarks

It will have been noticed that late twentieth-century technological innovations in brain imaging and in genome profiling have led to the incorporation of neurophysiological and genetic microunits (mirror neurons, the FOXP2 gene) into the early twenty-first-century literature on evolutionary psychology. Prior to these innovations, most progress in the measurement of human brain activity came from the electroencephalograph (EEG), first devised, in 1929, by Hans Berger (1873–1941). Refinements of his original techniques for studying the “brain waves” associated with an ongoing level of conscious alertness have included the study of evoked potentials, isolated events associated with the presentation of a particular stimulus. Schröger (2007) has identified a newly discovered event-related potential as an indicator of a “mismatch negativity” (MMN); it arises when a repetitive auditory sequence unexpectedly includes a deviant event, for example, a momentary and non-repeated change in the frequency of a repeated tone. MMN might indicate to its animal or human possessor that a change has

occurred in the ongoing auditory context (for example, a sudden change of this kind might be speculated to be a signal of danger). A number of inconsistencies in the current literature on the immediate auditory recognition of tones have been reconciled in the light of this MMN perspective (Mercer and McKeown 2010).

The future of evolutionary psychology will surely be one in which a knowledge of behavioral or cognitive psychology will have to be supplemented by an understanding of microbiology and neurophysiology to an extent that might have surprised even the founding fathers of evolutionary psychology, Charles Darwin and George John Romanes. However, the skeptical inquirer will assuredly understand that the latest findings in neurophysiology, microbiology, and science in general, findings often informed by technological innovation, are fundamentally a product of human activity, which in any discipline is subject to human error, unintentional or otherwise (Johnson 2010).
