western religions, while remaining primarily concerned with Christianity and, to a lesser extent, Judaism. During the heyday of US Psychology of Religion, they invariably figured in discussions of the origins of religion and mysticism for example, but the stance taken was almost always that Christianity was the most evolved or “highest” form of religion. During the post-1945 period, and into the 1960s, there was a surge of interest in Buddhism (especially Zen Buddhism) and Hinduism which more positively sought to redress the perceived imbalance in prevailing occidental Psychology by incorporating the insights of these. Jung had always been fascinated by the symbolism of oriental religions and endorsed such works as Richard Wilhelm’s (1960) translations of the *I Ching* and *The Secret of the Golden Flower*. In the United States, it was Zen Buddhism which initially attracted most attention, Erich Fromm, for example, coauthored *Zen Buddhism and Psychoanalysis* (Fromm et al. 1960). Lao Tzu’s *Tao Te Ching* also enjoyed popularity in new translations. It is though hard to disentangle the specifically psychological interest in these faiths from their vogue in the broader cultural – and counter-cultural – climate of the times. Nonetheless, it is a fair generalization that many “Growth Movement” psychotherapists took the Buddhist and Hindu ideas and techniques for achieving self-knowledge seriously and found them insightful.

Since around 1990, the situation has changed significantly due to the increasing globalization of Psychology and the recent emergence of Postcolonial Psychology. This has resulted in numerous works bearing titles such as *Heart, Self and Soul: The Sufi Psychology of Growth, Balance and Harmony* (R. Frager 1999), *Islamic Psychology: Emergence of a New Field* (A. Husain 2006), and *The Positive Psychology of Buddhism and Yoga* (Levine 2000). There were also several earlier works of a similar character. As Psychology globalizes, so those in non-western cultures naturally seek to incorporate their own indigenous, usually religious, psychological wisdoms into the discipline, offsetting its western biases and assumptions. This raises an important problem for which there is no easy resolution. Whatever its internal diversity, western Psychology is, unambiguously, a discipline embedded in the western academic tradition, including both the sciences and the humanities. Whatever their disagreements its

practitioners are at least agreed on one thing – they are engaged in some kind of knowledge-generation activity. That is to say there are active frontiers at which they labor and their work continually challenges, changes or expands on existing knowledge. Psychologists have trouble enough maintaining a sense of unity, but on this at least there is a consensus. If however we add Hindu, Buddhist and Islamic “Psychologies,” this is necessarily challenged, for while such religions contain elaborate and sophisticated accounts of the psychological, they are not, by their very nature, engaged in generating new knowledge. Their task is to teach and spread the knowledge they already have. In the west only Catholic Thomist “rational Psychology” is similar, and that, as we saw, managed to adjust to Psychology by deploying the empirical versus rational distinction (itself a religious doctrine in their case). Note that the globalization of the physical sciences faces no similar problem, there are no currently active religious rivals, no Buddhist geology or Islamic physiology.

Psychology is thus in a dilemma, as yet not fully appreciated, regarding what to do about these Psychologies. It cannot simply reject them as “unscientific” since to do so would be to endorse western Psychology’s hegemony, with all its cultural biases, but to incorporate them is also impossible without sacrificing the notion of the discipline as a knowledge-generating project. Psychology’s current internal divisions are of three kinds: those pertaining to subject matter (yielding subdisciplines), those pertaining to theory (behaviorism, cognitivism, social constructionism, etc.) and those pertaining to methods (laboratory experimentation, field studies, discourse analysis, etc.). But non-western religious Psychologies are not definable in any of these terms. They are not even “theories” in the orthodox sense since they are total religious belief-systems, and do not generate testable hypotheses, etc., in the way Psychological theories do (or can be criticized for not doing). The momentum of the developments generating this conundrum is probably unstoppable, and the conundrum itself is no argument against it. In the end, one supposes, each non-western faith will have to travel the same path as Christianity has done and find its own way of adjusting to the presence of Psychology. Neither the religions nor Psychology will remain unchanged in the process.

Current Cognitive and Evolutionary Psychologies of Religion

This entry being about the relationships between Psychology and religion, rather than psychological theories of religion, these two recent trends (their significant presence dating back only to the late 1990s) can only be dealt with very briefly here. For our purposes, they are significant as representing a renewed attempt to produce a Psychology of Religion rather different from those of the past. One major contrast is that their keenest advocates tend, with varying degrees of qualification between authors, to offer reductionist scientific accounts of religion rather than, as previously tended to be the case, accounts motivated by a desire to demonstrate the compatibility of religious belief with scientific psychological theories. The second is that while earlier approaches were by and large eclectic in the psychological ideas they drew upon, both of these are concerned to show how a single specific theoretical framework can comprehensively “explain” religion. Only the initial psychoanalytic critiques of religion were so ambitious (though G.B. Vetter, 1958, was a behaviorist exception). Ironically, it may be only now, when sympathetic treatments of religion and “spirituality” are reappearing on the discipline’s psychotherapy and clinical wing, that something like a classic “science versus religion” contest is finally surfacing in these theoretical camps.

Even so, neither approach (and they have overlaps) is internally homogenous, with considerable variation in the extent to which their proponents espouse reductionist or antireligion positions. This is very apparent in the wide-ranging, 50-chapter, collection of essays *The Evolution of Religion. Studies, Theories and Critiques* (J. Bulbulia et al. 2008). It might though be noted that anthropologists greatly outnumber psychologists among the contributors (along with representatives of several other disciplines). Leading figures include, on the cognitivist side, P. Boyer (2010), S. Guthrie (1993), and H. Whitehouse (2004), and on the evolutionary side, J.L. Barrett (2004), L.A. Kirkpatrick (2005), J.P. Schloss and M. Murray (2009), and R. Sosis and C. Alcorta (2003). J.M. Nelson (2009) has a useful, if brief, critical resumé of their theoretical concepts and hypotheses. Evolutionary Psychology itself, based primarily on the sociobiological model, is of course vulnerable to numerous conceptual

criticisms. These cannot be explored here (see G. Richards 1987, Rose 2000 for instance), but one point should be made. Many writers, including the cognitivists, still tend to view religion as comprising a set of (usually “irrational”) empirical beliefs. This is surely misleading, as mentioned in the opening paragraph. Nor is “irrationality” self-evident, there was indeed a time in the seventeenth and eighteenth centuries when atheism was widely considered a form of madness, and William Paley’s “Argument from Design” was widely accepted as irrefutably logical by many scientists in the early nineteenth century (e.g., the authors of the *Bridgewater Treatises*). One cannot, by scientific fiat, simply differentiate the rational from the irrational as natural psychological categories.

Despite the increasing number of publications on religion from these two schools, especially since 2000, they have yet (in 2010) to achieve a powerful academic presence within the discipline as a whole, though this could change.

Conclusion

As we have seen, the relationships between Psychology and the religions (primarily Christianity) in its host societies have been of a variety of kinds. While psychologists have sometimes tried to “explain” religion away in theoretical terms as a quasi-irrational pathology (psychoanalysis, behaviorism, evolutionary psychology), they have also cooperated with it (numerous psychologists especially in the pre-1914 period), integrated it into their theories (G.W. Allport, Carl Jung), co-opted its insights in secular terms (“Growth Movement” psychotherapists), sought psychological correlates of religious belief in descriptive fashion (e.g., M. Argyle 1958), focussed on specific religious phenomena (notably religious experience and conversion), and simply accepted its underlying values in applied fields (notably “moral education”). The religious for their part have, while occasionally opposing Psychology, more typically sought to incorporate its concepts into their own psychotherapeutic and counselling practises, formulated theoretical reconciliations with it (e.g., Oscar Pfister), used it as a resource for reformulating and modernizing their doctrines (many of the more pious early psychologists of religion as well as more recent theologians), and, in the early days, welcomed it as a potential route for validating religious belief. More profoundly, it is

clear that, both consciously and unconsciously, psychologists' work can be deeply affected by their own religious backgrounds and motivations as well as, more obscurely, the religious characters of the societies in which they live (e.g., the "individualist" orientation of mainstream US Psychology in relation to its prevailing Protestant culture).

Explanations are attempts at resolving puzzles, and psychologists have found religion puzzling in numerous respects which the religious in turn may either dismiss as misunderstandings, share, or consider irrelevant. One common puzzle for psychologists is not anything about religion as such, but how their own favored theory can account for it, another is its perceived "irrationality" (as apparently disclosed by these theories), which as noted previously is a highly problematic accusation. Others may be puzzled, or at least curious, regarding the way religious belief correlates with social attitudes, or focus on more extreme varieties of religion such as cults. For personality theorists, the question is how religious belief functions in believers' lives. Yet others may just be concerned to ensure that their religious moral values can continue to guide their practise as educational psychologists or other fields of applied Psychology.

As Psychology globalizes, most of these issues are likely to become more acute as it has to negotiate its relationship with non-western religions (each with its own regional variants and branches), notably Islam, Hinduism, Buddhism, and various indigenous African religious concepts. Ultimately, the issues we classify as "religious" remain matters which we can only resolve at a personal level, albeit in the light of the public knowledge, ideas, and information available to us (including Psychological theories and findings) in combination with our individual experience and temperament. But even saying that perhaps reflects only the unbelieving author's Protestant cultural background.

Psychology in Modern India

GIRISHWAR MISRA¹, ANAND C. PARANJPE²

¹University of Delhi, Delhi, India

²Simon Fraser University, Burnaby, BC, Canada

The history of psychological thought in the Indian subcontinent may be divided into three distinct periods: *first*, a multi-millennial span from antiquity to the founding of the British empire in the mid-nineteenth century; *second*, about a century of British colonial times up to independence attained in 1947; and *third*, bit over half a century of the independence era. The first period is covered in a separate entry in this volume (see Pre-modern India and Psychological Thought). This entry covers the 2nd and the 3rd periods.

Psychology in the British Colonial Period (1857–1947)

The British East India Company adopted a policy of funding only European-style education within its territories several years before the subcontinent was formally accessioned to Queen Victoria's empire in 1857. The aim of this policy was to produce a class of Indians who would be brown in color but English in their thinking. The success of this policy was enormous; its results were at least twofold. While on the one hand the vitality of the indigenous intellectual tradition was reduced to a great degree, Indian intelligentsia became exposed to European thought and modern science. Education in colleges and universities was modeled after Oxford and Cambridge. Modern psychology was introduced at Calcutta University with the starting of a separate department of psychology in 1916. Dalal

(2002) has given an excellent overview of the history of psychology since that time onward. During nearly a century that has passed since, Indian psychologists trained abroad as well as those trained in India almost exclusively followed the Western brands of psychology. Their theoretical contributions will be discussed in a later section. But first let us take a look at psychology as it developed on the foundations laid by India's own intellectual tradition.

The tradition of spiritual self-development which gave psychology in India its most distinctive character continued to flourish despite the Anglicization and modernization of various aspects of the Indian culture. Numerous lineages of teachers and disciples (*guru, śiṣya*), that are recognized as distinct "sects" which followed their own brands of theory and practice, continued to proliferate and flourish. One of the many well-known pairs of teacher and disciple in the modern times was Ramakrishna Paramahansa, the great saint of Kolkata, and his disciple Swami Vivekananda. He is widely recognized as the first Indian monk whose lecture at the world conference on religions in Chicago in 1883 became a landmark in introducing Indian thought in the USA. The importance of his work for psychology follows from the fact that the Swami made a deep impact on William James and his ideas about the higher states of consciousness (Taylor 1988).

With the increasing prevalence of the distinctive Western world view promoted by Anglicized higher education and the inevitable influence of science, there was a great need to interpret traditional ideas in light of modern concerns and concepts. Among the important pioneers in interpreting Indian thought in the context of Western philosophy two names may be mentioned: Krishna Chandra Bhattacharyya (1875–1949) and S. Radhakrishnan (1888–1975). In terms of articulation of the basic principles and theories for psychological theory and practice, we may note the work of B.G. Tilak (1856–1920), who interpreted the Path of Action described in the *Bhagavad-Gītā* in light of post-Kantian philosophy and Darwinian thought. But beyond doubt the most important contribution to psychology in the Indian tradition was made by Aurobindo Ghose (1872–1950), widely known as Sri Aurobindo.

Sri Aurobindo was a genius. Educated from childhood in England, young Aurobindo mastered French,

Latin, and Greek, and learned enough German and Italian to enjoy Goethe and Dante in the original, before graduating from Cambridge University. He started his adult life as a freedom fighter and journalist, but spent later years as a poet, sage, and a yogi. Psychology was one of the important topics in his voluminous writings. He was not formally trained in psychology; he was a sage in the Indian tradition who wrote on psychological topics on the basis of his profound experience as a yogi. Prominent in his contributions to psychology is his work called *The Synthesis of Yoga* (Aurobindo 1949/1999) in which he brings together the essence of the three basic varieties of yoga, namely the paths of Knowledge (*jñāna mārga*), Devotion (*bhakti*), and Action (*karma*). Having mastered the Sanskrit language, which he learned as an adult, Sri Aurobindo wrote commentaries on the principal Upaniṣads as well as the Vedas. In this work, he gives symbolic interpretations of several hymns of the Vedas explaining the psychological significance of the parables therein.

Turning now to the academic psychology that was transplanted from the West, we may note two pioneers: Narendra Nath Sengupta of the Calcutta University, who was trained in experimental psychology with Hugo Munsterberg at Harvard, and his successor Girindra Shekhar Bose, who became a self-taught psychoanalyst to be admitted by Freud to membership of the International Association of Psychoanalysis (see Vahali 2011 for details). Thus, both Western experimental and clinical approaches were imported, and since then numerous psychologists trained abroad have continued to bring Western trends into psychology in India. Of these two strands of Western psychology, the experimental model flourished, while psychoanalysis lagged far behind. As to psychology of the Indian tradition mentioned in the first part of this essay, its theoretical side became a small part of philosophy courses in universities, while the applied aspect was completely sequestered away from the academe. With the exception of Indra Sen (1986), few psychologists recognized the great contributions to their discipline by Sri Aurobindo.

Mahatma Gandhi (1869–1948) is universally known as a saint, a freedom fighter, social reformer, and a great thinker, but not as an academic – let alone a psychologist. However, it is necessary to recognize his

contribution to what may be called “applied social psychology.” Seeped in traditional Indian thought and culture, Gandhi emphasized the principle of nonviolence (*ahimsā*), and developed *satyāgraha* (the word literally means insistence on truth) as a technique for nonviolent resolution of social conflict. Gandhi’s style of leadership demonstrates his deep understanding of what modern psychologists have called “group dynamics.” He may be legitimately considered an applied social psychologist par excellence. Gandhi’s work reflects the *practical* orientation of psychology in India. It is neither abstract theory-building nor empirical validation of propositions that take central stage in the tradition of psychology in India; the primary goal of human sciences is to devise ways that help in successfully dealing with problems of living.

Dalal (2002) quotes the following observations made by a prominent contemporary psychologist Ashis Nandy: “[T]he usual encounter between an ancient culture with its distinctive culture of science and an exogenous science with its own distinctive culture fractured the self-definition not only of Bose but of many others involved in the similar enterprise” (Dalal 2002, p. 83). Nandy’s words would convince anybody who has noted that, in the case of many Indian psychologists in recent times, their world view as quapsychologists seemed to be completely divorced from their world view as members of the Indian culture. This historical background is necessary to understand how and why the development of psychological theory in later years split into two loosely linked and yet rather distinct streams, one following the Indian tradition while the other remaining Western in style and spirit. In the mainstream, however, the Western impact continued with the choice of British, American, and Canadian Universities as preferred destinations for higher learning. The first generation of academic leaders in most of the Indian universities, therefore, were products of Western training and psychology modeled after natural science remained the dominant voice.

Psychology in Independent India (1947–)

Soon after India gained independence from the British rule, psychology witnessed an explosive growth with departments of psychology opening up in old

universities as well as in a continually widening circle of new universities and institutes of technology and management. There was a similar explosion in the number of research publications in Indian as well as international journals. Despite all the exceptional growth of the field, there has been acute restlessness about the significance of the accomplishments.

Dalal (2002) complains about the

- ▶ growing disillusionment with applicability of western theories and their mindless testing in India. Their failure to resolve inner conflicts of cherishing Indian cultural values at the personal level and maintaining western orientation at professional level was reflected in their methodologically sophisticated but socially irrelevant research. Western psychological theories and research were not effective in understanding the Indian social reality. As a result, Indian psychologists became increasingly marginalised in society. (p. 95)

Regardless of such restlessness, psychological research has continued at an ever-increasing pace. As far as theories are concerned, there are notable contributions that have followed both traditional Indian as well as a few Western models. A brief overview of the more important contributions is in order.

Theoretical Contributions Following the Traditional Indian Lines

A natural reaction to finding the cultural misfit and redundancy of imported models is to turn to the rich intellectual heritage of one's own culture. A clarion call in this direction was given by Durganand Sinha (1965) asking for the integration of modern psychology with Indian thought. In a national conference in 2002 well over 150 psychologists proposed the "Pondicherry Manifesto of Indian Psychology" (The full text of the Pondicherry Manifesto of Indian Psychology is available on the following link on the Internet: www.infinityfoundation.com/mandala/i_es/i_es_corne_manifesto_frameset.htm) which repeated Sinha's call in following words:

- ▶ By Indian psychology we mean a distinct psychological tradition that is rooted in Indian ethos and thought, including the variety of psychological practices that exist in the country... Indian models of psychology would have enormous implications for health

psychology, education, organizational management and human and social development. Emphasis on Indian psychology would provide a comprehensive foundation and a refreshing new and indigenous orientation to all other branches of psychology.

Two rather distinct but related lines of development in "Indian Psychology" can be identified which signify elements of resistance and protest. The first one mainly involves interpretation of traditional approaches in light of modern perspectives. In such works, attempt is usually made to explain the relevance of traditional concepts and methods with explanations given in currently popular idiom. Foundational issues underlying theory building in terms of ontological and epistemological issues are discussed in Rao et al. (2008) and Cornelissen et al. (2011a).

There is a wide range of studies that explain how insights of traditional Indian origin contribute to the understanding of specific psychological issues. Notable in this context are publications in the fields of consciousness (Rao 2002; Cornelissen 2001), self (Paranjpe 1998), emotion (Paranjpe and Bhatt 1997), and perception and cognition (Rao 2011).

Aside from such theory building efforts based on traditional foundations, there are efforts toward the empirical validation of theories with the use of Western-style tests and measurements. Several measures have been developed to assess personality typology based on the Sāṃkhya concepts of the three strands of Prakṛti, the principle of materiality. A remarkable effort was made by Pande and Naidu (1992) to empirically examine a set of propositions from the theory of acting without attachment to results of one's action described in the *Bhagavad-Gītā*. Then, they developed and validated a measure for an attitude of nonattachment, and correlated the strength of such attitude with various indices of mental health.

The dominant approach to psychological knowledge in the Indian tradition is, however, grounded in a different world view in which focus on self and self-development is valued, and the success of a theory is judged in terms of the usefulness of applications in existential benefits and spiritual progress. With the divorce of religion and science in the history of Europe typified by Galileo's inquisition, spirituality was driven into the religious camp, and it became an anathema for

the “science” of psychology in the West. Most Indian psychologists simply followed this trend. But things have changed more recently; research on meditation has become common in contemporary psychology, and yoga has become a household word. In this context, theories and methods of traditional Indian origin are being recovered and critically examined and articulated in the contemporary context.

First of all, there is a burgeoning body of literature on various techniques of meditation and the measurement of their success. A review of this literature with specific reference to Indian approaches may be found in Rao (2011) and Salagame (2011). Paranjpe (2008) has adopted a case-study approach; he has examined the life history of a modern sage, Sri Ramaṇa Maharshi, to see how the traditional Advaitic method of meditation is modified and practiced in modern times, and the kind of transformation it can lead to. Similarly, he (Paranjpe 2011) has examined the life history of B.G. Tilak, a modern exponent of the Path of Action (*karma yoga*) and tried to assess how and how far he brought into action the principles he preached. Such use of case studies for validation of theories fits the distinctive character of the Indian tradition where a personal application of psychological models is crucial. The worldwide popularity of Yoga and meditation indicates the relevance of the Indian approaches where similar goals are valued. Patañjali’s theory of Yoga provides the backbone of an ambitious and continuing program for the assessment of psychosomatic benefits of Yogic practices. Literature reporting the results of numerous studies is available from the website (See http://www.svyasa.org/research/research_publication.asp) of the Swami Vivekananda Yoga University, which has become the hub of research on Yoga. Another similar source of information about ongoing research focused on psychological theories of Indian origin is the website of the Indian Psychological Institute, which is closely associated with Sri Aurobindo Ashram in Pondicherry (See <http://ipi.org.in/>).

Theoretical Contributions Following Modern Western Lines

Since the growth of knowledge is socially conditioned, the developments of psychology in India including its theories and concepts need to be appreciated in the local and global historical and sociocultural matrix

in which the country has been positioned. Being a developing country with millennia-old culture, a richly diverse society, and a two-century-long colonial past, India is currently aspiring to emerge as a self-reliant and economically strong nation. Faced with the challenge of socioeconomic transformation, the country has been engaged in efforts toward industrialization, modernization, and globalization. Navigating through this difficult terrain has been a complex challenge and has shaped the developments in the academic disciplines also.

India has been engaged with rapid growth of higher education and rapid expansion of professional institutions to meet the increasing demand for trained personnel in various service sectors like health, administration, banking, police, military, and management. The cultural complexity of India due to diversity in ecology, language, religion, family structure, and uneven introduction of technology has put a challenge before the planners to ensure social welfare through democratic processes. This context has shaped the course of higher education in general and psychology in particular.

The challenge to relate India’s past and modern psychology was a main concern in the early period and continued since then. In fact, the search for a distinct identity for psychology in the Indian context has remained a key issue. Theoretical innovations came from the real world as well as the difficulties faced in applying psychological knowledge to the diverse problems faced in the Indian conditions. In the course of the disciplinary journey, the theoretical–conceptual ambience of the works of Indian psychologists has undergone several shifts in themes, alignments, and emphases.

The teaching and research in modern psychology began largely as an extension of the Euro-American tradition in the British period. Its initial emphasis was not so much on questioning and doubting the Western concepts and methods, but on preserving the essential configuration of the discipline and keeping it as similar to the one in the Western world, as possible. We also note that there existed a tradition of British psychoanalysts who tried to offer interpretations of the Indian psyche to justify the British rule. (Citing Christine Hartnack’s work Vahali (2011) has discussed at length how early British psychoanalysts tried to create

universal psychoanalytic conceptualizations that explain away Indian experiences of selfhood, or view them as essentially inferior, less worthy or simply pathological, or otherwise deficient. It acted as a tool to justify social oppression and colonial rule).

In the mainstream critical paradigmatic questions of ontology and epistemology were sidelined to give space for the newly emerging positivist scientific enterprise. We find that the Western model of research and teaching provided the initial necessary direction to Indian psychologists. Dependence on Western thought was deemed legitimate owing to unexamined theoretical suppositions about the universality of psychological knowledge. It was largely in the 1970s that many psychologists raised the issue of insufficient and inadequate attention to social-psychological problems. The Indian psychologists realized that they had been indifferent to the vast and rich collection of knowledge inherent in the Indian texts. However, the commitment to scientific inquiry was venerated and debates related to the philosophy of science and related arguments could not receive due attention until the 1980s (Mukherjee 1980; Misra and Gergen 1993; Varma 1995). Also, there has been a constant pressure for problem solving and application in the social world (Sinha 1986).

A scrutiny of the published literature suggests that the theoretical endeavors of Indian psychologists have taken many forms (for details, see Misra and Kumar 2011; Pandey 1988, 2004). They have been more interested in the use of theory as a heuristic device for problem solving in relation to the changing features of the social reality (e.g., technology, economy, media, environment, migration, and education) rather than formal theorization. The mismatch between western theories/concepts and Indian reality has led not only to the introduction of new concepts but also to the modification of constructs in vogue to accommodate newer aspects of reality as applicable in the Indian milieu characterized by a mix of factors demanding a balancing act between the age old traditions of oral culture, cosmological worldview, and hierarchical social order on the one hand and modern influences which emphasize more on technology, social and geographical mobility, secularism, and materialism, on the other. There are growing attempts to test the assumptions and predictions of psychological theories in the

Indian context. While culturally informed studies are on rise, full scale reconceptualization or indigenous theorization has been limited.

Early Efforts

Keeping in mind the colonial background of modern learning in India, the mandate of initiating scientific psychology in the prevalent Wundtian tradition and subsequently in the behaviorist tradition was a natural choice. The eagerness to attain an independent identity for the discipline constituted the package of academic delivery consisting of empirical work, positivist metatheory, a universalistic stance, and the presumption of cultural immunity of psychological concepts and theories.

In terms of the institutional structure, psychology was earlier a part of philosophy departments. Separate psychology departments were started largely between 1940 and 1960. In order to maintain a separate identity, the teaching and research practices opted to fashion themselves as differently as possible from the parental discipline of philosophy and similar to the physical and natural science disciplines. To this end, they over-emphasized experimental psychology and psychometry – the distinctive features of the new science – and made them the core of psychology curricula which continues till today. Indeed, empiricism and quantification made possible the flourishing of an empiricist-positivist brand of psychology aimed at generating and testing nomothetic laws as objectively as possible.

However, it will be a mistake to ignore another feature of the academic prowess of the first generation of Indian psychologists. They were also cognizant of their cultural roots and tried to address the academic as well as nonacademic audiences. In a pioneering work entitled *The Science of the Emotions*, Bhagwan Das (1908) presented a rich account of the Indian science of affect. G. S. Bose wrote about the Upanishads and mythology in Bangla language and had an academic fascination for psychoanalysis (see Dalal 2002). Early researchers did attend to the theoretical issues and noted the importance of traditional knowledge but did not reject modern theories.

It is interesting to note that even during the early part of the development in India, many indigenous lines of inquiry were also prevalent. Examples that

highlight this trend include Asthana's (1950) work on Sāṃkhya theory of personality and Indra Sen's (1986) elaboration of the integral psychology of Sri Aurobindo. E.G. Parameshwaran started research on the Triguṇa (*sattva*, *rajas*, and *tamas*) theory (Uma et al. 1971) which has been followed by several studies (see Salagame 2011). We also find works on the Indian typology of personality (Krishnan 1976/2002) and tantra (Mukerji 1926). Some notable works were undertaken from the Western tradition for further study. For instance, Asthana (1960) proposed that perceptual distortion is the function of the valence which an object acquires from the field structure in which it exists. In this way he tried to resolve the differences between gestalt and learning theories and incorporated Lewin's field theory. In the area of learning theories, the S-R theory was challenged by Kothurkar (1968).

Thus, we see a dual focus of the researchers. One set of works was focused on the study of phenomena pertaining to sensation, perception, psychophysics, and reaction time in the natural science tradition with the spirit of creating a universal theory which would be modern in its texture. Another set took a theoretically relevant initiative to interpret various Indian phenomena in the light of Western theories and constructs and vice versa, while also trying to develop theories based on traditional Indian concepts. The scholars were cognizant of the possibility of indigenous knowledge resources but considered scientific enlightenment as more important. The coexistence of the two traditions which had some overlap but maintained separate identities was gradually replaced by a move that led to a greater gap between the Indian ethos and the academic pursuit of psychology. The assumptions of universally shared computational notion of the mind/brain and strong empiricism were very powerful in creating the boundaries of the discipline and furnishing the criteria of inclusion and exclusion.

Under the prevailing academic culture, Indian psychologists' theoretical engagement remained confined to attempts at enlarging the scope of a set of explanatory (independent) variables that may enhance predictive power in accounting for a set of chosen (dependent) variables. Thus mapping quantitative variations in psychological variables was the main research strategy. Other theoretical and methodological approaches (e.g., Indian, spiritual, qualitative, and

discursive) were marginalized on account of their doubtful scientific status and consequently underrated as knowledge claims.

Against this backdrop, it was natural that testing (western/universal) psychological ideas on Indian samples or creating the Indian version of Western tests/tools/concepts became a major preoccupation. This led to proliferation of adaptation and adoption of tests in different areas like intelligence and personality. The practice of psychology remained Western in content and orientation, and used Western academic developments as standards for comparison. This was done as an authentic and legitimate academic practice and got reflected in teaching programs and choice of research topics. The traditional Western models from behaviorism, schema theory, Gestalt school, Pavlovian theory, and information processing theory were popular. Similarly, theories by Cattell, Eysenck, Erikson, McClelland, Piaget, and Herzberg served as some of the dominant frameworks of Indian psychologists for conceptualizing psychological issues and explanations. The researchers were dominated by the mindset that psychological characteristics are stable and reliable dispositions subject to quantification. On the other hand, cognitive processes were handled in terms of concrete and manipulable entities. The positivist methodology was dominant and critical determinant of the choice of problems, variables, processes, and practices. Theory was treated as a copy or map of reality. A strong correspondence between the two was emphasized. There was explicit and implicit endorsement of biology as the ultimate, and reductionism became a strong belief. Affective and social phenomena were mere derivatives of biological and cognitive processes which were foundational. All this was going on in terms of an image of science and scientific practices that did not bother about the dynamic nature of social reality and social conditioning of knowledge. The "basic problem", as Nandy and Kakar (1980) have observed, involved "dependence on conceptual frameworks which are not intrinsic to the experience of society" (p. 159).

A Socially Relevant Psychology

In the 1980s, several lines of investigation across many domains of social psychological processes showed that many of the phenomena reported in Western research literature required different explanations rooted in the

Indian cultural milieu. Examples of this kind are found in the areas of social cognition. Thus predictions from attribution theory with socially and culturally specific causal categories were tested for understanding achievement, health, and other aspects of human behavior (Dalal 1988). The change took place when psychologists found the applications of Western theories/methods to be either ineffective or irrelevant in real life situations in India. A selective overview of some of these developments in key areas is presented below.

Human cognition: Researches on attention, emotion, and consciousness (see Srinivasan 2011), by using multiple methods and approaches, have shown cross-cultural aspects of emotion as well as of meditation, in terms of underlying neurophysiology. There are also researches on philosophical aspects of cognition that view cognition and other mental phenomena as central to the functioning of all living beings. To put it another way, the fundamental principles governing cognition run from a single cell to human societies.

Planning is a key intellectual function. Extending the earlier work on PASS (Planning, Attention, Successive, and Simultaneous Processes) theory, Das et al. (2000) have brought out its significance in various cognitive functions. Srivastava and Misra (2007) have developed an indigenous conceptualization of intelligence and termed it integral intelligence. It has four dimensions: cognitive competence, social competence, competence in action, and emotional competence. The analysis of creativity has been undertaken from a culturally informed position (Misra et al. 2006).

Sinha (see Misra and Tripathi 2004) was perhaps the first one in India to emphasize the role of sociocultural context in understanding cognitive development. Following this tradition, R.C. Mishra (1997) has been investigating the ways in which basic cognitive processes like perception and memory get shaped and manifested under diverse eco-cultural settings. Pirta (2011) has investigated native cognition in Himalayas and has endeavored to develop a bio-ecological framework integrating ecology, biology, and behavior.

Attitude and social cognition: With the political independence of the country in 1947, the highest challenge was that of the problem of communal tension arising out of partition. This led to studies of conflicts, prejudice, stereotypes, discrimination, and violence. Since then it has remained a productive area of

research. These studies were directed toward measuring attitudes, stereotypes, and cognitions and relating them to a number of contextual and dispositional variables. Also, there was the challenge of social and national development of reality and psychology played the role of identifying the facilitators of, and resistances to, the process of development.

In interesting rumor studies, Prasad (1935) examined the responses to an earthquake in Bihar, and published a comparative analysis of earthquake rumors which provided basis for cognitive dissonance theory.

Ashis Nandy's *The Intimate Enemy* (Nandy 1983) and *Illegitimacy of Nationalism* (see Nandy 2004) and Sudhir Kakar's *The Colors of Violence* (Kakar 1995) have touched on the cultural-historical aspects of selfhood and intergroup relations, indicating the need to attend to macro aspects to capture and understand the psychosocial systems. Further, such works encouraged psychologists to employ other methods to understand human behavior. A major programmatic and cross-cultural work based on studies in the Netherlands and India is by De Ridder and Tripathi (1992) recognized the prominence of group norms in intergroup behavior. They pointed out that norm violation by one group leads to a chain of negative reactions by both groups and, if this sequence continues, it is likely to escalate violent behavior.

Singh (2011) has systematically examined judgment and decision-making within the framework of information integration theory. His work spanning over a period of more than 3 decades has found that Indians use averaging, subtracting, multiplying, and dividing rules and their combinations. Such cognitive algebra, however, represents causal beliefs and not mathematical calculations.

Research in the area of distributive justice has focused on principles of distributive justice. L. Krishnan (2005) has analyzed the Indian notion of *dāna* (charity) and has drawn attention to its nuances with respect to deservingness in the Indian tradition.

The above works demonstrate a significant shift in research thinking and execution, where the psychologist seeks a realistic appraisal of the problems in the Indian context. This socially relevant focus helps in understanding everyday social issues, caste, and religious identities, intergroup behavior, justice, and nation building. The need for Indian psychologists to

be rooted within the sociocultural and historical contexts was and is repeatedly emphasized.

Psychology of poverty and deprivation: The study of poverty and deprivation has been an important area of research where researchers in different parts of the country (e.g., Rath at Bhubaneswar, A.K. Singh at Ranchi, D. Sinha at Allahabad, L.B. Tripathi and G. Misra at Gorakhpur) moved in many directions and have mapped the diverse effects of poverty, social disadvantage, and deprivation (for a comprehensive review see Misra and Tripathi 2004). Most of these studies have situated deprivation in the experiential-environmental context and have traced its detrimental influences back to aspects of development. The detrimental effects of poverty are accentuated by the unfavorable proximal environment of the child. Thus, intervention should address not only the cognitive-attentional drawbacks of the children but also the conditions prevailing in the family and school settings. They should be planned to create in the people a sense of empowerment to effect change in their life conditions. Unfortunately, the planning rooted in the Western model of development often ignores the traditional attitudes, beliefs, and values, and considers them antithetical to development ideology. There is growing evidence that social-psychological problems of Indian society are now being increasingly addressed by psychologists.

The challenge of achievement: The economic and social development was an important concern for a developing country like India. The theoretical analysis by McClelland underscored the significance of achievement motivation (n-Ach) as a driving engine for development. The lack of emphasis on individualistic and competitive spirit and independence were identified as the main causes of underachievement. This became the basis for a major intervention program at Kakinada in Tamil Nadu, as reported in *Motivating Economic Achievement* (McClelland and Winter 1969). It provided impetus for promoting entrepreneurship. The relevance of achievement motivation theory was, however, Indian challenged (e.g., Sinha 1968). The perceived value of various achievement goals is determined by the expectations of significant others. The concepts of “extension motivation” (Pareek 1968), “dependency proneness” (Sinha 1968), “achievement value” (Mukherjee 1974), and

“dissatisfaction-based achievement motivation” (Mehta 1972) are important contributions.

Organizational behavior: Rapid industrialization in the 1960s led to recognition of the need to study the labor-management relationship and organizational effectiveness. Chakraborty (1995) has brought into focus the critical role of values in managerial transformation, as well as ethics in management. R. Gupta (2002) emphasized the need to go beyond the American and Japanese models of organizational behavior, and develop models specific to the Indian conditions.

The concept of “nurturant task leadership” proposed by J.B.P. Sinha (1980) was an innovation showing the need for developing a theory relevant to culture-specific aspects of organizational behavior. It emphasized nurturance, dependency, personalized relationship, and status consciousness from the Indian cultural context and combined them with the contingency approach and the principle of reinforcement.

Individualism-collectivism, self, and identity: Indian scholarship has shown that the elements of Indian selfhood are complex and it is difficult to categorize it as either individualist or collectivist. Sinha and Tripathi (1994) see that there is the presence of individualist as well as collectivist aspects of self indicating a kind of “coexistence of opposites.” Mascolo et al. (2004) have demonstrated multifacetedness of the representation and experience of Indian self. They propose four ways of conceptualizing selfhood: independent, interdependent, relational, and encompassing. In addition, there are text-based, theoretical, in-depth, and extensive analyses – like the ones on the Indian views of self and identity (Paranjpe 1984, 1998), concept of self in the Sufi tradition (Beg 1970) – which offer insights to selfhood and identity embedded in the Indian traditions in which higher or “spiritual self” occupy important place.

Sinha and Pandey (2007) have proposed that Indian people function with diverse mindsets in different contexts. Thus, they manifest a materialist mindset in multinational organizations, and dependence prone or collectivist mindset in family owned, bureaucratic, and/or traditional organizations. They noted that Indians are holistic in terms of combining excellence in work, personalized relationships, abstract thinking, emotionality, rationality, and spirituality in those

organizations that valued both performance and people. Materialistic mindset was associated with manipulative behavior, and a holistic mindset with a proactive stance that manifested in innovative and extraordinary performance under inspiring superiors; both materialistic and holistic mindsets were instrumental to success at work, in different organizational contexts. The use of mindset varied depending on the cultural context.

Cultural psychology of emotions: In this area, certain indigenous concepts with culturally specific implications such as *lajjā* (shame) (Menon and Shweder 1994) and *bhakti* (devotion to God) (Paranjpe 1998) have been recovered and elaborated. At another level, depersonalized, transcendental and transformative aspects of the *rasa* experience have been delineated (Paranjpe and Bhatt 1997).

Health, human development and well-being: The Indian ideas and concepts like *ahamkāra* (Salagame 2011), *anāsakti* (Pande and Naidu 1992) have been explored, as are implications for health of various issues particularly relevant for the Indian context, for example, experience of crowding (Jain 1987), notions of health and well-being (Dalal and Misra 2005), and Hindu parents' ethno theories (Saraswathi, and Ganapathy 2002). Neki (1973) has tried to build therapeutic interventions for the promotion of mental health and well-being using yoga and has come up with a model called *Guru-Chela* therapy which involves the teacher-disciple relationship developed in the Indian tradition. Kakar's *Shamans, Mystics and Doctors* has become a classic which talks about indigenous healing practices. It clearly indicates the role of traditional healers in maintaining mental health in traditional societies. In *The Inner World*, Kakar has tried to present the interplay of the universal processes of development and the specific aspects of Indian social reality. He comprehensively tries to weave the story of development, health, passion and relationship by drawing from various sources including religious ideals, traditions, and institutions that constitute a society (see Kakar 1996; Vahali 2011).

These dimensions of psychology are leading psychologists to develop theories and concepts which do not take from any Western thought, but derive entirely from Indian traditions of thought.

Move Toward Indigenization

The indigenous thought systems remained neglected because there was a strong aversion toward them owing to doubts regarding their scientific status, contemporaneous relevance, and ontological suppositions (see Gergen et al. 1996). Psychological theories and constructs were taken as intrinsically biological, materialistic/objective in content, and quantitative in methodological approach. Therefore psychology, like other natural and physical sciences, was thought to be culture and psychological processes as distributed/shared uniformly across diverse cultures and sub-cultures.

This spurred the need for a radical change in cross-cultural psychology's universalist stance, and its almost exclusive focus on the discovery of panhuman patterns of behavior. "There was an implicit assumption that the definition of... concepts and their measurement as proposed by the Western research workers will also hold good in our cultural context" (Mukherjee 1980). The signs of efforts to outgrow the alien frame were noticed in the 1970s. The search for a new identity became a major question. Culture-specific concepts, and a search for culturally appropriate methods and tools were emphasized and the relevance of culture was realized. In this context, the interaction with cross-cultural and cultural psychologists has provided important impetus. Gradually, blending scientific ways with indigenous concepts emerged as an important academic agenda (Sinha 1997). Ramanujan (1990) has emphasized context sensitivity as the key feature of Indian way of thinking. Critical reflections (Misra and Gergen 1993; Nandy 2004; Varma 1995) have drawn attention to the limitations of natural science-based approaches and to new possibilities. It was realized that an understanding of Indian social reality would benefit from indigenous psychological knowledge and the discipline should contribute to the programs of socioeconomic development.

Rao (2002, 2011) has discussed human cognitive processes from the perspective of *Sāṃkhya-Yoga* system. According to this system, there are two principles that govern our existence – *puruṣa* (consciousness) and *prakṛti* (matter). *Puruṣa* is pure consciousness and has no quality or characteristics of its own; it is inert and formless. *Prakṛti*, on the other hand, is the material basis of our being. In *Yoga*, *citta* denotes the functional

mind, which comprises of not only the cognitive processes, the ego and the senses, but also contains instinctual tendencies (*vāsnās*) inherited from previous lives and the effect of past actions in the present life (*samskāras*). They influence our cognitions and predispose us to behave in certain ways.

In Yoga, *citta* controls our actions. Information processing in *citta* may take place at three levels that is, *buddhi*, *ahamkāra* (egoic self), and *manas*. *Manas*, the central processing unit, selects information provided by the sensory system and processes them. *Ahamkāra* (the emotional self) appropriates the processed information from *manas* and considers it as required by the perceiving person. And, *buddhi* decides and plans the actions and reactions in an appropriate manner.

The above discussion indicates the gradual inclination of Indian psychologists to move from Western theories, models, and modes of research toward an indigenous approach to theories and methods. We note the continued use of Western theories; yet they are consistently being tested in the Indian context. A beginning toward cultural sensitivity in the form of culture-based concepts, theories, and methods has been made. Today an Indian psychology is emerging which promises a broad theoretical foundation for the exploration of human consciousness (Yoga), and radical psychological transformation. Its applications are found in modern areas like organizational behavior (Chakraborty 1995; Gupta 2002). Accounts of the states and contents of mental functions regulating responsible human conduct available in vast Indian texts and practices is being rediscovered in a more contemporary context. It emphasizes a kind of perspective which is practical path or life ways that allow pursuit of balanced living and enjoying well-being and equanimity through self transformation and personal growth. The universal consciousness and transcendence requires methods that combine sensory, mental and spiritual tools and innovative theoretical paradigms. The recent publications on Indian psychology (e.g., Cornelissen et al. 2011a, b; Gupta 1999; Joshi and Cornelissen 2004; Misra 2011; Rao 2011; Rao et al. 2008; Salagame 2011) clearly indicate a serious move in the direction of creating and using *samvada* (dialogue) for better understanding. The conceptual network is being extended. The current theoretical developments

such as feminism, subaltern studies, critical theory, and post modernism are providing new ways of engaging with reality. The life world is being appreciated in newer ways and options are generated. There have been enabling moments that have helped Indian psychologists to go beyond the constraints. Promising elements of critique as well as reconstruction are seen.

Concluding Observations

Indian psychology in the twenty-first century shows that the initial emphasis on the replication of Western studies has given way to socially relevant research, and that there is a shift from experimental work (micro) toward understanding the psychocultural contexts (macro) using qualitative approaches.

Academicians have come to appreciate the depth, wisdom, and insightfulness of Indian thought traditions, and that it is possible to develop a scientific psychology based upon them. There are small but definite steps toward changing the content and quality of Indian psychology. Indian psychology endeavors not only to study the person and the causes and consequences of his/her behavior, but the process of transformation of the entire self, its growth and well-being. It is being realized that the psychological world is an intentional world that evolves in the matrix of the culture. Therefore, we need to look at psychological processes within cultural contexts, holistically. With these directions and prospects, the move toward indigenous psychology holds promise for the future of the discipline. The journey toward an indigenous psychology is in progress.

Psychology in Pre-Modern India

ANAND C. PARANJPE¹, GIRISHWAR MISRA²

¹Simon Fraser University, Burnaby, BC, Canada

²University of Delhi, Delhi, India

Indian cultural and intellectual tradition is a living tradition; it has continued in an unbroken form from hoary antiquity to the present. Psychological phenomena were an integral part of systematic inquiry and investigation in numerous schools of thought in this tradition.¹ The vitality of this tradition was reduced during British rule from 1857 till independence in 1947 as its world view and sciences were denigrated in an Anglicized educational system. During the British rule, Western psychology was introduced in the Indian

subcontinent, where it took roots and continues to flourish. Traditional approaches, which were pushed to the back seat for long, are currently getting attention and being introduced to the world. Since the cultural context in which these approaches developed is distinct from the European background of modern psychology, it is necessary to first explain certain substantive and stylistically distinctive features of Indian approaches to psychology.

The Historical and Cultural Context of Traditional Indian Psychological Thought

Foundations of psychological thinking in India were laid in the ancient texts called the *Vedas*, the first of which was composed about two millennia BCE. But more specific concepts can be traced to a set of texts called the *Upaniṣads*, which are dated around 1500–600 BCE. Yearning for spiritual uplift was a dominant feature of the Upaniṣadic sages. This yearning has continued to dominate the thought and practices of not only the “orthodox” schools that accepted the authority of the *Vedas*, but also the many schools of Buddhism, Jainism that rejected it. Although the two main branches of Buddhism, namely, Theravāda and Mahāyāna, originated in India, their influence in the Indian subcontinent nearly ended around the eighth century CE. Thereafter, the Buddhist traditions flourished outside India. Psychology in Buddhism is a vast field in itself; it deserves separate treatment of its own. Here reference to Buddhist concepts will be restricted to their dialectical relationship with few of the “orthodox” schools of thought. In the fourteenth century compendium called the *Sarvadarśana-saṁgraha*, Śāyaṇa Mādhava (14thc./1978) outlined over a dozen schools of thought, including orthodox as well as unorthodox. Within the limited scope of this essay, distinguished contributions of only the Advaita Vedānta, Sāṁkhya-Yoga, and Nyāya will be emphasized.

A major concern for several such schools of thought was spiritual uplift by means of self-knowledge. However, for millennia, the Indian culture advocated and encouraged the pursuit of four major goals of human life: fulfilling one’s social obligations and doing one’s duty (*dharma*), acquiring wealth and power (*artha*), fulfilling natural desires including sex (*kāma*), and

radical liberation from the fetters of living (*mokṣa*). Although some of the most distinctive Indian contributions to psychology arose from the spiritual quest for liberation, psychology flourished in other areas as well. Systematic study of experience and behavior in worldly pursuits is evident in highly regarded works such as Vātsyāyana’s (n.d./2002) *Kāma Sūtra*,² a treatise on sexuality, and Kauṭilya’s *Arthaśāstra* (n.d./1992), which deals with state craft and group conflict, and Bharata Muni’s *Nāṭya-śāstra* (n.d./1996), a comprehensive work on dramatics, which deals with the expression and transformation of emotions. As well, the indigenous system of medicine called *Āyurveda* deals with certain issues in health psychology.

There is a wide range of psychological topics on which sophisticated theories developed in India. Important among these are consciousness, self, person, cognition, action, emotion, the experience of art, language, nature of suffering and pathology, positive mental health, and varied technologies for self-transformation and self-realization. The material available is vast; discussion of theories of specific topics such as consciousness or cognition warrant volumes. Given the international scope and audience of this encyclopedia, emphasis will be on those aspects of theories that are distinctive or complementary to their more commonly known Western counterparts.

Some Distinctive Features of Conceptualization and Analysis

Since the historical development of Indian thought proceeded on distinctive lines, it is necessary to explain some of its unique stylistic features. Insofar as the ancient texts were preserved in an oral tradition where entire texts were meticulously memorized and passed on to the next generation, it was important to condense ideas in aphorisms to minimize the burden of memorization. In an attempt to make the most succinct statement of a given system of ideas, a specific genre of texts called the *Sūtra*, which literally means aphorism, evolved around a couple of centuries before and after the beginning of the Common Era. The *Vedānta Sūtra* of Bādarāyaṇa, Patañjali’s *Yoga Sūtra*, and Gautama’s *Nyāya Sūtra* are examples of well-known texts of this genre.

Further development of systems of thought in India proceeded through a series of glosses (*vivarāṇa*) and commentaries (*bhāṣya*, *vyākhyā*) on important texts, and commentaries on commentaries (*tīkā*). Over the centuries, many of the commentators explained and elaborated ideas of the original texts of the originators of their specific school of thought. In this process, they often critiqued ideas of rival schools in a way that would first state the position of a rival school (called *pūrva pakṣa*), which they refuted (*khaṇḍana*) by giving contrary arguments and evidence. Thus, the authors often stated their own thesis (*siddhānta*) by proving that the antithesis was false. There are several instances in history where eminent scholars toured the land challenging proponents of rival schools in open debates (*śāstrārtha*). It is important to note the development of systems of Indian thought through dialogues and debates, for it is through the development of theses and antitheses that rich and elaborate theories developed.

The system of logic that guided the development of theories was distinct from Aristotelian logic, which guided Western thought for over a millennium. Contrary to Aristotle's law of the excluded middle, which denies the rationality of a position between extreme affirmation and extreme negation, the Buddhist philosopher Nāgarjuna (second century CE) adopted a position midway between opposite extremes. The difference between these two approaches to logic is complex and the matter is controversial; and we need not examine this issue. But we may simply note that the distinctive and profound contributions to logic made by Buddhist, Nyāya, and the more recently (twelfth to thirteenth century CE) by Navya Nyāya traditions are widely recognized. The development of the Nyāya system is particularly important in providing guidelines for a disciplined inquiry. This system is sometimes known as *Ānvīkṣikī*, or science of inquiry. Nyāya is known for developing rules on how argumentation should proceed, and hence known as the science of reasoning (*tarka vidyā*). Since it also developed rules for debate, it is sometimes referred to as the science of debate (*vāda vidyā*). This is clearly an important aspect of the Indian tradition; it laid an essential framework for the development of sciences in the sense of systematic inquiry in various fields. The point is that psychological thought developed in India within the context of rigorous logic demanded by these traditions.

Ontological Bases and Epistemological Guidelines for Psychological Theorizing

Over the centuries, varied schools of thought evolved, and the fundamental issue of what constitutes the world was a central issue for most of them. A wide range of ontological doctrines developed as part of their inquiry. The Advaita school, for instance, held that there is a single principle of reality that is essentially indescribable, but can be generally characterized in terms of Being (*sat*), Consciousness (*cit*), and Bliss (*ānanda*). In contrast, the Sāṃkhya system proposed two principles of reality, one characterized by pure consciousness (*Puruṣa*) and the other by materiality (*Prakṛti*). On the opposite end of the spectrum, the Loakāyata school of Cārvāka insisted that matter is the only constituent of reality. The nature of psychological phenomena as conceived within such radically different views of reality was bound to be different. However, despite such highly divergent ontological doctrines, mind was more commonly conceived as fundamentally material in nature. Interestingly, mind and matter were not viewed in dichotomous terms as in the Cartesian scheme, and “mind–body problem” typical of Western thought did not arise in Indian thought. As will be explained later in this essay, a most distinctive feature of Indian perspectives was the concept of pure consciousness that transcended the processes and contents of the mind. Pure consciousness is thought of as having an ontic status beyond mind and matter.

Complex epistemologies developed as scholars criticized rival theses through logical argumentation (*tarka*) and adumbrated their own theses by citing specific evidence in their support (*pramāṇa*). The discussion of criteria for the validation of knowledge claims (*pramāṇa carcā*) is a very significant aspect of the development of theories in Indian thought. An important part of this discussion is the concept of valid cognition (*pramā*) as a proposition that remains unfalsified (*abādhitā*) in face of contradictory arguments and evidence. By and large, empirical statements are considered as having only provisional truth value; they remain open to revision. In the Indian tradition, testing knowledge claims through serious attempts at their falsification has been an integral part of testing theories centuries before Popper popularized the concept of falsification in modern philosophy of science.

Psychological theories are integral part of systems of Indian thought called the *darśanas*. The word *darśana* means a vision, and Sāyaṇa Mādhava's compendium of the principal schools of thought are alternative perspectives on life. Although it is common to consider the *darśanas* of Indian thought are systems of philosophy, whether they present philosophy in the Western sense, or constitute a unique Indian form of thinking called *Ānvīkṣikī*, is a matter of controversy. Whatever be the nuances in ways of thinking in Indian and Western styles, the *darśanas* nevertheless offer broad perspectives on a wide range of issues such as the nature of self, person, cognition, volition, and so on, which are important issues of modern psychology. Even as there are differences in Indian and Western styles of dealing with philosophical issues, there are distinct styles of psychological theorizing. Thus, while in contemporary psychology what matters most is empirical verification of theories, what matters most in the context of the Indian tradition is the application of a theory at experiential and behavioral level as part of a lived reality. As we shall see, Indian theory building commonly proceeds from whole to part, abstract to concrete, and not the other way around. Aside from such "stylistic" differences, there are differences in the assumptive framework adopted in theory building.

Key Concepts of the Assumptive Framework

Foundations for systematic thinking were laid in Indian thought in the *R̥g Veda*. There are two basic concepts from the earliest Vedic period that provided firm foundations for later developments. The first, called *ṛtam*, implies fixed and repeatable pattern of events, and the truth inherent in that pattern. The second called *satyam* implies absolute truth. The recognition of fixed and recurring patterns of events implies that the universe is a cosmos, not a chaos. Such a basic and axiomatic assumption implies the lawful relationship among events, and it is a necessary precondition for all systematic inquiry. A clear instance of lawfulness of behavioral events is the notion of *karma*, or action and its lawful consequences. The *Bṛhadāraṇyaka* Upaniṣad (4.4.5)³ declares that "According as one acts, so does he become... The doer of good becomes good, the doer of evil becomes evil." This is basically consistent with the Biblical

notion "as you sow, so you reap." Although the emphasis here is on the morally lawful consequences of action, in the course of history this basic idea led to a comprehensive view of lawfulness of events in physical, mental as well as moral spheres. The basic idea here is not fundamentally different from the notion of universal laws in science,⁴ except that the Law of karma extends far beyond the physical domain and beyond the scope of "value free science." The domain of truth uncontaminated by values was not unknown to the Upaniṣads, however. In the *Kaṭha* Upaniṣad (2.14), for instance, the young inquirer Naciketas insists on knowing that which is beyond good and bad, beyond right and wrong. As is widely recognized, with the lone exception of the school of the materialist Cārvāka and his followers, all schools of Indian thought, of Upaniṣadic as well as Buddhist and Jain persuasion, accept the Law of karma. This is particularly relevant for psychology insofar it deals with behavior and its consequences.

In later *pramāṇa*-based epistemologies, the concept of *ṛtam* mentioned above has a connotation of truth insofar as the truthfulness of a statement can be affirmed through the observation of a repeatable pattern of events. There is in the *Vedas* the notion of a higher order truth (*satyam*), meaning absolute truth that remains unfalsified at all times (*trikāla-abādhyam*). This does not imply apodictic statements that are open to rational proof and immune to empirical considerations as Kant suggested. Rather, *satyam* implies Truth inherent "in reality" or "in its own existence," and as such is open to direct experience in a trans-cognitive state of consciousness. This idea of a higher order truth is particularly significant for psychology insofar as it is based on a distinctive view of states of consciousness and their noetic significance. It involves a significant contribution of psychology in the Indian tradition, and will be discussed at some length in the remainder of this essay.

Consciousness

The idea of consciousness in the Indian tradition is traced back to the *R̥g Veda*. In it there is a hymn called the *Nāsadiya Sūkta* wherein a sage speculates on what may have happened at the time of the origin of the universe. He first suggests that perhaps it all began with some single undifferentiated entity devoid of basic

distinctions such as existence vs. non-existence, death vs. immortality, day vs. night; open air vs. the void beyond, and so on. That something, he speculates, somehow became *aware* of its lonely existence, and a desire (*kāma*) arose in it for becoming many. This primordial desire was the “seed of the mind” (*mānso retaḥ*), it suggests, from which the universe evolved. From the point of view of psychology, it is important to note that in this world view, such things as awareness, desire, and mind are taken for granted as *primordial*—and not in need of explanation as products of something else such as matter or evolution of life.

In the *Māṇḍūkya* Upaniṣad, we find an explicit account of four states of consciousness: wakeful, dream, deep sleep, and a fourth one simply called the Fourth State (*turīyā avasthā*). These states are distinguished in terms of being outer directed, inner directed, or directed in neither way. Although both deep sleep and the Fourth State are somewhat similar in not being directed in either outer or inner manner, the Fourth is much different from sleep; it has many extraordinary features. It is described as transcognitive, ungraspable, unspeakable, peaceful, and benign. Most of all, it is said to be the basis of experience of the Self, the unchanging basis of self-sameness underlying the continually changing images of the self. This extraordinary state of consciousness has been held in very high esteem throughout the Indian tradition, and many alternative paths have been suggested for the attainment of self-realization through the experience of such a state of consciousness. We will take up two of the most prominent trends in this direction. The first one is in the Advaita tradition, and the second in Sāṃkhya-Yoga.

In the Advaita tradition, the *Māṇḍūkya* Upaniṣad is followed by Gauḍapāda’s commentary on it in the eighth century CE. Gauḍapāda’s student Govinda passed on his interpretation to his famous disciple Śaṅkara (commonly called Śaṅkarācārya). Śaṅkara (788–822) proposed a strictly monistic ontology that takes pure consciousness experienced in the Fourth State as the single ubiquitous principle of reality (called *Brahman*). His approach is called Advaita, meaning non-dual, since it is based on the noetic value of the Fourth State in which the subject–object duality is transcended. It is also called the Vedānta system since it is founded on the Upaniṣads, which were composed

toward the end (*anta* in Sanskrit) of the Vedic era. A competing system called the Sāṃkhya finds its initial expression in some of the later Upaniṣads. Based on this lead, Īśvarakṛṣṇa wrote a treatise called the *Sāṃkhya-kārikā* around the second century CE. This system proposes an elaborate conceptual framework with two ontological principles: *Puruṣa*, which involves pure consciousness, as apart from Prakṛti, the principle of materiality. It declares the radical removal of suffering as its goal. This goal is attained, it claims, when a person realizes that the true Self is pure consciousness, and not the body or any other objective manifestations with which the self is commonly, but mistakenly, identified. The Yoga of Patañjali provides clear guidelines for the attainment of self-realization as explained and promised in Sāṃkhya.

Yoga: The Psychology of Higher States of Consciousness

Yoga is a generic term that connotes a theory as well as a wide range of techniques aimed at the removal of suffering and the attainment of bliss and spiritual development. Bodily postures and breathing exercises with which the currently popular image of Yoga is identified are only a small part of a branch of Yoga called the *Haṭha* Yoga. The origin of some of the Yogic practices is probably pre-Vedic. An iconic representation of a person in the lotus position found in the ruins of the ancient Indus civilization (about 2500–1900 BCE) is often cited as evidence of the antiquity of Yoga. The use of Yogic practices in spiritual development was well established in Buddha’s times, i.e., in the sixth century BCE. Patañjali, who composed the famous Yoga aphorisms (see Woods 1914/1972) around the second century BCE, did not invent the system; he explained the already established methods within a conceptual framework of the Sāṃkhya philosophy. Patañjali’s Yoga is concerned with controlling one’s stream of consciousness (*citta nadī*) so as to help discover the true Self in the state of pure consciousness. As such, the subject matter of Patañjali’s Yoga is clearly psychological, and the tradition avers that it is the most predominant system of psychology that originated in India.

Patañjali’s lists of eight means, or steps, leading to its goal are widely known. They include (i) a set of restraints, (ii) a set of observances, (iii) postures,

(iv) breathing exercises, (v) withdrawing of senses from their objects, (vi) concentration, (vii) contemplation, and (viii) a set of higher states of consciousness called the *Samādhi*. Patañjali mentions stability and comfort as the only two criteria for an adequate posture to help stabilizing the mind without being distracted by pain or discomfort. Important from a theoretical point of view are psychological concepts developed in Patañjali's tradition and detailed descriptions of experiences encountered in the progress of practitioners proffered by his followers. Historically important in this context is the work of a series of scholars who wrote glosses and expository commentaries on Patañjali's aphorisms, namely: Vyāsa (second century CE), Vācaspati Mīśra (ninth century), Bhojarāja (eleventh century), and Vijñāna Bhikṣu (sixteenth century), among others.

The Concept of Mind and the Technology of Restraining the Mind

Patañjali's Yoga aphorisms and the works of many of his commentators are a virtual treasure trove for Indian concepts of mind and higher states of consciousness. The core of Patañjali's system is the concept of the *processes* of mind (*citta vṛtti*) such as thinking, imagining, recollecting, doubting, determining, desiring, and so on. Patañjali's commentator Vyāsa uses the term mind-river (*citta nadī*), which recognizes the flowing character of mental processes as does James's expression the *stream* of consciousness. The idea of *flow* implies the recognition of continuity in mental states from past through present to future. Patañjali's system suggests that every mental event leaves behind its trace (*saṃskāra*). These traces are thought to be like seeds which get stored in the mind (*citta*). They sprout under appropriate conditions giving rise to experiences and behaviors similar to the original experiences and behaviors that left the trace behind. The *saṃskāras* are thought to remain dormant for indefinite periods of time. Remembering is cited as an example of sprouting of a seed sown previously within the same life cycle. And when an individual is prompted to feel or do something without an apparent connection to events since birth, it is attributed to *vāsanā*, a concept similar to drive in modern psychology. *Vāsanās*, like drives, are thought to originate from events prior to the beginning of the present life cycle, implying the concept of rebirth

and continuity of life across life cycles. *Saṃskāra* is an important concept in Indian psychological theories in that it is used to connote various cultural devices – such as teaching and rituals – that are designed to shape individual's behavior in a culturally desired direction.

The idea of the *flow* of thoughts in the stream of consciousness has a special significance in Indian psychology. Patañjali's Yoga aims at the attenuation and eventual arresting of the flow of thoughts by deliberate and systematic design. This is accomplished by two principal means: relentless practice (*abhyāsa*), and the cultivation of dispassionateness (*vairāgya*). Postures and breathing exercises are minor aids to ensure that discomforts do not distract the practitioner. A Yogi is supposed to first slow down the flow of thoughts, and then hold attention steadily onto a single thought. Then attention is withdrawn inward from the objects of thought, and taken successively into the inner domains of the mind. Attention is said to pass through meanings and mental images on which the meanings rest, and further inward till it rests firmly at the center of awareness. In this process, an adept is said to experience a graded series of higher states of consciousness called the *Samādhi*.

Attaining Higher States of Consciousness

Samādhi is an important concept suggestive of a series of successively higher states of consciousness. Patañjali describes two major types of Samādhi that arise in succession. In the initial set of states called the *Samprajñāta* Samādhi, the contents of consciousness are retained in experience. When one attains mastery on this state, one obtains the *Asamprajñāta* state, which is devoid of all content. During the course of this progression, the connotative and denotative meanings are dispelled from the mind. Insofar as meanings are added onto the input provided by the senses, what remains in experience are only the sensory images on which the meanings foisted. When even the sensory content is also shed, what remains is only the center of awareness. Finally, attention is made to rest firmly on the center of awareness, thereby providing a direct experience of pure consciousness which reveals the unchanging inner Self.

The central thesis of Yoga is that, while in common wakeful state the sense of self remains identified with

the ongoing thought, the true Self is experienced when the mind is emptied of all content. To put it in Sāṃkhya terminology, when attention is completely withdrawn from objects in the material world as well as from objects of thought, the true Self (*Puruṣa*) is experienced in its nascent form as pure, or content-less, consciousness. The experience of *Samādhi* states does not persist for long periods of time, and a yogi regains normal wakeful state. However, with repeated experience of *Samādhi* states, a complete personal transformation takes place. One no longer feels identified with the passing thought, feeling, or activity, and stops being tossed from elation to depression with successes and failures of mundane life. The person's experience becomes firmly anchored in an unchanging and blissful Self, thereby experiencing a non-diminishing inner calm and peace.

Yoga is not the only system offering a theory of mind; other systems also offer their own theories of mind, and distinctive ways of dealing with the mind. In the Advaita system, for instance, the word *manas*, rather than *citta*, is used to designate the mind's activities. However, the Advaita proposes a distinct technique for dealing with the mind which does not emphasize slowing down the flow of thoughts as in Patañjali's Yoga. Instead, in the Advaita, the mind (*manas*) is defined in terms of the twin processes of cognitive integration (*saṃkalpa*) and cognitive differentiation (*vikalpa*). The Advaitic technique of meditation accordingly focuses on the use of these two mental processes. Thus, it encourages a practitioner to first generate all possible alternative propositions in relation to a belief (*vikalpa*) such as varied self-definitions, and then choose the correct one among them (*saṃkalpa*) according to a specific criterion, namely, the true self is that which remains unchanged (*nitya-anitya viveka*). In other words, the logical principle of agreement (*anvaya*) and difference (*vyatireka*) is employed to put all self-definitions into two separate categories: those that are open to change vs. those that indicate permanence. The search for the true self thus follows a strict process of reasoning (*tarka*), and as such, this approach to self-knowledge is called the path of knowledge (*jñāna mārga*). The journey on this path ends when one discovers that pure consciousness is the only thing that remains unchanged, and hence reveals one's true identity (see Dharmarāja 1972).

A most important feature of the typical Indian view of mind is that the process of thinking is not equated with consciousness. While the ongoing mental processes are recognized as having a conscious character, they are viewed only as part of a broader spectrum of consciousness that includes pure consciousness. This stands in sharp contrast with the Western tradition where the Cartesian equation of consciousness with cogito is taken for granted. Also, unlike Brentano and his followers who insist that consciousness is always intentional, or directed to some object or other, in Indian thought the occasional occurrence of non-intentional states is taken for granted. In the West, there is tendency to consider non-intentional states as either impossible, or as "mystical" and unworthy of attention. But what proof does Yoga offer in support of its claims? According to Vyāsa, the chief commentator of Patañjali's aphorisms (#3.6), Yogic claims can be verified by *doing* Yoga. This is no different from the scientists' approach: their claims can be verified by anyone by replicating the experiment as specified.

Self and Identity

In the history of Indian thought, the self has been conceived of in terms of various aspects of selfhood. That selfhood often manifests itself in terms of the sense of "me" and "mine" with the attendant feelings of pride, and egotism (*garva*) is expressed by the concept of *ahamkāra*. The connotation of this term is similar to that of ego in modern psychology insofar as both indicate the sphere of self-love and its boundaries. That the individual's sense of belonging and attachment is usually spread over different spheres is expressed in Advaita by the concept of person (*jīva*) as multilayered entity represented by five concentric "sheaths" or layers like those in an onion. The outermost layers are (i) the bodily self ("made of food": *annamaya kośa*), followed in sequence by (ii) physiological functions driven by the life force (*prāṇamaya*), and by (iii) mental (*manomaya*), and (iv) higher cognitive (*vijñānamaya*) layers, with (v) blissfulness (*ānandamaya*) as the innermost core. To put it in contemporary terminology, what it means is that the sense of self manifests in the identification of the "I" with the body, with the functions and conditions of the body such as yawning in tiredness or feeling fresh and

energetic, with one's auditory, visual and other sensations, with ongoing thoughts, and with innermost feelings such as bliss.

A parallel conception of the manifestation of the self in one's thoughts, feelings, and actions is expressed in the Advaitic idea of the person as a knower (*jñātā*), enjoyer/sufferer (*bhoktā*), and agent (*kartā*). Paranjpe (1998a) has shown how such conceptualization has selective parallels in modern perspectives in psychology such as those of William James, G.H. Mead, Cooley, and others. But the most distinctive concept of self in Indian thought is that of *Ātman*, which, to put it simply, implies a *transcendental self* at the center of awareness. The *social* nature of the self is implied in the portrayal of important characters of the epics *Rāmāyana* and the *Mahābhārata* as players of multiple roles within the immediate family, as members of an extended kin group, and as players of political, military, and other roles in kingdoms spread across the subcontinent and beyond.

Aside from the concepts mentioned above, the concept of *Ātman* is an important concept regarding the nature of self as conceived of in Indian thought. It is somewhat similar to William James's (1890/1983) concept of the Pure Self, by which he means "the inner principle of personal unity" (p. 324). But unlike James who concludes that the ultimate inner principle of selfhood is just the passing Thought of a given moment and nothing beyond, the *Ātman* implies pure consciousness experienced when the mind is emptied of all Thoughts. The *Ātman* is one of the central concepts of the principal Upaniṣads, and the active search for the essence of selfhood is arguably the core of Upaniṣadic psychology. The central thesis is that the core and essence of selfhood is "pure" consciousness experienced in higher states such as the *Samādhi* explained before. The intricate relationship between self and pure consciousness centers around the question of what, if anything, accounts for the unity and sameness of self amid the many, varied, and continually changing images of the self one experiences throughout the life cycle. That the self is simultaneously one and many, same and yet changing is a paradox. It is a conundrum with which some of the greatest minds of the world have struggled. It has been called the "problem of identity." The Advaita position adumbrated in a medieval text called the *Dṛg-dṛśya Viveka* (n.d./

1931) is that the principle of unity and self-sameness is the self-as-subject as opposed to self-as-object. In other words, the *Ātman* is that which experiences, and not anything that is experienced whether in the form of sensation, thoughts, dreams, or feelings.

The thesis that self-as-subject is the foundation for, and the essence of, selfhood is one of the central features of the Indian tradition. As noted earlier, according to the *Ṛg Veda*, consciousness is the *primordial* principle of the universe; it is from the *awareness* of the original One of its lonely existence that the entire course of evolution started. And according to the Upaniṣads and its Advaitic followers, whatever exists (*sat*) is but a manifestation of Consciousness (*cit*), the fundamental principle of reality. Human beings, as part of this pervasive principle, have Consciousness at their very core. Besides, this principle is blissful (*ānandamaya*) by its very nature. Advaita, along with Sāṃkhya and varieties of Yoga, have devised spiritual practices that promise to help discover the Bliss at the center of awareness. Indeed, the Divine is often defined in terms of Existence (*sat*), Consciousness (*cit*), and Bliss (*ānanda*).

Although this is one of the dominant views of the nature of self in Indian thought, there is great diversity of opinion on this. Indeed, in the history of Indian thought, there has been an unending debate over it. On one side of the debate is the strong affirmation of the *Ātman* as the principle of the unity and sameness of a transcendental Self in the Upaniṣads, followed by a long tradition of Advaitic thinkers. On the opposite side is an equally strong denial of the Self by numerous scholars of the Buddhist tradition. The Buddha was well aware of the Upaniṣadic claim that there was an unchanging basis underlying the changing images of the self and that it was blissful in nature. According to Dasgupta (1922/1975), "We could suppose that early Buddhism tacitly presupposed some such idea. It was probably thought that if there was the self (*attā*), it must be bliss" (p. 109). However, as Dasgupta points out, Buddha's conclusion was the converse of this idea: "that which is changing is sorrow, and whatever is sorrow is not self" (p. 110). The doctrine of no-self (*anattā*) is one of the central theses of Buddhism. It involves a complex thesis expressed in various ways in writings ascribed to the Buddha, and also in the writings of scholars of many schools of Buddhism. There

is vast amount of literature on just this topic in Buddhism. It is neither possible nor necessary here to summarize what does the denial of self in Buddhism means, and how the doctrine stands in relation to the Advaitic affirmation of the self.

Putting the concept of self in a comparative context, we may note that the debate in the Indian tradition between the denial and affirmation of the self has a Western parallel. Thus, David Hume's famous denial of the self has Skinner (1974) as a follower of sorts in modern psychology, while on the opposite side, Erikson's (1968) view of the ego identity echoes Kantian affirmation of a transcendental ego. The comparisons among such apparent similarities and parallels are tricky. For upon closer examination, one finds that what is denied or affirmed, and on what grounds and to what consequence, is different in each case. A detailed discussion of the similarities, apparent or essential, can be found in Paranjpe (1998b).

Person and Personality Typology

The concept of self must be grounded in that of personhood; it cannot exist in a vacuum. In the Upaniṣadic tradition, the human individual is usually referred as *jīva*, which literally means a living being. All living beings are viewed as conscious, whether at a lower or higher level. In the Advaita tradition, the individual or *jīva* is conceptualized as a knower (*jñātā*), an experiencer of feelings (*bhoktā*), and an agent (*kartā*). In other words, a person has three fundamental capacities: of cognition, affect, and volition. This view clearly parallels the idea of person in John Locke and his followers.⁵

That persons have distinctive and stable characteristics is well recognized. In the *Bhagavad-Gītā* (5.14), for instance, it is suggested that the individual's own character (*svabhāva*) generally prevails, although it is not considered to be fixed and unalterable. The *Gītā* (as the *Bhagavad-Gītā* is commonly referred to) suggests three types of personality following the conceptual framework of the Sāṃkhya system. In it, everything in the material world (Prakṛti), including persons, manifests each of three basic "strands" or components: light or enlightenment (*sattva*), energy (*rajas*), and inertia (*tamas*). Although each of the three components is present in everybody and everything, individuals differ in terms of the relative dominance of the three. There

are extensive descriptions in the *Gītā* of persons in whom one of the three strands or qualities is dominant. In Buddhism, the concept of person is designated by the term *puggala*. An old Buddhist text called the *Puggala-Paññatti* describes various personality types based on their eligibility for spiritual development (Law 1922). The Indian medical system called the *Āyurveda* suggests three types of personality based on the relative dominance of three humors (*kapha*, *pitta*, and *vāta*) that are said to constitute the human body. Each type is described in detail in terms of the features of the body as well as behavioral characteristics, and this typology is used in diagnostics. These typologies are amenable to empirical research, and tests have been developed in this context (Murthy and Salagame 2007; Wolf 1998).

Personality Development and the Ideal Human Condition

A persistent theme of the Indian culture is that, on the whole, suffering exceeds pleasures and happiness. In the epic Mahabharata, the story of Yayāti, a mythical king, conveys that his appetite for pleasures could not be satisfied despite all his wealth and power, and despite borrowing his son's youth in his old age. The point of the parable is that desires are not sated by indulgence; expectations keep growing like fire fed by fuel. Buddha's message was not much different. Despite such rather pessimistic view of the human condition in some important classical sources, the thrust of the culture as a whole is far from kill-joy. In fact, the four goals in life that the Hindu tradition prescribes include not only spiritual liberation (*mokṣa*) and doing one's duty (*dharma*), but also pursuit of wealth and power (*artha*) and the pursuit of sensual pleasures (*kāma*). India is a land in which Lakṣmī, the Goddess of wealth, is unabashedly worshipped, and its culture produced a superb text of sexology called the *Kāma Sūtra*. Moreover, despite the oft-repeated message that the pursuit of pleasures often leads to a negative balance, the assumption has been that it is possible to overcome all common sources of suffering, and attain a state of undiminishing inner peace and bliss. The desired end point is a transcendent state, a stasis, not perpetual progress. Unlike the concept of perpetual progress implied in the currently popular idea of ever-growing gross national product, the ideal of individual and

social life in the Indian tradition is that of a sustained stability. To put it in different words, the ideal of human life is not self-actualization, meaning an expression of unlimited inner potentials manifest through an ever-increasing level of accomplishments – as is implied in Western thinkers from Aristotle to Abraham Maslow. But rather the ideal is self-realization through the inner experience of an unchanging basis for selfhood.

This basic theoretical principle is complemented through a variety of techniques, ways of life, or methods of spiritual development that form the core of applied psychology of the Indian tradition. The conceptualization of person as knower, enjoyer/sufferer, and agent has been used to develop distinct methods for spiritual development. These are based on sophisticated theories of cognition, emotion, and volition, and are, respectively, called as the Path of Knowledge (*Jñāna Yoga*), of Devotion (*Bhakti Yoga*), and Action (*Karma Yoga*). Each of these deserves a brief account.

Cognition and the Path of Knowledge

To properly understand the traditional Indian view of cognition, it is necessary to view it in the context of the distinctive world view in which it is embedded. In his introductory section (called the *Adhyāsa Bhāṣya*) of his famous commentary on the Vedānta aphorisms, Śāṅkara (n.d./1977) conceptualizes all living beings (*jīva*) as individualized centers of awareness reflecting the universal and infinite consciousness of the ultimate reality called Brahman (Rao 2002). In its individualized form, consciousness suffers from the inevitable limitations (*upādhi*) of the capacities of the sense organs and cognitive apparatuses typical of the species to which the individual belongs. Within each species of organisms, each individual may have deficiencies of its own, which characterize the conscious experience of that particular individual.

According to the Nyāya and Vedānta systems, humans are born, like animals, with a capacity for perception devoid of concepts and words (*nirvikalpa pratyakṣa*), but develop the capacity for the use of concepts and words (*savikalpa pratyakṣa*) during the course of development (Datta 1932/1972). Given the intrinsic limitations of the sense organs and cognitive capacities, humans cannot obtain complete knowledge

of most objects, let alone of an entire class of objects. As Śāṅkara explains in *Adhyāsa Bhāṣya*, all new knowledge is “veiled” (*āvāraṇa*) by existing knowledge; the new incoming information is “filtered” and is received only partially rather than fully. Reciprocally, what is known from previous experience is often “projected” (*vikṣepa*) onto what is newly encountered. To compensate for the deficiencies in cognition, and to fill in the gaps in the information available, humans make use of imagination (*kalpanā*). Thus, most human perception is *savikalpa pratyakṣa*, i.e., it involves at least some element of imagination. This added element involves, among other things, concepts and names given to classes of objects; thus, human cognition is mostly “constructed” or fabricated.

Based on this view of human cognition, Śāṅkara draws far-reaching implications for all human knowledge. What we know about the world (*jagat*) starts with intrinsic and inevitable limitations of our cognitive apparatus, and although we keep on adding new knowledge with experience and reasoning, what is incomplete at start continues to be incomplete despite continual improvements. He forcefully suggests that all empirical and rational knowledge based on transactions with the world (*vyavahāra*) is forever revisable and forever imperfect. This view of knowledge, it may be recognized, is basically compatible with the contemporary notion that scientific knowledge is forever revisable. Similarities between Śāṅkara’s and Piaget’s views of cognition and knowledge are particularly striking (see Paranjpe 1998a). Śāṅkara uses the Upaniṣadic term “*avidyā*” to designate the entire domain of rational-empirical knowledge. Following the *Īśa* Upaniṣad (9–12), Śāṅkara mentions a different kind of knowledge, called the *vidyā*, which is transcendental (*parā*), and is unconstrained by the contingencies of empirical knowledge. Knowledge at this higher level reveals absolute Truth (*satyam*), while rational-empirical knowledge reveals empirical generalizations that reflect a repeatable pattern (*ṛtam*) – which is true as long as it remains uncontradicted by a new set of observations or a fresh insight. Such an idea of two levels of knowledge is a matter of epistemology that many psychologists today would happily leave for philosophers to deal with. Nevertheless, the concept of transcendental knowledge should be of interest to psychologists insofar as the method developed for its attainment involves

a psychological technology. The technology relevant here is the same as the Advaitic method for self-realization.

Inspired by the teachings of the *Bṛhadāraṇyaka Upaniṣad* (2.4.5), the Advaitists advocate the following strategy to help discover the true Self hidden behind the changing images of the ego: (1) Study of the principles of Advaita (*śravaṇa*), (2) relentless critical examination of all self-definitions to see if they are open to change or not (*manana, nitya-anitya viveka*), (3) deep contemplation (*nididhyāsana*) of what is thus learned. In the course of critical examination, self-definitions based on identification with things, personal relations, or even values that often appear nonnegotiable change sometimes due to changed circumstances, sometimes by choice. It is gradually recognized that all objective self-definitions are open to change; it is only the awareness that underlies all understanding that remains unchanged. When this understanding sinks in deeply, an extraordinary state of consciousness called *Nirvikalpa Samādhi* is experienced. This is the same as the Fourth State in which the subject–object duality is transcended, and higher knowledge (*parā vidyā*) is attained.

This higher knowledge cannot be expressed in words, but the process of arriving at it can be expressed in cognitive terminology. One way of describing the process is to suggest that, at the beginning of inquiry, the self is accounted for in the form of an autobiography, and an attempt is made to see who its author is. If one compares what one thought of oneself at the age of say 15 and then at 20 or 50 and so on, it becomes clear that the author of the first description is not quite the same as the author of the later accounts; she or he has kept on changing. It is gradually recognized that autobiographical narrative is cognitively and socially constructed, and further that the surface structure of the knower is a set of cognitive structures and processes that are undergoing continual change. What accounts for true identity, i.e., self-sameness, is only the passive witness of the drama of life presented to an indescribable “I” at the center of awareness. In this process, the ego, or one’s view of the self and his/her world is “deconstructed” in a far more rigorous and radical manner than what is suggested in the postmodern idea of deconstruction.

What happens to the person who successfully deconstructs her or his ego? The *Śvetāśvara Upaniṣad* (4.8) describes the situation in a metaphor in which there are two birds perched on top of a tree: one of which is eating and enjoying a fruit while the other one is simply watching. The first one is the ego; it is involved with the world and cyclically enjoys or suffers with gains and losses as life unfolds. Self is the other bird dispassionately witnessing the ups and downs without being affected by them. The trick is to cultivate a dispassionate stance of an uninvolved witness of the drama of life. By doing so, one can experience inner peace and calm in an uninterrupted manner. This method of attaining trans-cognitive knowledge requires capacity for critical thinking and relentless effort in self-examination. It is not found easy by many people, although there are many examples throughout history of sages who have successfully followed the Advaitic strategy and attained self-realization. One way of understanding self-realization thus attained is to view the ego as a region marked by a boundary, a boundary between the self and the surrounding world, between self and the “other.” Repeated self-examination brings home the point that self concept is acquired in the process of socialization, and is continually modified under the influence of various factors. The boundaries between the Me and the not-Me are continually redrawn through interpersonal interaction, gains and losses, and individual will. In other words, ego boundaries are continually constructed and reconstructed. More specifically, they are open to deliberate modification – or “deconstruction.” Constant questioning of the place of Me and not-Me in the course of relentless self-examination, the ego boundaries lose their force, and get ultimately dissolved.

Great saints, who attained self-realization, have described their experience in poetic expressions. For instance, in a famous poem, the fifteenth-century saint-poet Kabir says that being in the world is like a pot in an ocean; there is water inside and water on the outside. Similarly, the modern Bengali saint Ramakrishna Paramahansa (1836–1886) describes self-realization metaphorically; he says that the ego dissolves like a doll made of salt immersed in water. In other words, the Me and not-Me distinction simply goes away. Correspondingly, the behavior of such self-realized

individuals shows a complete transformation of personality. Saint Kabir, for instance, was completely above the Hindu–Muslim divide, which was strong in his days, and taught to view individuals as human beings first, and then in terms of Hindu, Muslim, or other such categories. Ramakrishna is known to have practiced spirituality as taught by Vedāntic, Sufi, and several other traditions, and pointed out the commonalities in their teaching. The limitless compassion of such saints is a clear manifestation of their shedding of ego boundaries. Paranjpe (2008) has examined the biography of a modern sage and saint called Sri Ramaṇa Maharshi (1879–1950) to illustrate how the quest for and attainment of self-realization can manifest in a particular individual.

Emotion and the Path of Devotion

While the path to self-realization mentioned above focuses on the use of one's cognitive capacities to deconstruct the ego, a different way proposed since ancient times emphasizes the transformation of emotions. The key to this approach is to totally surrender one's ego in a strong emotional relationship with the Divine. The tradition of devotion to Lord Kṛṣṇa is traced back some four millennia to the Tamil poetry of Āḷvār saints. A basic outline of this perspective is found in a medieval treatise called the *Bhāgavatam*, which mainly describes the life of Kṛṣṇa as he grew up among poor cowherds in a small village. The hero is shown in endearing relationships with his adoptive parents, playmates, and in particular in amorous relationships with several young milkmaids. The thrust of the story is to show how normal relationships involve innumerable shades of love which have great potential for self-transformation. It is shown how intimate relationships in paired social roles such as parent and child, mutual friends, and especially lovers, offer opportunities to transform the ego by immersing it in a mutual bond of self-giving. When the emotions are exceptionally strong, as in love between man and woman – whether in licit or illicit relations – the ego of the lover can completely merge with that of the counterpart. When love is directed to a divine being, as Kṛṣṇa, the result of total surrender of the devotee's ego is the experience of limitless and unending love. Indeed, the *Bhāgavatam* suggests that even hatred for the divine can ultimately lead to the same result as intense and

unconditional love. The devotional approach to God-realization is explained in a well-known work called the *Nārada Bhakti Sūtra*.⁶ As we shall see, this view of religious devotion was developed in the sixteenth century on the basis of a theory of emotion that had its origin in an effort to understand the transformation of emotion in witnessing dramatic productions.

Understanding the Nature of Emotions and Their Transformation

In the history of Indian thought, a systematic analysis of emotions was provided by Bharata Muni, in a treatise called the *Nāṭyaśāstra* (n.d./1992), meaning the science of drama, composed within two centuries before or after Christ. While writing mainly as a guide for authors, directors, and actors of plays, Bharata deals extensively and in depth with human emotions. He identifies eight basic emotions, which he considers as relatively lasting and common to humans as well as other animals. He also describes 32 relatively transitory emotions along with their facial and physical expressions. A more important theoretical contribution of his work is the concept of *rasa*, which is roughly translated as aesthetic relish or mood. This theory was extended greatly by a great Kashmiri philosopher called Abhinavagupta (ca. 990–1020). There is a long tradition of scholars, which continues till this day, that follows the lead of Bharata and Abhinavagupta in the fields of aesthetics, poetics, dramatics, literary criticism, and various aspects of dance and other art forms.

Scholars in the tradition of Bharata Muni raised a simple but important question: Whose are the emotions that are experienced while witnessing a play? It was reasoned that they do not *exclusively* belong to either the playwright, or the actor (both of whom may not have experienced the pangs of separation which the play portrays), or the character (who could be imaginary), or by the audience (by a honeymooning couple witnessing separation, for instance). The conclusion is that the emotions experienced in a playhouse are *shared* in common. The concept designed to express this idea is the generalization (*sādhāraṇīkaraṇa*) of emotions. Another important observation in this context is the fact that the basic emotions such as sorrow, fear, and disgust are *transformed* in the process of their dramatic or other artistic presentation so as to lose their “sting,” or negative character. They are converted

into aesthetic moods (*rasa*) of respectively pathos (*karuṇa*), horror (*bhayānaka*), and the odious (*bībhatsa*), which are “enjoyable” by the aesthetes in the audience. The theory is developed further to explain why and how the vicarious experience of the spectators loses the negative character of the basic emotions as experienced in real life. It is suggested that the spectator leaves home, so to speak, her or his daily concerns and ego-involvements with situations that lead to such negative emotions, and the ego-distancing in the process allows for “relishing” of previously experienced “sting” (Dhayagude 1981).

Over the centuries, the development of the *rasa*-thesis (*rasa-siddhānta*) has gone through a series of heated controversies, revisions, modifications, and continued enrichment, and the process continues till this day. A few distinctive features of this theoretical position may be noted in the non-Indian context. *First*, the concept of the generalization of emotion implies that emotions do not belong only to the brain or bodily tissues of individuals; they are socially shared trans-individual phenomena. The underlying ontology is clearly far from the physicalism implied in many contemporary approaches. *Second*, the *rasa* perspective is closer to recent views of social emotions compared to the psychophysiological theories. *Third*, given its attempt to explain transformation of emotion with reference to the ego, it becomes open to use as basis for practical applications. In conformity with the long-standing trend, the practical application was found in the spiritual context.

In the sixteenth century, two scholars of the Guḍīya Vaiṣṇava tradition named Rūpa and Jīva Gosvāmī used the theory of *rasa* to help understand and advance religious devotion. Taking the lead from the *Taittirīya* Upaniṣad, which says that the Brahman is the essence (*rasa*) of reality, they use the *rasa* theory in Bharata’s tradition to help explain self-transformation through religious devotion to Lord Kṛṣṇa described in the *Bhāgavatam* as indicated above. Rūpa Gosvāmī (n.d./1981) and Jīva Gosvāmī (n.d./1986) suggested that the artistic portrayal of emotions have the potential for experiencing shared emotion by *temporarily* overcoming ego boundaries. When a devotee takes for herself or himself the role of a lover, sister/brother, child, servant, student, or whatever vis-à-vis the divine, and plays that role intensely, the devotee can merge with the Lord,

who is the Supreme Self (*Parama-Ātman*). It is important to note here that the concept of divine as defined in the tradition of devotion (*bhakti*) is that God is celestial love, a supreme *rasa* that fills the universe. He is an immanent principle that is said to sometimes manifest in human form. He is not a transcendent creator who controls the universe and punishes humans who disobey Him. The stories of divine beings, such as that of Kṛṣṇa in the *Bhāgavatam*, can serve as aids in total self-transformation through religious devotion. The Gosvāmīs were careful to specify, however, that while the joy in the experience of art was somewhat similar to the greatest Bliss of Brahman, it is not the same (Paranjpe 2009).

Volition and the Path of Action

As noted, the typical Indian term for action is *karman*, and the Law of karma is accepted by almost all schools of Indian thought, except for the materialist school of Cārvāka. The concept of free will is implicit in the notions of *karman*. This is succinctly expressed by Śaṅkara (n.d./1977) in his *Brahma Sūtra Bhāṣya* (1.1.2), where he defines *karman* as action which one can choose to do, not to do, or to do in different ways. According to the Law of karma, *all* actions have their natural consequences sooner or later, whether during the life time of the agent or sometime during later incarnations of the individual. The *Bhagavad-Gītā* (1963) (18.14) suggests five distinct factors that determine the nature of the consequences of every action: (i) the context in which it is done (*athiṣṭhāna*), (ii) the agent (*kartā*), (iii) the instruments available for performing the action (*karmaṇ ca prthagvidham*), (iv) the specific movements involved (*vividhāḥ prthak ceṣṭāḥ*) and finally, (v) the working of divine providence (*daivam*). The *Gītā* (18.15) adds that persons often do not realize the degree to which all these factors jointly determine the outcome, and egotistically tend to take all credit for success to themselves. It goes further to observe that what makes the action “binding” on the individual agent is the ego-involvement and passionate craving for the results of her/his actions. As long as the craving for desired results persists, the individual faces the inevitable consequences of his actions, then new actions and their consequences follow, and the individual gets inextricably bound with the perpetual cycle of actions and their consequences.

On the basis of such theoretical formulation, the *Gītā* proposes a practical strategy for the emancipation of the ego from the perpetual *karmic* cycle. Although it may not always be possible to perform actions without any intended goal, one can get rid of the craving and insistence for the intended fruits. One should rather learn to derive pleasure in doing the right actions, and leave it to nature to produce their lawful consequences. With the cultivation of increasingly dispassionate attitudes, the ego can be gradually freed from the clutches of the *karmic* cycle. To put it into contemporary terminology, whereas ordinarily behavior is conditioned and controlled through environmental factors, Karma Yoga offers a way for emancipating oneself from environmental control through a self-administered process of systematic “deconditioning.”

Person as a Social Being

On the first blush, it might appear that a typical Indian theory of personality, such as the Upaniṣadic and Advaitic view of person as *jīva*, is lacking in adequate attention to the social aspect of human beings. However, the opposite is true. An important aspect of the pervasive and persistent Indian world view, which is accepted by virtually all schools, is the concept of *dharma*, a concept that implies that the social aspect of human beings is an integral part of the very nature of reality. *Dharma* is one of those terms that are hard to properly translate into English. Its usual translation as religion is highly misleading, for the term religion has an inescapable connotation by the nature of Abrahamic religions, as a perspective on the sacred that is defined by one God promulgated by one Prophet, and explained in one Book. This connotation is not applicable to Hinduism, Buddhism, Jainism, Sikhism, and a myriad of sects of Indian origin, although these are commonly designated by the term religion. We need not here discuss the complex issue of what makes for the difference in the so-called “religions” of Western and Indian origins. To help understand the typical Indian perspective on the social nature of human beings, it is necessary to understand the concept of *dharma*.

Traditionally, *dharma* is defined in different ways: as duty, charity, something that “holds” the society together, as natural property of an individual or of a thing, and most importantly, as a society’s ethos.

There is a natural pairing of the term *dharma* with that of *karma*. A historical overview of these concepts is ably presented by P.V. Kane (1968) in a set of volumes titled the *History of Dharma-śāstra*, i.e., history of the “science” (*śāstra*) of *dharma*. While the concept of *karma*, as explained before, suggests lawfulness of all events in nature, *dharma* correspondingly indicates orderliness of life in society. What accounts for social order is a community’s ethos, or a set of guidelines for behavior that are consensually supported. A society “holds itself,” so to speak, to the extent that people follow rules designed for the welfare of society with a sense of duty – and that is what *dharma* is all about. In a spirit similar to Aristotle’s notion of man as a political animal, the common Indian view of human beings is that they are social animals. Insofar as this is widely presumed, it is part of tacit knowledge and as such in no need of explicit statement.

In the Indian tradition, social ethos is conceived of in two distinct sets of rules: one general and meant for all, and the other specific to a category of people in a certain role or a stage of life. The *Taittirīya* Upanisad (1.5) lists a set of prescriptions common to all (called the *sāmānya dharma*): that one must speak the truth, do one’s duty, never miss opportunities for learning, have respect for parents, offer hospitality to guests, and so on. It is recognized, however, that the right behavior for individuals in society requires guidelines appropriate to one’s station in society. It is taken for granted that behavior must be understood in its *context*, defined by space (*deśa*), time (*kāla*), and capacity and eligibility of the person (*pātra*) as appropriate to the context. Persons who play reciprocal roles such as teacher-student, parent-child, young-old, master-servant have differing obligations and duties toward each other, and hence their conduct must be judged by standards appropriate to their specific role. This idea of variability in the rules of conduct is encapsulated in the expression “*varṇāśrama dharma*,” which means duties and obligations appropriate to the different divisions of the society such as priest, warrior, trader, and worker (*varṇa*) and according to one’s stage in the life cycle (*āśrama*): that of the student, householder, a retiree, or a renunciate. Such rules are, again, considered not fixed for eternity, but as revisable from one era to the next. The ethical code was not viewed as fixed like the Ten Commandments as God-given and fixed, but

rather as a matter of conventions that keep changing with time as societies continue to evolve. Each era is supposed to have its own ethos, which would be codified by scholars on the basis of how the wise men of the times behaved. It is widely understood in recent times that the traditional division of the society hierarchically ordered with the priestly Brahmin caste at the top is a thing of the past; the current ethos is reflected in the constitution of the Indian republic. Unlike the old “*varṇāśrama dharma*,” which implied social inequality, the ethos of the present – the *yuga-dharma* of modern times – insists on egalitarian equality.

Traditionally, the two great epics of India, the *Rāmāyaṇa* and the *Mahābhārata*, provide in-depth portrayal of social life, the former emphasizing the social roles within family and royal contexts, while the latter offers an understanding of a society in turmoil and transition against the backdrop of a major war with rival cousins as main combatants. While these works may not be seen to offer formal *theories* of social psychology, they do offer deep insights into the nature of human social life. A formal theory of social conflict is offered by Kautilya (n.d./1992) in his classic treatise on statecraft called the *Arthaśāstra*. The relevance of this work for contemporary theorizing about social conflict is recognized by LeVine and Campbell (1972) in their book on ethnocentrism.

Theories of Language and Meaning

Language was an important topic of scholarship in the Indian tradition. It was initially part of the exegesis of the ancient Vedas. The study of grammar became an important part of any attempt in the study of a text, scriptural or otherwise. Pāṇini, who wrote a comprehensive grammar of Sanskrit, is now recognized as a great grammarian, and the influence of his work on modern linguistics is widely acknowledged. An important perspective on language is offered by the *sphoṭa* theory, which tries to explain how meaning “bursts forth” in the process of linguistic expression. Philosophical and psycholinguistic implications of this ancient theory have been recognized in recent scholarship (Coward 1980; Coward and Kunjunn Raja 1990).

Overview and Styles of Theorizing

Notwithstanding the great diversity within and between Indian and Western psychological theories,

certain dominant features stand out as distinctive of each tradition. The prominent features of theories of the Indian tradition may be identified in terms of the ontological presumptions, epistemological choices, overarching goals, and matching approaches to practice.

In terms of the ontological theses that provide the primary foundation for theories, the Indian tradition has generally favored the presumption of the primordial and irreducible nature of consciousness, while this is not the case in the West. India did not witness anything like the “mind–body problem,” which has remained unresolved, and material monism, which is strong in contemporary psychology, is accepted in an insignificant minority in the Indian tradition.

A most distinctive feature of epistemological foundations of psychological theories in India has been the acceptance of the noetic value of the higher states of consciousness. While followers of the Upaniṣadic tradition have insisted that the highest state of consciousness is blissful and holistic (*pūrṇa*), Buddhists have equally strongly insisted that the highest state is characterized by emptiness (*śūnya*). And regardless of their irreconcilable differences on such important issues, both camps have equally valorized the higher states. The higher states of consciousness are considered the basis for both, the highest form of knowledge as well as the culmination of highest happiness. Consistent with the value of higher states of consciousness, contemplative practices of Yoga in one form or another is integral part of praxis among followers of Hinduism, Buddhism, Jainism, Sikhism, and so on. The dominance of such spiritual goal does not mean the neglect of mundane goals as is illustrated by theories in the areas of social conflict, language, and sex. At any rate, the overall thrust of application of psychology in most schools of Indian thought is self-control, and not on controlling someone else or something in the environment.

The most dominant form of theory building is holistic and “top-down” in approach. Thus, in the Advaita, Sāṃkhya-Yoga, as well as Buddhism, one starts with a global view of reality, of the individual human being as a whole, and one aims for the attainment of ultimate happiness. This approach stands in sharp contrast with the “bottom-up” approach typified by behaviorist psychology where one starts with

a molecular unit such as stimulus-response, and strives to develop an understanding of increasingly complex forms of behavior. This observation, based on a long-range historical account of the development of psychological theories, is interestingly consistent with the observation by Nisbett et al. (2001) that cognitive styles of individuals from Eastern cultures tested in the laboratory tend to be holistic rather than analytic. Hajime Nakamura (1964) has made similar observations about dominant aspects of Eastern philosophies, which goes on to indicate the deep influence of culture on philosophical and psychological thinking.

Notes

1. A brief sketch of the major currents of psychological thought through this early period of history is provided by S.K.R. Rao (1962). References to psychological topics discussed in classical literature were compiled by Jadunath Sinha (1934/1958). Overviews of the classical literature are available in works on the history of Indian philosophy by Dasgupta (1922/1975) and Radhakrishnan (1927/1931), and in a series of encyclopedic volumes on important works in Indian philosophy under the editorship of Karl Potter. Bibliographic details of the first nine volumes published in this series since 1970 and a brief account of the ongoing series may be found on the World Wide Web at http://www.infinityfoundation.com/encyc_philosophy.htm.
2. The precise dates of these works are not known. The approximate period in which these texts were composed are: *Artha-śāstra* (fourth to third century BCE), *Kāma Sūtra* (first to sixth century CE), and *Nāṭya-śāstra* (first century BCE to third century CE).
3. For English translations of the principal Upaniṣads, see Radhakrishnan (1953/1994). Unless otherwise stated, translations of quotations from these texts are from this source.
4. For theoretical significance of the Law of karma see Potter (1980).
5. For a detailed discussion of Indian and Western views of personhood, see Paranjpe (1998a).
6. As is true of many old Indian texts, the date of the *Nārada Bhakti Sūtra* is not known. English translations of this work are widely available. See, for example, Tyāgīśānanda 1972.

Psychology of Alexander Bain

ROBERT W. RIEBER

Fordham University, New York, NY, USA

Bain published the first part of his Psychology, *The Senses and the Intellect*, in 1855, and the second part,

The Emotions and the Will, in 1859. John Stuart Mill and Herbert Spencer both wrote reviews. Mill was not only a good friend of Bain, but had personally guaranteed the publisher against loss from the venture, and he set the tone of his review in a terse opening sentence: “The sceptre of Psychology has decidedly returned to this island” (Mill 1859, p. 287). Spencer had no conflict of interest except the challenge to his own prestige. His review (Spencer 1860) was severely critical, and it described Bain’s book as “not in itself a system of mental philosophy . . . but a classified collection of materials for such a system” (1864, p. 301). The analytical passages, he said, are “incidental – they do not underlie the entire scheme, but are here and there added to it” (p. 317).

Scholars generally still see Bain through Spencer’s eyes, as an industrious author who borrowed freely, organized skillfully, but lacked the genius needed for theoretical contributions of high order. Thus, Flugel (1933) says that Bain was “dogged and persistent,” “lacked originality,” and “owes his place in history to his power of laborious collation of data and systematic exposition of results rather than to any striking ability either to discover the facts or to interpret them” (p. 79). Heidebreder (1933) says that Bain’s “importance lies so much in any specific contributions, . . . any particular theory or doctrine, as in the fact that his two books constitute a systematic and scholarly exposition of classic associationism at its height” (p. 57). Boring (1950) says that “there was never any school or great theory that derived from him” although he “anticipated much of later psychology.” Hearnshaw (1964) credits Bain with “seminal ideas” but adds that he failed to develop them and probably did not recognize their significance. So we have this paradox: a dogged and persistent worker who neglected to develop his own ideas, who achieved an influential textbook by the exercise of laborious collation, and who anticipated the future but originality.

The theme of my discussion might be taken from the rambling final sentence of Mill’s review. It was directed to those who found Bain’s empirical approach unacceptable, and it advised them that even if they were not “disposed to take up their abode” in the edifice which Bain had constructed, they should nevertheless give it careful study, for “so massive a pile, so rich in the

quantity and quality of its materials, cannot be used even as a quarry without abundant profit.” The advice is still timely, and it seems appropriate because Aberdeen, the city of Bain’s birth and death, has been a world center for granite quarrying since about 1600. I propose to take you quarrying, as it were, in the writings of Alexander Bain, and to inquire how many of the building blocks of modern psychology might have been taken from that source.

Aberdeen was also a very early center of paper manufacture, and during the eighteenth century became a center of textile industries. Historians, however, will better remember that Francis Galton, who fearlessly measured things sacred as well as profane, put Aberdeen “on the map” in a different sense, by stating that of all the cities in the British Isles had the plainest women (Pearson 1924, p. 341).

Bain’s asthma-ridden mother was doubtless one of these, a weaver’s wife who bore eight children, of whom only this one would live past 40. His father found Sunday sermons too mild, and he invariably added a Sabbath lecture in which he assured the members of his family that they were all bound for hell. (Bain’s (1904) *Autobiography*, will be used freely without further reference).

Bain had the usual parish schooling available to poor children in Scotland. His swift progress was a burden to the schoolmaster, who gave him an algebra text and freedom to shift for himself. When the pupil needed help with a difficult problem, the harassed master would provide the answer next day from the key which he kept at home. At 11 Bain left school to become errand boy for an auctioneer; at 13 he became a weaver. No doubt his growth was stunted by the poverty of his childhood, for in later years he was punningly described as a “wee vir.” Avid for scientific knowledge, he struck up friendship with an eccentric watchmaker who was something of an amateur scientist, and with the sons of a blacksmith who owned an English translation of Newton’s *Principia*. There were two colleges in Aberdeen, one founded in the fifteenth century and the other in the sixteenth, and several decades later the merger of these would form the University of Aberdeen. However, they were beyond a weaver’s horizon. For a working man, the only open road to learning was the Mechanics’ Institution,

forerunner of the public libraries. Only a decade after he became a weaver, in an early essay which I shall soon quote to other purpose, Bain wrote these lines:

- ▶ In monotonous employments which use the hands and not the head, there should be a separate provision for the head. One obvious provision is, knowledge of all sorts, and the associations and hopes connected with its acquisition. . . . When we think upon the needs of all classes of society, and the small provision made for them, we are forced to assert that in one sense the mind of man, the greatest thing in the world, is among the least attended to. (Bain 1842, p. 64)

When Bain was 17, a chance encounter suddenly opened new doors. A minister, who heard him conversing with a bookseller, urged him to seek admission to college, told him of the tempting possibility of prize stipends, and offered to help prepare him by correcting his Latin exercises. Bain had made a start on Latin, by teaching himself to read the *Principia* in the original. During the next few years, Bain wrote prize papers, tutored, served as substitute schoolmaster, kept the accounts for the Mechanics’ Institution, catalogued its library, gave courses in its mutual instruction program, and graduated at the top of his class, although he had to share nominal honors with the invalid son of a professor.

His search for literary work then brought him into correspondence with John Stuart Mill, who at once recognized a kindred spirit. Both men were products of atypical educations, but one was a hothouse product, while the other had, one might say, scratched his learning out of crevices in the cobbled streets of Aberdeen. By different routes, each had attained an open mind, but years later Bain (1882) wrote that there was one prejudice that Mill had received from his father and from which he could never free himself, despite all evidence: the belief that all men are essentially equal in innate intellectual potential. Bain’s experience had taught him that *that* was a delusion.

Since Bain did not dissemble his loss of religious faith, any worthwhile academic employment was closed to him in the years when he most needed it. His passion was psychology, but he earned a precarious livelihood by writing popular articles on a wide variety of scientific subjects. Bain was no mere hack in the

natural sciences. For example, he concluded from watching a blacksmith at work that kinetic energy can be transformed into heat. (Unfortunately, the paper on heat which he read to the Aberdeen Philosophic Society early in 1843 was not published). He served for a while as secretary to the Sanitary Commission for metropolitan London, during a severe epidemic of cholera. Amid such activities the psychology took shape, so that it was complete in outline and in most of its substance before he ever had a chance to teach the subject. That chance came with the creation of the Bedford College for Ladies, in London, but even there he had to content himself with teaching physical geography in the first year of his appointment, and got to teach mental philosophy only in the second. Bain was indeed “dogged and persistent.” If he were not, we should never have heard of him.

We shall look first at some of Bain’s central ideas. His key concept, of course, is spontaneity. Using the terminology which Skinner has given us, we may say that Bain rejected the account of behavior as all elicited, which is what a pure associationism comes to, and insisted instead on the importance of spontaneously emitted acts. In his words, “muscular action may, and does, arise from purely internal causes, and independent of the stimulus of sensations.” However, almost 10 years before he arrived at this formulation, we can see the *anlage* or disposition which made that development well-nigh inevitable, in the youthful essay which has already been mentioned. He had been offered the opportunity to review a book titled *Home Education*, which dealt in part with the educational value of children’s toys, and he seized this as a chance to illustrate the importance of similarity in thinking, which was a pet enthusiasm of his. But the resulting essay is even more remarkable as displaying how Bain’s own energetic nature led him to include action as well as thought within the scope of his work. Here are a few sentences culled from 15,000 words:

- ▶ The passion for handling is not duly appreciated. . . What utter nothingness is there in the mere sight of an ancient sword; the delight comes of unsheathing and sheathing it with our own hands, and going two or three times through the manoeuvres of fencing, stabbing, and amputating with it. . . When a companion standing beside us has a curiosity in his hand whose

wonders he is relating aloud, the cry is, ‘Let me see it, let me see it,’ from those looking on all the time at the full stretch of vision; but the cry means, let me handle it. . . With a stout stick in a road well grown with weeds, no one’s mind need come to a stand. . . . It is utterly impossible to lounge, even for a short time, in an artisan’s shop, without setting ourselves to work on his tools. . . We would fain hope that, at no distant time, it will be considered as barbarian cruelty to seat a person down in a naked lobby, beside a bare marble table, without one thing that he can take in his hand. (1842, pp. 52, 60, 61, 64)

It is all witticism, but there is an earnestness beneath it, and the article ends with a program and a promise:

- ▶ Having now had occasion to labour in a region of the human mind neglected by our written mental philosophy, we may remark on that science, that it will require to proceed a little farther into the minute anatomy of human life than it has ever yet done. . . No novelist, not even Dickens, has done full justice to the toy principle; and no one ever will until he conceive it aright as a principle. But let anyone first learn the principle, and then proceed to study life in search of manifestations of its workings, and we fear not to say, that he will find ten times as many as have ever yet been recorded, besides obtaining a more exact account of each. (pp. 64–65)

What Bain here called the toy principle, from the almost accidental circumstance of the nature of the book he was reviewing, he explicitly conceived at that time only as the principle of similarity in thinking, but it is linked intimately with an emphasis on the internal drive to activity, which ultimately would be expressed in the doctrine of spontaneity.

Bain’s concern with activity led him also to emphasize the newer physiological foundation of thought and behavior. The volume on *The Senses and the Intellect* had a short introductory chapter, perhaps 3,000 words, followed by a 20,000 word chapter on the nervous system. This became so much the model for later writers that we are in danger of forgetting that it was an unprecedented innovation. How great a departure it was may be judged by comparison with such books as Lotze’s (1852) *Medicinesche Psychologie*, Holland’s (1852) *Chapters on Mental Physiology*, Spencer’s (1855)

Principles of Psychology, and Laycock's (1860) *Mind and the Brain*. Even Wundt's (1863) *Vorlesungen zur Menschen und Thierseele* gave no attention to neuroanatomy or neurophysiology, except for a discussion of the schema of reflex movement in the fourteenth lecture. Yet Bain (1855), in 1855, gave a detailed account of the plan and finer structure of the nervous system, as far as it was then known. The innovation proved influential. Spencer adopted the same plan for his second edition, in 1870. In 1874, Carpenter (1874) used it in his *Principles of Mental Physiology*. Most notable of all, Wundt (1873), who meanwhile had become acquainted with Bain in the second edition, followed this plan in his *Grundzuge der physiologischen Psychologie*. Wundt, unlike Bain, had his physiology at first hand, but Bain achieved a more successful integration of neurophysiology with the topics of later chapters. The reason for this is Bain's peripheralism, which is another expression of his concern with action. Bain's chapter on the nervous system ended with a statement that "we cannot separate the centres from the other organs of the body that originate or receive nerve stimulus. The organ of the mind is not the brain by itself; it is the brain, nerves, muscles, and organs of sense. . . For although a large part of all the circles of mental action lie within the head, other indispensable parts equally extend throughout the body" (1855, pp. 60–62). In the second edition, the viscera were added to this inclusive organ of mind! More than half a century later John B. Watson wrote, with his usual disregard for historical precedent: "Why in psychology the stage for the neural drama was ever transferred from periphery to cortex must remain somewhat of a mystery. . . When the psychologist threw away the soul he compromised with his conscience by setting up a 'mind' which was to remain always hidden and difficult of access" (Watson 1914, pp. 19–20). But Bain is the clear root of behaviorism's peripheralism.

Bain is credited with having carried the association psychology to its highest development. More remarkable is the fact that this achievement was coupled with repeated insistence on the limitations of association psychology. This appears most clearly in the notes he wrote for the 1869 reissue of James Mill's *Analysis of the Phenomena of the Human Mind*. For example: "It is overrating the influence of association to make it a chief element in the pleasure of intoxicating

stimulants, or in the wretched feelings of diseased digestion" (note 17). Or this: "Our overweening tendency to anticipate the future from the past is shown prior to all association . . . It does not make belief, it conserves a pre-existing belief" (note 103). Or this: "The mere fact communicated to us, on a few occasions, that ghosts appear in the dark, and sometimes perform dreadful deeds, would not by force of association alone produce all that unnerving effect which children and weak or superstitious persons are liable to when, at night, exposed in a lonely place, or passing a Churchyard" (Vol. II, note 53). And as a last example: "On no reasonable and candid calculation, is the association strong enough to account for the intensity and diffusion of disinterested impulses as actually found among mankind" (Vol. II, Note 53).

The force of these instances would be greater if we could take time to give the arguments supporting these conclusions. But these fragments suffice to make our point: Bain was not prepared, as the Mills were, father and son, to explain all things mental by association. He used the principles of association more effectively than any of those who preceded him, but he did not expect it to unlock all psychological riddles. And by this contention for the "intrinsic efficacy" of primitive expressions of emotion he places one foot in the nativist camp alongside the followers of Thomas Reid.

Bain is also credited with introducing the concept of parallelism with regard to the mind–body issue. Actually, his concern in writing *Mind & Body* was not metaphysical, but antimetaphysical: he wished to demonstrate a connection so close that there need be no hesitation in using physiological data to interpret mental phenomena. He contended, therefore, for a double-aspect view according to which "all mental facts are at the same physical facts" (p. 133) which enter into a causal sequence through their physical aspects. It was just enough metaphysics to defend the physiological foundations of his work, but it did not imply that all physical facts have their mental aspects, and he explicitly rejected the notion that the mind might "make use of" the brain for its expression.

So much for Bain "in general." We are ready now to start quarrying, that is, to dig out some of Bain's many anticipations of later theories.

One of the most striking of these anticipations is the assertion that tactile pleasure is the primitive basis or

the affectional bond between mother and child. This idea was not developed in the first two editions of his work. Although he recognized that “there is a peculiar region of the body that is related to tenderness,” (1859, p. 96) including the breast, neck, mouth, and hand, he attached no special importance to this. Apparently it was in the process of annotating James Mill that the full importance of what we now call “contact comfort” was impressed on Bain, as a reaction against Mill’s cold analysis of the origins of family feeling through association. Bain rejected that analysis as “scarcely adequate to represent the reality” and he went on as follows:

- ▶ The case of greatest moment . . . is the contact of one human being or animal with another; such contact being the physical element in the tender as well as in the sexual affections. There is a combination of tactile sensibility and warmth in this instance, each counting for a part of the pleasure. The influence is well enough known as experienced among human beings; but the sphere of its operation in animals has been imperfectly explored.

If we observe carefully the first movements of a newborn animal, a mammal for example, we find that the guiding and controlling sensation of its first moments is the contact with the mother. In that contact, it finds satisfaction and repose in separation, it is in discomfort and disquiet. Its earliest volitions are to retain and to recover the soft warm touch of the maternal body. When it commences sucking, and has the sensation of nourishment, a new interest springs up, perhaps still more powerful in its attractions, and able to supersede the first, or at least to put it into second place; yet, during the whole period of maternal dependence, the feeling of touch is a source of powerful sensibility both to the mother and to the offspring. Among animals born in litter . . . the embrace is equally acceptable among the progeny themselves. The sensual pleasure of this contact is the essence, the fact, of animal affection, parental and fraternal; and it is the germ, or foundation, and commitment of tender affection in human beings.” (In Mill 1869, V. I, Note 12. See also V. II, Note 44; also Bain 1868, p. 168, 1875, pp. 126, 140)

Then comes this extraordinarily insightful statement: “It is the experience of this agreeable contact that prepares the way for a still closer conjunction

after the animal reaches puberty.” Thus, with only the farmyard for laboratory, Bain anticipated many of the important aspects of Harlow’s findings. However, it was William James, not Bain, who anticipated the design of the original Harlow experiment, in his caustic comment that “Prof. Bain does not explain why a satin cushion kept at about 98°F. would not on the whole give us the pleasure in question more cheaply than our friends and babies do” (James, 1890, v. 11, p. 552 n).

Bain’s emphasis on the role of tactile pleasure in promoting affection is one expression of the peripheralism which we previously discussed. Another is his position regarding the necessary participation of bodily structures in all emotional behavior. This was so important to him that it could not wait for his second volume, and he introduced it into his discussion of the Senses, in a footnote:

- ▶ The expression I look upon as part and parcel of the feeling. I believe it to be a general law of mind. . . that along with the fact of inward feeling or consciousness, there is a diffusive action or excitement, over the bodily members. . . According to this view, every variety of consciousness ought to have a special form of diffusive manifestation.” (1855, p. 86 n)

Here are a few sentences from his preliminary statement:

- ▶ The fundamental proposition, respecting emotion generally, may be expressed in these words: The state of Feeling, or the subjective consciousness which is known to each person by his own experience, is associated with a diffusive action over the system, through the medium of the cerebral hemispheres. In other words, the physical fact that accompanies and supports the mental fact, without making or constituting that fact, is an agitation of all those bodily members more immediately allied with the brain by nervous communication. . .

It is the common expression even with those who give full credit to the concurrence of the brain in every mental experience, that the brain is alone concerned, or that the agitation, whatever it may be, is confined to the encephalic mass. To this view I oppose the doctrine of the participation of the secreting organs in the circle of effects. . .

The emotion of Fear, for example, would not have its characteristic mental development if the currents from the brain to the moving organs and viscera were arrested. What we take merely as signs of the emotion are a part of its essential workings, in whose absence it would be something entirely different. (1859, pp. 5, 10)

This was published a quarter of a century before the earliest comparable statements by James or Lange. Bain does not reduce the emotion to peripherally aroused sensations, as James would do, but limits himself to saying that peripheral involvement is an essential component. This made him more correct, as we now know, but less eligible for quotation in the intervening years during which James' theory had serious defenders.

Another important application of the principle of peripheralism linked speech and thought. "In speech," Bain wrote, "we have a series of actions fixed in trains by association, and which we can perform either actually or mentally at pleasure, the mental action being nothing else than a sort of whisper, or approach to a whisper, instead of the full-spoken utterance" (1855, p. 341). Ferrier (1876) cited this passage when he presented his own theory that thinking is speech with the movement inhibited. Ferrier was of course acquainted with the intervening work of Sechenov (1863a) on inhibitory centers, but he was probably not aware of the *Reflexes of the Brain* (Sechenov 1863b), with its now famous phrase: "A thought is the first two-thirds of a mental reflex." John B. Watson, who is usually credited with originating the idea of thinking as implicit speech, undoubtedly read both Bain and Ferrier.

We turn now to a group of what may be called cognitive theories. The first of these represents a transition, because it still affirms the importance of action to thought. This passage is from Bain's chapter on Belief:

- ▶ While, therefore, action is the basis, and ultimate criterion as of Belief, there enters into it a necessary element some cognizance of the order of nature, or the course of the world. In using means to any end, we proceed upon the assumption of an alliance between two natural ~acts or phenomena, and we are said to have a trust, confidence, or faith, in that alliance. An animal, in judging of its food by the mere sight, or in going to a place of shelter, recognizes certain coincidences of

natural properties, and manifests to the full a state of belief concerning them. The humblest insect that has a fixed home, or a known resort for the supply of its wants, possesses the faculty of believing. Every new coincidence introduced into the routine of an animal's existence, and proceeded on in the accomplishment of its ends, is a new article of belief. . . . As the intellectual functions are developed, and become prominent in the mental system, the materials of belief are more and more abundantly reaped from their proper field; nevertheless, we must never depart from their reference to action, and the attainment of ends, otherwise they lose their fundamental character as things credited, and pass into mere fancies, and the sport of thinking. (1859, pp. 570–571)

It is the same view with which Tolman (1932) startled American behaviorists, when he introduced cognitive elements as hypothetical constructs in his discussions of animal learning. "Belief" demonstrated by "using means to any end" – what is this but "means-end expectation"?

Somewhat related to this concept of belief resting on observed coincidences in nature is the concept of discomfort arising from an awareness of contradictions. This theory grew out of Bain's own strong intellectual motivation – the force which propelled him through years of self-education, and later kept him from gaining coveted university posts because he could not pretend to beliefs he did not hold. In his *Autobiography*, he recalls how as a young boy he had "a strong sense of contradiction when varying statements could not be reconciled. From my earliest consciousness, I had this peculiarity to a degree beyond what I could observe in those about me. . . . Time only increased the disposition" (1904, p. 12). It led him to abandon all religion, which cost him more than one hoped-for appointment. And it led to this statement of the contrast between intellectual emotions. The pleasure that attends discoveries of unanticipated similarities and the distress which is an effect of perceiving contradiction:

- ▶ The labour of intellectual comprehension is reduced by every new discovery of likeness; and the first feeling of this gives a rush of delight, the delight we feel when we are relieved of some longstanding burden, or discharged from a laborious obligation. If the effect is

to solve an apparent contradiction, there is the same gladdening reaction from the depression of embarrassment. . .

Contrary statements, opinions, or appearances, operate on the mind as a painful jar, and stimulate a corresponding desire for reconciliation. . . Any strong emotion is sufficient to make the untutored mind swallow a contradiction with ease; but they that have been accustomed to sift opinions, and reject the untenable and contradictory, reel an intellectual revulsion when conflicting doctrines are propounded. This intellectual sensitiveness usually leads to the abandoning of one of the contraries, or else to a total suspension of judgment, that is to say, a repudiation for the time of both the one and the other. As a spur to the volition, therefore, no motive is stronger in the mind of the intellectual man than the pain of inconsistency. (1859, pp. 201, 205)

This is a clear statement of the theory of cognitive dissonance as a motivating force, although it is confined to one area, and not generalized as Festinger would do. Indeed, you have perhaps noticed by this time that Bain's theories are characteristically what have been called mini-theories, which are advanced to explain phenomena within a fairly restricted area. Perhaps because of his strong sense of contradiction, he does not succumb to the temptation of developing them into sweeping generalizations.

The obverse of this sensitivity to contradiction was Bain's emphasis on association by similarity. It was perhaps the point from which his interest in mental science began, for the *Autobiography* recalls that when Bain was barely 20, before he had had any course in mental philosophy, he gave a lecture on "Inventive Genius" to the Mechanics' Institution, and he adds: "I doubt not, the Law of Similarity, as far as then developed, had a leading place" (1904, p. 69). Of course, there was no need to invent the principle of similarity, known since Aristotle, and Bain had met it in his independent reading of Thomas Brown. He was then already in a sense an addict of that "rush of delight" which he experienced in discovering unexpected likenesses, and he seized on this principle with enthusiasm. Because Bain is commonly called a follower of J. S. Mill, and Mill is usually credited with reviving the principle of association by similarity, it is necessary to point out

that Bain's commitment to the importance of this principle in all creative intellectual work not only existed before he met Mill, but also long before Mill had written on this topic.

Let us turn now from the intellectual to the more purely motivational. Bain of course developed rather fully, as any industrious associationist would, the whole question of derived social motives. It is therefore not surprising that he should have arrived at a clear anticipation of what Gordon Allport (1937) called the "new principle" of the functional autonomy of motives. Bain wrote:

- ▶ It is well known that many things sought, in the first instance, as means, come, at last, to have a force in themselves, without any regard to those ulterior consequences, but for which they would never have been taken up. . . . The keeping of accounts is a common instance. This being an operation of trouble, we should never enter upon it, except for the facility conferred thereby upon our solid transactions. . . . Experience shows us that account-keepers are not always ready to abandon their operations, because there is no longer any real occasion for them. It is evident that a special liking for the machinery itself has been gradually contracted. . . . The avidity for the means is, therefore, no longer an accurate measure of our appreciation of the ends. (1859, pp. 429–430)

The illustration is evidently drawn from Bain's personal experience. It was as secretary to the Mechanics' Institution that he had his first experience in keeping accounts, and this discussion testifies that his interest in similar activities persisted. Another example throws some light on Bain's attitude toward experiment. He speaks of "the acquired fondness for experimental manipulation, beyond all question the greatest source of knowledge of nature. We constantly see the practitioners in this art spending their time in securing a precision irrelevant to the case in hand; a failing, no doubt, on virtue's side, but still indicative of an undue attachment to what only of the nature of means" (p. 430).

We can look at the functional autonomy of motives as only a special case of the functional autonomy of any organized response mechanism, which has one important expression in the principle of spontaneity. It also appears in many compulsive acts, which are so often

mentioned in Bain's writings that one cannot escape the feeling that he must have been himself quite compulsive. He writes: "There is such a thing as being laid hold of, through a sort of infatuation, by a feeling that in no way contributes to our happiness. We may be unable to discard from our thoughts the image of a person that we hate; or we may be goaded by a pursuit merely because we cannot shake ourselves free of a certain train of ideas. The fascination of a precipice, or of a serpent, belongs to this species of emotional influence" (1859, p. 35).

Another example, among many: "There is a standing mental determination, whereby all ideas tend to work themselves out into full actuality; a power that the will and other influences are constantly employed in checking" (1869, p. 384).

This brings us to the problem of motivational conflict. Bain discussed it in terms which anticipate much of the content of the related Freudian concepts of the ego, the reality principle, and the superego.

In the conflict of opposite motives, it is extremely common to have one feeling in the actual opposed to another in the idea. This is the case when present justification is restrained by the consideration of remote consequences. In order that the dread of the future may prevail over the present, it is necessary that the intellectual hold of the absent evil should be sufficient to keep alive the volitional spur belonging to the reality. Thus, it is that what is termed self-control, prudential restraint, moral strength consists in the intellectual permanency of the volitional element of our feelings (1859, p. 41).

In dealing with the problem of a supposed moral sense, Bain explains that this sort of "prudential restraint" is not a sufficient foundation for what is called conscience. He rejected both the traditional view of conscience as based on reason and the then popular view that it was based on an independent faculty, and he undertook to show that it was shaped by the early experience of external authority. In fact, he traced its development through stages which are strikingly parallel to those in Freudian theory of the growth of the superego.

- ▶ Conscience is an imitation within ourselves of the government without us; and even when differing in what it prescribes from the current morality, the mode of its operation is still parallel to the archetype. . .

The first lesson that the child learns as a moral agent is obedience, or acting according to the will of some other person. . . The child's susceptibility to pleasure and pain is made use of to bring about this obedience, and a mental association is rapidly formed between disobedience and apprehended pain, more or less magnified by fear. . . As the child advances in the experience of authority, the habit of acting and the dread of offending acquire increased confirmation. . . New elements come to be introduced to modify this acquired repugnance to whatever is prohibited by parents and teachers, and others in authority. A sentiment of love or respect towards the person of the superior infuses a different species of dread from what we have just supposed, the dread of giving pain to a beloved object. Sometimes this is a more powerful deterring influence than the other. . . When the young mind is able to take notice of the use and meaning of the prohibitions imposed upon it, and to approve of the end intended by them, a new motive is added, and the consequence is then a triple compound, and begirds the actions in question with a threefold fear; the last ingredient being paramount, in the maturity of the sympathies and the reason (1859, pp. 315–316).

A topic of limitless discussion has been whether the hostility which men display toward one another expresses an innate disposition, or results from social influences. Bain, as much a nativist as an associationist, set himself against the tide of his time, and I suppose of ours as well, by arguing for what he called "pure malevolence."

- ▶ The distinctive feeling of anger implies the impulse knowingly to inflict suffering upon another sentient being, and to derive a positive gratification from the fact of suffering inflicted. . . So great is the satisfaction thus derivable from malevolent sympathy, that we oppose it as a consolation to neutralize the original wrong.

What we have really to explain, therefore, is not the fury and vehemence of angry excitement, but the root or origin of the *pleasure of malevolence*, which, however we may disguise it, is a fact of the human constitution. . .

In endeavoring to analyze . . . the pleasure of irascible emotion, the first thing that I would notice is the sort of voluptuous excitement that by general remark

goes along with the infliction of suffering upon sentient beings, or the sight of suffering inflicted. . . . I do not profess to be able to account for a circumstance that seems at first sight anomalous . . . but to omit all reference to it would have left the explanation of the origin of the pleasure arising from malevolence palpably defective. (1859, pp. 165–167)

In describing each emotion, Bain always lists the typical circumstances which arouse it. Among the causes of terror, he lists pain, apprehension of evil, and uncertainties of many sorts. Under this heading there are two items that illustrate Bain's breadth. One example is "the sense of the unstable, or insecure," which is in effect Watson's "loss of support." Another is stated in this manner: "Any breach of expectation eminently discomposing. The whole frame being thrown into a certain attitude for meeting a given effect, there is a violent unhingement caused by the occurrences of something totally different" (1859, p. 75). It will be recalled that Hebb (1946, 1949) based his general theory of behavior in part on observations of how chimpanzees respond with fear to any unfamiliar object or to a familiar object in an unfamiliar setting, such as an arm or head detached from a body. These experiences, he reasoned, conflicted with expectations which might be embodied in stable "cell assembles." For Bain, as for Hebb, the recognition that fear is often based on a "breach of expectation" represents an important departure from associationist or S-R theory.

In the area of temperament, Bain (1861) suggested a classification of men into Active, Emotional, and Intellectual types. He based this scheme on the "three-fold division of mind into Emotion, Volition, and Intellect." Bain's categories have many points of agreement with Sheldon's (1942) somatotonic, viscerotonic, and cerebrotonic types. In Bain's treatment, although members of the first type are described as often muscular, they need not always be so, because their disposition to activity arises more from nervous than from muscular energy. He also introduces an interesting distinction in this type between dispositions to quickness and to persistence. Persons of the emotional type are described as having "a physical constitution formed for emotion, and not infrequently marked by the exterior characteristics of a rounded and full habit of body, a constitution apparently of great vigour in the

secreting organs, and less inclined to muscularity" (pp. 205–206). Physique does not enter into his description of the intellectual type, nor does the behavioral description include that element of defensiveness which is so strong in Sheldon's cerebrotonia.

My last example of Bain's anticipations of later psychological theories is perhaps the most interesting of all. Bain was by far not the first to apply the principles of association to actions as well as ideas: nearly for one, and others less well known before him, had done that. But Bain recognized that something more than association was needed, and he mixed three ingredients into his theory of learning, or, as he expressed it, that "process of acquirement in the establishing of those links of feeling and action which volition implies" (1855, p. 293). These are: first, spontaneity, or lithe instinctive germ of volition"; second, "trial and error"; third, an effect resulting from the consequences of the act. His first statement of this theory included most of the essential elements of a reinforcement theory of learning, although the neglect of positive reinforcement constituted a serious flaw.

- ▶ If, at the moment of some acute pain, there should accidentally occur a spontaneous movement, and if that movement sensibly alleviates the pain, then it is that the volitional impulse belonging to the feeling will show itself. The movement accidentally begun through some other influence will be sustained through this influence of the painful emotion. Once assume that the two waves occur together in the same cerebral seat – a wave of painful emotion, and a wave of spontaneous action tending to subdue the pain – there would arise an influence out of the former to sustain and prolong the activity of the latter. . . . This, as far as I can make out, is the original position of things in the matter of volition. (1855, pp. 294–295)

The last sentence betrays Bain's awareness that something essential is missing from this account. Nevertheless, in 1859, the same theory was affirmed with greater confidence, and in memorable phrases:

- ▶ It is the original property of our feelings to prompt the active system one way or another; but there is no original connexion between the several feelings and the actions that are relevant in each particular case. To arrive at this goal, we need all the resources of

spontaneity, trial and error, and the adhesive growth of the proper couples when they can once be got together. The first steps of our volitional education are a jump of spluttering, stumbling, and all but despairing hopelessness. Instead of a clear and distinct curriculum, we have to wait upon the accidents, and improve them when they come. (1859, p. 343)

This theory rests on two principles that are essential elements of Darwin's theory of evolution, as stated in that very year: spontaneous variation, in this case of behavior, and the selective value of success. That we must "wait upon the accidents, and improve them when they come" is also the basis of behavior modification as it is practiced today. What was lacking was a convincing rationale for the selective influence of success. Six years later, Bain (1865, still long before Morgan (1894), told how his dog, Tony, accidentally learned to lift the gate latch while sniffing excitedly at the road) shifted his emphasis from pain to pleasure as the reinforcing influence, with reduction of pain being viewed as the equivalent of pleasure. After arguing that pleasurable experience serves to augment the vigor of muscular actions, he goes on:

- ▶ But suppose now that the movements arising out of mere physical exuberance, should be accidentally such as to increase the pleasurable feeling of the moment; the very fact of such increased pleasure would imply the other fact of increased energy of the system, and of those very movements then at work. The pleasure would in this way feed upon itself, and we should have something substantially amounting to volition. Spontaneity, or accident, has brought certain movements into play; the effect of these movements is to produce a burst of new pleasure; but we cannot induce pleasure without inducing new energy to the physical system, and therefore to the members acting at the moment. So long as these movements add to the pleasure, so long they add to their own stimulation . . .

Before producing actual instances, let us complete the general statement by supposing the opposite condition, that of pain. Let movements be commenced as before, through the spontaneous energy of the healthy system, but let these movements occasion a feeling of pain. In doing so they occasion also . . . an abatement of the vital energies, which . . . brings them more or less to a stand-still. . .

A third case, of equal, if not greater, frequency in animal life, is the following: A creature is in pain, or under a depressing condition of mind; the direct consequence, or natural accompaniment, is a lowered state of the vital energies. Nevertheless random movements are still performed; the spontaneity may not always be exhausted; and perhaps the pain has produced that other effect of spasmodic irritation of the nerves. At all events movements occur; the limbs are thrown about, the head is tossed from side to side, and so forth. Now, let the pain instantly cease. Mentally, the result is a great reaction, in fact a burst of pleasure; physically, there concurs the usual elation of the system, moving members among the rest. The movements that were going on when the pain ceased, receive a sudden accession of power . . . and are made all the more energetic. (Bain 1864, pp. 307–309)

Thorndike (1911) varied this statement with a hypothesis that satisfaction and annoyance exercise positive and negative influence, respectively, on the growth of synaptic endings in use. He not only failed to credit Bain with an assist, but he later listed Bain as one of half a dozen men who "seemed to me to give wrong answers, more often than to verify or extend work which seemed sound" (Thorndike 1930, p. 268). But the other men on that list were born, on the average, 34 years after Bain, and one wonders whose work Bain might have been expected to verify or extend. Because Bain was so much ahead of his time, and because he has been read chiefly in later editions of his works, we tend to lose perspective on his place in history. For example, Boring says that "his importance is partly due to his longevity" (Boring 1950, p. 276). It is true that despite poor health Bain lived to be 85 but his chief works were written by the time he was 40, and everything quoted in this paper (except the bits of autobiography) by the time he was 50, which still 5 years before the appearance of Wundt's *Physiological Psychology*.

How was it possible for one man in the mid-nineteenth century to anticipate essential features in the systems of Freud, the father of psychoanalysis, and Watson, the father of behaviorism – of Allport, who scorned a nomothetic science, and Sheldon, the apostle of types – of Thorndike, the connectionist, and Tolman, the cognitive behaviorist? And how was it

possible for psychologists to overlook these and other theoretical contributions, while they readily accepted the assessment of Bain as a writer of great industry but little genius, an expositor but not a discoverer?

Surely one essential part of the answer is that Bain could do all this because he had no thought of system, but only of facts and their implications. Thus, he succeeded in escaping the rigidities of associationism while retaining its strengths, opening the way to a many-sided science. Spencer (1904) in *Autobiography* tells of his surprise that Bain was not offended by his unfavorable review, and states that he never knew another man so totally devoted to the search for truth. This uncompromising intellectual honesty never allowed Bain to present man simpler in theory than he was in observation. Therefore, he did not offer one of these grand syntheses which create enthusiastic followings, but which are always achieved by at least unwitting suppression of unpleasant inconsistencies. The only “system” he acknowledged was what he called the “natural history method,” that is, reliance on observation and distrust of a priori arguments, and the theories he formulated may fittingly be called mini-theories, because he did not attempt to generalize them beyond the field of observation which gave rise to them. On the other hand, these contributions were undervalued because psychology until recently had an adolescent fascination with system, and it is only as an expression of filial respect that American psychologists have condoned the lack of it in one man, their parent figure William James.

This fascination is not just a residue from the time when our philosopher forbears thought man was created according to a divine scheme. The roots lie deeper, in our innate perceptual dispositions, partly in that very “rush of delight” which we feel at the discovery of likeness and simplicity in nature, and which we are always tempted to enjoy at the expense of truth. The approved defense against such trifling the law of parsimony, but that law has many loopholes, and there are many examples in history of how it has been invoked to spare us the necessity of acknowledging the full complexity of the phenomena with which we deal. Scientists study the most complex phenomena in the universe, and esthetic simplicity is a self-indulgence which we should not carry to excess.

I say all this with diffidence, partly because my very best friends deplore the growing disregard for system, and partly because whenever I voice my distrust of the law of parsimony, the debate is likely to turn on a matter of semantics. So let us return to bedrock. Whether you are for system or against it, I would nevertheless urge on you Mill’s advice, that you take the time to explore this now almost abandoned Aberdeen quarry. There are a good many solid paving blocks strewn about, and here and there I do not doubt there are some fine building stones still waiting to be uncovered. It would be surprising you do not find something you can put to use, under any system. Of course, there are no monoliths, and for anyone who supposes human behavior is monolithic it may be a waste of time.

Bain wanted no epitaph, and only his books for monument. If we sought an epitaph, we might find it, surprisingly, in two lines by William Blake. Surprisingly, because Blake after all is a mystic, but in the lines I quote he was not expressing his own views but putting words into the mouths of the deists whom he despised. For them, he spoke thus:

- ▶ Art & Science cannot exist but in minutely organized particulars, And not in generalizing Demonstrations of the Rational Power.

(Jerusalem, Bk. 3, 62–63)

I think this accurately expresses the proper aim of science in a pluralistic universe, and as Bain pursued it.

ROBERT W. RIEBER

Fordham University, New York, NY, USA

James Rush was born on March 15, 1786, in Philadelphia, the third of 13 children born to Benjamin Rush and Julia Stockton. From 1806 to 1809, he attended medical school at the University of Pennsylvania, and from 1809 to 1811, took his post-medical training at the University of Edinburgh. James then went into private practice and taught, at the University of Pennsylvania, students of medicine in this early part of the nineteenth century. By 1819, he married Phoebe Ann Ridgway, daughter of millionaire Philadelphia merchant, James Ridgway (Bernstein 1974).

The leadership of Benjamin Rush as psychiatrist and politician has received considerable attention, particularly during the bicentennial celebration (Carlson and Wollock 1976). Less well known is his role as a father. This entry focuses on one of Rush's children, his third son, James Rush, who made significant contributions to scientific thought in the mid-nineteenth century.

James Rush, M.D., is best known for his major work *The Philosophy of the Human Voice*, first published in 1827, in Philadelphia. This was a highly original attempt to understand the physical properties of the human voice and how vocalizations are used to express emotions and to communicate ideas. With its emphasis on the actual sounds of speech, Rush's *Philosophy* anticipated some of today's research that use tape recordings and other objective methods for obtaining a precise inventory of the behavioral events during social communication.

The Relationship Between Benjamin Rush and James Rush

Benjamin Rush held James in very high esteem, and letter to James are filled with expressions of affection, concern about his health, and classes of sounds that people communicate with: (1) the “natural or vocal” signs and (2) the “artificial or verbal” signs. Rush was

aware that when a person speaks, these audible signs are rarely produced in isolation but are “united in a single act of expression and employed in every manner of compatible combination” (Rush 1893).

For purposes of analysis, Rush separated the human voice into five attributes which he called “vocality, force, time, abruptness, and pitch.” Using today’s scientific terminology (Ostwald 1973), we would translate these terms as follows:

Vocality – the voice spectrum

Force – vocal intensity

Time – the temporal organization of speech

Abruptness – onset and decay of characteristics

Pitch – intonation or melody of speech

Unfortunately, Rush was severely handicapped by the relatively crude state of the art of speech science in his day. He lamented the fact that most available texts were based on the teachings of ancient Greek and Roman authorities. He wanted to correct their errors by doing a naturalistic analysis of Anglo-American speech patterns, aided by direct listening and auditory analysis of sensorimotor components. Rush was strenuously opposed to an idealistic, “metaphysical,” and theoretical approach to the study of human behavior, but it was not until 1845, after he had already published three editions of the *Philosophy of the Human Voice*, that he was able to return to Europe, where physiological research in phonetics was under way in France and Germany.

In dealing with the verbal signs, Rush eschewed the alphabetic tradition of dividing speech into five vowels and 21 consonants. He described a total of 35 speech sounds, similar to what are called *phonemes* today. Twelve of these he called “tonic” sounds – mostly vowels and diphthongs like /ah/, /ee/, /oo/, etc.; 14 were called “subtonic sounds” – mostly voiced consonants such as /v/, /b/, /z/, etc.; and nine voiceless consonants, /sh/, /t/, /p/, etc., he called “atonic sounds.” In discussing the phenomenon of voice quality, Rush described four ways of speaking: a “natural” voice used in ordinary speech; a “falsetto” voice with breaks and excessively high pitches; “whispering” when the voice is held back; and an “orotund” voice, bombastic and exaggerated, used for oratory.

Quite remarkable for a pre-Darwinian writer are Rush’s ideas about bioacoustical continuity. He felt

that certain aspects of human speech closely resemble the noisemaking of animals. “There is no vowel in the voice of a man that is not heard from some speechless brute, or bird, or insect” he wrote (1893), while at the same time insisting that certain unique properties of human speech separate us as language users from all other forms of life. Only among humans does one observe that “speech is employed to declare the states and purposes of the mind.”

Above all, it was Rush’s wish to show how “the voice must have distinct means or signs” for declaring “our thoughts and passions.” He was determined to find precise relationships between inner psychological states and external social communication. Toward this goal, he postulated a tripartite mental organization in which *thoughts*, or what we today would call the more formal cognitive structures, were supposed to be externalized in the form of vocal signs consisting mostly of simple rising and falling intonations, short intervals, unobtrusive voice quality, moderate degrees of force, and short syllabic time. *Passions*, or what we would call the affective states, are signaled by the use of greater variability of intonation, rhythm, and vocal force. Into an intermediate or overlapping category, Rush placed what he called “inter-thoughts,” expressed in an “admirative” or “reverential” tone of voice with “orotund and a moderate, dignified force.”

Many chapters of *The Philosophy of the Human Voice* are devoted to extremely detailed descriptions of the speed, flow, and rhythm of speech. Rush used numerous examples from poetry, especially Milton’s *Paradise Lost* and also from Shakespeare’s plays. Because of a fear that his research might become a “curiosity only, if it does not lead to some application,” he also gave rules and instructions designed for improving the art of speaking. His thoroughness makes the book seem prolix and redundant, particularly in later editions, with its many footnotes and editorial comments. Some of these are however quite revealing from a biographical viewpoint. For example, Rush recalls his great admiration for the tragic actress, Mrs. Siddons, from his student days in England. He obviously felt at home in the theater, and it is of interest that right after completing his *Philosophy*, Rush wrote and published his own version of the play *Hamlet, a Dramatic Prelude in Five Acts* (Rush 1834).

Rush's auditory sensitivity not only enabled him to describe nuances of vocal behavior in extraordinary detail, but also caused him to resent people who make excessive noise. In a footnote that is prophetic of the problem of noise pollution in our own century, he described "the alarming bells of a whole city at once; the jangling clappers of horse carriages, the ceaseless roar of inarticulate trumpets; the screams of boys; the uproar of a thousand brutal throats; and the cautious absence of a 'non-committal' republican police" (Rush 1893, p. 282).

Not content just to comment on what he often considered to be a misuse of our "natural" vocal abilities, Rush, as he grew older, wanted to go so far as to reform the English language. His father had frequently commented on the importance of proper spelling, punctuation, and grammar, and criticized his children for their errors in writing. The later editions of James' books introduce a new spelling system that eliminates all double letters and other extraneous symbols. Thus we see "curent," "receve," "thot," and many other oddly spelled words. What is more, Rush liked the idea of a double comma to separate embedded clauses and other parts of sentences. He expected the English language to have an "unbounded prospect before it. The unequaled millions of a great continent, into whatever forms of Anarchy, or Despotism, they may be hereafter led – still hold community in the wide and astonishing diffusion of one cultivated and identical speech" (Rush 1893).

One of the more interesting features of *The Philosophy of the Human Voice* is Rush's attempt to utilize musical notation as a way to depict the melody of speech. In this respect his work resembles that of a contemporaneous English author, William Gardiner, whose book *The Music of Nature* was published in Boston in 1838. It too uses musical notation to describe biological phenomena. Rush fully realized the limitations of this method, which nevertheless is still applied today for certain kinds of research in the field of linguistics (Bolinger 1972). A much better method for denoting the sounds of speech, one which probably Rush would have adapted for his book had it been available in his day, is the well-known "Visible Speech" technique developed by Bell Telephone Laboratories (Potter et al. 1966).

James Rush and the Human Intellect

Following the death of his wife in 1857, Rush began work in earnest, work actually begun around 1814, on what was to become his other major accomplishment, the *Brief Outline and Analysis of the Human Intellect*. He wanted to develop the subject of the mind and integrate it with that of the voice, believing that "when we shall have a clear physical history of the mind as we now have of the voice, the two subjects will form the first and second parts, but not the whole of the physiology of the senses and the brain" (Rush 1865). Rush used the term "mentivity" to refer to thinking, and he conceived of the mind as basically a physical function of the senses and the brain.

One historian (Roback 1952) observed that Rush's "red-blooded temperament and mercurial nature" may have led him to emphasize "the motor phase of the nervous system which had been neglected by the early psychologists," thus crediting him with being the true founder of the "behavioristic" school of American psychology, long before J. B. Watson. But there is a great deal more in this book than the term behaviorism would imply. It contains references to free association, personality styles, social psychology, and what today might be called communication theory (Miller 1967; Ruesch 1975). Indeed, one can take Rush's "voice" and "intellect" as an attempt to formulate a comprehensive statement about human behavior, as observed with scientific detachment in the nineteenth century. There are definite premonitions of present day ideas regarding the special functions of verbal information processing.

Rush maintained the belief, throughout his study of the psychology of language and thought, that the mind basically comprises perception and memory. His conviction led him further to conclude that the manner in which the mind was capable of expression was a part of the function of the mind itself. In an effort to substantiate this theory, he embarked in a course of careful experimentation and observation of vocal expression to establish the relationship between this expression and its apparent complement, perception.

Mental processes, to Rush, are one and the same with physiological sensation and expression. Speech cannot be isolated or (to use a word coined by his father) disassociated from the physiological being or

whole personality. In Rush's system, speech is actually the fifth constituent of the mind itself.

Numerous authors of the period wrote textbooks based on Rush's *Philosophy of the Voice* and dedicated the books to him (Barber 1830; Comstock 1841; Murdoch and Russell 1846). Rush was not pleased, however, with attempts by others to abridge his own work, and he refused to undertake the task himself. There were authors, nonetheless, who were more than pleased to abridge their own work in the same field, men such as Thomas Upham.

Three basic assumptions underlay the system of constitutes of the mind according to Rush. First, the mind should be regarded as a physiological operation, as orderly as sensation itself, and as tangible as muscle movement. Rush saw the mind as comprising five constituents, rather than the three which Upham assigned to it.

Second, Rush considered thought and language to be inseparable. For instance, Rush believed that in order to fully understand the mind, it was necessary to show the inseparable connection between thought and language, and the reciprocal relationship that these have upon each other.

Third, the demonstrated interdependence of thought and language within the framework of mind as a physiological phenomenon leads to the conclusion that human communication is an integrated mental and physiological response.

The case of Rush's lack of acceptance is not unique. Another nineteenth-century psycholinguist, Alexander Johnson (1786–1867), similarly failed to attain the recognition that his important contributions would seem to demand (Tweney 1977). The circumstances of both Rush and Johnson raise the question: Why were only certain nineteenth-century theories of language popular and accepted within the scientific community?

The answer seems to be that only those theories of language that were by-products of theories of the mind were popular during the nineteenth century. The major concern of the era was for a systematic explanation of how the mind functions. Theories of language were important to nineteenth-century scholars, but such theories depended for their acceptance largely upon their compatibility within the larger framework of an establishment-approved mental and moral philosophy.

Many variables determine whether or not a particular theory becomes popular. For example, James Rush produced theories of both mind and language, but he still did not gain popular recognition. The major reason for this was that his basic philosophical approach was incompatible with the establishment and its goals. He also published his work on the mind at a time (the last half of the nineteenth century) when the circumstances of newly emerging, popular theories – those of Darwinism (Darwin and Spencer) and the physiology of mind (Laycock and Carpenter), to name two – were working against him. Upham, on the other hand, had published his system of the three-part division of the mind 30 years before, at a time when popular acceptance depended to a large extent on meeting the criteria of a traditional establishment.

The Place of James Rush in the History of the Behavioral Sciences

When Roback (1952) proclaimed James Rush to be “the most original American psychologist of the nineteenth century,” he bemoaned the fact that even the Harvard University Library did not own this man's remarkable books. Fortunately, that situation is now remedied, and excellent facsimile copies of *The Collected Words of James Rush* are now readily available (Bernstein 1974). The four volumes contain important biographical and scholarly notes by the editor, Melvin H. Bernstein, who mentions that “next to Dr. Benjamin Rush (Francis) Bacon was James Rush's greatest teacher.” Bernstein also provides valuable insights into Rush's work habits, his solitary existence, and the manner in which he seems to have used writing as a way of speaking to himself: “Read aloud, Rush's prose has the rhythm (he spelled it ‘rythm’) of an earnest speaker who is determined to indoctrinate the reader.”

James Rush certainly must be included among those who “came after” Benjamin Rush (Braceland 1976) to provide intellectual leadership in the United States. His book about the human voice, though almost forgotten today, had a legitimate place in the teaching of speech and theories before the invention of electronic media to make public elocution easier. For many years, the book was used as a text at Harvard, Yale, Columbia, Princeton, and Brown universities. In spite of his personal eccentricities, which he shared to some extent with his famous father and his psychotic

brother, James Rush was a very practical man. He was a product of what Professor Henry F. May (1976) has called the American era of “Didactic Enlightenment.” This period followed the “European Enlightenment” in emphasizing anything practical over anything abstract and in preferring “useful” arts – engineering, agriculture, and technology – over “useless” speculation in metaphysics and theology. In that respect, one may forgive Rush’s arrogance in claiming that whatever he personally observed to be true must indeed be the *truth*. The principles of relativity and uncertainty, which hopefully guide scientific thinking today, were not yet available in the nineteenth century. James Rush actually felt quite skeptical about the influence which his work might have in the long run, and his notes express both an undue modesty and an embittered sense of hurt pride and a feeling of neglect. As he said in his *Philosophy of the Human Voice* (Rush 1893), “there is a kind of hypocritical compliment always paid to originality, with this inconsistent purpose, that mankind are eager to receive what is new, provided it is told in the old way.”

Psychology of Religion, History of

BERNARD SPILKA

University of Denver, Denver, CO, USA

Introduction

Psychologists have always existed, though for most of history they were not known as such. Regarded primarily as philosophers, theologians, and writers, their interest was, in the broadest sense, the human condition. Over the centuries, their insights and understandings metamorphosed into psychology. Given the role of religion in history and society, a psychology of religion was inevitable. The last 200 years have thus witnessed the development of these disciplines. Still, turmoil pervades the latter field and its relationship to mainstream psychology. The following pages detail these issues.

Identifying the Psychology of Religion?

A number of problems plague this realm. For example, the psychology of religion cannot always be easily distinguished from anthropology and sociology. Some psychological historians fail to appreciate psychology’s relationship to religion. For example, Hilgard (1987) suggested an equivalence to the sociology of religion. Most authors of psychological history texts ignore the field altogether. Those who mention it usually do so superficially. Such desultory treatment may also reflect

ambivalence or negativism emanating from psychoanalytic and behavioristic views that tend to be unsympathetic toward religion.

Since rigorous definition of the field has generally been absent, we might initially claim that the psychology of religion studies, religious beliefs, behaviors, and experiences from an exclusively psychological perspective, the goal being an objective scientific understanding, is not a religious one. Though this description is abstractly correct, when operationally characterized, the religious aspect usually requires continuing psychological specification; that is, mystical experience, conversion, prayer, etc. These phenomena are invariably multidimensional. When treated simplistically, they also relate rather strongly to each other. Both of these factors get little, if any, recognition.

The term psychology was associated with religion from the sixteenth to the eighteenth centuries, yet scholars of psychological history offer at best a fleeting glance at religion when origins of psychology are discussed. The same is true of texts in general and social psychology. The relationship, however, of psychology to religion is surprisingly involved. The former has frequently been caught in the no man's land between science and faith. Unfortunately, the psychology of religion sometimes finds a value basis that is less scientific than religious (see especially the nineteenth-century writings of the American clerical psychologists).

A generally accepted argument asserts that no definition of religion is satisfactory to all social and behavioral scientists. Happily, the psychology of religion, even though it has spread its potential to virtually all of the 56 Divisions in the American Psychological Association, must embrace psychology as a science and completely separate itself from religion.

Identifying the Psychology of Religion: Parameters and Concerns

An overview of writing on the relationship of religion to psychology reveals a continuum from what might be termed religious psychology to a strictly scientific-empirical psychology of religion. The first is represented in an extensive literature largely from religious publishers who argue that church doctrines and Scripture preempt psychology in understanding human behavior. Some in the religious establishment

reject psychology. One book explicitly argues that there is a psychological war on religion (Cummings et al. 2009).

At the other end of the spectrum, are religionists who welcome and apply psychological principles and techniques. Though our concern is largely with the history of the former, the latter deals with the application of clinical and counseling psychology to those with psychological difficulties. This work is common found within religious institutions and is the domain of Clinical Pastoral Education and Pastoral Psychology.

Sources of Bias

Historically and contemporaneously, many, if not most, psychologists of religion enter the field with strong religious affiliations and backgrounds. Some received training in seminaries and schools of theology. Not a few have been ordained as clergy (Ragan et al. 1980). The psychology espoused by these scholars may be greatly influenced by such attachments (Wulff 2007). In his *Psychology of Religion*, Johnson (1959) identifies "a church as a corporate society of Christian life, a body of Christ" (1959, p. 279). Such restrictive abstractions along with a religious terminology counter a scientific approach but might be construed as relics of much of American nineteenth-century psychology. For example, John Dewey's (1889) elementary *Psychology* text asserts that "Every concrete act of knowledge involves an intuition of God" (p. 244). In later editions, reference to the deity was replaced by an undeveloped concept of the self. In this literature, much of what is perceived as objective and empirical has introduced notions of "good" and "bad" religion into contemporary psychology of religion research and writing (Kirkpatrick and Hood 1990). Despite his repeated appeals to science and empirical research, Starbuck (1914) claimed that "the psychology of religion sees in the scattered facts of religious experience an evidence that spiritual forces are at work" (p. 6). In other words, a desired scientific psychology of religion is subtly and not so subtly influenced by religious thinking.

A more general biasing factor is the culture in which we live. Ninety-seven percent of Americans claim a belief in God and about two thirds are affiliated with religious institutions (General Social Survey 2008). Even though psychologists as aspiring scientists aim for objectivity, this life-long societal milieu is likely

to find expression, possibly faint and indistinct, but nevertheless present.

A thorough history of the psychology of religion offers many avenues for exploration. These have been analyzed in depth primarily by Jacob Belzen, David Wulff, and Hendrika Vande Kemp. Their writings should be consulted for greater depth, breadth, and detail than can be provided here (Belzen 2009; Vande Kemp 1996; Wulff 1997).

Though not all agree, the history of the psychology of religion has been divided into three periods: The first is roughly bounded from 1880 to 1930, the second ranges from 1930 to 1950, and the third or current version continues from 1950 to 1980 (Beit-Hallahmi 1974; Strunk 1958). A fourth possibility is added here to note the current situation.

Period I: The Founding of the Psychology of Religion in America

Preparing the Way

Beit-Hallahmi (1989) points out that American psychologists were “the pioneers and the leaders of the ‘psychology of religion’ movement” (p. 19). Wulff’s (1997) claim that the “momentum” (p. 25) for a psychology of religion was greater in the United States than elsewhere further suggests that the American setting is a good place to begin our analysis. In the eighteenth century, figures such as Cotton Mather, Samuel Johnson, and Jonathan Edwards maintained the primacy of Christianity in mental philosophy (Fay 1939; Roback 1969). The pace of scientific development quickened during the nineteenth century but clergy still dominated the field in America. Frederick Rauch took the next step with the first book with Psychology in its title in 1841. It, however, maintained the primacy of religion. Concurrently, the growing prestige of science transformed the area verbally into mental and intellectual science yet clerical domination continued until shortly after the Civil War. A descriptive faculty psychology backed by Protestant theology ruled the higher learning. Rauch and others of his ilk explicitly denoted mental philosophy and theology to be sciences. A psychology that remained in the service of religion controlled much of education and European, primarily German, developments now appealed to American scholars. New emphases on practical

application, and active mental processes stressing consciousness appeared. Rather than simply accept the established wisdom backed by scriptural authority, the potential of research stimulated a rapidly growing appreciation of laboratory and field study. Even religion could become an object of psychological investigation. This road to the future was, however, to be far from smooth.

Those Early “Giants”

Six scholars stand out in the early phase of the psychology of religion: William James, Granville Stanley Hall, Edwin Diller Starbuck, James H. Leuba, George A. Coe, and James Bissett Pratt. Hall and Pratt studied with James, and Starbuck and Leuba were students of Hall. All came from homes in which religion played a major role. With the exception of James, they were exposed largely to orthodox Protestantism. James’ father, Henry, first identified with a conservative stance but then adopted a Swedenborgian view that allowed more freedom and individual expression. All six converted to liberal religious positions, even to the point of outright rejection of Christianity. Though he wrote in a kindly but firm professional manner, Leuba was most extreme. An argument might be advanced that James showed the most complex, if not ambivalent perspectives and actions toward faith in general. Coe maintained the strongest traditional attachment, yet he too softened his views. At one time or another, philosophy and theology were studied and this influenced their outlooks on psychology. Philosophy opened mental doors to psychology, though initially signs of a religious psychology were present in their approaches to the psychology of religion.

William James

Post Civil War education needed someone to bridge science and philosophy, and William James had the background and interests to accomplish what was required. Though religion was important to him, a liberal focus on spiritual experience was central to his personal faith from the late 1860s to the end of his life (Myers 1986; Richardson 2006). Still, it was his practice to attend early morning services in the Harvard Chapel before going to his classes (Allen 1967).

Scientific interests evidenced during his adolescence were strongly supported by his father in Europe and America. Some of these would now be regarded as basically psychological and biological. This was formally succeeded by the study of chemistry at the Lawrence Scientific School in Cambridge, where he also elected to take courses at Harvard College. After 2 years, with ambivalence, he attended Harvard Medical School but apparently without intending to practice medicine. Darwinian thought appealed to him. By 1867, he declared his intention to study “the nervous system and psychology” (Richardson 2006, p. 86). In 1876, he established a psychology teaching laboratory, however, in 1892 he indicated his dislike of laboratory work and criticized German laboratory experimentation (Allen 1967). Psychological ideas were his forte but philosophy allowed him to speculate in works like *Habit* and *Pragmatism*. James easily applied these notions to religion, hence we read “if the hypothesis of God works satisfactorily in the widest sense of the word, it is true” (James 1890, p. 299). The culmination of James’ philosophy and psychology relative to religion may be found in his most famous and popular effort *Varieties of Religious Experience*. Published in 1902, a 2009 survey of separate printings came up with 187 in English (Meyer 2009). James provided a foundation for the psychology of religion based on an active mind with a Darwinian underpinning. He valued empiricism, emotional and mystical experience, and stressed the importance of religious belief (Thayer 1983). The next stage was activation of research to realize these directions and the task began with James’ student Granville Stanley Hall. Wulff (2007) distinguishes two traditions in the psychology of religion, the interpretive and the statistical-empirical. James represents the former and Hall, the latter.

G. Stanley Hall and His Heritage

Even though Hall was James’ first doctoral candidate in psychology, they were radically different. James was always the thinker; Hall’s greatest strengths were empirical research and professional organization. In later years, he was often acknowledged as the founder or father of the scientific psychology of religion (Pratt 1908; Strunk 1958; Wulff 1997). He also began the study of the life-span development of religious beliefs, behaviors, and experiences. Known for his extensive

work on adolescence, few attend to his scholarly treatment and speculations about old age and death (Hall 1922).

Early in his career, Hall attended Union Theological Seminary, later stating that he deviated markedly from “the rigor of the Puritan faith in which I was reared to complete emancipation from all belief in all forms of supernaturalism” (Hall 1923, p. 422). He was, however, motivated to understand the development and expression of religious faith.

Twice in Hall’s career, he traveled to Germany in order to learn about the experimental psychology of Wilhelm Wundt. Apparently, neither he nor Wundt valued each other highly. Said to have adopted the questionnaire method begun by Galton after one of these trips, he used it to study religious experience, particularly religion in children and adolescence.

In 1904, Hall established *The American Journal of Religious Psychology and Education*, which was renamed *Journal of Religious Psychology* in 1912. Possibly recognizing the paucity of work on religion by psychologists, the journal was subtitled “including its anthropological and sociological aspects.” It was therefore not restricted to work on Christians and Christianity or the Western tradition. Unfortunately, this breadth was not enough to make the journal self-supporting and in 1914, with the death of its editor, publication ceased.

G. Stanley Hall seemed to do everything. Though known as the founder of the American Psychological Association, and its first president, he was also the first president of Clark University, where he established the Clark School of Religious Psychology (Schulz and Schulz 2000). In addition, he began a number of journals in which he and his students published many papers. His writings spanned theology, child, adolescent psychology, old age, philosophy, experimental psychology, many aspects of education, psychological history, race relations, and, of course, the psychology of religion. His final effort in this last area was his 1917 *Jesus, the Christ in the Light of Psychology*, two impressive volumes that interpreted Jesus and his believers in terms of basic psychological concepts. This approach was less than enthusiastically greeted (Ross 1972). Hall’s deviation from Christian orthodoxy resulted in similar recriminations by the cleric who conducted his funeral in 1924 (Ross 1972). G. Stanley Hall set the stage for a modern, empirical, scientific psychology.

Of those who followed in his footsteps, the most noteworthy for the future of the psychology of religion were Edwin Diller Starbuck and James H. Leuba.

The Hall Legacy: Starbuck, Leuba, and Coe

Edwin Diller Starbuck

Trained by both James and Hall, Starbuck took his Master's degree with the former and his doctorate with the latter. Utilizing Hall's questionnaire method, Starbuck studied conversion among over 1,200 Protestants and fixed its origin in adolescence at 16.4 years, (Starbuck 1914). Hall's data set it at 16.6 years (Johnson 1959). In order to understand the "awakening" process, as he often put it, he delved into the feelings, emotions, and motives of his respondents during their childhood, adolescence, and adult years. The book that details this work was the first volume to use the title *Psychology of Religion*. A prolific author of articles in religious, educational, and psychological journals, Starbuck influenced other early psychologists of religion to examine the process of conversion.

James H. Leuba

Like his associates, when young, Leuba joined the church and claimed to have been "deeply stirred by religion." He felt he "retained a sympathetic appreciation and understanding of the religious life" (Leuba 1912, p. 275). As the years passed, he manifested a growing unhappiness with its strictures. Finally, he considered religion irrelevant to living a good life.

Educationally, he joined Starbuck and others who worked under Hall at Clark University. Like Starbuck, he studied conversion but employed an interview method as opposed to questionnaires. This, he claimed, allowed him more flexibility to attain a deeper understanding of emotional-motivational factors underlying conversion. Adopting a strong naturalistic position, he rejected the popular notion of a distinction between a religious and nonreligious consciousness. His learning-cognition stance stressed the role of experience and the likelihood of human error in the beliefs and ideas that people held. A productive scholar, Leuba propounded a hard scientific view of religion. In the preface of a small, tightly written 1921 work on *The*

Psychological Origin and the Nature of Religion, he simply stated "Religion originated in the mind of man." On the last page of this book, he asserts "belief in a God seems no longer possible" (p. 95). Not one to tolerate myths propagated by religion, he rejected notions of immortality and life after death (Leuba 1921). Asserting that a scientific outlook invalidated religious notions, he moved the psychology of religion into the behaviorist mainstream of his time but did so without rancor or hostility (Leuba 1933). In one of his later researches, he showed that among scientists, psychologists and social scientists were in the vanguard of rejecting religious ideas (Leuba 1934).

James Leuba identified strongly with psychology's naturalistic core and his psychology of religion had no place for religious beliefs and explanations that could not be backed by observable evidence.

George A. Coe

George Coe, unlike his predecessors, maintained strong religious commitments yet accepted a more liberal theology. In graduate training at Boston University, initial intentions to enter the ministry were put aside for philosophy and the desire to apply psychology in Christian education. With further study in Germany came a commitment to science, adoption of Darwin's views, and a growing rejection of religious orthodoxy. While teaching at Northwestern University in the late 1890s, he became oriented toward the psychology of religion and wrote on temperament and personality in relation to spiritual expression and mysticism. The roots of an early stress on the self are well explicated in the first decade of the twentieth century and grew further over the next 40 years. Research was not his forte; he was primarily an expositor and interpreter with an appealing writing style. Books such as *The Spiritual Life* and *The Religion of a Mature Mind* freely joined psychology to the concerns of a liberal faith.

Concomitantly, an interest in religious education developed and he undertook an extensive program of writing for psychologists and educators. This resulted in 14 books and over 250 articles. His volume on the psychology of religion went through seven printings from 1916 to 1925. Not narrow in outlook, this tome united psychology with sociology, anthropology, evolution, philosophy, and, one can claim, a liberal Christianity.

Coe was not one to restrict himself and in the course of his later life, he identified with socialist and even communist ideologies. He seemed to be reaching for a harmonious philosophy that joined psychology, social thought, and liberal theology to attain an ultimate goal of social justice.

James Bissett Pratt

The last noteworthy American figure in this early period, James Bissett Pratt studied philosophy under James at Harvard and received his doctorate in 1905. His dissertation *The Psychology of Religious Belief* was published with modifications in 1907. Considered an outstanding work, it went beyond the psychology of religion to include anthropology, comparative religion, and religious history. Pratt goes well beyond what we would regard today as “religious belief.” Despite his frequent use of the word, he samples the entire range of religious attitudes, values, and relationships. Feeling and affect are everywhere in this treatment. One could argue that it displays elements of the modern association of social cognition with emotion (Josey 1927). Pratt also conducted questionnaire research to understand “the relation of argument and unreasoned experience to popular belief . . . as an experience of the presence of God” (Pratt 1908, p. 232). More than a few elements of what is religious psychology are present in his rather less than exacting use of data. A “soft” pattern of inference characterizes this psychology. In addition to having many articles printed in both professional and lay publications, Pratt authored 13 books, and one, *The Religious Consciousness* is regarded as second only to William James’ *Varieties* in representing the central values and concepts of the psychology of religion.

Where *The Varieties* is both philosophically and psychologically creative from the start, in Pratt’s *Religious Consciousness*, the first nine chapters offer an exhaustive overview of knowledge in the psychology of religion. The remaining 11 chapters convey not only what is known but also Pratt’s personal orientation toward the field. Attitude replaces belief and he employs the language of a nascent social psychology while almost desperately trying to maintain reliance on the individual. Since virtually all text authors at this time delved deeply into what we today consider sociology and anthropology, keeping the person in sight

posed a problem. In all of this, Pratt dealt with God belief, immortality, prayer, and mysticism (Ames 1921). Central to this effort is a subjective–objective breakdown, much of which parallels a spirituality – institutional faith distinction.

Though some others might be included in this founding period for the American psychology of religion, those cited above are considered the preeminent scholars.

Period II: 1900–1930

The years from 1900 to 1930 were prolific for the psychology of religion. Psychological professionals heard of it through annual reviews in the *Psychological Bulletin* from 1909 through 1933. The pattern of research begun by Hall was common and the questionnaire reigned supreme. Theory, however, tended to be weak or absent. Many still had the coloring of religious psychology while co-opting the rhetoric of science. Behaviorism was slowly dominating psychology, but Freudianism appealed to a broad segment of the field. The clash between these radically opposing positions is well illustrated in Knight Dunlap’s (1920) *Mysticism, Freudianism and Scientific Psychology*. Though the titular word, psychology, was extensively employed, distinctions between psychology, anthropology, and sociology continued to be vague. Most importantly, however, an objective, human-independent existence for divine beings was not the meat of science for such could not be demonstrated by psychological research and assessment. A positivistic empiricism dominated psychology. By 1930, psychology’s striving for scientific respectability meant a decline for the psychology of religion. As Beit-Hallahami (1974) called it, this was the time for a “fall of a psychological movement” (p. 84). The earlier time was one of “the rise.” As previously noted, not all scholars agree with this assessment (Belzen 2008).

Period III: 1930–1950

The early notables discussed above were now either deceased or advanced in age to the degree that most of their contributions were minor or seen primarily in religious publications. Strunk (1958) tells us that only three new texts appeared up to 1956. Paul Johnson’s 1945 volume was a mix of objective psychology and religious psychological writing. Furthermore, courses

in the psychology of religion were being dropped from college and university curricula. These were increasingly offered in seminaries and schools of theology. Psychoanalytic and clinical psychological approaches were increasingly popular among clergy and much energy went into pastoral training. The field of pastoral care began to develop. Behaviorism was not congenial to ties between religion and psychology and the psychology of religion was viewed in this light. Knight Dunlap's (1946) *Religion and its Functions in Human Life* apparently satisfied psychology's penchant for hard science. The advent of behaviorism further countered the philosophical tendencies of the earlier psychology of religion and demanded a rigorous, research framework to which seemingly objective statistics could be applied. Room no longer existed for theology or a religious psychology. With the current veneration of "hard" science, psychology took an antireligious stance. Among the struggles of a new generation of psychologists interested in the psychology of religion, most noteworthy was Gordon Allport who wrote a small significant work, *The Individual and His Religion: A Psychological Interpretation*. Despite extensive use of religious references and anthropological material, one might suggest it be put in third place as basic reading after James' *Varieties* and Pratt's *Religious Consciousness*. Allport integrated the psychology of religion into the realm of personality and also brought it into social psychology. This reached fruition in 1969 when Dittes described the field in depth in the second edition of the *Handbook of Social Psychology*. Unfortunately, this section was dropped in the third edition; however, the psychology of religion now merited inclusion in the *Annual Review of Psychology* (Gorsuch 1988; Paloutzian and Emmons 2003).

Period IV: 1950–Present

The 1950s revealed a new young breed of scholars interested in the psychology of religion. Texts stressing empirical research slowly began appearing, though those of Johnson (1959) and Clark (1958) still showed religious influences. Each succeeding decade revealed more concern with scientific objectivity. Clinical and psychoanalytic-based volumes also put in an appearance and that by Paul Pruyser (1968) merits special attention because of its strong theoretical emphasis and excellent writing. Volumes on pastoral counseling

became common as seminary education emphasized such work relative to parishioner adjustment problems, particularly those concerned with death, dying, and bereavement. Large compilations of theory and research dealt with all aspects of life-span development. Handbooks, encyclopedias, and dictionaries have continued to be published, some going into multiple editions. A literal flood of such work keeps enriching the field.

Possibly reflecting classical behaviorism and its neo-behaviorist successors, an argument might be advanced that for most of the twentieth-century mainstream psychological publications tended to be wary of submissions that dealt with religion. The pressure, however, of research and writing in the area stimulated the creation of new journals. These initially catered to social science in general but psychology per se was rapidly becoming differentiated from sociology and anthropology. In 1949, the Society for the Scientific Study of Religion was established. Two years later the *Journal for the Scientific Study of Religion* was founded. In 1951, the Religious Research Association was formed and in 1959 it sponsored the *Review of Religious Research*. Despite the fact that the journal *Sociology of Religion* had a long well-regarded history, the new efforts now offered the bulk of contemporary research and writing in sociology and psychology of religion.

Though psychologists of religion continue to publish in the above journals, a desire to "have" their own publications prevailed and in 1991, the *International Journal for the Psychology of Religion* appeared. In its section on "Contributor information," readers are "informed" that this new journal attempted to continue G. Stanley Hall's journalistic effort mentioned earlier. This was supplemented in 2008 by the *Psychology of Religion and Spirituality*, an offering of Division 36, Psychology of Religion, of the American Psychological Association. Slowly but surely, the psychology of religion has been entering the mainstream of professional psychology. This is also evidenced by the increasing appearance of research and theory articles in many of the central journals of the American Psychological Association.

Mention should be made of efforts of religious bodies to develop their own psychological journals. Examples are the *Journal of Psychology and Christianity*, a product of the Christian Association of Psychological

Studies and the *Journal of Psychology and Judaism*, which began in 1976. We should not overlook *The Journal of Psychology and Theology* that has demonstrated considerable breadth in the papers it publishes. These publications largely, but not exclusively, emphasize clinical and pastoral counseling and care concerns. While seeking psychological objectivity, they also include elements of traditional religious psychology.

The psychology of religion has increasingly emulated mainline work with growing sophistication in research design and statistical analysis. Current studies commonly employ multivariate techniques and all forms of Factor Analysis. Journal reviewers and editors demand theoretical foundations for research papers submitted for possible publication. The day has passed, if it ever really existed, that the psychology of religion can be distinguished from psychology, in general.

The Psychology of Religion Outside of the United States

As noted above, the early psychology of religion attained its fullest orderly expression in the United States. With some exceptions, the goal was an objective, scientific understanding of religious thought and behavior, largely relative to conversion and religious experience. When we look to Europe, philosophy and theology plus a more subjective phenomenological stance were common. In contrast to the American situation, relatively little coordination seems to have taken place across national borders until recently (Belzen 1994).

There have been a number of efforts to treat the psychology of religion in different countries. Aletti (1992) focused on Italy; Belzen (1994, 2009) on the Netherlands; Castro, Lafuente, and Jimenez (2009) on Spain; Richards (2009) on Britain; Vandermeersch (1994) on France; and Wikstrom (1993) on Scandinavia. Expanding our horizons, O'Connor (1991) examined Australian developments.

Countries such as Spain, France, and Italy evidenced conflict between psychology and the Catholic Church (Aletti 1992; Kugelmann and Belzen 2009). In some instances, tension and conflict correlated with political forces and cultural contexts. After 1945, differences became less significant as many priests and nuns adopted psychological viewpoints, and courses with a modern psychological orientation were

increasingly given in Catholic colleges and seminaries. This trend was most fully expressed in the United States with the creation of the American Catholic Psychological Association in 1947. In 1976, it became Division 36 of the American Psychological Association, Psychologists Interested in Religious Issues (PIRI), and in 1993, it was renamed Psychology of Religion. The detailed history of this development has been provided by Kugelmann (2009).

Even in societies with many different religious bodies such as the Netherlands, stress was present between psychology and religion. It is not amiss to comment that some conservative Christian evangelical groups in the United States are not comfortable with contemporary psychological orientations in general and certainly relative to the psychology of religion. Overall, however, more and more clergy appear to be seeking advanced degrees in psychology and the psychology of religion, as already commented, continues to move into the mainstream in both the development of psychological theory and research.

Some Limited Specifics

It is not possible in these pages to track fully the history of the psychology of religion in the European nations. A few examples should suffice to give the flavor of these efforts. Nineteenth-century beginnings, for example, were most evident in England and Germany. In many nations, the psychology of religion became a viable realm after the Second World War.

England

Science flourished in Victorian England with Darwin, Huxley, Lord Kelvin, Faraday, and Maxwell among others. One major figure who crossed scientific frontiers into both psychology and the psychology of religion during this period was Francis Galton. Credited with the discovery of various statistical methods and the questionnaire method, he conducted studies of the relationship between piety, prayer, and longevity. Contrary to popular belief, he found that pious people did not live longer than their less religious peers. Furthermore, prayer for the great and famous did not lengthen their lives.

In the early to mid-twentieth century, a few individuals stand out. Evelyn Underhill who Walter Clark (1958) called a "convinced and practicing mystic"

(p. 465) wrote extensively about worship and mysticism. Even though she stressed the metaphysical and tried to be psychologically relevant, her writings do not appear to have influenced the psychology of religion.

Robert H. Thouless, a Cambridge Don and psychologist, was primarily an expositor of the psychology of religion from 1923 to the 1970s. While writing main-line texts in the area plus articles in general and social psychology, he was involved in parapsychology and questions about life after death. A number of similar psychologies of religion texts followed those of Thouless, but research studies were infrequent. This situation has been rapidly changing since 1970 with work tying cognition and social and personality psychology to religious activity and understandings.

Germany

If one nation, or many small nations, manifested images of scholarship in the 1800s, it was Germany and the pre-1870 German states. Here, psychological and social-scientific philosophies dominated the European scene with the likes of Schopenhauer, Hegel, Marx, Herbart, and Nietzsche. German psychological science boasted Helmholtz, Goethe, Fechner, and Wilhelm Wundt. The last was at one time particularly concerned with the psychology of religion (Wundt 1916). Despite his elaborate efforts to provide an individual psychological foundation for personal faith, he wrote most about the collective nature of society and culture. Attempts to make these social referents fundamentally individual in nature were not successful, and today his writings would be consigned to anthropology and sociology.

Despite having come from a conservative Lutheran home, his father being a minister, Wundt moved from this beginning to discuss objectively, the “god idea” (Wundt 1916, pp. xv, 352). He believed that “the god-idea resulted from a fusion of the hero-ideal with the previously existing belief in demons” (p. xv). This was explicitly offered as a hypothesis. Though not averse to using the term, instinct, Wundt avoided it when speaking of the human origins and expressions of gods. He did claim that his folk psychology was based on empirical data but this was countered by Haerberlin (1916) who claimed that it was largely a historical construction. Despite its inclusion of strong evolutionary and developmental content, it has never been viewed as

a theoretical work that eventuated in testable hypotheses. Given its temporal distance from today, *Elements of Folk Psychology* stands as a relatively isolated classic philosophic-social science tome. E. L. Schaub, its translator, called it a monumental work and it probably may remain a thing apart with few connections to the psychology of religion, then and now.

Oswald Kulpe, a student of Wundt’s who founded the Wurzburg school, adapted Wundt’s introspective method to the study of religion. Proposing a much broader view of what could be studied than his mentor, his experimental psychology became a general psychology that included the psychology of religion (Allik 2007). In like manner, Karl Girgensohn, a Kulpe student and primarily a theologian, introduced questionnaires and other means of stimulating religious thinking in the laboratory. He is credited with establishing the Dorpat school of religious psychology at the university at Dorpat, Estonia. Prior to 1919, for 200 years this was part of the Russian empire; however, religion, education, local governments, etc., were largely controlled by Germans. Wulff (1985) has extensively detailed how the Dorpat school emphasized work in and out of the laboratory on religious experience.

France

Relative to the French experience, Wulff (1997) offers the most balanced view. He discusses religion in psychopathology citing the work of Pierre Janet and Theodule Ribot who dealt with religious symptomatology in individual patients. Vandermeersch (1994) ignores Ribot and emphasizes psychoanalytic thinkers such as Hesnard who confronted Catholic moral theology relative to sex, sin, and guilt. The Vatican became involved and viewed psychology as essentially stressing sexual morality. After a period of questioning and doubt, the Catholic Church approved of psychoanalysis and used it as a basis for pastoral psychology (Vandermeersch 1994).

The controversial psychoanalyst Jacques Lacan found common philosophical ground with Catholicism and focused on mysticism, ego structure, and function relative to religion.

Though French psychologists such as Jean-Pierre DeConchy have written conceptual and theoretical works in the psychology of religion for some years, this subfield of psychology has little history in France.

Belgian scholars such as Antoine Vergote and Andre Godin, all primarily twentieth-century scholars, are treated as inseparable from the French. The same seems to hold true for the Swiss with Theodore Flournoy and Jean Piaget. All made noteworthy contributions to the psychology of religion. Wulff (1997) and Vandermeersch (1994) describe a French psychology with a strong philosophical-psychoanalytic-theological flair far different from that which developed in the United States.

The Netherlands

The Netherlands is a small country, but according to its premier historian of the psychology of religion, Jacob Belzen (2009), it occupies a unique place among all nations in its treatment of this discipline. Though essentially founded in 1957, in the ensuing 50 years, at least ten professorial chairs in the psychology of religion were created. This is hypothesized to be more than in any other country in the world, a believable inference. The psychology established was primarily empirical (Belzen 1994).

Prior to 1957, during the first decade of the twentieth century, there was much awareness of the psychology of religion in Dutch religious circles, especially that of James, Hall, and their students. The field achieved a surprising popularity, and in 1920 an Association for the study of the Psychology of Religion was founded. Still, the psychology of religion remained under the aegis of religion and theology (Belzen 1994, 2009). Belzen (1994) suggested that its existence as a field by itself was a work in progress.

Scandinavia

Scholars in Denmark, Finland, Norway, and Sweden were surprisingly active in the psychology of religion throughout the twentieth century. Wikstrom (1993) and Holm (2004) have impressively detailed these developments since 1901, when the noted Danish philosopher and psychologist Harald Høffding's writings made religion of psychological concern in Denmark. Concurrently, Nathan Soderblom, a Swedish theologian with broad interests in the social and behavioral sciences worked on conceptualizing types of mysticism. In his writings, psychological influences were examined relative to cultural and historical factors. Focusing on

religious experience, he expressed reservations about William James and downplayed Freudian possibilities. His students and successors continued working on these topics through the 1920s. Despite the fact that the psychology of religion adopted psychoanalytic ideas and increasingly attended to psychopathology and psychotherapy, the area remained under the theological umbrella.

The 1930s saw the inclusion of Jungian ideas and the study of hypnotism, suggestion, and yoga relative to psychophysiology. In 1938, a chair for the history and psychology of religion independent of theology was created in Sweden's Uppsala University. This was a first, yet religious forces continued to dominate the social sciences. The ensuing dozen years witnessed greater interest in pastoral work and the ideas of Alfred Adler entered the study of religious experience.

In 1959, the formulation of a role theory by Hjalmar Sunden rapidly stimulated research and remains today possibly the primary foundation for work in the psychology of religion in Scandinavia. Interestingly, it has significance psychologically and theologically. This is a major characteristic of Scandinavian research. It reflects both into the psychology of religion and theology itself (Wikstrom 1993).

Conclusion

History has few limits but almost always requires a restricting focus. In this effort, that aspect of the history of the psychology of religion most emphasized has been empirical research and theory. Clinical psychological approaches have been seriously slighted. Many American and European thinkers have written about analytic approaches, most notably those of Freud, Jung, and Adler and successors such as Fromm and Erikson. More recently, this work has been supplemented by the object-relation theorists (McDargh 1983). Objective empirical testing of these ideas has been rare though they have often proved useful in pastoral counseling and care circumstances. Unfortunately, these topics have also not been treated here. The complexity of the pastoral realm is well demonstrated by the over 1,300-page *Dictionary of Pastoral Care and Counseling* (Hunter 1990).

Simply put, this article is designed to stimulate readers to examine further the history of the psychology of religion by citing its main sources and directions.

R

Rank, Otto

E. JAMES LIEBERMAN

George Washington University, Washington, DC, USA

Seiner Salutaris zu seinen Harcourt

Basic Biographical Information

Born: April 22, 1884, Vienna; Died: October 30, 1939, New York.

Ph.D., University of Vienna, 1912. Co-editor, *Zeitschrift für Psychoanalyse* and *Imago*. Secretary, Vienna Psychoanalytic Society.

Born Otto Rosenfeld, second son of an artisan jeweler in a working class Jewish section of Vienna, Rank took his last name from a character in *Doll's House* by

Ibsen, a favorite playwright. His older brother became a lawyer; Otto became a locksmith as his parents could not support higher education for him. A self-educated polymath, he read Sigmund Freud's works, kept a literary-philosophical diary, and wrote a psychoanalytic essay on the artist published in 1907 at age 23. By then, he was secretary of the Vienna Psychoanalytic Society and kept the *Minutes* from 1906–1916 (four volumes, published 1961–1975). Freud funded Rank's education through academic high school and the University of Vienna (Ph.D. thesis on *Lohengrin*, 1912). With a small book *The Myth of the Birth of the Hero* (1909, English trans. 1914) he gained recognition, which grew with the publication of *The Incest Theme in Literature and Legend* (1912), a world survey of 700 pages. Rank helped Freud update *Interpretation of Dreams*, and by 1914 contributed chapters on drama and poetry. His name appeared below Freud's on the title page in the 4th–7th editions (1914–1922), the only person so honored (Lieberman 1985; Taft 1958).

Major Accomplishments

A small, homely, smart, loyal, hard worker, Rank endeared himself to Freud and witnessed the departure of Alfred Adler from the VPS and Carl Jung from the International Psychoanalytic Association before World War I. He was one of the seven members of Freud's "Ring" Committee that ran the IPA. Drafted into the Austrian Army, he served in Poland as editor of the *Krakow Zeitung*, an Army newspaper. At War's end, he returned to Vienna with his Polish bride, Beata Mincer. She hosted social events for the Freuds and became a lay analyst, rising to prominence in Boston after World War II. The Ranks had one child, Helene, in 1919: She became a clinical psychologist and settled in California. Rank headed the Psychoanalytic Press (Verlag) in Vienna and began to treat patients and train analysts. He continued to write articles, reviews, and books, collaborating with Sandor Ferenczi on *The*

Development of Psychoanalysis (1923) that promoted a more active therapy, and *The Trauma of Birth* (1924) that focused on the pre-Oedipal phase and the importance of the mother–child relationship. He visited New York as a celebrity that year, at age 40, becoming an honorary member of the American Psychoanalytic Association.

Tensions built up in the Committee, intensified by the diagnosis of Freud's oral cancer. He tried unsuccessfully to heal a breach between conservatives Ernest Jones and Karl Abraham and liberals Rank and Ferenczi. Having initially praised Rank's latest book as the best innovation since the beginning of psychoanalysis, Freud changed his mind. Rank reconciled for a time but finally broke away, moving with his family to Paris in 1926. He sailed to the USA every year or two until settling in New York in 1934. By then he and Beata had separated. Rank had treated the writer Anais Nin, then became her lover in competition with Henry Miller, whom he also knew and influenced. From 1935, his companion, whom he married in 1939, was Swiss-American librarian Estelle Buel. He taught at the Pennsylvania School of Social Work at the behest of psychologist Jessie Taft, his former analysand, strong advocate, translator, and biographer. He conducted seminars with New York analysts, and lectured widely. His *Psychology and the Soul*, *Modern Education*, *Art and Artist* were followed by *Will Therapy* and *Truth and Reality*, all in the 1930s.

Rank's important contributions to theory include: (1) Attention to the mother–child relationship and separation-individuation, vs. Freud's father-centered sexual psychology; (2) Emphasis on conscious will vs. unconscious wish; (3) Therapy through egalitarian relationship vs. transference toward authority figure; (4) Existential creativity – including shaping one's personality – as a healthy response to death-fear and life-fear; (5) Valuing the irrational and the importance of emotion vs. intellectual insight. Rank was dropped – excommunicated – from the APA in 1930; his American analysands had to be reanalyzed by an approved Freudian or lose APA membership. His ideas about end-setting helped legitimize brief therapy, but were wrongly caricatured as advocating a 3 month formula (Menaker 1982; Rank 1996).

Textbooks and Freud biographies generally give Rank short shrift, misstating the trauma of birth as

a physical event rather than the prototypical psychological separation followed by weaning, walking, etc. For decades, psychoanalysts would not quote or even read his works because he was a dissident. The three-volume biography *Freud* by Ernest Jones (1953–1957) explained away Rank's deviation as mental illness. Many texts dismiss Rank as having little impact on psychology and psychiatry; an important exception is Ruth Munroe's *Schools of Psychoanalytic Thought* (1955). His reputation grew through the writings of Frederick Allen, Ira Progoff, Phillip Freund, Ernest Becker, Esther Menaker, Carl Rogers, Jessie Taft, Paul Goodman, Rollo May, and Irvin Yalom.

Otto Rank applied for US citizenship and married Estelle Buel in August, 1939. He planned to move to California. After a hiatus in writing he composed his final book in English, *Beyond Psychology*, published posthumously in 1941. Never in robust health, he contracted an infection and died at 55 just a month after Freud's death in London.

Ratner, Carl

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/Major Accomplishments

Carl Ratner is a North American cultural psychologist. For the last 45 years he has published over 200 scientific papers and seven books in the field of cultural historical psychology. He is an active member in many psychological, philosophical, sociological, epistemological, and

methodological organizations as well as on the board of editors of a dozen of scientific journals.

He refuted the mentalistic and abstraction views of culture and argues that “the relationship between culture and psychology is an interaction of mental processes” (1996, p. 407). Ratner shows in his extensive research studies how important the fundamental preconditions of an understanding of reality, truth, and insight are. These preconditions influence our way of thinking, our scientific work, and our ideas about human nature. Ratner states that there is a common *reality* to be understood and we are able to *grasp it*, and *understand it*. Ratner’s theoretical framework is grounded within the dialectical historical materialist conception of history. Like Marx, Ratner argues that social existence precedes consciousness. He applied Marx’s description of the capitalist political economy to psychological issues such as culture, developmental processes, mediational means (tools, signs), and activity. He argues that political economy structures not only our workplaces, but our way of life, belief systems, ways of thinking and behaving, family structures, education, schools, health, food consumptions, shape and weight of our body, consciousness, and ideology. This means, cultural psychology should study the psychology of oppression, class struggle, repression, and exploitation. In other words, psychology “[It] operates within the individual and appears to belong to the individual; however, it actually allows culture to enter the individual and guide his behavior from within” (2006, p. 16). Human abstract competencies are structured, formed, shaped, and curved within socially organized political economy, the dominant mode of production. Ratner concluded that, “We cannot *rely* on our abstract competencies to guide us and give us strength because they have been captured and corrupted. They only hold out the *possibility* of new psychological and cultural forms. But it is up to us to realize this possibility; and we only do so through a critique of concrete forms and an analysis of viable improvements” (2008).

He articulated in a well-defined cultural historical theory Marx’s ideas developed in the *Theses on Feuerbach* as well as *Das Kapital*. He believed that the meaning of truth is not a question of propositions, postulates, and axioms, but is a question of reality. It is not question of theory but a question of practice.

According to Ratner, human individual is embedded in a cultural, social, and historical system (this is the kernel of the sixth Thesis on Feuerbach). Ratner attacked the liberal philosophy for its defense of civil society against new human society. Ratner was aware of the circumstances of concrete life and social reality on the health of human mind and the development of higher mental functions.

Ratner argues that complex problems require complex solutions. In his writings, he tackled many complex issues, such as social injustice, social inequalities, social reform, war, prejudice, fascism, slavery, poverty, terrorism, and social exclusions. Ratner is a very active scholar. He published a series of scientific papers and books on: cultural psychology, liberation psychology, activity theory, Vygotsky’s cultural historical theory, qualitative methodology, epistemology of psychology, Marxist psychology, dialectics, cross-cultural psychology, and indigenous psychology. He lectured in many universities around the world, in Germany, Holland, Denmark, Italy, Russia, Spain, Turkey, China, Belgium, Hungary, Thailand, Scotland, Costa Rica, Poland, France, Canada, Mexico, Cuba, Brazil, Argentina, Guatemala, and Saudi Arabia. In Trinidad, California, Ratner established the Institute for Cultural Research and Education, a world center for training in qualitative methods, educational practice, and cultural psychology.

Reich, Wilhelm

CORY H. MORRIS

Touro Law School, Central Islip, NY, USA

Reich, Wilhelm (24 March 1897–3 November 1957), was a psychologist and psychoanalyst, father, medical doctor, a staunch advocate of civil rights and freedom, and best known as a self-proclaimed orgonomist who worked with natural energy within living and nonliving processes.

Basic Biographical Information

Wilhelm Reich (aka “Willie”) was born in 1897 in an eastern part of Galicia (now Ukraine). He grew up on a farm and was home tutored until he was 13 (The Wilhelm Reich Infant Trust 2004). When his father discovered his mother was having an affair with one of the tutors, his mother committed suicide. His father died of tuberculosis in 1914, the same year World War I breaks out forcing Reich to flee from the family farm. He enlisted in the Austrian army in 1915. After the war was over, Reich enrolled in the medical school in Vienna. In 1920, Sigmund Freud indoctrinated Reich, still an undergraduate, into the Vienna Psychoanalytic Association. While completing his education in Vienna, he studied, not only with Freud, but also with Professor Wagner-Jauregg, a Nobel Prize winner in medicine. Wilhelm Reich had a close working relationship with Freud. He became the First Clinical Assistant at Freud’s Psychoanalytical Polyclinic in Vienna from 1922 to 1928, headed the dispensary

from 1924 to 1930, was Vice Director from 1928 to 1930, and later Director of the Seminar for Psychoanalytic Therapy at the same institution. Additionally, from 1924 to 1930 Reich taught a seminar on technique at the Vienna Psychoanalytic Clinic. He gave lectures and conducted research that led to conflicts with some of Freud’s ideas but were generally aligned with his written theoretical principles. Reich would later go on to develop theory and work with professors in Germany, Oslo, and New York (notably, Albert Einstein). He died on November 3, 1957, in a Federal Penitentiary at Lewisburg, Pennsylvania.

Sigmund Freud’s ideas were considered extremely controversial; yet, his young apprentice, Wilhelm Reich, formulated ideas and theories that were far more revolutionary and was, unlike his predecessor, ultimately met with silence and dissension. Reich was an open advocate of communism during the late 1920s while both Sigmund and Anna Freud were not (Rubin 2003). His outspoken views against Hitler and the rise of the Nazi party stirred dissension in both circles. Reich also began to refute Freud’s Death Instinct, a view held in tandem with communist’s ideals at the time. Reich, unlike Freud, believed society should be built to conform to man’s needs rather than man conforming to society’s needs. He gave lectures about woman’s civil rights and advocated sexual freedom. Reich’s outspoken political views had set him apart from Psychoanalysis and were the driving force behind his official expulsion from the International Psychoanalytic Association in 1934 and, ironically, also led to condemnation and denunciation by the communist party.

Major Contributions

Reich helped formulate the basis of character pathology, notably with “The Impulsive Character - A Psychoanalytic Study of Ego Pathology” (Reich 1975). This work was later carried over into Anna Freud’s book, *The Ego and its Defenses*. The development of contemporary theories of personality was greatly impacted by Reich’s work on character pathology, most notably Reich’s idea of Body Armor, a characteristically stagnant set of pathological traits. In *Character Analysis* (originally published 1933), Reich devotes a significant amount of time addressing negative transference and formulated ideas on how to

deal with latent negative transference, making a lasting impression in contemporary therapeutic practice and technique and becoming commonplace in psychoanalytic theory today.

As a psychoanalyst, Reich drew conclusions from working with patients and generalized his experience into theory. From private practice and his pro bono clinical work, he hypothesized an “Orgasm theory”:

- ▶ I believe that my view of the importance of genitality, particularly the genital orgasm, to the theory and therapy of neuroses and of the neurotic character, is a direct continuation of fundamental psychoanalytic theory and makes possible a more consistent application of the theory of neurosis to therapy. *Genitality* (1980)

Reich attests to the somatic function of libido as opposed to the nuanced meaning of libido as a psychic disturbance. He draws from Freud’s book, *The Three Contributions of Sex* (1920), that sexual neurosis is most similar to an intoxicating chemical substance. Reich believed the substance that Freud alluded to was a detectable substance and the driving force of sexuality in which a block (stasis) could lead to neurotic symptoms. He believed the orgasm was a function of regulating the libido, the sexual energy, in a human being. As mentioned in the interview transcribed in *Reich Speaks of Freud* (1967), Reich claims that Freud never strayed from the sexual theory of libido, a theory that lost its luster in the later years of psychoanalysis.

Reich postulated that Orgastic Potency “is to be understood as the ability to achieve full resolution of existing sexual need-tension” (Reich 1980 p. 18); also a term that would later be used in a distortion of Reich’s theory and practice by reporter Mildred E. Brady (1948). Reich makes a strong connection between the mind and body and eventually deviates from psychoanalysis markedly, believing that talking cures were not as effective as treating the body directly. Further experimentation revealed a charge at the skin’s surface that fluctuated with anxiety and pleasure (Reich 1971). From this, Reich discovered a biological type of energy, similar to Freud’s theoretical libido, which existed throughout the body and the atmosphere. He called it orgone. By working directly on the body, Reich believed he could cure ailments related to the stress a person experienced and retained in the body, much like a deep-tissue body massage (Reich 1949). After years

of research, Reich claimed that this energy helped maintain a homeostasis in human beings and the environment, a disruption and lack of which could result in cancer developing in the body or desertification on earth (The Wilhelm Reich Infant Trust 2004).

Controversy

Numerous slanderous articles were written that yielded no effort to administer any recognized objective scientific study or experimental reproduction; however, some of these efforts, particularly the Brady article, were successful in evoking a judicial response. In 1954, the Food and Drug Administration (FDA) filed a complaint for an injunction, later granted by default, ordering that various materials and books could no longer be distributed. A violation of this injunction by an associate of Dr. Reich ended with the incineration of a gross amount of literature and materials. This incineration had destroyed Reich’s *Character Analysis*, written well before any reference to orgone, and a book that is still used in psychoanalytic schools and widely referenced in a number of books, notably Nancy McWilliams’ *Psychoanalytic Diagnosis* (1994). Because Reich did not properly respond to the court, the injunction was issued without any scientific investigation as to the validity of the FDA’s claims.

In mainstream psychology, Reich is often blacked out or rarely mentioned in lieu of other psychoanalysts with numerous eccentricities (Carl Jung and Melanie Klein are still widely taught). Most of his books have been reprinted and are now available, but this is after a condemnation and suppression of his literature (The Wilhelm Reich Infant Trust 2004). There is still no objective scientific study that is recognized by academia or the scientific community to clarify the validity or falsity of Reich’s more controversial claims.

Wilhelm Reich was an idealist and believed he could defend his theories and findings in a scientific venue, thinking it would be ludicrous to have a courtroom judge science. Very few men and women have stood their ground in the face of overwhelming opposition. Reich was a man who openly spoke against fascism when it was heresy to do so, did pro bono psychoanalytic work, spoke in favor of better housing conditions, divorce rights, birth control, and equal rights well before the civil rights movement. Reich shared the prominence of the psychoanalytic circles in Vienna

later to be silenced and censored, not only by the Nazis, but also by the FDA in America. Wilhelm Reich died in prison in 1957 and is widely known today as founder of the “orgone pseudoscience” that is strewn over the Internet rather than a psychoanalyst and the victim of FDA censorship.

Religion and Early Norwegian Psychology

SVEN HROAR KLEMPPE
NTNU, Trondheim, Norway

Introduction

One may say that three figures constituted and formed the very early modern Norwegian psychology.

These were Johan Ernst Gunnerus (1718–1773), Niels Treschow (1751–1833), and Johan Sebastian Welhaven (1807–1873). Despite the fact that they had three quite different positions in the Norwegian society, and covered more than 150 years, they also shared some common aspects. One of them was that they were all influenced by the German idealism, the other was that they were pioneers in academic psychology, and the third was that they were all theologians. The fourth aspect they shared was that Lutheran theology seems to have been a premise for how their psychology was shaped.

What Lutheran theology is or is not is an open question. In a profound study on secularity, the Canadian philosopher Charles Taylor presents three different definitions of changes in religious worship that came out of the reformation in Western civilization (Taylor 2007). One is the emptying of the public space of religion, the other is the decline of general belief, and the third is the changes of opinions of what it is to believe. It is the third definition Taylor primarily is pursuing in his investigation, and this is probably also a definition, which summarizes some of the core aspects of the entrance of the modernity. This definition does not deny religion as a part of the modernity, but it focuses on the changes of religion's role. According to Giddens, the doubt must be said to be a salient trait of a modern critical reasoning in general (Giddens 1991/1996, p. 11), and of course, the doubt must be said to be an important aspect of the religious faith within the framework of the modernity.

In this perspective, one may say that reformation in many ways grew out of the entrance of the modernity. Also Lutheranism represented a change in the opinion of what it means to have a belief. It was not longer sufficient just to be a part of a society, which was more or less ruled by the church. In addition, it was necessary to have an individual faith, which ended up in a certain confession revealing the faith as personal. Doubt stands in opposition to faith, thus it is a term that more or less defines faith counterfactually: faith is a state of absence of doubts. Doubt, therefore, is a precondition for confession and faith also in Lutheran Protestantism.

In this entry, I will focus on these aspects as a kind of background for the rise of the very early modern psychology in North Europe in the eighteenth century. By focusing on the three pioneers in Norwegian psychology, one may say they are very much representing

the North German Lutheran enlightenment. This is certainly true for Gunnerus, who in 1742–1744 studied in Halle when Christian Wolff was still active as a professor. After having been abroad for several years, Gunnerus was in 1758 offered a position as bishop in Nidaros, in which Trondheim was the center (Gunnerus 1758b). To him this was an opportunity to establish a scientific society in Norway. This was a kind of society he knew very well from Jena, where he also studied and had been working for some years. In his Episcopal letter from 1758, he proclaimed that he would establish this scientific society in which several topics were supposed to be focused on – not at least empirical psychology. Thus, Gunnerus represents a Wolffian tradition when it comes to psychology.

Treschow, on the other hand, published in 1812 a book in psychology with the informative title: “About the human nature in general, especially its spiritual aspects.” This is presented as a “psychological anthropology,” which mirrors the turn of perspective on psychology launched by Immanuel Kant. The book, however, demonstrates some interesting aspects of the relation between theology and psychology. One important aspect is that psychology is considered as something quite different from theology. This implies that “spirituality” is not referring to the religious sphere, but different aspects of the mind in a very broad sense of the word. As a theologian he also wrote a book about the spirit of the Christianity (Treschow 1828). In this book, on the other hand, a lot of psychological issues are thematized.

Welhaven represents an anti-Hegelian form of German Idealism, which can be seen as parallel to Søren Kierkegaard’s existentialism. There were some relations between the two, and Welhaven’s psychology is very much an attempt at combining religious faith with subjectivity. In this sense all the three Norwegian psychologists are closely related to three quite different continental philosophers, where all of them contributed with great impact on the development of psychology. The perspective on this entry, however, is the close relationship between their psychology and corresponding movements in theology.

Lutheranism and Early Modernity

There are a lot of aspects that open up for the reformation of the church in the sixteenth century. One may at

least mention three different perspectives: A political, a theological and an existential. The political aspect might be traced in a very close relationship between the powerful European Medici-family and the papacy. Pope Leo X (1513–1521) was Giovanni de Medici (1475–1521) (Luther 2004, p. 33), and the Italian Medici-family had great impact, not only in Italy, but also in many of the other important European countries. The big discussion about sale of indulgences is also to be understood in a political perspective. The church’s management of the indulgence had some important theological aspects too. These were Martin Luther’s (1483–1546) main goal in his attack on the papacy. The existential aspects must be regarded as a consequence of all these political and theological issues. The changes in politics and theology had great impact on how the individual lived their lives.

During the middle ages, the prevailing form of Western Christian penitential exercise consisted of four different aspects. (1) The sinner had to feel anger (*contritio* or *attritio*). (2) This was followed up by a confession (*confessio*) by the one who do penance. (3) Then the priest replied with forgiveness (*absolutio*). (4) The penitential candidate then had to follow up with satisfactory acts and behavior (*satisfactio*) (Luther 2004, p. 34).

According to Luther, the 95 theses from 1517 represented a spontaneous reaction to a practice he was quite sure did not have its legitimacy from the Pope (Luther 2004, p. 25). He had no idea that the theses should cause such a great discussion, persecutions and end up with a new branch of Christianity. The three opening theses present the theological foundation for the rest of the theses. In addition, the three theses define very much the changes in the understanding of the church. The sale of indulgences was legitimized by the canonical rules administrated by the clergy, and the church was defined in terms of those rules, whereas Luther tried to define the church in terms of the congregation consisting of individuals.

1. Our Lord and Master Jesus Christ, when He said *Poenitentiam agite*, willed that the whole life of believers should be repentance.
2. This word cannot be understood to mean sacramental penance, i.e., confession and satisfaction, which is administered by the priests.

3. Yet it means not inward repentance only; nay, there is no inward repentance which does not outwardly work divers mortifications of the flesh. (Luther 1915).

“Repentance” is the key word, which summarizes the relationship between the mankind and God. Because of the fall of man, there is an insurmountable gap between God and mankind. Christ restored this relationship, but not without man’s anger and repentance because everyone is an unforgivable sinner. For Luther, the crucial question was to clarify the differences between the roles of the church and the individual. This is what is stated in the three first theses. There are some forms of repentances that are administrated by the clergy on behalf of the individual. The third theses, however, point out that the individual is obliged to do repentance both as an inwardly spiritual act, but also as a visible act to control the flesh.

According to Luther, the most fundamental aspect of a religious life is faith. “Faith is God’s work in us, that changes us and gives new birth from God” (John 1:13) (Luther 1854, p. 28). Thus, faith presupposes that the individual has admitted a need for God’s grace to restore the relationship to Him and by this obtains faith. Repentance must be said to be the act in which the need for this is admitted. Thus, repentance presupposes a certain knowledge about man, especially that everyone is a fallen sinner. According to Luther, sin is not only a question about how people act, but even more about how they think and their whole attitude, expressed by the terms “heart” and “spirit.” The knowledge that was required was primarily about man’s nature: its drives, needs, volitions, thinking, etc. Thus, the aim of this entry is to examine if psychology was the subject to provide this kind of knowledge about man’s nature.

Gunnerus and the German Enlightenment

The Norwegian bishop Johann Ernst Gunnerus (1718–1773) must be said to be the one that published the first Norwegian thesis in psychology (Gunnerus 1757). This thesis, however, was a part of his metaphysics, which at that time normally included psychology in addition to ontology, cosmology, and natural theology. Gunnerus founded the royal Norwegian society of

science in 1760, contributed a lot in botanics, and must be said to be a true polyhistor. He studied abroad, primarily in Copenhagen, but also some years in Halle before he graduated in Jena in 1748. After that he wrote several volumes on nature and international law, lectured in Hebrew at Copenhagen University before he became bishop in Trondheim in 1758.

The most important aspect of this very short biography is the fact that he spent 2 years in Halle (1742–1744). At that time, Christian von Wolff (1679–1754) had returned to his position as a professor. He had to exile from Halle 20 years earlier because of a conflict with his pietistic colleagues, but the new king of Prussia, the more open minded and a spokesman for the enlightenment Fredrick II, invited him to come back. Wolff had so great impact that he “acted as a kind of philosophical educator of his nation” (Copleston 1964, p. 135). His main contribution to philosophy and the reason for why he came in conflict with pietism was his rationalism, which, among other things, underlined the importance of natural theology.

The philosophy of Wolff is very often described as a reproduction of Leibniz. It was a contemporary, Georg Bernhard Bilfinger (1693–1750), who first launched the term “Leibniz–Wolffian philosophy” (Copleston 1964). Wolff rejected this combination, but it is still in use. The difference between Leibniz and Wolff is first of all connected to the monadology. Wolff understood it in another way, and did not refer very much to it. An even more interesting difference between the two, however, is the understanding of metaphysics. Wolff’s radical contribution to metaphysics concerns two aspects. One is the way he systematized it. He defined the four parts by dedicating one or two volumes to each one of them: ontology (1730), cosmology (1731), psychology (1732/1734), and natural theology (1736/1737). The other aspect is that psychology became so important that it required two volumes instead of one. This way to systematize metaphysics influenced his contemporaries, not at least Immanuel Kant, but also to an even larger extent, Johan Ernst Gunnerus.

The empirical psychology was about the relation between the sense impressions and our ideas. It was a generally accepted opinion since Aristotle proclaimed that all our ideas stem from sense impressions. Sense impressions, however, were subjective and singular, so

to get general and objective knowledge, the mind had to be involved. That is the reason why Leibniz refused sense impressions as sources for scientific knowledge (Leibniz 1985, p. 309). Wolff changed this by investigating how subjective sense impressions constituted our notions (*psychologia empirica*) but also how our notions and concepts represented a general knowledge (*psychologia rationalis*). Hence the *psychologia empirica* and the other three parts of the metaphysics must be said to be a kind of handbook in scientific methodology, which is underlined by the subtitle: *Methodo scientifica* (Wolff 1732/1738).

This must be said to be the point of departure for Johan Ernst Gunnerus. His *Metaphysica* from 1757 is by himself regarded as a methodology, which on the one hand summarizes his theological and anthropological perspectives. On the other hand, it formulates the fundament for his activities in natural sciences. This is exactly what Gunnerus is known for. His *metaphysica* and the eight volumes in nature and international law are not known at all, but his contribution to natural science, which he developed in close collaboration with Carl von Linné, is highly recognized. There are no doubts about the importance of his contribution to botanic, but the fundament for this activity is given by his *metaphysica* in which *psychologia empirica* has a very special role.

One may say, therefore, that Gunnerus' theological background might be traced on two different levels in his scientific activity. One is the fact that his scientific activity is primarily legitimized in *theologia naturalis*, which also by Wolff is subtitled with "Methodo scientifica" (Wolff 1737). This is the part of the metaphysics, in which it is argued that God is revealed, not only in the Bible, but also in nature. This is exactly how Gunnerus formulates himself, especially in his letters to Carl von Linné. The first letter opens like this: "Since Trondheim is so rich when it comes to the nature, especially fish and seabirds, [...] I have started to collect almost everything that have come to me, and I have done my best to regard this as glory to the eternal name of God" (Amundsen 1976, p. 1). This is a perspective on nature, which apparently does not have much in common with modernity or Protestantism. Thomas Aquinas opened up for the same theological thinking in the sense that he referred to the fact that God's existence is confirmed through nature because

nature is a consequence of his creative acts (Thomas Aquinas 2001, p. 281ff).

There is another aspect, however, which represents a reformatory perspective to a larger extent. This is given by the interest in human nature: its affects, drives, volitions, and notions. This is exactly what is focused on in the empirical psychology: "In my main thesis or metaphysics I have presented a complete science about affects, and brought this confusing area into complete order" (Gunnerus 1758a, s. 54 f). On the one hand, to have an understanding of the role of affects is central when it comes to the scientific method, because all these aspects represent a kind of filter with great impact on the sense impressions. In addition, however, all these aspects imply a kind of incompleteness of the human nature, both when it comes to its notions, but also when it comes to its volitions. Thus, our knowledge appears as incomplete when it comes to the world we live in, and it is probably even more incomplete about the transcendental. To have an opinion on that can only rely on faith. Thus, faith is the only means for prevailing an idea of the need of God. This coincides with what Luther focused on.

Treschow and the Anthropological Psychology

Niels Treschow (1751–1833) must be said to be an influential figure in Nordic philosophy. When the University of Oslo was founded in 1811 he became the first Norwegian professor in philosophy. Before that he had been professor in philosophy in Copenhagen since 1803. He also was the Norwegian minister for education and church affairs from 1814 to 1825. In regard to his philosophy he was a bit influenced by Kant's critical philosophy, but one may trace some differences too. He rejected Kant's conclusion about our ignorance of the objective reality (Treschow 1798, p. 81), but also his interests in religion as an overall important aspect of a normal human life indicated a difference between the two.

In this matter Treschow's perspective differed from Gunnerus' too. "Natural theology" is still referred to, but is regarded as more old fashioned and is therefore connotated more negatively. The reason is that natural theology implies a kind of philosophical system that lies behind the theology. Despite the fact that Treschow developed his own philosophical system, he would not

combine it directly with theology (Treschow 1828, p. v). This is probably a consequence of Kant's critical philosophy. According to Kant, the idea of God must be said to be a "regulative principle" (Kant 1781b/1974, A699/B727), which influences all our thinking, but is not a part of the philosophical reasoning. According to Treschow, the true understanding of religion is given as a consequence of the Scripture alone. In that sense he is a true Lutheran. Not in the sense that Luther was the only one to preach the truth, but in terms of the fact that he opened up for everyone, even the layman to go to the Scripture itself to find out what is wrong and what is right (Treschow 1828, p. III). This is a rational theological perspective due to the age of enlightenment.

One may say there is a close connection between what Treschow says about religion and religious life on the one hand and his psychology on the other. Although Treschow did not adhere Kant's critical philosophy, he was quite influenced by him anyway (Treschow 1798). This is also true when it comes to the psychology. In opposition to Gunnerus, Treschow's psychology is not formulated as a part of metaphysics, due to what Kant had claimed. Kant said that psychology did not belong to metaphysics at all (Kant 1781b/1974, A848/B876). He did not acknowledge psychology as a science either (Sturm 2001, Makkreel 2001). Instead he defined psychology as a part of his anthropology, which also was the last book he wrote (1798). This publication had a more amusing tone, too. Treschow followed up this in the sense that his psychology is primarily anthropology and it does not pretend to be a science (Treschow 1812).

The psychology of Treschow must be understood in terms of three different aspects. On the one hand, the content is very close to what had earlier been defined in terms of *psychologia empirica*. Generally, this is an understanding of how knowledge is acquired through sense impressions. But this is a kind of knowledge which is very much depending on the man's nature – including its weaknesses and strengths. What Kant did was to highlight these anthropological aspects of the empirical psychology. This is the second aspect, namely to define psychology in terms of anthropology. Despite the fact that Treschow is critical to Kant, he is following up this definition of psychology. Hence, psychology is regarded neither as a science nor a basis for scientific

methodology. The third aspect is about the relationship between psychology and theology. The changes in belief after the reformation weakened some of the bounds between the two. Natural theology did not form a basis for Treschow's psychology. In his book about Christian spirituality he is explicitly distancing himself from natural theology (Treschow 1828 p. v, see also p. 45). But the reformatory theology was even more focused on the man's nature, which required an anthropological understanding as a basis for theology. This implied that Treschow's introduction to religious spirituality involved more psychology (Treschow 1828) than his introduction to psychology involved theology (Treschow 1812).

The theological challenge therefore was to reconstruct a sort of relation between man and God despite the fact that there is almost impossible to trace any relationships between the two. The Lutheran answer to this challenge is "faith," which is intimately related to the psychological, or anthropological term "spirit." This is why this term is so central in Treschow's two books on religion and psychology (Treschow 1828, 1812). The two books, however, are referring to at least two different forms of spirit. The religious spirit refers to a living faith, which represents something more than empty rituals (Treschow 1828, p. 28). Psychological spirit, on the other hand, is a bit more complicated. Treschow presents several different meanings, which all represents a mixture of different aspects of the personality and the mind (Treschow 1812, p. 23). The point is that spirit is very much connected to the subject, and in that sense primarily represents the individual.

According to Treschow, however, subjectivity is neither satisfying nor sufficient. The reason is that subjectivity represents the individual and therefore is fragmented. In addition, there must be something that unites all the diversity connected to subjectivity. In this matter, Treschow repeats very much Leibniz' famous reply to Locke. The consciousness is immediately given, not through senses, but as something self-evident. It has no reason to exist except for the fact that we are conscious. Thus, what we immediately register as consciousness is at the same time the reason for the consciousness. This is the objective aspect of the consciousness. It represents on the one hand the subjective and fragmented individuality, but on the other hand,

the fact that we are able to conceptualize our consciousness is at the same time the objective reason for its existence. “Without an objective reason the consciousness is anyway incomprehensible” (Treschow 1812, p. 24).

This implies that the conception of God is not to be regarded as an issue for the psychology. The soul is not the human entity that reflects God, the human counterpart to God’s order or something that transcends this world. On the contrary, the soul is an immanent entity, which unites the human mind with the body: “A spiritual being combined with an organic body is what is called a soul” (Treschow 1812 p. 29). In other words, the *psychologia rationalis* says something about the spiritual or intellectual mind, whereas the *psychologia empirica* tells us about the relationship between the spiritual mind and the sensual body. The empirical psychology is primary about ideas acquired through sense impressions, which requires knowledge about human nature. This is probably the reason why *psychologia empirica* changed from being a kind of scientific methodology to become anthropology.

One may say, therefore, that theology is not very much included in psychology, but the opposite: Theology seems to presuppose a certain psychological competence. This is very much true when it comes to Niels Treschow. In his book about “The Spirit in Christianity,” he refers very much to the human nature and psychological concepts like “soul,” “ideas,” “experience,” etc. To be a Christian, everyone has to know about the limitations of the human spiritual mind, about the deceptions in notions, thinking, feelings, volition, drives, and passions. All these topics are, however, exactly what Treschow’s book on psychology from 1812 is about. This explains probably one aspect of the close relation between psychology and metaphysics. But there have been a lot of changes from the scholastic thinking and psychology in the early nineteenth century. This is probably also the reason for the change in the identity of psychology, from having been a sort of scientific methodology to become anthropology.

Welhaven and Anti-Hegelian Psychology

Like the two forerunners, Johan Sebastian Welhaven (1807–1873) was also educated in theology. He is, however, most famous as a Norwegian poet, and very

few recognizes that he was an important professor in philosophy. Even fewer are aware of the fact that he regularly gave series of lectures in psychology for more than 25 years. The reason for this collective oblivion is that he had very few publications in philosophy, and almost none in psychology. What is left is just some of his student’s notes from his lectures, in addition to one thesis he wrote by himself: “Metaphysics in 100§§” (Welhaven 1965). This thesis is apparently in the tradition of Wolff as psychology was regarded as a part of the metaphysics.

One may ask, however, if Welhaven really was up to date in regard to contemporary philosophy. This question can be raised by the fact that he does not refer very much to Kant and his writings are apparently pointing at Wolff. This implies that he might be considered as a very conservative philosopher. This is, however, not a necessary conclusion, and must be said to represent a more superficial understanding of him. A closer look at his metaphysics reveals that he is not following the traditional four parts, which are ontology, cosmology, psychology, and natural theology. He presents a lot of aspects of all of the four parts, but what he primarily attempts at is to demonstrate how shortcoming ontology, cosmology, and natural theology really are as a basis for acquiring knowledge. Thus, he more or less stands left with psychology.

Welhaven is focusing on psychology because it is the only reliable field that stands left in metaphysics. Especially when it comes to theology, there will be no evidence for the existence of God neither through ontology, cosmology, or natural theology. The reason is that all these fields, but especially cosmology, presuppose a suggestion of causality to end up with an idea of the Absolute as the first mover. This inference, however, represents circularity because the dependency of the reality is something our minds presuppose and therefore project into the reality (Welhaven 1965, p. 24, §18). The Absolute, in other words, depends on a subjective reason in the sense that we presuppose that everything in the reality must depend upon something independent. Thus, our suggestion of the Absolute appears as if it is something necessary given in our intellect (*forstand*), but it is not. It is depending on a subjective suggestion. Thus, we talk about faith instead of knowledge when it comes to the concept of God.

This means that subjectivity is the only reliable ground for assuming the existence of God. Thus in metaphysics, psychology is the only part that treats subjectivity. Welhaven's metaphysics, therefore, considers all the aspects of traditional metaphysics, but they are all treated in a way that ends up with psychology because psychology is the only field that says something about what it all depends on, namely, the individual subject. Associations to the Danish philosopher Søren Kierkegaard (1813–1855) are highly motivated. They knew very well about each other, and they had a reciprocal influence upon each other. How tight this relation really was is an open question. Some historians have documented that Kierkegaard referred to his "good friend Welhaven" for having applied the term "existence" for the first time in an attempt at describing a philosophy which focused on questions about the art of living (Slagstad 2001. s. 89). They also shared an interest in attacking Hegel and Hegelianism (loc. cit).

Religion and Psychology in Early Modernity

If we now reconsider this development of early Norwegian psychology, one of the most striking conclusions to be drawn is that it mirrors some aspects of the development of the continental German psychology. There are clear similarities between Gunnerus and Wolff, not only when it comes to psychology, but also when it comes to theology. Wolff was first of all a free minded and open Lutheran due to his central position in the German enlightenment. This open-mindedness was something that characterized Gunnerus as well. One may say that Gunnerus was the one who imported the German enlightenment to Norway. His contributions in science were superior to his contributions in theology, and as a part of the metaphysics psychology was regarded as the methodological basis for doing observations in science. By opening up for subjective observations, psychology must be said to be a true child of the enlightenment. The other parts of the metaphysics, especially natural theology, neutralized this subjectivity. In this first phase of modern psychology, one may say that the theological aspects were not an issue to discuss, but taken as something given and explicitly articulated in the natural theology.

This perspective changed very much with Immanuel Kant. His refusal of empirical psychology as relevant to

science implied that he left no space for it in his *Critique of Pure Reason*. Instead, empirical psychology was defined in terms of anthropology. Although Kant included observation as an important aspect of acquiring scientific knowledge, he did not call it psychology, but discussed it under the heading of "aesthetics." Natural theology was definitely thrown overboard and replaced by God as a regulative idea. Hence, God and the Holy Scripture were regarded as irrelevant to science. Niels Treschow was the one to introduce this new thinking of Kant – first in Denmark and then in Norway. He was also a liberal Lutheran theologian, with apparently more interests in philosophy and cultural affairs than in theology. Although he had some objections to Kant's philosophy, he was highly influenced by defining psychology in terms of anthropology. Leaving natural theology aside was also a perspective adopted from Kant. This created a sharp distinction between psychology and theology in the sense that his psychology is not referring to theology. His theology, on the other hand, is very much referring to psychology. To have an insight in human nature seems to be a vital question in theology. One may say, therefore, that there is an important change in the religious perspective at this time. God is not revealed in nature as an objective entity, but through the individual believer's faith. Thus, the cultivation of faith is primarily a question of how to avoid doubts. This presupposes a control over thinking, which requires insight in the human nature, not only in regard to the mind, but also in regard to having an understanding of the body. The understanding of faith as a consequence of an understanding of the human nature required of course deep anthropological knowledge. This unilateral relationship between psychology and theology still can be traced in the sense that preaches very often involve psychological considerations, whereas psychologists more rarely refer to theological issues.

In his *Critique of Pure Reason*, Kant attempts at restoring objective knowledge. In this sense, the book can also be read as a reaction to what *psychologia empirica* opened up for. By the twelve categories of the intellect one may say he managed to form a basis for objective scientific knowledge. Although the thesis can be read as an answer to the subjective challenge of the empirical psychology, Kant did not avoid the

challenges of subjectivity. What he did was to place subjectivity in categories and under headings beyond science. The *Critique of Judgment* (Kant 1790) is one place where subjectivity is discussed. Despite the fact that an aesthetical experience appears as if it brings in new knowledge, it is not scientific. Consequently, this form of subjectivity is put aside from what is called science. The same is true for the anthropology, which is the other category of subjectivity (Kant 1798/2006). One may say that Welhaven's contribution is a reaction to this marginalization of the role of subjectivity. Thus in contrast to Treschow, Welhaven introduces God as an important aspect of the psychology. Our conception of God is just given by the faith and must therefore be regarded as the most superior form of subjectivity. This is exactly what Søren Kierkegaard does in a more consistently and elaborated way. To him, empirical psychology represents a direct point of departure in his argumentation for subjectivity (Kierkegaard 2009).

In this regard, we can see that psychology, religion, and the relationship between them went through three very different phases during the early age of modernity in the German-influenced North Europe. Psychology started as a basis for applying modern scientific method, and by this opened up for observations. In addition, psychology was regarded as a science in itself. Then it was separated from science and defined as anthropology. In the third phase, it was focused on subjectivity, which on the one hand was based on the anthropological aspects of psychology, but on the other hand did not separate it from science. The same sort of subjectivity was regarded as a factor both in anthropology and science. In the same period, religion was first regarded as an objective entity given in the nature as well as in the Scripture. In the second phase, religion and nature was totally separated, which implied that also religion and science were separated. Whereas religion was not so much included in psychology, psychology was very much included in theology. In the third phase, religion was very much defined in terms of the individual's faith, which also highlighted subjectivity. The relationship between religion and psychology in these phases must be said to be very close, but very different as well. In the first phase religion was regarded as a basis for psychology, in the second the two were parallel but independent to each other, whereas in the

third phase one may say that psychology formed the basis for religion.

Each of these phases lasted for about 50 years. The first one was introduced by Wolff's *Psychologia empirica* from 1732. This opened up for a very hectic period, which ended with the introduction of Kant's critical philosophy at the beginning of the 1780s. Both Welhaven and Kierkegaard started with their lecturing and writings in the late 1830s. The three phases must be said to be so different that they have their own characteristics. The first one might be called the "idealistic." It is very influenced by Leibniz' idealism in regard to both religion and psychology. The second phase coincides with the highpoint in the era of the enlightenment and must be said to be the "enlightened." The third phase then is the era of "subjectivity."

Conclusions

The announced aim of this entry was to examine if psychology contributed with the anthropological knowledge required by theologians due to the reformatory theology in early modernity. Although three very different phases of the development of modern psychology has been revealed, one may conclude that reformatory theology played a role in all of them, but also that psychological knowledge seems to have been even more important to theologians in all the three phases. As doubt defined the entrance of the modernity, doubt has been a running theme in both theology and psychology in this period. In theology doubt has been a very clear premise for the faith, whereas in psychology doubt must be regarded as a premise for the subject itself. One may even say that psychology is the subject that thematized the doubt by opening up for an investigation of subjectivity. This started with Wolff, and was fulfilled with Kierkegaard. The two Norwegian scholars, Gunnerus and Welhaven, respectively, mirrored their positions. One may say that Kant in one respect represented an intermediate phase by redefining an objective basis for knowledge, as Treschow also did in Norway. On the other hand, Kant is the one that has dominated philosophy for the future, and especially philosophy of science. Psychology, however, was on the way to be released from philosophy in the late nineteenth century. Thus, the challenge of subjectivity, which was introduced by *psychologia empirica* and followed up in a consistently way by Kierkegaard, seems still to be an

issue in psychology. Hence, the very early period of modern psychology tells us a lot about what psychology is about, and not at least that it stands in a natural relationship with religion.

Rettig, Salamon

JOHN JACOBS

Southern Connecticut State University, New Haven, CT, USA

Basic Biography

Salomon Rettig was born to a Jewish family in 1923 in Berlin, Germany. His father worked as a salesman and his mother was a live-in maid until the advent of Nazism. Each member of the Rettig household managed to successfully escape the Nazis and establish “a second life” in another country. In Germany, his family was largely socially isolated because of the rampant Anti-Semitism that included acts of violence directed toward Jews. Rettig had few social interactions with other children as nearly all of his schoolmates belonged to the Hitler Youth. Nevertheless, he was an excellent student, and his academic abilities literally saved his life.

At the age of 11, his father and brother had successfully fled the country. His mother placed him in an orphanage hoping that the orphanage might select him

to be sent to Palestine. Three years later, he was indeed selected and sent to Palestine because of his academic “promise.” Shortly afterward, the Nazis disbanded the orphanage and all the children and staff were sent to concentration camps. Feelings of depersonalization and traumatic memories of Nazi Germany have persisted throughout his life and thoughts of the Holocaust continue to be a daily occurrence.

Salomon Rettig lived in a Kibbutz that he found refuge in for 10 years before coming to the United States. In the early 1950s, while working as a busboy at a Poconos resort, he learned English and met his first wife. They moved to New York, where he attended Harlem Evening High School, NYU, and later Temple University in Philadelphia. His Doctoral work was completed in 1956 at Ohio State University after only 3 years in the graduate program. He then joined the Department of Psychiatry at the Ohio State University for the next 11 years, achieving full Professorship in the department. In 1967, he was invited to join the department of Psychology at Hunter College of the City University of New York, where he is still working full time as of this writing. In the ensuing years, Dr. Rettig has published over 75 articles, most of them as primary author and a book on discourse analysis. The book was published by the Plenum Press and is titled: *The discursive social psychology of evidence: Creating symbolic reality*. This substantial body of work has received recognition in both the United States and abroad. Two of Salomon Rettig’s most valued experiences were Visiting Professorships at Tel-Aviv University in Israel and the A.N.S. Institute of Social Studies, in Patna, India.

Major Contributions

His publications cover a period of over 60 years, and the content of those 75 publications have varied considerably. His early work involved the perception and self-perception of professional and nonprofessionals, which was first published in 1956 and continued into the 1970s. The area of research involved nearly 50 primary author publications and cemented his quick rise from graduate student to full professor at Ohio State. During the later end of this period, these publications focused increasingly more on morality and alienation. Of this work, two subtopics clearly stand out: ethical risk taking and changes in moral values over generations. His work on the “risky shift”

phenomena was controversial as he argued that an individual’s willingness to take chances or behave in an extreme manner was not some indefinite pull of the group to de-individuate the person/subject but rather best accounted by the individual calculating the degree of censure and gain. In the group, the degree of censure is appreciably underestimated, the person/subject feels less vulnerable, and the amount of gain becomes the focus instead. The individual behaves less responsively because he/she believes there will be lighter penalties for their trespasses.

The individual experiences the group not as a “herd” confounding rational thought but rather as a protective guard that allows the individual to be more self-serving and less concerned with the consequences of their actions. His work continues to be cited almost a half of century later and has gained attention among a range of applied topics such as the judgments of professionals and fertility research.

Rettig’s work on generational changes in morality is still cited in textbooks and on chapters in moral development and judgment. The first publications examined social responsibility among low-pay and marginal status employees, a neglected group in the mid-1950s, and the research was later expanded to include a full range socioeconomic groups. The shift in moral values in groups and through generations became a more prominent focus in the early 1970s and continued to be a topic published upon until 1990. Rettig’s work looked at generational changes in morality among American College students from the 1920s until the 1980s, employing multiple samples over generations in different countries, including Korea, Israel, and the United States.

During this period, he published several articles critically examining life in the Israeli Kibbutz. Rettig’s work noted as early as the mid-1960s that critical differences exist on values such as affluence, religion, and family principles between first generational Kibbutz workers and in subsequent second and third generations. The moral outlooks of kibbutzniks converged with other non-collective farmers. The third generation Kibbutz children engaged in the stealing of cars and drug use, and police interventions were needed which were unheard of with the first two generations of Kibbutzniks. Also, what seemed to emerge with the third generation of Kibbutzniks was the emphasis on personal gain. The acceptance of

having few personal choices and the demanding routine of Kibbutz life declined as later generations believed less in the common good and that the Kibbutz was a superior society. The Kibbutz was an unrealizable utopia, as founding members could not convince future generations to greatly restrict personal freedoms for the common good. The amounts of restrictions on the self were perhaps unreasonable for generations who were not directly threatened by the devastation of the Holocaust. The Kibbutz movement exists today because it was able to initiate dramatic changes such as introducing private property and outside labor.

In the late 1980s, Rettig's work became less empirical, focusing on hermeneutics, in particular with how people understand, convey information, reach consensus, and create meaning. Rettig began publishing on the topic of discourse analysis, which is not interested in developing predictive laws but rather a mutual understanding of the reality of individuals. The jury system became one his exemplars, particularly how jurists, strangers to each other, might interpret facts or decide what exactly should be called facts, and then reach a consensus about guilt or innocence of the plaintiff. In the juror system as in everyday life, the perception or belief in true consensus, whether others authentically agree becomes important a basis of validation of social facts. His work addressed a number of famous court cases, such as the Levin-Chambers and O.J. Simpson case, but was interested in consensus formation in general and not as it only pertained to the legal process. These included death, organ donation, and designer babies, a topic which his early work on the "risky shift" is still cited.

Salomon Rettig's work from 1988 has shifted from "empirical research" (which he still considers quite valuable) to hermeneutics and discourse analysis that has been neglected by psychologists in the United States. Rettig has been strongly concerned with issues in the "social epistemology" in human subject research in Psychology, particularly the process of discovery and verification of discursive evidence in the construction of meaning. The core tenant in his work is that human behavior is categorically different from the type of physical phenomena studied in the natural sciences. His argument has always been that the researcher's interest, values, and presence can never be fully removed from the experiment or the study. The

researchers' influence on subjects needs to be acknowledged and incorporated in the discovery process. The experimenter to subject relationship is similar to any other interaction between human beings, nearly all of which involve significant normative considerations.

A second difference between social and "natural phenomena" is that humans understand and communicate that understanding of the world through language. Humans build the world of meaning by means of language usage that expresses desires and motives that require understanding. Hence, language usage is not reducible to solely biological correlates and cannot only be studied only in the physical domain. It must entail mutual engagement and attempts at consensus formation via discourse.

Rettig's shift from the "empirical model" to hermeneutics was facilitated by a number of personal events. He was asked in the early 1970s by the Dean of Faculty at Hunter College to leave Ohio State in 1977 and that offer was quickly accepted. However, due to a number of factors, lab space with doctoral students did not materialize. The setback did provide other opportunities: Rettig chaired the department at Hunter for 6 years overseeing "open admissions" for students, the doubling of faculty, and the access of computers for faculty and students. He mentored students such as myself, often directing their intellectual process through readings and long patient discussions on various topics in psychology, ethics, and philosophy of science. As chair, he had become more involved in a highly diverse student community, advising many more students than he would have likely encountered as a faculty member in his prior position. During this period, and perhaps facilitated by his years as chair, Rettig's interest became more focused on the individual and a heightened obligation to actively seek how others understood and reasoned. The appeal of discourse analysis is in part related to that moral imperative: We are obligated to understand others. The subject is no longer an object but a citizen in the process of research. Although, in any social interaction, disagreements might emerge, but output (their grounds for understanding) are not to be devalued. This more humanistic approach might help account for diverse perspectives such as racial divisions in well-publicized legal cases such as the O.J. Simpson murder trial, incidents of alleged police brutality, or attitudes among believers and nonbelievers

about the possibility of an afterlife. Dr. Rettig continues to produce work at 87 and has several articles in press. A book arguing for the importance of hermeneutics in general and discourse analysis in particular is nearly complete.

Rieber, Robert W.

ROBERT J. KELLY

Brooklyn College, Brooklyn, NY, USA

Robert W. Rieber, historian of psychology and writer on various topics and psychological theories holds academic appointments as a research professor at Fordham University in New York, and as a Fellow in psychiatry at Columbia University in New York City. He was formerly professor of psychology at John Jay College, City University of New York where he taught in the University's PHD programs.

The son of Jewish immigrants from the Austro-Hungarian Empire who came to the USA and took up residence in Philadelphia, Robert Rieber attended Pennsylvania State University and received a Master's degree from Temple University. It was at Temple University in the 1950s that he studied with a student of Kurt Lewin. In 1957 James Page, a prominent textbook author of abnormal psychology was his advisor and recommended him for membership in the American Psychological Association where he would eventually become a Fellow.

His career took another momentous turn when Prof. Rieber moved to New York City and took a job at the Rusk Institute of New York University Medical Center. At the Rusk Institute, he worked as a clinician, specializing in speech pathology and related communication disorders. He also developed interest in psychotherapy as a treatment technique. Another intellectually formative experience occurred at the Alfred Adler Institute where he was admitted for study and training with the assistance of Prof. Emil Froeschls who acknowledged him as an honorary Viennese citizen – given his intellectual interests and predilections.

In the early 1960s, Prof. Rieber taught courses in speech pathology and psychology at Pace University in

New York and consulted with Dr. Froeschls on a project about speech pathology research and theory from an international perspective. The result was a book entitled *Speech Pathology*, which Rieber edited and contributed to with his colleague Brubaker. The volume was very successful and led to another publishing venture, namely, the *Journal Communication Disorders* which he edited for 25 years.

In the late 1960s, Rieber received an offer from John Jay College, CUNY whereupon he joined its psychology department. In 1962 at a speech communications conference in Padua, Italy, Rieber became acquainted with Dennis Fry of University College, London. Needing a Ph.D. mentor, Rieber completed his dissertation under Fry on the relationship of stuttering and cluttering. Some years later, Rieber brought to the international intellectual community the neglected works of the great Russian psychologist Vygotsky. The outcome was *The Essential Vygotsky* [2004]. This massive project contains essays and analyses by many of the world's most prominent scholars.

In 1970, he created *The Journal of Psycholinguistic Research* and has remained its editor for the last 40 years, the duration of which is unprecedented in the social sciences. This editorial tenure was followed by the creation of another journal, *The Journal of Social Distress and the Homeless* in 1990 which publishes articles, monographs, and studies across a broad range of issues including political and social questions. The journal is in the 21st year of publication.

In the 1980s as CUNY rapidly expanded, Prof. Rieber was instrumental in bringing the distinguished writer and psychiatrist Robert Jay Lifton to CUNY and John Jay College.

One of the most controversial episodes in Rieber's career at CUNY and John Jay involved the "Sybil" case. The book, *SYBIL*, made the idea of multiple personality disorder (MPD), a fashionable illness with its emphasis on child abuse, and stimulated interest in two mental/emotional phenomena relating to obsession. One such idea, for example, was the belief that people were being poisoned by buried memories, and the other related notion was that only by re-awakening those memories through hypnosis was recovery possible. Together, the three phenomena constituted what Rieber referred to sardonically as "a trinity of affinity" (Rieber 1999).

In 1994 the erstwhile notion of MPD was renamed Dissociative Identity Disorder (DID) which broadly refers to a disruption in the various parts and linkages of mental functioning that constitutes consciousness: forming and holding memories, assimilating sensory impressions, making sense of cognitive data, and maintaining one's identity. By stressing the dissociation dynamics experienced by the individual rather than the splitting of the personality, the name change of MPD reflected a groundswell of critical response to the whole idea of MPD. In Rieber's opinion, the book and film versions of SYBIL are best understood as symptoms of social distress and the psychopathy of everyday life, a subject he elaborated on in his book *Manufacturing Social Distress* (1997). For a more detailed discussion, see Dr. Rieber's autobiography.

Dr. Rieber also wrote a book with his colleague Harold J. Vetter in the mid-nineties, entitled the *Psychopathology of Language and Cognition*.

Much of his recent work has focused on the concept of social distress and its expressions across social institutions. Research and writing on films, which is in its formative stages, will examine the role of film as a quintessential medium for the transmission of "social dreams" – another important concept in his psychological theorizing. There is an aspect of the phenomenon of social distress which when lodged in social dreams is likely to induce parlous effects such as normalizing psychopathy which may become ubiquitous in the culture and whose tolerance borders on social acceptability. This is, to say the least, a frightening prospect.

During the 1980s and 1990s, Rieber worked assiduously in international settings and professional organizations encouraging scholarship in psychology that is transcultural and transnational. Research was carried out with David Ho (Hong Kong) and Anand Paranjpe (Canada), which produced a seminal book on the indigenous psychology of Asian countries (Paranjpe et al. 1986).

In the course of a prolific career, Robert Rieber has been concerned with the "crisis in psychology." In the midst of these controversies, he describes himself as a humanist with methodological and theoretical interests that transcend the narrow paradigms of positivism.

Roback, A. A.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: 19 June 1890; Died: 5 June 1965.

Born in Poland, Abraham Aaron Roback was raised in Quebec City, Canada and attended McGill University in Montreal, graduating in 1912. He then migrated to Harvard, where he was Münsterberg's last Ph.D. student, receiving the doctorate in 1917, signed by Langfeld after Münsterberg's untimely death (Taylor 1999). He then dropped experimental work and embarked on a long itinerant career as a teacher of psychology, which he did successively for shorter or longer times between 1917 and 1925 at Pittsburgh, Brown, Northeastern, Harvard, Radcliffe, and MIT. From 1926 through 1948, he lectured for the extension division of the Commonwealth of Massachusetts, and then from 1949 until his death, he was associated with Emerson College in Boston as a professor and as psychology department chair.

Major Accomplishments/Contributions

His dissertation concerned the interference of will-impulses, meaning the competition between tasks and intentions to do them. Based on his study, which involved making competing responses to two

concurrent tasks, he offered several observations and suggestions to educators. For instance, Roback noted that if the choice was between a difficult and an easier task, it was on the whole better to start with the more difficult one. And he made distinctions between “undulators” who focus on single tasks in a series and leave some undone, and “equalizers” who deal with competing tasks by working a little on all of them and leaving them all partially undone. But, promising as this work was, ultimately he adopted an outsider’s stance toward academia, preferring to maintain his independent iconoclasm. He had a long career as an editor and journalist, starting with his work in Canada on the Yiddish newspaper *Keneder Adler* (Jewish Daily Eagle) for which he wrote and served for a time as editor, and then in the USA where he founded his own publishing company, Sci-Art, which, though it did occasionally publish others, served mainly as an organ for Roback’s teeming writings. Roback apparently knew everyone: He published correspondence with Freud, Jung, Bernard Shaw, and Albert Schweitzer among others, though how intense these relations were was debatable. Nonetheless he was able to attract persons into his orbit (for instance, he was able to enlist George Sarton as a co-editor on his 1946 commemorative volume about Albert Schweitzer) and he was friends with members of William James’s family as well as Cambridge Jamesians. One of his most significant actions was in persuading the Harvard library to accept hundreds of James’s books on “fringe” subjects along with those “serious” works that their staff had handpicked after James’s death. Roback also wrote the first monograph on James’s marginalia (Roback 1942a), which have since proved, in their detailed analysis by Eugene Taylor and his collaborators, a highly productive guide to the intellectual background of James’s work (Trochu 2009). Although he wrote many books on psychology, including works on personality, business psychology, self-improvement, and on Freud, Roback’s main activity was history, both as a psychologist and as a first-rank Yiddishist. It is difficult to say, out of the many works on Yiddish culture which Roback wrote and published, which are the most important, but his *Story of Yiddish Literature* (Roback 1940) would be a good start. He was also well-read in linguistics and published interesting linguistic

monographs: One of these, on ethnophaulisms (ethnic slurs) (Roback 1944), has continued to generate some research interest. His historical style ranged between listmaking and a raconteurial, occasionally inaccurate, and often irreverent biographical approach (anyone who could title a chapter on George Trumbull Ladd “The Last of the Church Mohicans” was certainly unique among practicing historians of psychology of his time.) His personal style was contrarian and probably grated on some of the powers that were in Cambridge. E. G. Boring observed that the “eminent” Roback wouldn’t hesitate to tell you he knew more than you, every day (Winston 1998, p. 31). But Roback would not be moved from Cambridge and, for all of his eccentricity, lived a life of integrity and of speaking truth to power. Most significantly, a part of his 1942 collection *Psychorama* (Roback 1942b) details how he, in correspondence in 1939, held Jung to account for his ambiguous relations to Nazi Germany. Recent historical scholarship (e.g., Barenbaum 2003) finds Roback to be an essential element in the story of the relation of Jewish/Yiddish culture and psychology.

Robinson, E. S.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: April 18, 1893; Died: February 27, 1937.

Edward Stevens Robinson was born in Ohio and graduated from the University of Cincinnati in 1916. He next was at Carnegie Tech during the early development of industrial/organizational psychology there, and then a student at the University of Chicago. During the First World War, he worked on trade testing for the military and afterward, briefly, as an instructor at Yale University. He returned to Chicago and obtained the PhD with Harvey Carr in 1920. He continued teaching at Chicago until 1926, when he returned to the East Coast, first to Yale in 1926 and then as a visiting instructor at Harvard during 1926–1927. He returned permanently to Yale in July, 1927. He became associated with the Institute for Human Relations and also was prominent in student academic life, becoming master of one of Yale's residential colleges in 1936.

Major Accomplishments/Contribution

Robinson was a commonsense psychologist who was interested in everything, good at weighing evidence and sorting out the more from the less believable, and sober counsel against hoping for easy solutions and a “bag of tricks” approach to psychological knowledge. For the most part, Robinson was interested in the details of learning and followed in the tradition of Ebbinghaus and later scientists who focused on the minute analysis of the performance of simple tasks. For example, Robinson conducted several studies on a single effect in learning, the work decrement, the observed drop in performance observable in the work curve constructed for performance of a repetitive task. Robinson first posited a theoretical structure for the explanation of the decrement based on expectations that it would be due to the effect of several factors including recency of function of the S-R connection involved, the frequency of previous functioning, the connection between the specific stimulus and other possible responses, the general strength of the S-R

connection, variations in the stimulus, and other decrements in parallel S-R connection systems. A simple task, for example, the writing of strings of letters, was then performed with variations (see, e.g., Robinson and Bills 1926). This experimental procedure was compatible with the microanalysis of behavior advocated by Hull and others and very typical for its day. Exciting it was not, but it was a respected research style which found its best expression in the work of Robinson's contemporary and friend John McGeoch (1897–1942). It was a precursor of the development of mathematical learning theories in the 1950s and 1960s and ultimately led to the development of those parts of modern cognitive psychology with a similar focus. As might be expected, Robinson was among the few psychologists to directly challenge Gestalt psychology, which had made many inroads during the 1920s. In a critique published in the *New Republic* in 1929, he chided the Gestaltists for setting up a straw foe in the person of the analyst of behavior blind to its larger structure and meaning (Robinson 1929). Robinson was among the best-qualified psychologists to make this complaint, because he had another side to his career, an applied side intensely focused on practical problems. His early experiences in industrial psychology were further reinforced by his marriage to Florence Richardson in 1920, a 1908 Chicago Ph.D., protégé of James Angell and J. B. Watson, who was one of the earliest female academic industrial psychologists and also an early member of the League of Women Voters and a civic activist. Together the Robinsons published several joint articles and a widely used book of readings in psychology. After moving to Yale, Florence, now Florence Richardson Robinson, continued her social activism which was reflected both in her career, which led to political consulting, and reinforced her husband's activities as well (Devonis and Froese 2000). Between 1928 and 1936, Edward Robinson conducted studies on museum behavior (Robinson 1928), wrote on the relations of psychology and social work, and studied the relation of radio information to the outcome of political campaigns (in which he was directly assisted by his wife, who was able to gain access to research populations). Also he became associated, through the Yale Institute of Human Relations, with legal realist scholars at Yale and developed in conjunction with them a view of law as grounded in and

responsive to human psychological facts, especially those relating to differential capacity to understand and process information. This view was expressed in a seminal monograph on the relation between law and psychology, *Law and the Lawyers* (Robinson 1935). Three months after the sudden death of his wife from an infection, Robinson was struck by a bicyclist and suffered a fatal brain injury while crossing a New Haven street.

Rodríguez Arias, Enerio

CARLOS B. RUIZ-MATUK
 Universidad Autónoma de Santo Domingo,
 Dominican Republic

Basic Biography

The Professor Enerio Rodríguez Arias (1939–) can be considered the first and one of the most influential psychologists in Dominican Republic. He graduated from the *Universidad Nacional Autónoma de México* on December 11, 1968, although he previously had studied philosophy for 6 years at the *Universidad Autónoma de Santo Domingo*, where he obtained his doctorate in philosophy after his return from México. Dr. Rodríguez Arias then became an important and influential force in the Dominican psychology, helping to shape the future of psychology. In fact, he became Director of the psychology department at the *Universidad Autónoma de Santo Domingo* from 1970 to 1981 and hence became intimately involved in the

preparation of future psychologists. He is credited with introducing to the Dominican Republic one of the most important theoretical debates in the Psychology of the twenty century between behaviorism and phenomenology, which started in 1963 during the *Symposium of Rice* and extended for several decades. He was the first in introducing to the Dominican Republic Thomas S. Kuhn's ideas about the development of scientific knowledge and the first to teach a course on Behavior Analysis in 1970. He was also the first to make the concepts of Chomsky's Generative Grammar and its impact on the psychology of language familiar to Dominican students, as well as the central ideas from cognitive science. The first course on the psychology of reasoning was also introduced by him in the 1980s.

Major Contributions

In terms of his intellectual legacy more specifically, we can distinguish five distinctive areas: (1) Issues related to the philosophy of science, (2) elucidation of the problems in statistical analysis and inferences procedures in psychological research, (3) metapsychology considerations, (4) relevance or irrelevance of learning research for educational practice and research on human reasoning, and finally (5) notions about behavior analysis and its applications.

Concerning scientific epistemology and research methods in psychology, Rodríguez Arias has been concerned throughout his life with the “relative character of the method.” Over the years, he has emphasized the importance of first asking what the research problem is and to then determine what methods may be most appropriate to answer that research question, warning us about the danger of taking the inverse process.

With regard to statistics, he has emphasized the importance of reestablishing the supplementary and subordinated character of the statistical analysis in psychological research. By so doing, as I understand it, he is trying to bring to our attention the danger of confusing the inductive quality of statistical inference as a magical instrument to determine “the truth” or certainty of a phenomenon, as if coming from a deductive process.

In looking at the philosophy of science, some of Rodríguez Arias' recent works on the impact of the evolutionary theory on epistemology and philosophy of science call to task the “Popperian falsificationism”

approach of Karl Popper to evolution and exposes the way this philosopher applies the natural selection mechanisms to the development of human knowledge. In this context, he was particularly concerned with the problem of demarcation between science and metaphysics.

The same (philosophical) analysis is seen consistently in his dealing with any aspect of psychology. Indeed, he is considered one of the most influential authorities in Dominican Republic as a metapsychologist. His focus was on analyzing the history of psychology, establishing comparisons between its theories, deliberating over the validity of the arguments from these theories and examining their relation to the efficacy of the professional practice. His strict loyalty to the scientific method has gained him tremendous respect among the Dominican scholars. He has brought to the psychological community of Dominican Republic the only account on what may represent the history of the origins of the psychological studies in this country. Dr. Rodríguez Arias has been acknowledged (Ardila 1986) as the most prestigious Dominican psychologist for his scientific contributions. In February 2010, the Department of Psychology at the *Universidad Autónoma de Santo Domingo* published a special issue of its journal, *Perspectivas Psicológicas*, and included 24 Rodríguez Arias's selected papers.

Dr. Eнерio Rodríguez Arias is a member of Philosophy of Science Association (PSA) and an International Affiliate of American Psychological Association (APA).

Rogers, Carl R.

PEGGY BRADY-AMOON

Seton Hall University, South Orange, NJ, USA

Basic Biographical Information

Carl Ransom Rogers was born on January 8, 1902, in Oak Park, IL, the fourth of six children born to Walter

Rogers and Julia Cushings. Both of Carl Rogers' parents were of English/settler heritage and both were college educated. His father was a civil engineer and his mother, a homemaker. The family had a housekeeper. Carl Rogers later wrote of his family's Christian roots; that his family was very strict in observance and discipline, that the *Protestant work ethic* was instilled in him at an early age.

In accord with the family tradition, Carl Rogers enrolled at the University of Wisconsin. While there, he visited China, a trip he considered transformative, and was elected to Phi Beta Kappa. He earned his B.A. in History in June 1924.

He married Helen Elliott, a childhood playmate, on August 28, 1924, in River Forest, IL, and entered Union Theological Seminary in NY that fall. Their children, David and Natalie, were born in 1926 and 1928, respectively.

His interests shifting, Carl Rogers entered Teachers College, Columbia University in 1926, where he studied with E.L. Thorndike and Leta Stetter Hollingsworth. He earned his M.A. in Psychology in 1928 and his Ph.D. in 1931, focusing his dissertation on children's adjustment.

Between 1928 and 1938, while serving as a psychologist and, later, Director of the Child Study Department at the Rochester (NY) Society for the Prevention of Cruelty to Children, Carl Rogers continued to explore new ways of understanding and working with children, including strength-based approaches and case conferencing. He advanced the cause of multidisciplinary collaboration, incorporating best practices in psychology, psychiatry, and social work in his work. His first book, *The Clinical Treatment of the Problem Child*, was published in 1939.

Carl Rogers was appointed full professor of Psychology at the Ohio State University in 1940, a position he held until 1944. At Ohio State, Carl Rogers established one of the first university-based training programs to include supervised – and recorded – therapy experience. Rogers also broke new ground in recording his work, the most famous of which are *The Gloria Tapes*, recordings of his – and other psychologists' work with a client named Gloria.

From 1945 to 1957, Carl Rogers served as Professor of Psychology and Executive Secretary of the Counseling Center at the University of Chicago where he

established the University's first counseling center. Between 1957 and 1963, Carl Rogers was on the faculty at the University of Wisconsin during which he consulted with the CIA and expanded his research on non-directive counseling and psychotherapy to clients diagnosed with schizophrenia. In 1964, Rogers joined the staff of the Western Behavioral Sciences Institute (WBSI), which gave him the freedom to return to his earlier investigations of humanism and the newly emerging encounter groups. From 1968 through his death in 1987, Rogers was affiliated with the Center for Studies of the Person in La Jolla, CA. His wife, Helen, died 1979.

Carl R. Rogers died at his home in La Jolla, CA, on February 4, 1987, at 85 years of age. Much of Carl Rogers' papers and other documents are housed at the Carl Rogers Memorial Library, hosted by the Center for the Studies of the Person.

Major Accomplishments/Contributions

Carl Rogers is best known for his theory of person-centered counseling and psychotherapy and his humanistic approach to psychology and allied fields. Carl Rogers contributed to the transformation of the profession by focusing on people's strengths including their self-actualizing tendencies and developing a systematic approach to help people reach their own goals (Kirschenbaum 2007).

Rogers is also credited with being one of the first to refer to people who participate in psychotherapy as clients. He formally introduced that term as well as the concepts of client-centered and non-directive counseling in his 1942 publication of *Counseling and Psychotherapy*. In 1977, he revised and updated his terminology, thereafter referring to his theory and approach as *person-centered*.

His theoretical conceptualizations of the self, and the necessary and sufficient elements for change: congruence, empathy, and unconditional positive regard, made a significant contribution to theoretical and applied psychology and allied fields in a wide range of settings that continues today.

During his career, Carl Rogers published 16 books and more than 200 theoretical and research-based articles (Rogers n.d.). Rogers was also active professionally, making significant contributions to the foundation of

Humanism in Psychology, the American Board of Examiners in Professional Psychology, and the American Psychological Association (APA), which he served as President, from 1946 to 1947. At the same time, Rogers published in and worked in diverse yet allied fields, including psychology, education, and social work, and worked to promote interdisciplinary collaboration.

Not surprisingly, Rogers was the recipient of numerous professional awards including the APA's first Distinguished Scientific Contribution Award in 1980, its highest honor at the time, and APA's first Distinguished Professional Contribution Award in 1972.

Carl Rogers remained active professionally and personally up to his death at the age of 85. Toward the end of his life he published *A Way of Being* (1980) while continuing to develop and apply his work with groups and in education more fully to cross-cultural and international peace-building (Raskin and Rogers 1995).

Romanes, G. J.

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Romanes (1848–1894) was born in Kingston, Ontario, Canada. His Scottish father, a minister and professor at Queens University, received a large inheritance and moved the family to England before Romanes was a year old. He lived thereafter in England and died in Oxford at age 46 of a cerebral hemorrhage following

a long illness. He earned an A.M. degree at Cambridge University, specializing in physiology and evolutionary biology. While he made significant contributions in neuroanatomy, physiology, and physiological evolution, including work that contributed to Sherrington's development of the concept of the synapse, Romanes is best remembered in psychology for his work on behavioral and mental evolution. Impressed by something Romanes published in *Nature* (1873), Charles Darwin contacted Romanes, initiating a close friendship until Darwin's death in 1882. Darwin's chapter on "Instinct," originally intended for *Origin of the Species*, was given by Darwin to Romanes to publish as he saw fit, and Romanes included it as an appendix to his most important book, *Mental Evolution in Animals* (1883).

Major Accomplishments/ Contributions

Romanes legacy in psychology is mainly embodied in *Animal Intelligence* (1882), the aforementioned *Mental Evolution in Animals* (1883), and *Mental Evolution in Man* (1887). David Murray (*A History of Western Psychology*, p. 262) wrote that *Mental Evolution in Animals* "is now being recognized as one of the most important books in the history of psychology." Unfortunately, Murray's appreciation of Romanes is a minority view among current authors of history of psychology textbooks (Thomas 2007).

Romanes reputation has long been unjustifiably and, occasionally, sarcastically diminished, and it is appropriate to consider this in some detail. When developing his views on mental evolution, relatively few scientific data were available. *Animal Intelligence* was intended be a compendium of data to be used as a basis for his theoretical views to be developed in the other two books. Most of the available data were anecdotal. Unfortunately, readers such as E. L. Thorndike, Wilhelm Wundt, and Margaret Washburn who criticized Romanes for his use of anecdotes overlooked Romanes' carefully prescribed criteria for using anecdotes and his acknowledgement that their use was fraught with difficulties (see Preface to *Animal Intelligence*).

Worse, most critics failed to distinguish the anecdotes' authors' interpretations of the behavior from Romanes' more carefully considered interpretations.

One example used by Wundt and Washburn involved the burial habits of ants. Romanes was merely interested in documenting that some ant species bury their dead, and he reported several anecdotes confirming that. However, as stated in the Preface to *Animal Intelligence*, Romanes felt obligated to quote anecdotes fully often including far-fetched interpretations by the original observers. Wundt and Washburn criticized, even ridiculed, Romanes for such interpretations while failing to note that they did not represent Romanes' views. Consider his very reasonable interpretation of why some ant species bury their dead. It was "no doubt due to sanitary requirements, thus becoming developed as a beneficial instinct by natural selection" (*Animal Intelligence*, p. 89).

The gravest injustice done to Romanes was done by authors who argued that Morgan's canon was aimed at Romanes. Morgan's canon:

- ▶ In no case may we interpret an action as the outcome of the exercise of a higher psychical faculty, if it can be interpreted as the exercise of one which stands lower in the psychological scale. (*Introduction to Comparative Psychology*, 1894, p. 53)

As early as 1896 and persistently thereafter, Morgan's canon was misrepresented in several ways that continue to be perpetuated in too many current histories of psychology textbooks (Thomas, 2007). Two misrepresentations have been that Morgan aimed the canon at Romanes' use of anecdotes and anthropomorphic reasoning. Quotations from Morgan contemporary with his formulation of the canon show that he understood that anthropomorphic reasoning with respect to animal behavior and intelligence was the only path available, and Morgan described Romanes' collection of anecdotes to be valuable in the context of the way that he used them. It is true that in Morgan's later years, perhaps, having derived so much fame from the *misrepresentation* of his canon, he was somewhat critical of Romanes' use of anecdotes. In any case, the applicability of Morgan's canon to Romanes must be seen in the light of Morgan's views of Romanes at the time he wrote the canon.

Criticism of Romanes occurred mainly after his death, and it seems likely that had he lived to address them, he would have done so effectively as he did

criticism by his contemporaries. At times, Romanes may have gone too far in some of his interpretations, but some of his questionable interpretations by past standards appear more compatible among some of those offered by researchers in animal cognition today.

Morgan eventually found it necessary to clarify that “the psychological scale” mentioned in the canon referred to a psychological scale of evolutionary development, but Morgan did little to specify what such a scale might be. Romanes developed an evolutionary scale of intellectual and emotional evolutionary development that may be one of his greatest theoretical legacies. It may be seen in a foldout chart in *Mental Evolution in Animals* (reproduced in Murray’s textbook mentioned above and in Robert Boakes’s *From Darwin to Behaviourism*, 1984).

Roscoe, Stan

VALERIE J. GAWRON

The MITRE Corporation, McLean, VA, USA

Basic Biographical Information

Stanley Nelson Roscoe was born on November 4, 1920, in Eureka, California, as the elder son of Martha Beer Roscoe and Stanley Boughton Roscoe. He died on November 18, 2007, also in Eureka, California. Dr. Roscoe completed a bachelor’s degree in speech and English at Humboldt State College. During World War II, Dr. Roscoe was a flight instructor and transport pilot in the Army Air Corps. At the end of the war, he

enrolled in the Engineering Psychology graduate program at the University of Illinois at Urbana-Champaign and received a master’s in Experimental Engineering Psychology in 1947 and a doctorate in 1950. After graduation, Dr. Roscoe joined Hughes Aircraft in Culver City, California, and founded the first human factors program in aircraft and air traffic control system design and training. After 17 years at Hughes, he returned to the University of Illinois as the Associate Director for Research at the Institute of Aviation and founded the Aviation Research Laboratory. During a short hiatus from the University, Dr. Roscoe returned to Hughes to complete apparent size research at the NASA Ames Research Center. Soon afterward he started a company, ILLIANA Aviation Sciences, to continue research in pilot selection and training. Dr. Roscoe retired from the University of Illinois in 1979 and accepted a professor position at New Mexico State University (NMSU) in Las Cruces, New Mexico, where he founded the Behavioral Engineering Laboratory. Dr. Roscoe retired from NMSU in 1986 and returned to Eureka, California. He continued to publish until his death.

Major Accomplishments/Contributions

Dr. Roscoe applied his experience as a pilot in World War II as well as his academic training as an engineering psychologist to enhance cockpit display design, pilot selection, and training of pilots and air traffic controllers. He was a founding member of the Human Factors and Ergonomics Society (HFES) and as such contributed to the writing of both the HFES constitution and the HFES bylaws. He served as the fourth president of the HFES. Dr. Roscoe’s greatest legacy, however, may be his students, six of whom are HFES fellows.

Cockpit Display Design. Dr. Roscoe conducted a series of experiments over 4 decades to quantify the effects of visual accommodation on perceived size of objects. The experiments examined a number of visual anomalies relevant to aviation. One of these was the 1.25 magnification in out-the-window views in flight simulators needed to make objects appear at the correct distances. This also applied to periscopes – including periscopes through which a pilot flew an aircraft. Another anomaly was the Mandelbaum Effect, the tendency of eyes to focus at resting distance leading to missing objects

beyond that distance. In Dr. Roscoe's words, "When Day is Done and Shadows Fall, We Miss the Airport Most of All." His research with size and distance judgments based on the Moon Illusion (the moon appears largest at the horizon) was applied to the design of imaging displays. Dr. Roscoe also completed early research in moving horizon displays in aircraft. This research resulted in flight standards for primary flight reference displays in both commercial and military aircraft.

Pilot Selection. Dr. Roscoe was a partner in the design of the Wondrous Original Method for Basic Awareness Testing (WOMBAT), a PC-based system to predict pilot response to in-flight emergencies. The system is being used on the MIR space station to test the effects of long duration space missions on cosmopolitan situational awareness.

Training of Pilots and Air Traffic Controllers. Dr. Roscoe was part of teams to develop pilot training simulators as well as the first air traffic control simulator. He led efforts to measure the transfer of training from simulators to actual flight including the development of the Incremental Transfer Effectiveness Ratio to measure the effectiveness of each consecutive hour of training in a flight simulator. As part of this effort he identified methods for augmenting the visual scenes to enhance the transfer of training. Dr. Roscoe also collected data to assess the effectiveness of simulator cockpit motion on transfer of training, showing that in some cases motion decreased the transfer of training.

Student Research. Dr. Roscoe was a member of 60 thesis committees.

Rosenthal, Robert

CAROLYN BAUER

Pace University, Manasquan, NJ, USA

Basic Biography

Robert Rosenthal is currently a professor of psychology at the University of California, Riverside. Rosenthal was born on March 2, 1933, in Giessen, Germany, and left his hometown at a young age. He received a Bachelor of Arts degree in Psychology from the University of California, Los Angeles, in 1953, and went on to receive a Ph.D. in Psychology from the University of California, Los Angeles, in 1956. After receiving his doctorate, Rosenthal taught at the University of North Dakota for 5 years beginning in 1957. Following his time at the University of North Dakota, Rosenthal went on to teach clinical psychology at Harvard University, and eventually began teaching social psychology.

Main Contributions

The main focus of Robert Rosenthal's research has been on the role of self-fulfilling prophecies in everyday life and in the laboratory. The specific interests of Rosenthal's research on self-fulfilling prophecies include: the effects of a teacher's expectations on a student's academic and physical performance, the effects of experimenters' expectations on the results of their research, and the effects of clinicians' expectations on their patients' mental and physical health.

In addition to researching the self-fulfilling prophecy in everyday life and the laboratory, Rosenthal has been interested in the role of nonverbal communication. Rosenthal's research includes the influence of nonverbal communication on interpersonal expectancy effects, and how it influences the relationship between the members of a small work and social groups. Rosenthal has also been interested in studying the sources of artifact in behavioral research in many quantitative procedures. Main interests in data analysis include: experimental design and analysis, contrast analysis, and meta-analysis.

One of Rosenthal's most widely known contributions to the field of social psychology is the "Pygmalion

Effect in the Classroom,” which studied the idea that children could become brighter when expected to by their teachers. The results of this hypothesis suggested that when children were expected to be more intelligent they showed a higher level of intelligence when compared to the control group. Also well known for the experimenter-*efficacy* effect, or Rosenthal Effect, Rosenthal found that when a researcher has expectations about a hypothesis, it becomes a self-fulfilling prophecy of the subject’s responses.

Robert Rosenthal’s most recent publications are on the topics of data analysis, nonverbal communication in situations where relationships are formed. For example: teacher–student, doctor–patient, manager–employee, judge–jury, and psychotherapist–client interaction. Rosenthal has also published work on the strategies to improve the design and analysis of studies. In addition, Rosenthal has played a key role in the introduction of the binomial effect size display, the file-drawer problem, and the counternull statistic, to name a few.

In adding to the work and many contributions of Robert Rosenthal, are some of the most prestigious awards he has received. Among the many awards is the Gold Medal Award for Life Achievement in the Science of Psychology of the American Psychological Foundation, which was received in 2003. Additionally some awards include: Distinguished Scientific Award for Applications of Psychology, APA in 2002; James McKeen Cattell Award, American Psychological Society, 2001; Distinguished Scientist Award, Society of Experimental Social Psychology 1996; and the Donald Campbell Award, Society for Personality and Social Psychology, 1988. Robert Rosenthal has also been a Guggenheim Fellow, Senior Fulbright Scholar, and a Fellow at the Center for Advanced Study in the Behavioral Sciences. Rosenthal has also been the Co-Chair of the American Psychological Association Task Force on Statistical Inference.

Rotter, Julian B.

EZRA N. COWAN

Lander College, Flushing, NY, USA

Julian B. Rotter (October 1916–) is a clinical psychologist, educator, and author, known for his theories in social and personality psychology, who was influential in establishing psychology as an independent field from medicine.

Basic Biography

Julian B. Rotter was born in October 1916 to a Jewish middle class family in Brooklyn, New York. Rotter’s family’s circumstances were comfortable until the Great Depression when his father’s stationary business failed. In high school Rotter started reading works by eminent psychologists Freud and Adler. In 1933 he entered Brooklyn College with a serious interest in psychology but chose to major in chemistry since it led to a more reliable source of income. However, Rotter still attended many psychology courses, some of which were offered by Solomon Asch. He started to attend lectures given by Viennese psychiatrist Alfred Adler at a medical school nearby, and later attended monthly meetings of the Society of Individual Psychology in Adler’s home (Rotter 1993).

After graduating from Brooklyn College in 1937, Rotter decided to pursue a master’s in psychology at the University of Iowa despite his financial concerns, due to the encouragement of Asch and other professors. At Iowa he studied under the prominent psychologist Kurt Lewin and under the general semanticist, Wendell Johnson, both of whom influenced Rotter. Johnson was known for his works on stuttering, the topic of Rotter’s master’s thesis (Rotter 1993).

Following a year in Iowa, Rotter was accepted to a clinical psychology internship at Worcester State

Hospital in Massachusetts. The notion of such an internship was new at the time, and very few were available. Rotter gave up a full assistantship offered by Wendell Johnson for the rare opportunity to attend the Worcester internship. At Worcester he met his future wife, Clara Barnes, whom he would marry in 1941. They would have two children (Rotter 1993).

After some time at Worcester, Rotter began to have doubts about the practiced approach to psychopathology and psychiatric diagnosis. He observed that “most of the diagnoses were more predictable from the psychiatrists’ biases than they were from the patients’ behavior.” Due to these doubts, and further fueled by reading C. M. Louttit’s book *Clinical Psychology* Rotter decided to apply for a Ph.D. at the University of Indiana, where Louttit taught. Rotter liked Louttit’s approach, which identified a field of application involving the treatment and diagnosis of many psychological disorders. Louttit became Rotter’s dissertation advisor and he gave Rotter an assistantship position at the university’s psychological clinic. Rotter liked Louttit as a mentor as well as a friend, and attributed much of his academic and personal growth to him. Rotter completed his dissertation in 1941 on the “level of aspiration,” a topic he started studying at Worcester. Upon receiving his doctoral degree he became one of the first clinical psychologists to be trained in what would be called in later years the traditional model (Rotter 1993).

After receiving his Ph.D. Rotter started working as a clinical psychologist at Norwich State Hospital in Connecticut, where he remained for 13 months. In 1942, amid WWII, Rotter entered the army as a private. After a month he was transferred to the Armored School at Fort Knox to work in the Office of the Military Psychologist. For the next 4 years he served in the Army and Air Force as a psychologist. He helped reduce the numbers of those who went absent without official leave (AWOL) – a serious problem among base personal, and also improved some environmental conditions to upgrade the general efficacy of the army (Rotter 1993).

In 1946, Rotter took up an assistant professorship at Ohio State University where he began to work systematically on constructing a social learning theory of personality. In 1954 he published *Social Learning Theory and Clinical Psychology* (Rotter 1993).

Rotter always saw a need for improvement in the training and role of clinical psychologists. In 1949 he participated in a conference on graduate training for clinical psychologists in Boulder, Colorado. The results of the conference are known as the Boulder Model, or the Scientist-Practitioner Model. At the conference he strongly opposed the movement that tried to shift the training of clinical psychologists into medical schools. At Ohio State he resisted the emphasis on techniques for diagnosing adult psychopathology and put a greater emphasis on methodology for construction and validation of psychological measuring instruments. In 1951 Rotter replaced George Kelly as director of the Ohio State psychological clinic and training program. In 1963 Rotter left Ohio State to direct the clinical training program at the University of Connecticut, and stayed there for the remainder of his career. He now serves as professor emeritus there (Rotter 1993).

Rotter is considered one of the 100 most eminent psychologists of the twentieth century. In a study he was found to be the eighteenth most cited psychologist and rated as number 64 in overall eminence (Haggbloom 2002).

Major Contributions

Rotter believed that individual’s psychological outlooks in life are shaped primarily by their past experiences. These experiences can be looked at as what behaviorists would consider positive and negative reinforcement. In his *social learning theory* Rotter proposes that people’s behavior can be predicted based on three factors: *behavior potential*, *expectancy*, and *reinforcement value* and developed an equation to explain behavior based on this model: $BP = f(E \& RV)$. Behavioral potential (BP) refers to the idea that behaviors that most frequently lead to positive reinforcements, or any rewarding experience, have the greatest potential of reoccurrence. The second concept, expectancy (E), suggests that for a behavior potential to be high, individuals must *expect* for it to lead to positive reinforcement. The third concept, reinforcement value (RV), is the desirability of an outcome – how much one values an outcome of a behavior will affect the potential of the behavior’s reoccurrence (Millon 2004). Everyone has different variables in the equation, which is a result of each individual’s unique, what Rotter called, *psychological situation* (Friedman and Schustack 2006).

Rotter is most widely known for his personality theory *locus of control* which is the concept of external versus internal control of reinforcement, or how much power a person feels he or she has over a situation to influence the outcome. An *internal locus of control* is the generalized expectancy that the individual's own actions lead to desired outcomes. Conversely, an *external locus of control* is the belief that things outside the individual, such as chance or any other external forces, determined the outcome (Friedman and Schustack 2006).

Rousseau, Jean Jacques

NRITYA RAMANI

Pace University, Brooklyn, NY, USA

Rousseau, Jean Jacques (June 28, 1712–July 3, 1778). “Man is born free and everywhere he is in chains.” These were the famous lines of a man who was one of the most influential thinkers of the Enlightenment period in the eighteenth century Europe, and whose novels inspired the French Revolution.

Basic Biographical Information

Jean Jacques Rousseau was born on June 28, 1712, in Geneva. His mother Suzanne Bernard died soon after his birth and his older brother ran away from home. As a result, Rousseau was primarily brought up by his father, Isaac Rousseau, a clockmaker, with whom he studied ancient Greek and Roman literature. Risking imprisonment owing to a quarrel with a French captain, his father left Geneva forever and the barely

educated Rousseau was sent to study in the village of Bosey. In 1725, he worked as an apprentice to an engraver but fled to Annecy in 1728 as he considered his master a tyrant. In Annecy, he developed a romantic relationship with Louise de Warens, who influenced his conversion from Calvinism to Catholicism, which ultimately led to him forfeiting his Genevan citizenship. During this time, he earned money through secretarial, teaching, and musical jobs. In 1740, he acquainted himself with the brothers Abbe de Condillac and Abbe de Mably while tutoring in Lyon. This was the beginning of a turbulent relationship with the Paris *philosophes* with whom Rousseau would have a continual cycle of love and hate. In 1742, Rousseau went to Paris to become a musician and composer but ended up serving two unsatisfactory years at the French Embassy in Venice. He returned to Paris in 1745, where he befriended editor of the *Encyclopedie*, Denis Diderot, a man who would ultimately commission Rousseau's writing. It was also at this time that he met Therese Levasseur, a maid who was to become his lifelong companion and whom he eventually married.

Rousseau died suddenly on July 3, 1778, at Ermenonville (north of Paris) while engaged in his favorite botanical studies. When looking at his life, the very essence of it is captured in his *Confessions* which provide the air of tension between an individual seeking forgiveness for his faults and one paranoid about proving his uniqueness among the academic community. And yet, his influence extended not only to the Revolution, but to present day socio political agendas, moral compasses, and philosophical ideologies. “If he eventually came to be known as a psychologist, group psychologist, and eloquently accusing *moraliste*, he was one of the last and latest Renaissance men.” (Riley 2001).

Major Contributions

In 1750, the Academy of Dijon's essay contest posed the question, “Has the restoration of the sciences and arts tended to purify morals?” Rousseau's reply *Discourse on the Arts and Sciences*, not only won the prize, but made him famous owing to its broad circulation and controversial nature. It was the Enlightenment period and Rousseau's opposition to the arts and sciences was in conflict with the spirit of the movement: progress. His opera, *Le Devin du Village* (*The Village Soothsayer*), was

a great success and earned him even more recognition, making him one of the leading citizens. He was always one to be critical of France's opulence, and in his *Letter on French Music*, this was evident in his approval of Italian simplicity and rejection of French extravaganza.

In the autumn of 1753, the Academy of Dijon held another essay contest. This time, the question was, "What is the origin of inequality among men, and is it authorized by the natural law?" Rousseau's response would become the *Discourse on the Origin of Inequality Among Men*. The government according to him was a farce put together by the rich as a pretext to convince the poor that such an institution would guarantee them their rights and provide equal opportunity for all. But the judges were annoyed by the discourse's outright boldness. However, Rousseau arranged for its publication, and by 1755, it too had been widely distributed and read. His campaigning for the common man continued in the uncompleted yet profound work *Letat de Guerre* (1754) where he harshly criticizes Hobbes and Hobbism for characterizing ill-behaved and uncouth Englishmen as the "natural" man.

In 1756, Rousseau left Paris after being invited to a house in the country by Mme. D'Epinau, a friend to the *philosophes*. But his stay was short lived, and in 1757, after many quarrels, Rousseau moved to lodgings near the country home of the Duke of Luxemburg at Montmorency. It was during this time that Rousseau wrote some of his most important works.

In 1761, he published a novel, *Julie or the New Heloise*, which was one of the best-selling novels of the century. A year later, he published *The Social Contract* in April and *Emile* in May. The former was a treatise on political philosophy while the latter focused on education. Owing to his statements concerning religion in them, the books were condemned and publicly burned. When Rousseau fled France from Paris authorities, he found no refuge in Geneva as the public prosecutor had leveled charges of impiety against him. He settled in Switzerland and in 1764 began writing his autobiography, his *Confessions*. But he continued to encounter difficulties with the authorities and moved to England at the invitation of David Hume. The period spent in England was an unhappy one, and Rousseau eventually shifted back to France incognito in 1767.

His later works including *Rousseau: Judge of Jean-Jacques* (1772) and the *Reveries of the Solitary Walker*

(1777) were published posthumously. The former in particular is an extraordinary work where Rousseau bifurcates his personality with one half commenting on the other. Schizophrenia was being addressed in pure literary form. The other work, a self-confession, is remembered primarily for its famous words, "Here I am, then, alone on the earth, no longer having any brother, or friend, or society except myself."

Royce, Josiah

DEBORAH F. JOHNSON

University of Southern Maine, Portland, ME, USA

Josiah Royce is best known as one of the last American proponents of Absolute Idealism. In lectures published as *The Spirit of Modern Philosophy* (1892) and in his Gifford lectures on metaphysics, published as *The World and the Individual* (1900–1901), Royce presented a theory of knowledge resting on idealism and posited the Absolute Knower as a defense against relativism. From 1883 to 1898, as he developed his philosophical system, Royce was also exploring the new field of psychology. In addition to numerous articles and lectures on psychology, Royce wrote an introductory textbook, *Outlines of Psychology* (1903). In 1901–1902, he served as President of the American Psychological

Association. Though scant attention has been paid to this work, Royce regarded psychology as a valuable concrete source for philosophy.

For psychologists interested in exploring alternative foundations for the discipline, Royce merits further study. Royce rejected naïve realism and developed a constructivist theory of knowledge, arguing that we postulate, rather than simply register, knowledge of reality. Royce recognized that this theory of knowledge ran the risk of slipping into a relativistic subjective idealism, with no standards of truth and, therefore, no possibility of error. Royce fended off this danger by postulating and then “proving” the existence of the Absolute Knower, without whom error would be impossible. In his later work, Royce more fully develops the Absolute Knower as the “Community of Interpretation,” maintaining that a continual process of shared interpretation yields knowledge.

In various works, Royce distinguished between the phenomenal “world of description,” or the realm of physical facts and science – and the spiritual/feeling “world of appreciation,” or the realm of values, to argue that science and religion/ethics can live side by side harmoniously; indeed they must, because the “world of description” rests upon and draws from the more fundamental “world of appreciation.” Royce’s position was echoed by others and enabled his student Mary Whiton Calkins to argue for the necessity of a double standpoint in psychology – including both an experimental science of ideas and a science of the ethical self. Royce’s doctrine might be employed to defuse conflicts between psychology’s “two cultures” and inform a more pluralistic psychology.

Royce also rejected the postulate of the autonomous individual at the foundation of much modern psychology. Initially, Royce submerged individuals in the Absolute, but criticism from George Holmes Howison, and his own reading and research in psychology, led him to a more nuanced account of individual action and morality. In Royce’s revised account, the individual Ego is developed through interaction with and imitation of others within a social context; the self-conscious individual is first and foremost a social being. Further stages of individuation involve not just imitation, but reflection; it is through reflective commitment to particular social goals and ideals that individuals become unified and unique. Royce’s account of

the socially constituted character of individuals might serve as a critique of much, though not all, contemporary psychology.

Josiah Royce was the foil for William James’ attacks on the Absolute and as the prototype for James’s “tender-minded thinker.” Royce also had a significant influence on the psychology and social ethics of his students, Mary Whiton Calkins and Richard C. Cabot. With the rise of pragmatism and realism, in the early twentieth century, Royce’s philosophical system was set aside. In recent years there has been a revival of interest in Royce (Kegley 1997, 2008), though much of his work in psychology and its implications remain in the shadows.

Biographical Notes

Royce, Josiah (November 20, 1855–September 14, 1916), American idealist philosopher. Born and raised in California, Royce was youngest of four children of pioneers from upstate New York who had settled in the rural mining community of Grass Valley. His father, never successful at business ventures, relocated the family to San Francisco when Josiah was 10. Royce entered public schools for the first time and, at the age of 14, enrolled at the newly established University of California to train as an engineer.

Though from an impoverished family, Royce’s intellect was recognized and nurtured at the University. Abandoning engineering, Royce became a serious student of science and literature, earning his A.B. degree in Classics in 1875. President Daniel Coit Gilman, impressed with Royce, helped raise funds for his further studies in Germany. During 1875–1876, Royce studied at Heidelberg, Leipzig and Göttingen, attending lectures by Wilhelm Wundt, Wilhelm Windelband, and Hermann Lotze, among others.

Though Royce had hoped to continue his studies in Germany, his funds were depleted. Instead he accepted an offer from Gilman, now President of Johns Hopkins University, of a 2-year fellowship and the opportunity to continue his study of philosophy. At Hopkins, Royce worked with other serious students of philosophy and deepened his commitment to neo-Kantian idealism. Royce earned his Ph.D. in 1878.

His formal education complete, Royce had few prospects. In 1878, he reluctantly accepted a position teaching English literature at the University of California, knowing there would be limited opportunities to

pursue his philosophical interests at Berkeley. During this period, Royce met and, in 1880, married Katharine Head, the daughter of a prominent Berkeley family who had relocated from Boston. Their first child, Christopher was born in 1882; two more sons, Edward (b. 1886) and Stephen (b. 1889), later completed the family.

In 1882, Royce was invited to Harvard as a temporary replacement for William James and George Herbert Palmer; in April 1885, he was appointed assistant professor. Royce remained at Harvard for the rest of his life, and played a key role in what has been called “Harvard’s golden age of philosophy.” See Clendenning (1999) for further details. Royce died in 1916.

Rutgers University, History of Psychology at

SEYMOUR ROSENBERG

Rutgers University, New Brunswick and Piscataway,
NJ, USA

This is a history of the emergence of psychology at Rutgers during the nineteenth century and its subsequent development during the twentieth century into one of the university’s leading academic disciplines.

This history is organized around five rather distinct time periods for Rutgers psychology during these two centuries. Each period is identified either by significant innovations in the psychology curriculum at Rutgers, occasioned in turn by innovations in American psychology generally, or by changes in the status of psychology as an academic discipline of the university.

The first period dates back to the nineteenth century when conceptions of mind were typically taught in American colleges under the rubric of mental philosophy rather than psychology. Actually, the ancestry of psychology at Rutgers goes back to the eighteenth century when conceptions of mind were already part of the content of courses in general philosophy, in ethics, and in theology at the handful of colleges in colonial America. And Rutgers College – founded in 1766 by the Dutch Reformed Church and first named Queen’s College (renamed Rutgers College in 1825) – was one of these colonial colleges.

A year-long course in mental philosophy was first offered at Rutgers College in 1864. At the time, the course content was generally dominated by the Scottish school of mental philosophy. One of the aims of the Scottish school was to construct a mental science consistent with a devout belief in God. Scottish mental philosophy thus met the needs of American colleges in the eighteenth and nineteenth century when religion exerted a strong influence on parts of the curriculum.

Mental philosophy was revised in content in the ensuing decades to reflect changes in conceptions of mind during this period, changes clearly evident in the textbooks assigned for the course. Rutgers professors of mental philosophy, although trained ministers in the Dutch Reformed Church (as were many of the professors at Rutgers College during this period), were committed to these innovations in line with the spirit of the times in America following the Civil War.

The second period began to take shape at the end of the nineteenth century. It was marked by the introduction of the “new psychology,” so dubbed at the time, into American colleges and universities. The new psychology meant ridding the curriculum of mental philosophy in which theories of mind were supported largely by philosophical introspection and replacing it with an empirically based science of psychology. The shift to the new psychology was a radical

transformation in the study of mind and was a gradual one both at Rutgers College and at other American colleges and universities. The beginning of the new psychology at Rutgers College is marked by the first listing of a course in 1906 with “psychology” in its title, replacing the course in mental philosophy that had been taught for over 40 years. Over the next two decades, Rutgers’ first psychologist, appointed in 1909, continued to incorporate the many innovations in the new psychology into the curriculum. However, typical of most other American colleges and universities, psychology remained part of a more inclusive department of psychology and philosophy during this period.

After the First World War, Rutgers began its transformation from a college to a university. Part of this transformation was the establishment in 1918 of the New Jersey College for Women (NJC), with Rutgers College remaining as a men’s college (NJC was renamed Douglass College in 1955). With the founding of NJC and other autonomous colleges, Rutgers was beginning to experience the growing pains that would persist and, indeed, increase for several decades.

The third period in the history of psychology at Rutgers began with the founding of a psychology department at Rutgers College in 1928, separate from philosophy. This was an era when other colleges and universities in America also experienced the organizational separation of psychology and philosophy, although at NJC the psychology faculty remained in a department of philosophy and psychology until 1955. The psychology faculty at the two colleges each developed its own, quite comprehensive, undergraduate curriculum. The Psychological Clinic was founded in 1929 and provided a training and research facility for the department’s first graduate program, that of clinical psychology, while rendering psychological services to the community. These ambitious developments were soon slowed as the colleges struggled through the Great Depression and World War II. Rutgers, unlike many other state universities, was slow to recover after the war, given the limited financial support that the state of New Jersey gave to higher education until the 1960s. In psychology (and in other disciplines as well) at Rutgers, the graduate and research programs languished for almost two decades after the war.

The fourth period in this history spans two decades, the 1960s and 1970s. It is marked by a transformation

of Rutgers into a major state university as the state gradually began to give it adequate financial support. For psychology, this support was coupled with generous research and training grants that became available to American psychology from federal agencies and resulted the explosive growth of psychology both at the undergraduate colleges and in the graduate program.

By the end of the 1960s, there were four undergraduate colleges – Rutgers College, Douglass College, Livingston College, University College – each with its own psychology department, and with a graduate program in psychology gleaned from the faculty of these colleges. This kind of structure, in which the colleges retained considerable autonomy over hiring and promotion of its faculty, was unlike the academic organization present in virtually all American universities. The Rutgers structure represented a handicap to the cohesive development of university-wide academic disciplines particularly at the graduate level.

It might be noted here that in addition to these colleges, there emerged in the 1960s and 1970s several other units at Rutgers with psychology faculties and researchers: The Graduate School of Applied and Professional Psychology, Rutgers Medical School, and the Center of Alcohol Studies. The psychologists in these new units then began to play a critical role in the growth and diversity of graduate psychology at Rutgers. The graduate areas at the time consisted of experimental psychology, personality and social psychology, developmental psychology, and clinical psychology.

The fifth and final period as of this writing began in 1981 with a major change in the organization of Rutgers University: the unification of the separate college departments within a discipline into a university-wide department. This meant organizing the university along academic disciplinary lines like that at other major universities – a single department of psychology, of physics, of sociology, and so on – rather than such departments in each of the autonomous colleges. Thus, within each of the major academic disciplines, one centralized department with one chair to direct and coordinate both the undergraduate and graduate program replaced the several college departments.

A full length book of the history of psychology at Rutgers is available, at no cost, at: <http://psych.rutgers.edu/history/history.html>

In addition to the historical narrative, there are three appendices in the book. Appendix A is a listing of the titles of all PhD dissertations through 2008, including the names of the students, their dissertation advisor, and the year the degree was awarded. Appendix B is a listing of the names, dates, and ranks of all tenured faculty since the inception of a psychology department, including the small handful of mental philosophy professors of the nineteenth and early twentieth centuries. Appendix C is a 32-page synopsis of the book, which appeared initially in the souvenir booklet distributed during the celebration of the department's 75th anniversary in 2003.

A history of Rutgers in its first 200 years is available in Richard McCormick's book, *Rutgers: A Bicentennial History* (Rutgers University Press 1966). McCormick's book describes the events surrounding the founding of

Rutgers as a private men's college by the Dutch Reformed Church in 1776 and its gradual emergence into the state university of New Jersey.

A full-length book of this history (Rosenberg 2008) contains, in addition to an extensive historical narrative, appendices listing (1) the titles of all Ph.D. dissertations in psychology through 2008, including the names of the students, their dissertation advisor (2), and the names and ranks of all tenured faculty since the inception of a psychology department. The book is available as an e-book (see references).

S

Salzinger, Kurt

RICHARD S. FELDMAN
New York, NY, USA

Kurt Salzinger has been a forceful advocate for behaviorism as the basis for a science of psychology throughout his professional career. Not long after receiving his doctorate from Columbia University in 1954, where he had a teaching assistantship with Otto Klineberg, he was hired by Joseph Zubin, the chief of the recently established Biometrics Unit at the New York State Psychiatric Institute, remaining there as a research scientist until 1991. The principal theme of his work then and to the present day quickly became evident: the heuristic value of the behaviorist approach and the utility of behavior analysis for furthering an understanding of the full range of human behavior, both normal and pathological. When countering competing theoretical perspectives, he has used the opportunity to offer alternative, behavioral formulations; in taking issue with aspects of the cognitive perspective, for example, he presented a behavioral analysis of cognition itself (Salzinger 1987).

Salzinger has always had a particular interest in verbal behavior. In a series of studies beginning in the late 1950s, he and his colleagues demonstrated that both the quantity and the content of the speech of schizophrenic patients and of normal individuals, elicited in an interview-like situation, could be influenced by basic operant conditioning procedures – i.e., by reinforcement given (or withheld) by the experimenter/interviewer contingent on objectively defined response classes (Salzinger and Pisoni 1958; Salzinger and Portnoy 1964; Salzinger et al. 1964a). These studies added to a growing body of evidence that clinicians could be systematically, albeit

inadvertently, influencing the very behavior on which their diagnostic and therapeutic decisions were made. In line with the rapidly expanding field of behavior modification, Salzinger applied the same operant conditioning technique therapeutically in an attempt to instate speech in young speech-deficient children (Salzinger et al. 1965), and he trained parents of behavior-disordered children to employ similar procedures with their own children (Salzinger et al. 1970a).

A continuing interest in schizophrenic speech led from studies of its conditionability to studies of its comprehensibility. The cloze procedure, borrowed from the field of journalism, where it had been developed to measure the readability of news articles, was employed to demonstrate objectively that the speech of schizophrenics is less comprehensible than that of normals (Salzinger et al. 1964b). Other measures were proposed as methodologically more reliable and potentially more informative than the subjective judgments commonly used in describing what makes schizophrenic speech “schizophrenic.” One such measure was the degree of accuracy with which a panel of native speakers could reconstruct the original spoken sequence of segments of continuous speech presented in random order (Salzinger et al. 1966). Salzinger argued that such measures were promising as objectively derived determinants of overall communicability as assessed by the cloze technique.

Salzinger’s interest in formulating a theoretical organizing principle for the behavior of schizophrenics led to the Immediacy Hypothesis (Salzinger 1973, 1984; Salzinger et al. 1966, 1970b; Salzinger and Serper 2004), which posits that schizophrenics tend to be disproportionately responsive to temporally or spatially proximal stimuli (including their own response-produced stimuli) at the expense of more remote stimuli. One test of this with respect to verbal behavior again employed the cloze procedure. The Immediacy Hypothesis was supported: The comprehensibility of the normals’

speech hardly varied over the length of the speech samples, but the comprehensibility of the schizophrenics' speech markedly declined (Salzinger et al. 1964b). Put in terms of the general hypothesis, this was seen as an example of the failure of the schizophrenics' behavior to be adequately governed by stimuli which, although more remote (the interviewers' initial instructions and the speakers' own earlier verbal behavior), were nonetheless relevant to maintaining normal behavior. Salzinger claims that the principle of immediacy helps to explain many diverse aspects of schizophrenics' behavior, including hallucinations and delusions, memory deficits, and the rapid extinction of operantly conditioned verbal behavior after continuously available reinforcement ceases.

In the 1960s, with the burgeoning interest in Noam Chomsky's theoretical position on language and how it is learned, and the controversy it sparked with the behaviorists, Salzinger became one of the most outspoken of Chomsky's critics and behavior theory's defenders. He argued that when Chomsky made linguistic "competence" a property of the individual – that is, the ideal speaker-hearer's innate knowledge of language, rather than simply a descriptive characteristic of language as people actually speak and write it – that is, "performance," he put it largely out of reach of objective investigation (Salzinger 1975). Salzinger insisted that a science of linguistics must include data from all the sources of influence – social context being one important example – that are known to be relevant to how people behave. Psycholinguistics continued to be one of his major interests (e.g., Salzinger 1995b).

Salzinger has been a prolific writer and speaker: the author of two books (a basic psychology text in 1969 and a book on schizophrenia from a behavioral perspective in 1973); the editor or coeditor of 12 books, one of which, coedited with Robert Rieber (Rieber and Salzinger 1998), on theoretical-historical perspectives of psychology, appeared in three editions; author of over a hundred papers, several dozen book chapters, and over 150 presentations at professional meetings; and, in the period 2001–2003, columnist for *Psychological Science Agenda* and the *APA Monitor on Psychology*. His papers show his ongoing interest in psychology as a profession and as a science, in exploring the applicability of behavior analysis to the understanding and modification of psychopathology,

and to extending the range of behavior analysis. In the clinical realm, he has applied the principles of behavior analysis to psychopathology in general (Salzinger and Serper 2009), to psychiatric diagnosis (Salzinger 1978), and to such specific areas as anger and aggression (Salzinger 1995a) and delusional speech (Salzinger 1998; McKay et al. 1995). In the case of schizophrenia, he provided a detailed overview of the manner in which behavior theory and analysis can inform therapeutic interventions (Salzinger 1998). He has also addressed the teaching of clinical behavior analysis (Salzinger 2000). His interest in exploring the usefulness of behavior analysis beyond its clinical applications has encompassed communications between pilots and air traffic controllers (Salzinger et al. 1979), bureaucratic behavior (Salzinger 2002), political behavior (Salzinger 2006), and animal research with rats on the effect of bioelectromagnetic fields (Salzinger et al. 1990), goldfish on conditioned reinforcement (Salzinger et al. 1968), and dogs on operant conditioning of barking (Salzinger and Waller (1962), among many other topics.

Along with his research activities, Salzinger has held a variety of influential elected and appointed positions in professional organizations and in academia. He has been particularly active in the American Psychological Association, where he worked as Executive Director for Science and where he is a Fellow of seven divisions, a past chair of numerous committees, and a past president of the divisions of the Experimental Analysis of Behavior and Society for General Psychology. He worked at the National Science Foundation in Washington, DC, from 1979 to 1981, where he created and managed the Applied Experimental Psychology Section, for which he received NSF's Sustained Superior Performance Award. He is a past president of the New York Academy of Sciences and, most recently, president of the Eastern Psychological Association.

Salzinger's major academic affiliations have been with Polytechnic Institute of New York University and Hofstra University. At Polytechnic, where he taught from 1964 to 1992, he was professor and head of the Department of Social Sciences. At Hofstra, where he taught from 1992 to 2001, he was professor and Director of the Graduate Program in Clinical/School Psychology. He is currently Senior Scholar in Residence in the Hofstra Department of Psychology.

Sarason, Seymour

MELISSA SAPIO

Hudson County Community College, Jersey City, NJ, USA

Basic Biography

Seymour Bernard Sarason was born on Jan 12, 1919, in the Brownsville section of Brooklyn to poor Jewish immigrant parents, Maxwell and Anna (Silverlight)

Sarason. He grew up in Newark, NJ, with his brother, Irwin, and sister, Mildred. He contracted polio in high school, and wrote to President Franklin D. Roosevelt (who also had polio) with the encouragement of his mother. To the family's surprise, Roosevelt responded to the request for help by making arrangements for treatment that the family could not otherwise afford. Dr. Sarason made an almost complete recovery, but the experience of disability caused him to become an advocate of the less fortunate and to recognize social context as critical factors in determining or impacting one's potential.

Seymour Sarason earned his BA from Dana College in Newark (now Rutgers University) in 1939. He was granted his master's degree in 1940 from Clark University and his doctorate in clinical psychology in 1942 from the same institution. He was mentored by Saul Rosenzweig. Dr. Sarason married Esther Kroop, a fellow graduate student, in 1943. Two weeks after their 50th wedding anniversary, in 1993, Esther and Seymour were in an automobile accident which resulted in Esther's death.

Dr. Sarason first worked as chief psychologist at the Southbury Training School in Connecticut, a state institution for individuals with intellectual disabilities. Although he spent less than 4 years at the institution, his experiences there shaped his scholarly research interests across his career. In 1945, he became a faculty member of the psychology department of Yale University, where he worked for his 45-year career, and eventually became professor emeritus.

Seymour Sarason died on Jan 28, 2010, at the age of 91 in New Haven, Connecticut. He was survived by his daughter Julie Sarason, her husband Paul Feuerstein, his grandson Nathaniel, and his companion Irma Miller. His brother and sister-in-law, psychologists Irwin and Barbara Sarason, and his brother-in-law and sister-in-law, Irving and Eugenia Kroop, also survived him.

Accomplishments

Seymour Sarason is considered to be a visionary and pioneer in the field of community psychology and in the study of school culture. In 1961, he founded the Yale Psycho-Educational Clinic, which led the

movement in community psychology. He investigated how social settings and institutional cultures could be changed in order to address psychological and learning problems within a preventative framework. Dr. Sarason's work as director of the clinic until 1970 led to several seminal works, including the following: *Psychology in Community Settings* (1966), written with several coauthors; *The Culture of the School and the Problem of Change* (1971); and *The Creation of Settings and the Future Societies* (1972).

Over the course of his career, Dr. Sarason authored more than 45 books and 66 articles, becoming a prominent researcher on a wide range of topics, including test anxiety, school culture, productive learning, teacher preparation, and charter schools. He was also a vocal social critic. Dr. Sarason's first book, *Psychological Problems in Mental Deficiency* (1949), included social cultural factors as important considerations in a paradigm shift for understanding mental deficits in terms of the factors which nurture the potential of individuals. Many of Dr. Sarason's works are considered classics and his contributions were particularly significant in addressing educational reform.

Sarason served as President of APA's Division of Clinical Psychology and was Chairperson of the Educational and Training Board. He received honorary degrees from Syracuse University, Queens College, Rhode Island College, and Lewis and Clark College. Sarason was the recipient of awards from the American Association on Mental Deficiency and from the Divisions of Clinical Psychology, School Psychology, and Community Psychology of the APA. Established in 1993, the Seymour B. Sarason Award for Community Research and Action recognizes contributors following the meaningful work of Sarason.

Schachter, Stanley

MILOSLAVA KOZMOVÁ

Independent Research Psychologist, Boston, MA, USA

Basic Biographical Information

Stanley Schachter was born April 15, 1922, in Flushing, New York, to émigré Jewish parents. His father was born in Vasilau and his mother in Radowitz (now Radauti); both cities are located in today's Romania and were previously part of Austro-Hungarian Empire. Stanley Schachter died June 7, 1997, in East Hampton, New York. He was survived by his second wife, former Sophia Thalia Duckworth, and his son Elijah, born in 1969. Stanley Schachter's papers are archived at the Bentley Historical Library of the University of Michigan.

Education and Professional Development

Schachter's early education started in James Monroe High School in New York and at Yale University, New Haven, Connecticut, where he completed his B.S. and M.A. degrees. At Yale, at the Institute for Human Relations, Don Marquis initiated him to research and Clark Hull to Socratic teaching technique.

In 1946, Schachter started his graduate studies at Massachusetts Institute of Technology (MIT) in Cambridge, Massachusetts, in the Research Center for Group Dynamics established by German social psychologist Kurt Lewin. At MIT, he became a research assistant to Leon Festinger while working in the Westgate study investigating sources of housing satisfaction and dissatisfaction. This study eventually guided Festinger's study of social influence, comparison, and communication theories. Through working on Westgate study, Schachter became aware of his love for discovery through contemplating the data; this approach he considered a source of strength and dilemmas in research. His subsequent self-reflective position on research included understanding that he preferred research discovery process as the way of life instead of doing research just for publication or for display of appreciating or discrediting colleagues in psychology (Schachter 1989).

After Lewin's death, Schachter moved, in 1948, along with the remains of Lewin's research center, to University of Michigan at Ann Arbor to complete his thesis about social deviation and rejection (Schachter 1951). There he worked under the supervision of Leon Festinger in the Institute for Social Research. In the spring of 1949, he moved to University of Minnesota with the appointment of assistant professor in the Department of Psychology cojoined with the work at the Laboratory for Research in Social Relations.

During his University of Minnesota times, Schachter married for the first time and divorced, and considered his stay at the University to be critical toward his scientific development which included breaking away from his mentors (Schachter 1989).

In the beginning of 1950s, Schachter's main research focus was repetition of his thesis in seven cross-cultural studies of deviation and rejection conducted in Belgium, England, France, Germany, Holland, Norway, and Sweden. In the 1950s, experimental research has not yet been extensively tried in European psychology and Schachter also felt that Europeans might be more accepting of differences than his American colleagues (Schachter 1989).

In 1953, back at the University of Minnesota, Schachter started a series of case studies of social isolation which guided his research of affiliation (Schachter 1959). At the same time, on a less serious note with Leon Festinger and Henry Riecken, as collaborators located in Chicago, this research team decided to write an amusing book called *When Prophecy Fails* (Festinger et al. 1956) to address rumors about the end of the world. Upon return to University of Minnesota, he felt that his research work was taking a shape as his own contributory work to psychology finally out of the shade of his connection with Leon Festinger, his previous mentor and collaborator. Schachter's experimental focus on emotions and physiological states described in *Psychology of Affiliation* (1959) had won him the AAAS Social Psychological Prize completion. The main findings assert that tendency toward affiliation increases with increased anxiety and hunger and that birth order acts as a discriminator of extent of affiliative tendencies. Schachter also formulated an anxiety-affiliation

relationship inasmuch as ambiguous situations or experiences of feelings give rise to a desire to be with others for the purposes of evaluating and determining, now in the context of social situation, the suitable reaction to these circumstances.

In 1961, Schachter joined the Department of Social Psychology at the Columbia University in New York as a professor of psychology. In 1962, during his tenure at Columbia, Schachter with his students Jerome E. Singer proposed a new theory of emotions that took into account cognitions. The authors postulated that state of visceral arousal was essential for the experience of emotion and that the different emotional experience could arise from the same visceral conditions. As a next step, Schachter proposed that individual descriptions of the feelings will occur in terms of available cognitions (either thoughts, past experiences, or environmental contexts) which individuals have available during that time. If these cognitions are deemed satisfactory, the individuals no longer look for alternative cognitive explanation of their aroused emotional states. However, if the same cognitive situations previously used as explanations arise, Schachter postulated that the emotional experience occurs only to the degree to which the individuals are physiological aroused (Schachter and Singer 1962).

In his subsequent work, Schachter turned his attention to study of physiological state of hunger in relationship to gastric motility and obesity. The studies presented facts that obese individuals tend to eat by external prompts not linked with hunger. The obese individuals considered externals and some feelings other than hunger – presence of food, environmental conditions, time of day, and elicited strong emotions – as signals to eat instead of internal feeling of hunger and gastric motility signaling the time to eat (Schachter 1986).

Next phase of Schachter research focused on field research of physiological addiction of smoking cigarettes and manipulating smoking behavior by manipulation of degree of urinary acidity (pH; Schachter et al. 1977). Different interest in relationship between mass media reported violence and decrease of sales in department stores (Schachter et al. 1986) lead Schachter to investigations of stock market phenomena with the goal to determine that market is influenced by

social and cultural pressures of individual participants instead of economical principles (Schachter 1989; Schachter et al. 1986).

Major Contributions

Schachter's main research interests in social psychology focused on interaction of social and physiological determinants of behavior. Through experimental research paradigm, he studied cognitive, social, and physiological determinates of emotionally arousing states (Schachter and Singer 1962), the physiological basis for nicotine addiction (Schachter et al. 1977), the causes of overeating and obesity (Schachter 1986), and predictions of stock market movements (Schachter et al. 1986). His main contributions to psychology are experimental studies of human affiliation (1959) and the Schachter-Singer theory of emotion (1962).

In addition to his career as a researcher, in 1966 Schachter was named Robert Johnston Niven Professor of Social Psychology. In 1992, Stanley Schachter retired from Columbia with an emeritus designation.

Schlick, Moritz

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: April 14, 1882 Died: June 22, 1936.

Born in Berlin, Friedrich Albert Moritz Schlick pursued his University education at Berlin, Heidelberg, and Lausanne and then completed the doctorate with Max Planck at Berlin in 1904 with a thesis on the reflection of light in inhomogenous media. This purely physical start set the fundamental tone for his career, which was devoted to bringing physical science and philosophy together in diverse ways. Between 1904 and 1907 he traveled extensively, including to America, where he met and married Blanche Hardy, who was instrumental in preserving his literary legacy. Between 1908 and 1911, when he began his professorial career at Rostock, he published on conceptual issues of happiness, ethics, and truth, all of which proved enduring developing interests during his subsequent career.

Major Accomplishments/Contributions

Similar to Ernst Mach, he advanced a view of psychology as an irreducible source of knowledge, and conceived of scientific concepts as reducible to philosophical ones (Schlick 1910/1979). During the next half decade, Schlick adapted his correspondence theory of truth and his ideas of verification through an appeal to experience to an analysis of contemporary physical theory, which gained him the friendship of Albert Einstein. His culminating achievement was his *Allgemeine Erkenntnislehre* which appeared first in 1918 and in a second edition in 1925 (Schlick 1925/1974). In 1922, after a brief stint at the University of Kiel in 1921, he became Professor of the Philosophy of Inductive Sciences at the University of Vienna, successor to Ludwig Boltzmann and Mach (Moritz Schlick Project 2009). In 1924 he began meeting in the University with several like-minded colleagues, a seminar first named after Ernst Mach and which later became well-known as the “Wiener Kreis” (Vienna Circle) which was

a vibrant center for the exchange of ideas that led to the formation of various realistic and physicalistic philosophies with shared commitments to logical empiricism and which soon gathered a worldwide following. While Schlick was recognized as the leader of the Vienna Circle, he was not a doctrinaire head of a school but rather a facilitator of several lines of independent thought. Schlick's own later development was strongly influenced by his meeting Ludwig Wittgenstein in 1926, with whom he entered into a period of intense correspondence and discussion that extended for several years until Schlick's career was suddenly ended by his being shot by a student with an unknown grudge. Schlick's effect on psychology was mixed. On the one hand, pragmatic American neobehaviorists such as Tolman found Schlick's emphasis on knowledge embedded in conceptual systems congenial (Smith 1986). On the other, Schlick's rootedness in Central European traditions (Johnston 1972) rendered much of his work outside the boundaries drawn by objective psychological science in the 1930s. For example, Schlick, bridging the nineteenth and twentieth century, was more interested in delineating the difference between knowledge and intuition rather than ruling out intuitive knowledge completely: thus, he was somewhat peripheral to the operationalist movement in psychology which derived from more aggressive logical positivists in the Circle (Green 1992). Schlick's ethical theory could have been congenial to the various naturalistic hedonisms that emerged in psychology in his era. However, Schlick held a positive view of pleasure as an end state and was something of a eudaemonist (Schlick 1930/1939), and this ran counter to the repressive or dismissive views of pleasure as a motivator or as a goal that accompanied the rise of both psychoanalysis and behaviorism. The Vienna Circle's activity ceased when Schlick was murdered and when Nazism forced its members to flee Europe. After this time the most specific conduit for Schlick's influence on American psychology was Herbert Feigl at Minnesota, who via his connection with the Minnesota Center for the Philosophy of Science and his friendship with Paul Meehl supported a vigorous program of integration of philosophy of science and psychology during the 1950s and 1960s. Other émigré psychologists and psychologically

oriented philosophers in the ambit of Schlick and the Vienna Circle were Karl and Charlotte Bühler, Gustav Bergmann, and Egon Brunswik, all influential and more directly connected to psychology than Schlick.

Science, Philosophy, and Religion in Psychology, The Legacy of William James

EUGENE I. TAYLOR

Harvard Medical School, Boston, MA, USA
 Saybrook University, San Francisco, CA, USA
 Massachusetts General Hospital, Boston, MA, USA

William James, M.D. (1842–1910), Harvard Medical School Class of 1869, Father of American Psychology, internationally known philosopher of pragmatism, and a key figure in bringing Harvard into the twentieth century as an international university, was born in

the Astor Hotel in New York City, January 11, 1842. He was the eldest of five children by Henry James Sr. and Mary Robertson Walsh. Henry James Sr.'s father was William James of Albany, a businessman who successively had three wives, two of which he outlived, and 13 children. William of Albany, a staunch Calvinist in the Presbyterian Church, had made one of the largest fortunes in the American colonies, investing in, among other projects, the Erie Canal. This caused his grandson Henry the novelist, William's younger brother, to claim that "the family was not guilty of doing a lick of business for two-and-a-half generations." Henry James Sr., a Christian socialist, had attended theology school for two-and-a-half-years before dropping out to become a public lecturer. He saw himself as a theologian of an altogether new religion that he characterized as "The Physics of Creation" a melding of science and religion in the "Divine Natural Humanity" (James 1884b).

Living in New York at the time, the James Family was ensconced in one of William of Albany's houses on Washington Square. When Horace Greeley and Albert Brisbane introduced James the Elder to Ralph Waldo Emerson, during one of the Concord philosopher's lecture tours in New York, Henry James Sr. thought he had found the embodiment of the spiritual personality at the heart of his own system (Allen 1968). He invited Emerson over right away, and when Emerson got there, he was immediately ushered upstairs to see four-and-a-half month old William, "the little philosopher to be," as Henry James Sr. called him. Emerson's own son had just died in infancy and there was some affectionate sympathy over William's crib that caused Emerson to say a blessing, which the James family accounted from then on as William's christening by one whom they then referred to as "William's GodFather." From that moment on, young William became heir to the Swedenborgian and transcendentalist philosophical legacy, which was an intuitive literary psychology of spiritual self-realization that William had to adapt to the more rigorous dictates of the scientific age in which his own career matured. One could from then on say that every book that William wrote as a psychologist and a philosopher was an answer to this overarching Swedenborgian and Transcendentalist metaphysics of spiritual experience (Taylor 2002).

William James's Early Family Life and Peripatetic Education

William James's early education was accomplished by visits to the great museums abroad, a little schooling here and there in different countries, mastering French and German, encounters with great men and women of the era through Henry James Sr.'s social connections, and the center of it all, the James family dinner table, where all five of the James children were expected to have an opinion about everything. The first trip the family took abroad was in 1843–1844, where, through Emerson, Henry James Sr. (hereafter referred to as HJ Sr.) was introduced to Thomas Carlyle and at Carlyle's dinner table a host of other luminaries, including Alexander Bain, John Stewart Mill, and others. From this community of his father's friends, young William eventually began to align himself with the British Empiricists, at the same time that he became familiar with the reigning Associationist philosophy that would come to dominate the scientific study of the object in the center of attention within normal everyday waking consciousness. On that first trip, HJ Sr. also experienced what was initially diagnosed as a psychotic episode, but later reinterpreted as a spiritual "vastation," described by the scientist and interpreter of revealed religion Emanuel Swedenborg as an emptying out of the ego in preparation for the experience of higher spiritual consciousness. It was through Carlyle that HJ Sr. had been introduced to James John Garth Wilkinson, surgeon and translator of Swedenborg's scientific and medical writings, and later homeopathic practitioner, who became something of a pastoral psychiatrist to the James family, and a friend and host to Emerson when he went to England to lecture. In 1855, for instance, the James family traveled to London, then Geneva, and then returned to London to winter over in St. Johns Wood next to Wilkinson's family. There, William (age 13) and Henry (age 12) witnessed mediumistic seances, hypnotic trances, and cases of multiple personality treated by Wilkinson.

In 1856 the Family moved on to Paris, then to Boulogne sur mer, and by 1858, they had landed back in the USA, where William James began painting in Newport, Rhode Island, under the Barbizon stylist William Morris Hunt. Here, James experienced in depth, color, light and shadow, and perception, all of

which would later define his radical empiricism. But in 1859 the Family suddenly went to Geneva, but then in 1860 returned just as abruptly to Newport, where James resumed painting with Hunt.

William James at Harvard and the Darwinian Circle

HJ Sr. hereafter supported William, because William had said that he wanted to be a painter. Since HJ Sr.'s main vocation was actually raising his children, however, he told them that they could be anything they wanted, "Only don't be too narrow." This injunction only made the uncertainty worse for William because he knew his father was supporting him in an activity in which the father, nevertheless, did not agree. HJ Sr. wanted William to take up the scientific portion of the family's intellectual and spiritual legacy of establishing "The Physics of Creation." William finally caved in to the pressure and in 1861 entered the Lawrence Scientific School through his Father's connections to the Saturday Club, which included Louis Agassiz, and his Godfather Emerson, who by then had become a Harvard Overseer.

As a chemistry major, James became involved in Darwin's inner circle through Botanist Asa Gray at Harvard. Right away, he also met the eccentric logician of science, Charles Sanders Peirce, after which James began a tutorial in the history and philosophy of science under Peirce and Chauncey Wright. Wright's positivism would soon enable James to flee from the Christian metaphysics of HJ Sr. and the monistic transcendentalism of RWE, at least for the time being. Nevertheless, when in 1864 James transferred to the Harvard Medical School, the James family moved to Boston to be closer to their boys. (Henry, William's younger brother, was enrolled in the Law School at the same time.)

In 1865, William James produced his first two publications in the *North American Review* edited by Charles Eliot Norton, a friend of his father's. They were both about the impact of personal consciousness on natural selection (James 1865a, b). That same year, James accompanied Agassiz on the Thayer Expedition to the Amazon, hoping to find a place in the field of anthropology; but James returned, exhausted after a year of pickling specimens, camping in the bug infested Amazon, and spending a great deal of time in

the homes of the natives, whom he found more interesting than his own colleagues. He returned in a dejected state with viraloid, a form of typhoid fever. The following year the James family moved to Quincy St in Cambridge, providing James with a home right next to the College Yard. But in April, 1867, William sailed by himself for Europe, ostensibly to hear Wundt and Helmholtz lecture in Germany. Mainly, he wandered adrift through Dresden, Heidelberg, and Teplitz, as well as Paris and Geneva, until returning to Cambridge in 1868. During this period he continued to write and publish extensively, mainly reviewing works on hypnotism, and advances in physiology and anthropology in France, plus two reviews of Darwin (James 1868a, b).

In the spring of 1869 James received the MD from Harvard Medical School under The Parkman Professor of Anatomy and Physiology, Oliver Wendell Holmes, Sr., his father's good friend. That year James also reviewed Sargent's *Planchette: Or the Dispair of Science* and works on the subject of women's suffrage. Scholars are still in dispute about a near-suicidal episode that James later described as having occurred during this period, but it was likely sometime between 1867 and 1870. One explanation has been that it followed the death of his beloved cousin, Minnie Temple in 1870, and he collapsed in unspeakable grief, but other evidence also suggests that it was over lack of a vocation and the internalized conflict over free will versus determinism. Which path should he take? In the end, he eventually recovered by reading such authors as Coleridge and Renouvier and by "believing to believe in free will." He was then free to draw from both sides of the dilemma – the Swedenborgian and Transcendentalist metaphysics of his Father and his Godfather, on the one hand, and the ultra-orthodox positivism of Wright and Peirce on the other.

William James, Physiological Psychology, and Pragmatism

Henry Pickering Bowditch, Harvard's first research professor of physiology, in 1871 had opened a laboratory at Harvard Medical School, where, among other researches, he and James Jackson Putnam, and William James, who had all been Harvard Medical School classmates, had begun experiments on brain neuropathology and vivisection in Bowditch's

laboratory. Meanwhile, by 1873, James had landed a job at Harvard teaching Jeffries Wyman's old course in anatomy and physiology of vertebrates to undergraduates in Harvard College. Still uncertain if that was the right direction, however, he postponed it and left for Europe instead. He returned in 1874 and then again took up the position. At the same time, keeping one foot in philosophy, Peirce and James begin meeting alternately at each other's houses, along with Nicholas St. John Green, Chauncey Wright, and others in what came to be known as The Metaphysical Club, which would later become the germ of the Pragmatist movement in America (Fisch 1981).

Under the influence of Peirce, who had introduced James to the new experimental psychophysics in Germany considering the continued influence of French clinical, and experimental physiology in the tradition of Pierre Marie and Claude Bernard, and the influence of continuing experiments in Bowditch's lab, by 1875 James was motivated to open the first laboratory for student instruction in experimental psychology in the world over at the Lawrence Scientific School. That year he also taught the first course ever taught at Harvard in physiological psychology. In his own new setting, James then undertook to appropriate the categories of philosophy into the physiological laboratory. A controversy had also erupted by then, where James became embroiled with the followers of Herbert Spencer, the Social Darwinists, over the place of the individual in the process of natural selection. His writing started to become voluminous, as he published scientific and philosophical analyses in American and British periodicals that were also translated into French (James 1878a, b, 1879).

Starting to feel his mettle, in 1878 James contracted to write the *Principles of Psychology* in 2 years (it took him 12). There were many reasons for the delay: That year, he married Alice Howe Gibbons, July 10, and they eventually had five children within a short span. James also awarded G. Stanley Hall a PhD in psychology in 1878, at the same time that Charles Sanders Peirce published "*How to Make Our Ideas Clear*," his formal statement on pragmatism within the history and philosophy of science. Meanwhile, James delivered his first series of Lowell Lectures on "*The Brain and the Mind*" (1878a) in Boston after presenting them as part of an unsuccessful job application at Johns Hopkins.

They were to define several important chapters in his *Principles of Psychology* (1890b). The following year, The James's first son Henry was born. Publishing-wise, already retailing Peirce, who was by then teaching at Johns Hopkins and working on a project on scientific genius, in 1880 James published, among other works, "*Great Men, Great Thoughts and the Environment.*" It was a statement on how the laws of variation and selection operate in the minds of solitary geniuses, who lead the way for the rest of us. He spent the summer in Europe and at the same time was elevated to Asst Prof. of Philosophy at Harvard.

In the next phase of his career, still trying to finish his *Principles of Psychology*, James helped to launch Psychical Research in American scientific circles, while he also continued to appropriate the categories of philosophy for physiological psychology, such as the study of the emotions. While acknowledging German experimental science, during this period he also became more of an advocate for the French Experimental Psychology of the Subconscious, upon which he began to have a significant influence through Theodule Ribot. In 1881, thinking of making a contribution to the field of otology, he conducted experimental studies on the question of why deaf mutes seemed impervious to dizziness, which he published as "*The Sense of Dizziness in Deaf Mutes*" (1881). He also conducted laboratory research into the consciousness of lost limbs (1887), and reaction time in the hypnotic trance. As well, he collected data for an international census on hallucinations, and he performed extensive studies on automatic writing and post hypnotic suggestion. Such studies debunk the experimentalists' continued claim that James did no scientific research.

Then a calamitous year befell him. In January, 1882, his beloved Mother died; his Godfather, Emerson, followed a few months later. Then, Joyfully, James's second son, William, was born in June, but 6 months later, in December, HJ Sr. died. James was on sabbatical in Europe at the time, having brought in Josiah Royce on a temporary appointment to cover his courses. While abroad, among other things he visited Charcot's lectures at the Salpetriere, made initial contact with Theodule Ribot and Alfred Binet, and then met with the founders of the newly launched Society for Psychical Research in England around F.W.H. Myers and Edmund Gurney. These encounters began to draw his

attention away from the positivist tradition in reductionistic science that had guided his writing in what became *The Principles of Psychology* (1890b). That work when finally completed had two competing centers of gravity. What was to be the primary center of gravity, based on the rational ordering of sense data alone, focused on only what was in the center of the field of attention in waking consciousness? The other suggested that there were multiple states of consciousness within us, waking conscious being only one among many, further suggesting that experimental laboratory psychology, with its exclusive focus on the rational waking state, might be nothing more than a colossal elaboration of the Ego.

But before all that happened in 1890, in 1883 James had returned to Cambridge in March. There, he confronted the reality of his dying brother. Long suffering from wounds sustained in the Civil War, Wilkey died in November. This was followed in 1884 by the birth of James's son Herman, who unfortunately died a year-and-a-half later. Nevertheless, James continued to work. He published "What is an Emotion?" (1884a) to great controversy, because he claimed emotions were the physiological reaction invoked by our perceptions, not grand categories of what was true and good and beautiful in classical philosophy. He also attended preliminary meetings that blossomed into the American Society for Psychical Research (ASPR), and he published his first book, *The Literary Remains of the Late Henry James* (1884b), which contained a 100 page introduction to his father's largely obscure literary and philosophical gifts to the world.

In 1885, when it was officially founded, James was elected a co-Vice President of the ASPR. Among other tasks, he chaired the Committees on Hypnotism and Mediumship. Grief-stricken, in a search with his wife Alice for their little lost Herman, James was also first introduced to Mrs. Lenora Piper, the Belmont medium. Though he never contacted his dead son across The Divide, James did find in Mrs. Piper his single case study to reconstruct the dissociative model of consciousness of the era and to give evidence for a growth oriented dimension to personality. After 1886, he also intensified his experiments in automatic writing, hypnosis, and dissociative consciousness in the Harvard Psychological Laboratory.

Further, regarding his family, in 1886 James was able to purchase a summer home in Chocorua, New Hampshire. His daughter Margaret was born, March 24, 1886. By 1889 the Family was able to move into their newly built home in Cambridge at 95 Irving St., where James lived for the rest of his life. That year, Harvard also named James its first Allford Professor of Psychology. Soon after, James traveled abroad again and attended the First International Congress of Experimental Psychology, held in Paris. Then, 1890 became another banner year. He published “*The Hidden Self*,” (1890a) a review of the work of Janet and Binet on dissociative consciousness in *Scribner’s Magazine*, but this was overshadowed by publication at the same time of *The Principles of Psychology* (1890b) in two volumes to international acclaim. He declared in a letter that he was finally glad to get that “dropsical, tumescent mass” off his desk. To top off the year, his youngest son Aleck was born in December.

Publication of *The Principles of Psychology* marked a major turning point in James’s career as his acclaim grew. In the new phase after 1890, he concentrated more on experimental psychopathology, mental healing, and the psychology of religion, though he also continued to teach traditional subjects in psychology and philosophy. Meanwhile, his growing stature became a major vehicle by which he was able to launch pragmatism as the first uniquely American philosophy to have international consequences. The problem was that from then on philosophers read only his philosophical texts, while psychologists only read his *Principles of Psychology* (1890b) and to this day ignore the rest. Led by such anti-Jamesians as G. Stanley Hall, the returning students who had garnered their PhDs from Wundt set up laboratories and to assure their needed finances launched a movement to debunk James’s functional psychology in favor of psychophysics, mental testing, and a reductionistic epistemology of materialistic positivism, where they maintained psychology was a science that followed physics, not philosophy. James was famous, but given only lip service among the neo-Wundtians as a scientist of any worth.

In addition to his Harvard appointment he became a public lecturer. He defended the spiritualists and mental healers against licensure by the MDs; he became an ardent interpreter of French advances in

psychopathology; he continued to champion the emerging clinical tradition; and he became a permanent critic of the German Experimental Laboratory Tradition, made up of the so-called brass instrument psychologists. These were all things that played into the hands of his detractors as poor examples of hard science. He also continued to work on an entirely new epistemology for the way experimental psychology should be conducted. The experimentalists were just beginning to get their mettle, however, so James’s new claim that a different epistemology was needed for how experiments should be conducted fell on deaf ears. Experimental psychology was busy separating itself from philosophy, and the philosophers were urged to form their own national organization. James, however, rejected the artificial boundaries being thrown up to demarcate the disciplines, but was now cast into a no man’s land between the barriers.

At the same time, James had family matters to deal with. In 1891 he went on sabbatical to England, where he was able to reconcile with his ailing sister Alice and to see his brother Henry. In 1892 James also managed to produce a cut-and-paste version of the two-volume *Principles* in one volume, entitled *Psychology: Briefer Course* (1892), which became a standard college textbook for the next 20 years. In it, he eliminated one of the key characteristics of the Stream of Consciousness; namely, that there appears to be a world out there separate from the person. It was, rather, he would later say, always (what we might call today) an “inter-subjective connection,” an idea that launched American Functional Psychology. In August of 1893 James returned to Cambridge and began teaching a graduate course on Experimental Psychopathology at Harvard until 1898. Meanwhile, he received news in 1893 of his sister Alice’s death from cancer.

The American Psychological Association, which had been organized by G. Stanley Hall in 1892, elected James its second President in 1894. His Presidential Address was on “*The Knowing of Things Together*” (James 1895). There, he repudiated logical positivism as the basis for psychological science, and forecasted a new epistemology for experimental psychologists that would redefine psychology as more of a person-centered science. Also, that same year, James first introduced the work of Breuer and Freud to the American psychological public (James 1894) in the inaugural

issue of James Mark Baldwin and James McKeen Cattell's *Psychological Review*.

There, he reviewed Janet as the originator of the psychogenic hypothesis – the concept that a physical symptom could be caused by an idea buried in the subconscious, mentioned one of Breuer and Freud's recent publications as “corroboration for Janet's already old findings,” and used these French and German medical sources to claim in his simultaneous review of Whipple's *Philosophy of Mental Healing* that here was proof that the mental healers had been practicing sound methods of psychotherapy all along.

In 1896 James delivered a second set of Lowell Lectures, this time on the subject of “Exceptional Mental States” (Taylor 2010). In these lectures he presented a dynamic psychology of subconscious states within the individual and showed its same pathological working in the social sphere. The lectures launched a loose-knit group of physicians, psychologists, and philosophers which became known in retrospect as “The Boston School of Psychopathology.” (Taylor 1983) But his philosophical endeavors also intervened. In 1897 he published *The Will to Believe* (1897), a book of his collected papers in which he named his new metaphysics in the preface “Radical Empiricism” (James 1897). For these endeavors, in 1898 James had his professorship revert to philosophy from psychology. That year he also injured his heart in a hiking accident in the Adirondacks, a condition that would later lead to his premature death. At the time, this did not deter him from traveling out to California, where he first enunciated Peirce's Pragmatism to the philosophical world before the Berkeley Union at the University of California, giving Peirce full credit. His talk was on “Philosophical Conceptions and Practical Results” (1898). Peirce repudiated James's interpretation of his own work, however, saying he had only meant to enunciate a rule of logic – that to be clear, one must consider the effects of one's thought, not actually see them worked out. James, on the other hand, maintained that it meant beliefs are always to be tested by their consequences. The work on pragmatism, particularly James' version, began to spread through James and his association with Josiah Royce at Harvard, John Dewey at Chicago, F.C.S. Schiller in England, Giovanni Papini in Italy, and soon Henri Bergson in France. James returned to Cambridge,

Massachusetts in 1898, and delivered the Ingersoll Lectures on Immortality at Harvard, published as *Human Immortality: Two supposed Objections to the Doctrine* (1899a). He also published *Talks to Teachers on Psychology and to Students on Some of Life's Ideals* (1899b), which he had been giving as public lectures for almost a decade.

James had received an invitation to deliver the Gifford Lectures on Natural Religion at the University of Edinburgh in 1897, but due to his heart ailment, which had significantly weakened him, he had to postpone the lectures and even tried to cancel them at one point. In 1900 he was still in Europe, trying to recuperate while preparing for the lectures, having dragged with him a giant trunk of books on religious subjects. It was finally decided that he would deliver 20 lectures in two sets, the first half in June 1901 and the second half in June 1902. In the interim, he returned to Cambridge, Massachusetts, where in the spring semester of 1902, he gave the only graduate course of his career at Harvard on the psychology of religion. His students were, in fact, the first American audience to hear the contents of *The Varieties* before it was published. When he traveled back to Edinburgh and delivered his second set of talks in June, at the same time the full complement of his 20 Gifford Lectures appeared in print as *The Varieties of Religious Experience* (1902), again to international acclaim.

He spoke to his audience, he said, as a psychologist of religion, and he would define religion as that which is centered in the personal experience of the individual. He further maintained that an exploration of subconscious states was the road to understanding the ultimately transforming effects of the mystical experience, being the highest states of consciousness that human beings had been able to describe, despite the fact that they were beyond words and even any conceptualization while having them. The truths of these states, however, were always to be tested in terms of their fruits for life; that is, in terms of their effect on enhancing the moral and aesthetic dimensions of daily living.

As such, with the *Varieties*, James had covered the full spectrum of human consciousness, from a cognitive psychology in *The Principles* (1890), to a dynamic psychology of subconscious states in his “Exceptional Mental States” Lectures of 1896, to the

ultimately transforming effects of the transcendent experience in *The Varieties* (1902). He was then required by his conclusions as a philosopher of psychology to step back and ask “is a science of consciousness really possible?” To answer this question, he devised a tripartite metaphysics of pragmatism, pluralism, and radical empiricism, his own rendition, seemingly, of Charles Peirce’s basic categories of existence, namely, Firstness, Secondness, and Thirdness (Taylor *in press*). Even in germinal form, then, *The Varieties* serve us as James’s most coherent statement on his tripartite metaphysics, the further elaboration of which occupied his professional career for the remainder of his life.

William James’s Tripartite Metaphysics: The Unfinished Arch

James died in 1910 without finishing the articulation of his metaphysical system, thus leaving us with an unfinished arch. His pragmatism was perhaps the most well developed. He made a start of his radical empiricism, and his ideas about noetic pluralism were scattered throughout his writings, although he did produce an entire volume on the subject, his Hibbert Lectures on *A Pluralistic Universe* (1909a). Pragmatism was both a method for resolving differing truth claims about the nature of ultimate reality and also a way of gauging beliefs, which are always tested by their consequences. Pluralism or “noetic pluralism” as he called it, referred to the unique individuality of each person’s way of working out the nature of ultimate reality. All of us were capable of having a transcendent experience of oneness, for instance, but that one great experience of unity might not be the same from person to person. Radical empiricism, probably the center of his system, referred to pure experience before the differentiation of subject and object. He so named it because he saw himself as an empiricist, but traditional science and philosophy interpreted empiricism to mean sense data alone, while James’s redefinition required that it be understood as the full spectrum of human experience, not simply confined to the senses; hence he called it radical empiricism to differentiate it from its more common definition, and from then on advocated that experimental psychologists adopt empiricism and not rationalism as their standard.

He had mentioned it before in his writings, but in 1903 he devoted an entire lecture to the subject of radical empiricism at Glenmore in the Adirondacks. It was not until 1904 that he first published two of his most important statements on the subject. One was an article on “Does Consciousness Exist?” (1904a), and the other, “A World of Pure Experience” (1904b). James’s answer to the question “Does consciousness exist?” was an emphatic no, if by consciousness psychologists and philosophers meant consciousness as an object of scientific study. He said that it did exist, however, but it was a process not an object that always had to be connected to someone’s personal consciousness somewhere. The idea scandalized the philosophical community, because it contradicted the basis upon which analytic philosophy and rationalist science had always been conducted. An examination of 25 years of philosophers and psychologists who had addressed James’s ideas demonstrated that the majority wrote authoritatively, but had no clue whatsoever about what James was getting at (Taylor and Wozniak 1996). This colossal misunderstanding by the analytic philosophers persists to this day.

Nevertheless, accolades for his previous work continued to mount. In 1904, he was elected a second time as President of the American Psychological Association. The following year, 1905, he delivered a talk on his Godfather, Ralph Waldo Emerson, at the Emerson centenary in Concord, Massachusetts. In order to prepare, he reread Emerson’s works in their entirety. The beloved task had major consequences, as he had already emancipated himself from his own Father’s Swedenborgian metaphysics by publishing *The Varieties*, and now he settled his accounts with Emerson’s legacy, electing to reject his monism, but embrace his pragmatism. That year James also traveled to Europe to meet Bergson for the first time, visit with his old student Gertrude Stein, who by then was collecting Picasso and Brock. He also attended an international Conference on Psychology where he was pressed into delivering an unplanned speech on the subjective experience of consciousness in French (James 1905).

In 1906 James lectured at Stanford, where he experienced the San Francisco earthquake and he talked at Berkeley on “The Moral Equivalent of War” (James 1910). In 1906, he also delivered a third series of Lowell Lectures, this time on *Pragmatism* (1907). That year,

after 24 years of teaching at Harvard, he also retired. This gave him the opportunity to travel to England where in 1908, he delivered his Hibbert Lectures on “A Pluralistic Universe” (1909a). Running out of time, in 1909 he produced *The Meaning of Truth* (1909b) and he gave his final impressions as a psychical researcher, the case of the Piper-Hodgson Control (James 1909c). In September of that year he met Freud and Jung at the Clark University Conference.

The picture taken of the speakers and the audience who heard them contained many of the greats in nineteenth- and twentieth- century psychology. James, Freud, Jung, Brill, Ferenczi, Ernest Jones, and Hall were there, as was Edward Bradford Titchener, James McKeen Cattell, Edwin Holt, Joseph Jastrow, William Stern, Alfred Binet, Adolf Meyer, and others. The photo depicted the crossroads where two eras met for just a brief moment, just as the Jamesian epic was coming to a close and the era of Watsonian behaviorism and Freudian psychoanalysis was just beginning.

In March of 1910 James sailed to England with wife Alice to see ailing brother Harry, but quite ill himself, James disappeared, alone, for 2 weeks in Europe. There is some evidence that he may have tried to visit Freud in Vienna at that time, but this remains uncorroborated. With great difficulty, prepared at any moment to just “sit his bucket down,” he and Alice returned to the USA in the late summer, where William James died August 30 in Chocorua, New Hampshire. There is a grave stone in the family plot at Cambridge Cemetery, but as the family tells it, he was cremated and his ashes scattered over his favorite swimming hole in Chocorua. One year after his death, *Some Problems in Philosophy* (1911) was published, and 2 years after his death, *Essays in Radical Empiricism* (1912) appeared, edited by James’s biographer, Ralph Barton Perry. These posthumous publications also acknowledge the unfinished arch that James has left us as strongly articulating the central core of his philosophy.

With his death, a major figure was acknowledged to have passed from the American scene. The intellectual historian Page Smith said 70 years later that the reason Harvard was great at the opening of the twentieth century was because William James was great, meaning that James was likely the most prominent faculty member at Harvard with the widest

international reputation, and Harvard, in addition to all its other great accomplishments as a national university, was immeasurably enhanced by being able to bask in that glow.

Seashore, Carl E.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: January 28, 1866; Died: October 16, 1949.

Born in Sweden and quietly proud of that heritage, Carl Seashore – the Americanized form of his original name, Sjöstrand – grew up in Iowa and, after his undergraduate work in education at Gustavus Adolphus College in Minnesota and his graduate work in psychology at Yale under first Ladd and then Scripture, began in 1897, a career at the University of Iowa which lasted for the rest of his life. He became head of the Department of Psychology and Philosophy in 1905 and Graduate Dean in 1908, a position he held until 1936 and which he resumed during the Second World War for 4 years.

Major Accomplishments/Contributions

In psychology Seashore was an experimentalist, about equally balanced between apparatus-driven laboratory experimentation and psychological testing. Over his career he constructed many devices for the measurement of vision, audition, and learning and regularly provided reviews of newly developed apparatus. He advocated teaching introductory psychology via an organized series of focused demonstrations of principles and phenomena. The contents of his manual for this course, *Elementary Experiments in Psychology* (Seashore 1908), reflect the wide range of Seashore's expertise and some of his many research interests, including auditory space, tactual space, cutaneous

sensation, Weber's law, mental images, association, memory, affective tone, apperception, normal illusions (Seashore 1896), reaction time, visual afterimages, visual contrast, the visual field, and the spatial sense of taste (Seashore 1911a). Ordinarily, his parallel interest in testing in that era would have led to a focus on individual differences and intelligence, and in fact he wrote many occasional papers for educational journals dealing with differential abilities in classrooms. His personal talent for music and his desire to make it more accessible to everyone coalesced in his studies of musical performance, summarized mid-career in *The Measurement of Musical Ability* (Seashore 1919). Many of the tests for musical aptitude and skill that Seashore invented persist, with revision, in the field today. Through the 1920s, Seashore continued to work with students on phonophotography, the photographic reproduction of waveforms of music which could show graphically why a particular vibrato, for instance, was superior. At one time, Seashore was invited to teach at the Eastman School of Music, but he preferred his laboratory and the university environment. Seashore also collaborated with N. C. Meier at Iowa on the measurement of responses to visual art (Seashore 1929).

In his administrative and policy-making roles, Dean Seashore – immortalized by Grant Wood in *Honorary Degree* (1937) – was one of the Solons of the developing profession of psychology in America. He had an optimistic vision of psychology's potential effect in the world, neatly summed up in his adoption of the term "euthenics" – living wisely, or living well – to connote the application of science in the service of optimal child development (Seashore 1941). Seashore's philosophical and theoretical spirit is captured in his *Psychology and Daily Life* (Seashore 1913). Herbert Langfeld, reviewing it, approved of its principled ethics while another sympathetic reviewer, Leonard Troland, saw Seashore's conception of a mind constructing itself on the basis of natural scientific principles and growing into right conduct in harmony with his own developing views of the mind in relation to the world and society. Seashore was always ready, too, with wise saws and sage advice conveyed in professional journals of education as well as popular sources, even extending to prescriptions for healthy sleep (Seashore 1910), and was very interested in the development of Iowa's undergraduate

students, offering a compendium of principles for sound living in *Living and Learning in College* in 1927. Seashore's interests in development and growth bore fruit in the establishment of the Iowa Child Welfare Research Station in 1917, largely due to Seashore's support of the philanthropist Cora Bussey Hillis's plan to replace "corn culture" with "child culture" in Iowa and nationwide. The Station was a foundation stone of child developmental study in America. As Graduate Dean, Seashore wielded great power in the academic arena and there too was able to realize his panoptic view of psychology, articulating all of the academic departments, including psychiatry, social work, and even the arts, in psychology's academic activity. This vision, shared with other colleagues, was largely realized in increased cross-disciplinary initiatives during his era and afterward which have been essential to the progress of the field. He was an early proponent of the profession of consulting psychology (Seashore 1911b). While Seashore left little correspondence, he wrote a comprehensive memoir that included several of his papers (Seashore 1942). Many of his family also entered psychology, including his son Robert (1902–1951) who was a specialist in learning and applied psychology and head of Psychology at Northwestern University, and his two nephews Harold and Stanley Seashore, both of whom achieved eminence in applied psychology. His most well-known student was ► [Miles, Walter R.](#) of Yale University, who continued Seashore's tradition of omniscient application of the experimental method across all areas of human life.

Seligman, Martin E. P.

LEAH FREDMAN

Lehman College, Bronx, NY, USA

Basic Biography

Martin Seligman was born on August 12, 1942 in Albany, New York. He completed his undergraduate studies at Princeton University and his graduate studies at the University of Pennsylvania.

Seligman’s interest in psychology piqued at age 13, when his sister introduced him to Freud’s works, which she had been reading in college. Seligman, who had failed to make his 8th grade basketball team, initially read Freud to pass time, though quickly became fascinated with the insights he encountered. His original interest flourished into a hope of better understanding human psychopathology, leading him to participate in research on rats during his undergraduate studies as a philosophy major at Princeton University.

The day before his graduation from Princeton in 1964, Seligman married his first wife, Kerry Mueller. Currently Seligman lives with his wife Mandy McCarthy whom he married in 1988.

After graduating from Princeton summa cum laude Seligman decided to become an experimental psychologist, aspiring to discover ways to ease people’s suffering. He completed his doctorate at the University of Pennsylvania in 1967, after which he accepted a teaching job at Cornell. Seligman was dissatisfied with Cornell’s administrative policies, and after a request came from Dr. Aaron T. Beck at the University

of Pennsylvania to assist with his formulation of a new treatment for depression, Seligman left Cornell and returned to the University of Pennsylvania as an associate professor. In 1976 he was promoted to professor and awarded the American Psychological Association’s Early Career Award for his theory of learned helplessness. Upon his return, Seligman took his student’s advice and received clinical training at Penn’s psychiatry department.

Between the years 1980 and 1994 Seligman acted as the University of Pennsylvania’s Director of Clinical Training of the psychology program. He is currently a Zellerbach Family Professor of Psychology, as well as the director of the Positive Psychology Center at the University of Pennsylvania.

Accomplishments

Seligman’s most famous contribution to psychology was his theory of “learned helplessness.” At age 13 Seligman’s father became paralyzed following a stroke, and watching him go from an able-bodied man to one struggling with helplessness and despair, first fueled Seligman’s interest in helplessness and pessimism. He formed his theory of learned helplessness, in 1967 during his studies at the University of Pennsylvania. Together with Steve Maier, Seligman conducted a series of experiments where he subjected dogs to electric shocks. Some of the dogs had the ability to terminate the shock while others, yoked to the first dogs, did not. Dogs that previously learned their actions could affect the outcome later quickly learned to avoid a shock when placed in a shuttle box. Dogs subjected to the inescapable shock learned helplessness, displaying symptoms similar to humans suffering from chronic depression. When placed in the shuttle box, two thirds of those dogs simply lay down and accepted the shocks in defeat, forgoing any endeavors of escape. These revolutionary experiments supported the idea that a large part of depression is learned, the outcome of a previous perception of uncontrollability, and therefore reversible.

In the mid-1990s Seligman refocused his interests, shifting from depression and learned helplessness to optimism. Following an incident where his 5-year-old daughter reprimanded him that just as she had found the strength to stop whining, he had the power to stop

being a grouch, Seligman realized he should focus on nurturing personal strengths. Drawing on the concepts of the humanistic movement he decided to branch out and create the field of positive psychology, concentrating on what causes humans to burgeon. He has utilized his earlier findings of learned helplessness to devise ways to imbue positivity and promote flourishing in humans; redirecting the field's attention from deficits to virtues.

Positive psychology conceptualizes happiness as a trichotomy composed of the domains pleasure, engagement, and meaning. Its declared positivity research goals include positive emotion, character strengths, and institutions. Seligman established the Positive Psychology Center at the University of Pennsylvania to help achieve and apply these goals. When elected the APA's president in 1996 – by the largest margin ever – Seligman received his chance to significantly impact the mental health field. As president he declared his initiatives the study of ethnopolitical warfare, together with positive psychology's mission of amplifying human strengths, and preventing psychopathology.

Seligman sought to modify clinical psychology's traditional focus on the rehabilitation of human weaknesses, since even when successfully curing psychopathology, former patients often did not feel fulfilled or happy. Therefore positivity, Seligman concluded, should be researched in its own right independently of negative traits. In 2004, in an effort to promote the methodological aspect of the field, Seligman and Christopher Peterson created a classification handbook for character strengths and virtues. The product of a 70-nation study, Seligman has referred to the handbook as the “DSM-I of Positive psychology.”

A major concentration of Seligman's research has been on explanatory styles as a predictor for helplessness. Pessimists explain bad life events as permanent, pervasive, and personal; they explain good events as temporary, localized, and engendered by external forces. Their lack of hope leaves them susceptible to depression. Building on these findings, Seligman devised a new treatment for depression called positive psychotherapy. Contrary to more classical forms of psychotherapy, positive psychotherapy focuses on increasing positivity in a person's life as

opposed to minimizing negativity. In addition to treating current psychological problems, positive psychotherapy aspires to fortify a person in order to prevent future depressive episodes.

The applicability of positive psychology is wide ranging. Seligman's patriotism led him to implement his finding in military settings. In 2002 he lectured at the San Diego Naval Base, utilizing his knowledge of learned helplessness and positive psychology to help immunize American troops from torture. In 2009 he addressed a group of army sergeants on positive psychology and resilience as part of the Comprehensive Soldier Fitness program in hopes of preventing suicide and posttraumatic stress disorder among soldiers. A second important application of his findings is the prevention of depression among children at risk through positive cognitive behavioral exercises. The Penn Resiliency Project is such a program at the University of Pennsylvania, and together with other similar worldwide programs, thousands of children have been helped. In the form of best-selling self-help books and numerous articles in newspapers and magazines, positive psychology has impacted popular culture as well. Seligman's books have been translated into 20 languages and his research has appeared in such publications as the New York Times, Newsweek, and Parents.

Seligman has received copious awards over the years. Among them are the MERIT Award of the National Institute of Mental Health in 1991 for his research on preventing depression, the Pennsylvania Psychological Association's award for “Distinguished Contributions to Science and Practice” in 1995, and two Distinguished Scientific Contribution awards from the American Psychological Association. Additionally, he has been awarded an honorary Ph.D. from Uppsala, Sweden, and a Doctor of Humane Letters from the Massachusetts School of Professional Psychology. Seligman's many awards and honorary degrees demonstrate recognition of the importance of his accomplishments, ranging from pessimism to optimism, to the field of psychology.

Sève, Lucien

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/ Major Accomplishments

Lucien Sève is a French Marxist philosopher and psychologist who played a major role in the process of developing a Marxist theory of human individuality. His magnum opus *Man in Marxist theory and the psychology of personality* (translated into more than 25 languages) has been a major contribution to the project of Marxist psychology. It significantly enriched the discussion when it appeared four decades ago. It was a truly innovative departure from different versions of West European Marxism (Frankfurt school, different trends of Marxist structuralism, Marxist humanism, existentialism, etc.), showing how Marx's psychological ideas might enhance our understanding of human mental life and human nature. Sève concluded that we are in need of a Marxian scientific psychology. Sève has engaged in polemical exchange with Louis Althusser, Adam Schaff, Roger Garaudy, Maurice Godelier as well as with the tenet of Marxist humanism. He served on the Central Committee of the

French Communist Party and directed the party's publishing house from 1970 to 1982. Sève's theoretical psychology is grounded within Marx's ideas developed in *Die Grundrisse* and *Das Kapital* as well as *German Ideology*. He was very critical of Marxist structural psychologists, Marxist hermeneutics, Marxist phenomenologists, Marxist existentialists, Marxist humanists, and Freudo-Marxism. It is difficult within this space to assess the magnitude of Sève's theoretical research paradigm. I was exposed to Sève's ideas since 1975 when I was a university student. I earned an enormous amount of knowledge from his writings; it shaped my theoretical framework. It is through Sève's writings that I discovered Marxist psychology, Polizer's concrete psychology, Wallon's dialectical materialist psychology, Leontiev's activity theory, and Vygotsky's cultural historical psychology. In Sève's work, I discovered the answer to why the excellent minds and respected scholars turn to Marx and not to Freud, Pavlov, William James, Skinner, or Lewin, when they deal with the structures, functions, and formations of psychological processes. Sève was credited with completing historical materialism by a Marxist theory of human individuality. His theory of personality was conceived implicitly and explicitly as a counter project to Althusser's reading of Marx and Freud's psychoanalysis as well as to the whole project of different trends of structuralism. Sève stated that, "it is true to say that the theoretical-anti-humanist interpretation certainly does not, as it claims, finally provide a strict reading of Marx, which goes beyond Marx himself, but is in fact a contamination of Marxism with alien approaches" (1972, p. 80). In 1980, he fulfilled Marx's project of *Treatise of dialectics* by the publication of his *Principia dialectica* written within Marx's theoretical framework. For unknown reasons, Sève has never been affiliated with any French academic institutions. He still is a very active scholar in publications as well as in the assessment of communism in theory and practice. Since the fall of the Berlin wall, Sève has published a dozen books on what went wrong with the state Communist experiment.

Shakow, David

ROBIN L. CAUTIN

Manhattanville College, Purchase, NY, USA

Basic Biographical Information

David Shakow was born on January 2, 1901 to Abraham Chaikowitz (aka Shakow) and Eva Leventhal, Russian immigrants who had recently settled on Manhattan's Lower East Side (A. Shakow, personal communication, July 21, 2009). Although raised in an Orthodox Jewish household, as a teenager Shakow abandoned the traditional customs of Judaism. He attended the High School of Commerce in preparation for a business career, but his vocational interests would change, owing in part to his participation at Madison

House, a settlement in NYC for new immigrants. It was there that he encountered the ideas of Freud and Jung. He would also soon encounter the works of William James, whom he considered his "lifelong hero," and to whom he attributed his abiding interest in psychopathology (Cautin 2006).

Shakow wanted to study where James had taught, so after some effort to disentangle himself from the family business, he entered Harvard in 1921. There he benefited from significant mentorships with William McDougall, E. G. Boring, and Frederick Wells, *inter alia* and from various field experiences at McLean Hospital and Boston Psychopathic Hospital, institutions central to the history of American clinical psychology. He later characterized his early training as being of a "do-it-yourself" character, and this idea would inform his later contributions to the professionalization of clinical psychology (Cautin 2006).

In 1924, immediately upon graduating from Harvard, Shakow worked for 15 months as a psychological assistant under the supervision of Grace Helen Kent at Worcester State Hospital (WSH). The following year he began graduate studies in psychology at Harvard, and met Sophie Harap, whom he married in June 1926. In 1927 Shakow earned his M.A. The following year, however, Shakow's dissertation research on subliminal perception, under the supervision of E. G. Boring, had produced equivocal findings. As he was soon to be in the position of supporting a young family, Shakow delayed completion of his dissertation and left Harvard to accept an appointment as Chief Psychologist and Director of Psychological Research at WSH. There he directed a group of researchers who were part of an interdisciplinary team dedicated to understanding the nature of schizophrenia. He would ultimately return to Harvard in 1942 to defend a refocused dissertation, *The Nature of Deterioration in Schizophrenic Conditions* (1946), which was based on this work.

In 1946, Shakow left WSH to become professor of psychiatry at University of Illinois College of Medicine; 2 years later he accepted an additional professorial appointment in the University of Chicago's Department of Psychology. During the next 8 years, Shakow was deeply involved in teaching, training, and educational policy, curricular development, and served as a consultant for various branches of the federal government (Cautin 2006, 2008).

In 1954, Shakow became the first chief of the Laboratory of Psychology in the Intramural Research Program of the National Institute of Mental Health (NIMH). There he collaborated with a distinguished interdisciplinary group of researchers who studied a broad range of psychological topics. Shakow retired in 1966, but remained active as a senior research psychologist and scientist emeritus. Shakow died on February 26, 1981, a few days after suffering a heart attack at work.

Major Accomplishments/ Contributions

Shakow was one of the first to apply experimental methods to the systematic investigation of psychopathology (Cautin 2008). With his novel research on schizophrenia, he not only redefined the standards of methodological rigor and sophistication in the field, but he helped to establish many basic facts about schizophrenia, forming a solid foundation for subsequent researchers. Two methodological areas in which Shakow and his colleagues made particular progress were psychiatric classification and conditions of testing. For example, in an effort to obtain pure rather than representative samples, Shakow instituted strict exclusion criteria based on factors such as physical illness and other mental disorders. He was judicious when interpreting differences in performance between normal controls and patients with schizophrenia, discerning whether discrepancies were due to a lack of interest or to a genuine inability to perform the task.

Shakow and his colleagues demonstrated, for example, that schizophrenic disturbances are not evidenced at the sensory or reflexive levels of organization, but rather at more complex cognitive-perceptual levels of organization. And they showed that performance deficits pervade all voluntary behavior. Some of his most consequential work was his series of reaction time studies, in which he and his colleagues discovered the crossover effect. This body of work formed the foundation for Shakow's theory of schizophrenic cognition, known as segmental set theory, which he continued to develop throughout his tenure at NIMH (Cautin 2008).

In addition to his scientific contributions, Shakow played a critical role in the professionalization of clinical psychology (Cautin 2006). In the early twentieth

century, there were competing conceptions of clinical psychology's role in an applied setting, and it was in this respect that Shakow would help shape the field. He worked primarily in medical-psychiatric contexts, where the main professionals' jobs tended to overlap in scope. His ideas about the goals and functions of the clinical psychologist were inspired by his experiences in such settings. Shakow identified the clinical psychologist with three functions – diagnosis, research, and therapy. He maintained, however, that the research function was primary, holding that research reflects the unique set of skills and abilities that should distinguish the clinical psychologist.

Shakow promoted these ideas through the influential training programs he helped develop. During his tenure at WSH, he initiated a clinical psychology internship program that would ultimately be a model for other institutions. Prior to World War II, training in clinical psychology had been largely piecemeal. But the war produced an unprecedented increase in the need for mental health professionals, and this acute demand quickly brought into focus the problem of training. Shakow laid out a number of iterations of his model for training, first in 1941, then in 1945 in what became known as the Shakow Report. The model reflected Shakow's emphasis on diagnosis, research, and therapy. Its fundamental principle – combined scientific and professional training – was endorsed by the APA in 1947 and affirmed at the Boulder Conference and at several minor subsequent meetings, ensuring the report's strong and lasting impact on the development and professionalization of clinical psychology (Baker and Benjamin 2000; Cautin 2006).

Shakow was one of only two individuals ever to have been awarded both the American Psychological Association's Distinguished Scientific Contribution Award and its Distinguished Professional Contribution Award (Cautin 2006). Shakow was also one of the first to systematically investigate the psychotherapy process. In honor of this work, Shakow received the 1965 Helen Sargent Memorial Award of the Menninger Foundation. He also coauthored a monograph on psychoanalysis, *The Influence of Freud on American Psychology* (Shakow and Rapaport 1964).

Shinn, Milicent

ELISSA N. RODKEY

York University, Toronto, ON, Canada

Basic Biographical Information

Born: 1858, Died: August 14, 1940

Milicent Washburn Shinn was born in Niles, California, a small town about 30 miles from San Francisco where her family owned a farm. The family orchard nursery business would eventually become quite prosperous; her father, James Shinn, was one of the first American agriculturalists to import plants from Asia (Burnham 1971). The Shinn family valued education and sent Milicent to the 6-year-old University of California, Berkeley. In 1874, the year Shinn started at Berkeley, the school had only two buildings on a campus that was little more than a field and had only begun admitting women the year before. Shinn found she loved the academic life and though she would have liked to pursue graduate studies at the Harvard Annex after her graduation from Berkeley in 1880, her close family ties kept her in California. However, family connections also encouraged her interest in psychology: Edmund Clark Sanford, who went on to become president of the APA in 1902 and associate editor of the *American Journal of Psychology* was her first cousin.

In 1882, Shinn became the editor of a San Francisco literary magazine, the *Overland Monthly*. The magazine

was on the verge of financial collapse, crippled by debts and unable to pay contributors, let alone its editor. However, Shinn was convinced that her labor was worthwhile: California desperately needed a literary magazine. Shinn felt that the *Overland Monthly* would combat post–Civil War California social ills by inducing Californians to better themselves by writing. Shinn remained editor until 1894.

In 1890, Milicent's older brother, Charles Howard Shinn, who became a well-known naturalist and the first superintendent of Yosemite Park, and his wife Julia had a daughter, Ruth, the first grandchild in the family. While the whole family was delighted by the baby, Milicent Shinn took a particular interest in her niece and began recording the details of Ruth's development, including physical growth, reflexes, and language.

As a result of this developmental record, Shinn was invited to speak at the World's Columbian Exposition in Chicago in 1893 on *The First Two Years of the Child* (Shinn 1895). Subsequently, Shinn received several invitations for graduate study at such prestigious schools as Stanford, Johns Hopkins, and Clark University; however, she chose to stay close to home and pursue her Ph.D. at her alma mater. Shinn was under the impression that the process would be a short one, given the preexisting data at her disposal.

However, the process took much longer than she expected, both because of the high requirements and because of her familial responsibilities. Finally, after 5 years in graduate school, Shinn insisted that she be allowed to graduate. Her family had a heavy mortgage, and during her years at the *Overland Monthly* and in graduate school her younger brother Joseph, who would become an influential water-rights pioneer for California, had been sacrificing his career to take care of the family farm.

Despite the success of her publications, Shinn returned to the family farm after graduating to care for her invalid mother. By the time her mother died in 1915, Shinn was in her fifties and had a heart condition herself. Although she had wanted to keep up with her academic work, she was absorbed by family affairs (Scarborough and Furumoto 1987). Shinn was, however, involved with several societies and committees, such as the Association for Collegiate Alumnae, which promoted women's higher education. She also remained deeply interested in pedagogical issues and

lobbied for educational reforms in California. Shinn avowed that she was content with the later portion of her life; her many nieces and nephews were a source of great enjoyment and gave her the opportunity to test her pedagogical theories. Although she did not conduct any more formal educational research, she did tutor her younger brother's four children, converting her den into a school room and creating a series of exercise books with hand drawn illustrations to teach reading.

Major Contributions

Although there had been baby diaries prior to Shinn's, such as Darwin's 1877 *A Biographical Sketch of an Infant*, the only other comparably systematic record was *Die Seel des Kindes* or, *The Mind of the Child*, a 1882 book written by German doctor Wilhelm Preyer, recording his son's early growth. Shinn read and was influenced by Preyer's book but also departed from it as she compiled more than 2 years of detailed data on Ruth.

Shinn graduated in 1898, becoming the first woman to receive a Ph.D. from the University of California, Berkeley. Her dissertation, *Notes on the Development of a Child*, was published in installments between 1893 and 1907 (Shinn 1893–1899). In 1900, she also published a popular version of her findings, called *The Biography of a Baby* (Shinn 1900). Her works received widespread acclaim, and for years her *Notes on the Development of a Child* was considered a foundational text for developmental psychology classes. Even Wilhelm Preyer was impressed and called for the work to be translated into German.

Siegel, Gerald M.

HARRIS WINITZ

University of Missouri-Kansas City, Kansas City, MO, USA

Gerald M. Siegel (BA and MA, Brooklyn College; Ph.D., University of Iowa) spent most of his career at the University of Minnesota where, in addition to his role as professor in the Department of Speech, Language, and Hearing Sciences, he also served as the director of the university's Center for Cognitive Sciences and the director of the Office of Research Development in the College of Liberal Arts. Siegel received various awards from his university and from the profession during his career. At the University of Minnesota, he received a Distinguished Teacher Award in 1973 and was appointed a Scholar of The College in 1993. Professionally, he received an ASHA Foundation Award in 1957, became a Fellow in ASHA in 1966, won an Editor's Award for an article published in the *Journal of Speech and Hearing Disorders* in 1969, and Honors of the Association in 2002. In 2003 he was given a lifetime Achievement Award by the Minnesota Speech and Hearing Association. He retired from the University of Minnesota in 1997.

During the course of his 40-year career, Siegel published well over 100 articles and book chapters. His most significant research contributions came in a series of programmatic studies in collaboration with Richard Martin that examined the role of learning and punishment in stuttering and normal nonfluency. The stuttering articles helped upend the long dominant views of the diagnosogenic theory that had made it virtually impossible to focus directly on the stuttering behaviors of adults and children who stuttered and led to innovative therapy procedures that allowed direct intervention with these clients. He also had a long collaboration with Herbert L. Pick of the Institute for Child Development at the University of Minnesota. Together they published numerous articles on the role of feedback in the regulation of speech. Siegel also published a series of more philosophical articles exploring the relationship between theory, research, and therapy in the field.

Simon, Herbert A.

GRANT J. RICH

University of Alaska Southeast, Juneau, AK, USA

Basic Biographical Information

Herbert Alexander Simon was born on June 15, 1916, into a Jewish family in Milwaukee, Wisconsin. His father, who held several patents, was an electrical engineer who had emigrated from Germany around the turn of the century. His mother was a pianist.

Simon's early education was in the Milwaukee public schools, where he graduated from high school at age 17. Simon received both his B.A. (1937) and Ph.D. (1943) from the University of Chicago. As he notes (1991) in his autobiography, "the Milwaukee I grew up in was hardly a backwater, but neither was it an avant-garde center of the arts or of intellectual adventure... When I arrived at the University of Chicago in 1933, it was all the things- artistically, intellectually, and politically- that Milwaukee was not... It was the best possible environment for growing up" (pp. 36-37). There his mentors included Harold Laswell, Charles Edward Merriam, and Henry Schultz. Both of his degrees were in political science.

In 1937, a year after earning his bachelor's degree, he married Dorothea Isobel Pye, who became an educational psychologist. They had three children, Katherine, Peter, and Barbara. He spent much of his career in Pittsburgh, Pennsylvania where he was a member of the Unitarian Church, a Democrat politically, and where he sometimes advised the public on issues such as public funds use and methods of generating tax revenue.

From 1939 to 1942, while completing his Chicago doctorate largely by mail correspondence, Simon directed a research group at the University of California Berkeley which focused upon municipal administration. Next, he served on the political science faculty of the Illinois Institute of Technology until 1949. At this point, Simon became a professor at Carnegie Mellon University (formerly Carnegie Institute of Technology), where he chaired the Department of Industrial Management, and was a professor in a variety of departments, such as computer science

and psychology until his death. In addition, he served as a distinguished visiting professor at New York University (1960).

Simon died February 9, 2001, in Pittsburgh, Pennsylvania. He was 84.

Major Accomplishments

A true polymath, Simon had a broad range of interests, both professional and otherwise. Professionally, he made significant contributions to artificial intelligence, cognitive psychology, economics, management, political science, sociology, and related fields (Augier and March 2004). As a hobbyist, he loved the arts and playing piano, for instance. His other avocations included travel (from France, Mexico, and Peru to Japan, China, and the Soviet Union and elsewhere), and studying and learning languages, from more commonly studied ones such as French, to lesser known ones such as Hungarian and Turkish.

Simon's contributions to artificial intelligence involved numerous collaborations with Allen Newell, who had been his graduate student. In particular, Newell and Simon created the Logic Theory Machine and the General Problem Solver (GPS) computer programs in the mid-1950s. Famously, Simon began a January 1956 class at Carnegie Mellon by telling his students, "Over Christmas holiday, Al Newell and I invented a thinking machine" (Crowther-Heyck 2005, p.1). These programs, aimed to model human problem solving processes were developed with the Informational Processing Language (with its NSS memory) invented by Newell, Simon, and Cliff Shaw. Such programs paved the way for later more complex problem solving programs, such as those that played chess. Other important work on human problem solving included Simon's work on verbal protocol analysis and on understanding the role of knowledge on the development of expertise with Anders Ericsson.

Simon's contributions to economics focused upon the role of uncertainty in organizational and other decision-making. Simon argued that in the real world, decision-makers often do not have sufficient information to make fully rational decisions. Thus, the decision-makers have only "bounded rationality," and must make decisions by "satisficing," which is selecting decisions which may not be perfect or ideal, but which satisfy a sufficient number of conditions with

satisfactory results. For instance, a person in a super-mall selecting a new pair of jeans may be confronted with a veritable plethora of options in terms of style, color, size, and price. Rather than collect all of the information about each variable at each store, and make a fully rational decision, the person may make a purchase decision that “satisfices.” Simon’s work on uncertainty in decision-making, and his linking of economic theory to applied mathematics, was central to the work that led to his 1978 Nobel Prize award.

Simon published prolifically. His publications included nearly 1,100 articles, and numerous books, including *Administrative behavior: A study of decision making processes in administrative organizations* (1947), *Public administration* (with Victor Thompson and Donald Smithburg) (1950), *Models of man* (1957), *The sciences of the artificial* (1969), *Human problem solving* (with Allen Newell) (1972), *Models of thought* (1979), three volumes of *Models of Bounded Rationality* (1982, 1982, and 1997), *Reason in human affairs* (1990), and *Organizations* (with James March) (1993). His autobiography, *Models of my life* was published in 1991.

Simon served as chair of the board of directors for the Social Science Research Council (1961–1965), and chair of the Division of Behavioral Sciences, National Research Council (1967–1969), and was a member of the U.S. President’s Science Advisory Committee (1968–1972), appointed by Lyndon Johnson. He also was a consultant to the RAND Corporation (circa 1952–1970) and received funding from the Office of Naval Research.

Simon was a fellow of the American Psychological Association, the American Economic Association, the American Sociological Association, the American Association for the Advancement of Science, the American Academy of Arts and Sciences, and the Econometric Society. He was one of the first social scientists admitted to the National Academy of Sciences (George A. Miller and Neal Miller among those who were already such members)

His many awards included the Distinguished Scientific Contributions Award (1969) and Gold Medal Award in Psychology (1988) from the American Psychological Association, the Turing Award (1975) from the Association for Computing

Machinery, the National Medal of Science (1986), and the Nobel Prize in Economics (1978). When one considers the truly extraordinary breadth and depth of Simon’s lifetime contributions, the term “Renaissance man” comes immediately to mind.

Singer, Edgar

DAVID O. CLARK

Independent Scholar, Lincoln, NE, USA

Edgar Arthur Singer Jr. (1873–1955) was born in Philadelphia. He earned Bachelor of Science in engineering from the University of Pennsylvania in 1892, and he received his Ph.D. in 1894 under the supervision of George S. Fullerton (1859–1925). In the historical consciousness, Singer was a philosopher at the University of Pennsylvania during the first half of the twentieth century, but by any criteria he deserves recognition in the history of psychology. He received graduate instruction from supervisors who are recognized as important psychologists, he published psychological articles, he carried out laboratory research in psychophysics, and he taught psychology. He also mentored a president of the American Psychological Association. Although known as a philosopher, Singer was also a psychologist whose contribution played a significant role in early behavioral psychology.

Singer’s Ph.D. supervisor at the University of Pennsylvania was George S. Fullerton. Fullerton was an important figure in the new psychology in America. He was among the founding members of the American Psychological Association, hosting the first annual APA conference, and serving as its fifth president. He helped James McKeen Cattell establish the psychology laboratory at the University of Pennsylvania in 1887, and in 1892, Fullerton and Cattell coauthored “On the

Perception of Small Differences.” Although Fullerton used James’s *The Principles of Psychology* as a textbook, at the 1893 APA conference, he criticized James’s concept of consciousness. Fullerton protested that it was an unanalyzable indivisible unit, and he argued ideas must be capable of representing complex things, and therefore consciousness must be made complex to serve a scientific psychology’s need for an object of analysis. Soon after, in 1894, Singer’s dissertation was titled, *On the Composite Nature of Consciousness*. Singer argued consciousness was a sociohistorical product, and therefore not an object suitable for a scientific psychology.

Singer challenged the existence of consciousness as an object of study when the new psychology assumed it was the medium of introspection. He argued the word consciousness was confusing because it was used indiscriminately to describe the Soul or the mental phenomena that held psychological states. Although it was found in different situations, no state of consciousness was a simple or indivisible state of mind. In general, this was a prologue to Singer’s life’s work to find an object suitable for a scientific psychology.

In December 1884, William James began his president’s address to the American Psychological Association with, “The nature of the synthetic unity of consciousness is one of those great underlying problems that divide the psychological schools.” James said Fullerton taught his students that the beginning of all sound method was to know what it meant to know things and to know the same things together. This suggests that Fullerton’s emphasis was on a structural epistemology as opposed to an empirical theory. James conceded that mental contents were complex. Singer’s dissertation suggests that he emerged as an influential psychologist from this debate between James and Fullerton.

Next, Singer became James’s assistant at Harvard from 1895 to 1897. Singer helped develop the undergraduate course in laboratory research, he contributed ideas to the graduate seminar in psychology, and he managed the psychology laboratory. Trained in laboratory techniques by Hugo Munsterberg (1857–1916), in October 1895 Singer was doing independent psychophysics research. In January 1896, James desired to cut his connection with the psychology laboratory, and he considered Singer for his replacement. In Singer’s

graduate course at Harvard, the students were assigned experimental problems that illustrated the fundamental psychophysics method. James praised Singer’s invention of experimental apparatus, and in James’s lecture notes there was a section that alluded to Singer’s dissertation. Singer’s influence on James may appear in the 1904 article “Does ‘Consciousness’ Exist?” and also in James’s epistemology of radical empiricism. In 1896, Munsterberg wrote to James that he believed strongly in Singer’s capacity and expected much from him. He thought Harvard should keep him as an assistant professor; however, Singer returned to the University of Pennsylvania in 1889.

In 1909, Singer became a full professor. In 1910, when he was chairman of the Philosophy, Ethics, and Pedagogy Department, Singer delivered a paper, “Mind as an Observable Object,” to the American Philosophical Association. In this paper, he rejected consciousness as an object for psychology, and in its place he suggested behavior. In 1924, he published a collection of his articles, *Mind as Behavior and Studies in Empirical Idealism* (Singer 1924). In the introduction, he argued the living and spiritual objects of human interest could be studied by experimental methods. He divided this work into two categories: the scientific object for psychology and its attending epistemology. In part one, Singer’s essays describe mind as an observable object. However, Singer insisted that he was not the father of Behaviorism. His conception of behavior was different than that associated with Behaviorism. He believed radical Behaviorism was restricted by a mechanistic interpretation, and Singer’s psychological categories were teleological.

Part two contained his epistemology for a scientific psychology. Singer was emphatically not an Empiricist. He believed that experiments failed unambiguously to resolve questions, but he also believed that questions must be conceived so that they could be put to experimentation. Also, he did not believe that everything was learned through experience. He believed that even the most exact science was merely a picture of Nature created by the scientist’s art.

Singer said science was a reconstructive enterprise. He believed that the immediate sensation was not the starting point of knowledge because the experience of fact was always mediated. Scientists continuously reconstructed Nature. Singer argued for a systematic

approach to natural science, and this suggests a structural approach to objectively construed reality. Singer argued scientific facts resulted from human needs, they represented choices, and no account of Nature was possible without a series of choices. Choice had four characteristic features: First, it did not mean science was capricious, only that facts resulted from choices. Second, the choice was not an individual's. The choice was consensus. Facts emerged from history, they were inherited, and they constituted the discourse where judgment became meaningful. Third, any single interpretation emerged from among several alternative accounts of nature, and at no point was the construction of natural science so factual that it could not be reinterpreted. Although observation was fundamental, making more and more observations did not necessarily mean progress. Rather, continued observation facilitated new theories. All theories of nature were incomplete, but they served as a principle of choice to create new facts.

Singer's philosophy of nature began with the insight that nature and science were not capable of independent definition. Nature was the object of scientific knowledge in the sense that the goal was the object of an endeavor. The scientific endeavor was a series of ever-expanding, yet always finite interpretations, and in the end, nature was the final image that science approached as the error of the observations approached zero. Nature was not a thing in itself: it was the name of an Ideal, and as an Ideal, nature was a completed science. Science, by definition, was nature in the making, and those who practiced science, made nature – and because the construction of science was not passively receiving of facts, Nature was a product of creative imagination. There was no such thing as raw unmediated experience. To him people had just forgot that they had previously accepted what they later regarded as self-evident. Knowledge was not built from data like a house was built out of individual bricks.

Singer's theory of mind as behavior and the attending epistemology played a significant role in neo-behaviorism through his student Edwin Ray Guthrie Jr. (1886–1959). Guthrie's theory of learning was an important feature of neo-behaviorism, and in that respect Singer significantly contributed to American psychology.

Skinner, B. F.

EDWARD K. MORRIS

University of Kansas, Lawrence, KS, USA

Basic Biographical Information

The American psychologist, Burrhus Frederic (B. F.) Skinner, was born on March 20, 1904, in Susquehanna, Pennsylvania, and died on August 18, 1990, in Cambridge, Massachusetts. In revolutionizing behaviorism, he became the most eminent psychologist of the twentieth century.

Majoring in English at Hamilton College (1922–1926), Skinner aspired to be a writer, but writing failed him. It described the human condition, but did not explain it. So, he turned to the newest science, psychology; enrolled at Harvard University (1928–1931); and earned a doctorate for research and theory in psychology's newest system, behaviorism. Remaining at Harvard on fellowships (1931–1936), he invented and refined apparatus (e.g., the Skinner box) and conducted pioneering research on basic behavioral processes (e.g., reinforcement; see Skinner 1938). At the University of Minnesota (1936–1945), he continued his research and extended it (e.g., to behavioral pharmacology), undertook behavioral engineering (e.g., in simulating bombs guided by pigeons), delved into conceptual issues (e.g., operationism; see Skinner 1947), and wrote a behaviorally inspired utopian novel (i.e., *Walden Two*). As the chairperson of psychology at Indiana University (1945–1948), he held the first conference on his science, but soon returned to Harvard (1948–1974). There, he established a Pigeon Lab, made his science into a system (see *Science and Human Behavior*), developed a technology of teaching (e.g., programmed instruction), analyzed everyday human behavior (e.g., *Verbal Behavior*), and addressed the implications of his science for human agency

(e.g., *Beyond Freedom and Dignity*). Although he retired in 1974, he remained active as a public intellectual until his death, addressing topics in biology, psychology, cultural anthropology, ethics, and world peace (see Skinner 1999).

Major Accomplishments/Contributions

Among Skinner's major accomplishments and contributions were establishing a natural science of behavior, accounting for behavior's natural history, and formulating a philosophy of them, all of them contributions to psychological theory. First, Skinner's subject matter was operant behavior – behavior that operates on the environment – the consequences of which (e.g., reinforcement) affect its probability and subsequent control by its antecedents (e.g., discriminative stimuli). The functional relations among these events – the three-term contingency – were Skinner's unit of analysis. His theory of these relations was empirically and inductively derived, economic and efficient in style, and true in the sense that it promoted effective action – the prediction-and-control of behavior (see Pragmatism).

Second, aside from some nonhuman-based simulations (e.g., of insight), Skinner's accounts of behavior's natural history were "behavioral interpretations" that were based on and constrained by the basic behavioral processes. Among his interpretations were those of values, thinking, and language. These, too, were theories, but like those of the ocean tides, plate tectonics, and the planets and stars, they were based on established processes, not on "events taking place somewhere else, at some other level of observation, described in different terms, and measured, if at all, in different dimensions" (Skinner 1950, p. 193). Behavior was Skinner's subject matter, not an index of occult forces or an ambassador to the mind.

Third, Skinner formulated radical behaviorism as the philosophy of his science of behavior – both a natural science and a natural history of behavior – where radical meant "basis." Psychological terms (e.g., knowledge, memory, intelligence) are ultimately based in behavior's relation to the organism and its environment (e.g., knowing how, remembering that, behaving intelligently). Behavior also encompassed both public and private events, the latter of which included those

that occurred within the organism (e.g., toothaches, problem-solving, dreaming), whose functions he interpreted in terms of the basic behavioral processes of public behavior – theory, again.

These accomplishments and contributions made Skinner not only eminent, but also the founder and father of today's discipline, profession, and field of behavior analysis.

Smith, Adam

DAVID L. SEIM

University of Wisconsin – Stout, Menomonie, WI, USA

Basic Biographical Information

Adam Smith was a Scottish moral philosopher and political economist who achieved never-ending fame for his authorship of *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776). While the exact date of Smith's birth is unknown, we know that he was baptized in the small village of Kirkaldy, Fife, Scotland, on June 16, 1723 (old calendar: June 5, 1723). Smith's father was no longer alive at the time. All contemporary accounts describe Smith as always tall for his age, and also as an odd looking fellow with "bulging eyes." In 1738, at about age 15, Smith entered Glasgow University on scholarship, where he had the "never-to-be-forgotten" good fortune to study with Frances

Hutcheson. Smith entered Balliol College, Oxford, in 1740, where he remained until 1746, and where he became knowledgeable, especially in European literature. About the years 1748–1750, Smith became acquainted with the likes of Lord Kames and David Hume, and in 1751 he was appointed professor of logic at Glasgow University, where he received promotion to chair of moral philosophy the following year. Smith would go on to a successful professorship, which he decided to leave voluntarily for private tutoring work in 1763. While he was regarded as a popular teacher and tutor, above all Smith's successes include two grand books: one primarily on moral philosophy and the other primarily on political economy. Smith never married, and he died in Edinburgh on July 19, 1790. He is buried in the Canongate Kirkyard (or Churchyard) (Buchan 2006).

Major Accomplishments/ Contributions

Smith, while famous as a founder of modern economic thought, was, perhaps even most fundamentally a philosopher of human motives. In 1759, he published his first major book, *The Theory of Moral Sentiments*, which was based on some of his Glasgow lectures. Smith's focus in the book is to explain phenomena of moral approval and disapproval. The major shift in thought partly owing to Smith's reasoning was a conceptual move away from the idea of a special "moral sense" in favor of a learned habit, or "propensity," for empathy – although rather than use the word empathy (which was what he meant), Smith actually used the word "sympathy."

Historians have amply explored the consistency between two fundamental human motives in Smith's writings, empathy and self-interest. This historical project has even been dubbed "the Adam Smith problem" (Smith 1998). Of course, what such a potential conflict refers to is the subject matter of Smith's two books: *Moral Sentiments*, which puts an emphasis on a general harmony of human motives implanted by a beneficent Providence; and *Wealth of Nations*, which in spite of the general theme of "the invisible hand" promoting the harmony of interests, provides many occasions for pointing out cases of conflict resulting from a narrow human selfishness. A conclusion reached by historians is that the two books simply emphasize different

aspects of human nature, each of which is capable of varying depending upon the situation.

Smith's *Moral Sentiments* is seen as providing philosophical, psychological, and methodological underpinnings to his later works, including *Wealth of Nations*. *Moral Sentiments* tends to divide its subject matter into categories of motives and consequences from these motives. With respect to the motives, there are three basic ones: self-love, reason, and moral sentiment. With respect to the consequences, it seems there are four such areas: ethics and virtue; private rights and natural liberty; familial rights; and state and individual rights.

Smith employs an understanding of the source of human motives that is, throughout *Moral Sentiments*, something of a response to the philosophies of Hutcheson and David Hume, two great thinkers who had employed a kind of dedicated "sixth sense" to explain morality. Smith rejected this concept of a special sense, preferring instead a kind of "pluralistic" approach to explaining morality based on a variety of psychological motives. Smith sets up a distinction between the three categories of motives at the outset of the book, which opens thusly: "How selfish soever man may be supposed, there are evidently some principles in his nature, which interest him in the fortune of others, and render their happiness necessary to him, though he derives nothing from it, except the pleasure of seeing it. Of this kind is pity or compassion, the emotion we feel for the misery of others, when we either see it, or are made to conceive it in a very lively manner." The developed "sentiment" of sympathy was to take the place of the moral "sense." Humans are then to use innate reason to reflect upon the internal struggle between selfishness and compassion.

To make things more complete, yet also more confusing, Smith shifts over to two other divisions. One division is threefold, between "social passions," "unsocial passions," and "selfish passions." The other is twofold, between those "passions which take their origins from the body" and those "which take their origins from a particular turn or habit of the imagination." Some of each of the categories of passions within the threefold division originate in the body, while others originate as habits. Throughout the book we return, from time to time, to Smith's well-known interplay between self-interest and moral sentiments, as mediated by reason.

Much of *Moral Sentiments* at least aims to answer one direct question: Where did the original basis for human capacity for empathy come from? Empathy arose from an innate desire in each person to identify with the experiences and emotions of others, doing so by becoming an “impartial spectator.” While there are a number of “original instincts” that drive some of our behaviors, humans must use “reason” to find out “the proper means” to our “desired ends.” Smith writes: “Nature has directed us to the greater part of these by original and immediate instincts. Hunger, thirst, the passion which unites the two sexes, the love of pleasure, and the dread of pain, prompt us to apply those means for their own sakes, and without any consideration of their tendency to those beneficent ends which the great Director of nature intended to produce by them” (1759, Ch. 5).

Smith’s great work of 1776, *Wealth of Nations* (originally published as a five-book series), extends a theme actually in *Moral Sentiments*, which is how to promote the functioning of an “invisible hand” to gather the potential benefits to society when people act out of self-interest. Whereas *Moral Sentiments* was about shift from a “sense”-based theory to a “sentiment”-based theory of human motives, *Wealth of Nations* is about exploring the working out of one motive that Smith called the “chief propensity” (Coase 1976).

Wealth of Nations extends from principles of motivation to consequences for society. A person who earns money by his or her own labor will benefit oneself. Yet also this person benefits society; Smith reasoned that a person only makes money by producing something that others will pay for. As Smith expressed in a recognizable quotation: “By directing that industry in such a manner as its produce may be of greatest value, he intends only his own gain, and he is in this, as in many other cases, led by an invisible hand to promote an end which was no part of his intention” (1776, Bk. IV, Ch. II).

Wealth of Nations makes it clear that empathy and self-interest are not to be viewed as antithetical. “Man has almost constant occasion for the help of his brethren, and it is in vain for him to expect it from their benevolence only.” And, in Smith’s other particularly famous sentence: “It is not from the benevolence of the butcher, the brewer, or the baker, that we can expect our dinner, but from their regard to their own interest” (1776, Bk. II, Ch. II).

Something else that Smith attempted to distinguish in *Wealth of Nations* was between necessary and unnecessary consumption. Although one cause of the market price of an item was the amount of the item that was supplied to the market, another cause was the willingness of people to pay for an item. Market prices come ultimately from the interplay of supply and demand, or what Smith called the “higgling and bargaining” of the marketplace. On the demand side of the equation, Smith also distinguished between goods that are physiologically necessary and those that are psychologically luxurious: “The desire of food is limited in every man by the narrow capacity of the human stomach; but the desire of the conveniences and ornaments of building, dress, equipage, and household furniture seems to have no limit or certain boundary” (1776, Bk. I, Ch. XI). When it came to the source of individual wants, Smith believed that an innate principle of frugality could, ultimately, override any socialized, passionate principle of expense. On the subject of the “principle of frugality,” in particular, Smith suggested that “the principle which prompts to save, is the desire of bettering our condition; a desire which, though generally calm and dispassionate, comes with us from the womb, and never leaves us till we go into the grave” (1776, Bk. II, Ch. III).

Smith’s modern-day reputation rests on his explanation of how rational, individual-level self-interest in a free-market economy can lead to overall, group-level economic well-being. *Wealth of Nations* has served as a policy guide for attempting to realize a greater wealth of nations. Economic development, Smith reasoned, was best fostered in an environment of free competition that operated in accordance with universal “natural laws.” In turn, these natural laws for what emerge at a societal level reduce to (or at least stem from) natural laws at the level of human motives. Smith’s economic thought became the basis, by the middle 1800s, for “classical economics.” Certain specific policy arguments that follow from Smith’s economic theory include: to oppose economic concentration because it distorts natural laws of markets; to establish reasonable prices and returns on land, labor, and capital; to limit governmental economic activity to construction of bridges, lighthouses, mints, and the like (Buchan 2006).

Smith also wrote three other books, all published posthumously – *Essays on Philosophical Subjects* (1795);

Lectures on Justice, Police, Revenue, and Arms (1763); and, *A Treatise on Public Opulence* (1937). Beyond these works, we don't know as much as we wish we knew about what else Smith thought and wrote, owing to the fact that shortly before he died Smith had nearly all of his manuscripts destroyed (Schneider 1970).

Social Constructionism

KENNETH J. GERGEN

Swarthmore College, Swarthmore, PA, USA

The phrase, *social construction*, typically refers to a tradition of scholarship that traces the origin of knowledge, meaning, or understanding to human relationships. The term “constructivism” is sometimes used interchangeably, but most scholarship associated with constructivism views processes inherent in the individual mind, as opposed to human relationships, as the origin of people's constructions of the world. Although one may trace certain roots of social constructionism to Vico, Nietzsche, and Dewey, scholars often view Berger and Luckmann's *The Social Construction of Reality* as the landmark volume. Yet, because of its lodgment in social phenomenology, this work has largely been eclipsed by more recent scholarly developments. One

may locate the primary stimulants to the more recent development of social constructionist thought in at least three, quite independent movements. In effect, the convergence of these movements provides the basis for social constructionist inquiry today.

The first movement may be viewed as *critical*, and refers to the mounting ideological critique of all authoritative accounts of the world, including those of empirical science. Such critique can be traced at least to the Frankfurt School, but today is more fully embodied in the work of Foucault, and associated movements within feminist, black, gay and lesbian, and anti-psychiatry enclaves. The second significant movement, the *literary/rhetorical*, originates in the fields of literary theory and rhetorical study. In both cases, inquiry demonstrates the extent to which scientific theories, explanations, and descriptions of the world are not so much dependent upon the world in itself as on discursive conventions. Traditions of language use constructs that we take to be the world. The third context of ferment, the *social*, may be traced to the collective scholarship in the history of science, the sociology of knowledge, and social studies of science. Here, the major focus is on the social processes giving rise to knowledge, both scientific and otherwise.

My aim here is not to review the emergence of these three movements. There are numerous and detailed accounts already available to the reader (see, e.g., Gergen 1994; 2009; Hacking 1999). Rather, in what follows, I shall briefly outline a number of the most widely shared agreements to emerge from these various movements. To be sure, there is active disagreement both within and between participants in these various traditions. However, there are at least three major lines of argument that tend to link these traditions and to form the basis of contemporary social constructionism. This discussion will prepare the way for a brief account relevant to developments in organizational scholarship.

The Social Origins of Knowledge

Perhaps the most generative idea emerging from the constructionist dialogues is that what we take to be knowledge of the world and self finds its origins in human relationships. What we take to be true as opposed to false, objective as opposed to subjective, scientific as opposed to mythological, rational as opposed to irrational, moral as opposed to immoral

is brought into being through historically and culturally situated social processes. This view stands in dramatic contrast to two of the most important intellectual and cultural traditions of the West. First is the tradition of the individual knower, the rational, self-directing, morally centered, and knowledgeable agent of action. Within the constructionist dialogues we find that it is not the individual mind in which knowledge, reason, emotion, and morality reside, but in relationships.

The communal view of knowledge also represents a major challenge to the presumption of Truth, or the possibility that the accounts of scientists, or any other group, reveal or approach the objective truth about what is the case. In effect, propose the constructionists, no one arrangement of words is necessarily more objective or accurate in its depiction of the world than any other. To be sure, accuracy may be achieved within a given community or tradition – according to its rules and practices. Physics and chemistry generate useful truths from within their communal traditions, just as psychologists, sociologists, and priests do from within theirs. But from these often-competing traditions, there is no means by which one can locate a transcendent truth, a “truly true.” Any attempt to establish the superior account would itself be the product of a given community of agreement.

To be sure, these arguments have provoked antagonistic reactions among scientific communities. There remain substantial numbers in the scientific community, including the social sciences, that still cling to a vision of science as generating “Truth beyond community.” In contrast, scientists who see themselves as generating pragmatic or instrumental truths find constructionist arguments quite congenial. Thus, for example, both would agree that while Western medical science does succeed in generating what might commonly be called “cures” for that which is termed “illness,” these advances are dependent upon culturally and historically specific constructions of what constitutes an impairment, health and illness, life and death, the boundaries of the body, the nature of pain, and so on. When these assumptions are treated as universal – true for all cultures and times – alternative conceptions are undermined and destroyed. To understand death, for example, as merely the termination of biological functioning would be an enormous impoverishment of

human existence. If a nourishing life is of value, there is much to be said of those who believe in reincarnation, the Christian dogma of “a life hereafter,” or the Japanese, Mexican, or African tribal views of living ancestor spirits. The constructionist does not abandon medical science, but attempts to understand it as a cultural tradition – one among many.

The Centrality of Language

Central to the constructionist account of the social origins of knowledge is a concern with language. If accounts of the world are not demanded by what there is, then the traditional view of language as a mapping device ceases to compel. Rather, a Wittgensteinian view of language is invited, in which meaning is understood as a derivative of language use within relationships. And, given that games of language are essentially conducted in a rule-like fashion, accounts of the world are governed in significant degree by conventions of language use. Empirical research could not reveal, for example, that “motives are oblong.” The utterance is grammatically correct, but there is no way one could empirically verify or falsify such a proposition. Rather, while it is perfectly satisfactory to speak of motives as varying in intensity or content, discursive conventions for constructing motivation in the twenty-first century do not happen to include the adjective, “oblong.”

Social constructionists also tend to accept Wittgenstein’s (1953) view of language games as embedded within broader “forms of life.” Thus, for example, the language conventions for communicating about human motivation are linked to certain activities, objects, and settings. For the empirical researcher there may be “assessment devices” for motivation (e.g., questionnaires, thematic analysis of discourse, controlled observations of behavior) and statistical technologies to assess differences between groups. Given broad agreement within a field of study about “the way the game is played,” conclusions can be reached about the nature of human motivation. As constructionists also suggest, playing by the rules of a given community is enormously important to sustaining these relationships. Not only does conformity to the rules affirm the reality, rationality, and values of the research community, but the very *raison d’être* of the profession itself is sustained. To abandon the

discourse would render the accompanying practices unintelligible. Without conventions of construction, action loses value.

The Politics of Knowledge

As indicated above, social constructionism is closely allied with a pragmatic conception of knowledge. That is, traditional issues of truth and objectivity are replaced by concerns with that which research brings forth. It is not whether an account is true from a god's eye view that matters, but, rather, the implications for cultural life that follow from taking any truth claim seriously. This concern with consequences essentially eradicates the longstanding distinction between *fact* and *value*, between is and ought. The forms of life within any knowledge-making community represent and sustain the values of that community. In establishing "what is the case," the research community also places value on their particular metatheory of knowledge, constructions of the world, and practices of research. When others embrace such knowledge they wittingly or unwittingly extend the reach of these values.

Thus, for example, the scientist may use the most rigorous methods of testing emotional intelligence, and amass tomes of data that indicate differences in such capacities. However, the presumptions that there is something called "emotional intelligence," that a series of question and answer games reveal this capacity, and that some people are superior to others in this regard, are all specific to a given tradition or paradigm. Such concepts and measures are not required by "the way the world is." Most importantly, to accept the paradigm and extend its implications into organizational practices may be injurious to those people classified as inferior by its standards.

This line of reasoning has had enormous repercussions in the academic community and beyond. This is so especially for scholars and practitioners concerned with social injustice, oppression, and the marginalization of minority groups in society. Drawing sustenance in particular from Foucault's (1979, 1980) power/knowledge formulations, a strong critical movement has emerged across the social sciences, a movement that gives expression to the discontent and resistance shared within the broad spectrum of minorities. In what sense, it is often asked, do the taken-for-granted

realities of the scientist sustain ideologies inimical to a particular group (e.g., women, people of color, gays and lesbians, the working class, environmentalists, communalists, the colonized) or to human well-being more generally? Traditional research methods have also fallen prey to such critique. For example, experimental research is taken to task not only for its manipulative character, but its obliteration of the concept of human agency.

These three themes – centering on the social construction of the real and the good, the pivotal function of language in creating intelligible worlds, and the political and pragmatic nature of discourse – have rippled across the academic disciplines and throughout many domains of human practice. To be sure, there has been substantial controversy, and the interested reader may wish to explore the various critiques and their rejoinders (see, e.g., Gergen 1994; Nagle 1997; Parker 1998). However, such ideas also possess enormous potential. They have the capacity to reduce orders of oppression, broaden the dialogues of human interchange, sharpen sensitivity to the limits of our traditions and to their potential offerings, and incite the collaborative creation of more viable futures. Such is the case in psychology as it is in the global context.

Social Construction and Psychological Inquiry

Scholars from across the social sciences and the humanities have contributed to and drawn significantly from social constructionist theory. Owing to the stronger commitment of psychologists to a logical empiricist vision of science, its impact on psychological inquiry has been slower to develop. Yet, as the problems with positivist foundationalism have become increasingly apparent, and psychologists have become increasingly conscious of developments in the broader intellectual context, so has constructionist theory given rise to a new and significant range of initiatives. Constructionism has played a particularly important role in the emergence of six domains of exploration.

Critical Psychology

As outlined, ideological critique in the social sciences was a major stimulus to the development of social constructionist initiatives in psychology. Yet, the early

critiques of professional psychiatry, along with class- and gender-based criticism cited above, have since expanded in both depth and breadth. Such inquiry is typically based on demonstrating the constructed character of dominant discourses and practice, the otherwise hidden ideology thereby sustained, and the resulting impact on society. Such inquiry abandons the positivist attempt to “predict and control” human behavior (itself often characterized as sustaining an oppressive ideology), and replaces it with a goal of *liberation*. Once the ideological underpinnings of dominant reality claims are revealed, it is reasoned, one is liberated to pursue alternative activities of greater societal promise. Feminist psychologists have been among the vanguard of the critical movement, pointing to the gender biases pervading many of the concepts and research practices of the field at large. Similarly active have been constituents of the gay and lesbian movement, much concerned with the constructed character of sexual categories, their implicit values, and their impact on cultural life. Major critiques have also been launched against assumptions and practices of the mental health professions. An extensive literature illuminates the constructed character of the psychiatric concepts of mental illness and points to the ideological and political interests served by diagnostic categorization. A large volume of work has also pinpointed conceptual and ideological problems inhering in such areas as cognitive theory, evolutionary psychology, positive psychology, experimental methodology, along with the ways these professional investments are injurious to the culture. Broad compilations and discussions of critical psychology may be found in Fox and Prillettensky (2009) and Shulman and Watkins (2010).

Discursive Psychology

Publicly shared discourse serves as the chief site of world construction. Inquiry into discursive practices has thus been both rich and substantial. Important inquiry has been devoted to deconstructing essentialist views of mental life, illuminating the constructed character of the emotions, memory, the sense of smell, erotic experience, boredom, intellectual disability, and teenage desire (for a summary, see Gergen 2009). Such research raises profound questions concerning the utility of empirical research into what amount to conversational objects. These deconstructive pursuits are

coupled with alternative attempts to demonstrate that mental predicates are not descriptive, but performative. Thus, for example, researchers show how an “attitude” is more fruitfully understood as a public action or, essentially, a position taken in a conversation; rational thought is more adequately viewed as a social process of argumentation. This line of reasoning has been a significant stimulus to one of the most significant lines of constructionist inquiry, namely, into *communal memory*. Here the grounds have been established for viewing memory not as a personal, mental process but as a social process (see Middleton and Brown 2005, for a review). As proposed by Edwards and Potter (2000) a fully discursive psychology should properly replace cognitive psychology.

Discursive inquiry also includes the analysis of conversation. Here the focus shifts from the content and form of particular discursive segments, to relational interdependence as conversation unfolds over time. Such inquiry has been useful, for example, in demonstrating the microprocesses of establishing power in relationships, and cogenerating identities in ongoing conversation. For more comprehensive accounts of discourse analysis in psychology see Wetherell et al. (2001).

Narrative Psychology

The abiding interest in linguistic construction has also brought with it a particular interest in narrative. Narrative is the critical means by which the intelligibility of events across time is generated. Volumes by Sarbin (1985) and Bruner (1990) gave the study of narrative a prominent place in psychological study. Open for inquiry were such topics as the relationship of narrative to personal identity, moral behavior, social acceptability, personal memory, self-acceptance, social efficacy, intimacy, and even the intelligibility of psychological theorizing itself. Prominent, for example, is the work of Dan McAdams (2005) on the significance of narrative for self-understanding. A series of eleven volumes edited by Josselson and Lieblich, along with the journal, *Narrative Studies*, have provided significant venues for narrative researchers to present their work. Among the vast array of topics covered have been the stories of Israeli holocaust survivor families, bodies and autobiographies, the poetics of research, professional practice within a mental hospital, and loneliness among Asian refugee women.

Theoretical Psychology

On the constructionist view, empirical research, along with “the phenomenon under study,” is dependent upon an a priori domain of shared understandings. Within scientific enclaves this socially negotiated forestructure is more formally viewed as theory. Thus, as the theoretical discourse of psychology is expanded, so are the possibilities for meaningful observation and practices. The challenge for science is not to strive for a single, unifying theory of the real, but to enrich the forms of intelligibility and thus the potentials of human action. Emblematic of this expanded interest in theory and its potentials is the emergence of such journals as *Theory and Psychology*, *Theoretical and Philosophical Psychology*, *Theory and Feminism*, and *The International Journal for Dialogical Science*. Of particular significance, constructionist theorists have opened a space for a major reconceptualizing of human action. Moving beyond the traditional image of biologically based, universal psychological processes – an image associated with Sampson’s (2008) critique of self-contained individualism – there is active exploration of the potential of a relational ontology. Resonant with Vygotsky’s early work (1978), the major ingredients of human functioning are given birth within social process. However, as one moves closer to constructionist premises, the focus on relationship becomes sharper, and the distinction between *inner* and *outer* begins to fade. Many of the contributions to a discursive psychology, as discussed above, lend themselves to this end. A fully developed account may be found in Gergen (2009).

Practices of Inquiry

While a constructionist view of knowledge does not eliminate any particular method of study, it does provide a vital stimulus for critical reflection on traditional empiricist methods and an invitation to develop alternative departures. As reasoned, methods of inquiry are inevitably tied to particular assumptions about the world, and about human functioning. Since all such assumptions are also lodged within particular cultural and political traditions, limits on methodology function to suppress alternative traditions and values.

By expanding forms of research, the field of psychology becomes increasingly rich in potential. On the critical side, many constructionists express discomfort

in traditional validity claims, and particularly truth claims about research subjects. No claims to validity are “true in all worlds,” and the elimination of the voice of those under observation is subtly exploitative. On the more positive side, constructionist theory has been an active stimulant in the development of such journals as *Qualitative Research in Psychology*, *Qualitative Inquiry*, and *Forum: Qualitative Social Research*. In addition to their contribution to discursive and narrative methods of inquiry, as discussed above, psychologists with a constructionist orientation have also come to play a prominent role in the development of action research (Reason and Bradbury-Huang 2007), and performative inquiry (Gergen and Jones 2008). For a more extended view of the range and innovation in qualitative inquiry in psychology and related disciplines, see Camic et al. (2003) and Denzin and Lincoln (2008).

Constructionism and Societal Practices

Finally, constructionist theory has played a major role in the development of professional practices. Perhaps the most visible of these developments has been the emergence of narrative therapy (White and Epston 1990). Committed to the view that people largely understand themselves in terms of storied constructions, the attempt in therapy is primarily to enable clients to develop new and more viable personal narratives. Similarly, Brief Therapists shift from “problem talk” (which sustains the reality of the problem), to talk about solutions or new possibilities for action. Closely tied to these developments in therapy are explorations into diagnostic practices that give voice to a wider circle of engaged parties (Seikkula et al. 2003). In the educational sphere, limitations are realized in traditional forms of pedagogy centered on the improvement of individual minds. In contrast, constructionist interest shifts to the relational genesis of knowledge and education. Special emphasis is placed on the potentials of collaborative pedagogies and more equalizing classroom dialogue. In organizational psychology, we find a strong movement concerned with the social construction of organizational realities (cf. Weick 1995). Practitioners have developed a variety of new practices relying on narrative and metaphor for reducing conflict in organizations and inspiring positive change. Appreciative Inquiry is among the leading practices

(Barrett and Fry 2005). For a more complete account of the forms of inquiry and practice stimulated by constructionist ideas, the reader should consult Holstein and Gubrium (2007).

Social Psychology

SAMVEL JESHMARIDIAN

Borough of Manhattan Community College, The City University of New York, New York, NY, USA

Social psychology is the scientific study of how people's thoughts, feelings, and behaviors are influenced by the actual, imagined, or implied presence of others (Allport 1998). By this definition, *scientific* refers to the *empirical* method of investigation. The terms *thoughts, feelings, and behaviors* include all of the psychological variables that are measurable in a human being. The statement that others may be *imagined* or *implied* suggests that we are prone to social influence even when no other people are present, such as when watching television, or following internalized cultural norms.

Social psychology is an empirical science that attempts to answer a variety of questions about human behavior by testing hypotheses, both in the laboratory and in the field. Such approach to the field focuses on the individual, and attempts to explain how the thoughts, feelings, and behaviors of individuals are influenced by other people.

A relatively recent field, *social psychology* has nonetheless had a significant impact not only on the academic worlds of psychology, sociology, and the social sciences in general, but has also influenced public

understanding and expectation of human social behavior. By studying how people behave under extreme social influences, or lack thereof, great advances have been made in understanding human nature. Human beings are essentially social beings, and thus, social interaction is vital to the health of each person. Through investigating the factors that affect social life and how social interactions affect individual psychological development and mental health, a greater understanding of how humankind as a whole can live together in harmony is emerging.

Links Between Social Psychology and Sociology

Social psychology is a branch of psychology that studies cognitive, affective, and behavioral processes of individuals as influenced by their group membership and interactions, and other factors that affect social life, such as social status, role, and social class. Social psychology examines the effects of social contacts on the development of *attitudes, stereotypes, discrimination, group dynamics, conformity, social cognition and influence, self-concept, persuasion, interpersonal perception and attraction, cognitive dissonance, and human relationships*.

A significant number of social psychologists are sociologists. Their work has a greater focus on the behavior of the group, and thus examines such phenomena as interactions and social exchanges at the micro-level, and group dynamics and crowd psychology at the macro-level. Sociologists are interested in the individual, but primarily within the context of social structures and processes, such as social roles, race and class, and socialization. They tend to use both qualitative and quantitative research designs. Sociologists in this area are interested in a variety of demographic, social, and cultural phenomena. Some of their major research areas are *social inequality, group dynamics, social change, socialization, social identity, and symbolic inter-actionism*.

Social psychology bridges the interest of psychology (with its emphasis on the individual) with *sociology* (with its emphasis on social structures). Most social psychologists are trained within the discipline of psychology. Psychologically oriented researchers place a great deal of emphasis on the immediate social situation, and the interaction between person and situation

variables. Their research tends to be highly *empirical* and is often centered round lab experiments. Psychologists who study social psychology are interested in such topics as attitudes, social cognition, cognitive dissonance, social influence, and interpersonal behavior. Two influential journals for the publication of research in this area are *The Journal of Personality and Social Psychology* and *The Journal of Experimental Social Psychology*.

History

The discipline of *social psychology* began in the United States at the dawn of the twentieth century. The first published study in this area was an experiment by Norman Triplett (1898) on the phenomenon of social facilitation. During the 1930s, many Gestalt psychologists, particularly *Kurt Lewin*, fled to the United States from Nazi Germany. They were instrumental in developing the field as something separate from the behavioral and psychoanalytic schools that were dominant during that time, and social psychology has always maintained the legacy of their interests in perception and cognition. Attitudes and a variety of small group phenomena were the most commonly studied topics in this era.

During World War II, social psychologists studied persuasion and propaganda for the US military. After the war, researchers became interested in a variety of social problems, including gender issues and racial prejudice. In the 1960s, there was growing interest in a variety of new topics, such as cognitive dissonance, bystander intervention, and aggression. By the 1970s, however, social psychology in America had reached a crisis. There was heated debate over the ethics of laboratory experimentation, whether or not attitudes really predicted behavior, and how much science could be done in a cultural context (Gergen 1973). This was also the time when a radical *situationist* approach challenged the relevance of self and personality in psychology.

During the years immediately following World War II, there was frequent collaboration between psychologists and sociologists (Sewell 1989). However, the two disciplines have become increasingly specialized and isolated from each other in recent years, with sociologists focusing on *macro variables* (such as social structure) to a much greater extent. Nevertheless,

sociological approaches to social psychology remain an important counterpart to psychological research in this area.

Social psychology reached maturity in both theory and method during the 1980s and 1990s. Careful ethical standards now regulate research, and greater pluralism and multicultural perspectives have emerged. Modern researchers are interested in a variety of phenomena, but attribution, social cognition, and self-concept are perhaps the greatest areas of growth. Social psychologists have also maintained their applied interests, with contributions in health and environmental psychology, as well as the psychology of the legal system.

Social psychology is the study of how social conditions affect human beings. Scholars in this field are generally either psychologists or sociologists, though all social psychologists employ both the individual and the group as their units of analysis. Despite their similarity, the disciplines tend to differ in their respective goals, approaches, methods, and terminology. They also favor separate academic journals and professional societies.

Research Methods in Social Psychology

Social psychologists typically explain human behavior as a result of the interaction of mental states and immediate, social situations. In Kurt Lewin's (1951) *Heuristic* behavior can be viewed as a function of the person and the environment, $B = f(P,E)$. Experimental methods involve the researcher altering a variable in the environment and measuring the effect on another variable. An example would be allowing two groups of children to play violent or nonviolent videogames, and then observing their subsequent level of aggression during free-play period. A valid experiment is controlled and uses random assignment.

Co-relational methods examine the statistical association between two naturally occurring variables. For example, one could correlate the amount of violent television children watch at home with the number of violent incidents the children participate in at school. Note that this study would not prove that violent TV causes aggression in children. It is quite possible that aggressive children choose to watch more violent TV programs.

Observational methods are purely descriptive and include naturalistic observation, contrived observation, participant observation, and archival analysis. These are less common in social psychology but are sometimes used when first investigating a phenomenon. An example would be to unobtrusively observe children on a playground (with a video camera, perhaps) and record the number and types of aggressive actions displayed.

Whenever possible, social psychologists rely on controlled experimentation. Controlled experiments require the manipulation of one or more independent variables in order to examine the effect on a dependent variable. Experiments are useful in social psychology because they are high in internal validity, meaning that they are free from the influence of confounding or extraneous variables, and so are more likely to accurately indicate a causal relationship. However, the small samples used in controlled experiments are typically low in external validity, or the degree to which the results can be generalized to the larger population. There is usually a trade-off between experimental control (internal validity) and being able to generalize to the population (external validity).

Because it is usually impossible to test everyone, research tends to be conducted on a sample of persons from the wider population. Social psychologists frequently use survey research when they are interested in results that are high in external validity. Surveys use various forms of random sampling to obtain a sample of respondents that are representative of a population. This type of research is usually descriptive or co-relational because there is no experimental control over variables. However, new statistical methods, like structural equation modeling, are being used to test for potential causal relationships in this type of data.

Regardless of which method is used, it is important to evaluate the research hypothesis in the light of the results, either confirming or rejecting the original prediction. Social psychologists use statistics and probability testing to judge their results, which define a significant finding as less than 5% likely to be due to chance. Replications are important to ensure that the result is valid and not due to chance or some feature of a particular sample.

Famous Experiments in Social Psychology

Famous experiments and studies have influenced social psychology as well as public understanding of human nature.

Solomon's Conformity experiments in the 1950s starkly demonstrated the power of conformity on people's estimation of the length of lines. On over a third of the trials, participants conformed to the majority, even though the majority judgment was clearly wrong. Seventy-five percent of the participants conformed at least once during the experiment.

In *Muzafer Sherif's Robbers' Cave experiment* (1954) boys were divided into two competing groups to explore how much hostility and aggression would emerge. It is also known as realistic group conflict theory, because the intergroup conflict was induced through competition over resources.

Leon Festinger's Cognitive Dissonance experiment subjects were asked to perform a boring task. They were divided into two groups and given two different pay scales. At the end of the study, participants who were paid \$1 to say that they enjoyed the task and another group of participants were paid \$20 to say the same lie. The first group (\$1) would later believe that they like the task better than the second group (\$20). People justified the lie by changing their previously unfavorable attitudes about the task (Festinger and Carlsmith 1959).

Stanley Milgram's Obedience to Authority experiment has shown how far people would go to obey an authority figure. Following the events of the Holocaust in World War II Stanley Milgram's experiments of the 1960s/1970s showed that normal American citizens were capable of following orders to the point of causing extreme suffering in an innocent human being.

Albert Bandura's Bobo Doll experiment has demonstrated how aggression is learned by imitation (Bandura et al. 1961). Bandura's experimental work was one of the first studies in a long line of research showing how exposure to media violence leads to aggressive behavior in the observers.

In *Philip Zimbardo's Stanford Prison experiment* a simulated exercise between student prisoners and guards showed how far people would follow an

adopted role. This was an important demonstration of the power of the immediate social situation, and its capacity to overwhelm normal personality traits (Haney et al. 1973).

Harold Takooshian has conducted experiments in the field of *City Life*. The results of the experiments have revealed factors and sources for social indifference, irresponsibility, and apathy.

Ethics of Socio-psychological Research

The goal of social psychology is to understand cognition and behavior as they naturally occur in a social context, but the very act of observing people can influence and alter their behavior. For this reason, many social psychology experiments utilize deception to conceal or distort certain aspects of the study. Deception may include false cover stories, false participants (known as confederates or stooges), false feedback given to the participants, and so on.

The practice of deception has been challenged by some psychologists who maintain that deception under any circumstances is unethical, and that other research strategies (such as role-playing) should be used instead. Unfortunately, research has shown that role-playing studies do not produce the same results as deception studies and this has cast doubt on their validity. In addition to deception, experimenters have at times put people into potentially uncomfortable or embarrassing situations (for example, Milgram's *Obedience to Authorities* experiments, Zimbardo's *Stanford Prison* experiment), and this has also been criticized for ethical reasons.

To protect the rights and well-being of research participants, and at the same time discover meaningful results and insights into human behavior, virtually all social psychology research must pass *an ethical review process*. At most colleges and universities, this is conducted by an ethics committee or institutional review board. This group examines the proposed research to make sure that no harm is done to the participants, and that the benefits of the study outweigh any possible risks or discomforts to people taking part in the study.

Furthermore, a process of informed consent is often used to make sure that volunteers know

what will happen in the experiment and understand that they are allowed to quit the experiment at any time. A debriefing is typically done at the conclusion of the experiment in order to reveal any deceptions used and generally make sure that the participants are unharmed by the procedures. Today, most research in social psychology involves no more risk of harm than can be expected from routine psychological testing or normal daily activities.

Spearman, Charles Edward

SANDY LOVIE¹, PAT LOVIE²

¹Liverpool University, Liverpool, UK

²Keele University, Keele, Staffordshire, UK

Charles Edward Spearman was born in London on September 10, 1863, as the third son of a minor aristocratic family. By his own admission (Spearman 1930), Charles was no academic high-flier, preferring sport to study, and so chose military service after leaving school in 1882. The next 12 years were spent mainly in India where Spearman served in several campaigns, played much polo and poker, but also became increasingly fascinated by philosophy (claimed as a boyhood interest) and by psychology, especially the scientific brand flourishing in Germany.

Spearman then returned to England to embark on an Army Staff College course for officers keen to further their military careers. But, after completing it in 1897, Spearman resigned his commission to study experimental psychology in Wundt's Leipzig laboratory, whence he obtained a Ph.D. in 1906.

Although Spearman was recalled to military duty in 1900 during the Boer War, his two years away from Germany were by no means wasted. Not only did he meet and marry Frances Aikman in 1901 during a posting to the Channel Island of Guernsey, but he

also developed an interest in intelligence and mental testing. Before returning to Leipzig, Spearman undertook, apparently on his own initiative, a series of such tests on some schoolchildren and adults which laid the foundations for his pioneering work on developing a theory of intelligence and what is now known as factor analysis.

On finally returning to England in 1907, Spearman took up the post of Reader in Experimental Psychology at University College, London (UCL), where he stayed as Grote Professor of Mind and Logic (1911) and then Professor of Psychology (1928) until retiring as Emeritus Professor in 1931. Under Spearman's leadership, UCL became the first notable British center of psychological research. The trademark of the "London School" was its emphasis on applying Galtonian principles of statistical and psychometric rigor to the study of human abilities.

After retirement, Spearman continued writing as well as traveling widely on lecture tours and research. But his health began to fail and he took his own life on September 17, 1945, at the age of 82.

Contributions

For practitioners of psychology, for historians of the subject, and for Spearman himself, there are three separate aspects of his work of especial interest. For the first group, it is rank correlation and test reliability; for the second, it is his pioneering work on intelligence and factor analysis; while Spearman himself would have chosen his cognitive system of noëgenesis (the generation of new knowledge).

Spearman first attracted attention with two linked articles on the formal definition and measurement of human intelligence which appeared in the *American Journal of Psychology* in 1904. It is on the second paper, defining his approach to intelligence, that Spearman's early reputation rests, though the other, relatively neglected, article provided the statistical tools (including rudimentary formulae for rank correlation and test reliability) on which his claim to have isolated and measured intelligence lies. However, unlike later workers such as Louis Thurstone, Spearman did not treat the study of intelligence as an empirical search for its nature; rather he began with an assumption about its form which he then proceeded to demonstrate empirically.

For Spearman, intelligence had a simple, two-part structure, namely, a general or common factor *g* underlying all mental abilities and a special factor *s* specific to a particular task. The definition and measurement of *g* occupied much more of Spearman's time and effort than *s*. However, he was always somewhat reluctant to equate *g* unambiguously with intelligence, perhaps feeling that intelligence was more elusive a concept than could be reduced to a simple score.

Spearman maintained that the hierarchical nature of the pattern of intercorrelations between tests of differing special abilities was consistent with the notion of a general factor underlying any mental task to a distinct and *quantifiable* extent. The foundations of factor analysis were thus laid. However, so simple and explicit a structure attracted much criticism, particularly from Edward Thorndike, for whom it was too simplistic, and Godfrey Thomson who dismissed the hierarchy as a statistical artifact. In 1928, moreover, the entry of the formidable American statistician Edwin B. Wilson into the debate uncovered the still-unresolved issue of factor indeterminacy and helped to propel the development of factor analysis out of the hands of psychologists and into those of the mathematicians.

Spearman's other great contribution to psychology is contained in his 1923 book, *The nature of "intelligence" and the principles of cognition*. Although aspects of his system of noëgenesis have been revived in recent years, most notably in Robert Sternberg's recasting of analogical reasoning, Spearman's ideas are richer and more complex, embracing in principle all aspects of intellectual activity. In his system, cognitive activity was also constrained in a way that generated testable hypotheses concerning observed problem solving, for example, the limited mental energy available to the person could be flexibly allocated to different cognitive tasks.

The major problem with noëgenesis as a fundamental system of psychology is that, although in principle designed to generate testable predictions, it was not itself founded on much experimental work; rather it was derived from various philosophical sources, and thus seemed primarily a contribution to the somewhat ambiguous area between psychology and philosophy. Hence, the concept virtually disappeared until its

partial resuscitation within certain areas of modern cognition.

Over his long academic life, Spearman published more than a 100 articles and six books. He also received many honors, in particular, being elected a Fellow of the Royal Society (1924), serving as President of the British Psychological Society (1923–1926), as well as becoming an honorary member of several foreign academies of science. See Lovie and Lovie (1996) and Spearman's autobiographical essay (1930) for further material about his life and work.

Spence, Kenneth

CARA ALOISIO
Fordham University Graduate School of Social Service,
New York, NY, USA

Basic Biographical Information

Kenneth Wartinbee Spence was an American neo-behavioral psychologist, recognized for his theoretical and experimental studies of conditioning and learning.

Spence was born in Chicago, Illinois in 1907 to Mary E. Wartinbee and William James Spence, an electrical engineer, and raised in Montreal, Quebec, Canada.

Spence attended West Hill High School, followed by McGill University in Montreal, earning a bachelor's degree in psychology in 1929, and a master's degree in 1930.

Prior to graduation from McGill, Spence married Isabel Temte, and had two children (Amsel 1995, p. 335).

At McGill, Spence was awarded the Wales Gold Medal in Mental Sciences and the university's Governor-General's Medal for Research. After completion of his master's, Spence attended Yale University to study with the renowned primate biologist Robert M. Yerkes and behavioral psychologist Clark L. Hull. Spence's research at Yale focused on discrimination learning in animals, and in 1933 he received his Ph.D. in psychology, with a dissertation on visual acuity in chimpanzees. Spence continued his research with chimpanzees as a National Research Council fellow and research assistant at the Yale Laboratories of Primate Biology in Orange Park, Florida (Kenneth 2008).

In 1937, Spence became an assistant professor of psychology at the University of Virginia. He then moved to the University of Iowa, where he remained for 26 years, becoming the head of the psychology department in 1942. Together with his colleagues Kurt Lewin and Gustav Bergmann, Spence developed the University of Iowa into a leading center of psychological research and theory. As the head of the department, he supervised more than 70 doctoral dissertations, leaving a mark on future generations of psychological theorists (Alic 2001, p. 620–621).

Spence married his former graduate student, Janet Taylor in 1959, and relocated to the psychology department at the University of Texas in Austin, in 1964.

Spence died of cancer in Austin, Texas in 1967 at the age of 59.

Major Accomplishments

Spence was a pioneer in the development of the neo-behaviorist theories of motivation and learning. His contributions to psychology are often categorized as follows: (1) learning and motivation theory, (2) the experimental psychology of learning and motivation, and (3) methodology and philosophy of science (Amsel 1995, p. 337).

The majority of Spence's research was focused in the area of discrimination learning, developed through stimuli–response experiments with chimpanzees and rats. His work analyzed classical conditioning and

measured basic learned behaviors such as salivating prior to eating, and eye-blinking in response to anxiety, attempting to develop a mathematical equation to describe how learned behavior is acquired (Kenneth 2008).

Spence did not turn his focus toward human behavior until the end of his career, and he cautioned that his previous theories of learning were only to be applied to nonhumans, as human behavior is significantly influenced by cognitive factors (Kenneth 2008).

Hull–Spence Hypothesis

Spence, along with Clark L. Hull, established the foundation of the neo-behaviorist theories of condition, learning, and motivation, and their collaboration of ideas came to be known as the *Hull–Spence Hypothesis* of conditioning and learning, which examined stimulus–response association, and found that reinforcement serves to motivate and increase the performance of learned behavior (Kenneth 2008).

Spence built upon the behavior theory developed by Hull, which stated that behavior was learned through habituation. Spence enhanced Hull's theory with his knowledge of discrimination learning, and found that improved performance in learned behavior was not due to habituation, but a result of motivational forces. Spence believed in “latent learning,” meaning that reinforcement was not necessary for learning to occur, but was a strong motivator for performance. His studies found that reinforcement encourages a response, but does not play a role in learning the response (Alic 2001, p. 621).

Additional Contributions

Aside from the Hull–Spence hypothesis, Spence also contributed to learning theory as a systematist, analyzing and interpreting the theories of others, through contributions in academic journals including the *Handbook of Experimental Psychology* (1951) (Amsel 1995, p. 338).

Spence's early papers on discrimination learning, produced during his years at the Yale Primate Laboratories and his continued research at the University of Iowa in the 1940s are widely considered

his most influential contribution to behavioral psychology (Amsel 1995, p. 339).

Between 1936 and 1966, Spence published 13 papers on the theory of learning in *Psychological Review* and numerous other articles and books. His publications were cited more often than those of any other psychologist in the years from 1962 to 1967 (Wiseman 2000, p. 262).

Throughout his career Spence received numerous awards and recognitions, including the Howard Crosby Warren Medal of the Society of Experimental Psychologists in 1953 and the first Distinguished Scientific Contribution Award of the American Psychological Association in 1956. Spence was the only psychologist ever selected to deliver the prestigious Silliman lectures at Yale University (Amsel 1995, p. 347). Spence was elected to the National Academy of Sciences in 1954 and was a fellow of the American Association for the Advancement of Science and the American Psychological Association. He also served on the U.S. Air Force Committee on Human Resources and the Army Scientific Advisory Panel (Kenneth 2008).

Philosophy of Science

Spence believed that psychologists faced unique challenges in psychological research and in the formulation of theories, as human behavior is unpredictable and does not always follow the logical laws as outlined in theory. Spence wanted to lessen the gap between physical sciences and psychology by reducing psychological laws to mathematical formulas (Kenneth 2008).

Sperry, Roger W.

MICHAEL J. FIGUCCIO

Boston University, Boston, MA, USA

Basic Biographical Information

Sperry, Roger (August 20, 1913–April 17, 1994) was an American neurobiologist, psychologist, and philosopher. Roger Sperry was born in Harford, Connecticut, to Francis Bushnell and Florence Kraemer Sperry. Sperry's father was in banking, while his mother was trained in business school. Roger had a younger brother, Russell Loomis, who eventually studied Chemistry. Roger's father died when he was 11. Roger attended Hall High School in West Hartford, Connecticut, where he excelled in athletics. In 1935, Sperry graduated from Oberlin College with a Bachelor in English. Sperry continued at Oberlin to earn a master's degree in Psychology. In 1941, Sperry obtained a doctorate in Zoology from the University of Chicago under the mentorship of Paul A. Weiss. After completing his PhD, Sperry did a year of post-doctoral research as a National Research Council Fellow at Harvard University under the guidance of Professor Karl S Lashley. Sperry was a Biology Research Fellow from 1942–1946 at Harvard's Yerkes Laboratories of Primate Biology. In 1946, Sperry returned to the

University of Chicago with an appointment of Assistant Professor in the Department of Anatomy. On December 28, 1949, Sperry married Norma Gay Dupree. They had two children: Glenn Michael Sperry (born October 13, 1953) and Janeth Hope Sperry (born August 18, 1963). In 1952, he became Section Chief of Neurological Diseases and Blindness at the National Institutes of Health. In the same year, Sperry was promoted to Associate Professor at the University of Chicago. In 1953, Sperry accepted a position as a Professor of Psychobiology at California Institute of Technology, where he remained until his retirement in 1984.

Major Contributions

Roger Sperry's professional career can be divided into four areas of study: Nerve Regeneration (1939–1946), Visual Functioning (1946–1963), Corpus Callosum/Split-Brain (1957–1975), and Consciousness/Values (1973–1993) (Trevvarthen 1994). Prior to the late 1930s, there was a long held belief that the mammalian brain was essentially plastic and capable of change. Sperry conducted a series of elegant experiments debunking this theory. Sperry transposed the nerves of muscle flexion and extension in a rat's leg (Sperry 1945). When the bottom of the rat's foot was injured, the rat would straighten its leg rather than withdraw. As the rat's foot worsened, the rat would push harder. This experiment showed that the rat's motor cortex was "hard-wired" and incapable of being modified through training.

Next Sperry conducted a sequence of experiments with salamanders. The optic nerve of salamanders can regenerate. Sperry severed the nerves and rotated the eyeballs 180°. When the salamander's vision returned, it saw everything upside down for the duration of its life. The experiments showed that neural connections are under genetic control and are essentially fixed postembryonic development. This culminated in Sperry's chemo-affinity theory (Hubel 1994).

Sperry became enthralled by the corpus callosum during his postdoctorate years. At this time, the corpus callosum, a series of connective fibers between the left and right hemispheres, remained a mystery to neuroscientists. Beginning in the 1940s, commissurotomy the practice of severing the corpus callosum was

a common surgical procedure in patients with severe epilepsy. Sperry and his colleagues conducted a series of tests to determine the effects on human perception, speech, and motor control (Sperry 1976). The left hemisphere was found to be superior in terms of analytical, sequential, and linguistic processing, while the right hemisphere was found to be advantageous in terms of holistic, parallel, and spacial abilities. These experiments resulted in the concept of lateralization of brain function. Sperry shared the Nobel Prize in Physiology or Medicine in 1981 along with David Hubel and Thorsten Wiesel for this research.

During Sperry's later life, he became increasingly interested in consciousness and ethical values (Sperry 1980). Sperry argued that brain mechanisms would never be understood solely on the basis of chemistry and biophysics of individual neurons. Sperry proposed a new mentalist theory of mind arguing subjective experience has a prime role in controlling brain function and behavior. Sperry describes consciousness as "macrodeterminism," in which, higher, more evolved forces exercise control over their lower counterparts in nature.

Roger Sperry has made numerous contributions to the fields of neurobiology, psychology, and philosophy throughout his lifetime. Sperry's groundbreaking split-brain experiments resulted in him being awarded the Nobel Prize in Physiology or Medicine and the National Medal of Science among many others.

Starbuck, E. D.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: February 20, 1866; Died: November 18, 1947.

Starbuck was born Edward Eli Starbuck in Indiana to Quaker farmers who traced their ancestry and religion back to the original settlers of Nantucket. He underwent a conversion experience at 20 which was expected in his community, but soon afterward went to the University of Indiana and began a long process of questioning religion which led him both to the empirical study of the grounds of religious experience and also to a career as a religious educator. Starbuck studied sciences and mathematics at Indiana: One of his instructors was David Starr Jordan, who later at Stanford University provided Starbuck with his first academic position. Starbuck completed his undergraduate work in 1890 having developed a liberal and somewhat skeptical religious outlook. In fact, he referred late in life to himself and his wife as “emancipated pagans” (Booth 1981, p. 103). Ultimately, this led him to associate only sporadically with organized religion, though he remained a person of faith who supported religion generally. After 3 years of teaching in Indiana preparatory schools and colleges, his continuing fascination with religious experience and a developing interest in psychology led him to seek out graduate education in psychology and religion.

Major Accomplishments/Contributions

He settled in Harvard, which provided him generous support and where he devised a questionnaire about the conversion experience in adolescence which proved to be his most enduring contribution to both developmental psychology and the psychology of religion. This questionnaire was open-ended and covered all aspects of the conversion experience, including the circumstances preceding the experience, sights, sounds and feelings during the experience, relation of the

change during conversion to the self or supernatural events, changes connected with the conversion experience, and ease or difficulty in following a new life course after conversion. Starbuck had some trepidation about offering this questionnaire to the public, but he found a friendly ally in William James, who of course had long-standing interests in conversion and religion generally. James’s signature on the original questionnaire sanctioned its distribution, but while Starbuck was able to secure data, he was not able to proceed to the Ph.D. in the psychology of religion, which had become his goal. In the meantime, some of his questionnaires had migrated to Clark University and, while Starbuck negotiated a transfer to G. Stanley Hall’s program which promised liberty to follow his chosen path, Starbuck’s method and questionnaire had already become swallowed up in rapidly rising tide of psychological studies of religion there. Starbuck had in a sense a double fortune or misfortune to have conceived an original idea in the presence of two eminent elder psychologists, James who was already on the path to his groundbreaking study of religious experience, and Hall, who had drives not only toward religion but also to a groundbreaking study of his own on adolescence. James, Hall, and their students by Starbuck’s work. By the time Starbuck had finished his PhD at Clark in 1897 and published on conversion (Starbuck 1897), had begun his career in education and psychology at Stanford, and had published his book on the psychology of religion in 1899 (Starbuck 1899) the field was crowded. James gave a prominent place to Starbuck’s findings in *The Varieties of Religious Experience*. But a large amount of data on religious experience that Starbuck subsequently collected at Stanford was lost in transit, and though he had a sabbatical with Meumann in Switzerland which led to some further consideration of religious feelings (Starbuck 1904), Starbuck spent the rest of his career at Iowa between 1906 and 1930 and then at the University of Southern California until 1943, teaching psychology, education, and aesthetics, developing programs of character education, and consulting on religious instruction. His subsequent writing, much of which is collected in *Look to This Day* (Starbuck 1945), is programmatic and homiletic, and he made no further empirical discoveries to match his earliest work.

Staudt Sexton, Virginia

JOHN D. HOGAN

St. John's University, Jamaica, NY, USA

Basic Biographical Information

Virginia Staudt Sexton is known primarily as a historian of psychology, but she made important contributions to other areas of psychology as well. Perhaps most significantly, she worked to raise the status of women in psychology, to integrate Catholics into psychology, and to promote a greater international perspective in the field.

Virginia Mary Staudt was born August 30, 1916, in New York City. In 1936, at age 19, she received a bachelor's degree from Hunter College with a major in classics. She taught elementary school for several years before completing a doctoral degree in experimental psychology at Fordham University in 1946. Her mentor was Joseph Kubis. She later completed a post doctoral year in neuroanatomy at Columbia University and in clinical psychology at the Psychiatric Institute in New York under the mentorship of Joseph Zubin (Denmark and Russo 1992).

Her first college teaching position was at Notre Dame College on Staten Island in 1944 where she helped to establish a laboratory and an independent

psychology major. She resigned from Notre Dame after receiving a Ford Foundation Faculty Fellowship that allowed her to pursue postdoctoral studies. In 1953, she accepted a position at the Bronx campus of Hunter College (later renamed Herbert Lehman College of the City of New York). In 1960, she married Richard Sexton, an English professor at Fordham University. Her husband had been widowed with four children, and Virginia took over their care. Richard and Virginia Sexton maintained a mutually supportive relationship in both their personal and professional lives.

Virginia Sexton retired from Lehman College in 1979 and immediately accepted a position at St. John's University where she was named a Distinguished Professor of Psychology. She remained at St. John's University until she reluctantly retired in 1990 due to poor health. She died on May 24, 1997, 5 months after the death of her husband (Hogan 1998).

Major Accomplishments/Contributions

Virginia Sexton's personal life and professional accomplishments were closely related. Her experience as a woman in academia who faced gender discrimination sensitized her to the struggles of women in psychology, both in contemporary and historical terms. Her strong Catholic background led her to promote greater participation of Catholics in psychology. Even her training as a classicist strongly influenced her emphasis on humanistic approaches to psychology.

Many of Sexton's books were coauthored with Henryk Misiak, a Polish-born Catholic priest, who had also received a doctorate in psychology from Fordham University and who continued at Fordham as a professor of psychology. Sexton and Misiak were a formidable pair, each with a strong philosophical and language background. Their first book together, *Catholics in Psychology* (Misiak and Staudt 1954), had multiple purposes. In addition to identifying Catholics who had been pioneers of psychology, they wanted to demonstrate that the Catholic faith was not a hindrance to the pursuit of psychology, but rather that faith could help to stimulate scientific inquiry. At the time, there were several prominent Catholics who considered psychology and religion to be inherently at odds with one another.

In 1966, they published *History of Psychology: An Overview* (Misiak and Sexton 1966), which gave greater legitimacy to the emerging subfield. Their approach to the history of psychology differed from some of the other notable approaches of the time. Not only did they emphasize the history of applied psychology in a way that few had done before, they gave considerable coverage to psychology in other parts of the world, including Asia. This international perspective anticipated their next book *Psychology Around the World* (Sexton and Misiak 1976), an edited volume, containing contributions from 31 countries, that was for many years the major source in English on national psychologies.

On her own, Virginia researched a variety of historical subjects, including several prominent Catholic contributors to psychology as well as women pioneers in psychology. She also became an organizational and professional leader. Among the offices she held were the presidency of the International Council of Psychologists (1981–1982), the New York State Psychological Association (1982), the Eastern Psychological Association (1983–1984), Psi Chi, the National (now International) Honor Society in Psychology (1986–1987), and five divisions of the American Psychological Association.

In all, Sexton published almost 200 articles and nine books. Much of her work explored her interest in the psychology of religion and humanistic psychology. When she served as president of the American Catholic Psychological Association (1964–1965), she joined with several other prominent Catholic leaders of psychology, notably William Bier, to lobby the American Psychological Association to allow the establishment of a division devoted to psychology and religion. Their efforts resulted in the establishment of APA Division 36, now called Psychology of Religion.

She received awards from several different organizations, including the New York State Psychological Association and the New York Academy of Sciences. She also received an honorary doctorate from Cedar Crest College. She was well known as a mentor for younger psychologists, several of whom have gone on to positions of national prominence. Despite her many honors and accomplishments, she considered herself to be primarily a teacher.

Stern, William

JAMES T. LAMIELL

Georgetown University, Washington, DC, USA

Basic Biographical Information

Stern, whose full given name was Louis William, was born on April 29, 1871, in Berlin, Germany. He would be the only child born to Sigismund and Rosa Stern, parents of modest means. He began his university studies in 1888 at the Friedrich-Wilhelm University of Berlin (today the Humboldt University), and in 1893 concluded his doctoral work there under the mentorship of Moritz Lazarus (1824–1903). After spending four more years in Berlin conducting independent research on the perception of change, Stern accepted the offer of a position as lecturer at the University of Breslau (a city renamed Wrocław after the cession of the German state of Silesia to Poland in the aftermath of World War II). At Breslau, Stern completed his *Habilitation* under Hermann Ebbinghaus (1850–1909) in 1897, and then continued as a member of the teaching faculty there for 19 more years.

In 1916, Stern left Breslau for Hamburg in order to replace Ernst Meumann (1862–1915) as Director of the Psychological Institute there. Stern played a major role in the founding of the University of Hamburg in 1919, and would remain a key member of the faculty there until Hitler's accession to power in 1933. In April of that year, Stern, a Jew, was forced to resign his faculty position and was forbidden all further access to

university facilities. Soon thereafter, he fled Germany, and after spending some months in the Netherlands emigrated to the USA in 1934, where he held a visiting professorship at Duke University in Durham, North Carolina, until his death on March 27, 1938 (cf. Bühring 1996).

Major Accomplishments/ Contributions

Stern's major contributions to the psychological literature fall into three major categories: child psychology, differential psychology, and theoretical and philosophical psychology.

Stern's contributions to child psychology were based to a large extent on observations made by himself and wife Clara concerning the development of their three children. Daughter Hilde was born in 1900, son Günther in 1902, and daughter Eva in 1904. Beginning with Hilde's birth, the Sterns' observations were recorded in diaries they maintained for 18 years, finally extending to more than 5,000 handwritten pages (Behrens and Deutsch 1991). Two monographs based on the accumulating records were coauthored by Clara and William Stern: *Die Kindersprache (Children's Speech)*, published in 1907 (Stern and Stern 1907), and *Erinnerung, Aussage und Lüge in der ersten Kindheit (Recollection, Testimony, and Lying in Early Childhood)*, published 2 years later (Stern and Stern 1909). Subsequently, William Stern alone authored *Psychologie der frühen Kindheit bis zum sechsten Lebensjahr (The Psychology of Early Childhood Up to the Sixth Year of Life)*, a work that was published in its first edition in 1914 (Stern 1914). Reflecting the popularity of that work and the high regard in which it was held not only by Stern's contemporaries but also by his successors, it would eventually reach a sixth edition (published in 1930), an edition which would in turn be reissued six times, most recently in 1987.

By his own account (Stern 1927), Stern's studies of his three children strongly reinforced his convictions concerning the need for a subdiscipline within psychology specifically devoted to the study of individual differences. This conviction first found expression in a book published in 1900 titled *Über Psychologie der individuellen Differenzen: Ideen zu einer "differentiellen" Psychologie (On the Psychology of Individual Differences: Toward a "Differential" Psychology; Stern 1900)*, and

Stern's views concerning the proper methods and research objectives of this new subdiscipline were set forth even more thoroughly and systematically in a sequel to the 1900 book published a decade later under the title *Die Differentielle Psychologie in ihren methodischen Grundlagen (Methodological Foundations of Differential Psychology; Stern 1911)*. In these two path-breaking works, but especially the latter, Stern set an investigative agenda for the study of individual differences that would guide the research efforts of personality investigators and applied psychologists for decades to come.

It was within the context of his own work as a differential psychologist that Stern suggested that researchers studying intelligence differences among children abandon the practice of expressing the level of a child's intellectual functioning as mental age *minus* chronological age, and adopt instead the procedure of computing the *ratio* of mental age to chronological age (e.g., Stern 1916). For this suggestion, which was widely adopted, Stern has properly been credited with having invented the IQ. Over time, however, Stern expressed his growing dismay over the excessive reliance on – and misuses of – the IQ index (e.g., Stern 1930), and he came to regret his role in that historical development (cf. Lamiell 2006).

In the domain of theoretical and philosophical psychology, Stern's *magnum opus* was a three-volume work on which he labored for two decades. He titled the series *Person und Sache (Person and Thing)*. Volume I of this work, *Ableitung und Grundlehre (Rationale and Basic Tenets)*, was published in 1906 (Stern 1906); Volume II, *Die menschliche Persönlichkeit (The Human Personality)* appeared in 1918 (Stern 1918), and Volume III, *Wertphilosophie (Philosophy of Value)* followed in 1924 (Stern 1924). Together, these three volumes set forth a comprehensive system of thought, or *Weltanschauung*, that Stern called "critical personalism." A highly condensed exposition of these ideas was published in 1917 under the title *Die Psychologie und der Personalismus* (Stern 1917).

As the title of the aforementioned series suggests, critical personalism is predicated on what Stern took to be the irreducible distinction between persons and things. At the core of this distinction is the notion that persons are entities that *evaluate*, whereas things are entities that can only be passively evaluated.

These convictions led Stern to question the adequacy of all reductively mechanistic conceptions of human mental life and behavior, and to advocate instead an explicitly teleological understanding of persons and their psychosocial development across the life span (cf. Lamiell 2003).

Sternberg, Robert J.

JENNIFER DORAN

The New School for Social Research, New York, NY, USA

Robert Sternberg is a prominent psychological theorist, psychometrician, and active researcher. He is most known for his Triarchic Theory of Intelligence and his work on creativity and love.

Basic Biographical Information

Robert Sternberg was born in Newark, New Jersey. His interest in psychology began at an early age based on his personal experiences. In elementary school, he suffered from severe test anxiety, performing poorly on IQ tests. Wanting to understand his shortcomings, he began to study intelligence testing. In the seventh grade, he found the Stanford–Binet scales in his local library, which he began administering to his classmates. The same year, he created his own intelligence test for his

school science project, referred to as the Sternberg Test of Mental Abilities (Spear 2001).

Despite various educational difficulties and discouragement from professors, Sternberg continued to study psychology. He earned an undergraduate degree from Yale University in 1972 under the mentorship of Endel Tulving. Three years later, he achieved a doctoral degree from Stanford University, where he studied with Gordon Bower. During his time at Yale, he continued to pursue his interest in assessment, working for the Education Testing Service in Princeton and the Psychological Corporation in New York on his summer breaks.

Robert Sternberg taught at Yale University from 1975 to 2005. He was the Director of the Psychology of Abilities, Competencies, and Expertise (PACE) Center from 2000 to 2005. He has actively studied intelligence, taking a lifespan approach and committed to demonstrating that intelligence is modifiable and subject to teaching and intervention (Glaveanu 2010). His interests have also focused on creativity, love and hate, thinking and problem solving abilities, social relations, and leadership. Sternberg notes that his interests have almost always developed out of personal difficulties and failures. His interest in intelligence testing came from his own subpar performance school, his interest in wisdom came from giving poor advice to a graduate student, and his interest in love emerged within the context of a failing romantic relationship (Glaveanu 2010). Sternberg historically seeks to understand the nature of his own personal challenges through psychological theory and scholarship. His pursuit of knowledge in these domains has advanced both theory and research in these areas.

Major Contributions

Sternberg has contributed widely to psychological theory. Perhaps his most widely recognized contribution is the Triarchic Theory of Successful Intelligence (Sternberg 1985). He views intelligent behavior as “beyond IQ,” a combination of analytical, creative, and practical abilities. He also devised a Triangular Theory of Love (Sternberg 1986), where he breaks relationships into three main components – intimacy, passion, and commitment – and outlines different types of love relationships. He also developed an Investment Theory of Creativity (Sternberg and Lubart 1995), a Theory of Cognitive Styles (Sternberg 1997), and

a theory of leadership known as Wisdom, Intelligence, and Creativity Synthesized (Sternberg 2003).

From 2005 to 2010 Sternberg served as the Dean of the School of Arts and Sciences at Tufts University, where he launched an experimental admissions process known as the “Rainbow Project.” Believing that SAT scores are flawed and should not be the sole determinant for university admissions, Sternberg added a creativity measure to the process. This new admissions criteria doubled the predictive capability of college success and decreased ethnic group differences typically observed in traditional assessment tools (Jaschik 2006). Throughout his career, Sternberg has investigated psychometric integrity and created strong assessment tools that aim to alleviate ethnic and cultural biases.

Over the course of his career, Sternberg has published over 1,000 books, book chapters, and articles. His work has revolutionized our understanding of the nature of intelligence, and emphasized the need to consider culture and context in our theories and assessment tools. His advocacy for a broader conceptualization of intelligence has shaped the way that human potential and success are conceived of and studied. He has dedicated his career to conducting novel and controversial studies, often going against the grain and being criticized for his work. He has questioned established theories on intelligence and the field of standardized testing, advocating for more inclusive and valid testing systems. He refutes the idea that intellectual functioning is inherent and stable, insisting that intelligence can be modified by good teaching and intervention. He sees the human potential for development and change throughout the lifespan. In addition to his theoretical and empirical contributions, Sternberg has devised several psychometric tools, among them the Sternberg Triarchic Abilities Test and the Sternberg Multidimensional Abilities Test.

To date, Sternberg holds ten honorary doctorates, an honorary professorate at the University of Heidelberg in Germany, and a distinguished associate of the Psychometrics Centre at the University of Cambridge. He has been the recipient of numerous prestigious awards, among them the Early Career Award of the American Psychological Association (APA) and the James McKeen Cattell Award of the American Psychological Society. The APA listed him as one of the “Top 100 Psychologists of the 20th Century,” and he was the

president of the organization in 2003. He has also served in editorial roles for the journals *Psychological Bulletin* and *Child Development*. He is the current Editor of *Contemporary Psychology*. In 2010, he was appointed as Provost, Senior Vice President, and Professor of Psychology at Oklahoma State University.

There is no doubt of the widespread influence and impact Sternberg's work has had on the field. He continues to bridge the areas and cognitive, developmental, and social psychology in his work, challenging previously held conceptions about intelligence and IQ. He also advocates for systematic change and strives to create psychometrically valid assessment tools. He is an active theorist, researcher, psychometrician, and advocate. In his endeavors to investigate intelligence and wisdom, Sternberg's work and dedication to the field clearly reveals his own.

Stewart, Joseph

HARRIS WINITZ
University of Missouri-Kansas City, Kansas City,
MO, USA

Joseph Stewart received his Ph.D. in 1960 in speech pathology and audiology from the University of Iowa, devoting his doctoral dissertation under the direction

of Professor Wendell Johnson to an anthropological investigation of the presence of stuttering among certain Indian tribes. Stewart interviewed mothers of children of the Cowichan Indians of Vancouver Island, a known stuttering group, and mothers of the Ute Indians of Utah, a known nonstuttering group. The Cowichans in contrast to the Ute Indians reported more severe punishment associated with toilet training and expectations for early development of motor skills, such as crawling and walking, and placed greater stress on language acquisition.

Stewart's research demonstrated that cultural factors are an important consideration in the study of speech and language development and its disorders and a significant area of study for investigators.

Stratton, G. M.

DAVID C. DEVONIS
Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: September 26, 1865; Died: October 8, 1957.

George Malcolm Stratton was among the last major American psychologists to have a primarily philosophical education and background. Son of a Gold Rush pioneer, he matriculated at the University of California (BA 1888) and after obtaining the M.A. at Yale in 1890 returned to California as a fellow in philosophy with the idealistic philosopher George Howison. With Howison's support, Stratton left for 2 years' study in Europe where he obtained another M.A. and the Ph.D. under ► [Wundt, Wilhelm](#) at Leipzig in 1896. He then returned to California, and except for a 4-year period between 1904 and 1908 when he was at Johns Hopkins, he spent the rest of his career there, was elected to the National Academy of Sciences in 1928, and retired in 1935, remaining active as an emeritus faculty member until shortly before his death.

Major Accomplishments/ Contributions

► **Tolman, E. C.**, a longtime colleague, said that Stratton's three main contributions to psychology were his investigation of space perception, his founding and development of the Berkeley psychology department and laboratory, and his contributions to international understanding and peace (Tolman 1961). The first of these is the most predominant: Along with Raymond Dodge's contemporaneous study of eye movements in reading, Stratton's study on perception with inverting lenses (Stratton 1897) was one of the most memorable phenomenal discoveries of the new experimental perceptual psychology. Stratton devised a pseudoscope, one of several which he constructed and investigated between 1894 and 1900, which presented, to his naive eye, an inverted view of the environment to which he adapted within a few days, able to perform normal tasks involving motion and eye-hand coordination. Stratton's studies have remained a point of departure for discussions of space perception, visual adaptation, and neural coding. After this, Stratton contributed to the debate about consciousness in the first decade of the twentieth century, combining a Wundtian conception of comprehensive psychic causality with Jamesian functionalism (Stratton 1906a, b). He also conducted empirical tests both in the laboratory and in the field of different arrangements of railway signal lights which confirmed the work of signal engineers on the superiority of position-light signals (Stratton 1907). Later, in the 1920s, he studied emotion, especially anger and fear, conducting some curious comparative studies of the conjectures that cattle were enraged by the color red and the sight of blood (Stratton 1923). Theoretically, he advanced a view of emotion as an undifferentiated organizing system for action (Stratton 1928). At Berkeley, he nurtured a psychology department independent of but friendly to philosophy, which reflected his eclectic interests and which became one of the most diverse and innovative in the USA. Stratton supported feminism (Stratton 1916), and this is reflected in his encouragement of inclusion of women on the Berkeley faculty. The first three Berkeley Psychology Ph.D.s, starting with Olga Bridgman in 1915, were women, and the first two, Bridgman and Jean Walker MacFarlane, formed the nucleus of the Berkeley faculty in the 1920s along

with Tolman, Warner Brown, and Stratton. The last of the three, Beulah May Morrison, Stratton's research assistant during the early 1920s on the cattle studies, was a core faculty member with Raymond Wheeler at the University of Kansas for many years. During the First World War, Stratton helped devise tests to determine who could become successful pilots. After the war he became convinced, because of long-standing religious convictions and recent experience, of the necessity of solving the problem of violence in international relations. He conducted experimental work demonstrating similarities in emotional response between persons of various ethnic groups, and wrote several theoretical papers and books on the theme of relieving violence by diminishing self-interest (Stratton 1944). This pacifistic psychology, though it was probably an influence on E. C. Tolman turning to the study of the motives for war, did not gain a wide hearing as it appeared mostly during the Second World War and immediately afterward when the priorities of American psychology were largely focused on national survival.

Strong, E. K., Jr.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: August 18, 1884; Died: December 6, 1963.

Edward Kellogg Strong received the B.A. from the University of California at Berkeley in 1906 and then, after a stint in the US Forestry Service and after taking the M.A. at Berkeley, entered the graduate program of Columbia University and became associated with new developments there in applied psychology. His 1911 doctoral thesis with Hollingworth concerned the effectiveness of advertising, which was a continuing interest for much of his career. After obtaining the doctorate he was, from 1912 to 1915, a research fellow for the Association of National Advertisers as well as a lecturer at Columbia, publishing extensively on applied aspects of memory, fatigue, and efficiency. He then was a professor of psychology and education at George Peabody College for Teachers until joining the Army in 1917 and serving with the rank of Lieutenant Colonel on the Committee for Classification of Personnel. This work (Strong 1918) foreshadowed his later achievements in personnel classification. After the war, he joined the nascent business psychology program at Carnegie Tech, and then, when that program dissolved, was recruited to Stanford University's psychology program in 1923 by ► [Terman, Lewis M.](#) In 1925, Strong became one of the first psychologists to have a primary identification with business education when he joined the newly formed business school at Stanford, from which he retired in 1949.

Major Achievements/Contributions

Strong's approach to psychology was bedrock empirical and highly quantitative, and he wrote for the practicing professional rather than for the academic community. Though his work was downplayed at first by academic psychologists, its practical usefulness carried the day and his influence became ubiquitous in American commercial practice. In advertising, the theory often associated with Strong (1925) and summarized by the mnemonic AIDA (Attention, Interest, Desire, Action), though now acknowledged as a simplification, persists

as a basic tenet of advertising education and practice. His distinction between advertising for want vs. advertising for solution (Strong and Loveless 1926) and his other early research on memorability of advertisements have been absorbed into the mainstream of consumer psychology. He was a pioneer in job analysis and to vocational curriculum theory. His largest contribution, both in volume and influence, was his synthesis of the work begun by Truman Kelley, Max Freyd, and others in developing a scale of occupational preference. Strong and his student Karl Cowdery, longtime statistician and enrollment specialist in the Registrar's office at Stanford, refined and perfected what became known as the Strong Vocational Interest Blank: Strong's definitive summary of its development and content is contained in *Vocational Preferences of Men and Women* (Strong 1943). The SVIB provided the theoretical grounding for much modern testing theory: Its underlying factorial structure was a starting point for the development of factor analytic assessment methods, and its empirical criterion-keying methodology was instrumental as a model for, among other tests, the Minnesota Multifactorial Personality Inventory. Strong, it is said, worked on the statistics of the SVIB every evening, and his involvement with its revision continued well after his retirement. The SVIB, extensively revised since its inception, remains one of the best-known and most-utilized psychological tests.

Another initiative of Strong's, though not as well known among psychologists, deserves notice because it was an instance of psychology mediating between high level social policy and the lowest common denominator of popular social ignorance. In 1929, the Carnegie Foundation, then headed by the former Columbia dean Frederick Keppel, who had a longstanding interest in the problems of immigrant assimilation and education and a particular interest in these issues in Asian American populations, commissioned a study at Stanford of the vocational and educational characteristics of second-generation Japanese Americans. Strong headed this work, which took several years and resulted in several publications by Strong and his students, several of whom were themselves members of minority groups. The summary of this work, *The Second Generation Japanese Problem* (Strong 1934) is, in light of the subsequent fate during the Second World War of the population which Strong and his coworkers showed to

be superior to “native Californians” in honesty, trustworthiness, education, and law-abidingness, an ironic comment on the effectiveness of psychology in its social context.

Structuralism

RAND B. EVANS

East Carolina University, Greenville, NC, USA

Introduction

Structuralism was a systematic, experimental, introspective psychology of the late nineteenth and early twentieth centuries. The term is typically identified with the systematic psychology of Edward Bradford Titchener (1867–1927). Titchener’s structuralism used analytical introspection as its primary method for most of its existence to reduce complex mental states to the simplest elemental mental processes that appear in consciousness. It explained those processes in terms of the physiological processes of the organism. The final form of Titchener’s psychology, called by him and his school “existential psychology,” diverged from the earlier elementistic form and used phenomenological description rather than analytical introspection and making no attempt at explanation. There is some question whether this last form of Titchener’s psychology, roughly between 1921 and 1927, should be called “structural” at all (Evans 1972).

The term “structuralism” has sometimes been used to describe the early psychological thought of Oswald Külpe, primarily the positivistic psychology he presented in his *Grundriss der Psychologie* (Külpe 1893). It was Külpe who introduced Ernst Mach’s positivism to Titchener while they were in Wilhelm Wundt’s Institute in Leipzig, Germany. Külpe’s early enthusiasm for Mach’s ideas soon waned, however, and the *Grundriss* did not appear in another edition.

The term is also used, though incorrectly, to refer to the psychological system of Wilhelm Wundt. While both Titchener and Külpe based their psychologies on the framework of Wilhelm Wundt’s psychological system, they differed fundamentally from Wundt in their assumptions and methodology.

Neither Külpe nor Titchener used the term “structuralism” to refer to their psychological positions. Titchener called his position “structural psychology” when making a comparison with functional psychologies. He called it “experimental psychology” when comparing his position to the nonexperimental “empirical psychologies.” In its final incarnation, Titchener used the phrase “existential psychology” for his uncompleted, multidimensional systematic psychology (Evans 1972).

The term “structuralism” to stand for Titchener’s psychology appears to have been introduced by James Rowland Angell in his 1907 article, “The Province of Functional Psychology” (Angell 1907). Angell’s functionalism was structuralism’s primary competitor in the United States until the appearance of John B. Watson’s behaviorism. Ignore it as he might, the de facto name for Titchener’s structural psychology became structuralism. Titchener considered his psychology as the “perfection” of Wilhelm Wundt’s psychology, divesting it of what he considered superfluous accessory doctrines and inferences and making use of physiological explanations of the observed processes.

History

Titchener’s earliest use of his term “structural psychology” appears to be in his article, “The Postulates of a Structural Psychology” (Titchener 1898). It is in this article that he justified a structural psychology as one of three fundamental approaches in psychology analogous to similar approaches in

biology. Titchener borrowed this view from Hermann Ebbinghaus's comparison of psychological approaches with different approaches in biology. Ebbinghaus argued that biology has morphology (anatomy), physiology, ontogenetics, and taxonomy (Ebbinghaus 1897, pp. 161–165). The equivalents in psychology as Titchener interpreted them are structural psychology for anatomy, functional psychology for physiology, ontogenetic psychology (the study of individual childhood and adolescence) for ontogenetics, and for taxonomy, parts of “descriptive psychology” that deal with classification of emotions, instincts, temperaments, and similar topics. “Descriptive psychology” and “empirical psychology” were for Titchener pejorative terms used to compare his structural, experimental psychology to nonexperimental, philosophical psychologies. Titchener was so confident his elementistic introspective method was sufficient to the task of an experimental psychology, he boasted in his 1899 article, *Structural and Functional Psychology*:

- ▶ Give me my elements, and let me bring them together under the psychophysical conditions of mentality at large, and I will guarantee to show you the adult mind, as a structure, with no omission and no superfluity. (Titchener 1899)

Beyond the superficial framework of Wilhelm Wundt's psychology, Titchener's structural psychology was influenced most by positivism, not only the overt positivisms of Ernst Mach, Richard Avenarius, and Oswald Külpe but also the influences of the more implicit forms of positivism found in the writings of George Berkeley, David Hume, James Mill, John Stuart Mill, Herbert Spencer, and William James. He was also influenced by the evolutionary views of Thomas Huxley and Francis Galton. While Titchener did not accept all or even most of the positions of any of these thinkers, they all played a role in the form his structural psychology would take.

Titchener was attracted to Wundt's psychology in part because Wundt approached mind as the sum total of ideas obtained through sensory experience rather than treating mind as a real, substantial entity, like a soul. Titchener rejected any sort of psychology that smacked of the powers and faculties of a corporeal soul, a real unit-being.

Titchener was also attracted to Wundt's laboratory. Titchener had encountered James Mill's *Analysis of the Phenomena of the Human Mind* (Mill 1829) while at Oxford. Mill described the process of analyzing a complex experience into its smallest, elemental components. Titchener later recalled that “The conviction flashed upon me – ‘You can test all this for yourself!’ . . .” (Titchener 1909, p. 96) Wilhelm Wundt, in his *Grundzüge der physiologischen Psychologie*, demonstrated that one could do this sort of analysis in a scientific laboratory and at Leipzig, Wundt had such a laboratory. Titchener was accepted into Wundt's Leipzig laboratory but, since he had no laboratory experience, he spent the year after receiving his undergraduate degree in the Oxford physiological laboratory of John Scott Burdon Sanderson.

Burdon Sanderson instilled in Titchener a reverence for laboratory methods. It also brought him to the view that physiology was the necessary explanatory principle for the processes of consciousness. Wundt, on the other hand, sought to explain the “facts of experience” primarily in terms of lawful relationships among psychological processes rather than in physiological terms. Wundt had one foot in science and another in philosophy. Titchener came to Leipzig for experimental, scientific, and systematic psychology. His background and views made him an unlikely Wundtian. What Titchener would take away from Wundt's laboratory was the superficial framework of Wundt's systematic psychology not the underpinnings of Wundt's philosophy.

At the same time, although he had gained much from his study of mental and moral philosophy at Oxford, by the time he left for Wundt's laboratory in 1890, Titchener had become disillusioned with major aspects of the British associationism of his day. This was due to their use of logical concepts to stand for processes that could be or should be directly observable.

It was Oswald Külpe, then serving as Wundt's assistant and Dozent, who introduced Titchener to the positivism of the German physicist and philosopher of science, Ernst Mach. Külpe taught the course in experimental psychology that Titchener attended. It was Mach's thought and to a lesser degree, that of the German philosopher Richard Avenarius, that influenced Titchener in his divergence from Wundt's ideas. Mach's positivism taught, among other things,

that one has no need for doctrines or inferred processes to analyze mental phenomena because everything one needs is available to direct, conscious observation (Danziger 1979; Watson and Evans 1991, p. 394).

Titchener's source for the ideas of Mach was Oswald Külpe and the initial format for Titchener's systematic psychology was Külpe's *Grundriss der Psychologie* (1893). Külpe began writing the book while Titchener was at Leipzig. It was considered something of a group effort, at least as discussed around the table where Titchener, Külpe, and a few others from Wundt's laboratory ate together.

In the Fall of 1892 Titchener was appointed assistant professor, not in a department of psychology, but in the Sage School of Philosophy at Cornell University in the United States. In 1895, however, Titchener was promoted to professor of psychology in the new Department of Psychology and head of the department.

Külpe's *Grundriss der Psychologie* was published in 1893, the year after Titchener arrived at Cornell University. Titchener translated Külpe's book as *Outlines of Psychology* (Titchener 1895) and used it in his classes starting in 1895 while preparing his own positivistic psychology, *An Outline of Psychology* (Titchener 1896) published the following year. These two books share a similar plan and the same Machian positivistic point of view, although they differ in detail. Külpe's book certainly counts as a founding document of what became known as structuralism. For all practical purposes, however, what would be known as structuralism became synonymous with Titchener's psychological views.

Basic Concepts and Development

Titchener's structural psychology can best be understood by following its development across the 35 years of his professional life. That development can be divided into three stages: The positivistic reformulation of Wundt's psychology, roughly 1893–1898; the establishment of an independent structural, elementistic psychology, roughly 1899–1915, and the reformulation of Titchener's structural psychology into an increasingly phenomenological, multidimensional descriptive psychology, roughly 1915–1927. The final stage was left incomplete at the time of his death in 1927.

Stage 1: The Positivistic Reformulation of Wundt's Psychology

The first stage is exemplified in Titchener's *An Outline of Psychology*, in its three editions of 1896, 1897, and 1899 (Titchener 1896; 1897; 1899a) and in his *A Primer of Psychology*, first published in 1898 and revised in 1899 (Titchener 1898; 1899b). These early books, particularly the *Outline*, form the first draft of Titchener's structural psychology and remained the core of that psychology through most of his career. Because Titchener's *Outline* is at the core of the structural system, it will be covered in detail and then the alterations on that initial system in later publications will be considered.

Wundt's psychological system dealt with consciousness from the perspective of an active will. Wundt's approach sought an alternative to the passive, static mental structures of the British Empiricists and Associationists. Underlying Wundt's system were his doctrines of apperception, creative synthesis, and psychic causality. These all were processes that involved the active participation of the will. Wundt's psychology, known as voluntarism, made use of these doctrines and other hypothesized psychological processes to explain observed facts. Wundt sought psychological laws to explain the processes of consciousness rather than looking to the underlying physiology for explanations (Blumenthal 2001). Titchener, following a positivistic approach, rejected to one degree or another all of Wundt's inferred processes and replaced them where replacement was possible, with directly observable processes. He replaced Wundt's mentalistic explanations with those pertaining to the physiology of the nervous system.

Titchener tried to steer a middle course between the German idealism of Wundt and the logical constructions of the British empiricists and associationists. Titchener sought, on one hand, to avoid Wundt's use of non-observable inferential concepts. On the other hand, he did not want to be guilty of the flaws he saw in British empiricism and associationism. One flaw was in their use of hard logical concepts, "things," rather than actual mental processes as their fundamental units. Another was their substitution of logic for observable processes. Titchener's system evolved gradually over his entire career, often discarding earlier ideas and adding new ones as his ideas progressed. Titchener's

structuralism differed depending on the stage of its development being considered.

Titchener showed his attempt at a middle course between the British associationism and Wundt's voluntarism in the first edition of his *An Outline of Psychology*. Titchener introduced the book with the statement:

- ▶ The general standpoint of the book is that of the traditional English psychology. The system which is outlined in it, however, stands also in the closest relation to that presented in the more advanced treatises of the German experimental school, Külpe's *Grundriss der Psychologie* (*Outlines of Psychology*) and Wundt's *Grundzüge der physiologischen Psychologie* (*Foundations of Physiological Psychology*) (Titchener 1896 p.vi).

Titchener defined psychology in his *Outline* as the "science of mental processes." A process as an object of scientific knowledge is not a "thing." A "thing," he said, is "permanent and relatively unchanging, definitely marked off from other things." A process is "a continuous operation, a progressive change, which the scientific observer can trace throughout its course." Psychology, according to Titchener, "always deals with processes and never with things" (Titchener 1896, p. 5). "The elements of consciousness," as he defined them are always processes. By "mental process," Titchener followed Mach and Avenarius, in defining it as experience that is dependent on the experiencing individual. The objects of the physical world exist whether or not there is an experiencing organism present, that is, they exist independent of an experiencing organism. Ideas, feelings, and other "subjective" experiences are dependent on an experiencing organism. So, 440 Hz is a frequency of sound, a fact of physics and thus independent of the experiencing organism. Our experience of the musical note A produced by a 440 Hz stimulus, for instance, is a mental process dependent on the experiencing individual and cannot exist without the individual experiencing it. Mind, Titchener defined as the "sum total of mental processes experienced by the individual during his lifetime" (Titchener 1896, p. 10). The graphic illustration Titchener used in the book to accompany this definition was derived from William James's stream of thought metaphor although Titchener referred to it initially as a stream of mental

processes to keep his terminology consistent. He represented consciousness, the "conscious present," as a cross section of the stream of mental processes.

To Titchener, the simplest mental processes people ordinarily encounter, what he called "concrete processes," are perceptions, ideas, and feelings. These concrete processes are, in fact, complex but appear simple to the ordinary person in "real life." The aim of psychology, according to Titchener,

- ▶ ...is threefold... (1) to analyse concrete (actual) mental experience into its simplest components, (2) to discover how these elements combine, what are the laws which govern their combinations, and (3) to bring them into connection with their physiological (bodily) conditions. (Titchener 1896, p. 15)

To Titchener, all science begins with analysis. Psychology is no exception to this rule. The psychologist's first object, he held, is to ascertain the nature and number of the mental elements, which he defines as "... those mental processes which cannot be further analyzed, which are absolutely simple in nature, and which consequently cannot be reduced, even in part to other processes" (Titchener 1896, p. 13).

The second step is to synthesize the elementary processes together to form the original "concrete" experience again.

- ▶ When we have analyzed a complex into the elements a, b, c, we test our analysis by synthesis, putting the components a, b, and c, together again, to get the whole complex again. If the complex can be restored, the analysis is correct, but if the combination of a, b, and c does not give us back the original complex, the analyst has failed to discover one or more of its ingredients. (Titchener 1896, p. 14)

In Titchener's psychology, every mental process is connected in some way to a bodily process. "We do not know anything of mind apart from body. Mind and body, that is, always go together in our experience" (Titchener 1896, p. 16).

Apperception and Attention. The method by which this analysis is obtained is introspection. Titchener viewed the introspective method simply as direct observation in the same way as it is in the physical and biological sciences. Experiment, to Titchener, was observation under certain methodological controls.

Wundt's doctrine of apperception was the process through which the will brings some aspects of consciousness into focus (*Blickpunkt*) making the portion apperceived appear clearer or more intense than other processes occurring at the same time at its fringe (*Blickfeld*). Wundt also used apperception as part of the process of creative synthesis by which complex mental states are formed. Titchener considered Wundt's concepts of apperception and creative synthesis to be functional and not structural concepts (Watson and Evans 1891, p. 291). Titchener avoided the term "apperception" except in one specific situation. He used attention to do much the same thing as apperception but described it in structural terms, that of the mental contents of sensations and affections, rather than in terms of an active will. Titchener described attention as follows:

- ▶ Attention . . . has two sides, an inside and an outside. Looked at from the inside, attention consists of a certain well-marked phase or aspect of the stream of consciousness; or mental processes when we are attentive, are in a different state from our mental processes when we are not attending. Looked at from the outside, attention consists of a certain attitude of the body, and especially of the head. The problem that attention sets us is, therefore, twofold: we must describe and explain the state of consciousness, and we must describe and explain the bodily attitude. (Titchener 1896, p. 74)

In consciousness, attention, like Wundt's apperception, has a clear central focus and a less clear fringe or field. The part of consciousness that is at its focus appears clearer or more intense than the rest of consciousness at that moment and relegates the rest to less clearness or less intensity. This is essential for the analysis of a mental complex into its simplest components because it isolates one component from another in a complex experience.

The term apperception is not mentioned at all in the first two editions of Titchener's *Outline*. In 1910, in the second stage of the development of his structural psychology, Titchener separated off "clearness" as the structural product of the process of attention and made it an attribute of sensation (Titchener 1910).

Titchener considered the main states of consciousness to be attentiveness and inattentiveness and

described two kinds of attention, passive and active. Passive or involuntary attention exists when the focus of attention is drawn involuntarily to a sensory process because of its intensity or suddenness or the degree to which it aroused a pleasant or unpleasant affective experience.

Active attention is the maintenance of the focus of attention on a given idea or sensation or situation. Maintaining active attention is difficult for any length of time and tends to fluctuate. There are competing experiences, each vying with the one we are trying to keep at the focus of our attention. Over time, however, active attention may lapse into something like reflexive passive attention. That occurs when we become highly interested in what we are focused on in active attention. In that case, called secondary passive attention, the focus is held on a process to the exclusion of other competing processes just as involuntary, passive attention is evoked by a loud or sudden noise. Getting "lost" in reading an interesting book or so drawn into a problem or puzzle that the rest of the world is shut away is an example of this secondary passive attention (Titchener 1896, pp. 126–134).

When we attend to a complex like a perception or idea, changes occur in that idea and in the other ideas that are in consciousness at the same time.

- ▶ The idea attended to becomes clearer and more distinct. If I am listening to a four-part chorus, and suddenly give my full attention to the tenors, the tenor part stands out distinctly from the whole mass of sound. It does not become stronger, louder; but its tone qualities are detached from the tone qualities of the other parts. (Titchener 1896, p. 132)

Externally, there are bodily attitudes that are also related to attention. There is a:

- ▶ . . .brace of the whole body; the muscles are tense, ready for movement. More especially is there muscular tension in and about the head. If the object of attention is visual, the eyes are fixed steadily upon it, the eyebrows lowered, the scalp muscles tightened, the head settled squarely back upon the shoulders. If its object is auditory, the head is turned toward one side and thrust forward, the muscles which move the drum of the ear drawn taut, etc. In both instances the breath will be held, from time to time. All this means a complex of

sensations from skin, muscle, sinew and joint, and an accompanying affection. It means an experience of effort. . . . (Titchener 1896, p. 129)

Titchener used the term “kinesthetic senses” for these sensations from muscles, tendons, and joints.

The physiological basis for attention, he admitted, was not definitely known. He hypothesized, however, based on what was known in physiology at the time that there

- ▶ . . . is facilitation or reinforcement of cerebral function on the one hand (the idea attended to becomes clearer or stronger); there is widespread inhibition of cerebral function on the other hand (the remaining ideas grow dim and weak). (Titchener 1896, p. 133)

Titchener identified attention with feeling processes. “It is only when we attend to impressions that we feel them to be pleasant or unpleasant. Impressions which are not attended to are indifferent” (Titchener 1896, p. 133). The significance of this connection of attention with feeling is that it explains why one cannot direct attention to feeling experiences. When it is tried, the feeling (affective experience) disappears.

A key issue in Titchener’s views on attention was that while the ability to maintain active attention comes about naturally, it also can be developed or improved by training and education. The observer can be taught to call up secondary passive attention habitually, allowing the observer to be “naturally” attentive to certain aspects of consciousness over others. This training of attention became essential in the training of introspective observers.

It is attention that allows for the analysis of complex mental states into simpler mental states. Just as one can attend to a tenor section in a four-part choir and hear the tenor line become clearer while the other parts fade into obscurity, so one may attend to the various parts of a musical cord, like the musical C major and parse out its C, E, and G components. That is the essence of analytical introspection to Titchener (1896, p. 132).

Elements. Through the method of analytical introspection, Titchener was able to reduce the complex “concrete” perceptions and ideas of everyday life down to their simplest sensory components. At the simplest level, the elementary processes (elements)

Titchener listed in the first edition of his *Outlines of Psychology* (1896) were the same as those of Wundt: sensations (both those aroused externally and those aroused internally) and affections (called feelings in Wundt’s system). Sensations come by way of sensory receptors, whether they are external receptors such as the ear, skin, nose, eyes, and tongue, or those receptors internal to the organism such as those of the muscles and tendons and those of the esophagus, stomach, and intestine. Whether the receptors receive stimuli from outside the organism or from internal physiological structures, they are “external” sensations.

Titchener similarly held that there are also internally aroused conscious processes (experiences) paralleling externally aroused sensations that come by way of memory and imagination rather than from the stimulation of sensory receptors. For every sensation produced by external stimulation of sensory receptors, there is an equivalent internal imaginal process. These equivalent internal states differ primarily in terms of intensity. Internal memory states and imaginal experiences have less intensity than externally produced sensations. This use of sensation to stand for both sensations as they are ordinarily thought of and also as images was an awkward arrangement. Only later in Stage 2 would Titchener rename these internally aroused sensations as “images,” thus changing his list of elements to sensations, images, and affections (Titchener 1910, p. 48).

Attributes. Titchener, like Wundt, held that the elementary processes of sensation and affection are abstractions and are not, themselves, directly observed. The attributes of sensations and affections, however, are directly experienced and are the way we differentiate one sensory or affective experience from another. Wundt had the same two attributes for sensation as he did for “feelings,” quality and intensity. Külpe and Titchener added two others to Wundt’s attributes, duration (time) and extent (space). Like Mach, Külpe and Titchener believed that spatial and temporal events could be observed and described just as directly and certainly as one could do quality and intensity. Spatial attributes (extent) of sensations were found introspectively in sensations of vision and touch but not in other senses such as smell, taste, and hearing.

Quality is what the individual elementary process, the individual sensation or affection, is called.

A sensory quality is, for example, blue or cold or sweet. Without quality the element cannot exist.

A quality must have some intensity. A quality of zero intensity cannot exist in consciousness. A quality also has some temporal aspect. It exists for a certain time. A quality that appears for zero seconds does not exist in consciousness.

Extent, Titchener's term for the spatial attribute, is another attribute of a sensation in which the quality exists in some spatial arrangement. One visual sensory quality may appear larger than another. The perceived sizes are spatial aspects. Sensations of vision or touch cannot exist if their extent is zero.

By bringing extent and duration in at the simplest level of the structural system as directly observed attributes of sensation, Külpe and Titchener no longer required Wundt's doctrine of creative synthesis to infer space and time out of other sensory processes (Titchener 1896, pp. 29–32).

Affection and Its Attributes. Titchener used the term "affection" instead of Wundt's "*Gefühle*" or "feelings" as the name of the elementary emotional state that is at the introspectively simplest level of his system, at the same level of sensations. Affections accrue, that is, attach themselves to sensations whether the sensations are from internal or external sources. Affections accrue not to just simple, elementary processes but also to complex processes, the ideas and perceptions, into which the simpler states combine. Affections do not come from any specific organ, unless one wishes to consider the whole body as its "organ."

Titchener identified only two qualities for affections, pleasantness and unpleasantness. They are separate qualities but are on the opposite ends of an intensive continuum of affective experiences running from pleasant through indifferent to unpleasant. "Indifferent," is a neutral point, an experience which is neither pleasant nor unpleasant. Titchener and Külpe added duration to Wundt's quality and intensity in the list of attributes for affection since the qualities, if they are present, must exist for some finite time (Titchener 1896, pp. 92–101).

Titchener recognized that the analysis of emotional states into simple affective qualities, intensities, and durations was more difficult than with sensations. He believed other methods, specifically physiological methods, could be used to supplement introspective

analyses. Every feeling, he said, "has various bodily manifestations ... so that we can follow the course of a pleasure or disagreeableness by noting its physiological symptoms."

- We find that pleasantness is attended (1) by increase of bodily volume, due to the expansion of arteries running just beneath the skin; (2) by deepened breathing; (3) by heightened pulse; and (4) by increase of muscular power. (Titchener 1896, p. 103)

Unpleasantness, he found, was accompanied by the opposite, "lessened volume, light breathing, weak pulse, and diminished muscular power" (Titchener 1896, p. 103).

By recording these physiological manifestations with specialized instruments and bringing the subject into situations calculated to call up differing degrees of pleasantness and unpleasantness experimenters can determine from the changes in the records how the subject has felt from moment to moment of the experiment. In these situations, Titchener held that introspection may be "altogether unnecessary" (Titchener 1896, p. 103).

Since, to Titchener, the simple affective experiences parallel underlying bodily processes, he suggested that "pleasantness" results from "the building-up process (anabolism)" and "unpleasantness" from the "breaking down-process (catabolism)."

So, at the first, introspectively simple, level of the structural system are the elements of sensation (whether obtained through stimulation of sensory receptors or from internal processes of memory or imagination) and of affection. The elements are abstractions, categories. It is the attributes that are directly observable. It is through the attributes that the sensory and affective elements are defined and discriminated. Titchener estimated that there were 42,415 distinguishable elementary sensory qualities, more than half of which come from vision.

Perceptions, Ideas, and Feelings. After analysis, Titchener's aim for psychology was synthesis to discover how these elements combine and the laws of their combination. Elements and their attributes are the products of introspective analysis. It is the "concrete states," the perceptions, ideas, and feelings, that are immediately and directly observed in everyday life.

The way we get these concrete mental states in the first place, according to Titchener, is by means of association. His explanation is reminiscent of George Berkeley's explanation of how we perceive an object. It makes use of association by contiguity just as Berkeley used "constant connexion." Titchener said that perceptions and ideas are formed in everyday life by clusters of sensations occurring together as the result of the patterns of stimulation of sensory receptors due to stimulus events in the world around us. Titchener explained, "What the organism finds together in the world in which it lives . . . remains together in perception or idea . . . All the connections set up between sensations by the formulation of ideas tend to persist, even when the original conditions of connection are no longer fulfilled" (Titchener 1896, p. 208). These connections are associative but differ from the association of ideas as formulated by the British associationists. In Titchener's view, "it is not ideas which 'associate' but the elementary processes of which ideas are composed" (Titchener 1896, p. 190). Stated another way, objects or events in the outside world produce recurring patterns of stimuli that, in turn, activate our sensory receptors. These recurring stimulus patterns produce recurring patterns of sensory attributes. These attributes, such as qualities, are bound together by association and form those "concrete" perceptions or ideas. So, if the pattern of stimuli on the receptors of the organism produces sensory qualities of abcd, those four qualities become bound together and produce a perception, which comes to appear simple in everyday experience. At the same time, traces of that perception persist as an idea, a memory image and are called up to supplement other patterns that share all or part the abcd pattern and give them context and meaning.

- ▶ Factors that produce greater stability of the connection of these combinations in consciousness include frequency of the association in the outside world, recency of an occurrence and pleasantness or unpleasantness of an event that holds attention. Recency of the occurrence can give the same power of connection that it would have gained by frequent repetition. There is also our "mental constitution," our individual mental set, personality or mental attitude that "decides what shall be the line of least associate resistance." (Titchener 1896, p. 210)

By presenting the associations that form the "given," concrete level of perceptions and ideas as an association of attributes of sensory elements, Titchener was able to use the concept of association but avoided the logical baggage and the association of "things" of the traditional associationists.

Titchener held that individual "bare" sensations are, themselves, without meaning. They acquire meaning when combined together with other sensations to form ideas. To Titchener, meaning always involves context:

- ▶ My idea of lemonade is predominantly an idea of taste. But taste alone could not give me an idea of lemonade; there must be added to the taste qualities, sweet and acid, a pressure, a scent, a colour, a movement of gas-bubbles, etc. (Titchener 1896, p. 150)

Titchener often used the terms perception and idea as equivalents since he considered them the same except for their source. Perceptions come from externally derived sensations and ideas from internally aroused sensations, later to be called "images."

"Lemonade" was the name, the meaning, of the flavor complex of sensory qualities bound together by association and dealt with in ordinary experience as a single simple experience. The meaning is produced by the cluster of sensations, externally aroused (sensations) and internally aroused (memory images) providing context and giving the constituents of that "flavor"; taste, smell, touch (cold and pressure), its meaning of "lemonade." The images are essential. If someone has never had lemonade before, it would be a "pure perception" and, even though experienced as a single, simple experience, might not have a meaning in itself. If one has had lemonade before, however, the memory image, the idea, of the prior experience would connect with, in Titchener's terms, "supplement," the new perception and give it context. If something is missing in the complex, the flavor and its meaning may be lost with it. For instance, if the perception is of a fresh carbonated drink like a fresh, cold cola, its "flavor," a perception, would be made up of taste (sweet), smell (resinous, floral), and touch (cold, pressure, pain). The pain is very slight and is produced by the bursting of carbon dioxide bubbles on the tongue and back of the throat. That is the "sparkle" of a carbonated beverage. The idea of sparkling cola

remains as a memory image after the perception has ceased. If we drink from another bottle, one in which the carbonization has been lost, everything else in the complex will be present except for the slight pricking pain. In this case, the meaning would not be the same. Instead of the flavor having a meaning of “sparkling cola” the pattern would produce, perhaps, a flavor with the meaning “flat cola,” if we have experienced a “flat cola” before and associated a name with it. The first experience someone has with lemonade or sparkling cola may be meaningless until it has been repeated and associated with a name. The context created by the perceptual complex and the memory images of lemonade or something similar to lemonade would combine and give meaning to the whole.

So, Titchener, concluded that we can

- ▶ ...express the law of association by the formula *ab* – *bc*. One idea calls up another when it contains elements which are common to it and that other. Connections once formed (*bc*) tend to persist even when the conditions of their formation are not realized (when only *ab* is given).

...All connections set up between sensations by the formation of ideas tend to persist. It is the business of psychology to discover under what conditions they actually do persist. ... (Titchener 1896, p. 210)

The meaning “cola” might be maintained even though its flavor is experienced as “flat” rather than “sparkling.”

Titchener presented ideas and perceptions as taking three forms, qualitative, temporal, and extensive, depending on whether they involve combinations of qualities, durations, or extents. Qualitative perceptions are made up of two or more simple sensory qualities. A musical chord or “clang” is an example. It is a combination of certain simple musical notes. The C major chord is produced by sounding the musical notes C, E, and G together. These physical stimuli excite auditory receptors and produce simple sensory qualities. The three notes blend into a complex that Titchener referred to as a “clang” which, if the notes are sounded evenly, will bond together and be experienced as a simple whole. Even without training, many people can listen to a C major chord and analyze out the three simple notes, C, E, and G that make it up, and may also be able to sound those three notes. If one has heard the

three notes sounded individually and then as a chord, the analysis becomes much easier because the images of those notes are part of our mental makeup. This helps one focus attention on one or another of the components and they will stand out from the others. One by one each can be analyzed out.

Temporal perceptions or ideas are made up of two or more sensory qualities in some temporal sequence. Rhythm is a temporal perception or temporal idea made up of some sensory quality in a temporal pattern.

Extensive (spatial) perceptions or ideas are produced by the combination of some sensory quality or pattern of qualities in a spatial context. Spatial perceptions include position, movement, and rate of movement. In localization, Titchener used the term “local signs” to indicate a complex process of sensations that produce an experience of “place” on the skin (Titchener 1896, p. 157). He did not use it in the meaning of an innate ability. The ideas of form and magnitude are produced by the association of clusters of sensory qualities. Once combined into the idea “form” or the idea “magnitude,” they appear to be simple, unitary processes. Melody is made up from both qualitative and temporal perceptions or ideas. There are many more of these kinds of ideas and perceptions at this first, “concrete” level of perceptions.

Each of these perceptions or ideas carries with it some feeling of pleasantness, unpleasantness, or indifference. When these affective processes are part of a complex but do not predominate in the overall experience, we call the experience a perception or idea that is pleasant, unpleasant, or indifferent.

The combinations of processes do not stop at this second level of perceptions and ideas. In fact, as Titchener pointed out, again using perception and idea indiscriminately:

- ▶ When once an idea has taken shape – whether it be the idea of locality or of rhythm, of form or of melody – it is henceforth at the disposal of consciousness as a whole, as a total process. There is no need of its conscious reformation. However slowly we may have learned the fact that objects lie in space at a distance from us, and however many mistakes we made before the idea of distance was fully formed, we now have it as part of our mental furniture, ready for use upon all occasions. (Titchener 1896, p. 193)

Titchener discussed three forms of associations, simultaneous, successive, and supplementary, as relevant to this psychological process. He introduced these with an example:

- ▶ Suppose that I am sitting in my study, and find my train of thought suddenly interrupted by the perception of a loud rumbling noise. The perception . . . may call up in my mind the vague picture of some heavy vehicle on the street below my window; and if, earlier in the day, I have seen a traction engine somewhere in the neighborhood, this visual picture may be made definite, and further connected with the verbal idea, “traction engine.” There is no appreciable lapse of time between the original sound perception and the appearance of these other ideas: the noise is no sooner heard than picture and word are together with it in consciousness. In such cases we speak of a *simultaneous association*. (Titchener 1906, p. 189)

In some circumstances, this may be entirely of the situation. The sound pattern has pulled together several other patterns that were associated with the same or similar sound earlier in the day. A simultaneous association is made up of the same components as a perception or idea. In introspective analysis, they are both made up of “complexes of sensations” and they differ in that the idea is simpler than the simultaneous association because:

- ▶ . . . the elementary processes in the idea [or perception] are processes which have never before been in connection with others, whereas the elementary processes in the simultaneous association of ideas have already played a part in some idea. (Titchener 1896, p. 192)

So, Titchener is saying that if you hear a pattern of sound you have never heard before, this is a simple perception or simple idea. It has no meaning and does not call up associations since there are no images in memory. If, however, the sound or something similar to it has occurred in our past experience in combination with visual or other sensory complexes, the recurrence of the sound later on will call up the memory images that were part of the earlier sensory complex and give the meaning “traction engine.” The sound may call up the visual image of the traction engine as well or it may call up the verbal name and other associated components of the earlier experience.

The idea of the traction engine may also arouse a serial chain of other memory images, such as an accident witnessed in the past and that may lead to another image of a man encountered at that accident, and so on. This serial chaining is also called successive association as exemplified in the famous description by James Mill:

- ▶ I see a horse: that is a sensation. Immediately I think of his master: that is an idea. The idea of his master makes me think of his office; he is a minister of state: that is another idea. The idea of a minister of state makes me think of public affairs; and I am led into a train of political ideas . . . (Mill 1829, pp. 52–53)

This is the same process Titchener outlined as his “theory of learning,” $ab - bc$. The difference between Mill and Titchener’s association was that with Titchener it was made up of attributes of sensations or images that were bound together by association not fixed “things.”

The third form of association is a subform of simultaneous association, associative supplementing. Titchener wrote that

- ▶ “When once an idea has taken shape, whether it be the idea of locality or of rhythm, of form or of melody, it is henceforth at the disposal of consciousness as a whole, as a total process. There is no need of its conscious re-formation.” (Titchener 1896, p. 193)

Once a perception or idea is formed it is now part of our “mental furniture,” according to Titchener. When a complex of stimuli is presented to consciousness as a perception, some aspect of one or more of these existing ideas is called up which joins to the complex and supplements it. Titchener demonstrated the process as follows:

- ▶ Here we have a complex of sensations abc , some or all of which have been connected, in past experience, with other elementary processes, xyz . Hence, whenever ab or abc appears, xyz tends to appear with it.

The individual sensory attributes do not have meaning in themselves, but when combined together they acquire meaning by the context of the other attributes in the cluster. (Titchener 1896, p. 208)

An example of this kind of supplementing is found in our idea of the distance of an object from our body.

- ▶ This idea [of distance] was originally formed from sensation processes, whether sensations of strain from the muscles of the eyeball or retinal sensations, or both together. As bare sensations, these processes were meaningless; they acquired significance only when combined in the idea.

But when we are judging distance, in adult life, we are not concerned to notice the formative sensations of the original distance idea. An object is before us, and our perception of it is an object that is at once associatively supplemented by the idea of its distance. Thus . . . if the object is small, we regard it (other things being equal) as remote: the smaller a thing looks, the farther off must it be. The idea of size is here associatively supplemented by that of distance. (Titchener 1896, p.194)

Titchener treated the other associative processes in a similar fashion creating more and more complex perceptions and ideas.

In this case, the individual “units” were whole perceptions or ideas and not just attributes of sensations. So, to Titchener, complex processes can combine as units with other complex processes which can form even more complex units and processes. As these combinations become more complex, new meanings arise. This newness of meaning at each combination and at each stage is the process that sets Titchener’s associative process apart from mental compounding like that used by James Mill and the British associationists going back to John Locke. The meanings become something like the productive consciousness of John Stuart Mill’s “Mental Chemistry.”

Affective Components of Complex States. These perceptions and ideas also have affective components that accrue to them. The C major chord may evoke a pleasant feeling; a discord such as CDE may evoke an unpleasant feeling. In the same way, the memory of the sound of fingernails scratching a blackboard may call up an unpleasant feeling like that which accompanied it originally.

At the level of complexity that includes perceptions and ideas are complex affective states. While ideas can stand alone without affections, affections cannot stand alone without sensations or ideas. Titchener used the term “feeling” as the complex affective experience at the second level of complexity occupied by perception

and idea. “Feeling” was, to Titchener, “the mixture of perception and affection in which feeling preponderates.” Recall that he defined a “pleasant perception” as a perception in which affective qualities do *not* predominate. If the feeling does predominate, then it is called a “feeling of x” in which “x” is the name of the complex perception to which the feeling has accrued. There are only two kinds of feelings, pleasant and unpleasant, because they are related to the qualities of affection, pleasantness and unpleasantness (Titchener 1896, p. 214).

Emotion. Emotions are, in the affective track, at the third level of complexity, one step up in complexity from the “concrete” experiences of perception, idea, and feeling. An emotion, if “regarded as a single, total process has three attributes; quality (pleasantness and unpleasantness), intensity and duration.”

- ▶ On the side of sensation, consciousness advances beyond the stage of a patchwork of perceptions or ideas; the factors in different ideas run together and form larger wholes, each of which corresponds, not to an object or process, but to what we may call a *situation* or *incident* in the physical world. On the side of affection, consciousness advances beyond the simple feeling to the emotion. The organism does more than “feel cold” and “feel unwell”: it feels the pleasantness or unpleasantness of a certain total situation or predicament, of the whole complex of ideas which represents a certain concurrence of processes or collocation of objects in the outside world. (Titchener 1896, p. 219)

As an example Titchener goes back to his example of the rumbling sound that is associated with the heavy machine or wagon. This time, however, the rumbling noise is accompanied by a shrill scream. He wrote that

- ▶ these ideas are supplemented by the ideas of a child and a wagon; and the whole complex of ideas suggests at once that an accident happened. On the other, this accident is felt, in its totality; we have the emotion of pity or of fear. (Titchener 1896, p. 219)

Emotions have two classes, pleasurable and unpleasurable. This is the same arrangement as is found in the “feelings” and in the simple affections. Unlike the simplicity of simple affections, there are in

emotion a large number of “special feelings.” Emotions can be divided into “emotions of the present” and “emotions of the future.”

- ▶ Thus hope is an emotion of the future, which may become an emotion of the present in the form of satisfaction (hope fulfilled) or disappointment (hope unfulfilled) or despair (hope deferred) or relief (fear unfulfilled) or suspense (fear deferred). (Titchener 1896, p. 222)

The physiological responses that parallel an emotional response to a “situation” are more intense than to a simple feeling. They involve not only heartbeat and breathing changes but include the “voluntary muscles, secretory organs, and other involuntary muscles.”

- ▶ Thus in fear the skin is pale, the breathing shallow and hurried, the pulse weak and irregular, and the muscular strength diminished. At the same time, the salivary glands cease to act, so that the mouth and throat become dry; the body is bathed in a cold sweat; the bladder and intestine are affected (tendency to urination and diarrhoea): while there is a “sinking of the stomach” with consequent nausea, a tremor of the whole body (shivering and goose-flesh) and an erection of the hair due to the contraction of the unstriped muscles lying beneath the skin. (Titchener 1896, p. 255)

Titchener went on to describe the bodily attitudes taken in emotional states and facial expressions that accompany emotions and the role the sensations from those bodily attitudes take in the experience of the situation.

Mood, Passion, and Temperament. Just as with perception and ideas, feelings can combine into more and more complex states. Emotions can be described in terms of their intensity and duration as well as quality.

- ▶ It may be laid down, as a general rule, that the most intensive emotions have the shortest duration, and the weakest emotions the longest

The weaker emotive states, which persist for some time together, are termed *moods*; The stronger, which exhaust the organism in a comparatively short are called *passions*. Thus the mood of cheerfulness represents the emotion of joy. The mood of depression, that of sorrow. (Titchener 1896 p. 231)

Titchener listed Mood on the same level of mental development as is the “train of ideas,” the level of complex mental processes above that of the “concrete” perceptions, ideas, and feelings.

Mood is determined by affective constitution, or as it is more usually called, *temperament*. Titchener distinguished four temperaments, choleric, sanguine, phlegmatic, and melancholic:

- ▶ The man who thinks quickly and feels strongly is choleric; the man who thinks quickly and feels weakly, sanguine. The phlegmatic thinks slowly and feels weakly; the melancholic thinks slowly and feels deeply. (Titchener 1896, p.233)

Volition. Titchener studied the will in terms of actions. He differentiated between voluntary and involuntary actions. Involuntary actions are reflexive, mechanical movements of the bodily organs; they go on whether or not we are conscious. These are entirely physiological processes and so not a part of a study of consciousness. Voluntary movements are entirely different. They arise when there are two sets of ideas in consciousness, both strongly pleasant or strongly unpleasant. The conflict is not between two impulses. It is between on one hand an impulse to act, and on the other attention to a set of ideas which do not suggest action of any kind.

- ▶ Which complex gets the upper hand, whether action or no action results, depends upon the capacity of each to hold the attention. Thus I hear my alarm-clock and have the impulse to get out of bed. The impulse is opposed by an idea of another half-hour's sleep. If the impulse-ideas, the ideas of the time, of my day's work, etc., can hold the attention, I get up. (Titchener 1896, p. 256)

Automatic action stands to volitional action as passive attention stands to active attention.

- ▶ Just as active attention may become passive, when, e.g., we grow “absorbed” in the problem before us, so may a selective or volitional action pass into a reflex like form, which is termed *automatic* action. Some particular impulse may habitually gain the victory over its rival impulses, or over the ideas which compete with it for the attention. When this is the case, the idea of movement, contained in the impulse, and the organic

sensations aroused by actual movement, gradually cease to attract notice: the whole movement becomes indifferent, and is relegated to the lower nervous centres for guidance [A] practiced piano-player sits down to play a score at sight. He has the idea of the score, and some idea of the result of his playing (he knows that the composition is a March or a sonata); but the movements of hands and fingers are automatic. At a later stage the whole action becomes automatic (Titchener 1896, p. 256)

So, automatic actions of this kind are true reflexes. They have taken their form during the lifetime of the individual. “Most of the actions of our everyday life are of a mixed character, beginning as volitional or selective, but running their farther course as impulsive or automatic” (Titchener 1896, p. 257).

Higher Mental Processes. Finally, on the idea side of the idea/feeling divide, Titchener reached the higher mental processes such as memory and imagination and cognition and finally to self-consciousness and intellection, the formation of concepts and reasoning. These yet more complicated processes involve not only complex perceptions but also complex affective states such as feeling, emotion, and mood.

Recognition. Titchener described recognition as some complex perception such as “situation” or “incident” that calls up with it a “feeling of familiarity.” Titchener gave the example of a man entering a streetcar. He “runs his eyes” over the line of faces of the people in the car. The faces, one by one, are of strangers, “their faces arouse no interest, do not arrest your gaze.” At the end of the car, however, is a face you know, you recognize him. The mental processes involved in this recognition Titchener explained as follows:

- ▶ For one thing, our visual idea of your friend was *supplemented* by a number of other, centrally aroused ideas. As you looked down the line of strange faces, your present train of ideas was not interrupted: the visual ideas were indifferent to you. But as soon as you receive this visual idea, a host of other ideas, derived from your past intercourse, flock into consciousness The first characteristic of the recognitive consciousness, in this instance, is the supplementing of the given impression by a large number of ideas. Recognition has meant the formation of a highly complex simultaneous association. (Titchener 1896, p. 252)

At the same time that the association is being formed, your mood has changed. As you entered the car you were, we will suppose, thinking indifferently upon your immediate business. When you see your friend, the mood of indifference changes to a mood of pleasantness, which we cannot describe better, perhaps, than by the phrase “feeling at home.”

The mood contains, besides the pleasant affection, a complex of organic sensations, set up by an “easy” bodily attitude. The second characteristic of the recognitive consciousness, then, is a pleasurable mood.

Putting the various components together, we have (1) The presented idea; (2) its centrally aroused supplements; and (3) the mood of “feeling at home.” The union of these three factors gives us a “recognition.” (Titchener 1896, p. 263)

Self-consciousness. At the highest level on the sensory/perceptual side of the sensory/affective divide, Titchener finally arrived at self.

- ▶ My “self” is the sum total of conscious processes which run their course under the conditions laid down by my bodily tendencies. Selfhood, that is, is the special and peculiar way in which the process of an individual mind are arranged, in which they hold together or break part, follow or accompany one another. . . . My “self” then, is my mind conceived or as working in my way. (Titchener 1896, p. 288)

Intellection. Titchener held that speech and writing are the primary signs of intellection in human consciousness. The principal medium of intellection is verbal ideas. Conceptualization and reasoning are major categories of intellection as are discrimination and abstraction. Titchener described these processes in terms of complex combinations of associative processes and centrally aroused ideas.

Sentiments. At the highest level on the affective side, Titchener discussed the sentiments. He listed four sentiments, intellectual or logical (affective experiences which grow up round the judgments “this is true” and “this is false” as a matter of knowledge), ethical (affective experiences attached to “this is good or right” or “this is bad or wrong” pertaining to my actions or those of others), aesthetic (affective experiences concerning judgments of beauty, ugliness, the sublime, the comic, and the tragic), and religious (affective

experiences concerned with whether something is or is not sanctioned by Divine command or a Divine plan (Titchener 1896, p. 306).

Mind and Body. Titchener culminated this first draft of his structural system with a consideration of “The Ultimate Nature of Mind.” He posed three questions that arise from what introspection does not reveal: (1) There is no psychological evidence of a mind which lies behind mental processes. Mind is nothing more than the mental processes. (2) There is no psychological evidence of a mental “activity,” above or behind the stream of conscious processes. (3) There is “no psychological evidence of mental continuity and coherence which cannot be met by evidence of a contrary tenor.” While he used William James’ stream of thought metaphor, he held that his selfhood lapsed every night in sleep, that there are great gaps in mental experience (Titchener 1896, 341–342).

He admitted that these three questions could not be answered by introspection or psychology or by any of the known sciences, for that matter. The mind–body relationship Titchener adopted for his explanation between the mental and the physiological in his psychological system he presented simply as “a statement of fact, not an explanation of the relation of mind and body.” It merely says “Where there is a mental process, there is also a process in a living body.” For a causal relationship, one must turn to metaphysics (Titchener 1896, p. 342).

Polishing the First Draft

Titchener’s *An Outline of Psychology* went through three editions after its first printing in 1896. A second edition appeared the year later with some minor additions and revisions and a third, thoroughly revised edition in 1899. Interspersed among these editions of the Outline was a smaller, simpler textbook, *A Primer of Psychology* (Titchener 1898a; 1899a)

In the first edition of Titchener’s *Primer* (1898a), he made use of the term “apperception” although in only one limited sense. Titchener had replaced apperception with attention in the first two editions of his *Outline* (Titchener 1896; 1897). In the *Primer*, he used apperception for a situation with which attention and association could not deal, “mental constitution.” Titchener defined his use of apperception in this case as “a perception whose character is determined, wholly

or chiefly, by the peculiar tendencies of a nervous system, rather than by the nature of the thing perceived” (Titchener 1898a, p. 88). The example he gave of these tendencies is of someone scanning a newspaper and suddenly sees the word “grapnel” in the text and it “catches his eye.” The reader goes back to see if the word was really there. There are three possibilities: First, the word “grapnel” may, indeed, be there when we look back for it. It had just “stood out” from the rest of the text. Second, instead of “grapnel,” we may find the word “grape” or similar word instead and we have filled in the rest. Third, it may be the case that the word is not in the text we were reading at all, even though we believe we saw it there. In these cases, the reader may recall he had read an article the day before on anchors, something he found interesting. Fourth, there may be a situation where the reader may not have read about anchors recently at all but had had a lifelong interest in nautical matters. In the first case, the prior exposure to the word or the lifelong interest in the subject has “drawn” the eye to that particular word. It appeared to stand out even though it was no darker or lighter than the words around it. Titchener explained that in the second and third situation, the reading of the article on anchors had thrown open certain channels of tendency, the tendency that makes you interested in ships.

► . . . So you read what is before you not as it really is, but as you see it with your mind turned into these channels. . . . You were biased or prejudiced before you opened the paper. As for the last case, the ship-tendencies were so strong there that no opening of flood-gates was needed. Your mind is set so strongly in one direction that you are likely to see everything through shipping – spectacles. You do not realize that you are biased: it seems “natural” to you that ships should be interesting. But it is just because the love of ships is ingrained in your nervous system, rather than by the nature of the thing perceived. Sometimes . . . you can tell by introspection how the channels of tendency have been opened up (by the reading of the article on anchors); sometimes, however, the tendencies are so strong in themselves, and date so far back beyond the limits of your memory, that, while you see their effects . . . , you cannot tell what it is that takes your mind in their direction on any particular occasion. (Titchener 1898a, pp. 86–88)

These tendencies related by Titchener to “mental constitution” have similarities to Narziss Ach’s “determining tendencies,” that came out of the Würzburg school after the turn of the century.

Titchener’s *Primer* (1898b) also declared that the differences between the position of structural psychology and that of functional psychology were fundamental.

Titchener added a section on thought to the *Primer* that did not appear in any of the editions of the *Outline*. Thought, to Titchener, was “the verbal counterpart of active imagination. Active imagination is thinking in images, active imagination carried on in words.” To the question whether we can think without words, he answered that at one time active imagining and thought may have been the same thing but thought in modern human’s usage requires language. His position on the necessity of images in thought would bring Titchener up against the findings of Oswald Külpe’s Würzburg school of imageless thought after the turn of the century.

Self. In his discussion of the concept of self, Titchener listed several forms. First is the “primitive perceptual self,” which is described in terms of a

- ▶ ...mass of cutaneous and organic sensations, partly of visual sensations – the whole overlaid with an affection. Your “self,” the self that you perceive at this moment, is probably composed of pressures, temperatures, strains, breaths, etc.; That is a certain comfortableness or headachiness: together with the visual perception of hands and clothes. That is *you*, as you perceive yourself. (Titchener 1898a, p. 225)

The “idea of self” Titchener described as being principally of a visual picture of one’s body and its usual surroundings.

- ▶ You see yourself seated in your accustomed chair, clothed in your usual way, busied about your usual occupations. This self-figure is seen upon a dim and shifting background made up of memory-images of past experiences. (Titchener 1898a, p. 225)

Titchener admitted that this self rarely comes to mind so definitely as this description indicates. There is also the “logical self, the bare concept of the ‘I’ or the ‘ego.’” This is, “the philosopher’s special interpretation of selfhood, i.e., for a thought-object.”

None of this explication is presented in a research-oriented way.

The third edition of Titchener’s *Outline* (1899b), which appeared after Titchener’s declaration of his structural psychology in 1898, had further revisions. It is in this edition that Titchener used the terms “structural psychology” and “functional psychology,” making the same arguments he made in his articles in 1898 and 1899. Titchener went farther in the third edition of the *Outline*, saying that the psychology of function

- ▶ is constantly attended by an intellectual danger, hardly to be avoided even by the trained investigator. The danger is this. When we have found a function, we are tempted to translate the function off-hand into terms of structure. We are likely, unless we are extremely careful, to invent a structure to carry the function. (Titchener 1899b, p. 23)

Following his statement of the difference between structure and function, Titchener stated how the “new,” structural psychology he was presenting differed from philosophy and from the speculative psychology that had emerged from philosophy. His position was that experimental psychology must be separate from philosophy. He said of his structural psychology:

1. It has freed itself entirely from the influence of philosophy (epistemology and metaphysics), and it has done this most effectively by its insistence that mind is to be examined as a *structure*, and not merely as a group of functions.
2. It has introduced experiments into the study of mental processes. It insists that psychological method of introspection shall be employed under “experimental” conditions.
3. It seeks to bring mental process into close and accurate relation to the underlying bodily process (Titchener 1899b, p. 29).

The difference in Titchener’s estimation of philosophy and speculative psychology is shown by the fact that the statement made in the preface to the first, 1896, edition of the *Outline* that the “general standpoint of the book is that of the traditional English psychology” disappeared from the preface of the third edition of 1899. Titchener took his stance with psychology as a natural science as separate from philosophy.

Stage 2: The Final Form of Titchener's Elementistic Structural Psychology

Titchener's *Textbook of Psychology*, the half of which was published in 1909 and the entire volume published in 1910, his two books of lectures, *The Elementary Psychology of Feeling and Attention* (Titchener 1908) and his *Lectures on the Experimental Psychology of the Thought Processes* (1909), and his *A Beginner's Psychology* (1915), form the culmination of Titchener's psychology as an elementistic psychology. These books reflect the maturation in Titchener's thinking over that decade but also the controversies involving Titchener's structural psychology. One might also include here Titchener's four-volume *Experimental Psychology* (1901, 1905). While it was methodological and not systematic, it contained instructions on methodological procedures and training in introspection.

The *Textbook* was written as the revision and continuation of the *Outline*. It covered the same basic information as the *Outline*, but there were some important differences.

Analysis and the Stream of Thought. In the *Textbook*, Titchener defined mind and consciousness much as he did in the *Outline* and he continued to use William James's stream of thought metaphor and illustration. In the *Textbook*, Titchener countered William James's argument against all elementistic psychologies that define the "conscious moment" as a cross section of the stream of thought. James argued that such an analysis is necessarily an artifact, since the stream is ever moving and thus not repeatable. Titchener responded that:

- ▶ In strictness, we can never observe the same consciousness twice over; the stream of mind flows on, never to return. Practically, we can observe a particular consciousness as often as we wish, since mental processes group themselves in the same way, show the same pattern of arrangement, whenever the organism is placed under the same circumstances. (Titchener 1910, p. 19)

Those "same circumstances" were provided by the methodology of experimental control. Titchener's four-volume *Experimental Psychology* (1901, 1905) outlined and demonstrated a wide variety of experimental methods by which such control can be maintained. Titchener reiterated his position that the

method of science is observation and that the method of observation found in introspection is no different from that of the other sciences. The method of the physical and biological sciences may be called inspection and that of psychology introspection, but except for the objects of their study, they are fundamentally the same.

Elements and Attributes. Perhaps the most significant changes in the *Textbook* from the *Outline* and *Primer* come at the level of elements and attributes. For the first time, Titchener overtly used the elements and attributes of chemistry as his model for the elements and attributes of psychological analysis. He had previously held elements to be abstractions and not real existences and that the attributes were the real existences, the elements being merely categories, abstractions based on those attributes. In the *Textbook*, however, Titchener appeared to change his position and say that the elements of psychological analysis are no less real than the elements of chemistry (Titchener 1909, pp. 49–50).

- ▶ The psychologist arranges the mental elements precisely as the chemist classifies his elementary substances. The chemical elements are divided, for instance, into metals and non-metals. The metals have a high power of reflecting light; they are opaque; they are good conductors of heat and electricity; they have high specific gravities. So they are set off, as a group, from the non-metals. These latter, again, include both gaseous and solid elements. That is to say, the chemical elements possess certain properties or attributes, by means of which they may be distinguished and arranged.

It is just the same with the mental elements. These are simple, it is true, in the sense that they are mental experience reduced to its lowest terms; but they are still real processes, still actual items of mental experience. Hence, like the chemical elements, they show various aspects or attributes, present different sides, so to speak, each of which may be examined separately by the psychologist. It is by reference to these attributes that introspection is able to classify them under different headings. (Titchener 1910, p. 50)

Titchener also changed the awkward phrases "sensations of external origin" and "sensations of internal origin" to "sensations" for the former and "images" for the latter.

The attributes were treated differently as well. Titchener added the attribute of “clearness” to quality, intensity, duration, and extent, classifying it as a directly observed attribute of sensations and images (Titchener 1910, p. 54). Objects at the focus of attention are clearer, more vivid than those on the periphery. This change made Titchener’s attributes all structurally equivalent, all directly observable through introspection. With this change, Titchener’s psychology became more consistently structural.

Another change at the level of attributes was Titchener’s use of a multidimensional model to summarize the facts of experience concerning color and brightness sensations. In the *Textbook*, Titchener described his color pyramid as part of the discussion of visual qualities (Titchener 1910, p. 63). The use of models, particularly of color was not new, but Titchener’s model was particularly significant. It represented a multidimensional space in the form of two distorted pyramids, one inverted and the other upright, joined at their bases. In this model, Titchener summarized the facts of color mixture, saturation and desaturation, brightness, and other visual experiences. Later, in the 1920s, Titchener designed or modified models for touch, audition, and taste to attempt the same summarization in other senses. The color pyramid can be seen as Titchener’s first move toward a multidimensional approach in his systematic psychology of sensation (Evans 1972).

Affection. Wundt changed his theory of feelings (affections in Titchener’s parlance) in 1896, adding to the single continuum of pleasantness/unpleasantness, two others, translated as excitement/depression and tension/relaxation. This change led to a controversy in print between Titchener and Wundt. Titchener held to his criticisms of Wundt’s theory and retained the original single continuum of pleasantness/unpleasantness, its two attributes anchoring each end and with a neutral midpoint.

Meaning. Although it had been discussed in the *Outline* and the *Primer*, the topic of meaning took on new significance in the *Textbook* and in Titchener’s later thought.

In the *Textbook*, Titchener reiterated his position that sensations do not, in themselves, have meaning. Meaning is created by the context of the elementary

sensations and images that interact when a perception or idea is formed (Titchener 1910, pp. 367–371).

The two forms of context that are particularly important are kinesthesia and verbal image. Kinesthesia is the term Titchener appropriated for the organic sensations produced by bodily attitudes through receptors in muscles, joints, and ligaments, the same patterns of sensations that made up the “feelings of effort” in attention and apperception.

- ▶ We are locomotor organisms, and change of bodily attitude is of constant occurrence in our experience; so that typical kinaesthetic patterns become, so to say, ingrained in our consciousness. (Titchener 1910, p. 368)

Just as important are verbal images. Words themselves contain context.

Not all meanings are conscious meanings, however. For Titchener there was no unconscious, in the Freudian sense. If something was not conscious it was physiological (Evans 1975).

- ▶ [M]eaning may be carried in purely physiological terms. In rapid reading, the skimming of pages in quick succession; in the rendering of a musical composition, without hesitation or reflection, in a particular key; in shifting from one language to another as you turn to your right- or left-hand neighbour at a dinner – table: In these and similar cases meaning has, time and time again, no discoverable representation in consciousness. The course and connection of ideas may be determined beforehand and from without; a word, an expression of face, an inflection of the voice, a bodily attitude, presses the nervous button, and consciousness is switched, automatically into new channels. (Titchener 1910, p. 370)

This process comes about through habituation. Titchener held that

- ▶ ...all conscious formulations, as the life of the organism proceeds, show like phenomena of rise and fall, increase and decrease in complexity, expansion and reduction; so that, in the extreme case, what was originally a focal experience may presently lapse altogether. (Titchener 1910, p. 369)

What was once at the focus of attention has lapsed entirely and is carried by a kind of nervous set of the

nervous system. This mode of creating meanings is also the process by which sensations are combined to produce perceptions. This combination, according to Titchener, has four major parts:

- ▶ First, under the general laws of attention and the special laws of sensory connection, sensations are welded together, consolidated, incorporated into a group. Secondly, this group of sensations is supplemented by images. Thirdly, the supplemented group has a fringe, a background, a context; and this context is the psychological equivalent of its logical meaning. Fourthly, meaning may lapse from consciousness and conscious context may be replaced by a non-conscious nervous set. (Titchener 1910, p. 371)

Introspection and the Stimulus Error. Titchener's position that sensations are meaningless and gain meaning only when combined with other sensations and with images is the reason why he was adamant that, in analysis using introspection, one must separate out the meaning of a complex state from its contents and break down the contents into their simple meaningless constituents. The combining of sensory and imaginal attributes to form more complex mental states is an emergent process. The formation of meaning is how the new whole is different from the sum of its various components. To reduce the whole down into meaningful sensations or images is necessarily a false analysis.

In the *Textbook*, Titchener introduced Ernst Mach's concept of "point of view." This relativistic approach held that there was not one Truth, but many truths seen from different points of view. He differentiated the various sciences from their points of view. So, Physics describes the world in terms of its material elements. Physics explains what it observes in terms of mass, space, and time. Biology looks at the same world but describes it in terms of living systems, such as the reproductive system, respiratory system, central nervous system, digestive system, and the like. Biology explains in terms of the carbon, hydrogen, oxygen, and nitrogen elements of physics. Psychology describes in terms of sensations, perceptions, images, actions, emotions, and the like. Psychology explains in terms of the central nervous system of biology. This was Titchener's form of reductionism and the way he sought to escape the problem of infinite regression that plagues any reductionistic approach. This example demonstrates a single level of

reduction. A psychologist can explain only at the next simpler level, in this case, biology or more specifically physiology. If a psychologist sought to explain at a more molecular level, he would be functioning not as a psychologist but as a biologist. It is biology that explains at the physical, biochemical level, the level the carbon, oxygen, hydrogen, and nitrogen elements and the compounds they form. (Evans 1990)

This relativism is important in keeping disciplines consistent. Consider the old question, "If a tree falls in the forest and there is no one around to hear it, is there a sound?" Titchener would answer "it depends." What it depends on is the point of view taken. That point of view changes what "sound" means because it changes what is described. To the physicist sound is made of compression and rarefaction waves of air molecules. No organism needs to be around for that to occur when the tree falls and produces such waves. To the biologist, there is a sound only if there is an organism there with an auditory system that can be stimulated by the physical waves. The organism may be asleep or unconscious, but the physiological process of the hearing apparatus would still work. For psychology, there would have to be an experiencing individual. There is a sound only if it can be heard.

Titchener used point of view to distinguish different subject matters even within a science or discipline. One takes a certain point of view and sees the world in a given way. Changing the perspective causes one to see the same world in a different way. So, science views the world in one way, technology in another, and everyday common sense in yet another. When one shifts their point of view and mixes the different descriptive or explanatory categories, the result is "muddle."

Association. In the *Textbook*, Titchener was far less detailed in the use of association to describe the process by which simple processes combine to form more complex processes. He used the concept of associative supplementation as he did before but imbedded it within the process of attention. Titchener's definition of association was modified only slightly in the *Textbook* from his earlier books. Titchener defined the law of association as:

- ▶ Whenever a sensory or imaginal process occurs in consciousness, there are likely to appear with it (of course, in imaginal terms) all those sensory and imaginal

processes which occurred together with it in any earlier conscious present. (Titchener 1910, p. 378)

The difference from the earlier representations has to do with the increased importance of images and their use as supplementation as the process by which simple mental states combine to form more complex states. Titchener moved away from the complicated use of simultaneous and successive associations to emphasize supplementation by means of association by contiguity.

Titchener's general law of association and the hypothesized physiological processes that underlie it were treated as sufficient to explain the increasingly complex mental states. Titchener reiterated in this law, perhaps more clearly, his position that

- ▶ ...there are as many forms of association as there are forms of perception and idea; the pattern of the associative consciousnesses may be spatial, temporal, qualitative or mixed. The pure perception in itself an association of sensations, and the idea is an association of images. (Titchener 1910, p. 389)

Titchener held in the *Textbook* as he did in the *Outline* that there is no psychological difference between “perception and idea on the one side, and the association on the other.” The difference is, Titchener added, “in fact, rather a psychologist's than a psychological difference.” Titchener reiterated the position from the *Outline* that the primary difference between an association and a perception is that “the elements that make up the perception may never have been together before, while the elements of the association have manifold habits of connection already upon them” (Titchener 1910, p. 390).

Given this position, then, and his position that when complex states are formed from simpler states, they can be used in future combinations as a unit, Titchener was able to build more and more complicated mental states from the simpler states below them. Each combination of increasingly complex “blocks” produces new meanings in the increasingly higher-order process produced.

Thought. In his *Textbook*, Titchener emphasized the psychology of thought in more detail than in his previous works. The issue of the thought processes had dogged Titchener from the beginning of the century.

The most significant benefit from a positivistic introspective psychology is that it should be possible to delve, experimentally, into the higher mental processes, including thought, itself. Yet, until 1901, neither Külpe nor Titchener demonstrated a direct experimental assault on the matter.

At Oswald Külpe's Institute of Psychology at Würzburg, this kind of direct experimental assault began to appear in print in 1901. The first product of this research was a publication by August Mayer and Johannes Orth, two of Külpe's graduate students, on conscious processes involved in free association. The stimulus was a common word. After a ready signal was given the stimulus word was given and the subject responded with the first word that came into his consciousness. The reaction time was measured. Then the subjects were asked to describe all the experiences that went on in their consciousness between hearing the stimulus word and uttering the response word. Their descriptions came up, again and again, with an experience that was neither an image nor a volition. The result was the proposal of a third class of experience not previously encountered. Mayer and Orth named this new category of experiences *Bewusstseinslage*. Titchener translated the word as “conscious attitude,” although the Würzburgers intended a more neutral meaning such as “conscious state” (Humphreys 1953).

In studies coming out of Külpe's laboratory in Würzburg, Karl Marbe, Külpe's assistant, conducted a study on judgment, considered by logicians as a unit of thought. Marbe's findings, based on judgments of lifted weights, indicated that there were no discernable experiences involved in making a judgment. Orth published another study in 1903 supporting the existence of *Bewusstseinslagen*. There were other studies by Henry Watt in 1905 and August Messer in 1906, but perhaps the two most significant were those by Narziss Ach in 1905 and Karl Bühler in 1907, all supporting an experience separate from the orthodox categories of introspective psychology.

Ach found in an experiment on thought that if a certain task (*Aufgabe*) is suggested by the experimenter in instructions or if such a task is taken on independently by the person introspecting, the nature of the thought process will be different. The thought

process will be determined not only by past experiences and their associations related to the task but also by the influences of goals that come from those instructions or those set by the observer himself. These “determining tendencies” favor some associations and hinder others. The subject may be unaware of the influence of these determining tendencies. They may have no representation in consciousness at all.

In 1908, Külpe’s student, Karl Bühler, proposed an element of “thought” to add to the elements of sensations, images, and affections. Up to that point, except for some criticism of the methodology used by the Würzburg school, Titchener had remained relatively quiet about the “imageless thought” findings. Bühler’s suggestion for a fundamental change in the elementary level of elementistic psychology was apparently too much. Titchener devoted 45 pages in the *Textbook* to thought. This summarized the positions he had taken a year earlier with his *Lectures on the Elementary Psychology of the Thought Processes* (1909a). Titchener specifically rejected thought as an additional element. Titchener, like Wundt, argued against the *Aussage* method used as the experimental methodology by the “Würzburg school.” The *Aussage* method involved experimenters interrupting the observers in the process of their introspections, asking them questions about their experiences at that moment (Humphrey 1963).

Titchener criticized the Würzburger’s concept of *Bewusstseinslage* in thought experiments. Titchener argued that the vague impressions the Würzburgers were getting were meanings or, more accurately, the “carriers” of meaning, and not some new elementary experience. Meanings, according to Titchener, could be carried by physiological processes such as kinesthesia which are the sensory results of bodily attitudes, muscle strain, and similar processes. The images of these processes could be called up as well. Titchener explained that what Külpe’s students were getting when carrying out complex problems in judgment and reasoning were these vague images that accompanied the meanings involved in judgment and reason (Titchener 1909a).

Narziss Ach’s “determining tendency,” however, was another matter. Titchener’s description of “mental constitution” in the first edition of his *Outline* almost

a decade earlier demonstrated the existence of a “nervous or mental set” created by situations prior to the experimental observations. He wrote:

- ▶ ...there can be no doubt that, as the condition of mental “constitution,” bodily tendencies are of great importance for psychology. They mark out the paths, so to speak, which mental processes in general are to follow. No specific mental process is due to them, in the sense in which the specific sensation of red is due to a special excitation of retina and visual brain centre; but they cut the channels in which the stream of conscious processes flows, and consequently determine the direction which the stream is to take. (Titchener 1896, p. 112)

This mental set could guide mental processes and influence the results in much the same way as Ach’s determining tendencies. Titchener did not realize the importance of what he had found at the time did not follow it up. Titchener had explained that meanings could be carried by processes such as kinesthesia and that the meanings may have lapsed from consciousness altogether. Now, Titchener had to admit that thought may also be carried physiologically and thus not be available to consciousness for introspective analysis. He made the admission in his *Lectures on the Experimental Psychology of the Thought Processes* that these nonconscious processes “made it impossible for any future psychologist to write a psychology of thought in the language of content alone” (Titchener 1909, p. 163).

Still, in the *Textbook*, Titchener delved into questions of the higher mental processes such as memory, imagination, thought, language, abstract ideas, and judgment. When he reached the concept of self, for instance, Titchener differentiated between the popular notion of self and that shown in introspection:

- ▶ The word “self,” as a psychological rubric, means the particular combination of talent, temperament and character – of intellectual, emotive and active mental constitution – that makes up an individual mind. Self, as a conscious experience, is any complex of mental processes that means some temporary phase of this combination; and a self-consciousness is a consciousness in which the self, as a conscious experience is

focal. The self-experience may be as varied as are the objective relations which the organism sustains to its personal and impersonal environment. It has, however, certain fairly constant constituents: organic sensations, a visual perception or idea of the body, and the verbal ideas of "I" and "my." (Titchener 1910, p. 544)

Although introspection was invoked, the introspective details were scanty.

At the end of the *Textbook*, there was no mention of metaphysics as an arbiter of things yet unexplained by psychology as there had been in the first edition of the *Outline*. By 1910, Titchener apparently felt comfortable that such concepts were well out of psychology. He closed his *Textbook* with the following optimistic statement:

- ▶ The experimental method, having conquered the whole domain of nature and of life, is pressing forward to the highest reaches of mind, to thought itself. It needs no gift of prophecy to foretell that the first half of this century will mark an epoch in the history of scientific psychology. (Titchener 1910, p. 552)

As such, Titchener's *Textbook* represented the high water point of his version of analytical, introspective psychology, a psychology of elements and attributes leading to the highest mental processes.

After the publication of the *Textbook*, studies came out of the Cornell laboratory investigating the issues of the *Bewusstseinslagen*. Helen Clark's doctoral dissertation published in 1911 as "Conscious Attitudes," made use of introspective analyses and were able to demonstrate that "...conscious attitudes can be analyzed into sensations and images and feelings, or traced genetically to such analyzable complexes, and therefore do not warrant the proposal of an additional conscious element" (Clark 1911).

The issue of whether there were or were not images in the thought processes, however, was never settled and was one of the sources of stress in experimental psychology that led to the eventual desertion of psychologists from analytical introspective psychology. The controversy was one of John B. Watson's arguments for rejecting introspection as a psychological method and replacing it with behavioral measures.

Phase 3: From Elements to Dimensions, 1913–1927

This final stage of Titchener's structural psychology began in 1913 with a criticism of Titchener's psychology by Carl Rahn (1913), formerly a student of Oswald Külpe, who was then at the University of Chicago. Rahn attacked the logic behind the concepts of elements and attributes as Titchener had stated them in his *Textbook*. Titchener's somewhat unclear statement there about the reality of elements was one of the issues Carl Rahn leapt upon and used against Titchener. There were several telling attacks on Titchener's concept of elements and attributes. Perhaps the most serious was Rahn's argument that Titchener could not talk about the attributes of sensation as though they were the attributes of physical elements and still maintain that the attributes were processes. In short, he accused Titchener of the very thing he had taken pains avoid all along, that he was dealing with "things" rather than processes, the fundamental flaw of traditional associationism.

Rahn also argued that if an element is "not further analyzable by introspection," how does Titchener explain how he can say elements also present different aspects, the attributes, and says that these attributes can be separately attended to and discriminated. Rahn asked if this analysis to obtain attributes is any different from that used to obtain the elements themselves. In short, Rahn challenged Titchener on the existence of elements as real elementary processes as was stated in the *Textbook*.

Titchener mounted a response to Rahn, published in 1915, but one in which he seemed to pull back to his earlier position, saying "All observation of psychological objects of the first order is, I conceive, observation of attributes" (Titchener 1915b, p. 260). Although Titchener defended his newly clarified position against Rahn, the criticism may have led Titchener to question his conception of elements and attributes.

In 1915, Titchener published *A Beginner's Psychology* (Titchener 1915b) to replace the *Primer*. In the introduction, he announced that he had abandoned the use of the term "consciousness."

- ▶ Experimental psychology has made a serious effort to give it a scientific meaning; but the attempt has failed.

The term is too slippery, and so is better discarded. (Titchener 1915, p. x)

He added that the term “introspection” was also headed along the same road and that he could have avoided using it but felt the time was not yet ripe for that. He avoided the use of consciousness in *A Beginner’s Psychology*, replacing it, in the few places where he seemed to need it, with “experience.”

When he defended his position on elements and attributes, though not mentioning Rahn’s criticism, Titchener again used the analogy of chemical elements and their attributes to those of mental elements and attributes.

It is likely, however, that Rahn’s criticism led Titchener to admit that:

- ▶ ...a complete list of all the aspects or attributes of a sensation in all their possible aspects is the closest thing we can come to defining sensation. . . . But since that sort of statement is clumsy; since we cannot make it complete till we have observed the sensations under all their possible aspects; and since we know that mental processes are correlated with processes in the nervous system; we may adopt another plan, and *define sensation by reference to the special bodily organ with which it is connected*. Sensations are then elementary mental processes that come to us by way of skin, muscle, ear, and the rest of the sense-organs. (Titchener 1915b, p. 66)

This change left sensations as reality rather than as an abstraction but it also left only the attributes as the objects of introspective analysis.

By 1918, it must have been clear to Titchener that his boast of 1899 that if he were given his elements “. . .and let me bring them together under the psychophysical conditions of mentality at large, and I will guarantee to show you the adult mind, as a structure, with no omission and no superfluity” was no longer possible. That year Titchener had dropped reference to mental elements entirely from his course in systematic psychology at Cornell and started out from the “ultimate dimensions” of psychological subject-matter, his five attributes, now renamed as attributive dimensions of “. . .quality, intensity, protensity (time), extensity (space), and attentivity (clearness or vividness)” (Evans 1972).

By 1923, Titchener was able to announce that he was ready to entirely shelve the concept of elements “for something still more fluid and still more pregnant” – attributive dimensions. This took account of sensations and images, but what of affections? This question was resolved by the research of John Paul Nafe in Titchener’s laboratory. Nafe found that

- ▶ The affective qualities, pleasantness and unpleasantness turn out, under direct observation, to be modes of pressure: Pleasantness is a bright pressure and unpleasantness is a dull pressure. (Nafe 1924, p. 508)

With this finding that the affective attributes of pleasantness and unpleasantness were actually pressure sensations, Titchener’s psychology became a sensationism in which all three of the elementary processes of experience reduced down to one: sensation.

The method of introspection Titchener used also changed and became something closer to phenomenological description than analytical introspection. Still, Titchener’s method was set off from phenomenology. In Titchener’s method, there was the separation of the facts of experience from the meanings as before when dealing with the description of attributes.

It was phenomenology as method he was introducing to the Cornell laboratory – “meticulous, minute description, i.e., description in the most pregnant sense.” Titchener was still studying the “existential contents” of experience. In doing so, Titchener’s structural psychology became entirely descriptive and no longer explanatory. This meant that there was no longer a requirement to explain by reducing the psychological experiences into terms of physiology or explaining them at all, for that matter.

This new form of Titchener’s psychology was called “existential psychology” rather than structural psychology, even by Titchener (Boring 1938; Evans 1972). This psychology with its use of a specially constructed phenomenological method was still a work in progress when Titchener died suddenly in 1927 of a cerebral hemorrhage. Titchener’s posthumous *Systematic Psychology: Prolegomena*, (Titchener 1929) was put together from material, some already published, that had been written around 1917. The form Titchener’s systematic thinking was taking in the mid-1920s is shown best in the last doctoral theses Titchener

supervised, such as Elisabeth Moller's "The Glassy Sensation" (Moller 1925) and those he had in progress when he died (Evans 1972).

Structuralism After Titchener

By the time Titchener died in 1927, his graduate students were all working within the rubric of his new "existential" psychology. Some of these were completed under other staff members in the Department of Psychology until Madison Bentley took over the department and laboratory. The titles of the dissertations, such as F.L. Bixby's *A Phenomenological Study of Luster* (Bixby 1927) and George Kreezer's *Luminous Appearances* (Kreezer 1930), demonstrate the change in the direction of Titchener's psychology. Whether Titchener had given up on the attempt to explore the higher mental processes directly by the experimental method is a matter of conjecture. The fact is, however, that the topics during this last period were all at the perceptual level and did not involve higher mental processes.

Titchener's systematic psychology had survived into the 1920s largely through Titchener's personality and his ability to attract and maintain the loyalties of his students. Behaviorism, however, was quickly coming to dominate the field in psychology by the late 1920s and the use of introspection, of all sorts began to fade from the scene.

Experimental phenomenological methods became identified with Gestalt psychology and its proponents produced the bulk of perceptual studies through the period of the virtual hegemony of behaviorism in America that lasted until the rise of cognitive psychology in the mid-1960s. During the behaviorist period, sensation became part either of psychophysics or of physiological psychology.

Titchener's positivistic view of psychology did not disappear completely, however. Ironically, when John B. Watson formulated his behaviorism, he did to Titchener largely what Titchener had done to Wundt. He took Titchener's structural framework and replaced the mentalistic concepts with behavioral concepts. One can see in Watson's behaviorism the elements of simple muscles and glands functioning in more and more complex ways to produce more and more complex behaviors.

E.G. Boring, one of Titchener's former students, attempted, after Titchener's death, to salvage the

fundamentals of Titchener's psychology with his book, *The Physical Dimension of Consciousness* (Boring 1933). In that book, Boring made use of the same dimensions of consciousness Titchener had used in the 1920s but altered terms and some assumptions resulting in something superficially similar to the final form of Titchener's psychology but quite different in its fundamentals. By 1933, however, there was little left to salvage of Titchener's systematic psychology.

It is difficult to see anything of Titchener's structural psychology remaining in present-day psychology. One possibility would be the distinction among the physical, biological, and the psychological points of view seen in the distinction between color and hue and between frequency and pitch. This, however, is as much Mach as Titchener.

What survived was not the systematic theoretical aspects of Titchener's structural psychology. It was his emphasis on the laboratory as the center of the experimental psychological enterprise. Titchener warned his students of the ephemeral nature of theories and systems when he told them "Carry your theories lightly. You may wake up tomorrow and find them disproved."

Sully, J.

DAVID L. SEIM

University of Wisconsin – Stout, Menomonie, WI, USA

Basic Biographical Information

James Sully was born in Bridgewater, England, on March 3, 1842. He received from his parents a nonconformist religious upbringing, and for his undergraduate studies, he explored philosophy in line with his family's religious beliefs. In these studies, Sully received training, especially in philosophy of mind, where a vogue of the day was the “associationist” theory in the writings of John Stuart Mill, Alexander Bain, and Benjamin Davis. During Sully's M.A. studies, which were also in philosophy, he added greater attention to rigorous scientific research on the mind, and for part of his masters' work he studied in Germany, from January 1867 to March 1868 – under Hermann Lotze in Göttingen and Hermann von Helmholtz and Emil du Bois-Reymond in Berlin. Sully again visited the German labs during fall of 1871. By the 1870s, Sully had broad interests, including Darwinian theory and ideas of the “associationists.” He ultimately focused on childhood and developmental psychology. Sully published extensively from the 1870s to the 1890s (Gurjeva 2001).

Professionally, Sully eventually earned appointment to the Grote Professorship of Logic and Philosophy of Mind at University College, London, which he held from 1892 to 1903. In 1898, he was instrumental in setting up the first major psychological laboratory in Britain, at University College, London. In 1901, Sully was the one who, it is said, “called the meeting” at which the British Psychological Society was formed. Sully died in 1923 (Valentine 1999).

Major Accomplishments/ Contributions

During the early 1870s, based on some self-initiative as well as some encouragement from acquaintances, Sully began submitting articles to major British periodicals, including *Cornhill Magazine*, *Fortnightly Review*, *Saturday Review*, *Westminster Review*, *Contemporary Review*, *Academy*, and *Mind*. Sully also contributed to the French journal, *Revue Philosophique*. Topics of Sully's articles were as diverse as music, illusions, childhood, laughter, consumer psychology, German culture, and the relationship between psychology and art (Block 1982).

Among the earliest of Sully's more important papers was a July 1872 article on German psychophysics, published in the *Westminster Review*. Drawing upon his personal experience in the German laboratories, Sully introduced what he described as the already "famous" researches of Gustav Fechner and his followers. As Sully concisely put it, these Germans psychophysicists had studied human sensory input and response, and had discovered "that the greater the magnitude [of sensory input] the larger the minimum amount of noticeable difference" (Sully 1918).

The decades of the 1870s and 1880s were, in general, times of heightened emphasis on treating psychological issues in light of evolutionist analysis. Fairly common topics receiving such attention were animal intelligence, mental life of "primitive man," heredity of intelligence, genius, personality, dreams, illusions, nervous diseases, and "dual consciousness." Sully wrote on many of these topics, especially during his so-called "journalistic period." These writings by Sully display keen familiarity with such psychologically oriented science writers and defenders of evolutionism as George Henry Lewes and Grant Allen, and also the evolutionist-physiologists Henry Maudsley and Hughlings Jackson (Block 1982; Ryan 2009).

Next came Sully's "associationist period," during which he developed a deeper interest in what were called "the dualities" – these being the separation between normal and abnormal states of consciousness, and the split between "critical introspection" and "sympathetic introspection." These two dualities, potentially reconcilable with each other, come through in such works as Sully's *Sensation and Intuition* (1874) and his popular *Illusions* (1882), as well as in

his essays on "The Aesthetics of Human Character" (1871) and "Self-Esteem and Self-Estimation" (1876). The idea that there are fundamentally two kinds of introspection produced an inquiry as to whether dual mental perspectives inherited via the natural selection process might result in one strategy of introspection which requires that a human subject separate sufficiently "the judging part" from "the judged parts" of the mind; another strategy of introspection might result when a subject projects his or her own qualities and feelings upon others (Gurjeva 2001).

As Sully worked to reconcile associationist philosophy of mind with evolutionary ideas of Charles Darwin and Herbert Spencer, his project was not only to explain the dual modes of consciousness and the corresponding dual forms of introspection, but also to expand inquiries into primitive consciousness and the phenomena of dreaming. Sully's first essay of his first book (*Sensation and Intuition*) in fact defended "The Relation of the Evolutionist Hypothesis to Human Psychology." In the essay, Sully pointed to "that once universal tendency of the human mind" to project its feelings into or upon every object, animate or inanimate, which was a view in the tradition of the 1870s British anthropologist, E.B. Tylor (Sully 1918).

During the 1870s, Sully was selected to team with Thomas Henry Huxley to write tandem articles to be published together as one piece on "Evolution," for the 1879, ninth edition of the *Encyclopedia Britannica* – with Huxley initialing part one of the essay (subtitled "Evolution in Biology") and Sully initialing part two (subtitled "Evolution in Philosophy"). A close reading of Sully's contribution finds that Spencer is the theorist from whom Sully derived his most characteristic evolutionist principles of psychology. (Sully also received and accepted an invitation to compose two other articles for the encyclopedia, on "Aesthetics" and "Dreams.")

In 1876, in an influential essay on "The Laws of Dream Fancy," Sully contemplated that a confusion existing between perception and imagination in a dream state is essentially the same as certain confusions resulting from the intensity of "excited states of the imagination," including pathological conditions. Under such circumstances, Sully believed, "pure fancies of the mind, by acquiring a certain degree of vividness and persistence, become mistaken for real perception."

The comprehensive nature of Sully's efforts in the paper struck the attention of a commentator for the journal *Mind*, who identified Sully as endeavoring "to carry the physiological explanation of dream-phenomena as far as can be done in the present state of the science." A later figure of obvious importance, one Sigmund Freud, expressed much admiration for this 1871 essay, which (along with Sully's book *Illusions*, and his 1893 article on "The Dream as a Revelation") influenced his own thinking (Gurjeva 2001).

By the middle 1880s and then beyond, Sully's primary interest became childhood and developmental psychology – sometimes together called "genetic psychology." Sully was an especially strong promoter of the child study movement and was adept at playing the intermediary role between teachers, parents, and scientists. A period of about 2 decades, beginning in 1884, is thought of as Sully's "textbook period," during which he published five major textbooks: *Outlines of Psychology* (1884); *Teacher's Handbook* (1886); *The Human Mind* (1892); *Studies of Childhood* (1895); and, *An Essay on Laughter* (1902). These were textbooks for various audiences interested in psychology and its applications. In a number of cases these textbooks were the first published pieces to introduce new ideas and research in psychology to an English-language readership. In *Studies of Childhood*, in particular, Sully is recognized for including observations of his own son during the first 6 years of life, as well as for his original studies and analysis of children's drawings. Sully is also recognized for his early use of the questionnaire and for his training of mothers as scientific observers.

Sumner, Francis Cecil

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Sumner (1895–1954) was born in Pine Bluff, AK, USA. Educational facilities and opportunities were poor for blacks in the South, but Sumner received an acceptable elementary school education in Norfolk, VA, and Plainfield, NJ. However, the high schools were so inferior that Sumner did not attend. Nevertheless, with the assistance of his father, he learned enough to gain entry by examination to Lincoln University in 1911. In 1915, he was graduated with honors in English, Greek, Latin, modern foreign languages, and philosophy. With the encouragement of G. Stanley Hall, the eminent American psychologist and President of Clark College and University (Worcester, MA), Sumner earned a second bachelors degree at Clark in English (1916). Back to Lincoln and while teaching German and psychology, Sumner earned the M.A. degree (1917). Undecided whether to continue his doctoral studies in German or psychology, Sumner was offered full financial support by Hall, and Sumner returned to Clark University to study psychology.

A week after beginning his doctoral studies, Sumner passed the required examinations in German and French. By the end of the academic year, Sumner had completed a manuscript based on his study of the differences between Freud and Adler. Although not intended to be his dissertation, Sumner asked Hall to consider it for his dissertation. Before Hall could act, Sumner was drafted into the US Army for service in The Great War (World War I). Sumner quickly asked and received Hall's support for his admission to officer candidate school. However, it was too late, and Sumner was shipped to Europe as a Sergeant in the 808th

Pioneers. Pioneer infantry units, generally, were non-combat units, and Sumner's group was put to work building and repairing railroads. A great irony of American military racial segregation was that Sumner, who was fluent in the languages of the major combatants (English, German, and French), served on a railroad gang. Nevertheless, the 808th came under heavy artillery bombardment and was among the few non-combat units to be awarded combat decorations (Thomas 1999).

Sumner returned to Clark in the summer of 1919. His work on Freud and Adler was accepted as his dissertation and was published as *Psychoanalysis of Freud and Adler or Sex-determination and Character Formation* (Sumner 1922). Sumner was graduated on June 14, 1920, the first black to earn a Ph.D. in psychology. After moving about academically for a few years, Sumner joined the faculty at Howard University in 1928 where he remained until an untimely death by heart attack in 1954. He was buried with honors at the Arlington National Cemetery.

Major Accomplishments/Contributions

Sumner was identified as the “father of black American psychologists” by the eminent black historian of psychology, Robert Guthrie (2004). Guthrie used this appellation to acknowledge Sumner's being the first black Ph.D. in psychology and also for his significant role in the educations of early generations of black psychologists, although Howard University did not confer Ph.D. degrees in psychology during Sumner's lifetime. Arguably, Sumner's most important master degree student was Kenneth Clark. Clark earned his Ph.D. at Columbia University. Not only was Clark the only black President of the American Psychological Association to date, he and his wife Mamie, also a Howard student and later a Columbia Ph.D., conducted the famous doll studies which they had begun at Howard. The doll studies influenced the 1954 Supreme Court decision that outlawed racial

segregation in public schools and other public facilities as well as any private businesses that depended on interstate commerce.

Sumner's theoretical contributions include his dissertation (see above) that applied the theoretical tenets of psychoanalysis to explain fundamental differences between two of its major founders, Freud and Adler. Sumner also acquired an interest in the psychology of religion from his mentor, Hall, and he did extensive research on American and European religions. As described by Guthrie, Sumner produced a “massive manuscript” titled *The Structure of Religion: A History of European Psychology of Religion*. Should this manuscript ever be published, it might prove to be a major historical and theoretical contribution. Guthrie also reported that Sumner was the first to establish courses in the psychology of religion at black colleges and universities.

Finally, an important, indirect theoretical contribution by Sumner is that he was an official abstractor for *Psychological Bulletin* and for the *Journal of Social Psychology*. This was before authors were required to include abstracts with manuscript submissions. Guthrie reported that Sumner provided abstracts for more than 3,000 articles from German, French, and Spanish authors.

T

Teachers of Psychology in Secondary Schools

AMY C. FINEBURG

Oak Mountain High School, Shelby County Schools,
Trussville, AL, USA

Introduction

High school psychology teachers have more resources available today than ever before. High school psychology teachers can be members of several different professional organizations that offer resources such as lesson plans, activity ideas, newsletters, and professional development workshops. These opportunities are the direct result of tireless work of several advocates for high school psychology teachers over the years. The primary organization for high school psychology teachers that is endorsed and supported by the American Psychological Association (APA) is Teachers of Psychology in Secondary Schools (TOPSS).

Definition

TOPSS is an organization within the APA that supports high school teachers of psychology. The governing body of TOPSS is the Committee for Teachers of Psychology in Secondary Schools, which is a standing committee within the APA's Board of Educational Affairs (BEA) within APA's Education Directorate. The Committee is led by an elected group of high school teachers of psychology. The committee chair serves a 3-year term (1 year as Chair-Elect, 1 year as Chair, and 1 year as Past-Chair). All other officers serve 2-year terms. Two collegiate faculty who are APA members serve on the committee as well to provide guidance and advice on projects put forth by committee members.

History

The Founding of TOPSS

TOPSS was established in the early 1990s and provides teachers with teaching resources, instructional materials, professional development workshops, newsletters, and policy guidance for teaching the high school course (Ernst and Petrossian 1996). High school psychology teachers could join the APA as Teacher affiliates beginning in the 1970s, and a Committee on Psychology in Secondary Schools (CPSS) was established in the early 1980s to provide a formal place for high school teachers to belong within the APA. However, due to financial difficulties faced by APA during that decade, the committee was discontinued (Ernst and Petrossian 1996).

In 1992, Charles Spielberger, Ph.D., then president-elect of the APA, spoke to a conference of educators at St. Mary's College of Maryland. The conference was geared toward undergraduate education, but two high school psychology teachers were in attendance (Ernst and Petrossian 1996). Spielberger spent most of his talk focusing on the importance of teaching psychology in high schools, emphasizing the importance of fostering a pipeline for psychology beginning in high schools. Spielberger proposed to the APA that year to establish a new committee for high school psychology teachers, and he gathered together a group of high school teachers and interested collegiate faculty to discuss the focus and organization of such a committee. Members of that first group were high school teachers Bates Mandel, Karyn Hale, Randy Ernst, Charlie Blair-Broeker, Marissa Sarabando, and Laura Maitland. Collegiate faculty participating in these initial meetings were Ludy Benjamin, Ph.D., and Sam Cameron, Ph.D., both of whom had been principal investigators for National Science Foundation (NSF) grants that provided 4-week professional development workshops for high school psychology teachers in the early to mid

1990s. The Committee for Teachers of Psychology in Secondary Schools was established after a vote of approval by the APA's Board of Directors in early 1993.

The National Standards Process

Since its founding, TOPSS has provided instructional materials, professional development, and policy guidance for high school psychology teachers. In the mid-1990s, TOPSS committee members began a drive to create a set of national standards for the teaching of high school psychology. During the 1990s, a nationwide push began to establish national criteria for what content should be taught in the nation's public high schools. National professional organizations for high school teachers in many disciplines began to develop standards for teachers, school district personnel, colleges of education, and accreditation agencies to use to determine the quality of programs found in high schools. The TOPSS committee members established a task force to develop what became the National Standards for High School Psychology, which were approved as APA policy in 1999. Laura Maitland chaired the task force. Others serving with her were high school teachers Ruth Anderson, Charlie Blair-Broker, Carol Dean, Ed. D., Randy Ernst, and Bates Mandel. Collegiate faculty participating in the original task force were Jane Halonen, Ph.D., Wilbert McKeachie, Ph.D., and Marilyn Reedy. The original National Standards were comprised of five domains – Methods, Biological Bases of Behavior, Development, Cognitive, and Sociocultural – and these domains included content from typical units taught in high school psychology courses (Maitland et al. 2000).

After the National Standards were approved as policy, different groups within APA provided feedback for revising the document to reflect emerging changes in the field that ought to be reflected in the high school course. An APA working group was established and chaired by Laura Maitland to review the feedback and provide revisions. High school teachers Rob McEntarrfer and Kristin Whitlock served on the working group along with college professor Kenneth Weaver, Ph.D. This group worked until 2004 and did not produce a finished version of the revisions. Kristin Whitlock took over duties as chair of the working group, working with high school teachers Amy Fineburg and Marie Smith, Ed.D., and college professor James Freeman, Ph.D. This working group finalized

the revision comments and produced a new version of the National Standards for APA approval in 2005. The document was renamed the National Standards for High School Psychology Curricula. The 2005 version of the Standards also includes five domains – Methods, Biopsychology, Development, Cognitive, and Variations in Individual and Group Behavior. Some units were reorganized in order to align those units with their more primary domain of study. The Standards were also made available online and in print.

The National Standards were revised for the third time in 2011 to reflect further changes to the field. The working group consisted of high school teachers Amy Fineburg, Ph.D., chair, Hilary Rosenthal and Debby Park. Collegiate faculty participating were James Freeman, Ph.D., and David Myers, Ph.D. The working group utilized the advice and input from an Advisory Board consisting of two content experts from each of the five domains. Advisory Board members participating were Elizabeth Bjork, Ph.D, Joan C. Chrisler, PhD, James Kalat, Ph.D., Cheryl Luis, Ph.D, Morton McPhail, Ph.D, Jeffery Scott Mio, Ph.D, David B. Mitchell, Ph.D., Pat Puccio, Ed.D., Daniel Reisberg, Ph.D., and Susan Krauss Whitbourne, Ph.D. The 2011 version of the National Standards was expanded to seven domains – Scientific Inquiry, Biopsychology, Development and Learning, Sociocultural Context, Cognition, Individual Variations, and Applications of Psychological Science.

Unit Lesson Plans

TOPSS has been instrumental in providing quality instructional resources and professional development for high school psychology teachers. The main instructional resource developed by TOPSS is unit lesson plans. The unit lesson plans were originally authored by teachers attending NSF-sponsored institutes held during the early 1990s. These 4-week institutes were designed to promote the scientific teaching of psychology, and during that time few resources existed for high school psychology teachers. Groups of teachers at these institutes worked together to author unit lesson plans in such areas as research methods, biopsychology, statistics, cognition, and development. The institute directors then asked APA to publish and disseminate the plans to the TOPSS membership.

Since those institutes ended in 1999, the TOPSS committee took over the role of commissioning unit

plan development. As of 2011, TOPSS offers 19 unit plans highlighting each major unit plan found in a traditional high school course. The committee not only commissioned unit plan development for traditional units found in the high school course but also plans for units that might be considered ancillary to the traditional high school course. Units in positive psychology, cross cultural psychology, psychoanalysis and psychodynamic perspective, and the psychology of sexual orientation are also available for teachers. These unit plans are available online for members only. The plans include a content outline, procedural timeline, activity suggestions, and additional resource suggestions. In 2007, TOPSS tasked teachers participating in a week-long summer workshop to revise unit plans written in the 1990s. Units for motivation, emotion, development, introduction to psychology, and biopsychology were revised and are currently available online to members.

Professional Development

TOPSS has provided high quality professional development for high school psychology teachers for most of its history. In the 1990s, the main professional development opportunities for high school psychology teachers were the NSF-sponsored institutes, an institute hosted by Nebraska Wesleyan University, and workshops for Advanced Placement™ (AP) Psychology sponsored by the College Board. In the late 1990s, the institutes sponsored by NSF and Nebraska Wesleyan University were discontinued, so TOPSS stepped in to provide several types of professional development experiences for high school teachers.

In the late 1990s and early part of the 2000s, TOPSS sponsored 1-day workshops at various locations throughout the United States. Experienced high school teachers or college professors interested in translating introductory psychology pedagogy to high schools led these workshops. TOPSS also began offering workshops and sessions at APA's annual convention each year. The APA typically offers TOPSS up to 5 hrs of programming at the APA Convention each year. The Past-Chair of the TOPSS committee invites speakers from among both high school and collegiate instructors to speak to attendees. The speakers are typically invited around a theme relevant to teaching high school psychology. TOPSS has also worked with other teaching groups within APA, including Psychology Teachers at Community Colleges (PT@CC)

and the Society for the Teaching of Psychology (STP, APA Division 2) to sponsor lecturers at the APA Convention and other association meetings.

In 2004, the American Psychological Foundation (APF) received a donation from Lee Gurel, PhD, to establish professional development opportunities for high school psychology teachers in conjunction with Clark University, his alma mater and the birthplace of the APA. The donation led to the APA-TOPSS/Clark University workshop, an annual 3-day workshop that serves up to 25 high school teachers each summer. Faculty from Clark University present content-based sessions in their areas of expertise, and experienced high school teachers present activity and demonstration ideas. Participants also tour sites around campus that are of historical interest, including the statue of Sigmund Freud and the site of the founding of the APA.

In 2007, the APA and TOPSS sponsored a week-long summer institute designed to help teachers use the National Standards for High School Psychology Curricula in their classrooms. During this institute, teachers heard presentations from content experts in biopsychology and development and worked in small groups to revise unit lesson plans originally written in the 1990s. The workshop was held at the University of Wisconsin in Green Bay and directed by Regan Gurung, PhD, Wisconsin-Green Bay faculty member and TOPSS faculty advisor, and Amy Fineburg, high school teacher and TOPSS Past-Chair.

Key Issues

Psychology courses have traditionally been a part of the high school curriculum landscape since before psychology was founded as a scientific discipline in 1879. Throughout the years, however, high school psychology courses have typically focused more on personal development and growth rather than science (Engle 1974; Moore 1932; Liddy 1945, 1946). Early textbooks for high school psychology focused on the topics related to the behavioral and cognitive perspectives of the day including learning, forgetting, and emotions, but devoted space to practical problems like vocational choice and reading proficiency, reflecting a notion that high school students were less interested in the science of psychology than the practical application of psychology (Moore 1932; Woodworth and Sheehan 1951; Billig 1943). Many in

the field argued that teaching high school psychology should be designed to improve students' lives by helping them develop critical thinking skills, improve intellectual ability, and understand human nature (Abrams and Stanley 1967; Burgum 1940; Engle 1952; Berg and Brown 1942). Since the establishment of TOPSS and courses like AP Psychology and International Baccalaureate (IB) Psychology, the teaching of psychology has moved from a personal hygiene course to a more scientifically oriented course.

Certification of Teachers and National Standards

The issues that have dogged high school psychology have not changed much over the decades. Numerous articles dating back as far as 1932 cite problems with certification and standards faced by teachers of high school psychology (Moore 1932; Abrams and Stanley 1967; Engle 1952). Many early studies of the qualifications and resources available found that high school psychology teachers lacked proper training and pedagogical practices, did not teach practical psychology, and lacked a high school textbook in psychology (Abrams and Stanley 1967; Mikesell 1943). Content-wise, early high school psychology courses focused on personal development and growth rather than science, which is not surprising considering the lack of scientific training of high school psychology teachers. In the mid-twentieth century, researchers found that the average number of semester hours of psychological training was 18.49. By the 1970s, little had changed in the high school psychology landscape.

Even in the early 1990s when the APA was establishing the TOPSS committee, these same issues in teaching high school psychology existed. Content was typically determined by the individual teacher's personal preference rather than any standardized course of study. The typical high school psychology teacher was likely a man with twice as much experience teaching other subjects as psychology, with only roughly 12% teaching psychology exclusively and 63% teaching psychology less than half the day (Hakala 1999; Bristol and Ginis 2001). While only a small portion of teachers majored in psychology in college, the average number of semester hours in psychology remained consistent from the 1940s to the early 1990s.

All 50 states offer certification for psychology teachers in some way, indicating that schools with the means and desire can offer psychology, but whether they do or not is unknown. In most states, certification to teach psychology is packaged with certification to teach social studies, a discipline that includes history, government, and economics. Few states offer separate certification to teach psychology for precollege instructors. Researchers have found throughout history that teacher preparation programs significantly reduced the number of behavioral science credits one must earn to receive social studies certification in favor of increased preparation in history and geography (Evans et al. 1990). With the passing of the No Child Left Behind legislation in the early part of the 2000s, teachers of all subjects have to be declared "highly qualified" in order to continue teaching. Teachers had to have taken a certain number of courses during their college teaching preparation either in the specific discipline they taught or in a broadfield certification area. For teachers who did not have the requisite hours in college, teachers could participate in professional development or pass a national certification exam. Because of the placement of psychology in social studies, today's high school psychology teachers have little formal training in scientific psychology, have little time to devote to such preparation while teaching several different types of courses, and must rely on their own often minimal knowledge of psychology to determine what to teach.

The content and pedagogy of high school psychology has improved greatly since 1992. Both TOPSS and Advanced Placement Psychology were established in 1992 (Abrams and Stanley 1967). AP Psychology and IB Psychology courses, each with rigorous curricula, produce students with high levels of knowledge and ability in scientific psychology. Teachers of these courses must have significant professional development training in order to prepare their students to pass the difficult standardized tests required by these courses. The publication of the *National Standards for the Teaching of High School Psychology* addressed a long-held desire for consistency in high school psychology instruction. Several high quality textbooks are available for all levels of high school psychology. Today there is evidence that high school psychology is offered in all 50 states. Several TOPSS-sponsored surveys of high school psychology propose that almost one

million students take high school psychology each year, but the precise number is unknown (Ernst and Petrossian 1996). The growth in the AP Psychology program demonstrates the popularity of psychology as a course in high schools. In 1992, the first year the College Board offered an exam in AP Psychology, a little under 4,000 students sat for the exam. In 2010, over 180,000 students sat for the exam, making AP Psychology the sixth most popular test given that year.

The National Standards for High School Psychology Curricula are endorsed by the National Council for Social Studies (NCSS), the national professional organization for social studies educators. Many states use the APA's document as a framework for developing state and local standards for teaching high school psychology. The National Council for the Accreditation of Teacher Education (NCATE) uses the APA's document to evaluate the effectiveness of psychology teacher preparation programs. The APA has also made recommendations regarding the training of high school psychology teachers and promoted the alignment of psychology instruction from high school through the postgraduate degree.

International Perspectives

Teachers of high school psychology are found throughout the world. TOPSS has members from several countries, including Bolivia, Mexico, Thailand, Pakistan, Canada, and England. In the early part of the 2000s, TOPSS enlisted teachers to be Regional Coordinators to help promote professional development activities in each region of the USA. The TOPSS committee also felt it was important to enlist teachers outside the USA to be Regional Coordinators as well, tapping teachers in Canada and Latin and South America to coordinate activities and foster communication among international teachers of high school psychology.

The TOPSS committee has also been committed to promoting international perspectives in the teaching of high school psychology. The committee commissioned the development of a unit plan on cross cultural psychology and seeks to provide resources that emphasize a global perspective in teaching high school psychology content. Each unit plan under development undergoes diversity review by experts in the field to help make sure international and diverse perspectives are represented. TOPSS often features reports about international and global perspectives written by

various APA boards and committees on its website and in its newsletters so high school psychology teachers can keep up-to-date about current directions in the field.

Future Directions

The certification of psychology teachers and the dissemination of the National Standards are perhaps the most important issues facing high school psychology instruction today and for the future. How psychology teachers are prepared to teach the course should be of fundamental concern for organizations interested in promoting psychology instruction. The lack of separate guidelines for certification in psychology from state licensing boards and the subsuming of psychology into the social studies certification area leave psychology out of the current emphasis on science, technology, engineering, and math (STEM) disciplines. The APA's Science and Education Directorates have both endorsed including psychology as a STEM discipline, but the lack of recognition of psychology as a course within science departments makes those calls difficult to fulfill.

While adequately certifying psychology teachers would advance the cause of high school psychology instruction, promoting the adoption of standards for high school psychology will advance the cause of high school psychology in general. The adoption of standards by states and school districts would advance psychology on several levels. First, adoption of APA-endorsed standards would recognize psychology as a scientific discipline and represent the end of the perception of high school psychology as a self-help course. Second, adoption of standards would recognize psychology as a course taught in high schools. Because psychology is generally an elective course, it is not considered as crucial to the school program as a required course. Elective courses are taught only if there is enough demand or if someone is qualified to teach them or if funding is available to support the course. When funding gets cut, electives are usually the first to go. Third, when standards are adopted, teachers are accountable in some way (in the form of tests or submitted lesson plans) to follow the guidelines in their instruction. Accountability for what is taught will lead to emphasis on better training and preparation for high school psychology teachers to ensure they meet the standards. Last, standards adoption would

provide new teachers of psychology with a guide for what to teach in a psychology course. Without such guidelines, teachers are left to teach what they want to teach and not necessarily what should be taught.

Psychology in high schools has come a long way from its beginnings as a course in mental health and adjustment. Modern psychology is a vibrant discipline based in scientific inquiry. For many students, high school psychology is a first glimpse of what psychology is, making the certification, preparation, and guidance of teachers of psychology important. If students are going to receive an accurate picture of what psychology is, they will need teachers who are properly certified who have guidance about what to teach. Proper certification will ensure that teachers have taken more than one course in psychology before coming to teach the course to high school students. Adopting standards on the state and local levels will ensure that what is taught in the psychology classroom mirrors what is taught in college courses, preparing students better for the next level of instruction. A concerted effort by groups that promote psychology instruction to address these important issues will serve psychology as a whole for years to come.

Terman, Lewis M.

CATHERINE BRINCKERHOFF JENNI

College of Education and Human Sciences,
The University of Montana, Missoula, MT, USA

Terman's career spanned the development of academic psychology, beginning in the late nineteenth century and continuing under his leadership for many years. His leadership was crucial, though not without controversy, in the standardization of intelligence and achievement testing. Terman's longitudinal study of a cohort of individuals is well known for providing intimate understanding of the life course of the intellectually gifted.

Basic Biography

Lewis Terman was born the 12th of 14 children on January 15, 1877, in rural Johnson County, Indiana, to James and Martha Cutsinger Terman. His heritage was German, French, Scotch-Irish, and Welsh. There was no family history of college education and no one in previous generations had achieved prominence. Nonetheless, his family's farm was relatively prosperous. Though Lewis and his siblings engaged in physical labor, their home contained a large library. Terman was an avid reader from an early age.

Terman's family life included tragedy, not unrelated to a terror that hung over much of his life. Most of his father's siblings died from "consumption." Terman's father had tuberculosis and Terman's eldest sister died from the disease when Terman was 3. At age 22 Terman learned he too had tuberculosis and suffered several bouts of the disease, shaping his early research in school hygiene. His illness led him to locate to a more salubrious climate, and ultimately to a faculty position in education and psychology at Stanford University in 1910.

Beginning in 1892 Terman attended Central Normal College in Danville, Indiana, where he received a B.S. and B.Pd. in 1897, with country school teaching responsibilities in the middle years of his studies. From 1898 to 1901, he served as principal of a township high school. Terman borrowed money and earned two master's degrees from Indiana University in 1902 and 1903. Supported by additional family loans and a fellowship, he earned the Ph.D. at Clark University in Massachusetts in 1905. Seeking a healthier climate, he took a position as a high school principal in San Bernadino, California, for a year, and subsequently moved to a faculty position at Los Angeles State Normal School. In 1910, he was offered a position in Educational Psychology at Stanford University, where he remained for 46 years. Nearing the age of 80, on December 21, 1956, Lewis M. Terman passed away at his home on the Stanford University campus. Until shortly before his death, he was deeply engaged in the fifth volume of his longitudinal study of genius.

Major Contributions

Lewis Terman's contributions to his profession were legion. His academic contributions included the acclaimed revision of the Binet-Simon Scales, the Stanford-Binet (1916), and his concept of "IQ" became a household word. He later developed the Revised Stanford-Binet (1937) with Maud Merrill. With A.O. Otis, during his service as a Major in World War I he constructed the Army Alpha and the Army Beta. Terman developed the widely used Stanford Achievement Tests (1923) with T.L. Kelley and G.M. Rauch. Beginning in 1920, he commenced his study of gifted children (the "Termites"). With Catherine C. Miles he subsequently developed a masculinity/femininity and personality test, focusing his attention on the psychological factors in marital happiness (1936).

Terman was most devoted to his longitudinal study of "genius," a term he later changed to "gifted" (Terman 1925). The research was in part motivated by Terman's disagreement with prevailing negative stereotypes of highly intelligent children. He was particularly interested in the childhood experiences of these children and, beginning in 1920, he prepared for a longitudinal study of about 1500 children, drawn primarily from San Francisco, Berkeley, Oakland, and Los Angeles schools. It is a tribute to his dedication that 36 years after the study began, 98% of those of his "Termites" who were still living continued as active participants. Terman argued that both heredity and environment contributed to intellectual achievement, though he gave the nod to heredity. He argued that motivation made a significant contribution, a quality related to childhood environment, as much as to a yet unknown genetic contribution to personality (Terman and Oden 1947). Nonetheless, contemporary later critics noted that his study of the gifted included primarily children from White, educated and financially secure families and that there may have been biases in the teacher-based selection process. More male children were selected than female and the sample included few non-White children. Terman became so intimate with his subjects that he assumed a "fatherly" role and, at times intervened directly to assure that they were successful. He may have skewed his results, but he could not tolerate seeing potential wasted. His study included no control groups, not unusual for his era. It is impossible to know what effects the research itself, including being labeled as being a "genius" or "gifted" had on his findings. Terman sought to understand the childhood family and educational circumstances that enhanced the development of children with high genetically based potential for excellence.

Terman's honors included serving as President of the American Psychological Association (1923). He was a fellow of the American Academy of Arts and Sciences, and a member of the National Academy of Sciences. He served as Chair of the Stanford University Department of Psychology (1922–1942), during which time the Department grew to national prominence. He valued originality and astute critical thinking in his graduate students and colleagues. Between 1914 and 1937, he chaired 42 master's theses and 27 doctoral dissertations. He often collaborated with graduate students, launching their successful careers under his encouraging, demanding, and protective wings.

Terrorism and Politically Motivated Violence, Psychological Theories of

SHUKI J. COHEN

John Jay College of Criminal Justice, New York, NY, USA
 Yale University School of Medicine, New Haven, CT, USA

Introduction

Politically motivated intimidation and violence against individuals or groups has been a prominent element in practically every account of human history. Conversely, attempts to understand the underlying motivations and causes for certain behaviors in general, and violent

acts in particular, are arguably equally prominent in the history of human intellectual interests. Therefore, tracing the developments in the psychological understanding of terrorism and political violence is, in effect, tracing the history of psychology itself vis-à-vis social dynamics and violence. This review attempts to survey the development in modern psychological understanding of the complex phenomena of terrorism and political violence – phenomena that are still far from consensual definitions, research methodologies, and integrative conceptualizations (e.g., Schmid and Jongman 1988; Schmid 1997). The survey follows closely the history of psychology rather than related disciplines, or some that were even considered identical in their subject matter to psychology – such as philosophy, sociology, and anthropology.

Classical and Modern Psychoanalytic Theories of Political Violence and Terrorism

The inception of modern psychology is customarily chronicled around the end of the nineteenth century, and is frequently identified with the emergence of the psychoanalytic school of thought, attributed to Sigmund Freud. Early psychoanalytic accounts of violence regarded it as a pan-human determinant in the psychological development of humans, and as inextricably associated with other determinants, such as biological development and sociability. Freud's early models of the psyche surmised a tripartite structure, whereby the sole energy source is that of the sexual drive (dubbed libido). This energy emanates from the most basic and primitive parts of the psyche and therefore cannot be dealt with directly, not even by the person itself. In order to temper this energy and harness it as a source of human motivation for acceptable actions, other parts of the psyche have to counter it and negotiate between its wild nature and the calls of society for rationality, self-control, and morality. Thus, according to early psychoanalytic models, violence and antisociality are innate characteristics of human nature, and are derived by the primary goal of the unconscious to seek maximal egotistic pleasure while being incapable of consideration of others. It is also inherent to human nature through the constant internal conflict between the pleasure-seeking part of the psyche (known as "Id"), which is also the container of

the libidinal energy, and other parts of the psyche that counter it with realistic estimation of what is possible (known as “ego”), or with what is acceptable and right (known as “super-ego” or “ego ideal”). Thus, a person may engage in aggression against others as an extension of the internal conflict he has to eliminate the part in him that may resemble (or is associated with) them. Psychoanalytic Theory predicts that in order for such symbolic cleansing to be “real,” some people would not be able to sooth themselves with fantasies of such cleansing, but will have to engage in actual violence against the symbolic “enemy.” In particularly disturbed personalities with compromised reality perception, even the enactment of the fantasy would not be enough to make such enactments “real,” and there needs to be an audience, whose distress may serve as a “consensual” affirmation to the reality of the cleansing act.

One of the earliest attempts to understand political violence through the lens of Psychoanalytic Theory is exemplified in Freud’s book “Civilization and its discontents,” published in 1930. In it, Freud generalizes the internal neurotic conflict between the individual drive for egotistic pleasure and the need to be realistic or moral to the constant tension between the wishes of the people and the law, order and morality required of them by the society they inhabit. Thus, society is structured in parallel to the individual’s psyche, and people’s wish for personal gains has to be tempered with society’s longer term and general goals and values – hence the constant internal conflict of interest within both individuals and societies alleviating this conflict may be achieved displacing the tension outward, as in the case of waging a war. A special case of this generalization is the parallels that Freud draws between family life and dynamics and that of societies. For example, Freud contended that one of the most formative stages in the child’s development takes place around the ages 3–4, when the child starts to realize that, contrary to his wishes, he is not alone with his mother in the world. The crisis that ensues is dubbed the “Oedipus complex,” after the Greek prince who ended up (inadvertently) killing his father and marrying his mother. While the infant is focusing all his gratification efforts toward the mother, and thus attaches (“cathects”) all his libido onto her, his realization that the father exists in the world as a contestant to his mother’s love and attention is too disturbing to

handle. As a result (1) The child is filled with unbearable sense of loss and threat and harbors fantasies of killing the father or having him disappear – the overwhelming emotions, stemmed by real or imaginary traumas are all generated in the “Id,” in its capacity as the gauge of pleasure. In “normal” people, they are never to reach consciousness or owned up to. (2) The child applies internal maneuvers that help him be less aware of the problem, like denial, suppression, and other defense mechanisms that make the father less threatening. Conversely, disavowal of these inappropriate urges can be done by projecting the hatred onto the father himself, thus turning it into anxiety, lest they are castrated (“castration anxiety”) or killed (“annihilation anxiety”) by the father. The projection can be also displaced to another man in order to protect the father – these complex mental operations are largely formed in the “ego” part of the psyche. While the motivation for their existence is hidden to the person, psychoanalytic theories contend that it still affects their manifest feelings and actions. (3) Finally, the child fends off and mitigates the inappropriate (unconscious) sentiments toward the father by inventing personal rituals like obsessive thoughts or compulsive behaviors (largely with the help of the “super-ego”) or identifying the father as a desired role model and in the name of that identification curbing the anxiety that the inappropriate thoughts toward him will be enacted (largely with the help of the “ego ideal” part of the psyche).

Generalizing this complex psychic structure to the psychodynamics of groups, Freud posited that our need to avoid the pain and frustration associated with this world has morphed into an all-encompassing (“oceanic”) wish for unity with God, as a parallel to the wish for enmeshment with the mother (a point he first elaborated 3 years earlier, with the publication of “The future of an illusion”). Upon realization that other people are claiming the attention and love of the same object of love we once thought was entirely our own, societies engage in real or imaginary efforts to eliminate the contenders, and to ascertain their primacy. Thus, Freud conceptualizes religious wars as the generalization of the sibling rivalry and their associated fratricide fantasies or the Oedipal rivalry with the father and its associated parricide fantasies. In contrast to classical psychoanalysis and its emphasis on mitigating and harnessing libidinal energy through

defenses, modern psychoanalysis largely considers the attachment style that ensues between the child and their caretaker as a crucial building block of human psychology. The pattern of emotional interdependence that the child experiences early in their life is postulated to become engrained in the person's unconscious and thus serve as a template to all future relationships, real or imaginary. This emphasis on this "Object Relations" framework started in Freud's last years in London, but has received increasing support by both clinical practitioners and researchers.

Current psychoanalytic accounts of terrorism and political violence have drawn attention to the similarity between the narrative of terrorist organizations and that of the post-traumatically violent patients (e.g., Akhtar 1999). In both scenarios, traumas of the past are overrepresented and rehearsed in the emotional repertoire of the victim, and the unyielding internal terror associated with it must be alleviated by either terrorizing or attempting to eliminate an "other," which is associated with the primal aggressor be it in reality or in fantasy. Psychoanalysis also predicts that anxiety and distress that cannot be tolerated consciously would result in unconscious fantasies to destroy or distort the hurtful reality in order to return to the "oceanic bliss" that was felt when the person was pure, and unite with the primordial source of being (Volkan 2001). In contemporary psychoanalytic thought, this might constitute the leading unconscious motivation of terrorist organizations that are galvanized around religious fundamentalist worldview (Volkan 2002), or those with strong fanaticism around ideas of imminent apocalypse (e.g., Lifton 1999). Among politically violent organizations that espouse religious fundamentalism or apocalyptic fanaticism, as in the guilt-ridden neurotic, the unconscious anticipation, fear but also the wish to be punished, expiated, or annihilated is being projected into the wish for the world itself to be destroyed, and to be the chosen moral agents to usher this destruction – functioning as society's "super-ego." Psychoanalytic Theory, which seems to have dropped in popularity among contemporary psychological science nowadays. Is nonetheless one of the very few models that offer an explanation to the symbolic nature of the retaliation encapsulated in the terrorism acts. The punitive and sanctimonious sense of morality found among leaders and ideologues

of ethnic- or anti-colonial terrorist groups resemble the narcissists and their arsenal of attempts to undo a humiliatingly traumatic event in their formative past.

Psychoanalytic Theory is also helpful in understanding our need to denounce (as victims) and disavow (as perpetrators) terrorism acts and split them from any experience we may have been through. This need for splitting dichotomously the good "we" from the bad "them" patently resists the realistic acknowledgment of both the humanity of the terrorist and the fact that when similar deeds were done on our behalf we may have called the perpetrator a hero and lauded those deeds as heroic and auspicious. For the pathologically narcissistic, this presents as the psychopathic inability to perceive the self as on a par with others. For nations with such psychic organization, this manifests itself as the expectation to be treated preferentially, based on the sanctity supposedly conferred to them by their traumatic past. This sanctity, in turn, is expected to protect them against, say, international criminal courts for crimes against humanity. Psychoanalytic Theory also draws parallel between the narcissistic all-consuming rage that follows challenges made to this superiority, and to their communal equivalent in the form of genocidal proclivities, the dehumanization of any opponents, and their unrealistic association with the erstwhile perpetrator of the original trauma. By attributing a fundamentally psychopathic mode of feeling and thinking at the basis of human beings, Psychoanalytic Theory may circumvent, at times, the dehumanization of the perpetrator. In this context, it is worthwhile to mention that group psychoanalysis is one of very few theories to contend that a group of "normal" (albeit neurotic) people can perpetrate atrocities by projecting their unconscious (and at times disavowed) wishes onto the group, and expecting the group to fulfill these wishes. This can be seen in terrorist groups that serve a large number of constituents, most of whom denounce acts of terrorism, while at the same time admitting to fantasized counter-terrorism measures that are not dissimilar to the terrorists' acts. Psychoanalytic formulations of political violence contend that people who commit terrorist acts, and especially their ideologues, may be convinced in such cases that they are acting on behalf of this large body of silent constituents, whether or not these constituents explicitly demand or condone such acts.

Post-Freudian Psychoanalytic Theories of Group Violence

This last example could harbor an even more nuanced explanatory power when we consider a recent development in Psychoanalytic Theory: the notion of the “group as a whole” (Bion 1961). According to this development, a whole group (in our example: silent constituents and violent terrorists who share a real or imagined society) may act as a human being whose motivation and wishes are split off his consciousness but who, nevertheless, commits nonnormative acts (in our example: violent and terror-inducing acts), while being motivated by unconscious aggressive drives. Under such circumstances, a whole society (just like any group in group therapy), may induce certain predisposed individuals to act out the anger of the group, while consciously disavowing the anger underlying their actions and justify them sanctimoniously. Conversely, grandiose wishes may be unconsciously communicated to a predisposed tyrant, and create a matrix of forces that will make him or her rise through the ranks and assume this grandiose position, while the constituents may, again, sanctimoniously disapprove of their leader, as far as their conscious emotion is concerned. The unconscious mechanism by which individuals (or a group-as-a-whole of individuals) induce their disavowed mental states or fantasies onto another person is dubbed “projective identification” by the “Object Relations” school of psychoanalysis. According to this theory, the unconscious is defending against socially undesirable fantasies that arise within it by splitting them off and projecting them on others, with whom an intense relationship is still maintained. This ensures that the group’s consciousness can be defended against owning up to those undesirable wishes, while unconsciously still getting satisfaction from them by virtue of an identification with the person to whom they were projected. The borderline personality organization, marked by its constant need for conflict as a way to maintain emotional integration, is the quintessential personality organization to (over)utilize this defense mechanism. Research on Borderline Personality Disorder – thought to be the manifest personality type that belies a Borderline Personality Organization – is consistent with this formulation. Thus, for example, the two personality disorders most correlated with Borderline Personality

Disorder symptoms are the Paranoid and the Dependent Personality Disorders (Kernberg 2003).

Modern Psychoanalysis and Attachment Theories of Sanctioned Violence and Terrorism

Of the theories that descended from modern psychoanalysis, the most widely accepted framework is that of the “Attachment Theory,” originally conceived by John Bowlby – a contemporary of Ana Freud and other classical psychoanalysts, but also an archenemy to psychoanalysis in their eyes. In its current formulation, though, Attachment Theory is widely considered the most integrative, most compatible with cognitive and evolutionary psychological approaches, and most empirically supported of all theories that may be considered as descending from modern psychoanalytic thought. According to this theory, the earliest emotional patterns of the newborn in relating to their caregivers serve as templates for their relationship with most other objects throughout their lives. Objects could be persons, but also abstract identification frames, such as one’s job or one’s country. Empirical research has established 3–4 such stable patterns. The most emotionally balanced of all patterns is the secured attachment, whereby the person is confident in their explorations – physically and mentally alike – and seek their “safe base” (whether a person or a location or an object) only at times of danger or after trauma. The most relevant to violence in general, political violence in particular, and *inter alia* bears relevance to terrorism is the insecure attachment, also dubbed “disorganized” or “ambivalent.”

Empirical Support for Modern Psychoanalytic Theories of Terrorism and Political Violence

Generally, empirical research is in support of a generalized pattern of violence or of susceptibility to violent sentiments. Overall, empirical research is also in support of the hypothesis that intractable violent conflict leads to a heightened susceptibility among a fraction of the survivors for engaging in organized violence against random (and potentially noncombatant) representatives of the enemy (e.g., Cohen 2011a). The enemy in that case can be the actual enemy (like old ex-Nazi officers), an imaginary enemy (like old

Germans who might be suspects for belonging to the Nazi party), or a generalized enemy by association (like any person of German ancestry). Of the body of evidence for this process, research on the transgenerational transmission of the World War II trauma and especially the genocide of Jews is the most substantial. According to this line of reasoning, a violent political conflict disrupts the ability of its victims to adequately mourn the loss of their honor and identity. This, in turn, is postulated to promote an unconscious urgency to bear children as a manifestation of their anger and rebellion, but renders them suboptimal in tolerating their children's distress. The child's distress is perceived as a trigger to resurgence of the repressed traumatic feelings of helplessness and the unbearable pain associated with identification with loved ones who are being killed or tortured, and the parents react with emotional constriction, dissociation, and neglect, while sometimes compensating (or overcompensating) for it by becoming physically over-doting, intrusive, and overbearing (e.g., Finkelkraut 1994, pp. 104–108). Having their distress disavowed and sensing its intolerability, the infants then eschew from recognizing their own pain and, by extension, their own individualized or differentiated set of emotions. Instead, they identify with the emotional states of the caregiver and develop an enmeshed emotional relationship characterized by obsessive anxiety lest they hurt their parents. This obsessive anxiety is then manifested as overly rigid and compulsively controlling personal characteristics, accompanied by a splitting defense mechanism by which the world is divided to polarized extremes (e.g., winners and losers, all-good or all-bad, etc.), and the destructive quality of the innermost self must be controlled perfectly lest it would kill anybody with whom the child wants to have a loving relationship – a common combination of personality characteristics often referred to in the literature as “second generation survivor syndrome” (Fonagy 2002). This approach may explain the burgeoning of terrorism cells in areas mired with intractable political conflicts and trauma, and why many terrorists are capable of deeply caring for each other and at the same time practice cruel, unyielding, and hateful acts against random representatives of the culture which, for them, represent the enemy. It also may explain the quasi-militarism,

perfectionism, and rituals that are common in most politically motivated violent groups, from guerillas to undergrounds to suicide terrorism cells.

Behaviorist Theories of Violence and Terrorism: Classical Conditioning and Frustration-Aggression Theories

Historically, at least in the USA, psychoanalysis has reached its peak influence both as a theoretical framework and as a practical template for psychotherapeutic interventions in the mid-1950s, and by the 1970s was rivaled by behaviorism and/or cognitive theories of the mind. This is not to say, though, that behaviorism is necessarily a younger field than psychoanalysis. By 1904, Ivan Pavlov, a Russian scientist, has formulated a theory of human personality and behavior based on conditioning and learning that was by then largely supported empirically. This theory suggested an essential role for conditioning and associative learning in governing behavior and personality characteristics. Freud's first structural model of the mind was published only a year later, as the seminal “Three Essays on the Theory of Sexuality.” Similarly, Behaviorist theories postulating behavioral conditioning as underpinning violence and/or social interactions (the two main components of political violence in the behaviorists' viewpoint) were already almost fully articulated in the early 1900. Ivan Pavlov is perhaps best known for demonstrating that copresentation of a naturally motivating stimulus together with a neutral stimulus will cause dogs to react with the natural response to the neutral stimulus. For example, salivation – which is a natural response to presentation of food to a dog – would occur in response to a bell ring if this novel stimulus would consistently be presented to the dog along with food. However, Pavlov also studied the conditions under which dogs would get aggressive during his experimental paradigm. This seemed to have occurred under two related conditions: in the first condition, dubbed “frustrative non-reward,” trained dogs were hungry and expected food, but no presentation of food followed the bell ring. In the second condition, two mutually exclusive responses were equally suboptimal (e.g., bell ring was equally associated with both avoiding an electrocuted plate and eating from it with no ability to distinguish whether the plate is safe or not). Pavlov viewed the aggression potential of the

dogs as a combination of their innate ability to control themselves that makes up their basic character (later called “temperament”), and the empirical level of frustration that was induced in them (e.g., the hungrier the dog the higher the frustration of not being able to assess the safety of the food plate).

Pavlov’s theory of dogs’ temperament and aggression has later resurfaced as one of the most influential psychological accounts of aggression, and political aggression inter alia, when introduced by John Dollard and Neil Miller (among other scholars, mainly from Yale University) in 1939 as the “Frustration-Aggression” Theory (Dollard et al. 1939). Applied to social and political entities, this theory predicts that, for example, if hard work is widely associated with success but talented and hard working individuals that belong to a prejudiced minority encounter a “glass ceiling” that is not acknowledged, their frustration may turn to violence against the hypocritical system (e.g., Staub 1996; Holdredge 2007). A more recent incarnation of this hypothesis can be found in “Relative Deprivation Theory” of Ted Gurr (1970), which came to the fore in the early 1970s and highlighted frustration that stems from individuals not being able to obtain what they have been conditioned to expect by social norms (as compared to others in their society) as a major form of frustration that usually galvanize people toward political violence, rebellion, and acts of terrorism inter alia (Gurr 1970). It should be noted, however, that research found more evidence for aggressive frustration following humiliation, distress, and hopelessness than perceived deprivation or poverty per se (e.g., Stern 2003; Sageman 2004; Bloom 2005; Atran 2006; Awan 2008). It should be noted in this context that poverty per se has mostly been shown to be unrelated to the motivation to commit acts of terrorism (e.g., Krueger and Maleckova 2003; Abadie 2005; Merari 2007).

Thus, by the late 1930s, Pavlov’s theory was split between US scholars, with the conditioning-based frustration endorsed as the main cause of political aggression among social psychologists (e.g., Dollard, Doob, Miller, etc.), while temperament and character as the main causes of political aggression were highlighted by post-Freudian psychoanalysts like Alfred Adler, Erich Fromm, and Karen Horney, among others. According to the latter group, generally speaking, the frustration one may feel toward the political system, including any

aggression they may exert against it, was a product of a particular type of neurotic overreaction.

Behaviorist Theories of Violence and Terrorism: Operant Conditioning and the Behavioral Analysis of Politically Violent Acts

Another major development in Behaviorist theories of aggression was introduced in the late 1930s, with B.F. Skinner demonstrating that not only natural responses could be associated with novel stimulus, but also any action (dubbed “operant”) that, on average, consistently improves the situation of an animal will be repeated. This principle, known as the “law of effect” was posited some 30 years prior to its empirical substantiation by Skinner (Thorndike 1911). The theory helped explain complex behaviors that could not be reduced to a chain of natural responses – and therefore could not be explained by Pavlovian “classical conditioning.” It was therefore named “operant conditioning” (Skinner 1938). Skinner himself was the first to apply his theory to social forms of violence and governance. According to Skinnerian principles, individuals engage in violence if this violence brings about either some gain (called “positive reinforcement”) or a relief from oppression (called “negative reinforcement”). Applied to terrorism research, behaviorists have linked the rapidly increasing use of suicide bombing in the Middle East to the astonishing effectiveness of the use of this technique by the Islamic Jihad (most likely the Hizbollah – e.g., Shay 2004) in bombarding the barracks of the USA and France on October 23, 1983 – in the deadliest single attack on Americans overseas since World War II (and on the French since the Algerian war). A few years after the bombing, and despite public announcements by the presidents of both the USA and France that explicitly denied any intent for doing so, both the USA and France have withdrawn their forces almost completely. However, Skinnerian behaviorism affords another complementary explanation. Skinner’s studies have also demonstrated that, although undesired behavior is not likely to recur if it is met by punishment, it is most effectively eradicated by reinforcing an alternative, desirable, behavior rather than punishing the undesired one. Punishment, claimed Skinner, is not effective in that it requires a constant vigilance of the authorities, and any lapse

in punishment or retaliation gradually brings about an attempt for recidivism of the undesired behavior (Skinner 1948, 1971). Accordingly, popular opinion in the USA has blamed the steep increase in suicide bombings in the Middle East (and the growing popularity of the global jihad movement, leading to the events of September 11, 2001) to the relative lack of retaliation operations by the USA for the concerted bombings of American targets during the brief period of 1983–1984 (McFarlane 2008).

Despite the wide popularity of behaviorism in the USA and, to a lesser but substantial degree, in large parts of the world, it failed to provide adequate account for several key human sentiments, most notably the apparent dependence of our actions on our conscious motivations and feelings (e.g., Ellis 1955; Beck et al. 1979), our ability to absorb and utilize grammatical structures (Chomsky 1959), and our ability to learn by other people's experience (e.g., Bandura et al. 1961). Skinner contended that thought processes, or cognitions, are only constructed after we perform the behavior we were conditioned to perform, and serve as an ad hoc rationalization, but not as an internal motivating force that drives us to action. In the height of the disenchantment with his theory for its counterintuitive determinism, the *Time Magazine* wrote on its cover: "B.F. Skinner says: We can't afford freedom" – referring to free will, which behaviorists regarded as unnecessary to explain behavior on empirical grounds (*Time Magazine*, September 20, 1971).

The Disillusionment with Radical Behaviorism and the Rise of Cognitive Psychological Theories of Political Violence: The Ideological Roots of Terrorism

Although harbingers of theories that regarded thoughts and cognitions as the root cause of behavior can be traced back to the late 1930s, in Dollard and Miller's "Frustration-Aggression" Theories mentioned above, it was not until after World War II that cognitive psychology has become a viable contender to the hegemony of Skinnerian behaviorism, at least in the USA (although recent scientometric studies cast doubt on this alleged hegemony, see Virués-Ortega 2006). Today, many historians of psychology view the belatedly acknowledged criticism of US behaviorist hegemony delivered by Sir

Frederic Bartlett (UK), Lev Vygotsky (USSR), and Jean Piaget (Switzerland) as heralding the "cognitive revolution" in the USA, which is most symbolically inaugurated by Noam Chomsky's critique of Skinner's book "Verbal Behavior," arguing that language is too complex and generative to be acquired using operant conditioning alone. The ability of children to construct novel sentences they have not heard before, relying solely on limited exposure or conditioned sense of grammatical correctness defies the principles of operant conditioning (Chomsky 1959). Similarly, Bartlett's claims that our expectations do not stem solely from direct experience but rather from our memory of our past experience – a memory that is prone to inaccuracies because it is reconstructed anew whenever we call upon that memory – also contradicted Skinnerian tenets that personal experience is the only route to conditioning, rather than the memory of what this experience was. Bartlett's work postulated that our memories are constructed from familiar "building blocks" (called "schemas"), representing a distillation of the commonalities within our experience. For example, the sum total of our experience with dogs throughout our life is encapsulated in our "dog schema" (Bartlett 1932). Thus, theoretically at least, if one reads enough stories of dogs being unexpectedly violent and has little personal exposure to actual dogs to counter that impression, they may be inclined to shoot any dog on sight solely due to their expectations of being harmed by it. Contrary to the radical behaviorist formulations of aggression, the fear-based behavioral response in this case did not emerge from any previous experience of preventing personal harm by shooting any approaching dog.

Radical behaviorism is particularly problematic to the study of terrorism and political violence, since its strict emphasis on behavior and disregard for cognition obviate ideology and propaganda as root causes for terrorism acts. The extent to which ideology, communal victimization, and blame-attribution trigger and facilitate politically motivated violence is still a matter of debate. However, extant terrorism research literature rarely does away entirely with the idea that ideology has a facilitating effect on the galvanization and radicalization process leading to political violence or terrorism. Acts of terrorism are usually supported by systems of thought where good and evil are absolute, where

a group deems itself to be squarely on the side of justice, truth, and morality, while the opposing group is debased, dehumanized, and full of evil. Understanding the persuasive appeal and mobilization potential of this set of cognitions seems crucial to understanding terrorist ideology and effectively countering it (Baumeister 1997; Laqueur 1998; Kernberg 2003; McCormick 2003).

Early Cognitive Psychological Theories of Social Violence: Cognitive Dissonance Theories of Terrorism and Political Violence

Interest in the formation and modification of cognitive constructs has burgeoned in the late 1950s and the 1960s. For the study of violence, and in particular political violence, the most important of that era's cognitive studies seem to include Leon Festinger's "cognitive dissonance" and Jones and Harris' (1967) "Fundamental Attribution Error" studies. Although for the study of politics and violence both constructs are used mostly in social circumstances, they are inherently intrapersonal rather than interpersonal, and therefore could be viewed as part of the quest for understanding individual cognitions. Leon Festinger's initial observations concerned the paradoxical tendency of cult members to increase their efforts to recruit new members and proselytize their creed after prophecies made by their leaders have patently failed (Festinger and Riecken 1956). Later studies have shown that when external circumstances are discrepant with the internal evaluation of these circumstances, individuals would change their internal evaluation to fit external reality. Similarly, when circumstances bring individuals to behave in a manner that is at odds with their internal attitude, they will likely change their attitude to fit their overt behavior. The fact that the process may (and often does) take place outside the person's awareness makes this phenomenon indissoluble as mere rationalization, which was until the 1950s the main explanation for the phenomenon, following Anna Freud (1937). The explanation given by Festinger was that any discrepancy between external reality and the cognitive representation thereof creates a "dissonance" (hence the name "cognitive dissonance"), which induces discomfort in the person's mind and behooves it to change in a manner that will optimally reduce it. Since

changing external reality is not possible, the simplest way would be to change the internal cognitions while keeping this change process outside one's awareness (Festinger 1957; Festinger and Carlsmith 1959). While the phenomenon of cognitive dissonance has been thoroughly replicated, Festinger's explanation was challenged numerous times, and the mechanism underlying the phenomenon is still a matter of debate (e.g., Bem 1967; Harmon-Jones et al. 2011).

Despite being an inherently intrapsychic cognitive bias, cognitive dissonance has proven quite useful to the study of organized violence, mainly because of the strong effect of consensual and sanctioned systems in reducing the dissonance between perceived reality and individual attitudes and self-perceptions. According to this view, most ideological justifications for violence aim at reducing the dissonance between the violence sanctioned by the group and the largely nonviolent nature of the new recruits, in the name of their perceived common aim (Crenshaw 1986; Juergensmeyer 2000). For example, several contemporary theories of the processes underlying the growing ideological radicalization and aggression of recruits in violent organizations use the "foot in door" explanation of cognitive dissonance, whereby leading individuals to commit increasingly violent acts – albeit sporadically (e.g., in the spur of the moment, as part of a larger group, following a seditious speech by a charismatic leader, etc.) – compels their internal ideological leanings to radicalize along with their actions (McAdam 1986; McCauley and Segal 1989; Moghaddam 2007). The various rhetorical excuses and practices that invariably lead to "moral disengagement" (Bandura 1999) can also be seen as devices to reduce the dissonance between the internal attitude toward violence and the sanctioned tactical aims of the terrorist group – be it on national or subnational level (Maikovich 2005).

Early Cognitive Psychological Theories of Social Violence: Fundamental Attribution Error and Other Cognitive Biases Underlying Terrorism and Political Violence

Discovered in the late 1960s, the Fundamental Attribution Error (Jones and Harris 1967) is another cognitive distortion whereby one's thoughts are at odds with consensual reality in a predictable manner.

The tendency of individuals to view their failures as circumstantial while attributing other people's failures to basic flaws in their disposition was instrumental in reconciling both the importance and fallibility of human cognitions. Terrorist propaganda usually frames the violent actions and intents of its group members as a natural reaction to aggression, as fighting a "war of no alternative" (e.g., Morris 1999; Hotta 2007), and as resulting in atrocities only inadvertently (e.g., "collateral damage"), whereas the opponent group is made of inherently evil, vindictive soreheads (Juergensmeyer 2000; Bush 2001).

Contemporary views of human cognition have largely been consolidated by the late 1960s as an integration of the three main conclusions of the "cognitive revolution," namely: (1) cognitions are crucial to our mental life, and largely control our attitudes, emotions, and goal-directed behavior; (2) cognitions may or may not be conscious and volitional, and our ability to introspect and control them is limited and difficult; and (3) cognitions are prone to systematic errors and biases in the service of self-preservation.

By the early 1970s, the list of cognitive biases and errors has become rather extensive, and more attention was paid to the role of the error-prone cognition in emotions (including hate, anger, and fear) and emotional acts (including violence and terrorism). In tandem, cognitive therapies were then construed under the premise that changing faulty cognitions and attributions would lead to a more adaptive behavior and emotionality (e.g., Ellis 1955; Beck et al. 1979). The success of these forms of therapy added to the credibility of the growing cognitive psychology sub-discipline. One of the most cited cognitive biases among theories of psychopathology, psychotherapy, and terrorism is "negativity bias," whereby negative events are given disproportional cognitive resources compared to positive or neutral ones. This cognitive bias was observed in the attention, interpretation memory and expectation with which individuals process both autobiographical or reported events (Cohen 2011b). The bias is stronger when the person or the group is depressed or stressed – which may explain the allure of hate messages among disillusioned or disenfranchised groups or nations, and their higher likelihood to exercise prejudice-based judgment and be galvanized to act violently on these sentiments (Weary and Edwards 1994; Beck 2002;

McCauley and Bock 2004; Breckenridge and Zimbardo 2007; Kim 2010).

Contemporary Cognitive Bias Theories of Political Decision Making and Political Violence; Prospect (or Polyheuristic) Theory

A recent addition to the body of knowledge regarding cognitive distortions, biases, and errors is "Prospect Theory," developed by Daniel Kahneman and Amos Tversky in the late 1970s (Kahneman and Tversky 1979). The theory provides a unified framework for understanding the mental shortcuts that people may be unwittingly utilizing in making decisions under uncertainty conditions, and its well-rounded usefulness has won Daniel Kahneman the Nobel Prize in economics in 2002. Two of the most important concepts that Prospect Theories contributed to the psychology of political decision making are the principle of loss aversion and the elucidation of framing effects on evaluations and attitudes. These concepts have been used in the study of propaganda and radicalization. Loss Aversion is the preference to avoid losses over acquiring gains. To paraphrase tennis star Jimmy Connors – people hate to lose more than they like to win (quoted in Levy 1996, p. 181). Because this preference may underlie the tendency to overestimate projected regret after loss than joy after gain (e.g., Kermer et al. 2006), it is particularly salient when the individual or the community is depressed or under stress. A particular case of "loss aversion" is the endowment effect, whereby people value what they have (or, conversely, have hard time letting go of something they have) more than what they do not have. Colloquially, this sentiment is sometimes known as the "Garage-Sale Dilemma." Uses of the loss aversion phenomenon are widespread in persuasion studies, from marketing to propaganda. Thus, the mobilization potential of campaigns that promise a gain of \$5 is, on average, inferior to those which mobilize the individual to act toward not losing \$5. Combining elements from both negativity bias and cognitive dissonance, many public messages nowadays use the loss aversion phenomenon by capitalizing on the persuasive appeal of anxiety: from political fear tactics to epidemiological hygiene campaigns to marketing of hand sanitizers and deodorants (i.e., capitalizing on avoiding body odor vs. smelling

good). Seditious calls for violence have similarly emphasized loss aversion: calls for fights in the name of protecting “freedom,” justifying sending more people to losing battles so the blood of the fallen has not been spilled in vain (e.g., Elster 1993, p. 10; Bauer and Rotte 1997), and exaggerating the consequences of a defeat are all age-old tactics that help persuade people to commit indiscriminant violent acts against noncombatants (Levy 1996; Breckenridge and Zimbardo 2007; Arceneaux 2009; Hollander 2010).

As a comprehensive theory of the irrationality of decision making, Prospect Theory predicts some of the dependencies between attitudes or decisions and the order or the context in which the data leading to those attitudes or decisions are presented. This dependency is dubbed “framing effect.” In an increasingly democratizing world, where political decisions are based on a majority opinion, framing of the problem at hand may make all the difference (e.g., Turner 2007). Prospect Theory predicts that, for example, tax deductions for families with children would be preferable by the public to tax increase for the childless – although the economic implications are identical (Schelling 1984, p. 19). Similarly, framing the same 1% GDP growth in the USA as the lowest in US history (Bill Clinton) or as better than the world average (George Bush) could spell major differences in voters’ decisions. In terrorism research, it has been noted that framing the drop of two atomic bombs on Japan by the USA is considered terrorism by most definitions of the concept – except in the USA itself, where it is framed as the only way at the time to stop the war and avoid a much higher number of casualties. Similarly, framing terrorism as a crime implies that counterterrorism efforts are efforts toward a restorative justice, whereas waging “a war on terror” encourages a mindset of “à la guerre comme à la guerre” (all is fair in war), and has been postulated to relax decision makers’ morality stopgates to allow unbridled measures (e.g., torture, unprovoked invasions of sovereign countries, among other terrorism means of warfare), since the “justice” frame was effectively neutralized (Lakoff 2004; Kruglanski et al. 2007; Zhang 2007). Less research on framing effects exists vis-à-vis subnational terrorism groups, perhaps because their reliance on democratic majority decision making is rarer, and the decision-making process itself is less transparent, only its aftermath (but see Juergensmeyer 2000).

Framing and Loss Aversion represent two mental shortcuts (known as ‘heuristics’) that may mostly be effective but overreliance of them can lead to deeply irrational conclusions and decisions. Several viable heuristics for the situation at hand may at times contradict each other (e.g., placing a bet based on the probability of winning or the amount of the payoff). Recognizing that multiple heuristics may be at work simultaneously at any given decision, psychological studies sometimes utilize ‘Prospect Theory’ under the name ‘Polyheuristic Theory.’

Sacred Values Research and Contemporary Cognitive Theories of Irrational Decision-Making Mechanisms of Communal Violence and Its Ideology

Among the more recent popular frameworks for the systematization of the various cognitive biases, and especially those concerning religious fundamentalism, fanaticism, and faith-based terrorism, one may find along with Prospect (or Polyheuristic) Theory the “sacred values” set of studies. This body of studies seems to have been “imported” to psychology from behavioral economics research concerning “taboo” exceptions to the general economic rule where which trade-offs are the essence of personal and societal growth. Economists in the 1980s were perplexed by the possibility of a constitutive incommensurability of two values, or the individual or communal belief (see Durkheim 1925/1973) that bringing a certain value to the negotiation table undermines, obviates, or even mocks that value (e.g., Raz 1986; Kahneman 2003; Tetlock 2003). Thus, expecting the person or the community to negotiate this value (or the practices that symbolizes it, as is the case in key religious rituals) induces moral outrage, rather than being viewed as an auspicious readiness for a rational negotiative dialog in the service of the greater good. This frame of reference helped to put into perspective the “irrationality,” “fanaticism,” and “madness” associated with terrorism (Atran 2007; Atran and Axelrod 2008; Alderdice 2009; Ginges et al. 2007; Ginges and Atran 2009). For example, following the Jewish revolt against the Roman emperor Hadrian whose reign was exceptionally peaceful and tolerant otherwise, Jews largely preferred to defy the emperor’s prohibition on the circumcision of

newborns, on pains of death – much to the astonishment of the Romans, who considered it an hubric act of suicidal madness (Josephus, chap. 3, p. 115; Pucci Ben Zeev 2005; Baskin and Seeskin 2010). Similarly, both Rabbinical and Roman sources (against many modern scholars) attribute the very inception of the revolt to the absolute refusal of the Jews to allow a statue of the emperor in Jerusalem, as was the custom in all other notable cities throughout the Roman empire (Pucci Ben-Zeev 2005, p. 267).

In contemporary psychological studies, both Rational Choice Theories and theories that posit an inherently biased and irrational cognition in moral or ideological decision making are both being used successfully in terrorism research. Several contemporary lines of research aim at “mapping” the bounds of rational thinking and understand the conditions in which humans may think and make decisions deemed irrational. Current research also seeks interventions that may aid cognitions become minimally biased. Such interventions are purported to serve as useful tools for counter-propaganda, counter-terrorism, and using justice as the solution for terrorism (Atran et al. 2007; Alderdice 2009; Tenbrunsel et al. 2009).

Rational Choice Theories of Terrorism and Socially-Sanctioned Violence

As history of psychological ideas would frequently have it, along with the increasing realization of the irrationality of decision making and the fallibility of human cognition, another line of research has developed, which in contrast highlighted the rationality of the decision-making process. This group of theories is known collectively as “Rational Choice Theory,” and claims that people are mostly rational beings that always consider the “expected utility” of their actions and attempt to prefer decisions that maximize their gain and/or minimize their efforts (von Neumann and Morgenstern 1947). Soon after elucidating the development of the cognitive capacities that comprise rational evaluations of the environment (e.g., Piaget and Inhelder 1951), the cognitive capacities underlying rationalized moral attitude have become an intense area of research in cognitive psychology – arguably second only to intelligence testing (e.g., Kohlberg 1969; for a current account of this line of research see Turiel 1983).

In the psychological conceptualization of terrorism and political violence, Rational Choice theories have proven useful (e.g., Caplan 2006). This holds true even in cases where the actors are not rational in the consensual (western) sense, such as in the case of suicide terrorism. For example, rational choice theorists, using both real-life data and simulations taken from Game Theory, drew the world’s attention to the superior cost-effectiveness of suicide terrorism (e.g., Sprinzak 2000; Hoffman 2003; Pape 2005; Morgenstern and Frank 2009, p. 14). Several leaders of terror organizations have explicitly endorsed this line of reasoning. Specifically, leaders of terrorist organization reason that the cost-effectiveness of suicide terrorism is superior, considering the greater good. According to these accounts, one suicide bomber is the most sophisticated bomb imaginable, with much higher casualties than other “blind” explosives. Additionally, the resources involved in acquiring the explosives and for training are minimal, and there is no need for planning a retreat plan and risk additional fighters (e.g., Dr. Ramadan Shallah, quoted in Sprinzak 2000; Hassan 2001; Rantisi 2002; Mahmud Al-Zahar, quoted in Pape 2003). Jihadi Terrorism researchers (especially in the US) also add to these consideration the rewards promised to martyrs in Islam and the remuneration, social support, and honor that is usually bestowed of martyr’s family as additional factors that add to the perceived rationality of their decision to become suicide bombers.

Early Integrative Social-Cognitive Psychological Studies of the Factors Underlying Social Violence

As is often the case with the psychological research of individual differences, the interest in the cognitive basis of emotions and actions turned quickly into the study of the cognitive basis of social relations. Several formative studies have documented how our cognitions (and the actions they bring about) are shaped by social motivation. One of the earliest harbingers of this realization was Solomon Asch and his studies in tacit social pressure, back in the 1950s. A Gestalt psychologist, Asch showed that individuals would change their judgment concerning the length of a line to conform to the majority opinion, even if this opinion was egregiously discrepant from reality and was manufactured by planting “subjects” who were confederates of the

experimenter (Asch 1956). One of Asch's students, Stanley Milgram, further expanded the view that our actions and cognitions are socially motivated, although they do not always cohere and we may not always be able to reflect consciously how our cognitions follow our action and vice versa.

In a series of experiments conducted at Yale University in the early 1960s, Milgram has demonstrated that individuals from all walks of life who were led to believe that they partake in a scientific experiment of learning, delivered dangerous levels of electric shocks in response to wrong answers given by the designated "trainee." This "trainee" who received the shocks was a confederate actor who reacted with loud cries that were proportional to the level of shock they allegedly received. Despite knowledge of the harmful and potentially fatal nature of their actions, about 65% of the subjects delivered near-fatal or fatal levels of shock when ordered to do so by the experimenter (Milgram 1974).

The almost counterintuitive tendency of individuals to commit violent acts when their leader or their reference group (e.g., friends, peers, tribe members, etc.) commands it was most jarringly demonstrated by the (in)famous "Stanford prison experiment," conducted by Philip Zimbardo in the summer of 1971. A group of 24 students out of a total of 75 participants was randomly selected to assume the role of "prisoners" in a makeshift prison built for that purpose. The group of "wardens" have rapidly developed an increasingly cohesive practice of torturing the "prisoners" above and beyond the limits delineated in the protocol. After mere 24 hours some of the prisoners rioted. The riot could not be effectively contained and in the following days several "prisoners" became quasi-psychotic and screamed uncontrollably, while others have shown other signs of severe distress. Among the "wardens," post facto analysis determined that about a third exhibited signs of genuine sadism. The experiment, which was planned to last for 14 days, had to be terminated after about a week, with Zimbardo himself, in his capacity of "prison superintendent," internalizing his role to the point where he became complicit with the violence and developed authoritarian personality traits such as grandiose callousness and sanctimonious hostility toward his "prisoners."

Apart from corroborating Milgram's findings regarding the blind obedience and diminished capacities

for self-observation, self-control, and empathy in individuals while performing a "sanctioned" task, the prison experiment also shed light on some of the parameters that facilitate institutional violence. Firstly, the shabby clothes of the "prisoners" helped in their dehumanization and maltreatment. Secondly, the uniformity in the "wardens'" appearance has both contributed to their sense of group cohesion and solidarity against the "prisoners" and the diffusion of personal responsibility and accountability, which relieved them from individual scruples. Thirdly (and relatedly), the level of "wardens'" anonymity (e.g., by wearing mirror glasses, by having numbered tags instead of name tags, etc.) was correlated with their level of sadistic aggression.

Taken together, Asch, Milgram, and Zimbardo's experiments have demonstrated that cognitions and actions are heavily influenced by social or peer pressure – be this pressure implicit or explicit. Concomitantly, individuals under strong enough social or peer pressure may become uncharacteristically complicitous, unreflective, and irrational. Terrorism research has used these insights to explain phenomena like brainwashing in cult-like terrorism cells, state-sponsored terrorism, recruitment for terrorism, and torture-bound grievance (e.g., Atran 2003; Dawson 2009; Kruglanski and Fishman 2009). For example, remarkable similarity exists in the practice of recruitment, indoctrination, and the framing of violence against noncombatant civilians among several contemporary terrorism cells. These include Al-Qaeda, Aum Shinrikyo, Branch Davidians, Bhagwan Shree Rajneesh group, Jewish Defense League, and Christian Identity Movement, among others. Roy Baumeister, one of the strongest voices in contemporary social psychology, in a review of the root causes of social violence written before the tragic events of September 11, 2001, found that all groups that have committed terrorism (whether state-sponsored or sub-national) have exhibited all four of these components: ideological dichotomy between good and evil, revenge for perceived injustice, aspiration to break through enemy-imposed barriers to success, and sadism (Baumeister 1997). Documentation of the Jewish revolt against the Romans, culminating in the Massada massacre of 73 AD (Josephus 75 AD/1981) largely confirms that the routes to social radicalization and political violence have arguably not changed significantly in the last few millennia.

Social Learning Theory, Violence, and Moral Disengagement in Theories of State-Sponsored and Grassroots Terrorism

The 1960s have witnessed another decisive demonstration that “pure” cognitions, devoid of actual behavior, may still constitute a valid cause for aggressive and violent acts. Albert Bandura’s studies, that later gave rise to the influential “Social Learning Theory,” have shown that when children watch a person who seems to be enjoying themselves and not chided or punished while being aggressive toward a “BoBo Doll,” they expect similar unbridled fun from enacting the violence they have been exposed to (Bandura et al. 1961). In contemporary conceptualizations of terrorism, Social Learning theory plays a significant role. For example, the theory presents several advantages in explicating the reciprocal relationships often found between state-sponsored terrorism and “grassroots” terrorism, as well as the relationship between child abuse or trauma and terrorism in general and martyrdom terrorism in particular (Hudson 1999; DeMause 2002; Janowitz 2006). Child abuse and trauma related to political violence and terrorism are mostly inflicted by the state, with children representing a collateral damage in what is habitually justified as retaliatory or preemptive violence against a civilian population that presents a high risk for terrorism activity and support. However, conscription of children as soldiers, which is a popular practice in guerrilla warfare and terrorism (and particularly so in anticolonial terrorism) also results in exposure of children to violence and the concomitant activation of modeling behavior, which has been documented to result in similar mirroring of the violence, whereby the affected children engage in both homicidal and suicidal terrorism acts (De Silva et al. 2001; Blattman and Annan 2007). Social Learning theory also helps to explain the role of socially sanctioned propaganda in the willingness of group members to engage in political violence. Thus, public praise and worship of perpetrators of politically motivated violence and terrorists as heroes is considered a strong draw for community members to emulate them and join the armed combat in the hope of basking in similar glory – even if posthumously (Post et al. 2003; Post 2005; Abufarha 2009). Albert Bandura, in a balanced review written before the social-psychological

emphasis on Jihadi Terrorism spurred by the tragic events of September 11, 2001, identified four “techniques of moral disengagement” practiced by terrorist organizations. These include: (1) believing themselves to be righteous saviors who are morally justified to use all means to fight “evil”; (2) personal responsibility is either diffused by anonymity and indistinguishability of the individual or displaced to the leader or even to the enemy; (3) minimal exposure to the aftermath of the attack – either by suicide or by using timed explosives, poisoning water upstream, or other measures; and (4) dehumanization and prejudice against the opponent group (Bandura 1999). A recent review based on content-analysis of a large sample of statements made by terrorism groups has expanded this list fourfold, with many of the themes representing variants of the social-psychological processes delineated by both early social psychologists and Social Learning theories combined (Saucier et al. 2009). The overall pattern of social-psychological explanations to politically motivated violence, therefore, puts a large emphasis of the conscious and unconscious advantages of the transmission of ideology as an “action-oriented system of beliefs capable of explaining the world and of justifying decisions, of limiting and identifying alternatives and of creating the most all-embracing and intensive social solidarity possible” – to borrow a now-classic definition from Karl Dietrich Bracher (1984). The mechanisms underlying state-sponsored terrorism (sometime mistaken for “counter-terrorism” by the state) and non-state-terrorism (perpetrated by sub-national violent groups) are therefore postulated to be identical in the eyes of most social psychologists today.

Interestingly, the “moral disengagement” set of theories that originated from Social Learning theory has merged, in contemporary psychopathology, with the literature regarding splitting and dissociative processes. Modern psychopathology has documented how individuals may behave according to different moral codes in different situations while perceiving themselves to be morally consistent. Theories of psychopathology have tied this dissociative phenomenon directly to moral disengagement among individuals who committed acts of terrorism (e.g., Ben-Shahar 2009; Schwab 2010). Since dissociation is tightly related to trauma and psychological distress, it has been hypothesized to constitute the main device through

which leaders of terrorist organizations on both national and sub-national level act as “everyday psychopaths” and facilitate states of dissociation and their concomitant acts of atrocities among their armed forces (Rieber 1997; Hollander 2010). The idea that overt aggression is mediated by the unbridling of internalized morality that occurs under dissociative states was originally introduced to modern psychology by Classical Psychoanalytic theory (see review in Stein 2001).

The Second Wave of the “Cognitive Revolution” and “Social Cognition” Theories of Political Violence and Terrorism

The growing realization among psychologists vis-à-vis the discrepancy between the unconscious and conscious motivation for social behavior facilitated the integration of the 1960s “cognitive revolution” with the rapidly developing field of neuroscience, giving rise to an integrative school of thought, known largely as “social cognition.” Social cognition is arguably the most popular psychological framework in contemporary psychological studies in general and those pertaining to political psychology in particular. With the growing understanding of the manner in which the brain’s decision-making computation is carried out, cognitive scientists have begun to systematically contrast neurological activity with introspective reports from subjects explicating the reasoning behind their decision. This body of knowledge has led to the “Dual-Processing” or “Dual-Attitude” theories of cognition. According to this theory, information is processed on two mostly unrelated levels: the conscious, logical level that requires effortful deliberation and an automatic, fast, and largely unconscious level. Both information-processing routes are working in tandem, with differential and nonlinear impact on the final decision or judgment (e.g., Chaiken and Trope 1999; Wilson et al. 2000).

In political psychology, Social Cognition offered an empirically testable framework for understanding unconscious phenomena that heretofore could only be inferred from studies involving free associations and discrepancies between overt behavior and covert motivation, among other elaborate research designs. For example, the study of prejudice – a major

component in the process of terrorism-borne radicalization – could traditionally only be observed indirectly, rather than using direct questioning, considering the potentially overwhelming motivation of the individual to (consciously or unconsciously) manage their impression and represent themselves in the best possible light. However, experimental paradigms such as the Implicit Association Test (IAT; Greenwald et al. 1998), make the detection of prejudice more straightforward and less inferential. In the race IAT, which taps prejudice against, for example, African-Americans, the participant is shown a series of pictures and words that appear consecutively on the screen. The participant is then instructed to press the same key whether a picture of an African-American person appears or a negative word appears. Similarly, if a picture of a Caucasian person appears, they are to press the same key as whenever a positive word appears. In another, interleaved, block of the same experiment, the keys for an African-American’s picture and positive words are now the same, while the response to a Caucasian’s picture is the same as for a negative word that appears on the screen. The participants are instructed to work as fast as they can, while the pictures or words are flashed for a brief period of time. The difference between the average reaction time for each of the two blocks is a measure of how fast the brain associates an African-American face with good things compared to a Caucasian face.

IAT research has substantiated previous social-psychological studies, and has revealed considerable discrepancies between individuals’ responses to direct and indirect questioning paradigms. In the race IAT example above, participants’ behavior was reliably associated with their level of prejudice against African-Americans and their cognitive bias against African-Americans as assessed based on their performance on the IAT (see recent review in Payne and Cameron 2010). Although IAT studies in active terrorism cells has not been reported so far, implicit prejudice measurement proved invaluable to detecting popular prejudicial sentiments that may translate to public opinion in support of both state-sponsored and sub-national terrorism. For example, news about terrorism has been shown to increase the anti-Arab and anti-Muslim prejudice (as measured by the IAT) among Dutch or Swedish participants (Das 2009

quoted in Dora 2009; Agerström and Dan-Olof 2008. see also Correll et al. 2010). This finding is in line with a survey conducted shortly after the tragic events of September 11, 2001, by the Roper Center for Public Opinion Research, which showed that over 30% of Americans favored the incarceration of any Arab until their potential links to terrorist organizations are fully investigated (Verhovek 2003). The social undesirability of divulging anti-outgroup attitudes is in line with the finding that, on average, the more implicit the measure is, the higher the level of prejudice it detects. Thus, IAT suggests the most pervasive prejudice, while anonymous surveys, subtle prejudice measures, and blatant prejudice measures show decreasing levels of prejudice for approximately the same sample of respondents (e.g., McConnell and Leibold 2001; Bayoumi 2008; Echebarria-Echabe and Francisco 2008).

Drawing from both cognitive and social-psychological knowledge, and buttressed by technological advances in the neurosciences, Social Cognitive theories are currently among the strongest and most promising paradigm for studying terrorism. In addition to cognitive and neuroscientific developments in “classical” social psychology, two integrative theories have recently achieved a particularly promising level of explanatory power and hypothetico-deductive lucidity. These include Terror Management Theory and Self-categorization Theory – the latter still somewhat indistinguishable empirically from Social Identity Theory.

Social Identity, Self-categorization, and Terror Management Theories as Contemporary Paradigms to Study Terrorism and Political Violence

Social Identity and Self-categorization Theories posit a tension between coexisting personal and social identities. Reducing this potential tension or dissonance is presumed to be a major motivational force behind both personal and individual actions, cognitions, and emotions (e.g., McKimmie et al. 2003; Mackie et al. 2004; Hogg et al. 2008, 2010). To this aim, individuals often align their personal identity, values, and actions to that of their group of reference. Recent findings, however, suggest that the level of “belonging” (i.e., perceived similarity) to a group and the level of “identifying” with that group (i.e., the sense of esteem toward the group) may represent two separate processes. Although

these findings make a distinction between actual and aspired belonging to a group, both processes are nevertheless recognized as powerful motivations (e.g., Mayhew et al. 2010). Throughout the process of social identification, individuals construct idealized prototypes of their group members and act according to these perceived group “norms.” Concomitantly, individuals construct inferior prototypes of their outgroups (i.e., those groups that are not comprised of individuals of the categories that the ingroup member does not share or does not hold in high esteem) and tend to view these outgroups as more homogenous and indistinct. These complementary processes presumably serve to both motivate the ingroup members and enhance their self-representation and self-esteem (Turner et al. 1987, 2006; Hogg et al. 2008).

Several studies that sprung out of these theories helped to illuminate the radicalization process leading to indiscriminate aggression in the name of identification with the ingroup – arguably an essential component of political violence. Firstly, the two theories have helped shed new light on the “classical” theories of social psychology concerning communal violence. For example, revisiting the “Stanford Prison Experiment” (albeit with tighter external control and constant clinical supervision), Stephen Reicher and colleagues showed that the resilience of both “prisoners” and “wardens” was associated with their perceived level of belonging to their respective groups. Presumably, the more identity-relevant categories each person shared with the prototypical group member, the more they felt like they help the collective cause, the more they felt responsible and empathic toward group members, and, reciprocally, felt implicitly supported by the group. The cumulative effect of this set of social evaluations may have, along with other factors, contributed to the higher resilience to distress among individuals who saw themselves as exemplars of their group of reference. It should be noted in this context that the idea that resilience to distress or trauma is crucially dependent on the sense of social belonging or the perceived strength of the social “norm” within the ingroup is hardly a novel idea, and it was popularized almost in tandem with the rise of modern urbanism (e.g., Durkheim 1897).

Based on these and similar findings, Reicher’s group proposed a five-step model, anchored in Social

Identity Theory, to explain collective hate. According to this model, collective hate becomes consolidated (and therefore likely to be acted upon) when individuals first demarcate the identity of their group of reference and decide on the identity categories that are crucial for group membership. This is followed by portraying the outgroup as comprised of individuals that do not possess their identity-defining categories. Next, they perceive the members of the outgroup as posing a threat to their ingroup, which in turn aids their view of themselves and their identity categories as uniquely virtuous. The process culminates with the idealization of the sentiment that the members of the outgroup should be eliminated – an auspicious goal that should be celebrated once achieved (see review in Reicher et al. 2008). In this context, it is worth noting the emerging consensus regarding the process by which outrage, aggression, and violence are socially constructed. This consensus seems to transpire between the Social Cognitive theories, the Social Psychological theories (e.g., Baumeister 1997; Breckenridge and Zimbardo 2007), the Social Learning theories (e.g., Bandura 1999; Moghaddam 2007), and the Psychoanalytic theories (e.g., Stein 2002; Volkan 2002; Kernberg 2003). Despite differences in the putative motivation underlying terrorists' radicalization, these theories all seem to indicate a similar development of political violence that follows a logical sequence of escalation (see review at Hogg et al. 2008).

Another classical paradigm that Social Identity and Self-categorization theories have been able to replicate and explicate is the social learning of violence demonstrated by Bandura and his colleagues (Bandura et al. 1961). For example, Naoki Kugihara showed that a sense of threat augments the extent to which people would mimic aggressive behavior exhibited by a colleague (Kugihara 2001). Together with other studies, Kogihara's findings may help explain the "deindividuation" state of mind that is often observed in situations of unscrupulous conformity and violence. Both empirically and conceptually, this concept may explain the potential terrorist-like dangerousness of individuals' over-identification with their reference ingroup, and how this process leads to depersonalization and disinhibition that can (at least theoretically) lead to radicalization and perpetration of terrorizing atrocities. For example, while negative personal

feedback increases the sense of personal identity – and hence theoretically should decrease social identification – individuals who perceive their personal identity as greatly overlapping with their social group identity (a condition called "fused identity") perceive negative criticism as a blow to their ingroup as a whole and are willing to die and to kill in response. Studies of "fused identity" also suggest that in a state of outrage following personal criticism (interpreted by them as prejudice against their social group as a whole), individuals with "fused identity" experience a sense of depersonalization, whereby they view themselves as generic agents of their ingroup. Thus, identity fusion facilitates a depersonalized state under stress and is probably one of the key elements in the extent of violence that is often perpetrated by terrorists in a position of anonymous power, who believe they act selflessly (Swann et al. 2009).

In essence, the explanation provided by Social Identity theory for this "deindividuation" state is similar to that of classical Social Learning theory, only emphasizing the individual sense of invincibility, presumably mediated by the sense of "being one with the group and having the whole group behind you" (Ammerman 2003; Reicher et al. 2008). So far, this set of theories has identified the following social identity processes as relevant to communal aggression: (1) perceiving the ingroup as more homogenous than it is; (2) regarding the categories that define the ingroup membership as both more important and more positive than those of any other outgroup; and (3) ignoring discrepancies between personal identity (and their concomitant individual differences – most notably agendas, goals, and limitations) with the "prototypical" social identity of the ingroup. According to the tenets of Social Identity theory, these discrepancies are easier to ignore when the physical appearance of the ingroup is designed to mitigate individual differences to confer a sense of ideological similarity between the individual and the group. This was found in both the Stanford and the BBC Prison experiments and may explain why, throughout history, groups that were designed for collective action (e.g., soldiers, nurses, priests, etc.) have always stressed the homogenization of appearance – using uniforms, standard accessories and ranks or ID numbers in lieu of names, along with standardized jargon and meticulously prescribed rituals of initiation

and readiness. The fusion of individual and social identities and the facilitating role of homogeneity and anonymity in successfully mobilizing it seems to be a pan-human vulnerability, exploited throughout history by any violent group, whether national-militaristic, subnational paramilitaristic (terrorist), or even groups that prepared for a religiously apocalyptic war (e.g., the Jewish Essenes of the first century AD, section of the Muslim Global Salafist Jihad, or the Christian ‘Branch Davidians’ among many other apocalyptic terrorist groups).

Explaining deindividuation by charting the interplay between personal and social identities is a promising step toward an empirically validated psychological understanding of the conditions leading up to the ever-surprising capability of normal, caring people to commit atrocities. Social Identity and Self Categorization theories suggest that deindividuation, along with other individual states of consciousness associated with communal violence (e.g., depersonalization, mindless conformity, indiscriminant vengeance, sanctimonious rage, etc.), seems to be motivated by an unconscious fear of loss of the individual or the group identity (see also Terror Management theory, discussed in what follows). Generalizing the findings of this line of research may not only help explain perpetration of unfathomably inhumane acts, such as terrorism, genocide, and war crimes, but also may explain the *mélange* of conviction and mindlessness among action group members, often observed both in laboratory studies and testimonials of historical violence. The (re)introduction of distress and fear to the social-cognitive understanding of the communal motivation to harbor murderous sentiments may also open new venues for countering the root causes of political violence on its various levels.

Contemporary identity-based theories of social cognition, like Social Identity, Self-categorization, and Optimal Distinctiveness Theory (Hornsey and Imani 2004; Hornsey and Jetten 2004), among others, have so far replicated previous studies, expanded the explanatory and predictive power of extant experimental paradigms, and even helped find hitherto unnoticed patterns in existing data. Therefore, from a historical perspective, this line of inquiry represents a promising example of a mature psychological thought, moving farther from political a-scientific judgment and prejudice into scientific characterization of a pan-human

process (e.g., Cohen 2011a). As such, this pan-human process can be both kindled in the lab and observed in a more extreme form (e.g., terrorism) under more extreme circumstances (e.g., McFarland 2010).

Terror Management Theory, like identity-focused Social Cognition Theories, posits an unconscious process of anxiety reduction through heightened group affiliation (Hogg et al. 2008). The theory, in its most politically relevant formulation, claims that exposure to threatening information kindles an existential fear of death that drives humans to seek and follow larger, more enduring, and meaning-generating social constructs, such as conservative values, sentiments, and pursuits (Pyszczynski et al. 1997; Rutjens and Loseman 2010). The last decade has witnessed an impressive array of empirical evidence for the theory, especially in mimicking terrorism-relevant aggressive sentiments under controllable laboratory settings. Several carefully controlled studies have shown that, in general, individuals assume a more collaborative stance toward each other, while groups are more competitive and aggressive toward each other. This phenomenon is known as the interindividual-intergroup discontinuity effect, and is exemplified by the maxim “none of us is as cruel as all of us.” According to Terror Management theory, this effect is putatively mediated by fear of death. That is, when death is mentioned either directly or indirectly associated with the self or the members of the ingroup communally (a condition called “mortality salience” in the theory’s terminology), they would perceive any outgroup as more hostile and competitive (see review in McPherson and Joireman 2010). Similarly, in circumstances of heightened “mortal salience,” as in times of real or perceived war, people would generally prefer a charismatic leader whose message is simplistic, confident, stereotypical, and exclusive rather than a leader whose message is of promoting dialog, seeking understanding and collaboration with other groups or nations (for a recent review see Gordijn and Stapel 2008). The mitigation of this latent anxiety is usually achieved by resorting more vehemently to conservative and clear-cut ideology (e.g., Niemiec et al. 2010; Pyszczynski et al. 1999).

Terror Management Theory proved particularly useful to understanding religious fundamentalism – a condition that at times is associated with popular support for religion-based terrorism, and may

motivate certain individuals to actually commit terrorism acts. According to this theory, religion is a social construct that uniquely combines some of the most effective means to assuage existential fear of death. Many religions include the notion of an afterlife, thus explicitly ensuring immortality. Further, this immortality is especially bestowed on those who defended their religion – effectively disinhibiting the paralysis associated with mortal fear. The power of religion to impose moral rules makes it suitable as a candidate for a belief system that transcends personal interests, and the fact that most established religions are old additionally makes them suitable as promoting an ideal that transcends local and temporary agendas and is therefore considered enduring and general. Since faith, by most definitions, cannot be challenged or refuted using tools that otherwise may debunk other social constructs (such as social or scientific rules), its truth value is perceived to be the highest of all other social constructs. Taken together, these attributes make religion an attractive social construct to endorse in order to fend off the fear of death (both in general, but particularly so in times of heightened mortality salience), and may underly both theoretical support and actual motivation to perpetrate acts of martyrdom terrorism (Pyszczynski et al. 2003; Norenzayan and Hansen 2006; Pyszczynski et al. 2006).

Terror Management theory is both compatible and complementary to Social Identity and Self-categorization theories, in that society in general, and sanctioned social constructs in particular may have a superior capability to confer a sense of meaning and security in time of distress and threat (Greenberg et al. 1990; for a recent review see Castano and Dechesne 2005).

Historical Evaluation of Contemporary Integrative “Social Cognition” Theories of Political Violence and Terrorism

Broadly speaking, the social-cognitive paradigm, as exemplified in Social Identity, Terror Management, and similar theories, also exhibits one of the most humanistic approaches to terrorism research, since the same putative processes underlying terrorism can be kindled and measured under the controlled environment of the psychological laboratory, using community members as participants. This set of paradigms

thus transcends politically motivated value judgment, and obviates the known hurdle of defining an act as terrorism or “fighting for freedom” in a consistent manner, amenable to rigorous scientific examination (see Cohen 2011a for broader discussion). Historically, this humanist approach proved the most generative in philosophical, historical, and scientific thought. Philosophically, western thinkers in the renaissance and the enlightenment period, as Arab thinkers of the medieval ages who called for the separation of scientific inquiries from faith-based (not necessarily religious) prejudice, have inspired the most accelerated social and technological progress in their respective communities (e.g., Radest 1990; Lamost 1993; Rashed and Morelon 1996; Said 2003). Similarly, empirical science has made significant progress in relieving the world of fatal diseases whenever the designation of agents that might carry these diseases ceased to be based on prejudice and utilized hypothetico-deductive cognitive strategies. For example, the belief that the black plague, which erupted in its most vicious form in fourteenth century Europe, was brought about by Jews, lepers, foreigners, or cats proved counterproductive to eradicating this catastrophic disease. The futility of this belief ranged from the merely cruel – as in the case of blood libels against Jews and foreigners – to downright iatrogenic – as in the case of killing cats for their presumed ties to the devil – thus eliminating their contribution in eliminating the rats that harbored the bacteria-ridden fleas – the main vehicle for spreading the disease. Similarly, political decisions that were not based on the humanist assumption of basic equivalence among people and the rigor of research that this assumption commands, but instead were motivated by prejudiced and unchecked “gut” sentiments, have been proven misleading and counterproductive by historical scientific analysis. To take a recent example, most data-driven political analysts contend that the invasion of Iraq and the use of indiscriminant Islamophobic and Arabophobic practices of detention, humiliation, torture, and other breaches of human rights in the wake of the tragic events of September 11, 2001, were prejudicially misleading and counterproductive. Among several notorious examples of the counterproductivity of prejudice-based torture as a means of obtaining intelligence is the case of Ibn Shaykh al-Libi, whose false confession under torture has led the CIA to determine

that an invasion of Iraq is justified as part of an effort to neutralize Al-Qaeda from launching terrorist attacks that may potentially involve weapons of mass destruction. By the time the confession was refuted, the war against Iraq was already in a point of no return (for more examples see Harbury 2005; Yoo 2006).

In contrast, the study of political radicalization using pan-human hypotheses that can be tested in the laboratory promises not only an augmented ecological validity, but also the potential for early intervention and awareness in communities where unacknowledged grievances may radicalize the population to harbor terrorism-producing sentiments.

In addition to adhering to a set of historically fruitful humanist assumptions by pursuing laboratory paradigms to study “enemy” psychological dynamics, contemporary social cognition-based models of political violence also represent an integrative culmination of several once-discrepant theories. In doing so, they represent a promising step in advancing psychological science, in line with Kuhn’s (1962) observations concerning the pattern of scientific progress throughout history. In combining their experimental paradigms with implicit measures and brain signal analysis, social cognitive theories are directly testing (and at times substantiating) Psychoanalytic and Psychodynamic theories that were too elusive for hypothetico-deductive examination (but see a somewhat different opinion in Hassin et al. 2005). Similarly, in contrasting overt social behavior with conscious reasoning, attributions, and other cognitions, the paradigms of social cognition research integrate both behaviorist and cognitive approaches to social behavior in general and political violence in particular.

The history of the psychological theories regarding terrorism and political violence is inextricable from the history of psychology as a distinct field of scientific inquiry, from theories concerning the origin of violence and evil in the world, and from the history of terrorism warfare, dating back to the earliest records of human history. Having such a multitude of sources, sentiments, and agendas, and armed with techniques that are often inferior to the complexity of ideas they purport to study, makes for a fitful and nonlinear historical course of this line of inquiry. Historical lessons from other scientific fields, however, point to the promising

progress that contemporary psychological paradigms may present in understanding political violence as a complex pan-human psychological phenomenon.

Theories of Dissociation

ROBERT W. RIEBER

Fordham University, New York, NY, USA

Definition of the Concept

The standard dictionary defines dissociation as “the splitting off of certain mental processes from the main body of consciousness, with varying degrees of autonomy resulting.” The word probably owes its origin to the nineteenth-century physician Benjamin Rush, who presented lectures on cases typified by

difficulties in speech and rapidity of body movements (Carlson et al. 1981). He later incorporated these lectures (with some changes) on “physiological psychology” into his classical textbook, *Medical Inquiries upon the Diseases of the Mind* (Rush 1812). He devoted a chapter to what he called “dissociation,” which may be the earliest medical use of the term. Rush applied the term to people who were mentally deranged and who had “an association of unrelated perceptions or ideas, or the inability of the mind to perform the operations of judgment and reason.” In other words, Rush was using the term only to refer to pathological behavior whereas, as I shall show, dissociation can be a routine, everyday experience as well.

But of the various phenomena of dissociation large and small, normal and abnormal, the most spectacular examples are those associated with dissociative identity disorder (DID), formerly known as multiple personality disorder (MPD). My goal in writing this book is to trace the history of the theory of dissociation and related processes from the seventeenth century to the present. I will primarily use a case history methodology to illustrate the relationship between theory and practice from one decade to the next. I will proceed to do this in such a way as to illuminate the basic theoretical and epistemological issues that are necessary to understand the processes of dissociation – both normal and abnormal aspects – as well as the role of hypnosis and its relationship to organic and hysterical epilepsy. My discussion will draw freely on the theories of Pierre Janet, Morton Price, William James, Boris Sydis, Ernest Hilgard, Herbert Spiegel, and other influential thinkers in the field. Throughout the book, I will attempt to illuminate the various ironies and paradoxes which emerge from the story of the history of dissociation and its disorders. This issue is not new by any means. In fact, it has been with us at least since Aristotle. It comes down to the question of how to show the connections or integrative functions of different levels of knowing and existence without throwing the baby out with the bathwater. We will consider the biophysiological level, the self-forming experiential level, and the socially constructed level of life experience separately and in terms of their relationship to one another. Even to ask certain types of questions will require a reliance on data and explanations that give greater weight to one level or another.

On the one hand, our exploration will be scientific in nature – what is known, what is unproven, what is speculative, and what is sheer nonsense. On the other hand, we will try to understand the social construction of what I call the Myth of DID (formerly MPD). I wish to make clear that I am not asserting that MPD/DID itself is a myth; rather I will try to demonstrate that a mythology has developed about this relatively rare disorder and, further, that this mythology has been propagated by several therapists as well as people in the business of fabrication for entertainment purposes for agendas of their own. The myth is perhaps best exemplified by the case history of Sybil, which has made its appearance in various incarnations as book, as film, and as a popular cult (Rieber 2006).

I will elaborate upon how *Sybil* the book and *Sybil* the film can be understood as symptoms of social distress and the “psychopathy” of everyday life. (This thesis is discussed in greater detail in my books *Manufacturing Social Distress* and *Psychopaths in Everyday Life: Social Distress in the Age of Misinformation*). One of the major arguments will be that *Sybil* is best understood as a “social dream.” Our objective here will be to analyze and understand the messages society obtains from these social dreams. Taking my point of departure from the book and film versions of *Sybil* as well as other related social events, I shall explore the extent to which our contemporary social dreamers unwittingly reflect the underlying problems of our society. The next step, of course, is to understand them.

The phenomenon of normalized psychopathy and social distress tends to feed on itself, driving out the “good.” When bad moral currency is in circulation, it brings out the dark side of human nature. In other words, an individual’s crisis becomes a reflection of a larger identity crisis within our culture. When one breaks the connection of learning that takes place between the biological, psychological, and social levels of existence, one interferes with the healthy, creative aspects of human conduct and experience. Too many mirrors are dangerous because they reflectively distort and multiply the self. Therefore, one should hold the mirror up to nature in order to reflect upon the natural images of life rather than falling prey to the ostentatious self-righteousness of multiple selves. The book will conclude with a discussion and argument of the dangers inherent in fostering this kind of

ostentatious, deterministic, and/or reductionist theory of consciousness.

In introducing the concept of dissociation, I believe that it is essential to point out several important factors that will help us understand the nature of the concept. The most important aspect of this concept is that dissociation is a specific mental capacity or ability which *all* human beings utilize during the course of their life. The second important fact is that dissociation is a mental process and can be not only observed, but even to some extent measured, somewhat like a spectrum, with various quantities and qualities. Finally, we need to keep in mind that dissociation is a mental activity, which can be utilized by the individual for both creative as well as destructive purposes.

One may describe dissociation metaphorically by saying that it is a kind of shifting of mental gears which results in a high degree of concentration so that a kind of separation or shift occurs in consciousness between the “internal senses” and the “external senses” – between one’s imagination and reality.

All of us experience this kind of shift routinely as we descend into a deep sleep and awaken from it; there is an intermediate or transitory state in which we are neither fully unconscious nor fully conscious. While “waking logic and feeling of certainty” are not “altogether extinguished,” Froeschels writes in his essay, “A Peculiar Intermediary State Between Waking and Sleeping,” it is “interfered with by processes which went on in different spheres of the personality, namely, the sphere of ‘a peculiar pseudo-logic, and the sphere of another feeling of certainty . . . which is localized within the domain of transition.” That is to say, that “two levels of the personality are in conflict with one another. . . . The logic and the joined feeling of certainty, as perceived in the state of being awake, rejected as wrong the corresponding processes that were going on in the state of transition” (Froeschels 1949). Although Froeschels is referring here to a perfectly normal process of dissociation, he is also describing the type of process, which if the “interference” intensifies and becomes more frequent, can turn pathological.

Types of Dissociation

Different types of dissociative activity can be observed which stem from different motivational factors in the life history of the person. Since dissociation is not an

abnormal behavior but can be found in any kind of individual, both normal and abnormal, it might be of some value to simply mention the form of dissociation that is commonly found in normal people. It is called automatic writing. This is the execution of movement of the hand without the intervention of the will. The hand seems to act of its own accord, what appears on the page as much of a surprise to the consciousness of the writer as it would be to an outside observer. Analogously, some individuals can speak apparently without being aware of the source of their words, almost as if they were simply taking dictation. The great French psychologist, Alfred Binet, came to the conclusion that there may exist in the same person at the same time, not only two independent streams of activity, but also two independent centers of consciousness, which was commonly referred to as double consciousness. In the automatic writing condition, Binet would whisper instructions to his subject which were to be followed by an oral response. Thus, the writing and the oral response would go on independently, neither process consciously related to the other.

Morton Prince and others conducted experiments that demonstrated similar processes. For example, the hand that might be writing automatically could occupy itself with answers to mathematical problems, while the mouth and vocal cords would be occupied with reading aloud. Neither activity interfered with the other. If we grant that dissociation actually occurs, not only in the activity of the person, but also in his consciousness, we need to demonstrate evidence as to whether we are all able to dissociate in this sense. Then, we will need a means of finding out if individual differences in dissociation differ in quality and quantity. Over the years, psychologists and researchers have tried to test this hypothesis by assessing levels of hypnotizability. According to Dr. Herbert Spiegel, a pioneer in the field, hypnotizability is defined as the interaction of the individual’s dissociative capacity and his suggestibility capacity. I will discuss this issue at greater length elsewhere in the text especially since the condition of hypnosis, be it self-hypnosis or hypnosis induced by another party, is essential to uncover the dynamics of the dissociative process.

Divided Conscience

The concept of dissociation is closely related to the concept of consciousness, particularly divided consciousness or double consciousness, as some German scholars

prefer. The voluntary control of conscious activity of the human organism becomes a central issue in dealing with this subject. To the extent that direct control of human activity is split off from consciousness or is unconscious, as it were, we can say that the dissociative process is at work. The French term “desagregation” was used synonymously with dissociation in English and became popular through the works of William James, Morton Prince, and Pierre Janet in both the United States and France. The central question at hand, when dealing with dissociative processes, is directly related to self-integration and self-autonomy. Put in slightly different terms, one may pose the question of whether an individual can have more than one autonomous self, and if this is indeed possible, then is it possible for this self-process to be both conscious and unconscious?

Most of the controversy related to the theory of the process of dissociation relates to this issue. If one can bifurcate or dissociate oneself, how does this process take place? A number of issues must be dealt with before we can answer this question. First, what systems or patterns of behavior are more or less coherent in this process? Is there a degree of structure that facilitates the integration and/or the disintegration of the skills, memories, perceptions, etc., that are involved in this process? Second, we need to ask to what extent do amnesic barriers (or, in Freudian terms, unconscious and repression processes) prevent the integration and interaction of these systems? In other words, how do we explain the ego-alien “state of mind”? Since the middle of the nineteenth century, psychologists have theorized that in some individuals, consciousness may become split into two or more parts. The split-off or dissociated portion may be a fragment of the whole self or it may be so complex and extensive as to be capable of fulfilling all of the functions of an individual’s consciousness.

Ideas, feelings, and actions, which are associated in life experience, tend to become linked together into various processes in such a way that stimulation of one element of a particular process excites the activity of all the rest. This process is often referred to as a complex process. A complex formed in relation to some event that is accompanied by a great deal of affectivity may become dissociated from one’s personal consciousness so that recollections of the event, as well as feelings and actions connected with it, become inaccessible. Such a complex process of dissociation does not completely

disappear. In other words, it is still possible for the process to function in some manner. Various reports of normal and abnormal individuals have been described in the literature to illustrate this point. Thomas Mayo, for example, gives one of the earliest lucid recognitions of this process of the human mind in 1838 while describing what he called the moral cases of insanity. According to Mayo, there is a morbid state of the human mind in which the individual lives in alternate stages of two different beings. One is easily recognized as the person’s normal state of mind. It exhibits the ordinary aspects of his or her character or behavior. In the second state, the person appeared to have undergone a remarkable change. He or she has forgotten things or else saw them in a different light. He or she may lapse into one or another of these states without any clear recognition of the subjects and objects experienced in the other state. For example, Mayo says, “This morbid state, to which the name double consciousness is usually given, has a considerable affinity to the intermittent form of madness – so much so that it seems not unreasonable to suspect that their laws of causation may have some common points.” Mayo goes on to refer to the practice of mesmerism, which had only recently been brought to the attention of the British public, and concludes that “We have here also a form of double consciousness, which those who have seen the experiment (using mesmerism) made during the Spring of 1838, at a London hospital, will admit to have exhibited this affinity in a high degree.” Mayo contends that this form of double consciousness can be voluntarily brought about by an external agency. Mayo is referring to what we would now consider to be the process of hypnosis. The close relationship between the process of dissociation and the process of being hypnotized, putting the individual in a state of divided or double consciousness, thus becomes a crucial aspect of the story of how the theory of dissociation emerged and how it attempted to explain the normal and abnormal aspects of the normal mind.

Prying Open the Lid – The Origins of Hypnosis

Animal Magnetism Hypnosis and Its Links to MPD

During the nineteenth century, the problem of multiple personality was for the most part compatible with and

influenced by a more romantic view of human nature than its eighteenth-century predecessor.

The popular literature of the period flooded the minds of the public with fascinating macabre psychological novels that dealt with various aspects of mind brain stories about human beings' moral problems, including sanity and identity. The most popular of these novels, such as Mary Shelly's *Frankenstein*, Robert L. Stevens' *Dr. Jekyll and Mr. Hyde*, and many short tales by Edgar Alan Poe, had a formidable impact on the reading public. Something was clearly in the air that would manifest itself straight through from the scientific literature to pop culture and back again.

What became known as multiple personality disorder emerged at about the same time as what was known as "animal magnetism," later dubbed hypnosis.

Basic knowledge and practice of hypnosis may be traced back to the ancient Greeks and Romans, who used hypnosis for religious as well as therapeutic practices. Hippocrates, one of the founders of Greek medicine, recognized the importance of the role played by suggestion in the healing process; he would try to convince patients that they would soon become well. Not only this, but Hippocrates felt that a touch of his hand upon the subject would relieve pain, and that he could make an individual fall asleep by simply commanding him to do so.

In medieval times, hypnosis was used by wizards and sorcerers. The common people viewed hypnosis as being evil and dangerous. Those who practiced it were looked upon as agents of the devil who were anxious to place innocent people under their spell.

A more scientific approach to hypnosis and its use began in the sixteenth century with a man who called himself Paracelsus. Although he had many old-fashioned ideas and was greatly interested in alchemy and sorcery, Paracelsus is an important figure in the history of medicine, and, in particular, of hypnosis. He believed that the attitude that the patient had toward his own illness could have a powerful influence upon the course of a disease:

- ▶ It is not the curse or the blessing that works, but the idea. The imagination produces the effect. (Buranelli 1975)

Paracelsus also made use of magnets to concentrate in his patients what he believed to be a cosmic fluid that

possessed healing properties. Later on, James Maxwell would elaborate upon Paracelsus' theory of a healing cosmic fluid.

Years later, the first great faith healer Valentine Greatraks appeared. Greatraks eventually became famous as the Stroking Doctor for his success in healing by touch. He is reported to have cured, by the laying on of hands, fever, palsy, hysteria, and convulsions. Greatraks' powers were explained by the passing of invisible entities from his own body to that of the patient.

Yet while hypnosis may be traced back many centuries, it is popularly thought of as originating with an eighteenth-century Austrian physician, Anton Mesmer – indeed, an earlier term for hypnosis is still occasionally used today is that of "mesmerism." Mesmer felt that medicine could be turned into an exact science by extending cosmological laws to the physiology of the human body, and in this sense, his views were strangely foreshadowed by Valentine Greatraks. In particular, Mesmer hypothesized the existence of a universal fluid within the individual that, together with the indirect influence of the stars and planets, would act to make the person healthy or ill.

Mesmer was intrigued by the many psychosomatic illnesses of his time, seeing how often conventional medicine failed to cure the likes of paralysis, chronic nightmares, panic, depression, hysteria, and convulsions. In the cases of these maladies, Mesmer felt that classical medical diagnoses were inadequate. He believed that many of his patients suffering from hysteria were being bothered by the effects of a universal fluid, or animal gravitation, ebbing and flowing through their bodies. Mesmer felt that it was his job to find an agent that could be used to control this ebb and flow motion.

Mesmer found this agent in magnets. In their polar attraction and repulsion, magnets set up an ebb and flow that could be comprehended as one version of the general tidal effect, of which the gravitation of the heavenly bodies was another version. One of the first patients successfully treated with magnets was a woman who had been suffering from recurring hysteria, with convulsions, vomiting, depression, hallucinations, fits of blindness, and paralysis. The startling results of her treatment may be seen in the following statement written by Mesmer himself:

- It was on July 28, 1774, that my patient having suffered another of her attacks, I placed three magnets on her, one on the stomach and one on each leg. Almost immediately she began to show severe symptoms. She felt painful volatile currents moving within her body. After a confused effort to find a direction, they flowed downward to her extremities. Alleviation followed and lasted for six hours. A repetition of the attack on the following day caused me to repeat the experiment, with the same success. (Buranelli 1975)

Mesmer now felt that he had learned how to channel the universal fluid into his patients, and what he had earlier referred to as animal gravitation he now called animal magnetism. According to Mesmer, the proper balance of animal magnetism in the body of the individual makes the difference between health and illness. Vast psychological and many physical disorders were due, then, to the abnormal distribution of these fluids within the body, and cures could be brought about by having the ill person become “harmonized” with his fluids. This was achieved through the use of magnets and by bodily stroking or passes over the afflicted area. It was later found that many things other than magnets could be used to conduct the universal fluid. These included objects such as paper or wood, which, although not magnetic in the sense of mineral magnetism, are strongly magnetic in the sense of animal magnetism. Such objects became “magnetized” upon being touched by Mesmer.

Over the years, Mesmer’s theory of animal magnetism was almost constantly being refined and modified. The female hysteric mentioned above was likely Mesmer’s first classic “mesmerized” patient, although Mesmer himself was not aware of it. When he first began her treatment, Mesmer mainly relied on magnets to direct the flow of animal magnetism. Soon afterward, though, Mesmer saw that he only had to touch the patient in order for her to receive beneficial effects. Magnets, or magnetized objects, were not at all necessary (Buranelli 1975).

Mesmer further experimented with different techniques and found that he did not even have to touch the patient in order for effects to be seen. He dramatically demonstrated this phenomenon to the respected Dutch physician, Jan Ingenhousz, hoping to convince him of the reality of animal magnetism. Although

Ingenhousz admitted that he was impressed by the demonstration, he remained skeptical, an example of the poor responses that Mesmer typically received from the scientific world.

Nevertheless, today it is clear to us that Mesmer had, in fact, discovered how to put a patient into a hypnotic trance. While he still believed that the patient’s behavior was due to the effects of animal magnetism, Mesmer did recognize the important role played by suggestion. He made sure that he instilled the proper attitude in the patient, and usually told the patient ahead of time how he would behave during treatment. Today, it is widely agreed that subjects have a strong tendency to behave under hypnosis as they expect a hypnotized person acts, or as they are told they will behave when hypnotized.

As Dr. Herbert Spiegel noted, as a precursor of modern hypnosis, Mesmerism was dismissed for many of the same reasons that hypnosis is dismissed today. “(I)t is as if many clinicians and behavioral scientists not only reject Mesmer’s ‘fluid’ concept, he writes in his paper ‘Hypnosis: Myth and Reality’ in *Psychiatric Annals*, but also reject the observable data as well” (Spiegel 1981). By simply substituting the concept “imagination” for “fluid,” the observed behavior of Mesmerism becomes understandable in modern behavioral terms. In fact, the French Royal Commission studied Mesmerism then intensively dismissed it with the astute critique that it was nothing but “overheated imagination.” He also notes that Mesmer’s theory of fluid, which was based on a hypothesis about an invisible world, was conceived at a time when Newton was deriving his theory of gravity, Lavoisier was coming up with his theory of calories, Franklin was discovering the marvels of electricity, and Priestley and others were experimenting with heated gases, all in their way explorations of invisible worlds (Spiegel 1981).

In spite of the skepticism he generated among scientists, Mesmer became quite popular with the general public as a healer. Not having the time to treat all of his patients privately, he arrived at a method of “group therapy” that he called the baquet. This was a circular tub filled with magnetized fillings, and equipped with projecting iron rods that patients could touch while sitting around it. By holding hands around the baquet, the patients would set up a “current,” and by holding on to the baquet’s rods, the patients would receive

a magnetic flow directed to the pain areas. Eventually, Mesmer would abandon the use of magnets altogether, because he felt that their use was damaging to his hopes of scientific acceptance; having a reputation as a “magnetizer” was little better than being labeled a charlatan.

Mesmer unexpectedly found that he was able to throw his subjects into a state between sleep and wakefulness. In such a state, they would obey commands “even though their faculties had stopped functioning in the normal manner” (Buranelli 1975). The state that Mesmer had discovered was the hypnotic state. Realizing the importance of this form of trance, Mesmer made increasing use of it, until it became the essential component of his method of treatment.

Mesmer began to use the hypnotic trance to bring on what he called “the *crisis*.” The crisis had been a critical feature of a patient’s therapy since early in his career when Mesmer still relied almost totally on magnets. Unfortunately, however, many people were more afraid of the Mesmerian crisis than they were of their illness, and so avoided Mesmer entirely. Members of a French royal commission, investigating a follower of Mesmer by the name of Deslon, declared that they were “astonished and appalled by the sight of patients going suddenly into agonizing contortions” (Buranelli 1975). They described these convulsions as being:

- ▶ Marked by violent, involuntarily movements of the limbs and the whole body, by constriction of the throat, by throbbing in the chest and nausea in the stomach, by rapid blinking and crossed eyes, by piercing cries, tears, hiccups and uncontrollable laughter. These are preceded or followed by a state of languor and daydreams, a type of abatement or even slumber. The slightest sound causes a startled shuddering; and it has been observed that a change of tone or beat in music played on the piano influences the ill, so that a rapid composition agitates them and throws them back into convulsions. (Buranelli 1975)

Although the commission could not deny the occurrence of cures, the members felt that the crisis could hardly be considered a desirable element in the treatment process. Once again, Mesmer was denied scientific acceptance.

Government investigations, while noting Mesmer’s success in the treatment of his patients, refused to accept his explanations of just how his cures were brought about. They carefully studied Mesmer’s techniques, including his magnets, the baquet, the crisis, and the trance, and concluded that all cures were simply due to the individual’s imagination, and not to any actions of Mesmer. Mesmer was officially declared a charlatan; his reputation was hopelessly destroyed, and he eventually was forced to give up his practice.

Fortunately, however, Mesmer’s work was not forgotten. Several men carried on his research, and through it became quite well-known. The Marquis de Puysegur, although an amateur, was a dedicated follower of Anton Mesmer, and, as Mesmer himself had done, relied heavily on the presence of the trance in his practice. While unable to account for it, Puysegur noted the phenomenon of posthypnotic amnesia. Mistakenly, he referred to the trance state as “somnambulism,” which really means “sleepwalking,” but his most important accomplishment was being able to achieve, in his patients, a form of the Mesmerian trance that did not involve the crisis.

When in the trance, subjects would answer questions and offer suggestions, always coherently and intelligibly. Upon awakening from the trance, the subject would only remember what he had been told to remember. Puysegur also became familiar with the phenomenon of regression. His patients would recall and relive childhood events that had previously seemed forever forgotten. The Marquis also clearly showed that the methods and apparatus that Mesmer had relied upon, such as the séance, baquet, and eerie music, were not necessary, for the same results could be obtained without them. Puysegur had, in fact, achieved a true hypnotic state in his subjects, although scientists remained unconvinced.

In 1819, a Portuguese priest by the name of Abbe Faria published a work entitled *On the Cause of Lucid Sleep*. In it, he replaced the phrase “animal magnetism” with the word “concentration.” As Puysegur had done, Faria recognized that the séance and baquet were unnecessary; He called the trances he induced in his patients “lucid sleep.” To induce this sleep, Faria would have his subject sit in a comfortable position,

and instruct him to relax, lean back, close his eyes, and concentrate on sleep. This approach, Faria felt, required some confidence on the part of the subject. Then, he would issue the final command of “sleep,” and the subject would fall off into a lucid sleep, or, as it would be called today, a hypnotic trance. Faria also experimented with posthypnotic suggestion.

We owe the word “hypnotism” to James Braid, another important psychologist of the mid-nineteenth century. Braid decided that hypnotism, a word coined from the Greek word for sleep, should replace “mesmerism.” He also established that the true basis of hypnotism is psychological rather than physical, and that the power of the trance lay in suggestion. Stressing the role of concentration, Braid said that the patient must clear his mind of everything else, focusing only upon the concept of sleep.

As Braid’s views diffused across Europe, the nature of hypnosis was further defined in France by Ambroise Auguste Liebault (1823–1903), who wrote that:

- ▶ The characteristics of active somnambulism are what the hypnotist makes them by mobilizing the nervous energy accumulated as a usable power in the mind through suggested ideas. (Buranelli 1975)

Liebault emphasized his belief that suggestion plays the major role in any effective therapy. Together with his student Hippolyte Bernheim, Liebault led the Nancy school of hypnosis. The rival Salpêtrière school, led by Charcot, considered hypnosis to be a neurosis, a form of abnormal behavior. Charcot referred to the hypnotic state as an artificially caused “morbid condition,” and discussed what he felt were strong similarities between hypnosis and hysteria (Buranelli 1975). In fact, Charcot said, only those people displaying hysterical symptoms could be hypnotized.

The Nancy school, on the other hand, maintained that hypnosis belonged to normal psychology, believing that:

- ▶ hypnotic sleep is not a pathological sleep. The hypnotic condition is not a neurosis, analogous to hysteria. No doubt, manifestations of hysteria may be created in hypnotized subjects; a real hypnotic neurosis may be developed. . . But these manifestations are not due to the hypnosis – they are due to the operator’s

suggestion, or sometimes to the autosuggestion of a particularly impressible subject. . . Catalepsy, transfer, contracture, etc., are the effects of suggestion. To prove that the very great majority of subjects are susceptible to suggestion is to eliminate the idea of a neurosis. (Buranelli 1975)

The controversy between the Nancy and Paris (Salpêtrière) schools continued, but the superiority of the Nancy school emerged more and more clearly, as tests in hospitals and in consulting rooms were seen to support Bernheim’s claims that there was nothing at all abnormal in hypnosis.

In Germany, too, hypnosis began to make inroads in academia. In a series of articles published in *The Nation*, an important American periodical, Stanley Hall set down his observations about such German phenomena as the cult of war and its idolization of Kaiser Wilhelm as well as trends in German science, psychology, spiritualism, and recent studies in hypnosis based on his experiences in Berlin and Leipzig between 1878 and 1880. These reports were subsequently collected in his book *Aspects of German Culture*.

Hall was a great believer in Germany, convinced that it was in the forefront of a new science that would prevent a relapse of the world into barbarism of the Dark Ages. He opposed the admission of students into universities who were not prepared to accept this new scientific method and raised a vigorous protest against the threat of “Americanisms,” a term he uses to apply to ultra-materialistic tendencies – for example, making money as the all-consuming goal of life and the corruption that greed can lead to – that he associated with the United States. His objective was to promote a humanistic scientific culture for its own sake, putting aside all considerations of profit or personal advantage. It was an ideal that he found best exemplified in Germany.

In his reports, Hall noted the differences between Germany, on the one hand, and the United States and the UK, on the other in terms of what was then called mental philosophy (an early nineteenth century term for psychology) that concerned the essence, constitution, seat, origin, and future state of the mind – that is, metaphysical questions that psychology is based upon. Unlike sciences such as physics and chemistry, which

used the old deductive method, various forms of mental activities, or mental powers or faculties loosely connected with the ideas of Fichte, Schelling, and Hegel, were not quantifiable since these were phenomena that were thought impossible to be observed or controlled.

However, Hall noted, the new German research on psycho/physic methods did not feel obliged to honor the limitations established by their American and British counterparts by experimentally studying sensations and relating them to neurophysiological processes. Hall discusses some of the results of time reaction studies, especially the work of Wundt.

Hall also cites a very popular book by Rudolph Heidenhain, professor of physiology and director of the Physiological Institute at Breslau. Heidenhain and his colleagues, Hall wrote, were able to hypnotize one half of their subjects' brain and body. When the right side is hypnotized, they found, it produces aphasia, but not when the left side is affected. This is, of course, in agreement with pathological observations that locate the speech center in, or near, the left cerebral hemisphere. Hall goes on to explain how hallucinations can be induced, as well as other interesting phenomena.

Although Sigmund Freud practiced in neighboring Austria his views about hypnosis were shaped more by the Frenchman Charcot as well as through his associations with Liebault and Bernheim. As we have seen, Charcot had a great interest in the study and treatment of hysteria which he believed was caused by the congenital degeneration of the brain. To counter charges that hysterics were simply malingerers, Charcot would hold public demonstrations in which he employed hypnosis on young women who had been victims of rape and other forms of violence (Dillain 1925). Sometime around 1885, Freud attended one of these demonstrations and was sufficiently impressed to consider the idea of using hypnosis on his own patients. But it was from his colleague Joseph Breuer that he learned how to use of hypnosis as a means of uncovering memories of traumatic events that were inaccessible in the normal waking state.

Introduction

We are all experts on emotion – we were influenced by them before we could talk, we have been thinking about what they are and what they mean ever since we could reason, and we have all at one time or another wished fervently that we could better understand and manage them. In this chapter our primary focus is on formal Western scientific theories in psychology that aim to explain emotion's function, operation, and effects on behavior. Historical and current study of emotion is rich with theory. In psychology it is easy to count over 20 theories of emotion put forward since the 1960s (Strongman 2003). The scientific study of emotion from its earliest days has been an interdisciplinary enterprise; however, the scope of this chapter does not include theories grounded in philosophy, social history, sociology, or anthropology.

Some features of emotion make its study both fascinating and complex. These features include:

1. Emotion has multiple facets. Emotion can be described in terms of its physiological signs and symptoms (e.g., tears; churning stomach), expressive (e.g., eye gaze; configuration of the facial muscles of expression), experiential, and action-oriented or motivational qualities.
2. Emotion can have different meanings. What is encompassed by “emotion” differs across historical periods and across cultures. While post-industrial cultures today share many assumptions about what

emotion is and how it operates, there are still noticeable differences in beliefs about who should experience and show some specific emotions, and under what circumstances those emotions are socially appropriate.

3. Emotion has both “built-in” (hard-wired) and a “built” (socialized; learned) constituents. The *built-in* constituents of emotion encompass both functional (what does emotion do?) and structural (through which modalities can emotion be experienced and expressed?) aspects of emotion. The *built* constituents reflect how emotion is conceptualized, represented, and institutionalized within a culture. These built constituents include how emotion is described and labeled in language. Culture-wide beliefs about emotion are another example. Among the beliefs about emotion widely shared in modern Western societies are beliefs that emotion is different from ordinary rational thought, that emotion is something that “happens to us,” and that emotion is difficult or impossible to control.
4. How we know emotion in the self differs from how we can know emotion in others. The cues to emotion that we use introspectively are not the same as those we use for making inferences about others’ emotional state. We cannot access all of the information that we would like to use in knowing another person’s emotion. Some of the measures that we can use, such as heart rate, are not specific to emotion. And some indicators can “lie” – for example, a person can to some degree “act out” an emotion other than the one he or she is actually experiencing.

Definition

The modern Western definition of emotion has existed only since the early nineteenth century. Typically, researchers differentiate *emotion* from *mood* and from *affect*. Mood is regarded as a type of general emotional background that is objectless, that is, not specifically about an identifiable situation or person. Whereas emotions are generally about something, moods are not. *Affect* is a general positive or negative hedonic state with reference to self. Affect is often unconscious, representing automatic evaluations of the world as positive or negative. The term *feelings* is typically used by emotion researchers simply to refer to bodily perceptions and sensations.

Variety in Definition of Emotion

Oatley and Jenkins (1996) propose a three part definition of emotion closest to an all-inclusive definition that would be accepted by most contemporary emotion researchers. First, they propose that an emotion is usually caused by a person consciously or unconsciously evaluating an event as relevant to a concern or a goal that is important. The emotion is felt as positive when a concern is advanced and negative when a concern is impeded. Second, they propose that the core of an emotion is a readiness to act causing the prompting of plans. An emotion gives priority for one or a few kinds of actions to which it gives a sense of urgency – so it can interrupt, or compete with alternative mental processes or actions. Different types of readiness create different outline relationships with others. Third, they propose that an emotion is usually experienced as a distinctive type of mental state, sometimes accompanied or followed by bodily changes, expressions, actions.

Other more concise definitions of emotions focus on the components of emotion. Functional definitions of emotion are also common (Keltner and Gross 1999). For example, most recent models emphasize emotion’s function as relational, as the person’s attempt or readiness to establish, maintain, or change the relation between the person and her or his changing circumstances, on matters of significance to that person (Campos et al. 2004).

The complexity of these definitions of human emotion can be further distilled to “Emotion is *taking it personally*” (Shields 2002). That is, at its core, emotion concerns an event, situation, or object that is perceived as potentially having significance for one’s own well-being. Whether the emotion is love for one’s newborn baby, irritation at oneself for procrastinating, fear for a friend who has breast cancer, or pride in one’s country, each situation entails perception of someone or something as having urgent significance for my own well-being, interests, or goals. This definition emphasizes that something about the *self* is at stake in emotion and acknowledges that self can be narrowly defined in terms of personal identity or broadly in terms of social group membership.

Two Major Families of Emotion Theory in Psychology

The most influential contemporary scientific theories of emotion in psychology fall into one of two broad

categories: fundamental emotions theories and appraisal theories. Other types of divisions could be made (e.g., theories that stress evolutionary factors, behavioral manifestations, emotion as a feature of social relationships); however, the broadest classification distinguishes between those theories that explain emotion as a finite set of innate emotions and those that explain emotion in terms of the information-processing capacities that generate or constitute emotion.

Fundamental emotions theories assert the existence of a set of innate basic emotions which may interact with cognition and temperament, but which comprise a separate biologically based system. This theoretical approach has tended to focus on identification of culturally universal expressive features of emotion, using those features as the means to investigate emotion processes. Theorists taking this position often argue the modularity of emotion, that is, that structures and processes of emotion can be distinguished from those that subserve other behavioral and information-processing functions. While some of these theories focus on human emotion, others aim to construct a theory that is applicable across species.

Appraisal theories explain emotion in terms of its evaluative character and so emphasize the role of information processing in the generation or structure of emotion. These theories do not make a sharp distinction between emotion and cognition, but think of the relation as a kind of continuum that ranges between processing that is fairly automatic and executed without reflective self-awareness, and processing which constitutes or generates an emotional state. Information-processing models (e.g., Oatley and Johnson-Laird 1987) are an offshoot of appraisal theories that borrow from the concepts and approaches of computational modeling to map out the dimensions or steps in processing that lead to one emotion state or another.

Social constructionist models are related to appraisal theory and share with that perspective a focus on the meanings assigned to situations. Social constructionism, however, views emotions, emotional experience, and emotional display as cultural artifacts which emerge out of social discourse. The notion of wholly-formed innately programmed “basic” emotions is rejected. The constructionist (also referred to as *constructivist*) point

of view has played a significant role in the anthropology and sociology of emotion. American academic psychology, with some important exceptions, until recently was less welcoming to this approach. In fact, psychologists’ early critiques of constructionism erroneously tended to interpret constructionism’s emphasis on meaning-making as rejection of any built-in component of emotion.

In this field dominated by theory, there are, of course, other less widely held perspectives. One, distantly related to appraisal theories, derives from the philosophical standpoint of phenomenology. *Phenomenological* theories stress the embeddedness of the emotion in the relationship between the individual experiencer and the context in which emotion occurs. This approach has begun to have wider influence through the work of philosophers and European social psychologists. *Psychoanalytic* theory and therapeutically based psychologies have so far had more limited impact on current trends.

Neuroscience research, meanwhile, is on the verge of transforming many long-held assumptions about the dichotomy between emotion’s built-in and built features. Work with other animals has shown how biological features ranging from neural structures to hormonal state mutually affect and are affected by emotion-linked learning and experience. Research on humans, benefiting from technological advances in brain imaging and the burgeoning field of cognitive neuroscience, has revealed much about the interactive relation among brain structures and processes involved in emotion and emotion-linked social processes.

Historical Background

Prescientific Theory

Emotion has been a central theme of writers and philosophers since the earliest written texts, though the construct bears little resemblance to that of modern Western cultures. Emotions are discussed differently in those texts, typically focusing on emotions in a limited way mostly as base instincts or forces in one’s body. Nevertheless, this facet of life was a critical component of being human. For example, the *Epic of Gilgamesh* centers on Gilgamesh’s emotions of desire, anger, and fear, and his need to balance these emotions to act with virtue and heroism. In the creation story of the Hebrew

bible, Adam and Eve's exercise of free will results in their experience of shame of their naked bodies. The *Iliad* begins with Homer's invocation of the muse to speak of Achilles' rage, a rage which permeates and drives the epic. Sanskrit writings contained in the *Mahabharata* culminate in a complex discussion of mixed emotions where there is joyous celebration of the heroes triumph over evil, but remorse over realizing the evil the heroes committed to triumph.

Ancient philosophies also dealt extensively with emotion. Much of the discussion was concerned with understanding the role of emotion in relation to thought, and how to exercise control of emotional experience. For example, the Epicureans and Stoics viewed emotions as a threat to living completely rational lives. Plato, in the *Phaedrus*, valued emotions more than his predecessors, yet still believed that emotions interrupted rational thought. He viewed emotions as having a driving force (what modern emotion theorists would call an action tendency) that needed to be directed and controlled by reason. Aristotle describes bodily motions, thoughts and beliefs, and physiological changes as all essential parts of emotions (similar to a modern-day view of emotions). In the *Nicomachean Ethics* he argues that virtue lies in feeling correctly for a situation, for example, showing the appropriate amount of fear. These thoughts were echoed in Eastern traditions, for example, as Confucius discussed needing to feel an appropriate and matching emotion when performing ritual for that ritual to be deemed legitimate.

Though Aristotle tried to place strong value on emotions place in thought and action, this view was not widely held. A general distrust of emotion's capacity to overwhelm the individual permeates writing from early modern times to the present. This can be seen in the beginnings of modern Western science and the rationalist movement. Baruch Spinoza writing in the seventeenth century believed that we had to accept that emotions existed in the world, and thus by no longer having to fight them we can move beyond them. Note this stance does not try to appreciate or value emotions but rather to mitigate the effects of emotions on logic and reason. John Locke, writing in the same time, believed that emotion ultimately led to mistakes, and advocated reason as the path to truth. Other empiricists, such as David Hume, downplayed

the role of emotion by rating it as secondary to the knowledge we acquire through our senses and thought. The rationalist movement purported that the only reliable knowledge we can glean from existence is through thought and reason; emotions merely serve to disrupt that process and lead to errors.

The Nineteenth Century as Turning Point: William James and Emotion Consciousness

The Western scientific study of emotion has been a magnet for theory. Since the latter part of the nineteenth century a number of theories have been put forward with the goal of defining the essential constituents of emotion, emotion's function, how emotion is elicited in ordinary situations, and what differentiates one type of emotion from another. Early in the nineteenth century, the concept of "emotions" in psychology was developed in opposition to, and ultimately replaced, prevailing religious constructs of emotion as passions and affections of the soul. The study of emotion in psychology initially concerned the nature of consciousness, bodily experience, and brain function. Many who were involved in the disciplinary formation of scientific psychology in the USA, Britain, and Germany were concerned with emotion. Charles Darwin, William James, and Wilhelm Wundt are among those identified with the theories of emotion that of the last quarter of the century (Gardiner et al. 1937).

In the 1880s philosopher-psychologist William James' work represents a turning point in the study of emotion (<http://plato.stanford.edu/entries/james/>). While the theory itself has notable limitations, James' effort was fundamental in spurring interest in developing testable theories of emotion. James was extremely critical of what was being written about emotion because these accounts of emotion tended to be solely descriptive. His main complaint was that each emotion was looked at as an individual thing and that there was no attempt at systematic explanation of emotion phenomena. James (1884) proposed that theories aimed at explaining and predicting emotion were needed if understanding of emotion was to progress.

Through his theory, James aimed to explain felt emotion (emotion consciousness) as it occurs in strong emotion. James says that emotion is not an interpretation of bodily responses, but rather the awareness of

bodily reactions as they occur. Physiology is where we should go to look for an explanation of emotion. His theory can be described by a sequence of events. First, there is the perception of “an exciting object,” exciting, not as thrilling, but in the sense of sense of instigating the process. Second, the object is perceived by the brain. Third, perception of the exciting object reflexively elicits a reaction in skeletal muscles and gut (e.g., hair stands on end, fists are clenched, nausea). Finally, perception of the bodily change as it occurs *is* emotion. At about the same time, Danish physiologist Carl Lange (1885) proposed a similar theory emphasizing the primacy of bodily reactions in emotions. And so the theory is often referred to as the James-Lange theory.

James sets out three propositions as the foundation of his theory. The first is that bodily responses are reflexive (i.e., unlearned) and of unlimited variety in the way they may combine. These variations give us our incredibly varied emotional life; there can be as many emotions as there are patterns that people can perceive. The second proposition is that bodily responses are perceived as they occur. Emotion consciousness is therefore not a reflective interpretation of bodily response, but an awareness of them, and arguably, epiphenomenal. The final proposition is that emotion is not learned. Response to any “exciting object” is, at its core, a reflexive response to the situation. For example, nervousness at being in front of an audience, James noted, could be traced to primitive humans’ innate uncertainty as to whether strangers intended harm.

James’ views on emotion are important for us today in three ways. First, James broke away from the majority of workers in the study of emotion at that time, attempting to devise a broad theory which would explain emotion consciousness, rather than simply describe the attributes of specific emotional states. Second, he viewed emotion consciousness in terms of its biological basis, a trend in science largely influenced by Darwin’s then-new theory of evolution. Third, his ideas generated controversy which stimulated further discussion and research on emotion.

Responses to James’ theory were strong, legitimate, and generally negative. One of the most effective rebuttals was Walter Cannon’s in 1927. Cannon’s critique like many others, however, disputed the theory’s relevance to emotional behavior (not emotion

Theories of Emotion, History of. Table 1 Cannon’s critique of the James-Lange theory

1. Separation of the viscera from the CNS does not alter emotional behavior
2. The same visceral changes occur in different emotions and in nonemotional states
3. The viscera are relatively insensitive
4. Visceral changes are too slow to be the source of emotional feeling
5. Artificial induction of visceral changes typical of strong emotions does not produce emotion

consciousness, which James set out to explain). Cannon’s response also misunderstood James-Lange a theory of visceral feedback rather than bodily responses more broadly (e.g., skeletal muscles; facial expression) (Cannon 1927) (Table 1).

Not only was Cannon’s criticism taken as defeat for James’ theory, but its timing coincided with the beginning of what might be called the “Dark Ages” in the study of emotion in Western science. It is important to note that James understood his theory as a work in progress. In fact, he offered the theory as a much-needed first step in moving the study of emotion from a descriptive enterprise to a scientific enterprise.

Emotion in the Era of Behaviorism

As behaviorism grew in influence as the paradigmatic theory of psychology, the study of emotion became more narrowly defined. From the 1930s to the early 1960s, behaviorism was the dominant paradigm in experimental psychology in the USA. Devastating to emotions position, behaviorism advocated being able to measure and quantify a stimulus and its effects. Because felt emotion could not be directly observed or measured, many believed that it should not even be looked at. As Elizabeth Duffy (1941, p. 283) is famously quoted, the prevailing view at the time was that “‘emotion,’ as a scientific concept is worse than useless.” By this, Duffy meant that there was no place in a science of behavior for constructs that refer to psychological phenomena that are defined largely by their experiential properties. As experiences, Duffy argued, emotions were not subject to reliable measurement in overt behavior. She (and other psychologists) was not

denying the reality of emotional experience, but asserting that experience could not be objectively measured and therefore was beyond the purview of a scientific psychology.

Even aspects of emotion that could be directly observed, namely facial expressions, were discounted. With few exceptions, most notably Magda Arnold and Robert Leeper, each of whom developed a significant theory of emotion, emotion theory in the USA was dominated by an approach that reduced emotions to arousal states (e.g., Duffy 1941) and regarded emotions as essentially disorganizing or disruptive processes. Arnold (1970) described these Dark Ages of emotion research in the following way:

- ▶ A wall of silence began to close off emotion from the general theoretical and experimental endeavor of psychologists, particularly in this country [the U.S.]. Behavior theory, as it now began to be called, had finally succeed in banishing all thought of what might be going on in the 'black box' by convincing psychologists that any concern with 'mentalistic' events was thoroughly unscientific (p. viii).

While emotion was put on the periphery on psychological theory and research, it was not abandoned. The status of emotion research and theory at this point is best illustrated by an international conference on emotion held in 1948 (Reymert 1950), called the Mooseheart Symposium (so called because it was held at on the grounds of the fraternal organization of Moose which was called "Mooseheart"). The conference drew participants from a broad range of disciplines and the shadow of behaviorism was probably smaller at this conference than it would have been at other conferences in psychology (largely because the organizer worked in child development, a specialization that had not yet been completely been taken over by behaviorist models).

After Mooseheart, emotion research continued its decline, as scientific psychology came to be thoroughly dominated by a behaviorist version of learning theory that defined thought, mind, and experience as unobservable and therefore outside the boundaries of what good science could profitably study. Still, emotion research in the USA that was not entirely driven by behaviorism could be found. Facial expressions of emotion received attention, both in terms of the

range and dimensionality of expression and in terms of factors influencing accuracy in judgment of expression. By the time of psychology's "Cognitive Revolution" in the 1960s, significant articles and books on emotion (e.g., Candland 1962; Plutchik 1962; Tomkins 1962) and an international symposium organized by Arnold in 1968 set the stage for revitalization of emotions research which has grown consistently and considerably since then.

Felt Emotion Generated by Bodily Response

Arguably the most influential alternative to behavioristic explanations of emotion came about as a result of observations made regarding artificial stimulation of bodily responses typically associated with emotional states. Gregorio Marañón, a Spanish physician, published an article in 1924 which reported the effects of inducing changes in somatic states through injections of epinephrine (called adrenaline in British English) which stimulates the sympathetic nervous system (SNS). Marañón was generally interested in learning about emotional reactions to injections of adrenaline. He found that the large majority of his research subjects were aware of the SNS responses that the injection evoked and the bodily reactions consistent with SNS activation. Furthermore, his subjects on discussing their bodily reactions reported that it was "as if" they were actually experiencing the emotion, though the emotion itself was not present (e.g., "I feel as if I were afraid"; "as if I were awaiting a great happiness"). Less frequently, the bodily response was followed by a full blown emotional state, typically anxiousness. This complete emotional state often manifested "a psychological motif" that justified the feelings. Marañón's work is noteworthy for suggesting that it is the connection between bodily response and psychological account that combines to create an emotional state.

Some years later this idea was taken up more explicitly by Stanley Schachter and Jerome Singer (1962). They proposed that two factors were necessary for emotional experience: presence of bodily arousal and the availability of an explanation of that arousal as due to emotion. They reasoned that, given a physiological state of arousal for which an individual has no immediate explanation, the individual will label the state in

terms of the available context. Thus, they concluded, “precisely the same state of physiological arousal could be labeled ‘joy’ or ‘fury’ or ‘jealousy’ or any of a great diversity of emotional labels depending on the cognitive aspects of the situation” (pp. 381–382). Of course, if other, nonemotional explanations are more salient, emotion will not be labeled. And if no physiological arousal is present, emotion will not be labeled.

The initial paper presenting their theory (Schachter and Singer 1962) reported an experiment with serious flaws, including the omission of critical comparative conditions in the experiment. Nor did they obtain results that supported a strong interpretation of their two-factor theory. The publication is nevertheless noteworthy for challenging then-prevailing views of emotion that disregarded the meaning-making impulses of humans.

Schachter and Singer’s two-factor theory, despite its explanatory inadequacy, has been extraordinarily influential in psychological research on human emotion. The most useful application of Schachter and Singer’s two-factor theory has been in the area of “excitation transfer” – misattribution of arousal to a different source than actually caused the bodily response. If, for example, you just worked out (thus increasing activity in your SNS) and then started a conversation with a new friend, you might be likely to view that person as more exciting and interesting because you would attribute your SNS arousal to the conversation. If however, you attributed your arousal to the workout, your perception of your new friends would be unaffected.

Appraisal Theories of Emotion

Behaviorism’s prevailing view of emotion was challenged by the development of theories which relied on explaining emotion in terms of ordinary perceptual and cognitive processes. One of the earliest and most influential was Magda B. Arnold’s (1903–2002) comprehensive theory of emotion which was an ambitious fusion of research in cognition, motivation, neuroscience, and personality (Shields and Kappas 2006).

Arnold proposed that emotions are generated when an object or situation is perceived and appraised by the individual as good or bad for him or her at that moment. She proposed that this process is direct, immediate, and intuitive process which does not

initially require that we recognize the object, whether the “object” is the self, another individual, or something else in the external or internal environment. This direct process of perception is based on phylogenetically ancient subcortical brain structures. The immediate appraisals elicit action tendencies to move toward or away – or more accurately, “want” or “diswant” the object. Emotion is the felt tendency to want or diswant the object with respect to *oneself*. Reflective appraisals immediately follow and can modify, intensify, attenuate, or even change the initial unreflective appraisal. “Mixed” emotion reflects our capacity for sense judgments (the intuitive appraisals) to be about more than one aspect of a thing or person. The roots of Arnold’s theory can be traced to phenomenological psychology of the previous century in viewing emotions as having objects, that is, as being *about* something and, thus, intentional at some level.

Arnold’s theory includes constructs that characterize contemporary appraisal theories, most notably the distinction between an initial, automatic, nondeliberative appraisal and subsequent appraisals that may be conscious or have some overt intention associated with them. The direct and immediate evaluative process that occurs, Arnold (1960) would say, is automatic:

- ▶ The appraisal that arouses an emotion is not abstract; it is not the result of reflection. It is immediate and indeliberate. If we see somebody stab at our eye with his finger, we avoid the threat instantly, even though we may know that he does not intend to hurt, or even to touch us. Before we can make such an instant response, we must have estimated somehow that the stabbing finger could hurt. Since the movement is immediate, unwitting, or even contrary to our better knowledge, this appraisal of possible harm must be similarly immediate. (Arnold 1960, Volume 1, p. 172)

Arnold viewed motivation as the link between the wanting/diswanting-evoked action tendency (that is, emotion) and actual action. For Arnold, emotions are important in personality integration in that emotional responses are guided by one’s higher ideals. Deliberative appraisals help us harness and understand emotion and use it constructively as a motivating force in personality. Thus, emotion is firmly based in our evolutionary history and shares fundamental characteristics

of emotions in other animals. At the same time, however, human emotion is unique because of human capacity to think, and plan, and have a sense of enduring and central values.

Important appraisal theories have been put forward by Richard Lazarus (1994), George Mandler (1984), Nico Frijda (1986) and others. Appraisal theorists who followed Arnold share some common assumptions with her and with each other. Most importantly, they differentiate between primary (initial) and secondary (subsequent) appraisals and view appraisals as defining the emotional state's experiential quality and action tendencies. This view is succinctly summarized by Richard Lazarus, whose theory focuses on the relational nature of the person and emotion-evoking object or situation: "Each kind of emotion comprises a distinctive cognitive, motor, and physiological response configuration that is defined by the common adaptational (psychological and physiological) requirement of the person-environment relationship, as these are appraised" (Lazarus 1991, p. 202). The distinction between primary and secondary appraisals is important, but sometimes overlooked in critiques. In one well-known exchange, Lazarus and Robert Zajonc debated whether appraisals are "cognitive" in the sense of requiring inferential information processing a question which actually is a nonissue given the emphasis that appraisal theories place on automatic evaluation processes.

Two representative current theories are described here.

Phoebe Ellsworth and Craig Smith (1988) are concerned with the particular types of appraisals that distinguish one emotion from another. They propose that at least six kinds of judgments that together define a given emotional state. These dimensions of appraisal are: attention, pleasantness, certainty, anticipated effort, agency (i.e., who caused the situation), and perceived situational control. The configuration of appraisals determines which emotion is experienced and the configuration can change rapidly as new information becomes available or attention is redirected. Ellsworth (1991) stresses the heuristic value of examining appraisal dimensions.

Klaus Scherer (1987) and Scherer et al. (2001) views the generation of emotion as a process generated by a sequential information processing. He proposes that

anytime that an individual is faced with a new stimulus, she or he rapidly and automatically go through a series of Stimulus Evaluation Checks (SECs). The result of evaluation at each one of these check points further defines the specific emotional state. Thus, the appraisals that generate an emotion occur sequentially, from the first category of evaluation of novelty through the last and most cognitively sophisticated assessment of one's ability to cope with the stimulus. Each of the major categories of SEC has subjudgments that also are made. Thus, for example, the first SEC is whether the stimulus is it novel and it has subordinate judgments attached to it: Was its onset sudden? Is it familiar? Was onset predictable?

Scherer and his collaborators have studied the components of emotion extensively. They have, for example, compared various national groups' descriptions of the bodily symptoms of specific group. Scherer has also examined the vocal "signatures" of emotions.

These and other appraisal theories help us understand individual and cultural differences, for example, how different emotions can be evoked by what an outside observer would judge to be the same situation. These theories also help us understand how different emotions may be related to one another. They also give us ideas about intervention points in attempting to control or change emotion.

Social Constructionist Perspectives

As noted above, social constructionist perspectives in psychology have much in common with appraisal theories. James Averill (1983, 1991), for example, defines emotion as a deeply acted transitory social role which includes the individual's appraisal of the situation and which is interpreted as passion, rather than action. It is important to understand that "deeply acted" does *not* mean deliberate, disingenuous, or in any way superficial. Indeed, an important quality needed for emotion to "work," according the social constructionist perspective, is that we believe emotion happens *to* us, outside of our direct control. Thus, emotion offers a justification for expressing oneself in ways that may not be acceptable if one were believed to be in a completely rational state. The enactment of the role is not strictly scripted, though the conditions for genuine emotion do conform to certain rules regarding what the emotion can be about, who is appropriate to

experience and express it, what the time course is for the emotion, and so on.

Averill observes that any emotion can be described on any one of several levels of analysis. Anger, for example, can be described in terms of its experiential properties, its possible evolutionary history, or its codification in various social institutions and structures. The picture of an emotion differs depending on the level of analysis, and each level of analysis focuses on different facets of the origins, functions, and consequences of the emotion in question. No individual perspective is the single “correct” one because each is a level of analysis, not a stand-alone explanation. Thus, the capacity for anger, Averill argues, has a biological basis in humans’ innate capacity for reflective self-consciousness, motivation to cooperate, and capacity for aggression. At the psychological level, anger can be described as aiming to correct a perceived wrong, while from the perspective of interpersonal relations anger can be described as aiming to facilitate social order. According to Averill, anger, as a deeply acted social role, allows the individual to respond strongly to a violation of rights or social norms with the intent of bringing the individual(s) violating those norms back to social conformity.

The Nineteenth Century as Turning Point: Charles Darwin and Emotionally Expressive Behavior

Charles Darwin (1809–1882) was already famous for his publications on evolutionary theory when he published *The Expression of the Emotions in Man and Animals* (1872), the year after *The Descent of Man* (1871) (<http://darwin-online.org.uk/>). In *The Expression of the Emotions* Darwin outlined a view that emotional expressions are evolved, originating directly from adaptive behavior or through association with adaptive behavior. Darwin considered expressions as both an external manifestation of internal state and as having an important communicative function. He concluded that there are universal body postures that depict basic, primary emotions. For example, squinty eyes with tears are interpreted as sorrowful. For evidence Darwin relied largely on his own observations as well as anecdotes and observations of human and animal behavior that had been sent to him by naturalists from around the world. Consistent with

his evolutionary views, Darwin considered animal emotions to illustrate evolutionary antecedents of human expression and drew parallels between animal and human expression across emotional states. For example, he famously considered weeping in elephants. The only emotional expression he identified as uniquely human was blushing.

Darwin identified three principles to explain the innate of expression of emotion. The first is the *principle of serviceable associated habits*. These “habits” once had adaptive value, but may no longer serve that function in humans. One example is showing teeth to scare off predators, although today this is no longer useful, it still occurs when strong anger is evoked. The second is the *principle of antithesis*. This principle states that opposite frames of mind will have opposite expressive patterns. For example, defiance is expressed through expansive gestures and forward attitude, whereas submission is expressed with a concave body and bowed head. The third principle is *direct action of the nervous system*. This principle states that evoking situations “automatically” elicit the particular expressions for the feeling evoked in that situation.

In the 1960s Darwin’s approach to the study of facial expression was revived in the context of the search for universal, fundamental emotions. Carroll Izard and Paul Ekman are the leading theorists associated with the study of facial expression of emotion. Each was strongly influenced by Silvan Tomkins (Table 2).

Silvan Tomkins’ (1962) two-volume *Affect, Imagery, and Consciousness* presents a complex and

Theories of Emotion, History of. Table 2 Factors that influence accuracy in judging facial expression of emotion

<ul style="list-style-type: none"> • Number of photos to be judged, clarity of expression, and the context represented in those photos

comprehensive theory of what he preferred to call “affect,” especially as it relates to motivation. Tomkins viewed emotions as central to normal life, not a disruptive influence as was then the prevailing view. He derived his ideas from control theory’s conceptualization of feedback. Emotion is an innate system which amplifies the motivational impulse of basic and learned drives. So motivation for Tomkins was comprised of the basic drive (hunger, thirst, sex) that was amplified through its associated emotion. Emotion gives one drive priority over another and adds urgency – which is experienced as emotion – to the satisfaction of that drive. He argued that the face and its expressions, and the skin itself, are the primary amplifiers of emotions in humans, with physiological and muscular changes directing the individual’s focus on the goal state of the associated drive.

Izard and Ekman each built on the idea of the importance of innate, subcortically generated facial expressions to develop their own theory of emotion. Their ideas are described in some detail, not only because of their influence on contemporary research, but because they took quite different approaches to studying the question of the universality of emotional expression.

Carroll Izard (1977) began his career as a clinical psychologist and through his work began to think that all human problems had their basis in emotions. But there was surprisingly little research on this topic. His Differential Emotions Theory proposes that there is a set of ten basic emotions (fear, anger, surprise, joy, disgust, contempt, shame, sadness, interest, and guilt) which together comprise a distinctive subsystem of personality. These basic emotions are innate, emerge over the course of the first two years of life, and are uniquely defined by their expressions. Over the course of development individual emotions combine with one another and/or other personality subsystems (drive, perceptual, motor, cognitive) to form the complex emotional repertoire of adults. For example, romantic love is viewed as a combination of elements of the emotion subsystem (primarily joy and interest) with the drive subsystem (primarily sex).

Izard developed an objectively scorable coding system, the Maximally Discriminative Affect Coding System (MAX), for the study of facial expression. It is based on dividing the face into three regions and

coding expressions of each in terms of distinct facial muscle groups. For example, a face with brows obliquely raised, a slight squint, and the corners of the mouth turned down, indicates sadness. A face in which the eyes are squinted and staring, the mouth square, and the brow arched, indicates anger.

Paul Ekman (1982) proposed that there is a small set of fundamental, innate emotions that are characterized by unique corresponding expressions: happiness, fearfulness, surprise, anger, disgust, contempt, and sadness. These emotions are universally recognized, a finding Ekman established through research in a number of literate and preliterate cultures. Ekman also proposes that discrete emotions have identifiable physiological signature responses and cognitive qualities. Thus, basic emotions evident in three differentiated, yet interrelated systems: cognitive, physiological, and expressive. Ekman’s is a functionalist theory in that he stresses that emotion has evolved as a means to manage the fundamental tasks of life through self-regulation and interpersonal communication. Ekman’s theory has evolved considerably since its earliest formulations, with more recent statements emphasizing the interplay of innate and learned/cultural features.

Ekman and his collaborators have developed a widely used system of coding facial expressions of emotion in a moment-to-moment framework. The Facial Affect Coding System (FACS) involves identifying the specific facial muscles that are contracted and the intensity with which they are contracted. Among other uses, FACS is used to distinguish between authentic expressions and those that are inauthentic.

Ekman and his colleagues have extensively studied what they term *display rules*, the often tacit social rules directing when, how much, and which emotions should be expressed to others. In an early study, they showed one of two films (one neutral and one distressing) to American and Japanese university students (all men). In some cases, the students were alone as they watched the films, in others, an experimenter sat in the room with them. American students expressed disgust at the sinus surgery film whether they saw the film alone or with company. The Japanese students, however, expressed disgust at the surgery film when they were alone, but were more likely than American students to mask their disgust with smiles when

accompanied by an experimenter. Ekman and colleagues use results such as these to posit that cultures differ in social norms for expressing specific emotions. Ekman is also widely known for his work on the detection of deception.

Issues in the Study of Facial Expression of Emotion

Because facial expression of emotion has played such a significant role in modern theories of human emotion, some of the issues that arise in research employing expressive stimuli should be noted. It does not take much detail in facial expression to express an emotion. Small changes result in big differences in the emotions conveyed. Expressive muscles of the face are controlled by two separate neural pathways. One pathway reflects volitional muscle movement, while the other appears to be connected with involuntary muscle movement. Thus, a genuine “felt” smile has somewhat different characteristics than one that is deliberately posed. No one area of the face is more able to show emotions than others, but one area may be particularly good about revealing particular emotions. For example, in the USA, the eyes seem especially relevant to conveying sadness.

The majority of research on emotional expression is concerned with facial expression. There are difficulties, however, in interpreting facial expression as a direct indicator of emotion. Most important, sustained “pure” expressions of specific emotions are rare in everyday social interaction. The more familiar the face is, the easier it is to interpret facial expressions. In other words, in pictures showing the same face in a happy, sad, angry, or surprised expression, those expressions are easier to identify than if different faces are shown for each emotion.

The Nineteenth Century as Turning Point: The Brain and Nervous System

On September 13, 1848, Phineas Gage, a foreman for a railroad construction gang, accidentally ignited some gunpowder while preparing a blasting hole and shot a tamping rod through his left cheek and out his skull. Miraculously Gage survived the accident; however, he was not the same. Where prior to the accident he was described as quite amiable, he was now impatient and easily angered. Post-mortem analyses revealed that

Gage suffered damage to his frontal lobes (an area of the brain proposed to be involved in emotional and practical decision-making). In other words, Gage provided early evidence that damage to the brain altered personality and emotional functioning.

Following news of Gage, much of the research in the nineteenth century and early twentieth century examined the effect that strokes had on personality. Again links were found that when areas of the brain were damaged by strokes, a corresponding change in functioning ensued. For example, following strokes many patients experience blunted affect (feeling little or no emotion) or emotional lability (switching quickly between emotional extremes), all of which are consequences of damage to emotion centers in the brain. Using this research and his own patient studies, Korbinian Brodmann divided the brain up into 52 distinct areas (a classification system still in use today) which laid a scientific basis for understanding how damage to brain areas results in changes to emotional functioning.

Starting in the early twentieth century, more sophisticated measures were developed that could measure healthy, adult brains (rather than relying on post-mortem analyses). One of the first major advancements was electroencephalography (EEG), which is a technique that measures the electrical activity of the brain. Functional magnetic resonance imaging (fMRI) a technique only developed in the late twentieth century also provides an estimate of brain activity but measures blood flow instead of electrical activity. When the brain is actively using a specific region, that area of the brain requires more oxygen. By measuring blood flow patterns, it can be estimated what parts of the brain are being activated. Unlike EEG, fMRI allows for an image of blood flow to actual parts of the brain rather than just a surface estimate, however fMRI takes much longer. These techniques have helped to advance our understanding of emotional processes and are discussed further below.

The Nineteenth Century as Turning Point: Emotion and Psychopathology

No treatment of emotion theory would be complete without discussion of Sigmund Freud’s theory of neuroticism. Ironically, even though emotion plays a central role in Freud’s theories of personality and

psychopathology, he did not offer a theory of emotion to account for the processes of emotion more generally.

Freud referred to emotion in two distinct ways. Sometimes Freud treated emotion as *a* form or *the* form of psychic energy (libido). At other times he implied that emotion is a product of other psychodynamic processes, for example, viewing emotion as the discharge of instinctive energies or as the manifestation of instinctual conflict. The preoccupation of other emotion theorists of his time – what is emotion and what is the sequence of events that produces emotion – did not concern him. His treatment of emotion suggests that he views the unconscious as the substrate of consciously experienced emotion for personality functioning.

Freud's account of emotion is most fully worked out in his description of the acquisition of pathologies of anxiety. Anxiety, according to Freud, plays an important role in personality development and in the dynamics of personality functioning. Anxiety differs from other painful states by some specific quality of consciousness which is determined by distinctive features of visceral responses. Anxiety is a danger signal to the ego which can then take measures to deal with the anger. If one cannot deal with or avert the anxiety, the anxiety builds and eventually breaks down the ego's ability to maintain itself. We "deal with" anxiety either by getting away from it or in some other way nullifying it, by anticipating when it might happen and doing something about it in advance, or by employing ego defense mechanisms.

Freud distinguishes three types of normal anxiety. All "feel" the same to the individual, but they differ in the source of the anxiety. Anxiety can be a blend of the three (Table 3).

1. Reality anxiety has its source in the external world, although sources can be innate or learned. This state could also be labeled "fear."
2. Neurotic anxiety, unlike reality anxiety, has an intrapsychic source. Essentially, the fear is a fear of what might happen if defenses of the ego fail. This fear of what would happen if the ego cannot keep anxiety at bay and that they would be expressed through some impulsive action. This type of anxiety, in other words, is fear of being overwhelmed by an uncontrollable urge to commit some act or think

Theories of Emotion, History of. Table 3 How neurotic anxiety develops

1. Child expresses aggressive or sexual impulses and is strongly punished for acting on these impulses.
2. Reality anxiety is experienced when the child thinks about the punishment for these acts.
3. The child attempts to reduce anxiety by repressing whatever stimuli are associated with the punished impulses. Repression is the ego defense mechanism of wiping something out of consciousness through purposeful, but nonconscious "forgetting."
4. Neurotic anxiety represents the partial breakdown of repression. The anxiety seems objectless because the individual is not conscious of the original experiences that originally caused anxiety, having repressed them.

some thought by which will prove harmful to oneself. Phobias and free-floating anxiety are example of this type of anxiety.

3. Moral anxiety also has an intrapsychic source. In this case, the source of the fear is of what might happen if anticathexes of ego fail. Feelings of guilt and/or shame in the ego are aroused by perception of danger from one's conscience (an aspect of the superego which is the internalized agent of parental authority). It is loosely tied to neurotic anxiety because the chief enemies of the superego are all the things that the id wants (primarily sexual and aggressive impulses).

Key Issues

Many of the key issues surrounding emotions have grown out of tensions between differing theoretical perspectives or advancements in research methods and measurement techniques (e.g., qualitative research methods; instrumentation for measurement of autonomic and central nervous system activity).

Cultural Similarities and Differences

Examining similarities and differences across cultures has appealed to many researchers across a variety of viewpoints. Theorists in the Darwinian tradition believe that similarities across cultures inevitably point to a biologically driven emotion system. Whereas social constructivists believe differences are evidence that "emotion" is a culturally defined category of

behavior and experience. Both positions are supported by evidence. A small set of emotional expressions are expressed and understood in all cultures studied. Some general conditions typically elicit the same class of emotions from people all over the globe. Differences in emotion generally occur in the following ways: how situations are appraised what types of emotion are typically felt in response to situations, how emotion experiences are described as different from other types of experiences such as illness or spirit(ual) influence, how that emotion is dealt with and regulated, and how one should behave when experiencing an emotion.

The universality of any given emotion depends on the breadth of the category. The more general the level of cross-cultural comparison, the greater the universality. For example, “anger” involves the sense of having been wrongfully deprived of what one is due, whether that is a possession, reputation, or other object of value. Belief about what an individual is entitled to, of course, varies across cultures and historical time, but the realization of violated entitlement generally elicits an anger-like experience and behavior. In contrast, how that experience is represented in language and beliefs about what to do with the anger, such as what constitutes the appropriate response, the social consequences for acting on the anger impulse, and so on, reveal larger differences and greater variability across time and culture.

The Nature of Emotional Experience

Key issues in this arena include the extent to which emotion occurs unconsciously and the relation of experienced emotion to emotional behavior, especially facial and vocal expression of emotion. There are also ongoing debates regarding the structure of “mixed” emotions, that is, whether they represent an actual combination of discrete emotional states (e.g., anger plus fear) or are experienced as mixed because of the rapidity with which attention switching can take place. Related to this last point regarding mixed emotion is an ongoing debate as to whether emotion is best conceptualized as a set of discrete states, such as anger, fear, and happiness, or is better described as a two-dimensional space within which individually-identified emotions are distributed along bipolar dimensions of intensity and hedonic valence.

Emotion experiences occur on many levels and involve the integration of many systems of the body.

As a result, it is possible for one to experience aspects of an emotion or behave in an emotionally congruent way without even recognizing the presence of emotion. Emotion involves a hedonic judgment (i.e., this is good for me; this is bad for me) which is often made automatically and unconsciously. This information can be processed outside of conscious, directed awareness, thus emotion-consistent behavior may occur without awareness that emotion is affecting one’s actions. Fear offers a good example of how rapidly unconscious evaluations of potential threats are made (Le Doux 1996).

The relation between experience and expression is also debated. In this area, the question is whether emotional expression is a readout of experienced emotion, even if that unregulated, unedited expression occurs only fleetingly. An alternative view detaches experience from expression and views emotional expression exclusively as a means of communication. In this view, expression is only loosely, if at all, related to the motivational state or action readiness that characterizes emotion.

Embodiment theory posits that the body, through sensations and perceptions of the body’s relation to the external world, constitutes a system of knowledge influences how people process emotion-related information. For example, when facial expressions of emotion match the emotion in a task, such as smiling while looking for happy images in a collage, people perform the task faster. There is also research-based evidence that people tend to feel emotional states associated with facial expressions. Research on the *facial feedback hypothesis* (Laird 2007) shows that research participants induced to smile, for example, through holding a pencil with the teeth, report feeling more happiness than those induced to frown by holding a pencil with puckered lips. In contrast, those induced to frown report feeling more sadness than those induced to smile.

Mood and Emotion Effects on Information Processing and Decision-Making

Mood and emotion can have profound effects on cognitive processes and decision-making. For example, people in positive moods tend to think more broadly, are more likely to use heuristic processing, and will persist longer on a difficult task. In contrast, people in

negative moods are more likely to pay attention to detail, use systematic processing, and give up sooner. People's judgments typically reflect the mood they are in with those in positive moods judging people and events more positively than those in negative moods, and those in negative moods judging people and events more negatively than those in positive moods.

It is important to note that these are general patterns which are affected by whether people are alone or in a group, with the effects of emotions and mood stronger when individuals are alone. Furthermore, mood effects are influenced by one's perceived efficacy to achieve a goal. For example, according to the mood behavior model, when one is in a negative mood, but believes that one's goal can be achieved, that individual is more likely to persist than if the goal is not seen as achievable.

Beyond looking at how mood and emotion alter cognition, the interconnectivity of mood and emotion with cognition is becoming more widely recognized. For example, economists are proposing interesting emotion-based models of decision-making as alternatives to rational choice models. Investigation of emotion on decision-making grows out of the clinical finding that patients who retain high level of cognitive functioning, but lose their ability to experience emotion, have difficulty deciding between different options, especially when the options have relatively equal positive and negative components (e.g., Damasio 1999). This work suggests that an affective component of emotions helps lead to decisions, often unconsciously.

Emotion Stereotypes, Group Differences, and Intergroup Emotion

Some beliefs about emotion operate much like other stereotypes, a form of cognitive shortcut that entails quick and unconscious generalization about an individual based on his or her group membership. One of the most persistent beliefs about emotion is the stereotype which equates emotionality with females and inexpressivity or stunted emotion with males. These stereotypes, however, do not match what women and men actually report about their own experience as it occurs. When women and men are asked to report their felt emotion, differences are rarely if ever found when the reports are obtained close to the time that the emotion occurs, as for example, when people keep emotion diaries. On the other hand, if people are

asked to describe past experiences, describe what generally happens, or give a global self-evaluation, their reports more closely resemble gender-emotion stereotypes (e.g., Robinson et al. 1998). Thus, it appears that stereotypes can influence people's self-reports about their experience when questions are framed generally.

Another line of research has shown that stereotypes affect the emotions that are attributed to outgroups, that is, sets of individuals who are perceived to differ from one's own immediate reference group in definable, enduring ways (Leyens et al. 2001). Most notably, more primitive emotions are attributed to members of the outgroup, whereas more complex emotions (e.g., sympathy, remorse) are attributed to ingroup members. Furthermore, outgroup members are typically ascribed lower status emotions (sadness, fear, anxiety) that have action tendencies of withdrawal from the environment, whereas ingroup members are ascribed higher status emotions (anger) that have action tendencies to engage and alter the environment.

Investigation of emotion language and the cultural meaning assigned to emotion has thus revealed a political dimension in that beliefs about what emotion is, how it operates, and when and how it should be manifested are interpreted in the interests of regulating the organization and functioning of social groups. This has been an important line of work in contemporary sociology, but over the past decade has been given more attention in psychological research as well.

Emotional Development

Research on emotional development has come to focus on the intersection of emotion and cognition as developmental processes, exploring how individual socialization and cultural factors are involved in the integration of these two processes (Calkins and Bell 2010). Much emphasis has been placed on the development of emotion regulation as well as the role of emotion dysregulation in adjustment difficulties and psychopathologies (Cole et al. 2004). Neuroscience techniques are widely used in empirical research with infants and children. Recently, exploration of genetic mechanisms for the emotion-cognition link has surged in popularity. Other developmental investigation of human emotion has been explicitly concerned with emotion and emotion regulation capacities as they have an impact on adjustment in academic and social settings.

Emotional Intelligence

Interest in emotional intelligence (EI) has continued to grow internationally since the idea, which had been around in one form or another for decades, was popularized in the 1990s. There are two broad streams of thinking on EI that currently dominate research and applications. The first derives from Peter Salovey and Jack Mayer's (1990) four-branched abilities-based model and identifies EI as comprised of four distinct yet related abilities: *perceiving emotions*, which includes not only the ability to read one's own and others' emotions, but also to perceive emotion in cultural artifacts; *using emotions*, which entails using emotion in the service of various cognitive activities, such as identifying the optimal mood for completion of specific types of problem solving; *understanding emotions*, which involves understanding emotion labeling and the relation among emotions; and *managing emotions*, which is concerned with regulating one's own and others' emotions. Essentially, any emotion-relevant ability is encompassed by one of the four branches, making the construct's definition quite broad. The second model offers an even broader definition of emotional intelligence. It encompasses what some say is more accurately described as general social intelligence, rather than a uniquely emotional intelligence. Measurement using this model relies on self-reported personality attributes and behavioral preferences. This model is associated most closely with Reuven Bar-On's multidimensional EQ-i and Goleman's Emotional Competency Index (ECI), and it is most widely represented in commercial ventures.

Neuroscience

Neuroscience has the potential to examine a range of issues in emotion theory that continue to be debated. By presenting images of what area the brain is recruiting or inhibiting in order to complete a task, functional magnetic resonance imaging (fMRI), for example, can allow us to infer that certain emotion processes might be more active than others in a situation. Though fMRI is still a young science, it has already confirmed many initial expectations of how emotion is processed. For example, strong connections between the amygdala (a structure that is involved in processing negative emotions such as fear) and the hippocampus (a structure associated with memory) have helped explain why episodic memories are so

powerful. The almost immediate activation of the amygdala in response to negative stimuli in the environment has confirmed the early appraisal processes proposed by Arnold. The extensive connections between these structures and the prefrontal cortex (a structure that is responsible for higher order thought) demonstrate the great interconnectivity between "rational" thoughts and emotion.

Neuroscience has also advanced understanding of specific emotional experiences. For example, the capacity for empathy appears to have its neurological basis in the mirror neuron system, a system in the brain that is activated both when an individual performs an action and when the individual observes the same action performed by someone else. As a person reports empathizing with another, parts of the anterior insula, anterior cingulate cortex, and inferior front cortex are active, which some have suggested demonstrates that the empathic perceiver is experiencing the same emotional state perceived in another. In other words, neuroscience has helped to demonstrate that empathy does not just involve an understanding of another's emotional situation but actual coordination of emotion-relevant neural pathways.

Emotion in Other Animals

Great advances in understanding of nonhuman animal emotion have been made in the past 2 decades. For example, the capacity for self-awareness as demonstrated by mirror self-recognition has been shown in the great apes, elephants, dolphins. Intergroup cooperation between animals and other socially oriented skills in some species suggest that emotions are more developed and complex than originally thought.

Jaak Panksepp (2005) has developed a model of emotional processes that explains the continuity of emotional reaction across mammalian species. Building on the fact that a number of neurological circuits are common to humans and animals, Panksepp suggests that these circuits subserve four basic emotion types named in terms of their extreme manifestation: fear, expectancy, rage, panic. The difference between animal and human emotion lies in the significant role that cognitive processes and meaning-making play in human emotional life. Emotions afford the individual the capacity for flexibility in response to classes of similar opportunities or challenges.

Individual Differences and Personality

People will vary greatly as to what emotions they typically experience, and the range of that experience. Often referred to as temperament, this individual difference is believed to be innate rather than learned. Emotion is related to temperament in complex ways as though temperament can make a person more susceptible to emotional experiences, different kinds of environments also interact with what emotions should be typically experienced. For example, some individuals who report low agreeableness tend to be annoyed more easily than others, something which might matter when driving through a crowded, city street, but might matter less when on an open-road at night with no other cars around. Other individuals are high self-monitors, taking emotional cues from others in understanding and regulating their own emotional state. Yet self-monitoring might matter less in situations where strong emotions are expected, as in the context of the death of a loved one, than in situations with less pronounced emotion elicitors.

When explaining issues such as developing phobias or other emotion-related disorders, a diathesis-stress model is often invoked. The diathesis-stress model proposes that individuals may have a predisposition to a certain disease but without the required environmental influence, the disorder will not appear. For example, a person may have a predisposition for depression, but if the triggers for depression are never encountered in individual's social environment, depression will not manifest.

International Perspectives

The study of emotion has grown dramatically in the past 30 years and has done so as an international, interdisciplinary field. As is true for most of psychology, it is dominated by researchers in the USA and Europe, but there has also consistently been a strong representation of Japanese and Chinese researchers.

Multinational and cross-cultural studies have had an impact on core areas of emotion theory and research. General findings regarding areas in which cross-cultural similarity and differences are commonly observed are discussed in an earlier section of this paper. Among specific topics that recently have benefited from international perspectives, two stand out.

Developmental researchers have outlined the complex interplay between universal developmental milestones and culture-specific scaffolding for emotional socialization. A second area that continues to benefit from international perspectives is the study of emotionally expressive behavior. A number of researchers have shown that there is an ingroup bias in reading emotion content and intensity. Others have identified apparently culture-specific expressive “dialects” in some facial expressions of emotion.

Future Directions

Understanding of emotion has advanced dramatically since William James asked “What is an emotion?” Overall, one of the clearest directions for emotion research is integrating research across disciplines to achieve a common understanding of emotion. Another clear direction for emotion research is application, involving taking what has been learned in the laboratory and applying it to promote positive social change. Three specific areas of research are discussed below.

Neuroscience

Neuroscience is a young field, and full of promise. As methods advance, the cost of conducting this research will decrease and its effectiveness increase. fMRI holds some of the greatest potential for advancement and is beginning methods to move beyond its early stages where areas of the brain were simply mapped out to delineate their functioning. New techniques such as diffusion tensor imaging will allow for networks of activation to be mapped out. Such techniques will show how different brain regions are interconnected and allow us to better understand how emotional disorders such as phobias and bipolar disorder operate. Understanding these networks will also help to aid treatment and improve its effectiveness. For example, through neuroscience we can better investigate when and how memories form so as to help break linkages of certain thoughts and memories with negative emotions (such as with phobias or people suffering from post-traumatic stress disorder).

Artificial Intelligence and Face Recognition

Modern research has recognized the pivotal role that emotion plays in decision-making. Rational choice

models proposing that people weigh the costs and benefits of a situation and seek to optimize rewards do not infallibly predict behavior. Future work on creating “intelligent” computers that are able to mimic human behavior will need to factor in the numerous ways that emotions affect decision-making as have been outlined in this chapter. In addition to programming artificial intelligence, another field that will benefit from the application of emotion research is face recognition. Face researchers have demonstrated that the emotions conveyed on the face present a unique contribution of information regarding how people recognize and process social information.

Integrating Biology and Cultural Knowledge

Advancements in genetics have revealed that certain genes may predispose individuals to various illnesses such as depression and anxiety disorder. Psychologists and sociologists have demonstrated that stressful environments and cultural factors contribute to the development of these disorders. These two bodies of knowledge will enable research to move beyond simplistic nature vs. nurture debates to the development of when and how nature and nurture interact.

Conclusion

In this entry we have discussed the evolution of theory and research on emotion from the standpoint of Western scientific psychology. Theories of emotion are found in the oldest philosophical schools of thought. With the development of a modern definition of emotion in the nineteenth century, the longstanding view of emotions as antithetical to reason dominated early philosophy-based psychological theories. Contemporary emotion theory has evolved to consider emotion as a necessary element of rational decision-making and emotion communication a significant feature in promoting effective social relationships, self-understanding, and even physical and mental well-being.

Theories of Memory, History of

DAVID J. MURRAY
Queen's University, Kingston, ON, Canada

Introduction

In attempting to formulate a history of theories of memory, it must be noted that the English word

“memory” itself has a broadness of application that is not paralleled in other languages. In French, the words *la mémoire* refer to the ability that the mind–brain system has for retaining representations both of internal events and of external reality; and the words *un souvenir* refer to an individual retained representation generally identified by its content (referent). For example, if one wanted to translate the question, “Do insects have memory?” into French, one would use *la mémoire* as an equivalent for the English word “memory.” But if one wanted to translate the question “How strong is your memory of your first day at school?” one would use *le souvenir*. An analogous classification is found in German, where memory-the-ability is translated as *das Gedächtnis* and an individually experienced memory representation is translated as *eine Erinnerung*.

These observations lead to the surmise that the appropriate scientific language for the study of memory-the-ability is most likely to be the language of neurophysiology, and that the appropriate scientific language for the study of experienced memory representations is likely to be the language of experimental psychology and/or phenomenology. Above, both types of language were subsumed in the compromise expression “mind–brain system.” Looking back at the history of memory theories, those theories dealing with the brain substrates of memory can be considered to constitute one cluster of theories and those theories dealing with the experiential aspects of memory (such as recognizing, recalling, and identifying) as a separate cluster. It will come as something of a surprise, therefore, that two of the most important names in the history of memory theory shared the renegade belief that the word “memory” ought to be avoided in the course of developing a theory about retention and retrieval. J.B. Watson (1878–1958) believed that a scientific account of memory had to be firmly based on neurophysiological grounds, while J.F. Herbart (1776–1841) believed that because experience is all that humans have to go on in interpreting reality, a study of memory as experience took priority over the understanding of the brain mechanisms underlying memory. These points may be briefly elaborated because, in the major part of this article, theories of memory will be put into historical time-slots bounded by the names of Herbart and Watson, as well as by the “cognitive revolution” of the late 1950s.

Herbart wanted to emulate in psychology the success achieved by Sir Isaac Newton (1642–1727) in physics. Using his laws of motion, Newton had been able to explain how an array of physical objects could exert forces on each other at a distance in such a way that the array was transformed from a jumble of moving objects into an equilibrated “system.” An example is a solar system in which a set of planets move round a large central object (a sun) with predictable velocities at predictable distances. Herbart argued that mental experience could be described in analogous terms; at a single moment of time, one might potentially feel and see and hear and think a jumble of experiences, but, so quickly as to appear instantaneous, the jumble settles into a state of equilibrium in which one or two experiences dominate and others are no longer experienced. An “experience” is something mentally cognized; only the person experiencing, for example, an itch (*and* the desire to scratch it), experiences it firsthand. Herbart adopted the German word *Vorstellung* to refer to a single mental experience, which might be a sensation (like an itch), a sensory image (like an image of a movie in which somebody is scratching his head), a covertly uttered sentence about the present (“I wish I could get rid of this itch”), or about the past (“This itch reminds me of my first day at school, when I wore scratchy clothing”), or about the future (“This itch will go away by itself”).

In this theoretical framework, there is no need to distinguish between *Vorstellungen* on the basis of whether their content represented the present, the past, or the future. What mattered at any moment was the degree to which each of the *Vorstellungen* concurrently being consciously experienced dominated each of the others. Herbart’s laws of inhibition exerted between concurrently experienced *Vorstellungen* was his equivalent of Newton’s laws of gravitational force exerted between concurrently present physical objects (Boudewijnse, Murray, & Bandomir, 1999, 2001).

Almost exactly the opposite approach was taken by J.B. Watson. Watson knew far more about the brain and nervous system than did Herbart, and had concluded that brain tissue had the capability of providing neural substrates of what Watson called “habits.” The Russian physiologist I.M. Sechenov (1829–1925) had argued that the meaning of the word “reflex” could, with scientific justification, be extended to apply, not only

to unlearned reflexes such as the eyeblink or the knee jerk, but also to reflexes elicited as habits following a series of repeated pairings of the reflex with a stimulus that normally did not elicit the reflex. To give a twentieth-century example, a human might begin to blink to the sound of a tone if he or she has experienced a series of tones each of which is followed immediately by a harmless puff of air to the eye (Hilgard & Campbell, 1936). For Sechenov, an immediate and involuntary eyeblink to a tone could be classified as a “reflex” conditional upon prior training.

Sechenov’s legacy in the history of psychology was enormous. I. Pavlov (1849–1936) noticed that the dogs he was using for his studies on digestion would exhibit alerted behavior when the person feeding them could be seen or heard approaching; Pavlov soon moved on from studying digestion to studying salivation as a “reflex” response to nonfood stimuli that had been regularly paired with food stimuli in the dogs’ experience. Watson seized upon the Russian research on induced habits as a foundation for a theory of human development based on the acquisition of habits varying in sophistication from a baby’s responses to food to a scholar’s responses to a learned book. A chart showing how a six-year-old has been able to acquire the rudiments of language and of social behavior by way of conditioned reflexes that chain themselves into “habits” of responding can be found in Watson’s book entitled *Behaviorism* (1924/1930, p. 138).

During the 1920s and 1930s, Watson was not only being criticized by members of the fledgling Gestalt movement (see below), but also found himself attacking the beliefs of the psychoanalysts. He made the important point that what Sigmund Freud (1856–1939) and others had called “unconscious” memory representations may actually be “unverbalized” memory representations. A toddler might fall off the edge of a slide in a playground and be distressed; but he or she has not yet learned to speak, so does not say anything to himself or herself about the event; but the event, along with its accompanying emotions, might somehow be retained and show itself later in an otherwise hard-to-explain fear of children’s playgrounds. According to Watson, there is no *need* to talk about the unconscious, only about whether or not the event had been registered in the brain in terms of a verbal format (easy to access by fluent speakers) or in terms of an emotional

format that could be stimulated, for example, by the sight of a playground.

It was also during this period that Watson maintained that the scientific usefulness of the word “habit” implied that the introduction of the word “memory” into scientific discourse was both superfluous and potentially misleading. A careful reading reveals that Watson never denied that the brain had the capacity to retain what was needed to set up a habit (i.e., he never maintained that *la mémoire* should be dropped from scientific parlance), but he strongly denied that one needed to use the word “memory” for individual acts of nonverbal or verbal retrieval (i.e., he wanted to replace *un souvenir* with a “habit” or chain of habits). It should be noted that Watson published these opinions in magazine articles and these have been collected in the book entitled *The Ways of Behaviorism* (Watson, 1928).

Following Watson’s claims for a physiologically based approach to learning and memory, and his espousal of Pavlovian conditioning as the foundation for learning throughout a lifetime, attempts were made to build theoretical accounts of learning that, just as had been achieved by Newton and other physicists, would be axiomatic in nature. Of course, the best known of these ambitious theories was that of Clark L. Hull (1884–1952), which actually went through two stages of development. First came a theory of human learning in which individual memory representations (*les souvenirs*) were considered to be verbal habits describable in terms of physical stimuli and overt responses linked together by a chain of so-called mediating responses (Hull et al., 1940). For example, a list of nonsense syllables could be represented as a chain of individual verbal responses that, by force of repetition, could be learned “by heart” (“by rote”). The second stage was a theory of animal learning in which the number of trials needed to acquire individual learned habits (e.g., learning to turn left at a choice-point in a T-maze) could be predicted on the basis of an experimenter’s knowledge of the animal’s needs and of several other variables (Hull, 1943). In Hull’s animal studies and many others inspired by him, the most frequently used subjects were laboratory-bred white rats.

Following the 1950s, objections surfaced not only to the idea that human verbal behavior could be broken

down into simple chains of “mediated responses,” but also to the idea that the best subject for the study of retention in animals was the rat. With respect to the choice of subject, Kandel (2006, pp. 145–149) has described how, in the development of his theory of how the brain is able to retain simple habits, resistance was initially offered to his opinion that, in order to study, say, how the course of classical conditioning was paralleled by measurable events in the brain, the best kind of brain to study would be one much simpler than that of the rat. Such a brain is possessed by the giant marine snail *Aplysia californicus*, an organism capable of acquiring conditioned reflexes but that possesses a brain consisting of only about 20,000 neurons grouped into nine separate clusters; the typical mammalian brain, including that of the rat, has about 100,000,000,000 neurons.

With respect to the perceived inadequacy of accounts of human retention and retrieval that were based on Hull’s conditioning theory, a number of psychologists, including some influenced by the Gestalt theory, introduced into psychology a vocabulary that revived the use of the word “memory,” both in the sense of *la mémoire* (as in “short-term memory,” “working memory,” and “long-term memory”), but also in the sense of *les souvenirs*. Research on retention and retrieval processes in humans expanded from the study of rote memorization of nonsense material to the recall of autobiographical memories (*les souvenirs*), the recall of stories, the learning of foreign languages, and even the recall of intentions that had been formulated a short while earlier (“prospective memory”). This new vocabulary formed the backbone of a literature arising from the so-called cognitive revolution, generally asserted to have begun in 1956 (Baars, 1986; Murray, 1995), and which is still in vogue.

But earlier, it was remarked that *la mémoire* was most appropriately explicable in terms of physiological conceptions, whereas it has been just stated that modern cognitive theorists, when talking about short-term memory, long-term memory, and working memory, have extended conceptualizations of *la mémoire* into subclasses within psychological domains. A magnificent resolution of potential confusion has been achieved in Kandel’s (2006) summary of his lifetime’s work on memory, which took him from a biologically based account of how *la mémoire* operates in the snail

Aplysia to an equally biologically based account of how short-term memory, long-term memory, and working memory operate in humans. Accordingly, therefore, before presenting the events within each of the four stages into which the history of memory theory can be divided (pre-Herbartian, Herbartian to Watsonian, Watsonian to cognitive revolution, cognitive revolution), it will be shown how Kandel's research on the biology of memory storage— in species ranging from *Aplysia* through mice to humans— yields a corpus of factual data with which any psychologically based theory of memory has to be consistent.

Kandel divided the primitive memory of *Aplysia* into three kinds, all of which he subsumed under the heading of “implicit memory,” an expression popularized by Tulving (1972, 1983), during the cognitive revolution, to refer to those actions that indicated that retention had taken place that was nevertheless not susceptible to conscious inspection by humans (e.g., most motor skills and, possibly, some learned emotional responses, such as a preverbal child's fear of the playground). Let S be a weak or neutral sensory stimulus that activates a reflex movement response in *Aplysia*. For example, S can be a touch of moderate strength to the skin of the snail's siphon (an excretory tube). This stimulus initially yields an unlearned gill-withdrawal reflex (so that the animal's respiratory abilities are protected). But if S is repeatedly presented alone, the snail's gill-withdrawal reflex becomes less and less intense and frequent, as if the snail were learning that a touch to the siphon was not necessarily harmful. This kind of learning is called “habituation.”

Second, if a sequence of five rapid touches is given to a different pathway, and then, after a short interval, stimulus S (a single touch of moderate strength to the siphon) is administered, the gill withdrawal to S is stronger, faster, and more predictable than had been the case in the habituation studies. This increase in responding, based on recent experience with sustained and intense stimulation, is called “sensitization”; a history of how habituation and sensitization have been studied in vertebrates has been provided by Davis and Egger (2003).

Third, if a noxious stimulus, such as an electric shock to the tail, *regularly* appears just after the stimulus S (the touch to the siphon), it will be found that the neutral stimulus S eventually elicits a strong gill-

withdrawal response, almost as if S, previously neutral, had acquired aversive properties because of having been paired with the shock. The strength of the enhanced response to S when S is associated with classical conditioning is greater than the enhanced response to S when S is associated with sensitization (Kandel, 2006, p. 170). This was the task used by Kandel and his colleagues to study classical conditioning.

In these habituation, sensitization, and classical conditioning tasks, a stimulation of a sensory neuron (here, associated with the siphon) leads to a change in the response in the synapse connecting the sensory neuron to a motor neuron (here, associated with the gill). In *Aplysia*, it proved possible to isolate individual cells within clusters and thereby to study the changes in response at a single synapse separating a sensory neuron from a motor neuron. It was discovered that habituation weakened the responsiveness at the synapse with the motor neuron, that sensitization enhanced the responsiveness at that synapse, and that the time during which these changes persisted (a matter of minutes) depended on the length of time that the synaptic regions had been subjected to stimulation. Classical conditioning involved either weakening or strengthening changes, depending on the synapse being studied.

But intense and/or sustained stimulation can also lead to long-term habituation, sensitization, and classical conditioning (a matter of hours or days). When investigated, it was found that not only were there changes in responsiveness at the synapse, but that there were also outgrowths from the sensory neuron, outgrowths that made new, additional, synapses with the motor neuron.

Humans and other vertebrates possess a complicated brain that includes special clusters of neurons grouped into the “hippocampal formation.” From studies of rats and mice, it seems that the neurons in this area have become specialized for the retention of spatial information. There is good evidence that in a juvenile vertebrate, the hippocampal cells are not particularly activated simply when the animal is placed into a new environment; but within minutes of being kept there, hippocampal cells do respond to any sensory stimulus (visual, auditory, etc.) associated with that place. These cells, therefore, have been called “place-memory cells.” The subject is able to utilize this retained multisensory information

in the course of learning spatial tasks such as finding escape routes, finding where food was previously hidden, and so on. In these hippocampal cells, the long-term facilitation in responsiveness associated with sensitization and with classical conditioning is probably mediated by a form of synaptic retention mechanism that is different from the mechanism used in *Aplysia*; this vertebrate mechanism is called “long-term potentiation.” But, as in *Aplysia*, long-term retention is also associated with the growth of new neural appendages that form new synapses between sensory and motor neurons. Furthermore, damage to the hippocampus can be associated not only with defective spatial learning in rats and mice, but also with extreme kinds of human amnesia in which short-term memory is intact, but acquisition of new long-term memories (*les souvenirs*) is impossible (Scoville & Milner, 1957 on the case of H.M.; Neath & Surprenant, 2003, pp. 178–180 give updated information on H.M.).

Because a major difference between humans and *Aplysia* lies in the fact that the former possess consciousness as well as sentience, while the latter probably possess only sentience, and because the retention processes that had evolved in *Aplysia* are, therefore, probably not associated with consciousness, those processes underlay what Kandel had called “implicit memory.” Following the same logic led to Kandel’s conclusion that the hippocampal formation is crucial to the retention processes underlying “explicit memory,” because, in humans, the recall of narratives and of autobiographical *souvenirs* is carried out consciously.

The biochemical events responsible for long-term implicit memory in *Aplysia* are far more complicated than earlier historical attempts to explain the biology of memory would have led one to believe. Neural network models and S-R chain models of the kind that proliferated since Hull’s model of 1943 were perforce uninfluenced by three new findings intrinsic to Kandel’s model, because these new findings were only discovered after about 1980.

The first discovery was that, within a *single* sensory neuron, there are certain proteins located not at a synaptic junction, but in the *nucleus* of the neuron itself that control whether or not the synaptic transmission of information concerning a sensory stimulus will, or will not, be retained for long periods. A protein called CERB-1 acts to facilitate the transmission, and

another protein, called CERB-2, acts to prevent the facilitation of that transmission. The neurotransmitter in both cases is glutamate and the facilitation is caused by the growth of new synapses connecting the sensory neuron with the motor neuron.

The second discovery was that, again within a single sensory neuron, the way CERB-1 operates to facilitate the growth of a synapse is to send messages from the nucleus out into the cytoplasm near the point where the new synapse will grow. These messages are sent when CERB-1 acts on (“expresses”) a *gene* (part of a DNA molecule that is already present in the nucleus of the cell); this *regulatory gene* then switches on an *effector gene* that causes messenger RNA to go out of the nucleus, along with certain proteins, to those particular synapses, in that sensory neuron, that can be stimulated by serotonin. At the sites of those synapses, new proteins are synthesized locally to help the development of extra cell-tissue that will form a sidearm that extends from the cell body and, therefore, adds a new synapse, the neurotransmitter for which is glutamate that connects the sensory neuron to the motor neuron.

The third discovery was that one part of these new proteins has the ability to transform *itself* into a new structure, one that self-perpetuates, and thus allows the new synapse to retain its transmissive properties indefinitely. These new proteins resemble a class of proteins called *prions*. Prions have conventionally been thought of as disease causing because their transformed forms can actually be destructive to neuronal tissue (as in mad cow disease). But the property of self-perpetuation also appears to have evolved into a biologically adaptive mechanism that can be used as a vehicle for retention in implicit memory.

With certain modifications, the above account of the neuronal structures that form the basis of long-term memory in *Aplysia* holds also for events in the mammalian hippocampal formation. One difference is that the molecule that allows a stimulus to activate a sensory neuron is serotonin in *Aplysia*, but dopamine in humans. But, in both species, glutamate remains the neurotransmitter that mediates transmission from the sensory neurons (and/or associated interneurons) to the corresponding motor neurons in *Aplysia*, and from place-memory cells (and/or associated interneurons) to the corresponding motor neurons in rats and humans. The biochemical mechanisms underlying

habituation and sensitization in *Aplysia* involve other molecules that do not need to be discussed here, for example, cyclic AMP and protein kinase A (Kandel, 2006, pp. 262–267).

Standing back, it will be just seen how innovative Kandel's account was, involving, as it did, events in the nucleus of the neuron, genes that are localized within the neuron, and prion-like proteins that serve to perpetuate anatomical changes to the neuron. Kandel's own assertions about the relevance of his theory to psychological manifestations both of *la mémoire* and *les souvenirs* include five that deserve to be highlighted here.

1. He argued that a very intense stimulus could have the effect of turning on the CERB-1 protein but also of bypassing the turning on of the CERB-2 protein. Hence, little in the way of inhibition would stop the *souvenirs* of the intense stimulation from being perpetuated for a long time period (Kandel, 2006, pp. 264–265).
2. He argued that, in humans, only those stimuli that are consciously attended to might activate neural events that lead to long-term retention of those stimuli. The brain region in humans that is most responsible for ensuring that attention is paid to the stimuli most salient in importance is the hippocampal formation (Kandel, 2006, pp. 311–316).
3. He argued that forgetting was directly related to the amount of activity associated with CERB-2 proteins. For example, a low level of CERB-2 activity might explain why some individuals are exceptionally good memorizers; and (normal) increases in CERB-2 activity over the years might explain some of the (normal) forgetting associated with aging in humans (Kandel, 2006, p. 266).
4. He argued that it takes time for the regulator gene to switch on the effector gene that will then facilitate the growth of new synapses for long-term retention processes. This time period coincides roughly with the time period required for the consolidation of individual habits in vertebrates and of individual *souvenirs* in humans (Kandel, 2006, p. 262).
5. He argued that the mechanism of memory storage in neurons is extraordinarily similar for all animal species, ranging from *Aplysia* through *Drosophila* (fruit fly) through mice and rats to humans (Kandel, 2006, pp. 421–423).

The remainder of this article, therefore, will track the progress of memory theories through four time periods: the pre-Herbartian period, the period from Herbart to Watson, the period from Watson to the cognitive revolution, and the period of the cognitive revolution itself. In each of these four sections, separate subsections will be devoted to quantitatively expressed theories and to qualitatively expressed theories. Within each subsection, following the tenets of Paivio's (1971, 1990, 2003) dual coding theory, verbal memory will be discussed separately from visual memory. At the end of each section, special attention will be devoted to historical events within the period covered by that section that revealed insights into the first three of Kandel's manifestations, namely, (1) the long-lasting effects of over stimulation, (2) the role of brain localization in long-term human memory, and (3) hypotheses about the mechanism of forgetting. Psychological evidence concerning consolidation (4) will be introduced wherever appropriate. A conclusion section will elaborate on the importance for memory theory of Kandel's posited universality of near-identical neuronal retention mechanisms across species (5).

A Chronological Summary of Theories of Human Memory

Pre-Herbartian Memory Theories

Qualitative Theories

Memory for Verbal Material

The only book that has survived from ancient times that was devoted entirely to memory was the *De Memoria* of Aristotle, written about 350 BC (see McKeon, 1941). Aristotle pointed out that a conscious search for, say a word, could be conducted following a number of possible strategies. If one is trying to put a name to a face, one might try to imagine faces similar to the one given, or try to recall the time and place when one last met that person, or mentally exaggerate or change certain features of the face. In each case, one is hoping that the missing name will come to mind. These three strategies were named Aristotle's three laws of association, namely, association by similarity, association by contiguity, and association

by contrast. Over the succeeding centuries, these laws were modified or amplified by various philosophers of mind. Changes of particular interest include David Hume's (1739/1955, Book I, Part III) addition of association by causality and omission of the law of contrast (he thought it a special case of association by similarity); Sir William Hamilton's (1852, p. 913) suggestion that all three laws exemplified a mental process he called "redintegration," to be illustrated below; and William James's (1890/1950, p. 566) assertion that all three laws were by-products of a single "elementary causal law of association [namely]. . . the law of neural habit." A review of the history of Aristotle's laws of association has been provided by Warren (1921), but the exceptionally scholarly review by Hamilton (1852, pp. 889–910) should also be consulted.

Aristotle believed, in contrast to some of his predecessors, that the human memory system had no contents at birth; that is, at birth the system was like a blank wax surface, a *tabula rasa*, on which nothing had been written. Plato had believed that a newborn carried memories (*souvenirs*) from previous lives. Many scholars of the period between Aristotle's death and the start of the scientific renaissance in the early seventeenth century claimed, probably mistakenly, that Aristotle had asserted that individual *souvenirs* acquired during a lifetime might survive bodily death, becoming components of a nonmaterial entity called the Agent Intellect (Murray, 1988, Chapter 2).

The likening, by Aristotle, of *la mémoire* to a wax tablet and of *les souvenirs* to written symbols on that tablet was one of many attempts to find metaphors that would capture the essence of human memory. Plato had described *souvenirs* as being like birds flying in an aviary that could not easily be captured in the course of retrieval. St. Augustine compared *la mémoire* to a storehouse or a palace. A review of these and other metaphors was provided by Roediger (1980).

Verbal transformations were also made a basis for memorizing long lists of historical names and dates and even scientific data. A widely propagated example was Grey's (1730/1859) book entitled *Memoria Technica*. In this scheme, the memorizer learned to fluently associate each digit with a vowel and a consonant. For example, the number 1 was associated with *a* and *b*, the number 2 with *e* and *d*, and the number 3 with *i* and *t*. Then,

a number such as 312 could be transformed verbally into *tad* or *ibe* (both easily pronounceable). Practice at these transformations was supposed to help the memorizer learn the dates of the reigns of English kings, or of the years in office of Catholic Popes, or of the major battles of history.

Memory for Visual Material

It was in the context of the memorization of the successive points to be made in a speech that visual memory was harnessed in the mnemonic scheme known as the Method of Loci. A sequence of places was mentally visualized, for example, a plan of the seating-places of individuals at a banquet, or of the rooms in a house or palace. One mentally wandered in a set order through those locations, assigning to the first the first point to be made in the speech, to the second the second point, and so on. This mnemonic technique was first proposed in Classical Athens, but, from the medieval period until well into the nineteenth century, visual schemes of palaces, theaters with fixed seating arrangements, and so on were actually published. Some illustrations of these mnemonic schemes have been provided by Yates (1966); and Paivio (1971, pp. 168–173) show a scheme offered by Feinagle in 1813 that consisted of a combination of the method of loci (a room divided into 50 parts) and a simplified form of the number–letter transformation method popularized by Grey (1730).

In medieval manuscripts, the contents of a page were often highlighted by the uses of different scripts, colors, indentations, and illustrations designed to help the reader to retain those contents (Danziger, 2008, pp. 73–83).

Kandel's Psychological Manifestations

The Effects of Overstimulation

In a book on oratory addressed to a Roman named Herennius, its author, once thought to have been Cicero (106–43 B.C.), claimed that certain events could be retained reliably and with little effort because they were "exceptionally base, dishonourable, extraordinary, great, unbelievable, or laughable" (Caplan, 1954).

Brain Localization

According to Lones (1912), Aristotle's ascription of *la mémoire* to the heart might have been justified given

the current state of knowledge of human physiology. But at the time of Galen (ca. 130–200 A.D.), a general scheme of brain activity, illustrated by Murray (1988, pp. 40–43; 56–58), had ascribed the seat of memory to the third (posterior) ventricle of the brain. Interestingly, the first (anterior) ventricle was thought of as the brain region that pulled together information from the various senses (a property now associated with the place-memory cells of the hippocampal formation). The second (middle) ventricle subserved reasoning in humans and instinctive behavior in animals. For scholarly details, Wolfson (1935) should be consulted. This emphasis on the ventricles was only decisively broken down at the end of the seventeenth century, thanks mainly to Thomas Willis (1621–1675) (Spillane, 1981).

Theories of Forgetting

Both Aristotle and Plato had stressed that some forgetting was because the (metaphorical) writing on the wax tablet had been permanently wiped off, while other forgetting was due to a temporary failure to retrieve *le souvenir* that was being searched for. But the most explicit distinction between permanent forgetting (often called, somewhat misleadingly, “decay”) and temporary inaccessibility (often called, ambiguously, “interference”) explanations of forgetting was due to Juan Luis Vives (1492–1540). Vives also pointed out that a single stimulus could “fire off” a whole train of well-integrated visual and verbal associations, a property of retrieval that was later taken up both by Hamilton (1852), who named this part-to-whole kind of association “reintegration,” and by Pribram (1969), who compared human memory with a holographic record. Murray and Ross (1982) have provided an annotated translation of Vives’s contribution to memory theory.

Memory Theories from Herbart to Watson

Quantitative Contributions

Memory for Verbal Material

Herbart (1824/1890) deduced that three verbal *Vorstellungen* could inhibit each other to such an extent that the dominance of two of the *Vorstellungen* over the third could be sufficiently strong for the third to no longer participate in consciousness.

Memory for Visual Material

Again, if all three *Vorstellungen* were visual, one of them could be lost from consciousness because of the combined inhibitory forces of the other two.

On the other hand, if two *Vorstellungen* were verbal, and one was visual, the visual need not necessarily be forced out of consciousness; and if two were visual, and one was verbal, the verbal need not necessarily be forced out of consciousness either. This condition allows for the coexistence in consciousness at any one moment of *Vorstellungen* that differ from each other in their sensory nature. “Complications” was the name given to combinations of *Vorstellungen* that do not inhibit each other to the extent that one or more of them are driven out of consciousness. As noted by Murray and Bandomir (2002), this Herbartian postulate is consistent with twentieth-century evidence that verbal and visual mental representations can coexist in consciousness more easily than can an equal number of mental representations that are all verbal or are all visual. This evidence has been reviewed by Penney (1989), who has called the hypothesis of the coexistence in immediate consciousness of separate verbal (or auditory) and visual mental representations the “separate streams hypothesis.”

When only two *Vorstellungen* are in consciousness, both are diminished in strength by their mutual inhibition, but neither can actually be pushed out of consciousness. If, however, the two *Vorstellungen* arise from stimuli from the same sensory dimension (say, auditory) and those stimuli are equal in time of onset, duration, intensity, and frequency, then the two corresponding *Vorstellungen* (presumably almost identical) can fuse into one *Vorstellung*. However, two *Vorstellungen* that are clearly different in content, but are co-experienced at the same time, can partially fuse, so that if one of them rises into consciousness, it can help pull the other into consciousness along with it.

Herbart (1824/1890) argued that a memory *Vorstellung* would survive, even though it had temporarily been excluded from consciousness. In the present-day “free recall task,” 20 sequentially presented words, say, are to be recalled immediately in any order. Typically, some eight words are correctly reported in a minute or so. But 16 or more words can be recalled if participants are given an alphabetic or semantic “cue” to each word. Tulving’s (1983,

Chapter 10 and 11) “encoding specificity hypothesis” contended that preexperimentally established associations can indeed serve as effective retrieval cues in free recall tasks, but it also contended that the way in which each word had been encoded at presentation could be even more effective in enhancing the probability of recall of that word. Laming (2009) has produced a mathematical model based on the assumption that a failure to recall a given word in a free recall task can be due to a temporary difficulty in retrieving the memory representation of that word rather than to a permanent absence of that representation. Both Tulving’s encoding specificity hypothesis and Laming’s model are consistent with Herbart’s assumption that a *Vorstellung* A no longer in consciousness can be assisted back into consciousness if *Vorstellung* A has been partly fused with an associated *Vorstellung* B already in consciousness. With hindsight, *Vorstellung* B can be seen as representing a retrieval cue in a free recall paradigm.

Qualitative Contributions

Memory for Verbal Material

Abercrombie (1843) wrote a widely sold text designed to instruct readers in the findings of the fledgling science of psychology. In his chapter on memory, he emphasized that to ensure long-term retention of words and facts, they should be given maximum attention at the time of initial learning, and should also, as far as possible, be made to form associations with related words and facts. This view is exactly that of Kandel (2006, pp. 311–316).

Research and speculation on verbal memory took a sudden upturn in the 1880s; Wundt’s (1874) widely used textbook of psychology had said little about memory, and, for reasons outlined by Boudewijnse, Murray, and Bandomir (2001), had been critical of Herbart’s mathematical psychology. But Ebbinghaus (1885) reported his studies of the serial learning of nonsense syllables, materials designed to minimize the presence of verbal and emotional associations as facilitators of the memorizing process. He was able to confirm the Herbartian postulate that after a list of syllables A, B, C, . . . G had been learned by heart, the association between A and B was stronger than that between A and C or between A and G. He also put forward his famous forgetting curve, showing that the forgetting of a series

of syllables, as measured by the time it took to relearn the series after an interval, was relatively greater at short intervals than at long intervals. Kandel (2006, p. 210) describes this finding more precisely: “. . . forgetting has two phases: a rapid initial decline that was sharpest in the first hour after learning and then a much more gradual decline that continued for about a month.”

William James (1890) distinguished between “primary memory” where a memory representation has entered and remained in consciousness, and “secondary memory” where a memory representation had entered consciousness, then left it, and then returned into consciousness. Kandel (2006, pp. 209–212) considered that Ebbinghaus’s initial sharp decline in recall and James’s very temporary “primary memory” were important forerunners of the late twentieth-century distinction between short-term memory and long-term memory. Kandel then described how Müller and Pilzecker (1900) essentially repeated Ebbinghaus’s experiment on forgetting but showed that if one group of participants had to learn a new list *immediately* after having learned a first list, relearning the first list 24 h later was very difficult. However, if another group had learned a new list *two hours after* learning the first list, relearning the first list after 24 h was relatively easy. Müller and Pilzecker proposed, therefore, that learning the second list immediately after learning the first list had prevented the first list from being retained, much as if the *souvenirs* of the first list had not been consolidated into permanent *souvenirs*.

In an experiment designed to discover the number of separate objects that could be counted given only a single, very short glance at the objects, Jevons (1871) had found that only about four objects could be confidently described as being four in number; the number of objects greater than four had to be guessed at. Jacobs (1887) attempted to discover how many verbal stimuli (e.g., single digits) could be recalled in correct order after one presentation. The digit span turned out to be about seven, but extensive later research has shown that a claim can be made that the digit span, like Jevons’s “span of apprehension,” is actually more like four, with the extra recalls coming from intralist associative or elaborative subvocal rehearsal (Cowan, 2001). Nineteenth-century research on the memory span has been reviewed by Murray (1976), early twentieth-century research by Blankenship (1938), and late twentieth-century research by Watkins (2003).

Memory for Visual Material

Partly because of the role played by visualization in the practice of mnemonics, discussion of visual memory in humans was sufficiently widespread for Galton (1883) to feel justified in undertaking surveys of the prevalence of visual imagery among his colleagues. He found that there was wide variation in the ability to visualize, for example, the breakfast table at which one had eaten that same day; and that the digit series 1, 2, 3, . . . 10 was often mentally represented as a visual pattern with lines connecting the digits. In a related study of associations, he noted that a visualization of oneself “acting out” one’s emotions was surprisingly common (“histrionic” associations). He also invented “composite photographs,” in which the photos of each member of a family could be superimposed in such a way as to reveal those features that were common to most members of the family.

Galton fully accepted Darwin’s (1859) theory of evolution, and so did Darwin’s colleague G.J. Romanes (1848–1894), a physiologist whose work on invertebrates foreshadowed the discovery of the synapse at the end of the nineteenth century. Romanes (1882, 1883, 1888) attempted to explain how voluntary behavior, emotional versatility, and problem-solving abilities had evolved in animals, including humans. His analysis of problem solving led him to distinguish between “receptual memory,” in which an organism responded to a stimulus in a manner that had been learned because of prior acquaintance with that stimulus, and “conceptual memory,” in which an organism can respond to a stimulus by mentally relating it to other similar or contextually related stimuli. Clearly, conceptual memory is confined to species with a human-type consciousness, and Romanes (1888) was ingenious in the way he demonstrated, partly from observations of his own children, that language acquisition goes from an initial stage in which verbal responses are essentially receptual, to a final stage at which the responses are “conceptual” insofar as words can be consciously strung together to form sentences. This is mentioned here because the distinction between “receptual” and “conceptual” types of memory has close affinities with the later distinction between “implicit” and “explicit” types of memory.

It was also in the context of evolutionary theory that Wesley Mills (1847–1915) wrote diaries about the

behavior patterns of newborn kittens, puppies, and the young of other species (Mills, 1898). Mills described dogs as having exceptional memory for what had been experienced in particular places. But it would be decades before place memory in vertebrates would be investigated in laboratory settings and a link established between place memory and the evolution of the hippocampal formation.

Kandel’s Psychological Manifestations

The Effects of Overstimulation

In Pavlov’s laboratory in St. Petersburg, a flooding of the river Neva in 1924 penetrated the kennels and forced the laboratory staff to make Pavlov’s dogs swim from their kennels to the laboratory. As one historian has phrased it: “Subsequently many dogs reacted in a very irregular fashion in their experiments; this was attributed to the effect of the traumatic experience on ‘weak’ nervous systems” (Boakes, 1984, p. 130). More exact details of these “irregular” responses were given by Pavlov (1927/1960, pp. 313–318).

Brain Localization

T.A. Ribot (1839–1916) was at the forefront of science writers who introduced France to new developments in psychology (Nicolas & Murray, 1999); but he is best remembered for his book on amnesia in which he formulated what is now called Ribot’s Law. In global amnesia (and also in specific amnesias like aphasias), the disintegration of the ability to recall *souvenirs* follows a set order: recent *souvenirs* are the first to be forgotten and *souvenirs* acquired during childhood survive the longest. Ribot referred to recent *souvenirs* as “unstable” and to early *souvenirs* as “stable.” The law is consistent both with a theory requiring a consolidation mechanism and with Kandel’s discovery of specialized biological mechanisms that can ensure long-term retention over many years.

Mechanisms of Forgetting

It was understood that some forgetting is a consequence of a *souvenir*’s never having been consolidated. Herbart’s suggestion that two identical memory *Vorstellungen* can fuse into one adds “fusion” as a source of potential forgetting to “decay” and “interference.”

Memory Theories from Watson to the Cognitive Revolution

Quantitative Contributions

Memory for Verbal Material

Within the framework of S-R psychology, the model of Hull et al. (1940) of paired-associates learning, in which the first syllable or word of a pair is denoted as the “S-term,” and the second syllable or word as the “R-term,” attained its credibility from one postulate in particular. This was the assumption: given that there are both excitatory and inhibitory forces exerted on the *souvenir* representing a single S-R pair, the inhibitory forces decay with time more quickly than do the excitatory forces. Without this assumption, learning by humans, over a series of trials, of S-R associations might be impossible. According to this theory, each trial serves to add to the strength of the association of the S-R bond, an idea given further credibility by the later demonstration, by Martin (1965), that one can experimentally dissociate from each other the *souvenirs* of the S-term, the R-term, and the S-R bond for any pair in a to-be-learned list.

It had earlier been noticed by Ebbinghaus (1885) that in the serial learning of a list of, say, 13 nonsense syllables, participants could recall the first few syllables on the very first recall trial. In the Hullian model, it is not mathematically necessary that the strengthening to a maximum level of the bond between the S-term and the R-term of any particular pair should require at least two trials. A major challenge to the “cumulative” theory of bond strengthening in the Hullian model came when evidence was provided that a full-strength S-R bond could be acquired in one trial. The best-known demonstration that one-trial learning (sometimes called “all-or-none learning”) could take place in paired-associates learning by humans was given by Rock (1957). He presented a list of paired associates and found that a proportion of the stimuli elicited a correct response on the very first attempt at recall. He then deleted those pairs that had been wrongly responded to and replaced them with new pairs on the second trial. A control group had a second trial containing all the same pairs as had been used on the first trial. Rock reported that the number of trials needed to acquire *souvenirs* of all the pairs, such that

presentation of any S-term always yielded its correct R-term, was unaffected by the difference in presentation conditions in the two groups. To rephrase this conclusion: when the probability was 1.00 that every S-term yielded a correct response of its associated R-term, it did not matter whether an S-term that had yielded an incorrect R-term on trial n had been provided, or not provided, with a new R-term on trial $n + 1$.

Moreover, it had been known from Darwin’s time that some learned responses in animals could be acquired on one trial. Lloyd Morgan (1895) had reported that a bird could eat a bad-tasting caterpillar just once and avoid such caterpillars afterward. Much later, Garcia, Ervin, and Koelling (1966) demonstrated that a learned aversion by rats for a food that caused digestive problems *hours* later could be acquired in one trial. The ensuing skepticism about the need to assume that all learned responses in animals and humans necessarily entailed *repeated* exposures to the associated stimuli had a major influence on the understanding of classical conditioning in the ensuing decades (Berman, 2003).

One way of getting around the dilemma of having to choose between one-trial and accumulative theories was to choose a *measure* of responding that was neutral in the sense that measures of learning and of memorization efficiency could be obtained no matter whether one-trial or accumulative learning was operative. Such a measure is the *probability* of making a response, a measure that necessarily lies within the range 0.00–plus 1.00. Before Hull’s time, Thurstone (1930) had been the pioneer in applying probability theory to the prediction that, over trials, the increase in the probability that all the responses would be given correctly would go from 0.00 (or perhaps a little more if lucky guesses are possible) to 1.00; a follow-up model by Gulliksen (1934) was actually tested using rats in a discrimination learning task. In both models, the effect of a successful response (signaled by reward to rats, or by feedback to humans) on trial n was to enhance the probability that the same response would be given on trial $n + 1$, and the effect of punishment was to decrease the probability of the response on trial $n + 1$.

One development of probabilistic theory that would come to challenge the Hullian model in comprehensiveness was “stimulus-sampling theory,” started by Estes (1950) and applicable mainly to

humans. Here, the response to an S-term is presumed to be based on a process whereby the S-term itself is composed of one or more elements, each of which is associated with one response. On a single trial, a stimulus with only one element will probably be examined (“sampled”) in its entirety, but a stimulus with more than one element might have only a proportion of those elements sampled. The theory shares with those of Thurstone (1930) and Gulliksen (1934), the assumption that positive reinforcement enhances the probability that the response given on trial n will be repeated on trial $n + 1$.

Another development was the “operational” approach started by Bush and Mosteller (1955) and mainly applicable to animals. If the probability of giving a correct response on trial n of a learning task is p , then the probability of giving a correct response on trial $n + 1$, assuming no forgetting, is p plus a small proportion of responses that were wrong on trial n but are now correct on trial $n + 1$. The questions of interest are how that small proportion is estimated. Is its magnitude affected by punishment? Just *how* does the proportion vary with how close the animal is to the ultimate goal of achieving $p = 1.00$?

A valuable review of the history of mathematical learning theory from 1930 to 1970 is given by Coombs, Dawes, and Tversky (1970, Chapter 8); and a review of how the all-or-none approach compares with both the Hullian approach and the stimulus-sampling approach in the prediction of human learning curves was given by Restle and Greeno (1970, Chapters 1 and 2). Estes (2003) has recently shown how the thread underlying the move from Hullian to stimulus-sampling models and to Bush and Mosteller’s (1955) model was the appreciation that, in a learning task, animals are more likely to sample some of the stimuli within immediate view, whereas humans are more capable of treating any stimulus as a whole, making it possible to learn to respond to, or verbally memorize that stimulus on a single trial.

Memory for Visual Material

Because J.B. Watson was such a profound disbeliever in the existence of visual imagery, academic research on that topic was unfashionable in this period, especially in North America. In Germany, the term “eidetic imagery” had been used to refer to visual imagery that differs

from visual sensory effects in having the same colors (not the complementary colors) of the pictures that had just been studied (Woodworth, 1938, pp. 45–47). Haber and Haber (1964) surveyed 280 children aged between 5 and 18 and discovered that only 5–6%, almost of all of whom were 5–6 years old, possessed eidetic imagery. More recent work has been reviewed by Crowder (2003).

Qualitative Contributions

Memory for Verbal Material

The Gestalt school collected empirical data on the interface between sensory science and the science of knowledge. Their emphasis on the “unlearned” principles whereby the external world, as perceived through the senses, left neural representations that were automatically organized in such a way as to facilitate the perceiver’s mental interpretation of what had been sensed, leads one to ask if this ability to reinterpret the raw mosaic of sensations in a holistic manner was something that had evolved and that had been passed from generation to generation via a genetic encoding. Unfortunately, the Gestaltists wrote too little about evolution for more to be said other than that Köhler, who, in a series of articles, emphasized that all mental experiences can be explained without recourse to any natural forces other than those of physics and chemistry acting within, on, and/or between cells (Murray & Farahmand, 1998). But all three major Gestalt psychologists, Max Wertheimer (1880–1943), Kurt Koffka (1886–1941), and Wolfgang Köhler (1887–1967) consistently tried to link self-reports of perceptual experiences with activity in the nervous system; and it has recently been revealed that Max Wertheimer, over the course of his academic career, tried to quantify Gestalt psychology. D. Brett King and Michael Wertheimer (2005) describe communications between Hull and Max Wertheimer in which Hull challenged Wertheimer to produce an axiomatized quantification of Gestalt theory in the way that Hull (1943) had produced his axiomatization of behaviorist principles.

Among the consequences of their synthetic view concerning perception and knowledge was the insight, first reported by Köhler and von Restorff (1937), that

the law of grouping by similarity of objects in the visual field, essentially a law that concerns spatial grouping, had an analogue in the temporal domain. According to the law of spatial grouping by similarity, a display, say, of four triangles and five circles distributed randomly on a surface will be perceived as two groups of shapes, one containing triangles and the other containing circles. Now let those four triangles and five circles be presented successively, in random order, one after the other. The *second* triangle to be presented will be “recognized as” a repetition of the first triangle, and so will be mentally grouped with it. The same goes for the circles. Therefore, the act of recognition is a temporal analogue of the spatial law of grouping by similarity.

This way of considering recognition as a kind of Gestalt grouping led von Restorff (1933), working under Köhler’s supervision, to reinterpret what went on in paired-associates learning and in the serial learning of verbal materials. Items that were similar in a list were mentally grouped together by the participant, and if the material should be nonsense syllables, the lack of semantic, meaningful components would make that very grouping actually detrimental to learning. On the other hand, anything that made one pair stand out from the others, for example, being printed in red while all the other pairs were printed in black, would serve to isolate the red-printed pair from the “crowd,” and, therefore, be more distinctive and more likely to be correctly responded to on the first trial of a series of paired-associates trials. The notion that serial and paired-associates learning could be described in terms of crowding and isolation, rather than in terms of the acquisition of S-R chains, was not widely publicized and therefore did not succeed in challenging Hullian or probabilistic approaches to learning until the 1960s.

Memory for Visual Material

It was argued by Wulf (1922) that the *souvenirs* of visual targets, such as random shapes, underwent automatic changes in *la mémoire* in the direction of simplicity (“good figure,” e.g., a circle with a small gap in its circumference would ultimately be reproduced as a circle without a gap) or exaggeration (a sharpening of a particular detail of a shape). The ensuing literature was summarized by Riley (1962), who rejected the

notion that the Gestalt theory of autonomous changes in *souvenirs* with the passage of time had been supported in that literature. Moreover, an article by Hebb and Foord (1945) showed conclusively that random shapes are often remembered as verbal, rather than as purely visual, *souvenirs*. An ambiguous shape that could be described as “curtains in a window” or as a “diamond in a square,” when reproduced after an interval, would be more curtain-like or more diamond-like than the original ambiguous shape, depending on the verbal description assigned to it when it was first presented. This is a clear demonstration that labeling, using words, markedly influences the accuracy of reproduction, from memory, of visual material.

Kandel’s Psychological Manifestations

The Effects of Overstimulation

Freud theorized that forgetting was often “motivated” by an unconscious desire to “repress” *souvenirs* that were ego damaging. The discovery in World War I of cases where traumatic events on the battlefield, instead of being forgotten, were exceptionally well recalled both in dreams and in waking life, led to the adoption of this persistence of involuntary recall as a primary symptom of “war neurosis” (“shell shock”). Freud’s own explanation was that strong, physically traumatic, stimulation could override the ego-relevant aspects of the experience and overload the whole system, including the corpus of *souvenirs*.

Brain Localization

During this period, research on the brain tended to repeat with better neurological understanding and nineteenth-century controversies. Evidence that *les souvenirs* did not need to be localized to a cortical area other than the cortex used for the perceiving of, and responding to, a stimulus was provided, in the course of a lifetime’s research, by Lashley (1929, 1950/1960). Controversies persisted over whether the various forms of aphasia were caused by damage to specific areas of the left temporal lobe (Head, 1926). What is striking about this period is the lack of interest in the hippocampal formation as a mediator of retentive processes in the central nervous system. On the other hand, studies of brain injury to the cerebral cortex in humans,

often caused by motorcycle accidents, provided clear evidence that a severe trauma to the head could disrupt a consolidation process (Russell, 1959).

Mechanisms of Forgetting

It is often taken for granted that a memory trace, that is, the neural substrate of a *souvenir*, once consolidated is fixed and unchanging. Bartlett (1932) provided striking evidence, from studies of the repeated recall, by the same participant, of stories that not only was the recall of a written story rarely verbatim, but was also more in the nature of a conventionalized gist or summary; for Bartlett, a *souvenir* was more like a “schema”; repeated activation of the schema, in successive recall acts, served to alter details of the schema in much the same way as the serial telling, from person to person, of a scandalous narrative allowed that narrative to take on new characteristics in the course of gossip. The processes of conventionalization that he observed in serial and in repeated reproduction tasks are still of considerable interest in present-day sociology and social psychology circles (Danziger, 2008, pp. 137–141, 266–267).

A new form of forgetting was postulated in the Gestalt literature on crowding. If list A is learned well, followed by the learning of a second list B, relearning list A is usually harder than it is when there is no list B to be learned in the retention interval. Explanations of this phenomenon of retroactive inhibition in terms of interference theory, that is, in terms of S-R chains, were available (Melton & Von Lackum, 1941). But in Ceraso’s (1967) account, explaining retroactive inhibition in terms of response crowding, the forgetting of which list the memory representation of a given S-term had come from, list A or list B, was also demonstrated to be a factor determining the slow relearning of list A. When this kind of forgetting came to be evoked in later interference theories of retroactive inhibition, it was called a “failure of list differentiation” (Postman & Underwood, 1973). Proponents of post-Hullian verbal learning theories also found themselves obliged to view serial learning and paired-associates learning as if they were exercises in the “organization” of *souvenirs* rather than as exercises in the chaining of *souvenirs* of verbal stimuli and responses (Postman, 1971). A fuller account of this literature was given by Murray (1995, pp. 118–123).

Memory Theories during the Cognitive Revolution

Quantitative Contributions

Memory for Verbal Material

Bower’s (1961) all-or-none model of paired-associates learning was complemented by his use of a computer program that allowed the numerical magnitude of a variable to be estimated iteratively until, when a particular magnitude of that variable was inserted into Bower’s equation for the learning curve, the deviation of the obtained learning curve from the predicted learning curve was statistically insignificant. This technology played a fundamental part in making more persuasive a wave of mathematical models of human memory that appeared in the period following 1960.

In particular, a class of “stochastic” models of learning was invented, according to which a response to a stimulus entered or did not enter a “learned” state (from which it might then enter or not enter a “forgotten” state, depending on the model). Atkinson and Shiffrin (1968) delivered a model of human verbal learning in which immediate memory (primary memory) was identified with the presence of a very brief “iconic” or “echoic” sensory memory (terms introduced by Neisser, 1967) that was then encoded as a mental representation in a short-term auditory-verbal-linguistic store (STS). Secondary memory was identified with the presence of mental representations in a long-term store (LTS). The transitions from sensory store to STS, and from STS to LTS, depended on the amount of attention paid by the participant and were quantified in terms of transition probabilities. The incorporation of a “forgetting” state into a stochastic model was introduced by Bernbach (1965). Excellent introductions to these stochastic models of learning were provided in textbooks of mathematical psychology written by Coombs, Dawes, and Tversky (1970), Restle and Greeno (1970), and Laming (1973). Again, Estes (2003) throws light on the historical development of “state” learning theories by pointing out that if in stimulus-sampling theory, a memory representation of a stimulus should be encoded in its entirety during the sampling, it makes sense to say that that representation is in a learned (as opposed to an unlearned) state. Estes (1960) himself developed a way of investigating

whether paired-associates learning took place in a continuous or in an all-or-none manner.

In a typical stimulus-sampling theory, the number of potential “states” of learning achieved by a given trial has an infinity of possible values, as compared with the small and finite number of states typical of stochastic models. But state models had the incidental consequence of reviving interest in primary memory. Estes (1972) started his own program of research on the role of association forming in the retention of order information in memory span tasks. He suggested that the representation of an association between two adjacent items in primary memory should be specified in terms of a hierarchy of features. If, for example, the pair were *mif-zon*, the association between *mif* and *zon* was postulated to be the outcome of an association between *mif* and a control element and the outcome of another association between *zon* and that same control element. The association *mif-zon* was considered to constitute a single feature that had as its constituents two-syllable features and each of these in turn had as constituents three-letter features. Upon the initial input of two items, such as *mif* and *zon*, an

- ▶ [A]ssociative structure is established, with reverberatory loops connecting the representation of each item to a contextual control element. The structure reactivates the representations cyclically, initially following the input sequence... there is some constant probability θ of a perturbation in timing which will result in the next reactivation being advanced or delayed. . . (Estes, 1972, p. 180).

This “perturbation” model was to be amplified, not only by Estes (1997), but by others in a second wave of models, focused on human *souvenirs*, rather than on the acquisition of S-R associations, that dominated research at the end of the twentieth century.

In particular, the perturbational model underlay several models that purported to explain, not only the bow-shaped serial position curve of immediate recall (a primacy effect, a relatively hard-to-recall middle section, and a recency effect), but also analogous serial position effects found in the course of serial learning and paired-associates learning. The recency effect in the so-called free recall tasks, where the *order* of the to-be-remembered items did not have to be retrieved, was shown to reflect a recency effect containing some four

items, provided those final items were the first to be recalled (Glanzer & Cunitz, 1966). The primacy effect in free recall was shown by Tan and Ward (2000) to have resulted from the fact that the initial items of a list were more likely than were any later items to have received fleeting subvocal rehearsals during the presentation of those later items and would, therefore, be more likely to appear as recalled members in the context of a recency effect.

The feature model of Nairne (1990) integrated both the feature aspects and the perturbational aspects of Estes’s (1972) model with a model that assigned forgetting to an “overwriting” mechanism. This mechanism is closer to Herbart’s fusion mechanism than to retrieval failure (“interference”) based on inadequate cuing, because an overwriting mechanism, like a Herbartian fusion, leads to a genuine deletion of one of the two memory representations involved in the overwriting or fusion. In two subsequent feature models, the OSCAR model of Brown, Preece, and Hulme (2000) and the SIMPLE model of Brown, Neath, and Chater (2007), it was specified that forgetting due to decay could be discounted, especially in short-term memory. Lewandowsky, Duncan, and Brown (2004) claimed to have obtained experimental support for this assertion. In a serial recall task, Oberauer and Lewandowsky (2008) have provided further experimental support for the conclusion that “purely temporal views of forgetting are inadequate” (p. 544).

The Theory of Distributed Associated Memory (TODAM) model of Murdock (1983, 1993) includes “features” that were represented by one-dimensional arrays of values (0 and 1) called “vectors.” These vectors could be “convoluted” to form aggregated memory representations, and could be “correlated” with the vectors representing incoming stimuli whenever these incoming stimuli elicited recognition or recall responses. A rationale for using TODAM to provide a quantitative vehicle for comparing human *souvenirs* to Galton’s composite photographs was offered by Metcalfe (1991).

The Search of Associative Memory (SAM) model (Raaijmakers & Shiffrin, 1981; Gillund & Shiffrin, 1984) was a development of Atkinson and Shiffrin’s (1968) stochastic model concerning transition probabilities associated with the movements of memory

representations between a short-term store and a long-term store. In SAM, however, no memory representation is considered to be theoretically isolable from its spatiotemporal context in a list, and for this reason, the SAM model makes predictions about retroactive inhibition in laboratory tasks that are directly comparable with those of Ceraso's (1967) Gestalt model of list learning (Mensink & Raaijmakers, 1988; Murray, 1995, Chapter 4).

Tasks that involved retrievals from long-term memory of individual memory representations that had already been cognitively organized into unified groups in terms of hierarchical, rhyme/rhythm, categorical, and/or autobiographical principles were investigated in the laboratory of Gordon H. Bower, and reviewed by Bower (1972), who offered a Free Recall by an Associative Network (FRAN) model, and by Anderson and Bower (1974), who presented a more comprehensive Human Associative Memory (HAM) model. Anderson went on to produce a series of models that incorporated these principles of organization along with postulates concerning the mechanisms of retention. These Adaptive Control of Thought models include ACT (Anderson, 1983), ACT-R (Anderson & Mantessa, 1997), and ACT-R 5.0 (Anderson, 2004). The last of these models attempted to identify the psychological processes discussed by the model with the activities of different brain parts known, partly from brain-imaging studies in humans, to be excited in the course of mediating those processes.

Helpful summaries of Nairne's feature model, TODAM, SAM, MINERVA2 (Hintzman, 1984), and connectionist models (criticized by Ratcliff, 1990) can be found in Neath and Surprenant (2003, pp. 363–394). Several SOAR models based on the computer programming of "production systems" are summarized by Newell (1990). Elsewhere in their review of contemporary findings on human memory, Neath and Surprenant (pp. 214–217) discuss a phenomenon that none of the above models has found easy to explain, namely, the so-called mirror effect. In an immediate probed yes/no recognition task, a list of sequentially presented "target stimuli" is followed by one more stimulus (a "probe stimulus") that has to be judged as "old" or "new" with respect to the target stimuli. If there is a series of experimental *conditions* that increase in difficulty in such a way that fewer and fewer correct

"old" judgments to old probes (hits) are yielded, these same conditions will also yield more and more incorrect "old" judgments to new probes (false alarms). A false alarm rate cannot be derived from a hit rate simply by subtracting the hit rate from 1.0. The Partial Matching Theory (PMT) of Murray et al. (1998, 1999) did provide equations that successfully predicted the mirror effect.

In discussing retrieval processes, most of the above models, to which may be added that of Glanzer, Adams, Iversen, and Kim (1993), who also predicted the mirror effect, had included assumptions about the probability distributions of potential responses, probably a legacy of an influential and pioneering model of immediate probed yes/no recognition accuracy that had made use of signal detection theory (Wickelgren & Norman, 1966). The PMT model involved probabilities as variable names, but did not use signal detection theory, and did not need, therefore, to specify any probability distributions. Ratcliff and Starns (2009) have provided further criticisms of the uncritical adoption of signal detection theory into models of recognition memory.

Qualitative Contributions

Memory for Verbal Material

The Self-Organizing Consciousness (SOC) theory of Perruchet and Vinter (2002) included the assumption that if two mental representations are concurrently being consciously experienced, and the two are identical in content, the two will be recognized consciously *as* being identical. Perruchet and Vinter were able to explain a number of instances of *implicit* learning in humans; most of the models described in this and in the previous section had focused on *explicit* learning in humans. Tulving (1983) had classified human memory into several categories, including implicit (or "procedural") memory such as skilled movements or the recital of verbal material learned by rote; and explicit memory, with a distinction made between episodic memory (largely consisting of autobiographical *souvenirs* localized in a spatial and/or temporal context) and semantic memory (abstract, usually verbal, knowledge of such matters as history, science, and acquired second languages; the place and time at which these *souvenirs* were first acquired were not usually localized). One kind of implicit memory that had long puzzled

researchers was the acquisition, by children without formal training, of the rules of grammar in their first language. Perruchet and Vinter were able to give an account (of the acquisition of linguistic rules) that relied mainly on participants' abilities to recognize similarities between, or identities of, the contents of consciousness at differing times. More recently, Jones and Mewhort (2007) have developed a Bounded Encoding of the Aggregate Language Environment (BEAGLE) model that uses the order in which individual words are experienced in unsupervised everyday life to build up a lexicon whose usage illustrates an implicit acquisition of some of the regularities underlying sentence comprehension.

The Working Memory Theory (WMT) of Baddeley and Hitch (1974) was put forward to account for the fact that if one imagines the content of consciousness (primary memory) at a given moment to consist entirely of a recording-like short-term store, this cannot explain how patients with the damage to the STS are nevertheless capable of reasoning, identifying, and conversing; nor can it account for the retention of subsidiary information over and above that encoded verbally into STS. No flow diagram was offered by Baddeley and Hitch, but, 12 years later, Baddeley (1986, p. 71) offered a flowchart with three components: an articulatory loop that preserved, for a short time, what had been vocalized to oneself concerning the to-be-remembered material; a visuospatial scratch pad that preserved, also for a short time, what had been retained, perhaps in the form of a visual image, of the to-be-remembered material; and a central executive that masterminded whether the concurrent contents of consciousness were articulatory and/or visual and whether any of those contents would receive extra maintenance or elaborative rehearsal.

Much of the evidence for the articulatory loop depended on the evidence that the concurrent articulation aloud of irrelevant material ("articulatory suppression") during the attempted memorization of visually presented verbal material could reduce immediate recall of that material from maybe 70% correct to about 20% correct (Murray, 1967). If the same material were presented auditorially, the reduction was less (Murray, 1968). Much of the evidence for the visuospatial scratch pad came from the evidence, to be outlined below, for dual coding in human memory,

visual and verbal, provided by Paivio (1971). Baddeley (1986, p. 142) showed that the effects of articulatory suppression on memorization were less damaging when meaningful (and, probably, visual-imagery-evoking) words, rather than nonsense syllables, constituted the to-be-remembered material. The accruing evidence, summarized by Penney (1989), for the selective interference of visual inputs with visuospatial immediate recall, and of verbal inputs with verbal immediate recall, is a vital part of the evidence supporting Baddeley's (1986) model.

More recently, Baddeley (2006) has added an "episodic buffer" to WMT, allowing for a greater determination of the central executive's ongoing strategy by *souvenirs* laid down in the past concerning the participant's own moods and motivations. Among the criticisms of WMT are the arguments of Jones, Hughes, and Macken (2006, 2007) to the effect that the temporal "streaming" of successive inputs into consciously perceived "groups" categorized by communalities of sensory modality can provide an alternative to accounts based on "boxes" called visuospatial scratch pads and articulatory loops. Rebuttals of this objection were provided by Baddeley and Larsen (2007a, b). Other critics disparaged the use of "boxes" to represent cognitive structures; a preference for a feature analysis of memory representations characterized by sensory content runs throughout the feature models from that of Nairne (1990) to that of Neath and Nairne (1995) to that of Brown, Neath, and Chater (2007). New criticisms will probably emerge as a consequence of the discovery that single neurons can mediate more than one psychological function, rather than just one function (see below).

In terms of the lift WMT has given to research productivity on short-term memory, however, there is no question as to its historical importance. Surveys of the various changes in the names given to the "boxes" of WMT, as well as of the extension of WMT to various areas of applied memory research, will be found in a volume edited by Andrade (2001). The present-day value of WMT in the study of classroom learning by children, and in the study of normal age-related forgetting, has been emphasized by Moulin and Gathercole (2008). WMT can also be used to explain how distracting sensory inputs can be voluntarily ignored (Dalton, Santangelo, & Spence, 2009).

Memory for Visual Material

As indicated above, it was Allan Paivio (1971) who first amassed a large amount of scattered material in order to put together his “dual coding hypothesis,” according to which humans have evolved two major ways of thinking, one involving visualization, and one involving language. More corroborating evidence was added by Paivio (1990); and, most recently, Paivio (2007) has assimilated his dual coding hypothesis into a general theory of the evolution of the human mind, a theory characterized by the emphasis Paivio placed on his beliefs that visual memory emerged prior to verbal memory in geological time, that a high-quality visual memory is possessed by many animal species (especially vertebrates), and that the vestiges of this visual memory ability are still present in humans. Of course, these psychological speculations are consistent with the discovery of place-memory cells in the hippocampus. The possession by young children of nonverbal visual memory abilities that precede the acquisition of verbal memory abilities has been supported by evidence reviewed by Paivio (1990, Chapter 5). In animals, “Clark’s nutcracker, the mnemonic champion of the food-storing birds in field tests and laboratory tests of spatial memory (Kamil, Balda, & Olson, 1994), is the species most dependent on stored food and also has the largest hippocampus” (Paivio, 2007, p. 253). It is important to note that even though animals and pre-verbal children may possess some kind of visual memory representations, and maybe even visual imagery, the connection with consciousness as described in verbal reports by human adults remains controversial (Marks, 1999; Paivio, 2007, pp. 254–257).

Experimental demonstrations of how visual stimuli can be processed in such a way as to suggest that any retention thereof does indeed involve visual, rather than verbal representations, include Standing’s (1973) demonstration that after seeing as many as 10,000 pictures followed by a sample of those pictures intermixed with new pictures, the probability of giving correct “old” responses to old pictures was very much higher than was the case in a comparable experiment using words instead of pictures. Shepard and Cooper (1982) reviewed evidence that adults can mentally “rotate” an abstract shape sufficiently well that the shape, when rotated by a certain number of degrees, can still be correctly recognized as being the same

shape. With respect to children, Paivio asked his 7-year-old daughter

- ▶ to picture a “big” letter N in her mind. When she said she had it, I asked her to tilt it over on its side and asked “Now what do you see?” “I see a Z,” she promptly replied, which means she must have rotated the imaged letter 90 degrees. (Paivio, 2007, p. 53)

Whenever two or more categories of *la mémoire* are posited, it is persuasive if one can report that the different categories can be experimentally dissociated. For example, Tulving (1983, Chapter 5) gave examples of experimental dissociations between implicit and explicit memory, as well as between episodic and semantic memory. With respect to dual coding theory, Murray, Mastronardi, and Duncan (1972) were able to dissociate the effects of attending to verbal meanings of colored words from the effects of attending to the physical appearance of those same words. Several studies reviewed by Murray and Newman (1973) were able to dissociate the information that had been retained about the names of shapes scattered in a matrix from the information about the locations of those shapes in the matrix. Paivio (1971, Chapters 9, 10, and 11) reviewed experimental dissociations, in several different kinds of memorizing tasks, between memory for the names of the contents represented by pictures and memory for the visual characteristics of those contents. Farah, Hammond, Levine, and Calvanio (1988) reported that a brain-damaged patient showed a deficit on performance on tests designed to demonstrate “visual” skill, but no deficit on tests designed to demonstrate “spatial” ability. Garden, Cornoldi, and Logie (2002) were able to dissociate the effects of interference with visuospatial processing from the effects of interference with verbal processing during the learning of how to navigate around an unfamiliar town. When bilateral lesions of the posterior cerebral hemispheres are present in humans, the contents (the “what”) and the locations (the “where”) of visual images can be dissociated (Levine, Warrach, & Farah, 1985). In their review of face recognition, Hanley and Cohen (2008) have shown how it is possible to dissociate a sense of familiarity with a given face from the recall of the name of the person associated with that face. The fact that Baddeley’s (1986) version of WMT included a dissociation between the visuospatial and the

articulatory components of working memory is an indication of how influential Paivio's dual coding theoretical approach has been on memory theory in general.

Kandel's Psychological Manifestations

Effects of Overstimulation

After the Holocaust, World War II, and the wars in Korea and Vietnam, it was recognized by the American Psychiatric Association in 1980 that a special category of illness, to be called posttraumatic stress disorder (PTSD), should be incorporated into the Diagnostic and Statistical Manual of Mental Disorders (3rd edition). Often, the traumata in question involved more than one experience, of course; the political, legal, and psychotherapeutical consequences of the recognition of PTSD, as well as its importance for memory theory, are discussed by Danziger (2008, pp. 205–215).

Flashbulb memories for where and when one was when a major piece of news was announced have now become a topic of independent research.

- ▶ Hearing the news that President John Kennedy had been shot, the bombing of Pearl Harbor, the first landing on the moon, the terrorist attacks on the World Trade Center in September 2001, or the death of Princess Diana, are among the examples that have been studied. (Williams, Conway, & Cohen, 2008, p. 63)

Brain Localization

The great technological innovation of this period was the invention of brain-imaging devices such as positron emission topography (PET), functional magnetic resonance imaging (fMRI), and magnetoencephalography (MEG). A pioneering account of the initial findings of these devices relevant to an understanding of cognitive psychology showed that brain activity during visual searching was closely linked to cerebral activity indicative of selective attention (Posner & Raichle, 1994, pp. 47–51). Mentally imagining a letter F and looking at a letter F elicited brain activity in the same cerebral regions (p. 97). The anterior cingulate gyrus acts like an executive controlling the attention paid to visually orienting oneself, to individual features, and to the contents of working memory, be they visuospatial or verbal (p. 173). When pseudowords were being rehearsed subvocally in working memory, a PET scan showed increased

activity in those parts of the frontal cortex normally associated with speaking; but some participants also showed strong activation in the visual cortex as if they were trying to remember the visual appearance of the pseudowords as well (p. 234). Kandel (2006, p. 306) described an innovative employment of fMRI that showed that the hippocampus of London taxi drivers increased in size with their years of experience; taxi driving demands a high level of place memory.

The unexpected anatomical discovery of this period, pioneered by Rizzolatti, Fadoge, Gallese, and Fogassi (1996), was that some single cells, in an area of the premotor cortex of macaque monkeys that is concerned with arm movements, responded when a monkey saw *another* monkey perform, say, a grasping movement; furthermore, the monkey perceiving the movement actually imitated the movement despite never before having performed that particular grasping movement in that spatiotemporal context. Experimentation also revealed that the imitation seemed to mirror not merely the muscular actions observed, but also the intentions of the imitated performer (e.g., the grasping of a particular object when the animal was in a particular need-state concerning that object). When these observations were extended to humans (making use of PET, fMRI, and MEG recordings, but not single cell recordings) brain responses registered while preschoolers were watching, and imitating, other persons carrying out various gestures suggested that the preschoolers were also aware of the goals that the gesturing person had in mind (Iacoboni, 2009, pp. 62–70). These observations could also be extended to situations where adults observed the faces of other adults who were undergoing emotional experiences; the observers tended to imitate the facial movements. A particular pathway called the insula connects the area of premotor cortex to the limbic system, known to mediate the activation and expression of emotions such as fear and anger. But what was extraordinary about these new research findings was the evidence for the participation of individual neurons in the apparent storage not only of imitated actions, but also of the intentions motivating those actions, and of the emotions associated with those actions.

The boundaries between sensation, perception, emotion, and cognition seem to be blurring. The fact that single place-memory neurons in the hippocampus can

apparently store not merely where an event happened, but also the sights, odors, and sounds associated with that location, lead one to speculate that the boundaries between sensation, perception, and attention in immediate memory tasks might also be blurring. Earlier, Zeki (1992) had dramatically shown how, in studies of visual perception, the boundaries between color sensation, contour sensation, brightness sensation, and movement sensation are blurring. Future theories of memory may be less modular than they were in the past.

Mechanisms of Forgetting

Waugh and Norman (1965) reintroduced the term “primary memory” into the modern literature when they demonstrated, using an immediate probed recall task that the memory representations of visually presented numbers can apparently “knock out” the memory representations of numbers that had been visually presented earlier. The participants had been instructed to avoid verbal rehearsal of the numbers. The term “overwriting” was introduced by Broadbent and Broadbent (1981) in their study of the immediate yes/no probed recognition for seven cards on each of which was drawn an assemblage of three nonsense shapes. Grodzinsky (2000) surmised that a “trace-deletion hypothesis” could be used to demonstrate that Broca’s area (which is close to the insula) was involved particularly in processing non-syntactical or nonlexical components of language comprehension; Murray (2000) suggested that visualization and overwriting were involved in the comprehension task examined by Grodzinsky. “Knockout,” “overwriting,” and “deletion” are all words having in common the notion that a neurological substrate (a memory trace) can be changed to such an extent that the corresponding *souvenir* can be said to have been erased. “Erasure” can be added, therefore, to “fusion,” “decay,” and “interference” as a fourth potential cause of forgetting.

Conclusion

Toward the end of his Nobel-Prize winning career in research on auditory science, von Békésy (1967) wrote a book entitled *Sensory Inhibition*. Giving examples of how, in several sense modalities, neighboring receptor neurons can inhibit each other at the peripheral level prior to their sending sensory messages to the brain, von Békésy maintained that these inhibitory

mechanisms had evolved for the purpose of ensuring that the brain was not overwhelmed by too much sensory information at any one moment. Murray (1994) suggested that the memory system behaves analogously in humans. The most obvious kinds of inhibition are those afforded *during* perception by selective attention to competing sensory features in primary memory, and those afforded *shortly after* perception by consolidation mechanisms. But, if an overwriting or fusion mechanism depends on the identity or strong similarity to each other of two memory representations that are concurrently in consciousness, this mechanism will reduce redundancy and thereby help to preserve an acceptable level of distinctiveness between individual memory representations. Such a mechanism must be of adaptive value in an environment where competition between people must coexist with benevolence between people.

More generally, there is a difference between a history of theories of memory, such as this article, and “biographies of psychological objects”—histories of how the word “memory” has reflected social and medical beliefs down the centuries. Following the success of Foucault’s (1965/1973) study of the concept of “madness” in history, Hacking’s (1995) study of how memory was conceptualized in nineteenth- and in twentieth-century medical and legal circles, and Danziger’s (2008) study of the impact upon memory research of ongoing social concerns and fashions, provide outstanding examples of biographies of the psychological object called memory. Wright and Loftus’s (2008) account of the *impact* of experimental studies of eyewitness reports upon judicial administration systems in several industrialized countries shows how academic psychology can actually affect society.

Important earlier contributions to the history of theories of memory include Edgell’s (1924) survey of such theories, Gomulicki’s (1953) history of trace theories of memory, Young’s (1961) bibliography of memory (with special attention to mnemonic systems), Norman’s (1970) introduction to a number of competing models of memory, many of which incorporated mathematics, and Searleman and Herrmann’s (1994) review of discoveries in applied memory research. The new understanding of the biology of memory also had important precursors, including Gaito’s (1966) investigations into the role of RNA in human memory storage, and John’s

(1967) survey of evidence about how electroencephalography (EEG) and related methods have contributed to the understanding of human memory.

Thorndike, Edward

CHRISTINE ANDREOTTI

Pace University, Plainview, NY, USA

Indiana.edu

Basic Biographical Information

THORNDIKE, EDWARD LEE (August 31, 1874–August 9, 1949) might be regarded as the “father” of

American learning psychology (Craighead and Nemeroff 2001) and published around 500 books and articles during his 55-year career (Plucker 2003). Thorndike taught that psychology should not focus on mental elements or conscious experience but should study behavior and his research and theories of learning or association propelled learning theory into a very important place in American psychology.

Thorndike was born in Williamsburg, Massachusetts, married Elizabeth Moulton on August 29, 1900, and had five children including Robert Lee Thorndike.

He obtained his Bachelor's degree from Wesleyan University in 1895 and then graduated from Harvard University, obtaining his Master's degree in 1897 where he studied under William James and he began his animal research. In 1898, under James M. Cattell, Thorndike obtained his PhD at Columbia University and he was part of the faculty from 1899 to 1940 at the Teachers College, spending his entire 50-year career at Columbia. During this time, Thorndike continued his work with animals and this was published in a monograph titled, "Animal Intelligence," but he also did research and taught about human learning, mental testing, and education. In addition, he was an assistant professor of Pedagogy at Case Western Reserve University during this year (Craighead and Nemeroff 2001).

In 1912, Thorndike became the president of the American Psychological Association, and in 1934, he became the president of the American Association for the Advancement of Science. Also, from 1942 to 1943, he was a William James lecturer at Harvard University. In addition, Thorndike was the second president of the Psychometric Society (Plucker 2003).

It has been said that Thorndike was influenced by Wechsler, R. B. Cattell and that Thorndike's students included Bingham, R. Thorndike, and L. S. Hollingworth (Plucker 2003).

Contributions

He was once the leader in the human education field and used his animal intelligence studies, such as his puzzle box problems, to study human educational experiences. Thorndike played a major role in developing knowledge of operant conditioning. Early work in 1913 involved the use of cats and these puzzle boxes. The cat was placed in the puzzle box to see how they maneuvered through it and how long it took them to

maneuver through it to get to the reward. To escape and reach the reward, the cats had to pull out a bolt or pull on a string to open the door. Usually by accident, the cats would find their way out, but after repeating the process a number of times, the cats learned the correct response (Woolfolk 2004). This led to Thorndike's Law of Effect which was defined as any act that produces a satisfying effect in a given situation will tend to be repeated in that situation. Thus, this established the basis for operant conditioning. Operant conditioning is defined as learning in which voluntary behavior is strengthened or weakened by consequences or antecedents, events that precede an action (Craighead and Nemeroff 2001).

The law of effect, in Thorndike's view, was the basic governing principle of learning, but he felt that it could not be that simplistic. To account for all the learning that had or had not occurred, in addition to the law of effect, Thorndike proposed the law of exercise and the law of readiness (Craighead and Nemeroff 2001).

Thorndike believed that the two most basic intelligences are Trial-and-Error and Stimulus-Response Association. His Law of Effect states that responses to a situation that are followed by satisfaction are strengthened and that responses that are followed by discomfort are weakened. He added his Law of Exercise that states that stimulus-response connections that are repeated are strengthened and stimulus-response connections that are not used are weakened. The Law of Exercise was later found to lack validity. In addition, Thorndike added his law of readiness which was defined as the need to attend if one is to learn anything. He suggested that the nervous system had to be tuned for certain connections to operate; it had nothing to do with maturity or age. And, unlike the law of effect, the law of readiness was not something that could be manipulated; it just had to be there (Craighead and Nemeroff 2001).

The law of belongingness, suggesting some kinds of material were more easily learned than others, and the law of associative shifting, which was meant to incorporate the conditioning into the law of effect, were also proposed by Thorndike but were not very successful (Craighead and Nemeroff 2001).

Thorndike and his students used objective measurements of intelligence on human subjects as early as 1903, and by the time the United States entered WWI,

methods for measuring a variety of abilities and achievements were developed. A test of intelligence, known as the CAVD, was developed by Thorndike in the 1920s that consisted of completion, arithmetic, vocabulary, and directions test. It was intended to measure intellectual level on an absolute scale and became the foundation of modern intelligence tests (Plucker 2003).

Important distinctions were drawn among different classes of intellectual functioning by Thorndike as well. Standard intelligence tests only measured “abstract intelligence.” “Mechanical intelligence” was defined as the ability to visualize relationships among objects and understand how the physical world worked.” In addition, “social intelligence” was defined as the ability to function successfully in interpersonal situations (Plucker 2003).

Four general dimensions of abstract intelligence which included Altitude, Width, Area, and Speed were also proposed by Thorndike. Altitude was considered the most important and was described as the complexity or difficulty of tasks one can perform, width was defined as the variety of tasks of a given difficulty, area is a function of width and altitude, and the number of tasks one can complete in a given time was called speed (Plucker 2003).

Thorndike also developed psychological connectionism in which, through experience, neural bonds or connections are formed between observed stimuli and produced responses. So, intellect aids the formation of neural bonds. He theorized that people of higher intellect could form more bonds, as well as form bonds more easily, than people of lower ability and that the ability to form bonds was rooted in genetic potential through the genes’ influence on the composition of the brain. It was also theorized that the content of intellect was a function of experience. Thus, the idea that a measure of intelligence could be independent of cultural background was rejected by Thorndike. In short, Thorndike believed that connectionism was the connection between situations and response, not associations between ideas and that stimulus–response units were the building blocks from which more complex behaviors are formed (Plucker 2003).

Thurston, L. L

JANYCE OSENBACH

Fordham University, Bronx, NY, USA

Thurstone, Louis Leon (May 29, 1887–September 30, 1955) was a pioneering psychometrician, dedicated professor, and amateur photographer, best known for his work in factor analysis and for discovering the law of comparative judgment.

Basic Biographical Information

Louis Thurstone was born in 1887 in Chicago, Illinois. His parents were both Swedish immigrants who

changed the family name from Thunström to Thurstone due to the often misspelling and mispronunciation of the name. Thurstone's interest in mathematics may have stemmed from his father, Conrad (Thunström) Thurstone, who instructed arithmetic in the Swedish Army; and later became a Lutheran minister, as well as a newspaper editor and publisher. Both his mother, Sophia (née Stråth), and younger sister Adele, were musically talented. During his younger years, the family moved to several cities within the United States. When Thurstone was 8 years old, the family relocated to Stockholm, Sweden; while finally settling in Jamestown, New York when Thurstone was 14. Thurstone attributed his attitude of objectivity on his multicultural upbringing, often criticizing colleagues for their subjectivity in publishing.

In 1905, at the tender age of 15, Thurstone wrote his first publication – a letter to the editor of *Scientific American*, detailing a solution to utilize Niagara Falls as a power-source while also maintaining attractiveness. Three years later, as a college freshman at Cornell, he again published in *Scientific American*, this time as an academic contributor introducing a new geometric method for trisecting an angle (Thurstone 1912). Following this achievement, he decided to pursue studies in engineering and received a Master's degree from Cornell in 1912. It was during this time that he was submersed into the field of psychology which was then known as “human engineering.” After a short stint working in Thomas Edison's laboratory, Thurstone returned to academia, first as a professor at the University of Minnesota, and then as a doctoral student at the University of Chicago, where he received his PhD in psychology in 1917.

While pursuing his doctorate, Thurstone began an assistantship in the Division of Applied Psychology at the Carnegie Institute of Technology, where he later became a Professor and headed the department until 1923. Recruited to Washington, D.C., he began working for the Institute for Government Research. This was to be Thurstone's first experience with failure – an experiment on Navy officers on learning during sleeping foundered. All was not lost, however; as there he met and married Thelma Gwinn, a fellow psychologist. In the fall of 1924, the newlyweds relocated to Illinois, where Thurstone took on a professorship at the University of Chicago. He would remain there until his retirement in 1952 (Thurstone 1952).

Major Contributions

During his career at the University of Chicago, Thurstone established the Psychometric Laboratory in the Social Sciences Division. It was here that he began studying intelligence and learning, and came upon his discovery of the *law of comparative judgment* (Thurstone 1927). This model introduced the concept of discriminial dispersion in scaling operations, or using a pairwise comparison to measure psychological traits. Taking this mathematical reasoning into the world of social psychology, Thurstone explored the points of view toward several controversial topics, such as minorities, criminals, communism, birth control, censorship, and patriotism, and created the first attitude scale (Thurstone 1928). He then transitioned his experiments on the study of attitudes into the study of intelligence, creating a notorious debate within the field of psychometrics (especially with the prominent psychometrician Anne Anastasi). He believed intelligence existed in seven distinct areas: verbal comprehension, word fluency, number facility, spatial visualization, associative memory, perceptual speed, and reasoning. He later merged these studies into what he called Primary Mental Abilities, or PMAs, which would begin his significant and monumental discoveries in factor analysis (Thurstone 1938).

Credited with coining the term “factor analysis” (developed by Charles Spearman), Thurstone felt Spearman's *g*, with its unitary form, lacked the ability to analyze the dimensionality of the human mind, especially in terms of intelligence. In order to create a solution to this problem, Thurstone proposed the concept of multiple-factor analysis (Thurstone 1947). Since oblique rotations in factor analysis often achieve the optimal solution, Thurstone felt that factors of intelligence were correlated and therefore not statistically independent. He regarded second-order factors (the factor analysis of intercorrelations of first-order factors) as meaningful, and therefore justified the need for multiple-factor measurement and exploratory factor analysis.

Using his new analytical methods, Thurstone changed the world of intelligence testing and measurement for all time. Rejecting the use of a singular general intelligence score (such as raw scores or mental-age scores), he proposed the usage of a standardized mean and standard deviation for IQ

scores that are still in use today. His introduction of communality, or the sum of the proportions of common-factor variance of a test, laid the groundwork for such modern-day psychometric theories as item-response theory (specifically the Rausch model) and hierarchical linear modeling. In addition, his work on adapting Spearman's simple structures of factor analysis introduced methodology that has resulted in the interpretability of factor analyses in psychological constructs.

With his love of mathematics intertwined with psychology, Thurstone was disappointed to discover that most psychological publications rejected research that included mathematical equations or submissions that were deemed as being "too technical." In order to rectify this problem, Thurstone, along with E. L. Thorndike and J. P. Guilford, founded the Psychometric Society in 1935, becoming Society's the first president (based upon his experience as the president of the American Psychological Association, or APA, in 1932). The Society also created the journal *Psychometrika*, with the goal of advancing study of quantitative measurement in psychology. In addition, he became the president of the Division on Evaluation and Measurement of the APA in 1947.

The following year, the Thurstones embarked on a yearlong spell as visiting professors at the University of Frankfurt (Germany). With them, they brought a collection of American textbooks, including many of Thurstone's publications on factor analysis. Thurstone was shocked to discover that these were the first books from outside Germany that the University had experienced since the onset of World War II in 1939. This occurrence became the driving force behind Thurstone's acceptance of a Visiting Professorship at the University of Stockholm in 1954, where he would begin a European "tour," conducting lectures and seminars in Germany, London, Uppsala, Göteborg, Oslo, Helsinki, and Edinburgh. After Thurstone retired from the University of Chicago in 1952, he was appointed the Director of the Psychometric Laboratory at the University of North Carolina, where he continued his research and teaching until his death in 1955.

Tinker, Miles A.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: August 22, 1893; Died: March 4, 1977.

Miles Tinker got a late start on an academic career after service during World War I. Ultimately he became associated with the University of Minnesota and had a nearly 50-year career there.

Major Accomplishments/Contributions

His work was uniformly experimental and quantitative: One of his earliest studies involved variations in hand-drawing regression lines (Tinker 1923). At Stanford for the Ph.D., where his mentors were Terman and ▶ [Miles, Walter R.](#), he continued his interests in mathematics and measurement. His doctoral work (Tinker 1927) was a comprehensive study of the legibility of mathematical formulae utilizing Miles' modifications of Dodge's tachistoscopic apparatus. Tinker published several articles on this work (e.g., Tinker 1926; Tinker 1928) and, after joining the faculty at Minnesota, he dedicated much of his career to working out the details of legibility. He continued to develop modifications of tachistoscopic apparatus, and began, with ▶ [Paterson, Donald G.](#) in 1930, a long series of meticulous studies

of the factors affecting the readability of type. Paterson and Tinker considered type face, illumination, surface quality, spacing, and several other factors. This work culminated in their 1940 book *How to Make Type Readable* (Paterson and Tinker 1940) which became a standard reference in applied print areas. Tinker continued to modify this work and reissued a comprehensive summary in 1963, *The Legibility of Type* (Tinker 1963), which continues to be cited widely in typographic and other graphic arts contexts and legal contexts, including experimental typography, typeface law, and information design. Tinker and Paterson's work also has provided psychological substance to historical studies of reading and legibility (e.g., Saenger 1997).

Along with his studies of type legibility, Tinker also studied various other factors contributing to reading, and became a leading contributor not only to experimental reading research but also to the study of illumination, a field in which he also became a recognized authority. Tinker continued to publish extensively on reading well into his seventies and was influential in the area of reading instruction as well, authoring several textbooks in the area which went into multiple editions. Tinker also made significant contributions to the history of psychology, authoring, with Paul Farnsworth and Burton Thuma, an early study rating psychologists' importance to the development of the field (Tinker et al. 1927), and also tabulating the theses of Wundt's American students (Tinker 1932). Later he authored a monograph on the history of the University of Minnesota Psychology Department (Tinker 1953) which provided a good midcentury interim report on the development of one of the most productive academic departments in the USA. Within the Minnesota department, Tinker contributed a great deal to establishing the strong empirical tone of the department. He revised W. S. Foster's book of psychology experiments after Foster's death (Foster and Tinker, 1929) and also assisting in writing two further manuals of laboratory procedure connected with Minnesota's compulsory laboratory course. He was also, along with Paterson, a productive teacher and sponsor. One of Tinker's students, Saadia Gelb, who assisted in Tinker's work on susceptibility to optical illusions (Tinker 1938), became a noted Zionist.

Titchener, Edward Bradford

RAND B. EVANS

East Carolina University, Greenville, NC, USA

Edward Bradford Titchener was an Anglo-American psychologist and founder of the American school of psychology called structuralism.

Titchener was born in Chichester, Sussex England on January 11, 1867 and died on August 3, 1927 in Ithaca, New York (Boring 1927). He excelled in his public school education and attended Brasenose College, Oxford for his undergraduate education. He was attracted there to the ideas of George Berkeley,

Herbert Spencer, and James Mill, among others. It was from one of Mill's books that he realized that it was possible to analyze the mind into simpler parts (Titchener 1909). It was also at Oxford that Titchener discovered the ideas of Wilhelm Wundt. He was accepted to Wundt's laboratory in Leipzig, Germany but, to get laboratory experience, Titchener spent a year in the physiology laboratory of John Burdon Sanderson. Burdon Sanderson imbued in Titchener the importance of explanation of mental events in terms of physiology. What Titchener came away from Oxford with was a grounding in the philosophical empiricism and associationism of his day and also with a materialistic view of mind, considering mind and consciousness as natural processes without recourse to the notion of a soul. He respected the structure of associationism but did not accept its use of inference and hypothetical constructions over direct observation and description.

Arriving at Leipzig in 1890, he discovered that Wilhelm Wundt's ideas were as philosophical as they were scientific. Wundt's assistant, Oswald Külpe, the lecturer in the course on experimental psychology Titchener took at Leipzig, introduced Titchener to Ernst Mach's *The Analysis of Sensations*. Mach proposed a positivistic approach to psychology that would allow the analysis of complex mental states into simple elementary states using direct observation and description and not making use of logical constructions such as those used by Wundt and the associationists (Bradley 1971). What Titchener took away from Wundt's laboratory was the superficial framework of Wundt's system but without its philosophical and logical underpinnings.

After Titchener received his Ph.D. in 1892, he accepted an assistant professorship at Cornell University in Ithaca, New York. He remained there for his entire professional career. Initially teaching in the Sage School of Philosophy but, in 1895, he became professor of psychology and head of the newly formed department of psychology. He built on the laboratory set up the year before he came by Frank Angell and made of it one of finest psychological laboratories in the world.

Titchener found that there were no textbooks in America that represented experimental psychology as he viewed it. To correct for this, Titchener published his

Outlines of Psychology (Titchener 1896, 1897, 1899), based on Oswald Külpe's *Grundriss der Psychologie* (Külpe 1893), both influenced by Mach's positivism. Titchener tried to find a positivistic middle ground between British associationism and Wundt's voluntarism. He was a reductionist and sought a physiological explanation for all mental phenomena. In 1907, James Rowland Angell, then head of the Chicago functionalists, coined the name structuralism for Titchener's psychology in distinction to his own functionalism (Angell 1907). Titchener never used the term with the "ism" but the name structuralism was adopted de facto, nevertheless.

In the 35 years of Titchener's professional career, he produced over 40 Ph.D. graduates and many other masters degree students. More than half of his Ph.D. students were women. His first doctoral student, Margaret Washburn, was the first woman to receive a Ph.D. in psychology in America.

Titchener's *Outline of Psychology* (Titchener 1896, 1897, 1899), went through three editions before being replaced in 1910 by his *A Textbook of Psychology* (Titchener 1910). His four-volume *Experimental Psychology*, appearing between 1901 and 1905 became the standard experimental manual in psychology for over 30 years (Titchener 1901, 1902, 1905).

In these and other books, Titchener represented the task of the psychologist as analysis, synthesis, and explanation. Titchener's method was a form of analytical introspection that involved focusing attention on one aspect of the complex experience to the exclusion of others thus analyzing out each of the elementary components of the complex.

A key concept in Titchener's structuralism was meaning. He believed that pure sensations are meaningless. When groups of sensations appear together and particularly when there is a memory image of them in past experience, the context produced gives meaning to the whole. Because meaning emerges from that combination, the meaning is what is new in the resulting experience. As one combines larger and larger units, new meanings arise, continuing into the higher mental processes. For this reason, Titchener was adamant that when a perception or other complex processes were analyzed into their elementary components, the meanings found in the whole should not be projected into the elements. One had to separate the meanings from

the “facts of experience” in carrying out the analysis (Evans 1975, 1990).

Titchener was a purist in that he believed experimental psychology should have only the scientific goals of understanding the nature of things rather than applying them. Application, for Titchener, was something to be done by other fields of study.

Titchener’s psychology went through several changes over the years and his psychological position became widely represented in American colleges and universities.

A major change occurred after 1913. This was due, at least in part, to attacks made on the legitimacy of his concept of elements and attributes by Carl Rahn, then at the University of Chicago. Added to this was the imageless thought controversy with the students of his old schoolmate, Oswald Külpe, over the existence of images in the thought processes. The issue was never resolved and it turned many young psychologists against the use of introspection as a primary method in psychology. Some, like John B. Watson, called for its abolition entirely substituting for them behavioral measures and concepts (Evans 1972; Watson and Evans 1990).

In the 1920s, Titchener dropped his use of elements and developed a multidimensional psychology based on phenomenological observation rather than introspection. This “lost psychology” never found its way into print except for some of the dissertations of his last students. It was left uncompleted when Titchener died suddenly in 1927. After Titchener’s death, his psychological system evaporated. (Boring 1938; Evans 1972).

Titchener’s main contribution to experimental psychology, perhaps even more so than his system, was in his emphasis on the laboratory as the core of the psychological enterprise. That emphasis was codified in his four-volume *Experimental Psychology* (Titchener 1901, 1902, 1905).

Tolman, E. C.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: April 14, 1886; Died: November 19, 1959.

Edward Chace Tolman was born in Newton, Massachusetts, and followed his brother Richard, who became an eminent chemist, to MIT, graduating in 1911. He then entered Harvard for graduate work in psychology, obtaining the PhD in 1915 under Hugo Münsterberg, but influenced mainly by R. B. Perry, E. B. Holt, and R. M. Yerkes. His first academic post was at Northwestern University, but due to his pacifist views this became untenable. Through the influence of Herbert Langfeld, he was able to move to the University of California at Berkeley, where he remained for the rest of his career.

Major Accomplishments/Contributions

His early work involved imagery and memory, but after he arrived at California he threw himself headlong into the comparative psychology of learning with the aim of constructing a comprehensive objective account of all psychological phenomena based on behavioristic criteria. Early in this process he began to speak in terms not of isolated stimuli and response, but rather

of patterned responses defined by purpose (e.g., Tolman 1923). Alongside and integrated with this effort was Tolman's long association with Gestalt psychology, which he had encountered at its beginnings and with which he was associated throughout his career. This blending of objective behaviorism, pragmatic, and realism, and Gestalt ideas resulted in Tolman's major theoretical work, *Purposive Behavior in Animals and Men* (1932), the ideas in which were expanded and elaborated over the next two decades.

Tolman in his time was recognized as one of the chief behavioristic theorists in psychology, but his legacy to psychology is much larger. Some of the findings from his laboratory served as central points of discussion which moved behaviorism far beyond a primitive stimulus–response position, though it is fair to say that behaviorism never was that simple in any of its incarnations (Smith 1986).

Probably the most significant of these was his demonstration of “latent learning,” a form of incidental learning in which a rat, having knowledge of a maze and having been reinforced for running a particular route, would select a previously traversed but unreinforced route to a goal when the original route was blocked. This appeared as objective evidence for a species of memory or concept formation, an important step in establishing cognition and representation as scientifically valid subjects of psychological study. Another important contribution is Tolman's conception of an organism with embodied tunings responsive to differential fields of force in its environment, based on ideas drawn from Kurt Lewin and Egon Brunswik. Tolman's model organism, which he termed the “schematic sowbug” based on its elongated capsule shape in his diagrammatic representation of it (Tolman 1939), continues to be influential in both psychological and robotic thinking. The most enduring of Tolman's theoretical contributions is his idea of the “cognitive map,” an internalized representation of the necessary perceptual and motivational information necessary to successfully navigate a complex environment, which validated the early theorizing of cognitive psychology (Tolman 1948).

At the beginning of the Second World War, Tolman turned to an examination of the relations between drives, needs, and society. In his Presidential address to the Society for the Psychological Study of Social Issues (SPSSI) in 1940, he drew explicitly on Freudian ideas to

propose a utopian conception of “Psychological Man,” whose needs and drives would be fulfilled in the most complete, balanced, realistic, and socially nondestructive way possible (Tolman 1941). He expanded on this theme in an extended essay on war the next year, advocating fundamental changes in economic systems to relieve frustration of needs and the substitution of a supernational governing agency to replace narrow loyalties to national groups (Tolman 1942). At the end of his career, Tolman became identified with one of the most well-known cases involving academic freedom in the USA. The University of California, acting under national and state pressure, in 1950, required its employees to sign an oath of loyalty which, Tolman believed, violated both personal and academic integrity. Compelled to resign when he and many other members of the faculty, including the psychologists Warner Brown and Hubert Coffey, would not “sign on the dotted line” (Tolman 1950), he eventually prevailed in a lawsuit filed under his name and was reinstated in 1952, retiring in 1954. At the very end of his career Tolman, a master theory builder, said that the best that could be done in creating theory was to follow one's own inclinations and have fun – which he did (Tolman 1959).

Trauma Psychology

CHARLES R. FIGLEY

Tulane University Traumatology Institute,
New Orleans, LA, USA

Trauma psychology is both the name of a Division within the American Psychological Association (Division 56, Trauma Psychology) and an area of specialization within the practice of psychology by psychologists. Trauma psychology is a paradigm that permits investigators and practitioners to understand the process by which people perceive adversity, react to it, recover to a resilient or growth state or to an unwanted state; draw upon the experience with varying levels of psychosocial growth, at varying levels of trauma, for varying periods of exposure, and varying conditions of recovery.

Trauma Psychology as a Paradigm

The trauma psychology paradigm emerged in 1978 with the publication of the book, *Stress Disorders among Vietnam Veterans* (NY: Brunner/Mazel). Charles Figley noted in the Introduction: “The following is an attempt to capture the essential dynamics of the war environment to allow the reader to appreciate better the stress disorders which evolved from it” (p. xx). The book includes summaries of research that challenges the prevailing assumptions about mental disorders can be caused by adult traumatic experiences (trauma) and not be childhood adversities or flawed interpersonal relationships. In the Introduction and throughout the book, it was asserted that stress disorders were caused by war experiences, primarily; that trauma is primarily psychological in nature, though Traumatology’s roots are in medicine. The Introductions specifically included a description of trauma psychology by identifying trauma as a function of four major factors:

1. Combat stress
2. Protective factors especially unit integrity or morale
3. The psychosocial resources at the homecoming
4. Access to external resources

The trauma paradigm assumes that stress is the best universal marker for measuring psychological trauma. Though the origin of stress dates with Hans Selye, psychological trauma dates back far longer according to historians of the illness of hysteria, the modern-day equivalent of an anxiety disorder with a significant overlap with the symptoms of PTSD. The consensus is that of the earliest Egyptian medical textbooks that describe the “moving womb” to describe what today can be considered panic or anxiety attacks, most often affecting women. The treatment was, in effect, aromatherapy to “woo the womb back to its rightful place.”

Much later, seventeenth-century philosophers discussed the impact of stress on human temperament and physiology. Modern theories of stress begin with the nineteenth-century concept of traumatic neurosis. From the middle of the century, railway accidents resulted in increased litigation by injured persons suffering from chronic pain and stress-induced paralysis. Being a newer paradigm, it is only within the last 5 years has the concept made its way into psychology textbooks.

Perceiving Trauma

Perceiving trauma is as subjective as perceiving beauty. One person may be more or less affected by an intense experience (e.g., impact of a tornado destroying part of one’s home) based on, among other things, (a) their life experiences, (b) their demographics (e.g., gender, age, and ethnicity), (c) their level of responsibility for others – especially children – during the trauma, (d) their perception of their own actions, and (e) reports of fellow survivors. It is common that among a group of 100 exposed to a high noise, only a portion would actually register a disturbance in the Amygdale as a disturbing memory (i.e., trauma memory that triggers neurobiology reactivity).

Reacting to Trauma

Once the person perceives that there is a threat and especially when the person experiences fear (for self or others in their stead), there are large variations in

individual levels of stress exposed to the same stressor, as noted earlier. There are, similarly, large variations in individual levels of stress reactions most often highly correlated with the perceived stress, with considerable outliers. Most agree that reactions to trauma are largely determined by three factors: Trait resilience (lifelong adaptability), state resilience (e.g., coping style, social support), individual regulation (e.g., self control), thriving (level of human development thriving based on activities of daily living), and the recursive effects on learning (i.e., reinforcing beliefs about safety and hope) to survive based on experiences.

Traumatic Stress Injuries

These injuries occur when adversity overwhelms the person's capacity to function and errors occur in their experiences with the activities of daily living. This lowering of functioning as measured by ADL scores represents the impact or the deficits of injuries. Like physical injuries, however, there is a tendency to heal without any noticeable, lasting indicators. However, early evidence indicates that all traumatic stress-disorder cases first displayed indicators of lowered functioning weeks if not months and years before displaying symptoms of a traumatic stress disorder.

Traumatic (or Post-traumatic) Stress Disorders (e.g., PTSD)

Oppenheim coined the term *traumatic neurosis* to describe what he believed was a "molecular derangement" of nerve tissue. Initially, Freud accepted this notion, postulating with Breuer in their work, *Studies in Hysteria*, an organic "hypoid state" that made one vulnerable to hysterical stress symptoms when stimulated by a traumatic event. Freud held that the traumatic event in hysteria was sexual trauma stemming from oedipal stress. Yet, as Figley notes (1978), there was a gender bias toward believing that men rarely manifested fear-based symptoms when the evidence was overwhelming, dating back to the Allied Medical Services of 1916 believe that "shell-shocked" soldiers were suffering from a psychological disorders that are treatable. Indeed, the military psychiatry motto in those days was PIE (Primacy, Immediacy, and Expectancy) with considerable emphasis on expectancy of the traumatized to recovery and take their post. Indeed, we now know that enabling the traumatized to return to

the context – personally or virtually – and working down the traumatic stress response is the most cost-effective approach to the unwanted consequences of traumatic events.

Recovering from Trauma

Some have argued that you never recover from trauma; that there is no such thing as returning to normal, just a "new" normal. Recovery from trauma comes when one can take a deep breath, recall the event, and no negative consequences occur (e.g., uncontrollable crying, anger, sleeplessness, and other indicators of physiological arousal). What is required to meet that goal; that shift is unknown since there is so much variation in the trauma induction and reduction process.

Importance of Context

Trauma psychology has been one of the first to recognize early in the emergence of the field that context was critical in any model or framework. The context of the traumatic event, the state of mind of the traumatized person; the person's personal beliefs and how these beliefs was challenged by the traumatic event; the experience of racism, sexism, and many other transient social and interpersonal perpetration – purposeful or accidental, implicit or explicit, conscious or unconscious.

Troland, Leonard T.

DAVID C. DEVONIS
Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: April 26, 1889, Died: May 27, 1932

Troland could justly claim – although he never asserted it – to have the greatest command of scientific knowledge of all of the psychologists of his generation. A graduate of MIT in 1912, he pursued the Ph.D. at

Harvard under Münsterberg, where like his contemporary Tolman, he was drawn to the philosophers and to ► **Holt, E. B.** But Troland really blazed his own trail. After his doctorate, he spent his Sheldon traveling year at the General Electric's laboratories in Nela Park in East Cleveland, Ohio. He returned to Harvard in 1916 as an instructor and was promoted to Assistant Professor in 1922, the highest academic rank he held. While working on the doctorate he completed, with Daniel Comstock of MIT, a précis of physical theory for scientists in other fields (Comstock and Troland 1917). He had amassed enough skill in color theory and vision science to be the 31st member of the American Optical Society (after the first 30 charter members in 1916), and over the next few years authored many original contributions and reviews, culminating in his 1922 summary of the field, *The Present Status of Visual Science* (Troland 1922a). Troland's psychophysical acumen combined with his inventive and entrepreneurial skills to propel him toward the new technology of color motion photography: Between 1918 and 1932 he was intimately connected with the development of the Technicolor process and eventually became chief engineer of the Technicolor Corporation. His work with Technicolor eventually overtook his academic practice which he resigned in 1930 to move to California to be more closely involved in the commercial application of color film in Hollywood. He died in an accidental fall from Mt. Wilson in Los Angeles.

Major Accomplishments/ Contributions

Visual scientists rightly claim Troland as an eminent figure, but his ambitions went far beyond the boundaries of that field. Troland, already skilled in the translation of abstract science into accessible popular terminology, wrote two very well-regarded popularizations of psychology during the 1920s: *The Mystery of Mind* in 1926 and *The Fundamentals of Human Motivation* in 1928, both of which enjoyed a wide readership. He was also an adept historian and participated in the translation of Helmholtz's *Physiological Optics*. He had more than an amateur's interest in parapsychology, authoring a detailed analysis of the relation between parapsychology and Freudian theory (Troland 1914), and, while supported by the Hodgson Fellowship for Psychical Research at Harvard in 1917, constructed an

automated apparatus to present stimuli in experiments on clairvoyance (Troland 1917/1976). His negative results on the one hand were considered by parapsychologists a challenge to redouble their efforts, and on the other hand, its technological innovation reinforced the idea that parapsychology might be a legitimate area of scientific research. Troland's first love, however, was consciousness. The National Academy of Sciences' Troland Awards, supported since 1984 from a bequest from his estate, are presented to investigators less than 40 years of age interested in the connection between consciousness and the physical world. This description mirrors Troland himself, who devoted much time and energy over his short lifetime to working out the implications of a monism derived from W. K. Clifford's "idealistic monism" in which the psychic was the primary and ultimate referent of science. Troland viewed consciousness as a causal force: as he put it in a 1922 article, "Each introspective field of consciousness in the psychical monist's universe exercises an influence upon the course of events in the universe in conformity with exactly the same laws by which any other factor in this universe exerts an influence (Troland 1922c, p. 206)." Consciousness was, in Troland's view, embedded in a neural matrix whose operation was revealed by psychophysical study, the logical extension of the original psychophysical project of Fechner and Helmholtz (Troland 1922b). According to Troland, the neural elements of the mind each possessed physically determined conscious attributes, specifically the ability to sense pain (nociception) and pleasure (beneception). This implicitly panpsychic system, a monism with windows that opened outward, articulated with Troland's utopian vision for society. Derived from several sources but chiefly from the Fabian socialist and American philosophic visionary James MacKaye in *The Economy of Happiness* (MacKaye 1906), Troland's hedonist philosophy envisioned a world in which the determinate nature of consciousness would support engineered interventions to produce a world in which happiness might be maximized. Although Gordon Allport observed that Troland had, going beyond the environmentalist behaviorisms of his time, attempted to account theoretically and physiologically for the "stamping in" process of the law of effect (Allport 1929), Troland's philosophic view of psychology was so far at variance from current psychologies that it

could not gain much of a hearing: His version of hedonism served as the antithesis for Tolman's account of pleasure in *Purposive Behavior in Animals and Men* in 1932. In philosophy, he was an early influence on the philosopher Charles Hartshorne, but it is as a psychophysicist that Troland lives on: He is one of the few psychologists to have a physical unit named after him, the troland, a measurement of retinal illuminance.

Tulving, Endel

DAVID J. MCGARVA

University of Phoenix, Phoenix, AZ, USA

Tulving, Endel (May 26, 1927–present) is a leading researcher into human memory research, best known for proposing the now-accepted distinction between episodic and semantic memory (Bower 2000). His other contributions include demonstrating the separate roles of the right and left frontal lobes in memory encoding and retrieval.

Endel Tulving was born in Tartu, Estonia, in 1927, the son of a judge in a small town (Tulving et al. 1989). Endel attended a private school, where he was a good student, always first in his class (GCS Research Society 2009). Unfortunately, Endel found his classes uninteresting, having decided that everything interesting in the sciences had already been discovered (GCS Research Society 2009). He took more interest in track and field athletics (APF Gold Medal Award: Endel Tulving 1994). His energy went into beating his personal bests, constantly aiming to improve his performance (GCS Research Society 2009).

Life changed after Estonia was absorbed into the USSR in 1940. In 1944, when the Soviet Army entered Estonia, Endel and his younger brother were separated from their parents and were sent to Germany (Tulving et al. 1989). Endel was not to see his parents again for 20 years. He finished his schooling in Germany, discovering an interest in the mind and behavior, which presented him with puzzles yet unsolved (GCS Research Society 2009).

After leaving high school, he taught and interpreted for the American army, taught German to war orphans (University of Alberta 2008), and for one year attended medical school at Heidelberg (Tulving et al. 1989). In an American refugee camp, he met fellow Estonian Ruth Mikkelsaar, who was also from Tartu (Tulving et al. 1989).

Endel immigrated to Canada in 1949. After a year as a laborer, he became an undergraduate in psychology at the University of Toronto. Around the same time, he and Ruth were married. With her encouragement and support, he graduated in 1953 at the top of his class and with first-class honors. After a further year completing a master's degree, he went on to earn a Ph.D. in experimental psychology at Harvard, with a dissertation on oculomotor adjustments and visual acuity (Tulving et al. 1989).

In 1956, he returned to Toronto, where a lectureship had been created for him. He found this position challenging and rewarding but also found there was no laboratory space, equipment, or funding (APF Gold Medal Award: Endel Tulving 1994). It was not practical to continue his research on vision. Instead, he chose to study verbal learning, an area with which he was not familiar, because it seemed straightforward and needed little material support. At Toronto, there was little

pressure to publish: Endel was able to take his time in developing his work (Tulving et al. 1989). Meanwhile, he returned Ruth's support by encouraging her to enter Ontario College of Art, from which she graduated in 1962. Ruth has said that Endel helped her to find confidence and trust in herself, and to express herself fearlessly (Tensuda 2000).

Apart from a short period at Yale, Tulving remained at Toronto until he reached the retirement age of 65. During these years, he also had opportunities to spend time at Stanford, Oxford, and elsewhere.

Tulving is best known for proposing, in 1972, the distinction between episodic and semantic memory (Tulving 1972).

Episodic memory is the remembering of events, while semantic memory is the remembering of general facts and knowledge – in Tulving's words (1972, p. 386) a “mental thesaurus” (Tulving, 1972, p. 386). Thus, one may know the words of a song (semantic) or may recall a time when it was sung (episodic), but not necessarily both.

Episodic memory has a number of distinguishing features. Tulving believes that no other species has it. A dog or cat knows who its friends and enemies are, but there is no evidence that it can recall any encounters with them. A second feature is auto-noetic (self-knowing) memory. The experience of remembering an event has a personal quality not associated with any other form of knowledge. Another feature is chronesthesia, the subjective sense of past, present, and future. No other kind of memory is related to time.

Tulving also demonstrated that laying down a memory is distinct from retrieving it: that often one cannot recall a fact or is not even aware of its existence, and yet it can be accessed with an appropriate probe. This is the foundation of the “cognitive interviewing” used by police to help witnesses recover details (Memon and Bull 1991).

Tulving has said that his research has been strongly influenced by two factors – accidental discoveries and bright, stimulating collaborators and students. He has also been described as an engaging colleague and a charismatic teacher (Tulving et al. 1989).

He also likes to work hard and devote long hours to his research, an attitude he learned at Harvard

from such teachers as E. G. Boring (Tulving et al. 1989). He has explained “the more you learn and know in the area of your work, the more interesting your jobs and projects become” (GCS Research Society 2009). When he reached retirement age at Toronto in 1992, therefore, he was not inclined to stop. In his words again, “why would I stop something I like to do?” (University of Alberta 2008). Instead of accepting retirement, he was appointed as the first incumbent of the Anne and Max Tanenbaum Chair in Cognitive Neuroscience at the recently established Rotman Research Institute of Baycrest Centre, North York, Ontario (now affiliated with the University of Toronto).

In 1994, he used PET scans to show that the brain's right hemisphere is relatively more active during retrieval of episodic memories, while the left is relatively active in retrieving semantic information (GCS Research Society 2009).

In 1995, he proposed a fuller model of memory identifying five systems: working memory, episodic memory, semantic memory, procedural memory, and perceptive memory (Tulving 1995).

Now semiretired, Dr. Tulving continues to study episodic memory at the Rotman Research Institute, where he has been working on “mental time travel,” the human ability to recollect events we have observed or participated in, and also to think about the future (GCS Research Society 2009).

Ruth Tulving, meanwhile, is a distinguished artist. The couple have been married for more than 50 years and have two adult children and five grandchildren (Tensuda 2000).

U

Uexküll, J. von

VINCENT W. HEVERN

Le Moyne College, Syracuse, NY, USA

Basic Biographical Information

Jakob Johann von Uexküll was born on September 8, 1864, at Keblas, Estonia, on the estate of his aristocratic German family with long-standing historical ties to the Baltic region (Kull 2001). He attended the Domschule in Reval (now, Tallin) before entering the University of Dorpat (Estonia) in 1884 to study zoology. Receiving a *cand.zool.* degree in 1889, he moved to the Institute of Physiology at the University of Heidelberg (Germany) to study research methods under **Wilhelm Kühne**, the noted German physiologist and successor to **von Helmholtz**. Following Kühne's unexpected death in 1890 and freed by his family's considerable wealth, Uexküll decided to pursue research as an independent scholar and author. Until the mid-1920s, he worked in Heidelberg and, during the summers from 1892 to 1902, the Zoological Station in Naples, Italy. His discoveries involving the neuromuscular functioning of invertebrate marine mammals led to the grant of an honorary doctorate in medicine by the University at Heidelberg in 1907.

Entering middle age in the early years of the twentieth century, Uexküll began a decisive turn away from physiology and toward theoretical biology, the primary focus for the rest of his life's work. His biological studies led to the establishment of the Institute for Umwelt Research and appointment as honorary professor at the University of Hamburg (Germany) in 1926. Though he was formally retired from this professorship in 1936, he retained direction of the Institute until 1940.

An ardent opponent of materialism, mechanism, and Darwinian explanations in the sciences, Uexküll demonstrated in diverse ways a fundamentally conservative attitude toward government and society as well. Uexküll never embraced Nazi ideology or any party affiliation in the 1930s. However, his early close ties to Houston Stewart Chamberlain (1855–1927), the arch Teutonic nationalist, and his own promotion of the metaphor of the (German) state as a kind of unified organism (in *Staatsbiologie*, 1920, revised 1933) served to shield Uexküll from political danger or interference in the last decade of his life (Harrington 1996).

In 1903, Uexküll married a German countess, Gudrun von Schwerin. Between 1904 and 1909, the couple had three children, a girl and two boys. Following his full retirement in 1940, he moved with his wife to the island of Capri (Italy) for health reasons and died there on July 25, 1944.

Contributions

Uexküll's contributions of primary interest to psychology reside in his notion of the *Umwelt* (i.e., the phenomenal world or subjective universe) of every living organism and the ways in which living organisms necessarily differ from nonliving objects (and their scientific study). Beginning with his 1909 volume, *Umwelt und Innenwelt der Tiere* (*The Outer World and Inner World of Animals*, revised 1921), Uexküll argues that living organisms continually interact with the world, that is, all other living organisms and nonliving objects, according to their own array of sensor and effector organs. Thus, each organism experiences the world in a quite specific and individual fashion that is determined by the range of its own sensory apparatus and motor capabilities. These sensory and effector organs arise themselves according to the specific *Bauplan* (i.e., blueprint or building plan) of that type of organism and may further be shaped by both temporal

experiences and spatial locations. In Uexküll's famous example, to a tick, all mammals are the same thing, that is, they belong to the same *Umwelt*. Triggered by the odor of mammalian sweat, a tick will drop from its perch onto a mammal's hair that guides the insect to the mammal's skin and there, cued by the heat of that skin, the tick will begin to suck blood. Uexküll conceptualized such a sequence of sensory cues (*Merkmale*) and responsive behaviors (*Wirkmale*) as forming a "functional circle" (*Funktionskreis*) in which the organism itself serves to integrate the sequence. Such active processes are untrue for nonliving objects that do not possess intrinsic *Baupläne*. Indeed, objects in the form of machines can be understood as nonliving systems that merely carry out the plans they receive from others.

In 1920, Uexküll authored *Theoretische Biologie* (published as *Theoretical Biology* in 1926), a major philosophical review of his experimental and observational work in biology and its integration with his strong Kantian idealism. For Uexküll, reality as a whole (*Natur*) can never be accessed directly by any living organism which can only appropriate specific aspects of reality as *Umwelten*. In 1940, he published a final synopsis, *Bedeutungslehre* (*The Theory of Meaning*), in which he articulates an understanding that biology (as opposed to physiology) is a fundamentally semiotic undertaking (Uexküll 1940/1982). Biologists attempt to understand how organisms employ, decipher, and respond to signals in the environment as these living beings create their own external realities.

Commentators have noted similarities between Uexküll's notion of the *Umwelt* and Dewey's reflex arc in which both concepts seek to establish an essential dynamic unity between stimuli and responses. J. J. Gibson's concept of affordances echoes in some respects Uexküll's reflection on the dynamism and complexity uncovered in the relationship of organisms with their environments. A range of researchers – including comparative psychologists, ethologists, and biosemioticians studying animal behavior and communication – have found in Uexküll's work seminal ideas involving how the personal "microenvironments" of organisms powerfully determine how these organisms behave (Chang 2009). Finally, proponents of various theories of embodied cognition (e.g., Maturana and Varela) and researchers in robotic and artificial

intelligence confront conceptual challenges related to biological phenomena and activity examined throughout Uexküll's writings nearly a century ago.

University College London, History of Psychology at

ELIZABETH R. VALENTINE

Royal Holloway, University of London, Egham, Surrey,
TW, UK

University College London, London, UK

Basic History of the Department

University College London is the oldest and one of the largest constituent colleges of the University of London; it now has its own degree-awarding powers. Founded in 1826, on nondenominational principles (in contradistinction to the Universities of Oxford and Cambridge), it encouraged the development of a number of new subjects of university study.

Before the formation of a Department of Psychology, the subject was pursued in other departments, notably medicine, other science departments, and philosophy. Members of the College include the neurophysiologist Charles Bell, the physicians John Conolly, Henry Maudsley, and John Elliotson (the last of whom introduced mesmerism/hypnosis for surgical operations at University College Hospital), the biometrists W.F.R. Weldon and Karl Pearson, the statistician Ronald A. Fisher, and the geneticist Lionel S. Penrose. Francis Galton (q.v.) was also closely associated with the College and inspired much of the work later conducted in the Department of Psychology.

From 1853, lectures on psychology were offered under philosophy of mind. The syllabus included sensations, intellectual faculties, consciousness, the nervous system, phrenology, personality, emotions, and volition. George Croom Robertson, Grote Professor of the Philosophy of Mind and Logic 1866–1892, was an original and penetrating psychological thinker. A pupil of Alexander Bain's, who had also studied under du Bois-Reymond in Berlin, Lotze in Göttingen, and Broca in Paris, he stressed the active, physiological (especially muscular) nature of sensation. As the first editor of the journal *Mind* 1876–1892, he did much to make Continental work known to British readers.

James Sully (q.v.), Grote Professor 1892–1903, was the first genuine psychologist rather than philosopher to hold the chair. He too had studied abroad: under Lotze in Göttingen, and Helmholtz and du Bois-Reymond in Berlin. The author of many psychological texts, he played a crucial role in the institutional development of psychology in Britain and encouraged the development of child study and educational psychology. He called the meeting at University College in 1901 at which the British Psychological Society was formed and was instrumental in setting up one of the first psychological laboratories in the country.

William McDougall took over as director of the laboratory in 1900, before taking up the Wilde Readership in Mental Philosophy at Oxford in 1904 and moving to the United States in 1920. Carveth Read succeeded James Sully in 1904. He had studied under Wundt in Leipzig and Kuno Fischer in Heidelberg. His interests were more in theoretical than in experimental psychology.

Charles Spearman was appointed in 1907, taking over the directorship of the laboratory, succeeding to the Grote Chair in 1911, and becoming Professor of Psychology in 1928, when a separate Department of Psychology, independent of Philosophy was formed. He began the work on psychometric and differential psychology for which the Department became famous. He was succeeded by Cyril Burt in 1932, who continued this tradition of work on human intelligence, achieving his avowed aim of making the Department a focus for the study of individual differences.

The American Roger W. Russell was appointed in 1950. Interested in the biological basis of behavior, he introduced the study of animal learning. In 1959, he

was succeeded by George C. Drew, known for his work on skills, including the effect of alcohol on driving. Robert J. Audley, a pioneer in mathematical models of decision making, succeeded to the chair in 1979.

From 1993, shorter terms of office as head of Department were occupied by Henry Plotkin (1993–1998), an evolutionary epistemologist; Oliver Braddick (1998–2001), a vision scientist; and Alan Johnston (2001–2003), a cognitive scientist. The current head is David Shanks, a cognitive psychologist, who has been head since 2003. In a restructuring exercise in 2008, the Department of Psychology was replaced by a Division of Psychology and Language Sciences, containing eight research departments. These include cognitive, perceptual, and brain sciences; cognitive neuroscience; developmental psychology; clinical, educational, and health psychology; and human-computer interaction.

Significance

The Psychology Department at University College London has been one of the largest, strongest, and broadest in the United Kingdom. For many years, it has been the largest provider of taught postgraduate psychology courses in Europe. The College hosted the International Congress of Psychology in 1892 and in 1969.

The laboratory set up by James Sully, with support from Francis Galton (q.v.) and science professors in the College, opened in January 1898. Sully raised money to purchase equipment from Hugo Münsterberg who was leaving Freiburg for Harvard, and to employ W.H.R. Rivers, Lecturer in the Physiology of the Special Senses at the University of Cambridge, who had given occasional lectures on experimental psychology at the College and started to develop practical psychological work in Cambridge. The laboratory aimed to measure physical and physiological aspects of mental processes.

The work of Spearman and Burt constituted the London School of differential psychology and psychometrics. It aimed to provide scientifically rigorous measurement and statistically sophisticated analyses of human ability. Spearman proposed a two-factor theory of intelligence (1904): a single general factor (*g*) underlying all intellectual functions and specific factors (*s*) underlying particular functions. The method of correlation, building on the foundations laid by Francis Galton and Karl Pearson, was used to demonstrate the existence of *g*, originating what later became

known as factor analysis. Spearman provided both empirical and theoretical support for his hypothesized hierarchical structure of human ability. Though it met with much opposition (L.L. Thurstone and Karl Pearson were amongst his opponents) and was ultimately superseded, it became internationally recognized and dominated research on individual differences for 2 decades. Spearman also aspired to discovering fundamental laws of psychology, and hypothesized “noënetic” principles of educating and generalizing relationships. He was also responsible for the Spearman–Brown prophecy formula for assessing the reliability of psychological tests and the well-known rank correlation statistic. In 1924, he was awarded a fellowship of the Royal Society for his pioneering work on the application of mathematical methods to the analysis of the human mind.

Cyril Burt was appointed psychologist to the London County Council in 1913, “the first applied psychologist in the world.” This enabled large-scale mental testing of school-children, and led to developments in child guidance and educational psychology. Burt’s special interests were in subnormality and juvenile delinquency. Later in his career he concentrated on mathematically refining the technique of factor analysis. Burt believed in and worked to demonstrate the heritability of intelligence.

After his death he was accused of fraud – of fabricating data and analyses, particularly in connection with studies of monozygotic twins reared apart. A heated controversy ensued, inevitably entangled with political opinion, neither finally resolved nor probably resolvable because crucial evidence is now lost. Although these attacks tarnished his reputation, first-hand reports testify to Burt’s dedication and achievement as a scholar and teacher.

A sign of the Department’s eclecticism is the long tradition of teaching psychoanalysis. This began with J.C. Flügel, a member of staff in the Department from 1909 to 1944, at the time the only practicing psychoanalyst to hold a senior academic position in Britain (he was appointed senior lecturer in 1920 and assistant professor in 1929). Flügel acted as a sort of “liaison officer” between psychoanalysis and academic psychology. In Cyril Burt’s opinion, Flügel’s abiding work lay in his fruitful attempts to synthesize Freudian psychoanalysis with the orthodox tenets of British psychology as taught by Ward, Stout, and McDougall. Flügel was

followed by Cecily de Monchaux, another practicing psychoanalyst and member of staff in the Department from 1949 to 1977.

A Freud Memorial Chair in Psychoanalysis was established in 1974. For the first 10 years, this was an annual appointment. In 1984, its term of office was extended. Joseph Sandler was appointed, establishing a Psychoanalysis Unit, whose mission is to strengthen the links between psychoanalysis and other academic disciplines. The current holder of the chair and director of the Unit is Peter Fonagy, who succeeded in 1992.

University of Denver, History of Psychology at

BERNARD SPILKA

University of Denver, Denver, CO, USA

History

The University of Denver is the second oldest institution of higher learning in the Rocky Mountain West. Established initially as a private, church-sponsored school in 1864, it closed in 1867 and reopened as a true university in 1880. Among its first offerings was Mental Science also termed Mental Philosophy, both of which relied primarily on the religious orientations of pre-Jamesian American psychology espoused by Thomas Cogswell Upham and Lawrence Perseus Hickok. This single course was restricted to the senior year, taught by the Chancellor of the university who was a Methodist cleric and always associated with a corrective course in Christian Evidences. There was a potential danger in understanding how the mind works.

In 1898, Daniel Edward Phillips who earned his Ph.D. at Clark University was hired as a Professor of Philosophy and Pedagogy. He introduced the ideas of

William James and Titchnerian structuralism and developed a program of standard psychology courses. The department's main role was to support education. Phillips was not a researcher but did write an elementary psychology text.

Achievements

In 1929, with the departure of Phillips and the arrival of Thomas R. Garth and Lawrence W. Miller, a new emphasis on behavior and measurement took hold. An anti-clinical orientation, specifically opposed to Psychoanalysis, prevailed. Counseling, largely of an educational nature was acceptable. Garth conducted research primarily on Native Americans and Hispanics of the Southwest and published work regarded as "Race Psychology." Miller constructed objective questionnaires for use in education and counseling and wrote articles on a broad range of psychological topics. During this period, psychology was officially split between education with Miller as its head and a mainstream behavioristic course grouping directed by Garth. With the death of Garth in 1939, the two departments became one under Miller until his passing in 1961. A classical reinforcement learning view dominated teaching and research. An animal laboratory was constructed and the overall department orientation embraced experimental psychology. Though some mainline clinical training appeared, counseling with an educational emphasis remained primary. Slowly, the number of faculty publications was increasing.

Following Miller, the department radically changed under the direction of Kenneth B. Little, former director of the small grants division of NIMH. Hiring and evaluation now accentuated research, grant-getting, and publication. Rather suddenly, federal grants and contracts were being sought. Colloquia with national scholars and faculty were regularly presented. The experimental focus was now supplemented by Child-Development and Child-Clinical programs composed of new faculty with growing professional reputations.

In 1969, Little left the university to become Executive Officer of APA; however, the stress on research was greatly strengthened by Little's successor, Kenneth Purcell. Nonproductive faculty were either replaced or if they had tenure, were pressured to seek grants or leave. Again, the department grew in size and the Child Development program was soon recognized nationally.

In the mid-1970s, Purcell became a college dean for 8 years after which he returned to the department as head of the clinical program. During his absence, the voice of faculty in department administration increased and an atmosphere of heightened cooperation was evident. For the next 7 years, a number of chairs were elected by the faculty, each holding the position for 1–3 years until 1983 when G. Nicholas Braucht presided for 7 years. The stress on grant support was maintained and the department became second in the university in such funding. With surprising rapidity, undergraduate psychology majors joined faculty and graduate students in department laboratories and joint publications and convention presentations became common. This trend has continued along with a strong formal program to recognize and financially support undergraduate scholarship.

In the 1980s, university financial problems ensued and a number of faculty left the department. After a few years, these troubles were resolved and growth resumed. Currently, there are 22 full-time faculty plus a number of adjunct faculty. The stress on scholarly productivity has resulted in very active research programs and an annual output of many books and journal articles.

Currently regarded as one of the premier departments in the university, a 2009 U.S. News and World Report placed the Psychology Graduate program within the top 100 in the nation. In its 130-year history, psychology at the University of Denver has continued to grow in size and scholarly reputation.

University of Frankfurt, History of Psychology at

HORST GUNDLACH

University of Würzburg, Würzburg, Germany

Frankfurt has a glorious tradition as one of the leading free imperial cities in the German empire. Such cities generally disliked harboring troublesome universities inside their walls, an ancient attitude which changed only at the end of the nineteenth century. As a first step

for a future university, the affluent commercial city founded a *Commercial Academy* (*Akademie für Sozial- und Handelswissenschaften*) in 1900 which was transformed into a university in 1914. In 1905, the *Academy* established a psychological institute. Its founding director was Karl Marbe (1869–1953) who had studied with Hugo Münsterberg (1863–1916) in Freiburg, with Götz Martius (1853–1927) at Bonn, with Wilhelm Wundt (1832–1920) in Leipzig, and then had joined Oswald Külpe (1862–1915) at Würzburg. Not only was he himself wealthy, he also had an uncommon talent to acquire donations for the new institute which became one of the best equipped in Germany. As the teaching obligations during this early phase were modest, his attention could focus on research. The institute soon developed a substantial reputation, so that the *Society of Experimental Psychology*, the present *German Society for Psychology*, decided to hold their third biannual congress there in 1908. Despite the excellent research possibilities, Marbe preferred to work at a genuine university, and when Külpe left Würzburg to go to Bonn, Marbe accepted a call to Würzburg as his successor. Marbe's successor in Frankfurt was Friedrich Schumann (1863–1940), a disciple of Georg Elias Müller (1850–1934) in Göttingen and assistant at Carl Stumpf's (1848–1938) Berlin psychological institute.

Schumann employed as his assistants Kurt Koffka (1886–1941) and Wolfgang Köhler (1887–1967) whom he knew from Berlin. As a free researcher, Max Wertheimer (1880–1943) joined the institute, did his pioneering research on the phi phenomenon and drafted the theoretical framework for Gestalt psychology. Koffka's successor was Adhemar Gelb (1887–1936), and Kurt Goldstein (1878–1965) worked at the nearby neurological institute. The Frankfurt psychological institute therefore rightfully claims to be the birthplace of Gestalt psychology. When in 1928 Schumann retired, Max Wertheimer succeeded him, but was ousted in 1933 by the Nazi government. The chair was left empty, and Wertheimer's assistant, Wolfgang Metzger (1899–1979), managed the institute with modest means and political adaptability. When in 1941 the Berlin ministry decreed examination regulations for psychologists at German universities, as the *Wehrmacht* needed qualified psychologists, the university at Münster expanded its staff and called Metzger on

a chair of psychology. In Frankfurt, Edwin Rausch (1906–1994), who till then had worked as auxiliary assistant, kept the institute from passing away. After the war, he became the official director of the institute without, however, receiving the chair. This post was eventually given to him in 1964. In 1965, a second chair was installed, and a second psychological institute created, this one in the Philosophical faculty, whereas the traditional institute belonged to the Science faculty. This awkward situation was later remedied, and a larger, coherent institute forged. The hundredth anniversary of the Institute was commemorated in 2005, and a study of its history published (Moosbrugger 2005).

University of Georgia, History of Psychology at

ROGER K. THOMAS
University of Georgia, Athens, GA, USA

Basic History of the Department

The University of Georgia (UGA) in Athens, GA, is the oldest state-chartered University (1785) in the United States of America, although the University of North Carolina began operations in 1795 compared to UGA in 1801. Psychology was represented in UGA's first curriculum in a course titled "Moral and Mental Philosophy." Over the years, psychology-related courses evolved from "Mental Philosophy" to "Mental Science." "Psychology" first appeared as a UGA course in

1897, but the course remained philosophically oriented. In 1900, William James's scientifically oriented textbook, *Psychology, Briefer Course*, was used. Oscar S. Straus, a German-Jewish emigrant to Georgia who served as Secretary of Commerce and Labor under Theodore Roosevelt, funded the establishment of a laboratory at UGA in 1902. It was equipped similarly to E. B. Titchener's (1867–1927) laboratory at Cornell University, and Titchener's textbook and laboratory manuals were used.

From UGA's beginning until 1908, psychology was joined with philosophy within the Franklin College (later, the Franklin College of Arts and Sciences). When the Peabody College of Education was established (1908), psychology and philosophy were transferred to Peabody College. In 1912, the construction of Peabody Hall to house the Peabody College was nearing completion, and UGA's first *bona fide* doctoral psychologist, Ludwig Reinhold Geissler (Ph.D., 1909, Cornell, supervised by E. B. Titchener), was given the responsibility to design separate rooms for the study of vision, audition, other senses, and a room to study attention and memory.

Ludwig Reinhold Geissler 1879–1932

In 1916, Austin Southwick Edwards (Ph.D. 1912, Cornell, Titchener) replaced Geissler who moved to Clark University (Worcester, MA). Soon after his arrival, Edwards was called to the US Army where he served as a Captain under Major Robert M. Yerkes in

the group that developed the Army's Alpha and Beta tests. Returning to UGA in 1919, Edwards soon realized that the Peabody College administration did support psychology as a science, and Edwards led a successful "mutiny" (his word) to have psychology returned to the College of Arts and Sciences. The present-day Department of Psychology originated in 1921. Edwards also succeeded in having psychology grouped with the natural sciences, a legacy which today finds psychology grouped with the biological sciences as well as the social sciences; however, the department offers only B.S., M.S., and Ph.D. degrees.

Austin S. Edwards 1885–1976

Despite having earned his doctorate as an experimental psychologist, Edwards published in experimental, social, educational, and clinical psychological journals. He founded the Psychology Clinic (officially recognized in 1930) and served as its Director until 1950. Edwards also served as department Head until his retirement in 1951. Georgia was among the earlier states to pass state licensing laws for psychologists, and Edwards served on the committee that drafted the law, he served on the first state Board of Examiners, and he received license #1 in the state of Georgia.

Edwards was the only psychologist in the professorial ranks at UGA until 1930. System-wide budget cuts during the economic depression resulted in the reassignment of psychologists Florene Young (1901–1994) from the State Normal School and May Zeigler

(1882–1976) from the Georgia State College for Women to UGA. Florene Young served as assistant director in the Clinic until the directorship was passed to her in 1950; she remained as Clinic Director until her retirement in 1968. Young (1969) compiled an unpublished but accessible history of the department that includes an essay titled “Building a Department” by A. S. Edwards. Zeigler published an abbreviated history of psychology at UGA (Zeigler 1949).

When Edwards retired in 1951, the department had approximately seven faculty members; “approximately” applies to faculty numbers here because there has long been a mix of full-time and part-time appointments not necessarily resulting in a whole number. The faculty numbered 10 by 1959. By 1968, the department had 40 faculty members and was spread over three campus buildings. In 1969, a new six-story building was opened for psychology’s exclusive use, and today there are 45 faculty members. In 1970, the department was subdivided into five Ph.D. specialty programs: Applied which included Industrial-Organizational, Biopsychology since renamed Neuroscience and Behavior, Clinical, Experimental since renamed Cognitive-Experimental, and Social. In 1987, the Life-span Developmental program emerged, and these six represent the current organization. Discussion is presently underway to consolidate some programs as much cross-program integration has occurred in recent years.

As indicated with Geissler and Edwards, Titchener’s influence was strong in the early establishment of psychology at UGA. Two other Titchener students had a significant impact on psychology’s development at UGA. Preceding Geissler was Celestia S. Parrish who is best remembered for having established the first psychology laboratory in the south, which she did at Randolph-Macon Woman’s College (R-MWC) in Lynchburg, VA, in 1894. Parrish was in charge of mathematics and pedagogy at R-MWC when she volunteered to obtain the necessary education to enable R-MWC to offer psychology. She persuaded Titchener to take her on as a part-time student. By attending summers she earned a Ph.B. (bachelor’s) degree under Titchener in 1896. In 1902, Parrish became Professor of psychology and pedagogy at the Georgia State Normal School which was also located in Athens, GA. She also taught child psychology at UGA during the summers, before women were on UGA’s regular faculty and

before women were admitted as students. Circumstantial evidence suggests that she was likely instrumental in establishing the psychology laboratory at UGA in 1902 (see above). With funding donated by George Foster Peabody, she oversaw construction of a building on the State Normal School campus to be used for practice teaching, and she built a state-of-the-art experimental psychology laboratory modeled after Titchener’s and the one at R-MWC.

Celestia S. Parrish 1853–1918

William Thomas James (1903–1998) enrolled at Cornell in 1926 hoping to earn a Ph.D. under Titchener, and he had classes with Titchener before his death in 1927. James then earned his Ph.D. under H. P. Weld and subsequently worked with Howard Liddell at the Cornell Farm. Liddell had worked with Pavlov and was among the early American psychologists to bring Pavlovian research to the United States. In 1946, James established UGA’s first animal research laboratory where he did both comparative and physiological research. Young’s history (1969) also includes an essay by James titled “Establishing Animal Laboratories at the University of Georgia.”

Significance

Perhaps the department’s faculty’s first contribution to psychology beyond UGA resulted from L. R. Geissler’s role in founding and editing the *Journal of Applied Psychology*. It has recently been shown (Thomas 2009)

William Thomas James 1903–1998

that Geissler was the principal founder (together with G. Stanley Hall and J. W. Baird) and was chief editor for the first 4 years. It is also clear that Geissler began working to found the journal during his last year (1916) at UGA; he solicited the participation of the 19 “co-operating editors” shown in the first issue as well as manuscripts for the first issue. Geissler’s additional contributions included writing a defining article for the first issue, “What is applied psychology?” which, among other things, differentiated between “applied” and “pure” psychology on the dimensions of “AIM,” “STANDPOINT,” “SCOPE,” “PROBLEM,” and “METHOD.” In volume 2, Geissler published “A plan for the technical training of consulting psychologists” which outlined academic programs and requirements to become an “assistant consulting psychologist,” a “consulting psychologist,” or an “expert consulting psychologist” depending on one’s level of education (bachelor’s, master’s, and doctoral degrees, respectively).

Systematic records have not been maintained of faculty contributions to psychology, so information here should be seen as highly constrained by limited records. In the category of teaching, the department currently confers approximately 350 B.S. degrees each year, and for at least 3 decades has conferred approximately 20 M.S. degrees and 20 Ph.D. degrees each year. The quality of graduate teaching is reflected in faculty members who have been honored by former students

with festschrifts. Two can be identified: “From Perception to Social Organization to Conservation Biology: Research Contributions in Tribute to an Outstanding Mentor, Irwin S. Bernstein.” American Society of Primatologists, San Antonio, TX, August, 2006. Abstracts were published in *American Journal of Primatology*, 2006, v. 68, and “A Biopsychology Festschrift in Honor of Lelon J. Peacock” (occasioned by his retirement in 1990), Southern Society for Philosophy and Psychology, Atlanta, GA, March, 1991. Six papers (some had been committed to other journals) were published as a special issue of the *Journal of General Psychology*, 1993, v. 120, No. 1. Although UGA was slow to integrate racially (1961) and although statistics appear not to have been kept, the department has likely conferred the most Ph.D. degrees to African Americans at UGA. The first African American to earn a Ph.D. (1975), Samuel M. Turner (who died in 2005) had a highly successful career which culminated in his receiving the American Psychological Association’s Distinguished Professional Contribution Award in 1998.

Most faculty members over the years have published at high rates in highly ranked journals and many receive extramural funding with considerable success. Four faculty members at UGA have served as presidents of three international or national academic societies: International Primatological Society (Dorothy Frigaszy), American Society of Primatologists (Irwin Bernstein & Dorothy Fragaszy), and Comparative Cognition Society (Jonathan Crystal). There have been five presidents of four Divisions of the American Psychological Association: Development Psychology (Patricia Miller), Society for Personality and Social Psychology (Abraham Tesser), Society for Clinical Psychology (Karen Calhoun), and Society for Industrial and Organizational Psychology (William Owens & Donald Grant). Four members of this department have served as Presidents of the Southeastern Psychological Association (Henry Adams, Karen Calhoun, Joseph Hammock, and William Pavlik) as has one Ph. D. graduate of this department (Stephen Hobbs). Regional in name but national in membership, the Southern Society for Philosophy and Psychology has had five presidents from UGA (Austin Edwards, Ludwig Geissler, Lelon Peacock, Clyde Noble, and Roger Thomas) listed among such notable past-presidents as James Mark Baldwin, Shepherd I. Franz,

John B. Watson, E. K. Strong, Jr., Knight Dunlap, Karl M. Dallenbach, and Ulric Neisser. Celestia Parrish was a founding member of SSPP.

UGA psychology faculty members who serve or have served as Associate Editors, on Editorial Boards, etc., are too numerous to list, but Editors include those for the *Journal of Personality and Social Psychology* (Abraham Tesser), the *Journal of Psychopathology and Behavioral Assessment* (Henry Adams, founding Editor), and *Psychological Inquiry* (Leonard Martin). National honors and recognition include the Distinguished Primatologist Award (Irwin Bernstein), the Mentoring Legacy Award from the American Academy of Management (Lillian Eby), Fellows of the American Association for the Advancement of Science (Irwin Bernstein, Dorothy Fragaszy, Lelon Peacock, Robert Pollack, and Roger Thomas). Irwin Bernstein is a Fellow in the Animal Behavior Society, Dorothy Fragaszy is a Fulbright Fellow, and several Charter Fellows of the American Psychological Society came from this department. National research awards include the *Organization Research Methods* Article of the Decade (Charles Lance who is on this department's faculty and Robert Vandenberg who earned his Ph.D. in this department and is a faculty member in UGA's Terry College of Business), "Best Paper Published" in the 2005 volume of *Group and Organizational Management* (Lillian Eby), and "Research Article Award" for 2007 by a member of the American Society for Training and Development (Lillian Eby).

University of Heidelberg, History of Psychology at

HORST GUNDLACH

University of Würzburg, Würzburg, Germany

The institutionalization of psychology at Heidelberg University advanced along a confused and confusing chain of events, thereby mirroring the tangled path of psychology toward being an independent discipline at German universities.

Heidelberg, founded in 1386 and the oldest university in present-day Germany, had offered lectures on psychology in the eighteenth and nineteenth century as much as any other German university. Like everywhere else, there were no specialized chairs of psychology. Teachers of philosophy and of other disciplines dealt with this subject. In the middle of the nineteenth century, Heidelberg unexpectedly came to play an outstanding role in the development of the new, experimental psychology inspired by the experimental methods of physics and physiology. Friedrich Arnold (1803–1890), professor of anatomy and physiology, set up a physiological laboratory where research in sensory psychology was done. One of his students (Gundlach 1986), his nephew Wilhelm Wundt (1832–1920), later created the first Psychological Laboratory and Institute at Leipzig. Arnold's successor in physiology at Heidelberg, Hermann Helmholtz (1821–1894), established a physiological institute and did much of his research in sensory physiology and psychology here (Helmholtz 1863, 1867, 1924/1925). Helmholtz's first assistant, none other than Wundt, developed his main research projects in Heidelberg (Wundt 1863, 1874), kept a private physiological and psychological laboratory, and became professor extraordinarius for anthropology and medical psychology in 1864 in the Medical faculty. Helmholtz left Heidelberg in 1871, and when Wundt did so in 1874, experimental

psychology went with him only to return when Kraepelin accepted the call to the psychiatry chair in 1891.

Emil Kraepelin (1856–1926) had worked in Wundt's Leipzig Institute, had himself set up the world's second psychological laboratory at the Leipzig Psychiatry Clinic, and another, modest one at Dorpat University in the then Russian baltic province of Livonia. His Heidelberg laboratory was reasonably well equipped, served as his base for his pioneering research in work psychology and in pharmacological psychology. Kraepelin founded a journal, *Psychologische Arbeiten*, in 1896, and attracted many international students. When he left for Munich in 1903, the laboratory fell into disuse.

In 1919, the psychiatrist Hans Walter Gruhle (1880–1958) and the psychiatrist-turned-philosopher Karl Jaspers (1883–1969), both pioneers in phenomenological psychology, suggested to turn the neglected laboratory into a psychological institute, but post-war economic misery thwarted the project. Heidelberg obtained such an institute by windfall after the Nazis came to power in 1933 and shut up the *Commercial Academy (Handelshochschule)* in nearby Mannheim. Its psychological institute, directed by Wilhelm Peters (1880–1963) from 1919 till 1923 and then by Otto Selz (1881–1943), was transferred to Heidelberg University. The library and the experimental apparatus were stored in the neglected psychological laboratory at the psychiatric clinic. Selz as a undesirable non-Aryan was fired and later killed in or on the way to Auschwitz. In Heidelberg, the newly acquired institute was nominally run by nonpsychologists from the Medical and the Philosophical faculties and fell into a comatose state.

In 1941, the Berlin ministry decreed examination regulations for psychologists at German universities, as the *Wehrmacht* needed qualified psychologists. Heidelberg University, wishing to offer the relevant curriculum and remembering the scrapheap in the basement of the psychiatric clinic, the remnants of Kraepelin's laboratory and of Peters' and Selz's Mannheim institute, reorganized it as a psychological institute in the Philosophical faculty in 1942/1943. Willy Hellpach (1893–1974) was nominated the institute's director. He had done his philosophical doctorate with Wundt in Leipzig, studied with Kraepelin in Heidelberg, created

ecological psychology (*Umweltpsychologie*), later held high political offices, and had been teaching most branches of psychology as honorary professor at Heidelberg since 1926.

The institute survived the war, as Heidelberg was only minimally bombed, and kept operating. But it was not earlier than 1951 that a corresponding chair of psychology was created. Johannes Rudert (1894–1980), an adherent of the Leipzig school of *Ganzheitspsychologie* and former *Wehrmacht* psychologist, became its first occupant. His successor, Carl-Friedrich Graumann (1923–2007), had studied psychology by correspondence with the University of Saskatchewan as prisoner of war in Canada, and later at Bonn and Cologne. He came to Heidelberg in 1963 and thoroughly modernized the curriculum, introduced American textbooks, oversaw the growing of the institute into a sizable organization with five chairs and many work units, and organized the moving of the institute into the edifice built for Helmholtz where it still resides. The Heidelberg psychological institute now ranks amongst the preeminent institutes in contemporary rankings, and more than 3,000 applicants compete every year for the 100 study openings.

University of Würzburg, History of Psychology at

HORST GUNDLACH

University of Würzburg, Würzburg, Germany

Even before a Psychological Institute was founded in 1896, important impulses for psychology came out of the Philosophical and Medical faculties at Würzburg. Franz Brentano (1838–1917) taught philosophy and psychology from 1866 until 1873. His student, Carl Stumpf (1848–1936), obtained a chair of philosophy at Würzburg in 1873. Stumpf left for Prague in 1879, and later he founded the Berlin Psychological Institute. In the 1880s, psychiatrist Conrad Rieger (1855–1939) published experimental studies of the will and developed a scale for diagnosing impaired intelligence. His assistant, Wundt's disciple Robert Sommer (1864–1937), later founded the Psychological Laboratory at Gießen and was one of the driving forces behind the founding, in 1904, of the *Society for Experimental Psychology*, the present *German Society for Psychology*. Physiologist Max von Frey (1852–1932), in his fine physiological laboratory, investigated the cutaneous senses and invented various esthesiometers.

Succeeding Johannes Volkelt (1848–1930), Oswald Külpe (1862–1915) accepted the chair of philosophy and aesthetics at Würzburg University in 1894 and founded the Psychological Institute in 1896. He had been Wilhelm Wundt's favorite assistant at the Leipzig Psychological Institute, but disappointed his teacher greatly when in his *Outlines of Psychology* (Külpe 1893, English translation 1895) he rejected basic elements of Wundt's theoretical psychology. Karl Marbe (1869–1953), who had studied with Hugo Münsterberg (1863–1916) at Freiburg, with Goetz Martius (1853–1927) at Bonn, and with Wundt at Leipzig, started teaching in Würzburg in 1896, and was nominated professor and second director of the institute in 1902. Külpe and Marbe attracted a number of talented students. With their experimental research in thinking and cognition, they started what came to be known as the Würzburg school of psychology. Külpe is usually seen as the founder of this movement, but Marbe was no less

important (Marbe 1945). Among its adherents were Karl Bühler (1879–1963), Ernst Dürr (1878–1913), Narziss Ach (1871–1946), August Mayer (1874–1951), Albert Édouard Michotte van den Berck (1881–1956), Johannes Orth (1872–1949), and Henry Jackson Watt (1879–1925). Max Wertheimer (1880–1943) studied with Külpe in Würzburg before developing Gestalt psychology. Although not lavishly equipped, the Würzburg institute soon developed a superior reputation, and the *Society of Experimental Psychology* decided to hold their second biannual congress there in 1906.

When Külpe went forth for Bonn in 1909, Marbe who had left Würzburg in 1905 to establish the psychological institute at Frankfurt, returned to Würzburg as his successor. He induced the university to increase the institute's finances massively and transformed it into one of the best equipped in Germany (Marbe 1945; Schorn 1936). He established a journal for the work done at the institute, *Fortschritte der Psychologie und ihrer Anwendungen*, which encompassed a wide spectrum of topics, among them an uncommon amount of publications on applied psychology. Marbe retired in 1935. His successor, Carl Jesinghaus (1886–1948), had studied with Wundt and Felix Krueger and then made a career in Argentina. During the 10 years he ran the Würzburg institute, he published next to nothing in Germany. A politically shady character, he had to leave the university in 1945.

After the war, in 1947, Gustav Kafka (1883–1953) became director of the institute, woke it up from its slumber, and organized the training of professional psychologists according to the slightly modified examination regulations of 1941. In 1953, Wilhelm Arnold (1911–1983) succeeded Kafka as director of the institute and received a newly installed chair of psychology, the first such chair in Würzburg. This signaled the definitive institutional separation of philosophy and psychology. Arnold directed the institute until 1978, a period in which the number of chairs of psychology multiplied. The institute's hundredth anniversary was commemorated in 1996, and a rich survey of the history of psychology in Würzburg was published (Janke and Schneider 1999).

Since 2009, Würzburg accommodates the *Adolf-Würth-Zentrum für Geschichte der Psychologie* (*Adolf-Würth-Center for the History of Psychology*), the former

Institut für Geschichte der Psychologie at Passau University, with its large collections of historical apparatus and archival material from the history of psychology.

Vocational Psychology

MARGO A. JACKSON¹, JOSEPH R. VERDINO²

¹Fordham University, New York,
NY, USA

²Kingsborough Community College of the City
University of New York, Brooklyn, NY, USA

Introduction

This entry on theories in vocational psychology begins with a definition of the discipline and a summary of historical background for the development of major theories. An overview is provided of the following vocational psychology theories: Holland's (1959, 1997) theory of vocational personality types and work environments; the theory of work adjustment (Dawis and Lofquist 1984; Dawis 2005); Super's (1957, 1990) life-span, life-space theory of career development; L. Gottfredson's (1981, 2005) theory of circumscription and compromise; Krumboltz's (1996, 1996) social learning theory of career choice and decision making; and the social cognitive career theory (Lent et al. 1994; 2000). Key issues of each theory are organized by the subheadings of Explanatory Propositions, Assessments and Interventions, and Research Evaluating the Theory. A brief account is offered of international perspectives on comparative and cross-national theory development in vocational psychology. Future directions are highlighted for needed research in emerging theory development in vocational psychology that addresses the needs of marginalized and underserved populations and includes consideration of the role of work in people's psychological health and well-being (Blustein 2008).

Definition

Vocational psychology in the USA has been identified as a specialty within applied psychology that focuses on

scientific investigations “to advance knowledge about vocational behavior, improve career interventions, and inform social policy about work issues” (Savickas and Baker 2005, p. 15). Vocational behavior has been defined as an individual's thoughts, feelings, and actions in the process of choosing and adjusting to an occupation (Crites 1969). Beyond the developmental process of having and holding one occupation or career at a single point in one's life, the domain of vocational psychology has evolved to include a broader definition of work over the course of a life span in the context of educational, sociocultural, and economic influences. This includes the study of the role of work in people's lives and psychological health (Blustein 2006). Currently, vocational psychology is identified as a discipline primarily within the field of counseling psychology, with contributions from other applied specialties in industrial-organizational, educational, and rehabilitation psychology.

Historical Background

The vocational guidance movement in the USA developed in the early 1900s (Baker 2009). While there were benefits generated by the Industrial Revolution and the prevailing laissez faire economic view of industrial growth, there were also undesirable social consequences such as exploitation of workers (particularly children and immigrants), urban overcrowding and public health risks, and an increasing disparity between the rich and the working poor. Calls for reforms included the view of education as a right for all citizens. Frank Parsons, a social activist leader of the Progressive Movement, established the Vocation Bureau in Boston to provide education for the working poor and to help youth make wise decisions about their occupational futures. In his book, *Choosing a Vocation*, Parsons (1909) outlined a three-step paradigm that established a foundational framework for vocational choice and counseling:

- In the wise choice of a vocation, there are three broad factors: (1) a clear understanding of yourself, your aptitudes, abilities, interests, ambitions, resources, limitations, and their causes; (2) a knowledge of the requirements and conditions of success, advantages and disadvantages, compensation, opportunities, and prospects in different lines of work; (3) true reasoning on the relations of these two groups of facts. (p. 5)

The early development of a scientific basis for vocational psychology applied the psychology of individual differences (also called differential psychology or correlational psychology) to measuring a person's interests, abilities, values, and other vocational attributes, also known as self-knowledge. This was the first factor in vocational choice proposed by Parsons. The science of psychological and educational testing was also used to develop assessment measurements of the structure of work, i.e., occupational attributes and related educational and environmental aspects. Vocational knowledge was the second factor proposed by Parsons in vocational choice. The third factor was the degree of fit or match between personal attributes and occupational attributes, or reasoning on the relations between self-knowledge and vocational knowledge. In the first half of the twentieth century, research in vocational measurement (e.g., in education and military personnel selection) formed the basis of a matching model for person–environment fit, also known as trait-and-factor approaches, in vocational psychology theory development. John Holland's (1959, 1997) theory proposed that vocational choice and adjustment were maximized when individuals pursued careers in environments that matched with their personality type. The structural arrangement of Holland's six vocational personality types approximating a hexagon has been: (a) broadly used and well replicated in research; (b) applied to developing the most widely used vocational interest assessment measurements; and (c) used as a basis for counseling and self-directed tools for vocational exploration and choice, thus extending application of Parsons' framework.

The Theory of Work Adjustment (Dawis and Lofquist 1984), like Holland's (1997) theory, was also based on views of person–environment fit. While Holland's theory focused more on vocational choice, the theory of work adjustment predicted job satisfaction

and tenure (length of time in a job) by assessing the degree of fit between aspects of the individual (such as the employee's abilities and values) and aspects of the work environment (such as the ability requirements of the job and the employer's expectations). René Dawis and Lloyd Lofquist initially developed this theory as a framework to understand the data they had collected from empirical research on how to help vocational rehabilitation clients to adjust to work after a disability (Dawis 2005). Continuing from this scientific foundation, research to date has supported many of the theory's predictions with individuals from some groups. Much research has focused on the development of theory-guided assessments that are archived at the University of Minnesota. The theory of work adjustment has been used in vocational counseling practice to help clients who are dissatisfied with their jobs consider strategies and options for career change or adjustment to a current job.

Another foundational theory in vocational psychology was proposed and refined in the second half of the twentieth century by Donald Super (1957, 1990). Influenced by the discipline of developmental psychology, Super's theory of vocational development viewed vocational choice as a process over the life span that varied by individuals' life roles at different life stages. From Super's theoretical view, vocational choice is not a single event but rather an adjustment process of many vocational choices that are expressions of one's evolving self-concept made in the developmental course of one's life and changing roles. Super's theory spurred several longitudinal research projects; however, most results have not supported specific propositions of the theory. Nevertheless, Super's basic thesis, that vocational choice and adjustment is a process of development, has been well supported. Super's theory has been widely used as a framework for vocational identity development and career exploration activities in schools for children at elementary, middle, and high school levels. Assessment measures and tools guided by Super's theory have been developed for vocational counseling activities with college students and adults. Drawing on various theoretical perspectives, Super continued to develop and refine his theory until his death in 1994, and his theoretical propositions were published posthumously (Super et al. 1996). Savickas (2005) has continued to update Super's theory and has

incorporated a constructivist perspective, focusing on how individuals identify meaningful life themes in their career stories and actively facilitate career adaptability in their vocational choices and decisions.

Linda Gottfredson's (1981, 2005) theory of circumscription and compromise was also based on the view of vocational choice as a developmental process rather than as an event. Modifying Super's (1957) idea of self-concept, Gottfredson's theory focused on cognitive development from childhood through early adolescence to explain why individuals' vocational expectations vary by gender and social class. She proposed that as children grow in their awareness of themselves and their social place in the world, they begin to eliminate vocational options that do not seem compatible with their evolving self-image. Relatively little research attention has been devoted to evaluating Gottfredson's developmental theory of vocational aspirations. However, the theory has been used to ground vocational counseling interventions with children, adolescents, and adults.

Vocational psychology theories also evolved from social learning and social cognitive perspectives. John Krumboltz (1979, 1996) proposed a social learning theory of career choice and decision making. Krumboltz's premise was that individuals make vocational decisions based on beliefs they develop about their vocational preferences and aversions from their learning experiences in social interactions with their environment. Krumboltz's theoretical approach originated from general learning theory, rooted in reinforcement theory and classical behaviorism, and evolved to applications of cognitive behavioral theory. Research has supported some hypotheses generated by the social learning theory of career choice and decision making, particularly in the use of reinforcement and modeling with different media in group and individual settings. Based on his theory, Krumboltz developed occupational simulation tools and an assessment measure of career beliefs. His theory has been used in vocational counseling interventions with individuals in early adolescence through adulthood.

A relatively new vocational psychology theory that has been used to generate substantial research in recent decades is the social cognitive career theory of Lent et al. (1994, 2000). Self-efficacy theory, as one approach to the more general study of social learning and social

cognitive theory, was first used by Hackett and Betz (1981) to study applications to vocational behavior (to explain occupational segregation by gender). Anchored in an integration of social cognitive theory (Bandura 1986) and previous vocational theories, Lent and colleagues' social cognitive career theory focused on a model of how several psychological variables (self-efficacy, outcome expectations, and goals) interact with other personal background and environmental variables (such as gender, race/ethnicity, social supports, and barriers) to predict vocational interests, choices, and performance. Research has supported the use of this theory to understand a wide range of vocational behaviors across many developmental levels with individuals of both genders and various racial/ethnic and culturally diverse groups.

Key Issues

This section includes an overview of major vocational psychology theories. Key issues of each theory are organized by the following subheadings: Explanatory Propositions, Assessments and Interventions, and Research Evaluating the Theory.

Holland's Theory of Vocational Personality Types and Work Environments

Explanatory Propositions. Holland's (1997) theory is based on the premise that by late adolescence most people resemble a fairly stable combination of six types of personalities, or expressions of vocational interests, for which there are corresponding types of work environments. He proposed that the quality of individuals' vocational choices and adjustment varies by the degree of fit between their personality and work environment. Individuals typically can be described as resembling one dominant personality type among the six, along with one or two other types that are secondary. Each personality type describes a characteristic set of activity preferences, values, attitudes, competencies, and problem-solving styles. Drawn from repeated empirical investigations, Holland proposed the following six (RIASEC) personality types: Realistic (R), Investigative (I), Artistic (A), Social (S), Enterprising (E), and Conventional (C).

The Realistic personality type prefers technical, athletic, or outdoors activities and environments

that involve practical, objective, tangible, ordered, or physical manipulation of objects, tools, equipment, machines, plants, or animals. Realistic people may have mechanical problem-solving abilities, psychomotor skills, or physical strength. They may avoid activities demanding subjectivity, artistic expression, or social interactions. Realistic types are often described as reliable, practical, frank, thrifty, modest, natural, or athletic.

The Investigative personality type prefers activities and environments that involve systematically observing, learning about, evaluating, or solving abstract or ambiguous problems. Investigative people may have analytical, scientific, or mathematical abilities. They may prefer to work independently and avoid leadership tasks. Investigative types are often described as intellectual, curious, methodical, rational, and reserved.

The Artistic personality type prefers activities and environments that are unstructured, flexible, and free to allow self-expression, imagination, or creativity. Artistic people may have musical, literary, dramatic, or other artistic abilities (e.g., dancing, drawing, painting, sculpting, or designing). They may avoid activities demanding conformity or systematically ordered tasks. Artistic types are often described as expressive, original, intuitive, innovative, nonconforming, unconventional, or impulsive.

The Social personality type prefers activities and environments that involve informing, explaining, guiding, leading, or helping others. Social people may have interpersonal, verbal, teaching, or empathic abilities. They may prefer educational, therapeutic, or religious activities, and they may avoid mechanical activities. Social types are often described as helpful, humanistic, idealistic, ethical, responsible, cooperative, tactful, friendly, generous, patient, empathic, or insightful.

The Enterprising personality type prefers activities and environments that involve influencing, leading, or managing people. Enterprising people may have leadership, selling, speaking, financial, or managing abilities. They may value economic or political recognition and avoid scientific activities. Enterprising types are often described as persuasive, self-confident, enthusiastic, optimistic, ambitious, or competitive.

The Conventional personality type prefers activities and environments that involve organizing data and implementing detailed instructions. Conventional

people may have organizational, clerical, or numerical abilities. They may avoid ambiguous, unstructured, or unsystematic activities. Conventional types are often described as conscientious, precise, accurate, orderly, self-controlled, conforming, persevering, or dependable.

Based on a large number of empirical studies, Holland's theory of person–environment fit is summarized by an approximately hexagonal structure that represents predicted relationships among the six types (see Fig. 1). Types adjacent to one another share more in common than types at opposite points on the hexagon. For example, Social types are more similar to Artistic types (S and A are adjacent on the hexagon) than they are to Realistic types (S and R are at opposite points on the hexagon). Holland asserted that an individual's personality is a combination of types. Typically, the focus of assessment and intervention is on the individual's three highest letter scores (e.g., a three-letter code of SAE, or summary code, indicates the individual scored highest in S, next highest in A, then next highest in E among scores on all six types). Holland proposed four theoretical constructs to examine predicted relationships among the six types: congruence, consistency, differentiation, and identity.

Congruence refers to the degree of relatedness or match between an individual's personality type and his/her current or prospective work environment. For example, a Conventional individual is considered to

Vocational Psychology. Fig. 1 Holland's hexagonal model of relationships among vocational personality and environment types (From Gottfredson and Holland 1996. Copyright © 1982, 1989, 1996 by Psychological Assessment Resources, Inc.)

have a highly congruent match if working in a Conventional environment compared to a less-congruent match if working in an Artistic environment. Congruence is hypothesized to predict vocational choice, satisfaction, and performance. For example, individuals may be more satisfied and perform better in environments that match more congruently with their personality types.

Consistency refers to the degree of relatedness or match between the types within an individual's personality composite. For example, an individual with Realistic and Conventional interests would be considered more consistent than an individual with Realistic and Social interests. Individuals with more consistent types within their personality composite are hypothesized to more easily match with corresponding work environments. Whereas, it may be more challenging for individuals with less-consistent types within their personality composites to find work environments that allow them to express the diverse aspects of their personality.

Differentiation refers to the degree to which an individual's personality or environment is defined as clearly resembling some types and not others. For example, an individual with the most highly differentiated interests possible would resemble one type alone. Whereas, an individual with the least differentiated interests possible would have identical scores on all six types. Theoretically, individuals with more differentiated personality types would have more clarity to make vocational choices that match with corresponding work environments.

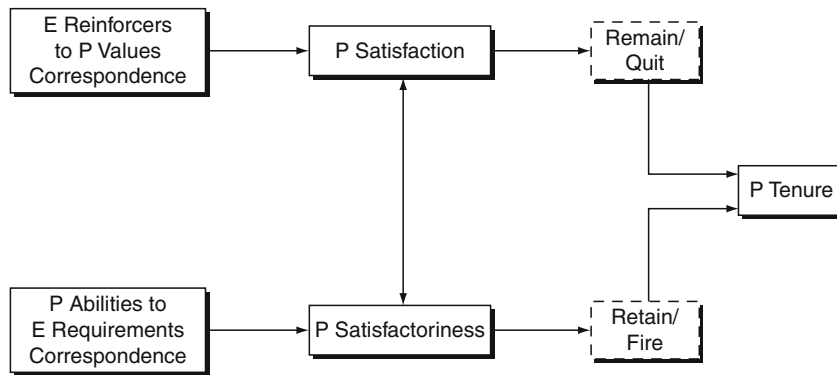

Identity in Holland's theory refers to a measure of the degree to which individuals or environments are clear and stable in their interests, talents, and goals. The constructs of consistency, differentiation, and identity are used to define the strength of personalities and environments. In sum, individuals with higher levels of identity, differentiation, consistency, and congruence with current or prospective work environments are predicted to be more satisfied, better adjusted, and stable over time.

Assessments and Interventions. Extensive research supports the practical applications of many of the theory's principles and related assessments and interventions for evidence-based career counseling practice. The strength of Holland's theory of person-environment fit is the relative ease with which it can be

understood and applied. Its strengths include the simple and intuitively meaningful premises on which the theory is based and its useful application with assessments to help individuals clarify how their interests may relate to vocational and avocational settings. Assessment instruments developed by Holland and others are commonly used to measure the theory's constructs, for example, the Self-Directed Search (Whitfield et al. 2009). The results from these assessments are used in career counseling and education to inform, explore, and promote vocational satisfaction and achievement. Other widely used vocational inventories include scales to assess Holland types. These include the Strong Interest Inventory, Armed Services Vocational Aptitude Battery, and O*Net governmental occupational system (Whitfield et al. 2009). The Dictionary of Holland Occupational Codes (Gottfredson and Holland 1996) is one example of a resource that links the Holland personality types with corresponding occupational classifications and information sources.

Research Evaluating the Theory. The body of research examining the validity of Holland's theory is the most extensive of any theory in vocational psychology. Overall, much of the research supports the six types, the underlying structure approximating hexagonal or circular relationships among the types, and the validity of instruments to measure vocational personality or interest types. On balance, research has found a modest relationship between person-environment congruence and job satisfaction. Limited research has supported the theoretical relationship between consistency and differentiation to vocational outcomes. Recent research that examines the validity and utility of Holland's theory with international cross-cultural groups is accumulating.

Some research has found that Holland's theory may apply across gender, ethnicity, and socioeconomic status in US samples of adolescents and adults (Spokane and Cruza-Guet 2005). However, employment data continue to show that women, members of racial/ethnic minority groups, and individuals of low-income status are disproportionately concentrated in lower-paying occupations within vocational types. Thus, caution is warranted in applications of Holland's theory if focused solely on personal preference without consideration of relevant sociopolitical and psychosocial barriers to career development.

Vocational Psychology. Fig. 2 Basic predictive model of the theory of work adjustment (Brown and Lent 2005. Copyright © 2005, by John Wiley & Sons, Inc.)

Theory of Work Adjustment

Explanatory Propositions. The theory of work adjustment (TWA; Dawis 2005; Dawis and Lofquist 1984), like Holland's (1997) theory, is based on the premise of person–environment fit and reciprocal interaction. Unlike Holland's and other career development theories that are primarily concerned with vocational choice, the TWA focuses on vocational adjustment. According to the TWA, individuals seek to achieve and maintain a sense of *correspondence* with their work environments, such that not only does the work meet the needs of the individual but also the individual meets the requirements of the work environment. Work adjustment outcomes include: the employee remains or quits, the employer retains or fires the employee, and tenure, which is the length of employment. These outcomes are predicted by both the individual's level of *satisfaction*, or how well his or her needs and values are fulfilled by the work, and the individual's level of *satisfactoriness*, or how well his or her abilities fulfill the requirements of the work environment.

The basic predictive model of the TWA is depicted in Fig. 2. The TWA proposes that people have needs, defined as values (e.g., safety, comfort, altruism, autonomy, status, and achievement), that may correspond with rewards of work environments or patterns of reinforcer factors (e.g., job security, compensation, working conditions, opportunities for advancement or to provide service). The level of correspondence or match between the person's values and the work environment's reinforcers are hypothesized to predict job satisfaction. In addition, the TWA proposes that

a person's satisfactoriness for a job can be predicted by the degree to which that person has a set of abilities that corresponds with the skill requirements of the work environment.

The TWA proposes that four personality style variables may influence how an individual interacts with the work environment: celerity, pace, rhythm, and endurance. Celerity refers to the speed with which workers initiate interaction with their work environments (e.g., quickly and impulsively or slowly and deliberately). Pace refers to the intensity or activity level of individuals' interactions with their work environments (e.g., with high energy or calmly). Rhythm refers to the pattern of interaction (e.g., steady, erratic, cyclical), and endurance refers to the degree of sustaining interaction. These four variables may help explain why individuals with similar values and abilities experience different levels of correspondence within a given work environment. These variables may be also used to characterize the structure of the work environment in terms of the nature of interactions reinforced with its workers.

From the perspective of TWA, correspondence and discordance (matching and mismatching) is a dynamic process because both the needs of the individual worker and the demands of the work environment change over time. Dissatisfaction on the part of either the person or work environment serves to motivate adjustment to restore equilibrium in the system. When there is a discordance between an individual's needs and values and the rewards provided by the job, there are ranges of tolerable and intolerable levels for maintenance or adjustment responses.

Individuals, for example, may remain within a range of tolerable discordance to the degree to which they can adapt with *flexibility* and *perseverance*. At the point at which the discordance becomes intolerable, the individual may attempt to adjust via an *active mode*, to make changes in the work environment (e.g., request a raise or promotion), or via a *reactive mode*, to make changes within oneself (e.g., learn more efficient time management skills). If the individual's strategies to adjust are unsuccessful and the level of discordance exceeds a tolerable and manageable level for adjustment, then he or she may change to another work environment or be fired. Over time, individuals develop a characteristic adjustment style, which can be useful information in career counseling.

Assessments and Interventions. The TWA can be used to help clients explore the sources of their job dissatisfaction and consider various options for work adjustment. Career counseling interventions grounded in the TWA commonly use assessments of abilities, values, and work requirements to facilitate matching individuals with corresponding work environments, diagnosing mismatches, and exploring strategies for work adjustment. Several assessment instruments have been empirically developed or used to test and apply the TWA, including the Minnesota Importance Questionnaire, Minnesota Job Description Questionnaire, Minnesota Satisfaction Questionnaire, and Minnesota Satisfactoriness Scales (archived and available through the website, Vocational Psychology Research, University of Minnesota).

Research Evaluating the Theory. A strength of the TWA is its empirical foundation and development in research. Strong support has been found for the theory's predictions of satisfaction, satisfactoriness, and tenure. There have been few studies and minimal support for the predicted relationships between the theory's personality style variables and work adjustment. While the research on the TWA has been predominantly with Caucasians, there has been some research to support applications of the theory with women and US racial/ethnic minority groups.

Super's Life-Span, Life-Space Theory of Career Development

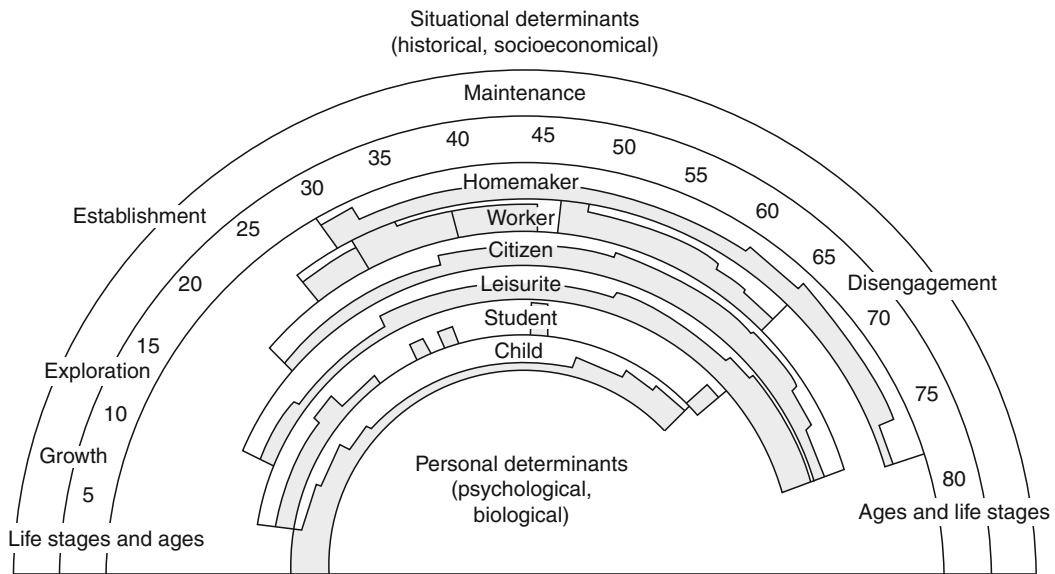

Explanatory Propositions. Super's Life-span, Life-space Theory of Career Development (Super 1957, 1990;

Super et al. 1996) evolved into 14 theoretical propositions, and his theory is depicted by a Life-Career Rainbow (see Fig. 3). Super viewed vocational development as a process of making career and life decisions, through developmental stages over the course of one's *life span* in relation to the importance of various life roles one holds in each stage, or one's *life space*. Career development is an adjustment process of many vocational choices that are expressions of one's evolving self-concepts made in the developmental course of one's life and changing roles. Various personal determinants (e.g., interests, abilities, values, needs) and situational determinants (e.g., family, community, economy, society) contribute to shaping the constellation of one's life roles over the course of one's life span, and these determinants interact to influence the development of one's self-concepts.

Super defined *self-concept* as one's image of oneself in a role, situation, or position engaged in performing a set of functions or in connection to one's relationships. One's self-concepts include both objective and subjective aspects. Objectively, individuals develop self-understanding by comparing themselves with others on given normative standards. Subjectively, individuals develop self-understanding through the meanings they construct from their personal life experiences and unique life stories.

According to Super, individuals differ in their personal characteristics and thus may be suited for several different occupations. Individuals also differ in the degree of importance or salience they attach to their work role relative to other life roles at any given stage of life. At various times, some life roles may expand and take priority over others (represented in the Life-Career Rainbow by the width of shading across life roles). Super noted nine common life roles that individuals hold, sometimes concurrently, over the course of a life span: child (son or daughter), student, leisurite, citizen, spouse (or partner), homemaker, parent, and pensioner (six life roles are shown in Fig. 3).

Super proposed that the career development process comprised an approximate sequence of five major life stages (or *maxicycles*): Growth (ages 4–13), Exploration (ages 14–24), Establishment (ages 25–44), Maintenance (ages 45–65), and Disengagement (over age 65). In response to various life events or transitions between stages, individuals may undergo smaller

Vocational Psychology. Fig. 3 Super's life-career rainbow (From Super 1990. Copyright © 1990, Jossey-Bass Inc.)

minicycles or recycling that involves new growth, re-exploration, and re-establishment. Within each stage, Super proposed characteristic developmental tasks for which successful mastery enables effective functioning and readiness to cope with the demands of the next stage. He proposed the construct of *career maturity* as a measure of one's readiness to master the developmental tasks of each stage effectively, particularly at earlier stages of development. For the developmental tasks of adults, the concept of *career adaptability* may better describe one's readiness to cope with changing work, working conditions, and career-life roles.

Assessments and Interventions. Super's theory culminated in an intervention model called the Career Development Assessment and Counseling (or C-DAC) model. This model applies three key aspects of Super's theory (life span, life space, and self-concept) to help individuals articulate their career concerns, examine the relative salience of their various life roles, and clarify their self-concepts. For clients seeking help in coping more effectively with changing demands or conflicting life roles, career interventions may focus on how they can make more satisfying adjustments in the process of career transitions. Super's developmental career theory has grounded career assessment and

interventions with elementary, middle, high school, and college students to help them develop competencies by learning more about themselves, exploring related careers and pathways, and planning and implementing strategies leading to future careers. Examples of assessment instruments developed or used to apply Super's theory include: the Career Development Inventory, Adult Career Concerns Inventory, Salience Inventory, Values Scale, and Career Maturity Inventory. Super's theoretical concepts have also been integrated in widely used comprehensive career assessment systems for educational and career planning.

Research Evaluating the Theory. Super's extensive body of writing on career development has significantly influenced the study of vocational psychology. A large body of research generally supports Super's theory and its foundational constructs. His theory has provided a useful framework for helping clients in developmental transitions to clarify their career-life role identities and the values they seek to express in their life roles. Yet, several of his theoretical propositions remain to be empirically tested. While there is some evidence of support for applications with women and racial/ethnic minority groups, group differences found in the relative importance of life roles and values suggest further research is needed within specific

developmental and cultural contexts. For example, research might examine the influence of current economic changes and the role of barriers for career development with women and various cultural minority members. Finally, research has provided useful examples of systematic applications of the C-DAC model.

Gottfredson's Theory of Circumscription and Compromise

Explanatory Propositions. L. Gottfredson's (1981, 2005) theory of circumscription and compromise offers a developmental and sociological perspective of career development. In common with Super's theory, Gottfredson's theory focuses on the process of career development as an expression of evolving self-concepts. Gottfredson's theory is distinguished by its focus on cognitive development from childhood to early adolescence to explain why individuals' vocational expectations become constrained by gender and social class stereotypes. She proposed that as children grow in their awareness of themselves and their social place in the world, they begin to eliminate vocational options that do not seem compatible with their evolving self-image on the basis of occupational stereotypes related to gender and prestige.

Gottfredson's theory emphasizes that individuals' understandings of the self and occupations develop early. The theory focuses on children's developing understandings of the social aspects of their self-concept (e.g., gender, social class, intelligence) more than personal aspects (e.g., interests, traits, values). With the growth in children's cognitive capacity to think abstractly, they form cognitive maps that categorize occupations based on dimensions of sex-type (masculinity–femininity), occupational prestige, and field of work. Over time, they may consider whether different occupations are compatible with their evolving self-concepts about gender (most important), prestige (next most important), and vocational preferences (relatively least important). By a process of *circumscription*, young people begin to progressively eliminate unacceptable occupational alternatives relative to their perceived self-concept and based on gender and prestige stereotypes. Through a process of *compromise*, they eliminate options and narrow their occupational choices to those that seem accessible. Thus, as children's self-concepts increase in

complexity and clarity regarding their perceived place in the social world of work, they progressively eliminate occupational options and develop vocational aspirations constrained by gender and prestige stereotypes. While the process of circumscription and compromise occurs gradually and, typically, without conscious awareness, individuals may be helped to reconsider vocational options they have ruled out as unacceptable in sex-type and prestige through formative new learning experiences or changes in their social environment.

Gottfredson proposed four stages of cognitive development to describe the circumscription process in career development. In Stage 1 (ages 3–5), Orientation to Size and Power, children classify people in simple concrete terms, such as big versus little. They recognize observable physical differences between women and men. In Stage 2 (ages 6–8), Orientation to Sex Roles, children become aware of gender role differences between women and men. They tend to think dichotomously and view their own sex as superior to the other sex. In this stage, children use their understanding of gender appropriateness to define the boundaries of their vocational aspirations. During Stage 3 (ages 9–13), Orientation to Social Valuation, children become aware of social status and prestige. They no longer consider occupations that do not meet with the approval of their social reference groups. They further narrow down the boundaries of their vocational aspirations to those they consider of high enough prestige and not too difficult to attain. During Stage 4 (ages 14 and older), Orientation to the Internal, Unique Self, adolescents become more introspective, self-aware, and conscious of the need to explore occupational options among those congruent with their emerging sense of self. They shift their focus from previous stages to identifying which of the acceptable vocational alternatives are most preferred, with greater attention to the psychological self. Stage 4 marks the beginning of the process of compromise.

Assessments and Interventions. Gottfredson's theory highlights the importance of providing career development and education interventions to young people in earlier stages of development than late adolescence. Incorporating Gottfredson's theoretical perspectives, developmentally targeted interventions with children, adolescents, and young adults have focused on

exploring a broader range of occupational options and constructively addressing occupational stereotypes related to gender and prestige that might unnecessarily restrict alternatives considered.

Research Evaluating the Theory. Research on Gottfredson's theory has not been extensive, and results have been equivocal. However, there has been some evidence from longitudinal research that found support for Gottfredson's theory of circumscription and compromise. Moreover, her theory addresses an important gap in the knowledge base of vocational psychology in its emphasis on career development in childhood and potential antecedents for constrained vocational achievement by gender and social status.

Social Learning Theory of Career Choice and Decision Making

Explanatory Propositions. Krumboltz (1979, 1996) proposed a social learning theory of career choice and decision making, based on behavioral and reinforcement theories, for which he further developed career counseling applications (labeled a *learning theory of career counseling*). Krumboltz's theory is based on the premise that it is through a multitude of learning experiences in social interactions with their environment that individuals form beliefs about their vocational preferences and aversions. Individuals' beliefs and other outcomes of individuals' learning experiences influence the vocational decisions they make and actions they take. The goal of career counseling is to help clients expand their learning experiences about potential vocational interests and values, skills they might develop further or acquire, and beliefs that might facilitate them in creating satisfying lives.

Krumboltz proposed that four factors influence career decision making:

1. *Genetic endowment and special abilities.* Innate aspects or inherited characteristics, rather than those that are learned, can be influences that restrict or enhance an individual's career development. Some examples are physical appearance; gender; race/ethnicity; musical, artistic, or athletic ability; intelligence; and predispositions to certain diseases.
2. *Environmental conditions and events.* Factors generally beyond one's control that may influence vocational options and opportunities include a range of cultural, social, political, economic, and natural forces. Some examples are government-sponsored employment and training opportunities; labor laws and union policies; technological developments; geographical location; cultural traditions; family, neighborhood, and community resources; educational systems; and natural disasters such as earthquakes and floods.
3. *Learning experiences.* *Instrumental learning experiences* occur when an individual gains knowledge or skills by acting on the environment to produce certain consequences. For example, a military veteran might use her education benefits to complete a degree program, learn new skills, and obtain a civilian job. *Associative learning experiences* occur when an individual gains knowledge or skills by observing real or fictitious models or by pairing events in time or location. For example, a student might learn about a new and interesting occupational option by attending a career fair and interacting with a representative.
4. *Task approach skills.* These are the competencies with which an individual approaches a task or a problem. Examples include work habits, performance standards, and values, perceptual and thought processes, decision-making skills, and problem-solving skills. Task approach skills not only influence outcomes but also in turn these skills themselves are modified by the outcomes.

From Krumboltz's theoretical perspective, the continuous interaction process with learning experiences and other factors produces four types of consequences: self-observation generalizations, worldview generalizations, task approach skills, and actions or steps taken to make progress in one's career. To address career decision-making concerns, Krumboltz suggests that career counselors can help clients to acquire more accurate self-observation generalizations and worldview generalizations (e.g., knowledge of oneself and the work world), learn new task approach skills, and take constructive actions to implement career choices and decisions. Furthermore, Krumboltz asserts that career counselors can help clients to: (a) expand their interests and capabilities and explore new career options; (b) prepare for an ever-changing work world by learning new skills and developing effective coping strategies;

(c) be empowered to take action to implement career decisions and be provided with ongoing assistance in the process of adjustment; and (d) address a range of career-related concerns beyond identifying a career choice, such as family members' reactions to career choices, job burnout, relationships with coworkers, and underemployment.

Assessments and Interventions. Krumboltz's theory has been used with individuals in early adolescence through adulthood in career counseling and educational interventions, using methods that are developmental, preventative, and remedial to address career concerns. One example of a social learning model of career counseling is the seven-step DECIDES model. Another example of an approach to career counseling advocated by Krumboltz is *planned happenstance*, or taking advantage of unexpected career opportunities (Krumboltz 2009). For interventions grounded in Krumboltz's theory, assessments are used to help clients identify suitable educational and occupational options as well as venues to investigate new learning possibilities. In addition to assessments commonly used in career development interventions (e.g., the Strong Interest Inventory, Myer's-Briggs Type Indicator, Values Scale), Krumboltz developed the Career Beliefs Inventory to help individuals identify beliefs that might hinder or facilitate them in achieving their career goals. He also developed various occupational simulation tools for career exploration.

Research Evaluating the Theory. Research on Krumboltz's social learning theory of career choice and decision making has been limited. Some evidence has supported certain hypotheses generated by the theory, particularly in the use of reinforcement and modeling with different media in group and individual settings.

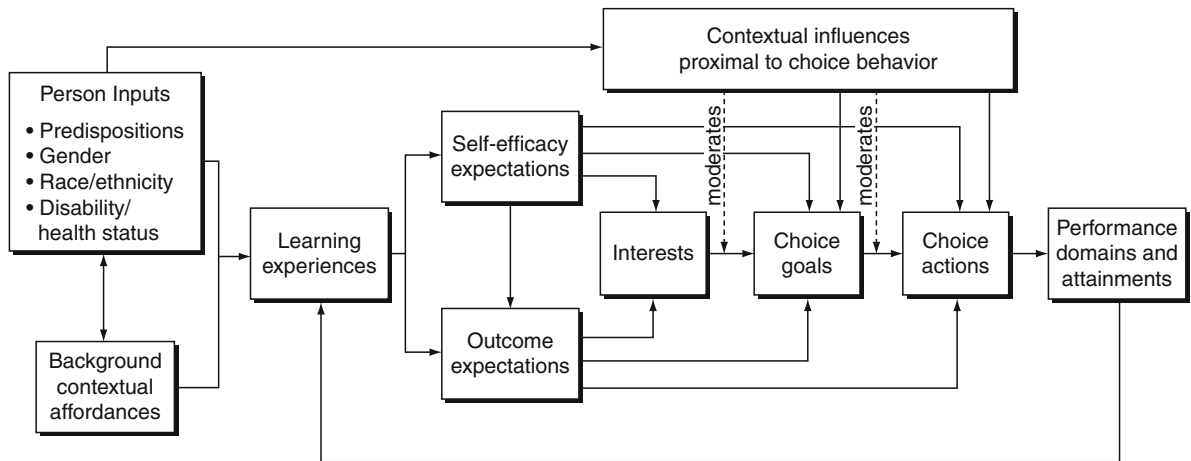

Social Cognitive Career Theory

Explanatory Propositions. The social cognitive career theory (SCCT; Lent et al. 1994, 2000; Lent 2005) provides a unifying conceptual framework for elements identified in previous career theories. SCCT is designed to help explain and predict how people: (1) develop vocational interests, (2) determine successive occupational choices, and (3) attain varying levels of career success and stability, or achieve performance outcomes. Applied to the domain of vocational psychology, SCCT

incorporates elements of Bandura's (1986) general social cognitive theory and its emphasis on a triadic reciprocal model of causality such that personal attributes, environmental factors, and overt behaviors mutually influence one another. Within this model, SCCT highlights self-efficacy beliefs, outcome expectations, and personal goals as the cognitive means by which individuals have personal agency to direct their own vocational behavior. Lent et al. propose that demographic and individual difference variables, or *person inputs* (e.g., predispositions, gender, race/ethnicity, disability/health status), interact with environmental variables, or *background contextual affordances*. These factors influence learning experiences that in turn lead to developing self-efficacy beliefs and outcome expectations (see Fig. 4).

Bandura (1986) defined *self-efficacy beliefs* as individuals' judgments or confidence about their ability to successfully perform a specific task or behavior (e.g., relevant to the question, Can I pass this math exam?). Individuals' *outcome expectations* are beliefs about the likely results (successful or unsuccessful) of performing a specific task or behavior (e.g., What job opportunities am I likely to have if I earn a degree in engineering?). From the view of SCCT, self-efficacy may override the influence of outcome expectations on career behavior (e.g., Even though I expect to have more job options with a degree in engineering, I am not likely to enroll in an engineering program if I have low confidence in my math ability). Extending Bandura's theory, SCCT notes that one's self-efficacy beliefs are subject to change and develop in response to four sources or types of learning experience: (1) personal performance accomplishments (e.g., a good or poor grade on a math exam), (2) vicarious learning (e.g., observing models of successful or unsuccessful math performance), (3) social persuasion (e.g., being encouraged or discouraged by a math teacher), and (4) physiological and affective states and reactions (e.g., an excessive level of anxiety while taking a math exam).

Individuals' *personal goals* may be defined as their intention to engage in certain activities to produce particular outcomes (Bandura 1986) (e.g., relevant to the question, How much do I want to earn a degree in engineering and how well do I want to do this?). In SCCT, *choice-content goals* comprise the type of activity or career one wants to pursue, and *performance goals*

Vocational Psychology. Fig. 4 Social cognitive career theory model of person, contextual, and experiential factors affecting career-related choice behavior (From Lent et al. 1994. Copyright © 1993, by R. W. Lent, S. D. Brown, and G. Hackett)

include the level or quality of performance one plans to achieve within a chosen activity or career. These goals provide an important means by which individuals exercise personal agency in their educational and occupational pursuits. Personal goals help to organize, guide, and sustain behavior over time (e.g., I will persist in learning math and earning good math grades because it is an important step toward completing my engineering degree and obtaining a job as an engineer). SCCT maintains that individuals' choice and performance goals not only are affected by but also, in turn, affect their self-efficacy and outcome expectations.

In addition to environmental realities, from the view of SCCT individuals play an active role in understanding contextual influences by cognitively interpreting, rather than passively observing, their surroundings. Environmental or contextual factors define the opportunity structures within which individuals formulate and implement career choices. These include: (a) distal influences or background affordances that shape learning experiences (e.g., childrearing environments and role models) and (b) proximal determinants (e.g., institutional barriers) that moderate vocational choice behaviors. Individuals' perceptions of contextual factors as barriers or supports may influence their vocational choice behaviors at certain points and through certain pathways in the SCCT model (see Fig. 4).

Assessments and Interventions. SCCT has been used as an organizational framework for developmental, preventative, and remedial career interventions with young children; students at elementary, middle, and high school levels; college students; and adults. The four types of learning experiences proposed to form self-efficacy beliefs have been used to guide psychoeducational interventions in specific skill domains to promote targeted development of vocational interests and aspirations. SCCT has also been applied in intervention approaches to help individuals expand the range of potentially satisfying career options by reexamining those on which they may have prematurely foreclosed. Career counselors administer standardized assessments that help clients to clarify their interests, skills, and values by focusing in particular on discrepancies in the results between the occupational options generated by the various measures. For example, results from the Strong Interest Inventory and Skills Confidence Inventory (Whitfield et al. 2009) are compared and options are considered for developing stronger self-efficacy in a vocational domain of high interest. In another approach, a card sort exercise is used to help individuals reconsider previously discarded career options by reexamining their reasons specific to self-efficacy and outcome expectations and then exploring alternative strategies. Finally, career interventions have been developed using an SCCT framework to help individuals

cope with barriers and build support to implement their career choices, promote work satisfaction, and facilitate work performance.

Research Evaluating the Theory. A large body of research on SCCT has accumulated in the past decades, and the predominant focus has been on self-efficacy. Substantial empirical support has been found for the theory's constructs, hypotheses, and model in understanding educational and career behavior during preparatory, transition, and adjustment phases of career development. Many studies have demonstrated positive outcomes for SCCT-based interventions with diverse client groups.

International Perspectives

Changes in the work world prompted by rapid technological growth, shifting economies, and globalization are concerns for international vocational psychology scholars and practitioners. Comparative or cross-national perspectives to address these concerns have been debated, for example, at the 2007 joint symposium of the International Association for Educational and Vocational Guidance, Society of Vocational Psychology, and National Career Development Association (Schultheiss and Van Esbroeck 2009). One theme addressed at this joint international symposium concerned the appropriateness of adapting vocational theories, assessments, and techniques constructed in one cultural context for use in another cultural context. Some maintained that traditional vocational psychology theories developed in the USA may be usefully revised for international applications. Whereas, many others offered a range of alternative recommendations for developing indigenous theories to inform vocational practice, research, and training that integrate local and global perspectives.

Future Directions

Theories in vocational psychology that inform what works best for whom and under what conditions can be used to expand access to educational and occupational attainment for all people, including marginalized and underserved groups. Models in vocational psychology theory and practice are evolving to attend to and more helpfully address influences of gender, age, race/ethnicity, culture, sexual orientation, socioeconomic status, and health/disability issues (Croteau

et al. 2000; Swanson and Fouad 2010). Other emerging theoretical perspectives in vocational psychology and career development are constructivist and narrative approaches to understanding the subjective experiences of clients and connecting their life themes to career goals (Savickas 2005).

Psychology-of-Working Framework

An emerging theory with implications for counseling practice and public policy is David Blustein's (2006) psychology-of-working framework. Blustein's framework was developed in response to critiques of the narrow applicability of prominent vocational theory, research, and practice that are focused on a relatively small proportion of people with the greatest access to, and choice in, educational and occupational opportunities. Blustein has proposed a broader conceptual framework that may be relevant for the majority of people worldwide who have more limited access to education and jobs that readily accommodate their interests, abilities, hopes, and values. As a constructive response to critiques by Richardson (1993) and others, Blustein's psychology-of-working perspective includes addressing the role of work in people's lives and considering the intersections of work with other life roles. Blustein's framework is intended to be used in conjunction with existing career development theories. Furthermore, because the role of work is central in people's psychological health and well-being, relevant research is needed to inform vocational psychology theory and practice (Blustein 2008).

Von Helmholtz, Hermann

ROGER K. THOMAS

University of Georgia, Athens, GA, USA

Basic Biographical Information

Helmholtz (1821–1894) was born in Potsdam, Germany, where his father taught languages and philosophy at the *Gymnasium* (secondary school) where Hermann attended. His mother was a descendant of William Penn, after whom the colony, later, the state of Pennsylvania (USA) was named. After completing studies at the *Gymnasium*, Helmholtz wanted to study physics, but financial considerations led him to study

medicine in Berlin, free of charge, in return for an 8-year service commitment to the Army. He studied under the great Johannes Müller, and among his friends and fellow students were Emil Du Bois-Reymond, Ernst Brücke, and Karl Ludwig. Despite Müller's acceptance of *vitalism* (the belief that life is based on a supernatural "force"), these students had in common opposition to it, and Helmholtz's research would serve well the rejection of vitalism.

Helmholtz's medical dissertation (1843) and his early work on conservation of energy (*Über die Erhaltung der Kraft*, 1847) gained him an offer to become Associate Professor of Physiology at the University of Königsberg which resulted in early release from his military commitment. He stayed at Königsberg from 1848 to 1855 when, among other accomplishments, he invented the first operational ophthalmoscope. In 1855, Helmholtz moved to the University of Bonn as Professor of Anatomy and Physiology, and in 1858, he became Professor of Physiology at the University of Heidelberg where he remained until 1871. Based largely on his extensive work in the physics of light and sound, in 1871, he was offered and accepted the Chair in Physics at the University of Berlin, the most prestigious chair in physics in Germany. He remained in Berlin until his death. While in Heidelberg, Wilhelm Wundt, a founder of experimental psychology, worked under Helmholtz as an assistant. In Berlin, Helmholtz's student, Heinrich Hertz, conducted investigations suggested initially by Helmholtz of James Clerk Maxwell's electromagnetic theory of light. Hertz was the first to demonstrate the existence of electromagnetic waves, the basis for wireless telegraphy among other things; it was in Hertz's honor that Hz became the unit for measuring wavelength. A significant American post-doctoral student in Helmholtz's laboratory was Christine Ladd-Franklin who became internationally famous for improving Helmholtz's theory of color vision.

Major Accomplishments/Contributions

Had Nobel Prizes existed during Helmholtz's lifetime, reasonable arguments can be made that he might have received a minimum of four, one for formalizing the principle of the Conservation of Energy, one for being the first to measure the speed of a nerve conduction,

one for his research and theories in vision, and one for his research and theories in audition. Disputes arose regarding priority for the Conservation of Energy principle, but Helmholtz freely acknowledged prior work and stayed above the fray. Upon his death, his classic paper was deemed by *Physical Review* to be "chief of the early attempts to give expression to the principle" (Gruber and Gruber 1956). Ironically, the paper had been rejected as too theoretical in 1847 and was published as a private pamphlet. Formalization of the principle of Conservation of Energy together with measuring the speed of nerve conduction (1850), previously deemed to be in a supernatural realm, helped to destroy vitalism, thereby, enabling biology to begin making great advances.

Helmholtz's accomplishments in the field of vision were too many to mention here, but they included the three-volume *Handbuch der Physiologischen Optik* (1856–1866), a thorough compendium of knowledge concerning vision, including much research conducted by Helmholtz himself. Other than the ophthalmoscope mentioned earlier, he is perhaps best remembered for his trichromatic theory of color vision and for his anatomical explanation of how the lens of the eye accommodates for near and far vision. Aply anticipated by Helmholtz's vision research and trichromatic theory was the subsequent Nobel Prize winning research associated with identification of retinal chemicals and processes that enable color vision (e.g., research by Ragnar Granit, H. K. Hartline, and George Wald).

In audition, Helmholtz's book, *Die Lehre von dem Tonempfindungen* (*The Sensation of Tone*), similarly to the *Optik* handbook, summarized existing knowledge about audition including Helmholtz's extensive research findings and theories. His research in the physics of sound as well as his place theory of hearing led to refinements by Georg von Békésy that gained him the Nobel Prize in 1961.

Apparently, Helmholtz opposed the idea of the necessity for an experimental psychology believing that physiology was sufficient, and E. G. Boring (1950), the eminent historian, wrote that Helmholtz would have opposed "mentalism" as much as he had opposed vitalism. Nevertheless, Boring identified Helmholtz as a significant founder of experimental psychology for his work in vision and audition. Some have written (e.g., Gruber and Gruber 1956;

Warren 1984) that among Helmholtz's most important psychological theories was his theory of "unconscious inference" to explain, for example, how humans acquire the concept of space; later, Helmholtz acknowledged difficulties with the term and changed it to "inductive inference." As noted, Helmholtz applied unconscious inference to explain how humans acquire the concept of space through empirical experience. Opposing the "intuitionists" who argued that knowledge of spatial relations is innate and intuitive, Helmholtz argued that concepts of spatial relations are acquired through an accumulation of experiences, many of which we are unaware (unconscious) when they occur. His empiricism and material reductionism were so thorough that, again opposing the intuitionists, Helmholtz argued that inductive inference explained how humans acquired the fundamental axioms of geometry. This author is unaware of any detailed arguments that Helmholtz presented, but a reasonable extension of his views would be that all mental processes result from how accumulated experiences modify the chemical and physical properties of the brain at molecular levels.

Von Restorff, Hedwig

DAVID J. MURRAY

Queen's University, Kingston, ON, Canada

Basic Biographical Information

Hedwig von Restorff was born in Berlin on December 14, 1906. After an education focused on classical

languages, she entered the University of Berlin at the age of 20 and studied philosophy, psychology, and the natural sciences; she obtained her Ph.D. under the supervision of Gestalt psychologist Wolfgang Köhler (1887–1967) in the year 1933, the year of her first publication, announcing her discovery of what is known to this day as the "von Restorff effect" or "isolation effect" (von Restorff 1933). In the words of one reviewer: "In 1933 von Restorff reported a series of studies the results of which may be summarized in the following statement: Isolating an item against a crowded or homogenous background facilitates the learning of that isolated item" (Wallace 1965, p. 410).

By the time the article appeared in the prestigious Gestalt journal *Psychologische Forschung*, Köhler had left Germany for the USA; he had unabashedly expressed his disapproval of the newly elected Nazi régime (Crannell 1970; Henle 1978), and, like other Gestalt psychologists, had felt it necessary to emigrate. After staying on at Berlin, working as a research assistant, von Restorff decided to study for a medical degree and was licensed to practice medicine in 1939. In 1942, her marriage to another doctor, Helmut Trendelenburg, was disrupted when he went missing in action not far from Königsberg, where the Germans were fighting the Russians. At the end of World War II, von Restorff moved to Freiburg in the Black Forest region of Germany, where she became a family physician. She passed away on July 6, 1962.

Major Contributions

With respect to her contributions to experimental psychology, it should be noted that her 1933 findings were not serendipitous. It had been felt by Köhler that the ease with which verbal (and even nonverbal) material could be memorized was a function of how well sequences of adjacent to-be-remembered targets could be mentally grouped and visualized as self-contained mental representations. Expressed in a different way, whatever sequences were difficult to memorize would be sequences contained in a set of mental representations that were highly similar to each other in terms of meaning, visual, or aural quality, providing few self-contained and well-grouped memory representations. In other words, mental representations that stood out from the "crowd" of other memory representations concurrently in consciousness would be easier to

memorize and would, presumably, also be retained longer than would memory representations that were camouflaged or “lost” in that crowd. von Restorff’s doctoral research was aimed at confirming Köhler’s speculations, which had been clearly stated in his semipopular book *Gestalt Psychology* (Köhler 1929, pp. 156–157). To the second printing of this book, Köhler (1947) added the following footnote (p. 161):

- ▶ The outcome of these studies (those of von Restorff and others) is perfectly clear: series of nonsense syllables constitute a difficult material to learn, not so much because the items have no meaning as because in such monotonous series sub-groups do not spontaneously form. (Köhler 1947, p. 161)

The role played by the von Restorff effect in the history of memory theory has been twofold. First, as was hinted at by the mention of nonsense syllables in the above quotation, the effect should not be treated as just another of the many “grouping” effects associated with Gestalt psychology, particularly in experiments on human perception. From the time of its first being reported, attempts have been made to integrate it into the ongoing literature on “verbal learning.” The paired-associates learning task breaks down easily into an analysis in terms of “stimuli” and “responses.” As an example, we can list the following pairs of nonsense syllables used by Ranschburg (1905): ber-tof, kid-sem, bel-fam. The participant has to learn to reply “tof” if “ber” is presented, “sem” if “kid” is presented, and so on. “Ber” can be designated as a stimulus term to which “tof” is required as a response. This technique was believed to be useful in psychology because it was thought to facilitate the comparison of verbal learning in humans with classical conditioning in animals, where a stimulus that is normally emotionally neutral (e.g., the sound of a metronome) can come to elicit a new and uncustomary response (e.g., salivation) if the sound is paired repeatedly with another stimulus that is not emotionally neutral (e.g., food). The literature on paired-associates learning had actually started when Mary Calkins (1894), in the USA, had demonstrated that a pair of words that stood out from other pairs in the same list because of their vividness of meaning were more quickly learned, and better retained, than were other pairs in the same list. That is, something

like a von Restorff effect had already been demonstrated in the pioneering days of the verbal learning literature.

By the late 1930s, the literature on verbal learning was focused intensively on demonstrations of how interference in learning and in retrieval could be succinctly demonstrated in human paired-associates learning tasks. The German pioneers, Müller and Pilzecker (1900), had used a variant of these tasks (the so-called “method of hits”) to distinguish between what are now called retroactive and proactive inhibition, and the upshot of the Köhler/von Restorff program of research was to show that both kinds of interference could actually be ascribed to the “crowding together” of the memory representations of the stimulus terms and the response terms when two paired-associates lists, L_1 and L_2 , had been acquired one after the other. If L_1 had been learned first and had been followed by the learning of L_2 , it had been assumed that memory representations from L_2 caused interference with the recall of memory representations from L_1 (retroactive inhibition exerted by L_2 on the retrieval of L_1). Alternatively, L_2 might be more difficult to learn if preceded by L_1 than if it had not been preceded by L_1 (proactive inhibition exerted by L_1 on the acquisition of L_2). But this S–R competition model would eventually come to be contrasted with an isolation/crowding model according to which participants forget whether a stimulus term like “ber” or a response term like “tof” had come from L_1 or from L_2 .

During World War II, theories about the paired-associates task had been bolstered by the evidence of Melton and von Lackum (1941) that erroneous intrusions of learned responses from L_2 into attempted recalls of the learned responses of L_1 were fewer than what might have been expected. Melton and von Lackum therefore devised a two-factor theory of retroactive inhibition, the two factors being (a) response competition between memory representations from L_1 and L_2 and (b) a postulated process according to which L_1 representations had been “unlearned” in the course of acquiring the L_2 representations. A boost to studies of paired-associates learning was later provided by Martin’s (1965) evidence that stimulus-term learning, response-term learning, and stimulus–response associations could be experimentally dissociated. And it was propitious for Köhler’s cause that the first issue of

a new journal named *Memory and Cognition* opened with a major article by Postman and Underwood (1973) that reviewed the evidence then available on what they called a “failure of list differentiation,” that is, evidence that participants not only forget stimulus terms, response terms, and stimulus–response associations, but also forget whether a given word or syllable that had come to mind belonged to L_1 or L_2 . Moreover, John Ceraso (1967), who had worked as a research associate in Köhler’s laboratory at Swarthmore College, formulated, via a series of elegant experiments, a rigorous account of how the results of experiments on retroactive inhibition that had used paired associates could be accounted for in terms of “crowding” and “isolation” just as efficiently as they could be accounted for in terms of response interference. Murray (1995, pp. 119–123) has argued that there is a strong degree of consistency between the model put forward by Ceraso (1967) and a later model of retroactive inhibition put forward by Mensink and Raaijmakers (1988).

Second, the discovery of the von Restorff effect also had a major impact on theories of human memory, because it forced researchers to consider that an important variable determining how easily particular items in a list could be memorized might be how “distinctive” those items were relative to other items in the list. Murdock (1960) initiated attempts to quantify the relative distinctiveness of individual members of a list vis-à-vis other members of the list, attempts which have yielded fruit particularly in a distinctiveness model of serial learning put forward by Johnson (1991). It has generally been agreed that primacy and recency effects in serial learning, memory span tasks, and paired-associates learning can be associated with the extra distinctiveness associated with items at the start and end of a list (Crowder and Neath 1991).

With respect to the von Restorff effect in general, three review articles are particularly recommended. Wallace (1965) reviewed early research on the effect; his article is replete with good advice on methodological matters that are easily overlooked in experimentation on the effect. Schmidt (1991) reviewed the various pitfalls that can be associated with the indiscriminate use of the word “distinctiveness” in memory theory. Hunt (1995) summarized and interpreted research on the von Restorff effect, and he made available online a translation of von Restorff’s (1933) paper. Because

von Restorff had acknowledged Köhler’s help alongside her naming of her own authorship, the translator listed this translation as if its original authorship had been joint (Köhler and Restorff 1995).

However, that article was not the only one von Restorff wrote in collaboration with Köhler. Naming themselves as joint coauthors, Köhler and von Restorff (1937) also described an extended series of experiments designed to demonstrate how the nature of any memorizing activity carried out during a retention interval could determine the efficiency of recognition and/or recall of to-be-remembered material that had been presented prior to the onset of that retention interval. They drew the analogy between the temporal “in-between field” (the time interval elapsing between the presentation of to-be-remembered material and a repetition of the identical material) and the spatial “in-between field” (the physical distance between two visually identical objects displayed simultaneously). The shorter and “emptier” the spatial “in-between field,” the more likely would it be that the two objects would be perceptually grouped; the shorter and less activity-filled the temporal “in-between field,” the more likely would it be that the repetition of the original material would be mentally grouped with the memory representation of the original material itself, that is, the repeated material would be judged to be “identical” to the original material. The experiments reported in this underknown article were quite elaborate and have been summarized by Murray (1995, pp. 76–85).

Vygotsky, Lev

MARY-JANE E. OJIE, JOHN D. HOGAN
St John's University, Jamaica, NY, USA

Basic Biographical Information

Although Lev Vygotsky lived in a much earlier era, he is sometimes referred to as the most modern of developmental theorists. His writings have been rediscovered and found to have a great deal of resonance with contemporary thinking about development. Consistent with his position as a Marxist, much of his theory of development has emphasized the power of the historical and socio/cultural environment in shaping behavior. This is in contrast to the typical Western view that development occurs primarily from within the individual. At the same time, he was able to incorporate intrinsic factors into his theory. He is sometimes seen as the link combining these two different approaches to understanding development.

Lev Vygotsky was born in Orsha (now Belarus) Russia on November 17, 1896. His family was Jewish and middle class, and both of these factors played an important role in his education and development. His early interests were broad and were not exclusively in psychology. His first intellectual endeavors focused on the interaction between art, literature, and later psychology. While at Moscow State, he also studied social sciences at Shaniavsky University. He graduated from Moscow State University with a degree in law in 1917. He taught for several years before completing his dissertation. It was titled “Psychology of Art” and employed William Shakespeare’s *Hamlet* as its main focus. His dissertation was published in 1925 and was his first publication.

He was invited to join the Institute of Psychology in Moscow in 1924 and remained there until 1934. While at the institute, he worked extensively on ideas about cognitive development, and became instrumental in the development of the educational program of the newly formed Soviet Union. He suggested that children with disabilities should be educated alongside children without disabilities because the social and cultural development of both parties would be likely facilitated

by the integrative environment. He reasoned that social isolation might be more harmful to the disabled children than their disability. At the Institute, Vygotsky was joined by two of his most famous students, A.N. Leont'ev and A.R. Luria. It became their mission to rework psychology into a new Marxist psychology. Vygotsky died at the age of 37 in 1934 from tuberculosis. Many of his works were published after his death. They were however relatively unknown to the West until 1958 because they were banned by Joseph Stalin for political reasons.

Basic Accomplishments/ Contributions

Vygotsky's theory of development was based primarily on his perception that psychological functioning is composed of both "natural" and "cultural" factors. He stated that the natural factors consisted of physical and cognitive biological growth, and the cultural factors consisted of learning to use psychological and cultural tools such as signs, symbols, and language. He viewed development and learning as acting in conjunction to create higher psychological functioning. In his view, an understanding of individual mental development begins by examining the social and cultural forces from which it derives. He also postulated that learning and development are facilitated in a hypothetical region which he termed "the zone of proximal development." The zone represents the distance between the child's independent cognitive ability and the child's potential with the help of an adult or a more competent peer. The child's natural ability is expanded upon through instruction and learning. Among other things, his view suggests that the most

effective intellectual assessment should place a greater emphasis on the potential for growth than does the more traditional "actual" assessment.

Vygotsky's most eminent work and contribution to the field of developmental psychology was his book "Thought and Language" (1986), published shortly after his death. In this highly influential work, Vygotsky developed the first ever theory of language development, which depicted the profound connection between both inner and oral language and the development of mental concepts and cognitive awareness. He theorized that language and logical thinking develop in young children during their interactions with adults and the world around them. These ideas laid the groundwork for future theories on the development of mental concepts and cognitive awareness.

Overall, Vygotsky's published works in the field of psychology were written over a 10 year period and consisted of six volumes. These volumes covered topics such as human development, learning, cultural mediation, internalization, the psychology of play, learning disabilities, higher mental functions, philosophy of science, and methodology of psychological research.

W

Wallin, J. E. W.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: January 21, 1876; Died: August 5, 1969.

J. E. Wallace Wallin, as he is usually known, was born to Swedish immigrants in Page County, Iowa, spent his early years in the Swedish town of Stanton, Iowa, and graduated in 1897 from Augustana College in Rock Island, Illinois. He then went to Yale for graduate work with Edward Scripture, obtaining the Ph.D. in 1901 for work on speech rhythms which was cited with some frequency thereafter. He spent a year with Hall at Clark and, with G. Stanley Hall, published on children's fantasy imagination connected with clouds (Hall and Wallin 1902). He next went briefly to Michigan and then to Princeton until 1906, and then took a post at a state college in East Stroudsburg, Pennsylvania, where he first became engaged with the profession of education. In 1910, he went to Vineland, NJ where he replaced H. H. Goddard at the Vineland Training School for a year. There he made contact with Lightner Witmer and firmly reoriented his career toward clinical psychology, mental hygiene, and especially the education of children with disabilities and special educational needs.

Major Accomplishments/Contributions

He moved to Pittsburgh in 1912 as a professor of clinical psychology and director of the psychological clinic at the University of Pittsburgh. While there he assisted in the smoke abatement studies carried out under the aegis of the Mellon Institute, and published on the psychological effects of atmospheric pollution, one of the earliest

environmental psychological studies (Wallin 1913). After this he embarked on a remarkable career distinguished by its itinerancy – he served on the faculties of at least 20 different colleges and universities – and its underlying constant message of the need to educate rather than segregate children with disabilities. By 1930, Wallin had served in a dozen different capacities related to the developing field of special education, not only as a professor of clinical psychology and psycho-educational clinic director, which he was at Harris Teachers College at St. Louis through 1921 and at Miami University in Ohio until 1928, but as a director of educational surveys connected with the delivery of psychoeducational services in Missouri, Ohio, and Maryland and as chair of several commissions and departments of special education in those states. This activity culminated in his membership on the Commission of Special Education for the White House Conference on Child Health and Protection in 1929. Overall, during his career, he opened eight psychoeducational clinics and six special education departments (Duchan 2009). Wallin dogged bureaucracies both psychological and educational, insisting on better quality control in educational testing and on more democratic, inclusive educational practices in a deluge of books and articles from the 1920s through the 1950s (see e.g., among many others, Wallin 1924; Wallin 1927; Wallin 1934; Wallin 1936). For this he may have been perceived as somewhat contentious, but there is ample proof of his success, first in the successful integration of special education into the process of primary and secondary education in the USA, and next in his many commemorations as the chief progenitor of special education, for example, the J. E. Wallace Wallin Special Education Lifetime Achievement award instituted in 1963 by the Council on Exceptional Children. Wallin remained active well into his 80s and published, along with specialist articles in education, several historical reminiscences.

His self-published *Odyssey of a Psychologist* (Wallin 1955) recounts in detail, from his perspective, his migration from early experimental to modern applied educational psychology, an account which mirrors developments in psychology as a whole.

Wallon, Henry

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/ Major Accomplishments

French Marxist psychologist Henri Wallon was the first to apply the dialectical materialist conception of history to psychology. The history of Wallon's family is filled with revolutionary ideas. His father was a freedom fighter (abolition of slavery, social injustice, repression, anti-colonization, etc.). Henri Wallon was introduced by his father to a major figure in politics known Emile Zola. Henri Wallon as a child still had a good recall of that meeting.

Henri Wallon, like Jean Piaget and Lev Vygotsky, focused on the creative nature of the psychological processes relating act, action, activity, and representation. He examined these processes as they develop in the course of the child's acquiring, understanding, and control of the physical and social environment. Wallon was among the first psychologists to systematically study the development of representational systems, beginning at the sensory motor stage and extending through all other forms of human activity to the stage of complex symbolic systems, including scientific thought.

The views of Wallon, who was a Marxist developmental psychologist, are considered to be complementary to those of Piaget, and both are considered to be among the greatest figures of twentieth-century psychology.

Marxist dialectics supplies psychology with a tool for explaining, understanding, and studying human higher mental functions. The dialectical materialism provides the normal base and guiding principles for the science of psychology and has made it a natural and human science, enabling it to comprehend human activity (instead of behavior) as a single, unified whole in constant interaction.

According to Wallon, humans are already social beings in the mother's womb, where they live in symbiosis with her. West European and North American psychologists, who withhold recognition of Wallon's theory, recognize and use his concept of bonding. Developmental psychologists might today find ways to capitalize on Wallon's theoretical framework. The uniqueness of Wallon's approach is his willingness to connect children's cognitive development to not only the rational, the logical, the educational, and the scientific, but also the collective social history, material tools, signs, symbols, culture, collective history, fictions, myths, and philosophies of societies, as well as the individual's personal history.

Although Wallon's work paralleled Piaget's in certain respects, the two men engaged in controversy on various theoretical issues. Piaget viewed Wallon as one of the greatest psychologists of the twentieth century. Wallon's theory converges with L. S. Vygotsky's formulations on thought and language; Vygotsky's ideas were shaped by Wallon's theoretical framework.

He published over 270 articles, books, chapters, monographs, and manuscripts. His oeuvre is inestimable. The power of his intellectual insight and the force of his political intervention in and for third world liberation are almost unsurpassed.

Psychologists and educators in the Soviet Union, Eastern Europe, Africa, and Latin America have found in Wallon's theoretical framework guiding inspiration. Wallon was politically active in various leftist organizations and became a member of the Communist Party. He maintained active contacts with Soviet psychologists such as Alexis N. Leontiev and Alexander Luria among others. He was appointed professor at the prestigious Collège de France. He founded the first *laboratory for the child development* (1927), *Circle of the friends of Russian revolution* in the beginning of the 1930s, and journal *Enfance* (1948). His approach to psychology has inspired psychologists such as Georges Politzer, Lev Vygotsky, Alexis N. Leontiev, René Zazzo, and Lucien Sève among others.

Warren, Howard Crosby

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: June 12, 1867; Died: January 4, 1934.

Warren had a lifelong association with Princeton University in New Jersey, attaining the B.A. in 1889 and the M.A. in 1891. He studied at Leipzig and Munich until 1893 when, recalled by ► [Baldwin, J. M.](#) to head the psychology laboratory, he returned to Princeton where he spent the rest of his career.

Major Accomplishments/Contributions

A member of the inner circle of the second generation of American psychologists who created modern scientific psychology, he was elected president of the American Psychological Association in 1913 and had an insider's influence on all aspects of the development of experimental psychology in the USA. Warren was associated with the *Psychological Review* since its founding in 1894 by Baldwin and Cattell, eventually becoming its editor after Baldwin, who himself had gained ownership of the *Review* by a coin toss with Cattell, lost his academic position at Johns Hopkins in 1909. Soon afterward, Warren became the owner of the *Review* as well and was instrumental in guiding its development and that of its cognate publications through the next 2 decades. In 1925, he sold the *Review* to the American Psychological Association on generous terms of credit which he terminated early. Meanwhile, Warren, after Baldwin's departure to Johns Hopkins, had full responsibility for the building of psychology at Princeton, where his task, similar to that faced by most psychologists of his era, was to separate psychology from philosophy, which he accomplished in 1920. His extensive activities on behalf of psychology kept Warren from obtaining the Ph.D., which he decided to obtain after his installation in the Stuart Professorship at Princeton in 1914, reasoning that a psychologist passing on doctoral examinations should also hold the doctorate. He managed this by teaching coursework

related to his Ph.D. at Princeton while arranging with the faculty of Johns Hopkins to supervise his dissertation, which he defended successfully in 1917 with the philosopher A. O. Lovejoy as chair. Ultimately this work, in gestation since 1903, emerged as Warren's most well-known book, *A History of the Association Psychology* (Warren 1921b). Warren, a consummate liberal academic, also became involved in issues concerned with academic freedom during his career and was a member, along with Lovejoy, of the committee of the American Association of University Professors which drafted the AAUP's 1915 *Declaration of Principles on Academic Freedom and Academic Tenure*. Throughout his career, Warren attempted to make psychology orderly through definition. He played a leading role in the creation and production of Baldwin's *Dictionary of Philosophy and Psychology* (Baldwin 1901) and was actively engaged in the American Psychological Association's efforts to define basic psychological terminology during and after the First World War. Ultimately he took on the task of the production of his own *Dictionary of Psychology*, which consumed over a dozen years and which appeared posthumously (Warren 1934). Warren himself produced little in the way of laboratory research but wrote many theoretical articles on purpose, consciousness, and general psychological outlook for both philosophical and psychological journals. He also had interests in evolution and genetics, explicitly advocated inclusion of a neural level in psychological explanation (Warren 1921a, 1927), and supported Leonard Carmichael's early work on innate behavior during Carmichael's time at Princeton. Warren also wrote an introductory textbook (Warren 1919) which he revised and reissued with Carmichael (Warren and Carmichael 1930). Toward the end of the 1920s, his vision began to fail and he wrote, in keeping with his early precise perceptual writings, on some of the effects. In 1931, Warren became interested in nudism, which was then a popular craze, and in 1932, returning from the International Congress of Psychology in Copenhagen, he spent several days at a famous nudist establishment in Germany. In his subsequent *Psychological Review* article, "Social Nudism and the Body Taboo" (Warren 1933), he described the conditions under which nudism was practiced and also his personal observations on the changes in attitude toward self-consciousness

which resulted from the nudist experience. This article has had a persistent presence in nudist literature since that time. Warren was very wealthy and gave generously of his riches to psychology: a bequest administered by his wife established the Howard Crosby Warren medal of the Society of Experimental Psychologists, first presented in 1936. The list of its recipients is a concise summary of the best contributions to an expanding experimental psychology, the realization of Warren's life work.

Washburn, Margaret

SHOSHANA GROSS, ROBIN FREYBERG
Yeshiva University, New York, NY, USA

Basic Biography

Margaret Floy Washburn was born on July 25, 1871, in Harlem, New York, and raised as an only child. She was very close with her parents, Rev. Francis and Elizabeth Floy Washburn, who took a keen interest in her academic accomplishments. Throughout her life, she

sought academic positions that would enable her to remain close to her parents' home in New York.

It would seem that Dr. Washburn was erudite and scholarly minded from the start. Though she only entered school at age 7, she learned how to read and write well before then and spent most of her time as a child reading books and in the company of adults (Campbell and Ross 2002). For her undergraduate education, she attended Vassar College from 1886 to 1891 where she studied chemistry and French; however, her interests ultimately led her to the field of psychology.

For her graduate education, she attempted to study at Columbia University under the renowned psychologist James Cattell; however, Columbia at the time did not accept female graduate students to its University. Dr. Washburn eventually chose to pursue her studies under Edward Titchener at Cornell University. She earned her Ph.D. from Cornell in 1894 and became the first woman in America to receive a Ph.D. in psychology.

There were not many academic teaching opportunities in psychology granted to women at the time; however, Dr. Washburn was ultimately offered a position as Chair of Psychology, Philosophy, and Ethics at Wells College, which she accepted. She remained there for 6 years after which she returned to Cornell for 2 years as the Warden of Sage College, the women's dormitory, and Lecturer in Psychology. She was then offered an Assistant Professorship with complete charge of the Psychology department at the University of Cincinnati. Though she enjoyed her time there, Washburn preferred to live closer to her parents and so she accepted the position of Associate Professor of Philosophy at her Alma mater Vassar College in 1903, where she remained for the rest of her life (Dallenbach 1940). In 1908, she became the Professor of Psychology and the head of the Psychology department at Vassar College. She eventually retired from Vassar College in 1937 as Emeritus Professor of Psychology. She never married. On October 29, 1939 after a long struggle with illness, she died from cerebral hemorrhaging at the age of 69 in Poughkeepsie, New York.

Accomplishments

Through her intense academic drive, Margaret Floy Washburn was able to leave a profound mark in the

field of psychology. In addition for being known as the first woman to receive her Ph.D. in psychology, Margaret Floy Washburn is best known for her work entitled *The Animal Mind*, which she published in 1908. This text was the first of its kind to exist in comparative psychology, which addressed animal behavior and cognition. Here she collected and critically analyzed all the previous existing literature on comparative psychology, as well as attempted to answer how similar the animal mind was to human cognitive processes. Dr. Washburn expressed her opinion that animals most certainly have consciousness, though she understood how hard it would be to study (Martin 1940). She therefore focused on which methods were best to use in comparative psychological research, and how one should analyze data on the animal mind. She most adamantly advised that the ideal study of animals would be in longitudinal studies within naturalistic environments.

Dr. Washburn was a prolific writer and besides for her work *The Animal Mind* (1908) was also recognized for her other writings such as her *Movement and Mental Imagery* (1916) where she first presented her own motor theory based on the notion that thoughts require movement, and her *Psychologies of 1930* (1930) where she related the different psychological perspectives in 1930 to motor theory.

Dr. Washburn's academic achievements and contributions to psychology extend well beyond her written works. She functioned as a member of the American Psychological Association (APA) Council from 1912 to 1914, was the vice-president of the American Association for the Advancement of Science (1927), a member of the International Committee on Psychology (1929), and chair of the Society of Experimental Psychologists. Furthermore, in 1921, Dr. Washburn served as president of the APA, the second woman to ever serve in this prominent position.

Dr. Washburn also served as an editor for various publications such as the American Journal of Psychology, Psychological Bulletin, Journal of Animal Behavior, Psychological Review, and Journal of Comparative Psychology.

Among the various awards that Dr. Washburn received, such as being selected as one of the top fifty American psychologists in 1903, one specifically exceptional professional honor she received was becoming

the first female psychologist to be elected to the National Academy of Sciences in 1932.

Finally, Dr. Washburn's accomplishments not only extended to the field of psychology, but she also had a groundbreaking impact on women's educational opportunities at a time when there were few. Throughout her teaching career, Dr. Washburn passionately encouraged her students at Vassar College to focus on furthering their education. Toward the end of her life, she also gave large donations to be used for young women's educational scholarships (Martin 1940).

Watson, John Broadus

EDWARD K. MORRIS

University of Kansas, Lawrence, KS, USA

Basic Biographical Information

The American psychologist, John Broadus Watson, was born on January 9, 1878, in Travelers Rest, South Carolina, and died on September 25, 1958, in New York City. He is recognized as the founder of behaviorism and among the most eminent psychologists of the twentieth century (Buckley 1989).

After graduating from Furman University (1894–1899) with a master's degree in philosophy, Watson enrolled at the University of Chicago (1900–1903), where he earned a doctoral degree in psychology for research on the developmental psychobiology of the rat (Watson 1903). He also earned minors in neurology and philosophy. As an instructor at Chicago

(1903–1908), he extended his research to the sensory systems involved in animal learning and investigated the evolutionary basis of behavior in ethological studies of terns. Moving to Johns Hopkins University (1908–1920), he became the department chairperson, continued his ethological studies, conducted research on animal psychophysics, and founded behaviorism as a system of psychology in his 1913 article, "Psychology from the Standpoint of a Behaviorist" (Watson 1913).

Following that, Watson became a systematist (e.g., describing the nature and scope of comparative psychology), was elected president of the American Psychological Association, edited its most prestigious journals (e.g., the *Psychological Bulletin*), and established a research program on the biological and behavioral basis of human emotion. After service in World War I (1917–1918), he continued this research and advanced psychology as a science (Watson, 1919). In 1920, a personal scandal forced his resignation from Johns Hopkins, but he was soon a successful advertising executive with J. Walter Thompson in New York City (1921–1935). During this time, he promoted behaviorism in magazine articles and books (Watson 1924, 1930) and became the first "pop" psychologist (e.g., Watson and Watson 1928). In 1945, he retired from William Esty and Company and lived reclusively in rural Connecticut until his death (Watson 1936).

Major Accomplishments/Contributions

Among Watson's major accomplishments and contributions were founding behaviorism, accounting for mind, and analyzing emotional development, all of them contributions to psychological theory. First, Watson made behavior, not mind, what psychology studied, but he held two views on the matter. In a metaphysical view, he denied the reality of mind; it was a prescientific construct and illogically used (e.g., in circular reasoning, affirming the consequent). In a methodological view, he accepted the reality of mind, but set it aside from science because it was not intersubjectively verifiable. This form of behaviorism was predominant in psychology for several decades, while a weaker form dominates psychology today: behavior is what psychology studies, but is no longer psychology's subject matter. Psychology's subject matter is the mind, whose structures and functions are inferred from behavior.

Second, although Watson rejected mind as a construct, he had to account for the activities identified by the concept of mind. Initially, he identified them with thinking, which he located in the larynx as subvocal speech – a motor theory of mind. Later, he identified mind with the covert activity of the sensory systems (i.e., awareness) and private and public responding to them (i.e., consciousness), which sometimes mediated other behavior. However, he never developed a comprehensive account of how consciousness and its mediational functions developed. B. F. Skinner (1904–1990) did that.

Third, Watson analyzed the emotional development of infants and children. He observed conditions that elicited their biologically based love, anger, and fear reactions (e.g., response restriction). He demonstrated the behaviorally based extension of these reactions to other objects and events through classical conditioning and stimulus generalization (see I. P. Pavlov, 1849–1936). And he eliminated conditioned emotional reactions through extinction and counterconditioning, methods still used today in behavior therapy.

These accomplishments and contributions made Watson the founder of behaviorism, both metaphysical, like Skinner's, and methodological, like cognitivism's.

Wechsler, David

DOMINICK A. FORTUGNO
Touro College, NY, USA

David Wechsler was a clinical psychologist and researcher who authored more than 60 books and articles on the structure and assessment of intelligence and created the Wechsler scales, a series of assessment instruments popular throughout the world.

Basic Biographical Information

Dr. David Wechsler was born in Lespezi, Romania in 1896, the youngest of seven children. At age 6, he moved with his family to New York City, where he attended school, graduating with his bachelor's degree from City College in 1916, then his master's degree the following year from Columbia University under the tutelage of Robert Woodworth. Wechsler's career in intelligence testing began in an unlikely location when he joined the army as a psychologist in 1918. He was stationed briefly at Camp Yaphank on Long Island before transferring to Camp Logan, Texas. Wechsler worked extensively on screening draftees alongside a number of prominent figures, including Army Alpha developer Robert M. Yerkes, statistician Karl Pearson, and prominent cognitive researchers Charles Spearman and Edward Thorndike. He went on to study with Spearman and Pearson at the University of London as an army student, then conducted extensive research in experimental psychology at the University of Paris until 1922. After a brief summer at the Boston Psychopathic Hospital, he returned to New York City and took a job as a psychologist with the Bureau of Child Guidance.

Wechsler completed his doctoral dissertation, titled "The Measurement of Emotional Reactions: Researches on the Psychogalvanic Reflex," in 1925, once again under Woodworth at Columbia University. The following year he began his private clinical practice. In 1932, Wechsler became chief psychologist at Bellevue Psychiatric Hospital, a position he would hold with distinction for 35 years. He also joined the faculty at New York University College of Medicine in 1933, serving as clinical professor in psychiatry. This marked the third and most productive phase of Wechsler's career.

In 1934, Wechsler married his first wife, Florence Felske, who died shortly after in a tragic auto accident. He later married Ruth Halpern in 1939, with whom he had two sons, Adam and Leonard. Wechsler continued to work developing numerous cognitive assessment instruments over the next three decades through his long affiliation with the Psychological Corporation. He retired from his positions at Bellevue and New York University in 1967, the same year he became Beber Visiting Professor of Clinical Psychology at Hebrew University in Jerusalem, whose psychology department he founded. He also held a number of eminent positions, including Trustee of the American Board of Examiners of Professional Psychology and President of the American Psychopathology Association.

Wechsler died in 1981 at his home in New York City.

Major Accomplishments

David Wechsler published more than 60 books and articles on the structure and assessment of intelligence. His series of books on assessment, including “The Range of Human Capacities” (1935) and “The Measurement of Adult Intelligence” (1939a), depicted his evolving view of intelligence as a multifaceted construct representing “the aggregate or global capacity of the individual to act purposefully, to think rationally and to deal effectively with his environment” (1939, p. 3). In “Non-intellective Factors in General Intelligence” (1940), Wechsler argued that the technical, compartmentalized structure of contemporary cognitive assessment ignored important noncognitive factors such as emotion, temperament, and impulse.

Wechsler incorporated these concepts into his renowned cognitive assessment instrument, the Wechsler Intelligence Scales for Children (1949), an adaptation of the Wechsler-Bellevue Intelligence Scale published 10 years earlier. The Wechsler Adult Intelligence Scale (1955) and Wechsler Preschool and Primary Scale of Intelligence (1967) followed, along with several other instruments assessing memory and other cognitive aspects. Wechsler’s scales featured a number of innovations, such as restructuring intelligence following Cattell’s Gf-Gc dichotomy and replacing Binet’s mental age with his own Deviation IQ, the preeminent scale for IQ today. Since their first publication, these instruments have been revised and re-normed numerous times, collectively forming one of the most widely

used assessment systems in the world for cognitive ability and academic achievement.

Wechsler’s immense contributions to both the theory and practice of intelligence testing earned him several prestigious honors, most notably the American Psychological Association’s Distinguished Professional Contribution Award in 1973. His work has become a cornerstone of intelligence testing, influencing the fields of psychology, neuroscience, industry, and education, and solidifying his legacy as a pioneer and central figure in modern assessment.

Wegener, Philipp

CLEMENS KNOBLOCH

University of Siegen, Swisttal, Germany

Basic Biographical Information

Philipp Wegener was born on July 20, 1848, the son of a protestant minister in Neuhaldensleben near Magdeburg (Germany). He was educated in Magdeburg’s *Gymnasium zum Kloster unserer Lieben Frauen* where later on he was to teach for a decade (1876–1886). In 1876, Wegener took up his university studies in Marburg, from where he soon moved to Berlin. He studied Classical and German Philology, comparative linguistics, and philosophy. After his doctoral dissertation on the history of the Greek and Latin case systems (1872), Wegener entered upon a career of high-school teaching. His academic teachers had been Moritz Haupt and Ernst Curtius in the field of philology, Friedrich Adolf Trendelenburg in philosophy, and the general linguist

and psychologist Heyman Steinthal. Wegener worked as a high-school teacher in Treptow (Pommern), Zeitz, Magdeburg, and Neuahaldensleben before he was appointed headmaster of the Greifswald Gymnasium. There he remained for the rest of his career. Wegener died in Greifswald on March 15, 1916, aged 67.

Major Accomplishments/ Contributions

In the history of linguistics, Wegener is considered a minor figure in the Neogrammarian movement – with considerable influence on the Neogrammarian view of syntax and dialect though. In psychology, Wegener's accomplishments lie in the field of language processing and communication. The Leitmotiv-questions of Wegener's main work are: "What is the function of language?" and "How do we understand language in our everyday life?" His answers can be considered proto-pragmatic in that they elaborate on utterances as social and communicative actions. Communicative function is thought to be the main motive of linguistic structure as well as the *movens* of linguistic change. The principle aim of speaking is to influence the state of mind, will, or action of the person(s) addressed. From the very beginning, speaking is purposeful action and not just expression of thought or sensation (as most of Wegener's contemporaries assumed). The relative ease of adult speaking (in accordance with the rules of grammar as well as the norms of social action) results from the continuous mechanization of means in language acquisition. According to Wegener, children first use words in the manner adults use sentences (a view which has become common knowledge since). In addition, children's one-word-utterances are shown to be "imperative" in character. They direct the addressee's actions in the field of joint attention. Being "imperative" is a quality that words retain to a degree, even if they become mechanized means of speaking in due course of time.

Any utterance relies on the assumption that the hearer can link its action value to the situation at hand. When speaking becomes more elaborated, it has to establish means to organize situational links verbally. This results in a functional bipartition of utterances. There are segments clarifying situational links and securing the preconditions of understanding (called "exposition" by Wegener), and there is the main point the speaker wishes

to make (awkwardly called "logical predicate" by Wegener). The logical predicate always contains what is new and important in the speaker's utterance. This bipartition roughly corresponds to the theme/rheme – architecture in linguistic functionalism of the twentieth century. But it surpasses the wisdom of modern linguistic psychology in its insistence on active contextualization of linguistic means by speaker and hearer. Just like modern functionalism in syntax, Wegener thought that most of the structural features of natural languages are the result of mechanized and grammaticalized discourse function. He traces the origins of grammatical constructions to their prototypical discourse function. All linguistic signs are considered to have been originally predicates that assume a wide range of secondary functions by combination and interplay with other signs.

Considerable attention has been paid to Wegener's analysis of situation and context. Three types of situational context are introduced: perceptual situation includes the ongoing activities and orientations of speaker and hearer. The second layer of situational context is provided by memory and links directive values of the utterance to past (common) experience. The third layer is called cultural situation and holds common knowledge and belief, shared by all competent members of a culture. Everything that can be uttered in or predicated upon a given situation, serves at the same time to recall that situation in its absence. Wegener's analysis of situational factors in understanding was later continued in Karl Bühler's theory of language and in British contextualism (Alan Gardiner, John Rupert Firth, Michael Halliday).

Wegener was very critical of the linguistic psychology of his contemporaries who relied solely on the expressive values of the linguistic sign. He termed their view "monological" and insisted on the dialogical character of all language. Consciously taking the stand of the sober everyday language user, Wegener held that (pragmatic and semantic) meaning of utterances consists mainly in learning to expect what their actual use in communication results in. This is why some historiographers put him in line with early behaviorism, which is not quite correct.

Wegener's *Untersuchungen* (Wegener 1991 [1885]) are his only book size publication and contain the bulk of his communication theory. Most of his other publications are school programs, treating subjects from the

history and methodology of education. Detailed accounts of Wegener's minor publications can be gathered from Grimm-Vogel (1998). In the (posthumously published) *Wortsatz* (Wegener 1921), Wegener aims at classifying the numerous variants of one-word utterances, claiming their priority over syntactic structure and arguing that a great many communication problems can be solved (and actually are solved) by means of monorhematic speech.

In the tradition of German *Sprachpsychology*, it was mainly Karl Bühler who later on advanced the understanding of Wegener's accomplishments. That understanding language sets out from the actional embedding of utterances in multiple contexts, is crucial for Bühler's approach to linguistic psychology.

Weiss, A. P.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: September 15, 1879; Died: April 3, 1931.

Albert Paul Weiss was born in Germany. His family moved to the USA when he was very young and he grew

up in the transplanted German community of St. Louis, Missouri. After beginning a career as an engraver, he matriculated at the University of Missouri at age 27, obtaining the B.A. in 1910 and the M.A. in 1912. By chance, he encountered the iconoclastic German-American psychologist ► Meyer, Max F. in 1909: He became Meyer's student and attained the Ph.D. degree – the only one sponsored by Meyer – from Missouri in 1916 (Weiss 1916). In 1912, Weiss had begun teaching at The Ohio State University, a colleague of ► Pintner, Rudolf and others who created the strong applied psychology emphasis there. He remained there for the rest of his relatively short professional life, from 1918 onward as Professor of Experimental Psychology.

Major Accomplishments/Contributions

At the time Meyer and Weiss met, Meyer was ready to publish his major theoretical contribution, *The Fundamental Laws of Human Behavior*. In this view, human movements – the basic datum of psychology – result from biologically and chemically determined antecedents mediated by a nervous system. By this monistic and reductionistic formulation, Meyer intended to exclude mentalistic discourse from psychology: Several commentators concur in calling Meyer's approach the first viable consistently behavioristic psychology in the USA. Weiss adopted Meyer's point of view and in 1925 published his own theoretic synthesis, *A Theoretical Basis of Human Behavior* (Weiss 1925b): A second revised edition followed four years later. Weiss placed special emphasis on observable social effects as the best measure of behavioral consequences, on the principle that behavioristic analysis is more concerned with the actions of others rather than self. He proposed a sociocultural metric expressed as a combination of absolute social status and relative position among others of the same status. He connected this social dimension of behaviorism explicitly to social evolution, and extended it as well to developmental psychology through programmatic research at Ohio State on the biosocial aspects of infant behavior (Weiss 1929, 1930). He also adopted and extended Meyer's account – based on the ideas of Lazarus Geiger – of thought as inner speech, related to humans' shared social activity.

Language, in Weiss's system, is key to bridging the gap between biophysical antecedents of behavior and socially significant consequences. If language is often ambiguous, disambiguation of utterances is straightforwardly achieved by reference to their social context, and unambiguous language is an indicator of underlying sensory and neural regularity. Weiss's mature behaviorism was expressed as a set of postulates describing synchronous, equivalently real though formally incommensurate levels of analysis (Weiss 1925a). Rather than an attack on introspection, Weiss saw his work as a positive statement of principles which could incorporate even introspective data if such data revealed a new measureable quantity of sensory activity. Indeed, much of his published work deals in some way with the problem of consciousness (e.g., Weiss 1919), though for the most part he saw consciousness as superfluous or unnecessary to psychological explanation, and took those psychologists most strongly identified with the study of consciousness, for instance Leonard Troland, to task (Weiss 1926). By 1930, Weiss's theory had lost ground against competing behaviorist systems grounded in comparative psychology: that and his early death diminished his influence in the field, although his system was included in several subsequent accounts of behaviorism. Also, he was not committed to perpetuating his theoretical system through his students: He was a significant influence and support for an eclectic group of mostly applied psychologists including the psychometric specialist ► [Paterson, Donald G.](#), the artist and art educator Bertha Couch Cox, the developmental psychologists O. C. Irwin and Wayne Dennis, and Alvah Lauer, best known for his work at Iowa State University but begun with Weiss and others at Ohio State, on factors related to driving safety (Weiss et al. 1930). The most explicit effect of Weiss's theoretical behaviorism was on a linguist, specifically on the behavioristic account of linguistics by Leonard Bloomfield, Weiss's colleague at Ohio State between 1921 and 1927.

Weld, H. P.

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born: September 22, 1877; Died: October, 1970.

Harry Porter Weld was born in LaGrange, Arkansas and later moved to Ohio, where he graduated from The Ohio State University with the Ph.B. in 1900. There he collaborated in compiling a collection of Ohio State college songs, *Songs of the Scarlet and Gray* (Gayman et al. 1900). After some further musical training at Shepardson College in Granville, Ohio, he taught as Professor of Music at Peabody College for Teachers in Nashville, Tennessee until 1910. He entered Clark University as a fellow in psychology (1909–1910), publishing an article on the mechanism of the voice and its hygiene (Weld 1910) and then serving as a research assistant to John Wallace Baird and as an instructor through 1912. His 1911 Ph.D. work was a plethysmographic and pneumographic study of the emotional response to music which included an analysis of the sensory dimensions of musical pleasure

(Weld 1912). From 1912 onward he was associated with Cornell University, full professor from 1919 and chair of the Department for nine years after Madison Bentley's retirement in 1939.

Major Accomplishments/ Contributions

Weld sponsored and published research with Cornell students on several perceptual subjects including the Bourdon rotation illusion and on changes in perceived meaning under various conditions of sensory fatigue or delay. One of his most prominent students was Forrest L. Dimmick, the eminent sensory and color scientist. Toward the end of his career, Weld developed an interest in the psychology of testimony, especially in the process involved in forming a jury verdict, and contributed articles and a textbook chapter in this area (Weld and Roff 1938; Weld and Danzig 1940; Weld 1954). These are still cited in the psychology-law literature. However, experimentation was not Weld's forte: His strength lay in his theoretical bent, his editorial abilities, and his general erudition. Just before the end of the Titchener period, he prepared a mimeographed set of notes for a course he offered on the relation of psychology and science. These notes were elaborated into a book in 1927, *Psychology as Science: Its Problems and Points of View* (Weld 1928), which was followed a year later by literally the last word of Titchener's psychology, the posthumous *Systematic Psychology: Prolegomena*, which Weld edited and for which he provided a preface (Titchener 1929). Both works restate the Titchenerian distinction, grown less common in psychological thinking by this time, between "empirical" psychology, with roots in Brentano evolving into various forms of functionalism, and "existential" psychology, with roots in both Wundt and Avenarius, evolving into the experimental analysis of conscious sensory experience. Contemporary critics observed that Weld's view in *Psychology as Science*, conciliatory toward applied psychology and technology, appeared more similar to the more inclusive systematization of Bentley, who returned to Cornell after Titchener's death.

After 1929, Weld teamed with ► [Langfeld, Herbert Sidney](#) and ► [Boring, E. G.](#) to edit a series of introductory textbooks intended to provide a comprehensive

structure for the discipline. These books which appeared in three versions over 13 years – *Psychology: A Factual Textbook* (1935), *Introduction to Psychology* (1939), and *Foundations of Psychology* (1948) – contained chapters by experts and presaged the scope of content of current comprehensive psychology textbooks. These "BLW" books, as they were called at the time, are a sensitive barometer of the shifts in interest and knowledge in the field, a tribute to the accuracy and relative neutrality of this editorial group (Webb 1991). Weld contributed coauthored chapters to the 1939 version including Perception, with Shammai Feldman, and Spatial Perception, with Robert MacLeod. The BLW team also edited a companion *Manual of Psychological Experiments* in 1937. Weld, steeped in the historical literature of experimental psychology, was an uncompromising critic: His generally positive review of the first edition of E. G. Boring's *History of Experimental Psychology* (Weld 1931) concluded with a list of 50 corrigenda, which depressed Boring as much as it must have impressed him. Apparently, it was no bar to productive collaboration.

Wells, Frederic Lyman

DAVID C. DEVONIS

Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born April 22, 1884; Died June 2, 1964.

Frederic Lyman Wells was the son of Benjamin Wells (Ph.D. Harvard, 1880), professor of languages and comparative literature at the University of the South at Sewanee, Tennessee, where Frederic grew up. He moved with his father in 1899 to New York and entered Columbia University. Graduating in 1903, he entered directly into the Columbia graduate program, where he studied the psychology of language, completing a doctoral thesis on linguistic lapses and also conducting a statistical survey of literary merit. After the doctorate, he took over the position in clinical psychology at McLean Hospital in Waverly, Massachusetts, a vacancy created by Franz's move to St. Elizabeth's in Washington, D. C. in 1907.

Major Accomplishments/Contributions

Wells was among that group of psychologists who pioneered clinical psychology in hospital settings. His early professional activity ranged over several areas: in his first 5 years at the McLean laboratory, he completed monographs on the therapeutic use of electricity (Wells and Forbes 1911), on Freudian interpretation, and on laboratory equipment and procedure in an abnormal psychology setting, and also authored, with R. S. Woodworth, a major part of the report of the committee composed of C. H. Judd, W. B. Pillsbury, C. E. Seashore, R. S. Woodworth, and J. R. Angell of the American Psychological Association on test

standardization (Woodworth and Wells 1911). Woodworth and Wells offered, along with their meticulous review of association testing, a test they devised, the Substitution Test, which, because it was a nonverbal test both in content and direction, soon made its way into Pintner and Paterson's 1917 performance test scale, influential for several years among testers and test developers. In 1910, Wells spent a year with August Hoch and George Amsden at the New York State Psychiatric Institute at Wards Island, NY, learning their system of personality analysis, in which a composite picture of personality emerged from the combination of the results of multiple tests and self-reports. Wells's 1914 article (Wells 1914) synthesizing this method was an early bridge between psychiatric and psychological personality theory. Wells's career from this point on consisted mainly in teaching psychometrics and writing extensively on clinical psychology and, often, on other general psychological subjects. Like Franz, Wells was sensitive to the precarious position of the clinical psychologist in the medical establishment and contributed several articles describing inherent tensions between medicine and psychology in education and in practice. Wells moved to the Boston Psychopathic Hospital as chief clinical psychologist in 1921 and from then onward was affiliated with Harvard University. In the 1920s, he conducted several empirical studies of sensation and attention (and, in connection with these, mentoring Gardner Murphy at an early stage of his career) and wrote two books, *Pleasure and Behavior* (Wells 1924), an overview of the concept of pleasure as it had then developed in psychology, and, in 1927, *Mental Tests in Clinical Practice*, (Wells 1927) which was used for many years as a standard text in clinical psychology graduate programs. However, although Wells's extensive contacts among personality theorists and psychometrists in the Boston area placed him at the nexus of a large network of practitioners, theorists, and teachers developing the intellectual basis of personality theory, he played only a supporting role: for example, he was only peripherally represented in the comprehensive edited volume on personality dedicated to Morton Prince (Campbell et al. 1925). Wells the teacher kept abreast of changing technologies of testing and was one of the early proponents of the Rorschach, mentoring Sam Beck and

writing on the relation of the Rorschach and association tests (Wells 1935). By the mid-1930s, in association with Johnson O'Connor, Wells had turned from pathological psychology to the study of normal individuals and, in 1938, joined the Harvard Grant Study as a psychometric specialist and remained affiliated with it through the early 1950s. In this capacity, he authored numerous reports on the Study's findings. Wells retired to McLean hospital, where he performed everyday jobs and wrote on the stresses inherent in the role of caregivers in mental hospital settings. Wells, along with his brother Henry W. Wells, professor of comparative literature at Columbia, and Henry A. Murray, became an intimate of the poet-psychiatrist Merrill Moore, whom he trained in psychometrics and Rorschach testing in the early 1930s, and contributed a psychometric analysis of Moore's personality to the British literary journal *Life and Letters Today* (Wells 1939). Wells's friendship with Moore underscores Wells's conviction that, beneath the technical apparatus of testing and psychiatric procedure lay a fundamental layer of art, a point of view that emerged rarely but clearly in his writings (e.g., Wells 1946).

Werner, Heinz

JOSEPH GLICK

City University of New York, New York, NY, USA

Every field can be characterized as having enduring analytical problems which must be deeply addressed, and issues which become topics of heated contemporary/temporary discourse. This entry is written in the spirit that both the enduring analytical problems and the issues of contemporary discourse have an important place in considering the contribution of theorists.

Entering a theorist into an encyclopedia is inevitably relegating his or her ideas to the past – to be consulted as “what was” instead of “what could or should be.” In dealing with theorists such as Heinz Werner, this is particularly misleading since many of the issues he addressed remain pertinent, important, and substantially unaddressed to this day.

This entry is written in the spirit that much of what Werner had to say is particularly relevant today. Many of the interests in the field have changed, many of its core methodologies have been redefined, but in a major sense, and for historical reasons, much of the story to be told is still untold.

Excellent chronologies of Werner's career, broken into four major phases: his discovery as a rising talent in Austria and Germany, his displacement by the Nazi takeover, his long search for an academic position in the USA, and his construction of a unique school of Developmental Psychology at Clark University have been well described and documented by Wapner and Kaplan (1964), Witkin (1965), and Valsiner (2005).

Heinz Werner was born 6 years before Jean Piaget and L. S. Vygotsky whose centennials have been celebrated and whose theories are still cited by many as contemporary references. Werner died in 1964, 30 years after Vygotsky's death in 1934, and 16 years before Piaget's death in 1980. Jaan Valsiner, in his masterful

book on Werner, *Heinz Werner and Developmental Science* (2005) raises the issue of why Wernerian Psychology seemed not to have outlived Werner, while followers of Piaget and Vygotsky still abound. These theorists and those related to them are often “reference-points” for contemporary discourse while Werner seems to have disappeared. This is particularly puzzling in light of the massive historical displacements (between authorship and acceptance) involved.

Werner’s life was profoundly influenced by the turbulences of the twentieth century both personally and theoretically. It is misleading to speak of the development of developmental psychology without taking into account the historical factors that deeply influenced not only the formation of theories, but also the conditions of their acceptance. Developmental theory has often been “consumed” in the context of pressing national concerns.

Born in Vienna in 1890 and receiving his degree from the University of Vienna where he worked in Exner’s lab, Werner made many of his early contributions in Hamburg, Germany, where he was hired as the principal member of William Stern’s laboratory (Kreppner 2005). Hamburg was an intellectual center, with Ernst Cassirer, Martin Scheerer, and Jakob von Uexküll as other major figures. It was home to a major ethnological museum where many ethnographic descriptions and artifacts were collected. Much of this material found its way into Cassirer’s magnum opus, *The Philosophy of Symbolic Forms* (1970). Some of that material also found its way into Werner’s theorizing.

While Werner was thriving in this environment, the newly elected Nazi government closed the Stern laboratory in 1933, leading, in one case, to the suicide of a major contributor (Martha Muchow) and to the exodus of those who could get away. Werner left Germany, and after a brief stay in Holland struggled to find a secure academic position in the USA. His travels were far and wide, with visiting positions at the University of Michigan, Harvard, and Brooklyn College, and a long stint at the Wayne Training School (for the developmentally challenged, in modern parlance). He finally found an academic home from 1947 to 1960 where he was named G. Stanley Hall professor in 1949 while he directed and formed the Psychology department at Clark University, with Seymour Wapner and Bernard Kaplan as close colleagues.

Throughout his career, Werner remained an experimentalist, seeking to synthesize emerging experimental and ethnographic data into a comprehensive description of developmental process. He saw all phenomena as essentially developmental ranging micro-genetically from the time processes involved in perception of contours or the understanding of words to macro-genetically looking at developmental aspects of cultural differences. This led to his publishing a masterful book describing and analyzing development which became known in English as *The Comparative Psychology of Mental Development* (first published in German in 1926 with a second edition in German in 1933 and then in English editions starting in 1940, with a second edition in 1948, third and fourth German editions in 1953 and 1959, and a third English edition in 1957) e.g., Werner (1957). He officially retired in 1960 and continued working until his death in 1964. A year prior to his death he published *Symbol Formation: An Organismic-Developmental Approach to Language and the Expression of Thought* with Bernard Kaplan.

At one time, Werner’s voice was among those of Piaget’s and Vygotsky’s in articulating a view of development that significantly differed from the behaviorism that had been rampant in American Psychology until the late 1950s.

Werner’s death in 1964 came roughly 2 years after the recognition of Piaget by important institutional representatives of developmental psychology in an SRCD monograph, published in 1962, edited by Kessen and Kuhlman (1962) representing the results of the Dedham conference held earlier about the nature of and future of Developmental Psychology. Vygotsky’s work was also made available to a large audience in the English Speaking world with the publication of *Thought and Speech* also in 1962 (Vygotsky 1962).

I have shown elsewhere (e.g., Glick 2004) that the initial recognition (in the USA) of Piaget was fueled by the aftermath of a major “shock” in the cold war relation of the USA and the USSR precipitated by the launch of Sputnik in the late 1950s and the consequent belief that the USA was losing a technological war. Piaget’s theory largely was identified in the popular and theoretical imagination with the development of logic, and with that the Science, Technology, Engineering, Mathematics (STEM) disciplines that became

a dominant focus in the context of a cold war mentality where technological advance was equated with national threat or success. Ironically, Vygotsky, who died well before the beginning of World War II, was “rediscovered” in the late 1970s, virtually as an “answer” to the structural conservatism of Piagetian theory. New social needs had arisen as a result of the Civil Rights Movement and the continuing Cold War. The structural limitations inherent in Piaget’s theory were supplanted by a notion which became identified with Vygotsky – that development could be accelerated in the Zone of Proximal Development. This “answer” to Piaget became amplified by a steady stream of “newly discovered” Vygotsky manuscripts that began to appear from Russian archives and put into visiting American scholars’ hands.

Somewhere in the process of the introduction of Piaget and the later rediscovery of Vygotsky, Heinz Werner’s psychological contributions became dwarfed and, to a great extent, muted. Werner’s death in 1964, after a long illness, effectively kept Wernerian psychology out of this particular “mainstream” argument (Glick 1983).

Ironically, though effectively out of the cold war/civil rights dialog between Piagetian and Vygotskian schools, Werner’s ideas are becoming increasingly relevant to contemporary issues facing educational policy.

During his brief stay, as a visitor at Harvard University, Werner wrote an important paper in 1937, distinguishing between an analysis in terms of “process” and analysis in terms of “achievement” (Werner 1937). The fundamental idea of that paper was that an “achievement,” for example, brightness constancy (in the particular case that Werner analyzed in that paper), could be achieved by a number of very different processes ranging from a sensorimotor reaction at the pupillary level (the pupil widens or contracts in relation to ambient light conditions) to a linguistic and conceptual level where what is known dominates whatever the perceptual conditions (“we know that coal is black even though under this intense light it might look white”).

The distinction between “process” and “achievement” is in principle different from either the notion that there are structural limitations, or that there are not. It basically says that what looks like the same (correct or incorrect) response can be based on very

different underlying processes, and it is these that must be understood (Glick 1994). In the remainder of this entry I will focus on the contemporary significance of the Wernerian project, as it relates to the idea of “development” on the one hand, and the distinction between “process” and “achievement” on the other. Both of these issues can be seen to be at the core of current concerns with educational policy and the “metrics” that may be applied to judge whether educational goals have been achieved.

What is Development?

Werner’s career interests had several important touch points that resulted in a form of developmental psychology that is distinctly different from many contemporary concerns. The key to this difference is in treating development as “organismic” – deeply rooted in the person, both culturally and physically. As an example, Werner and Wapner developed a theory of perception called Sensori-Tonic Field Theory that stood in opposition to the cognitivist “new look” psychology. Their essential point was that perceptual phenomena were not simple outcomes of cognitive processes (e.g., seeing a red spade card stimulus as black) but were as much the result of the relation of bodily states to stimuli: that things were not “only” cognitive, they were also “organismic.” This approach was extended by Werner and Kaplan (1964) into a distinct approach to symbolic activities in general.

Throughout his career, Werner was interested in developmental issues particularly related to “meaning” (Werner 1983). His earliest work was on the “origins” of such meaning forms as metaphors, and lyric beyond the search for cultural “origins” of such forms Werner sought to understand their developmental trajectory, starting with the study of the development of “micro-scales and micromelodies” and continuing through his last work on Symbol Formation.

Werner, throughout his career, kept in touch with the experimental literature on developing children, ethnography, and linguistics. He developed a unique principle – The Orthogenetic Principle – which looked at developmental phenomena in terms of their “form” and not their temporal placement in a life trajectory. Not all that occurs “later” is more developed. The Orthogenetic Principle states that wherever there is development, it is characterized by increasing

differentiation and hierarchic integration. This principle, in effect, means that developmental analysis can be applied broadly to a wide range of phenomena, and not just to those phenomena involving changes that occur from infant to adult. Successive drafts of a dissertation, for example, could be looked at as developmental phenomena. A life's work could be looked at in the same way. This broad application is signaled by the "ortho" in the Orthogenetic Principle.

Developmental Theory and Education

In the years surrounding Werner's death, the topics addressed by developmental psychology and developmental psychologists subtly changed, at first, and then changed radically. With the fascination with Piaget's theory as an "answer" to technological advance, interest shifted to whether, and how, development could be advanced or accelerated. Many "training" studies were conducted to see if there could be an acceleration of the development of logical forms. While, in Piaget there is still concern for the "form" of a developmental achievement, the concern was whether a given phenomenon was "truly" an operational achievement or a simulacrum of it (see, e.g., Piaget's distinctions between "reversability" or "renversibility" (Piaget, *passim*)).

However, these distinctions between "true" and "simulacrum" pointed out that there were structural limitations on the degree to which development could be accelerated. While simulacra could be created within training studies, the desired structural advances could not be easily produced.

Throughout the 1960s and 1970s, Piagetian concerns, and the concerns with overcoming the essential structural conservatism of the Piagetian position, were of central importance to many developmental psychologists with many attempts at "acceleration" of development ultimately frustrated by research findings.

An "answer" to the structural limitations of Piagetian theory was presumably supplied by the work of Vygotsky, reintroduced into contemporary discourse in 1978 with the synthesized and edited publication of "Mind in Society" (edited and pieced together from several different manuscripts) by Cole, John-Steiner, Scribner and Soubermann, which focused on the idea that structural limitations could be overcome since development occurred within a "Zone of Proximal

Development" where a child's unaided performance could be improved with the help of a more knowledgeable other (Vygotsky 1978). The ZPD came to be seen as emblematic of the work and position of Vygotsky, although Vygotsky himself mentioned the ZPD in only limited contexts.

Notions of "scaffolding" and acceleration by collaborative action began to dominate discourse as if, finally, an answer to Piaget had been found in the ZPD. These notions had profound implications for the relation between developmental theory and educational practice.

In an increasingly global economy, and with the competition between nations shifting out of a "Cold War" context, the educational system of the USA came under increasing scrutiny. Were schools merely an instrument of maintaining social inequality (in terms of manifest differences between rich and poor, black and white)? Were American schools failing American children in a global competitive context? Demands for "accountability" of the educational system increased, culminating eventually in the "No Child Left Behind" act, passed in 2001 and signed into law in 2002, which tied school funding to scores on achievement tests.

NCLB was a logical outcome of theoretical developments that began with the space race, and was accelerated by the Civil Rights movement, and which found political form in funding decisions based on achievement test outcomes.

It is precisely at this point where the fundamental insights of the Wernerian approach are most sorely missed. The focus on achievement (as represented in test scores) seems to ignore the fundamental distinction between Process and Achievement that was deeply routed in Werner's sense of what is involved in developmental process. It similarly ignores the theoretically critical distinction between developmental process and measured achievement. If achievement can be accomplished by a number of homologous processes which are of different developmental status, then what is being measured, and being taken as "accountable" is virtually unconnected to any sense of development. An achievement test score is not the same as a developmental advance.

Many of the critiques of the NCLB legislation are that large parts of the school curriculum are taken in anticipation of standardized achievement tests, and

that much school time is taken up with test preparation, with little attention being paid to development taken in larger and wider context. Process is thereby subordinated to achievement.

Forms and Factors

Much of the importance of Werner's theorizing hinges on a critical feature of developmental theorizing. Development may be seen in terms of factors that accelerate, or retard developmental progress. Much contemporary research addresses issues related to this problem. But what remains unaddressed is the more fundamental issue of what development is. Is it higher scores on tests of achievement? Or, is it something that may be identified in terms of its fundamental form and meaning within a developing life. These are different questions. In Aristotelian terms, the search for accelerative factors refers to material and efficient causes while the later question hinges on the equally important final and formal causes.

The task facing developmental analysis is similar to the task that Aristotle set centuries ago. How can we find a level of analysis that takes all of these causes – material, efficient, formal, and final – into a unifying approach that sees developmental progress as something that has definite defining characteristics, and is influenced by definite and accountable factors? This task still remains before us. Developmentalists have focused on one or the other of these sets of causes. Werner's unique contribution was to develop a theory that had (the, as yet unfulfilled) promise, of providing a full picture of developmental processes, recognizing their complexity, their form, and the levels of organization that underlie what seem to be similar outcomes. The task of unraveling that knot is one that Werner set. It is a task that is increasingly needed as matters have shifted to thinking of development only in terms of its external manifestations.

Wheeler, Raymond H.

DAVID C. DEVONIS
Graceland University, Lamoni, IA, USA

Basic Biographical Information

Born March 9, 1892 Died August 24, 1961

Wheeler was a late product of Clark University, taking his MA there in 1913 and the PhD in 1915. He had broad interests, which were in evidence early: his masters' work was on vocational guidance while his doctoral thesis, completed under J. H. Baird, was a thoroughgoing account, drawing deeply on French sources, of the process of choosing.

Major Accomplishments/ Contributions

Wheeler moved west and joined the University of Oregon faculty. There he met Thomas Cutsforth, a student who had become blind several years earlier, with whom Wheeler conducted several extensive studies of synesthesia, again showing vast command of the earlier Continental literature on the subject (e.g., Wheeler and Cutsforth 1922, 1925). This research figures in current investigations of synesthesia (Dann 1998). In 1925, Wheeler moved to the University of Kansas, where, with Beulah Morrison (1896–1949), the third PhD graduate of the University of California at Berkeley, he established the modern psychology department and was chair for the next 22 years. Wheeler handled the theoretical coursework while Morrison was responsible for psychometrics and other applied areas: this arrangement duplicated in miniature the successful plan of other Midwestern departments such as Iowa and Minnesota. Between 1929 and 1932 Wheeler completed several books including an introductory text, a reader, and his main theoretical work *The Laws of Human Nature: A General View of Gestalt Psychology* (Wheeler 1932). Wheeler advanced an eclectic framework that transmuted Gestalt and other psychological theories into a series of universal laws, for example, the Law of Individuation (wholes precede parts, which result from differentiation from the whole) and the Law of Configuration (interactions occur only between complex systems). Within this general framework, Wheeler advanced more focal theories, for instance his view of learning as successive stages of insight. Wheeler's work caught the popular tide of Gestalt and was, for a time at least, influential. Wheeler played another important role in promoting Gestalt psychological theory by providing an academic home at Kansas for influential Gestalt-inspired psychologists: Harry Helson was there briefly before moving to Bryn Mawr, and J. F. Brown, who combined Lewinian field theory with Marxism in his social psychology, was a regular member of the Kansas faculty from 1931 onward. Wheeler was also ready to provide asylum for Adhemar Gelb in 1935, but unfortunately Gelb died before this could happen.

During the mid-1930s Wheeler, a self-styled non-conformist (Lapan and Houghton 1995), took a path that diverged from the mainstream, starting with his

early contribution to the General Semantics movement (Wheeler 1938). Wheeler was among the most extreme environmentalists among contemporary psychologists and espoused a radical environmental and situational determinism. This led him to fixate on a project which he began around 1937 and which occupied him for the rest of his career, an extensive investigation of the influence of climate on behavior. Briefly stated, Wheeler's theory of climate classified historical periods – based on trace data such as historical weather records or dendrochronological evidence (which was Wheeler's original impetus for this research) – as either hot or cold, and wet or dry. Wheeler asserted that certain types of sociohistorical events were determined by weather and could be predicted based on the prevailing climatic conditions. Wheeler accumulated enough hand-drawn graphic data on various historical events and climatic variations to fill what became known as the “Big Book,” which was mounted on wheels because of its size, a collection which migrated to his student S. Howard Bartley's laboratory at the University of Memphis and which has since been lost. Some more portable versions exist to give a flavor of its contents (e.g., Wheeler 1951). Eventually Wheeler's iconoclasm, especially his Lamarckian views on the influence of current behavior on heredity, had a detrimental effect on his Kansas career: a personal indiscretion coupled with collegial dissatisfaction with his views resulted in his sudden removal from Kansas in January 1947. Irrepressible, he surfaced again soon at Babson College in Massachusetts. There he found a congenial environment in the company of Roger Babson (1875–1967), whose lifelong quest to find anti-gravity resonated with Wheeler's visionary style. Wheeler continued to work on his climatic theory and also contributed a short article on psychology and gravity to Babson's cause (Wheeler 1954). At Kansas, Wheeler was succeeded by Roger Barker who continued, along with Fritz Heider and others, Wheeler's holistic environmentalism in a soberer manner. Wheeler quickly dropped from view, but his ideas about cycles of climate and history continued to find an audience well after his death: his work on climate and behavior was assembled and republished in the 1980s (Zahorchak 1983) and it still has some currency, though no more validity, among those in business and other fields interested in cyclic theories.

Willis, Thomas

DAVID PATTON BARONE

Illinois State University, Normal, IL, USA

Basic Biographical Information

Thomas Willis, a seventeenth century English physician, is recognized as the founder of neurology. He lived from 1621 to 1675, during the trying times of the English Civil War, the Restoration, and London's great plague and fire. As a royalist, he was appointed by King Charles II to displace the Puritans at Oxford University, and he received the *imprimatur* of the Archbishop of Canterbury for his anatomical studies. He spent most of his adult life at Oxford, earning his

bachelor's, master's, and medical degrees, and then becoming professor of natural philosophy. Following his election as Fellow of the Royal Society, he moved to London for the final 9 years of his life. All of his lectures and books were in Latin, still customary at that time. They were translated into English shortly after his death.

Major Accomplishments/Contributions

Willis is best known for the arterial ring in the brain (the circle of Willis) that he discovered. His most famous contribution, from 1664 (in Latin), is *The Anatomy of the Brain, to Which is Added The Description and Use of the Nerves* (Willis 1681/1971). This book summarized his dissections of the brain and nervous system and provided evidence for brain localization of many psychological functions. His research team's innovations included preserving the brain and dissecting from the base up. Previous brain dissections at Italian universities, most notably by Vesalius, sliced from the top down as the brain rapidly collapsed. The book, including drawings by Christopher Wren, provided detailed coverage of the entire nervous system, showing side-by-side comparisons of human and animal brains and of normal and abnormal human brains. For the first time, it mapped out the autonomic nervous system. It reported neurophysiological experiments, such as organ failure after severing autonomic nerves and separable supplies of blood to brain regions revealed by dye inserted into cerebral arteries. The first half of this work is available as Willis (1681/1971).

Three of Willis's other books are of special interest to psychology and neuroscience: *An Essay of the Pathology of the Brain and Nervous Stock, Of Mental Conditions Called Hysteria and Hypochondriasis*, and *Two Discourses Concerning the Soul of Brutes, Which is that of the Vital and Sensitive of Man*. His neuropathology combined clinical reports of symptoms and disease progress with findings from autopsies. His psychopathology included his case-supported view of hysteria as a brain disease afflicting men as well as women. Informed by his laboratory and clinical knowledge, he discussed many psychological processes in *Soul of Brutes* in 1672, an advance over Descartes' posthumously published *Treatise on Man* in 1662. Sample

topics include interconnectivity of brain regions, voluntary vs. involuntary action, automaticity of skills, developmental disability, learning and memory, imitation, and reflexive thinking.

Much of what Willis wrote in *Souls of Brutes*, a term going back to Aristotle and including many psychological functions, developed from his lectures at Oxford. John Locke had attended them, and he heard the empiricist dictum that also goes back to Aristotle in a Willis lecture: Nothing is in imagination which has not been in the senses first. However, Willis inserted that he would rather say *brain* than *imagination* and proceeded to lay out how sensory perturbations move through parts of the brain that he had dissected. Locke reported that Willis referred to the cerebrum in infants as a *tabula rasa*, a term often attributed to Locke although he did not use it. Willis was positing a thoroughly neural account of mind while Descartes reasserted traditional dualism with reason separate from the brain. Locke rarely referred to neural bases of behavior, but when he did, it was a direct borrowing from Willis, as in associations as established neural pathways and ideas so established as not to be subject to reason but to their own natures.

Willis has been neglected and criticized by historians of psychology, who relied on earlier critics rather than their own first-hand knowledge of his work. Edwin Boring dismissed Willis's work as pre-scientific because Willis used the traditional term, *animal spirits*. But electricity had not been discovered; it was 100 years later that Galvani provided the updated term, *animal electricity*. Boring claimed that work on brain localization began in the nineteenth century, although Max Neuberger, a German historian of medicine, had dated it back to Willis's work. Gregory Zilboorg attributed medical psychology's nonpsychological orientation to Willis, although Willis was replacing soul with brain without reducing or simplifying psychological functions to the little that was known about the brain. There has been a resurgence of interest in Willis's work, including an excellent biography (Isler 1968), a popular science book (Zimmer 2004), and scholarly works (Martensen 2004; Molnar 2004).

Winitz, Harris

ROBERT W. RIEBER

Fordham University, New York, NY, USA

Harris Winitz received his Ph.D. in 1959 from the University of Iowa with emphasis in speech language pathology, child language, and psychology. His primary research emphasis was the investigation of learning principles in articulatory and child language development and disorders. He later turned his attention to the study of foreign language acquisition as a method for understanding normal and delayed language development. This endeavor motivated him to apply learning principles to the development of language learning programs for a number of foreign languages. Winitz concluded that foreign language learning should contain an extensive period of listening using picture sequences to provide the meaning of auditory-presented words and sentences. He called this teaching and learning procedure “The Comprehension Approach to Foreign Language Instruction.” In the beginning stages of language instruction, it was observed that short sentences containing common objects were quickly understood by students and that they enjoyed this approach and were eager to continue taking lessons according to this format. To introduce concepts that are not directly presented as static objects, Winitz determined that language scripts or sequences of events were critical components of the language learning process. For example, to introduce the concept of “pick up,” a sequence of dropping

followed by the action of picking up was essential in establishing the meaning of “pick up.” More complex and abstract concepts required several sequential links to establish their meaning. It was also determined that semantic fields were extraordinarily useful in establishing the meaning of abstract concepts. For example, the semantic field of “walk” was taught by teaching “walk” as the anchor word and words related to walk, such as ambulate, dash off, promenade, and hike as styles of walking. These procedures and others, Winitz concluded, enable the language student to internalize the mentalistic concepts of the second language in much the same way that first language children acquire their native language. Winitz further concluded that speaking, unlike instruction in the articulation of speech sounds, cannot be taught, but is the outcome of intensive comprehension language learning.

Witkin, Herman A.

PADMINI BANERJEE

Delaware State University, Dover, DE, USA

Basic Biographical Information

Herman A. Witkin was an internationally renowned American psychologist, a pioneer in the study of cognitive styles, and an authoritative and respected figure working with colleagues across different areas of specialization within psychology, including comparative, Gestalt, personality, social, and cross-cultural psychology. Born on August 2, 1916, Dr. Witkin was educated at New York University, where he obtained an A.B. in Biology in 1935, followed by an M.A. and a Ph.D. in Psychology in 1936 and 1939 respectively.

While at New York University, Herman Witkin worked closely with T.C. Schneirla on studies of animal behavior. As Research Associate, he spent a year

working with Gestalt theorist Wolfgang Koehler at Swarthmore College. It was here that he met and began an extended collaboration with Solomon Asch who was conducting studies on social conformity under pressure and other related issues in social psychology. In 1940, Herman Witkin joined the faculty of Brooklyn College in New York, continuing his work on perception under the sponsorship of Wolfgang Koehler and Max Wertheimer. He taught at Brooklyn College for 12 years, between 1940 and 1952. During this period, in 1943, he married geneticist Evelyn Maisel; their two sons Joseph and Andrew were born in 1949 and 1952 respectively.

In 1952, Herman Witkin left Brooklyn College to join the Department of Psychiatry at State University of New York (SUNY) Downstate Medical Center College of Medicine in Brooklyn, NY. It was here that he conducted most of his research on cognitive and learning styles. In 1971, he joined Educational Testing Service in Princeton, NJ, where he worked as a senior research scientist until his death on July 8, 1979, following a brief illness. His wife Evelyn Maisel Witkin continued her long and successful career as a geneticist, earning numerous honors and awards, including the National Medal of Science in 2002, and over the years, their larger family grew to include several grandchildren.

Major Accomplishments/Contributions

Herman A. Witkin's main contribution to the field of psychology was the notion of cognitive style (the “how” of what we do, rather than “how much”), based on the widespread observation that individuals tend to deal with their physical and social contexts in “self-consistent” ways. He became interested in studying the role of cognitive styles vis-à-vis self-organizing and integrative processes involved in the development of personality.

Herman Witkin conducted numerous studies, many interdisciplinary and cross-cultural, on perceptual differentiation and individual differences in how individuals process information. His findings and insights occupy a central space within both cognitive and cross-cultural psychology. At the time of his death, Herman Witkin was in the midst of conducting a longitudinal interdisciplinary study of differences in

the psychological development of different groups inhabiting the Central African rain forest.

Herman Witkin's construct of "field independence-dependence" is the most widely recognized cognitive style. A field-dependent person uses external rather than internal referents, and relies more on cues and people embedded in the situation. In contrast, field-independent persons rely more on themselves, seek cues that are not context-bound, and are, in general, less influenced by peer pressure or the presence of others. In a colloquial sense, field-independent persons tend to see the "trees" and not the forest while field-dependent persons may notice the "forest" rather than the "trees."

Herman Witkin developed the Rod and Frame Test (RFT), which consisted of a glowing rod surrounded by a glowing square frame presented to participants in a darkened room. The participant's chair and the frame are tilted at different angles during the experiment and he/she is instructed to adjust the rod so that it is perfectly upright. If the participant adjusts the rod to conform to the frame, it indicates field dependence. If the participant ignores the contextual cues and uses the information from their body to adjust the rod, it indicates a tendency toward field independence. Finding the RFT cumbersome, he developed a less elaborate measure, the Embedded Figures Test (EFT) and its group version (GEFT), which measure dis-embedding, a cognitive restructuring skill that develops from one's cognitive style. Each complex pattern or picture contains an embedded simple figure or geometric shape, and the participant's task is to identify or discern the embedded shape as soon as possible. Both sets of measures were successfully validated.

His research collaborators and contemporaries included Max Wertheimer, Wolfgang Koehler, Heinz Werner, Solomon Asch, John W. Berry, and Donald R. Goodenough. After his death, new interdisciplinary research has continued to emerge on field independence-dependence in relation to a wide range of variables which include perceptual abilities (L. Zhang), reflection/impulsivity (J. Jamieson), cognitive learning processes (B. M. Frank; F. P. McKenna), language learning and acquisition as well as ESL/ELL and second language learning (C. Chapelle; A. R. Elliott), and moral reasoning (M. Bloomberg).

Herman A. Witkin was listed among 100 most eminent psychologists of the twentieth century in an article that appeared in the *Review of General Psychology* in 2002. The Institute for Scientific Information listed him among 100 most cited authors by the social sciences citation index, in the same category as John Dewey, Sigmund Freud, and Margaret Mead. In 1976, Herman Witkin was made an Honorary Fellow of the International Association for Cross-Cultural Psychology and a year later, in 1977, he received an honorary doctorate of social sciences from Tilburg University awarded by Queen Juliana of the Netherlands.

Herman A. Witkin was an author and coauthor of several prominent books and articles, including a monograph published in 1950. His first book was *Personality Through Perception* published in 1954, with two subsequent editions, followed by *Psychological Differentiation* in 1962, *Field Dependence and Interpersonal Behavior* in 1976, and *Cognitive Styles in Personal and Cultural Adaptation* in 1978. Two other books, *Cognitive Style* and *Cognitive Style, Essence and Origins* coauthored with Donald R. Goodenough were published posthumously in 1981.

Wolpe, Joseph

GLENN DON C. GENTHNER
Montclair, NJ, USA

Basic Biography

Joseph Wolpe was born on April 20, 1915, in Johannesburg, South Africa, to Michael Salmon and Sarah Millner Wolpe (Milite 2001). He studied in Johannesburg where he obtained an M.D. from the University of Witwatersrand. At the onset of World War II, he enlisted as a medical officer in the South African army and was stationed in a military psychiatric hospital. During this time, he married Stella Ettman (1948) and had two children. When the war ended, Wolpe and his family moved to the United States where he accepted a teaching appointment at the University of Virginia (1960) but spent most of his career at Temple University Medical School (1965–1988), where he served as a professor of psychiatry. Concurrently, he directed the behavior therapy unit at the Eastern Pennsylvania Psychiatric Institute. He was the founder and served as the second president of the Association for the Advancement of Behavior Therapy, and earned a lifetime achievement award in 1995 (Milite 2001). Wolpe relocated to California after retiring from Temple University in 1988. Despite his retirement he continued to teach at Pepperdine University until a month before his death. His first wife, Stella, died of cancer in 1990, and he remarried in 1996 to Eva Gyarmati who strongly supported her husband's commitment to empirical treatment methods. Joseph Wolpe was 82 years old when he died of lung cancer at his home in Los Angeles on December 4, 1997 (Milite 2001).

Accomplishments

Joseph Wolpe was a pioneer in behavior therapy in that he considered it to be an applied science and had considerable influence in the direction of psychotherapy techniques. He is best known for his development of desensitization technique and assertiveness training. While he was a medical officer in the South African army he encountered soldiers who

experienced adverse behavioral reactions as a result of trauma. This condition was then known as “war neurosis” (Milite 2001). Today, the Diagnostic Manual of Mental Disorders-TR (DSM-IV-TR) refers to this as a diagnosis called Post-traumatic Stress Disorder (PTSD) (American Psychiatric Association [DSM-IV-TR] 2000). After Wolpe experienced marginal results by treating the condition with drug therapy he developed a psychotherapeutic technique called systematic desensitization. Although Wolpe was initially interested in Freudian theory, he was inspired by Ivan Pavlov and Clark Hull's animal experiments and subsequently led to his research with cats. Wolpe concluded that much of human behavior, both positive and negative, is learned. In cases where irrational fear is present, he proposed that individuals can “unlearn” their fear by exposing them to the stimulus gradually and systematically. Based upon his research, modern desensitization techniques pair systematic relaxation with rehearsal of graded levels of stressful situations, until the fear-triggered stimulus is made less sensitive (Poppen 1996). Simply put, he revealed that anxiety is incompatible with physical relaxation.

Assertiveness training also emerged from Wolpe's research. Not unlike individuals who irrationally fear because of trauma, people who do not effectively assert themselves fear conflict, confrontation, and subsequent rejection. Assertiveness training builds confidence by gradually introducing healthy, empowering behaviors.

In 1958, Wolpe first published his ideas in *Psychotherapy by Reciprocal Inhibition* (Wolpe 1958). Since most psychiatrists at that time were trained in the psychoanalytic tradition, many believed that Wolpe's theories did not adequately address the cause of anxieties and believed that his technique would eventually lead to “symptom substitution.” Despite criticism, Wolpe initiated the *Journal of Behavior Therapy and Experimental Psychiatry* and published five other books (Reyna Leo 1998). He also developed the Subjective Units of Disturbance Scale (SUDS) for assessing individual level of subjective psychological distress (Milite 2001). The scales have been successfully used in numerous psychotherapeutic techniques, including Eye Movement Desensitization and Reprocessing (EMDR), Trauma-Focused Therapy (TFT), and Emotional Freedom Techniques (EFT).

Perhaps more than any other, Wolpe's work has successfully reconciled divergent approaches to psychotherapy (Poppen 1996). While some clinicians favored approaches that were empirically based, others favored approaches that were humanistic in nature. Joseph Wolpe demonstrated that psychological techniques can be distinctly empathetic while rooted in the objectiveness of science.

Women and Feminism, History of

FLORENCE L. DENMARK¹, MICHELE A. PALUDI²

¹Pace University, New York, NY, USA

²Union Graduate College, Schenectady, NY, USA

Definitions

Feminism: Womanism; valuing women. Feminism favors the social and legal changes that are necessary to achieve equality between women and men.

Feminist Psychology of Women: Recognition of the inequality of social and institutional power between women and men; making values of the researcher central to scientific study; studying women's behavior and experiences within social contexts across the life cycle; advocating for change.

Introduction: The Need to Engender the Discipline of Psychology

In 1994 Florence L. Denmark called for “engendering psychology,” that is, for the field of psychology to cultivate a discipline that is sensitive to issues of gender and diversity; a discipline that makes women and women's experiences central, not marginal to research and theories. Specifically, Denmark brought attention to the fact that psychology had ignored, trivialized, and distorted women's (especially women in poverty, women of color, and lesbian women) realities and issues. Denmark (1994) argued that researchers had permitted their personal opinions about women and men to bias their research. Denmark's call for an engendered discipline was in direct response to psychology having the following dominant themes in the conception of human behavior: androcentrism, gendercentrism, ethnocentrism, and heterosexism (Worell 1990). *Androcentrism* refers to the assumption that men's experiences were normative and women's experiences were the deviation from the norm. *Gendercentrism* is evident when separate paths of development are suggested for women and men as a result of the biological differences between them. *Ethnocentrism* refers to theories assuming that development is identical for all individuals across all racial, ethnic, and socioeconomic class groups. *Heterosexism* refers to theories and research that assume that a heterosexual orientation is normative, while gay, lesbian, bisexual, transsexual, transgendered, or questioning individuals are deviations from the heterosexual norm.

In this chapter, psychology's value-laden science is reviewed with respect to androcentrism, gendercentrism, ethnocentrism, and heterosexism. The history of the psychology of women is addressed from the perspective of research methods and theories used to study women's realities. This discussion will note that sex, race, sexual orientation, ethnicity, and socioeconomic class were used as the explanation rather than the starting point for scientific inquiry. Psychologists rarely considered these variables; when they did, they were considered to be “nuisance variables” that must be controlled (Crawford and Unger 2004). Consequently, for example, women were rarely involved as participants in research so as to control for potential differences due to sex.

Feminist correctives to the biases in psychology will be discussed, illustrating ways the discipline has become engendered. Following this discussion of ways women's experiences in psychology were kept hidden for many years, an overview of how the first generation of American women psychologists were themselves kept hidden from the history of psychology will be presented. Thus, this chapter reviews the feminist psychology of women (Part One) and the feminist women of psychology (Part Two).

Part One: Biases in Psychology's Discussion of Women

Androcentrism

- Psychology has nothing to say about what women are really like, what they need and what they want, essentially, because psychology does not know.

Naomi Weisstein

In the formative years of psychology as a discipline, the majority of researchers as well as research participants were men. Therefore, it should not be surprising that these researchers relied on their own experiences and interests to set goals for the discipline. Theories and research on men's experiences perpetuated the male as normative theme in psychology. Sechzer and Rabinowitz (2008) reported that most researchers in the behavioral and biomedical sciences failed to report the sex of their participants or women were not even invited to participate in the research. For example, the classic theory and research on achievement motivation (McClelland et al. 1953) was based on boys and men only. When women were studied initially, researchers learned their responses differed from men's. Consequently, researchers stopped studying women all together rather than reformulate their theories and methodologies to explain women's responses. In fact, McClelland et al. (1953) chose to ignore data suggesting women strive for achievement in a variety of domains (Paludi and Fankell-Hauser 1986). Their theory was preserved; women participants were labeled as being different, that is, "deficient" vis-a-vis men.

Similar experiences occurred with testing the theory of moral reasoning (Kohlberg 1976). Furthermore,

nearly half of the research on aggression was conducted on boys and men as well, 10% with girls or women and 40% with both sexes. This 50% is higher than the percentage of male-only research in psychology in general (Sechzer and Rabinowitz 2008), supporting androcentrism in psychology: when researchers investigated a stereotyped "masculine" behavior they were less likely to include girls and women.

Gendercentrism

Psychology treated women as a "special group" and a "problem" since the mid-nineteenth century (Maracek et al. 2003; Shields 1975). For example, theorists and researchers used physical evidence to justify women's subordinate status. As Shields noted: "...science sought explanations for female inferiority that were more in keeping with contemporary scientific philosophy" (p. 740). In 1800, Franz Joseph Gall hypothesized that mental and moral faculties were located in areas of the brain, and thus deficiencies as well as excesses could be observed by an examination of an individual's cranium (Wikipedia 2009). Researchers subsequently noted they could distinguish between men's and women's brains in terms of differences in gross structure. Malebranche (see Hamerton 2008) hypothesized that women's "cerebral fiber" was softer than that of the men's in addition to it being "slender and long rather than thick" (cited in Walker 1850, p. 318). Malebranche believed that these differences made women's senses "finer" and their sentiment more "delicate" (Hamerton 2008). According to Hamerton (2008), Malebranche's beliefs about women's "natural disposition" "...makes them prefer perceptible objects to metaphysical realities, amiable qualities to essential qualities, the brilliant to the solid, luxury and ostentation to cleanliness and commodity . . . it's also what makes them sensitive to piety, inconstant and light, and often capricious" (p. 533).

When Hughlings Jackson (see Meares 1999) claimed mental capacities were located in the frontal lobe, researchers found that men's frontal lobes were larger than women's. A larger brain was equated with more brain and therefore more intelligence. However, at the turn of the century when it became popular to view the parietal lobe as the repository of intelligence, researchers claimed there was no difference between

women and men in the size of their frontal lobes but men's parietal lobes were identified as being larger than women's.

In the 1800s Havelock Ellis (see Hyde and Linn 2006; Shields 1975) noted the variability hypothesis could explain the wider range of intelligence for men than for women and the greater frequency of men on lists of distinction. The variability hypothesis was the assertion that "women as a species are less variable among themselves than are men; all women are pretty much alike but men range enormously in their talents and defects" (Hollingworth 1943, p. 114). The variability hypothesis was used against women in education and in social policy. As Shields (1975) noted: "If this tendency to mediocrity was natural to the 'fair' sex, as the variability hypothesis would hold true, then it would be wasteful of public and private resources to train or encourage women to high levels of achievement" (p. 6).

The variability hypothesis would have been supported if the distribution of women's and men's behavior is on a Gaussian distribution. It is not, however. Furthermore, greater male intellectual variability had never been proven. If it had, support would not have been given to an innate greater intelligence in men. According to Hyde and Linn (2006), this variability hypothesis is only a description of the data; it does not explain the data. Leta Stetter Hollingworth (Lowie and Hollingworth 1916) found no objective data to support innate female inferiority, but rather noted that "every sex difference that has been discovered or alleged has been interpreted to show the superiority of males" (p. 284). Hollingworth (1943) noted it would be more profitable to examine the interaction of social constraints and cultural barriers to women's achievement rather than continue to study the variability hypothesis. Therefore, the problem was not differences between the sexes, but how the differences were interpreted by researchers in an androcentric and gendercentric culture (Riger 2002).

Ethnocentrism

Sigmund Freud's (1968) theory certainly illustrated gendercentricism since personality development was posited separately for women and men as

a consequence of the biological differences between them. According to Freud, as a consequence of girls' identification process not being as strong as that of boys', girls have stunted superegos, that is, less well-developed consciences. Women were perceived as passive, emotional, masochistic, and narcissistic. As Freud (1968) stated:

- ▶ I cannot escape the notion . . . that for women the level of what is ethically normal is different from what it is in men. Their superego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. (p. 193)

Freud viewed women as less ethical than men, as having a lesser sense of morality and being more influenced by emotions than by logic. A woman who was in a "masculine" occupation or exhibited "masculine" personality characteristics was interpreted by Freud to be maladjusted to her anatomy.

His theory of personality is also ethnocentric. Many women of color view themselves not as the passive and submissive woman Freud described but rather as strong, self-reliant, and independent. These characteristics have been misnamed as deviant in African American women, that the "matriarchal structure" responsible for the alienation of African American men. There are well documented factors that contribute to the greater rates of female headed households among African American families, for example, lower marriage and higher divorce rates and discrimination African American men have faced when gaining access to and maintaining employment to support their families. Furthermore, there is an increase in the number of female-headed households among white and Latina families (Paludi et al. 2007; Population Reference Bureau 2009).

Heterosexism

Psychological theories, for example, Erikson's theory of personality across the life span (Erikson 1963, 1968) illustrates heterosexism. His theory posits that children develop "normally" when in the care of a nurturing, biological mother and father. However, research does not support Erikson's view that heterosexual parents are the only ones essential to ensure normal child development. There is empirical evidence that suggests

children socialized in LGBT (lesbian, gay, bisexual, and transsexual) families are well adjusted, resilient, and value social justice, diversity, and tolerance (Carter 2006; Gartrell et al. 2005; Golombok et al. 2003; Peplau and Beals 2004).

Androcentrism Revisited: The Psychology of Women as “Difference”

Maracek et al. (2003) noted that much of the psychological research about women in the decades preceding the second wave of feminism concerned finding differences between women and men. An overemphasis on differences illustrated by the review of the biases in the history of psychology provides confirmation of stereotype that women and men are “opposite,” that men are the norm and women are a deviation from the norm. Research that found no differences between the sexes were not published and instead placed in the researcher’s file drawer (Rosenthal 1979), contributing to a publication bias in psychology. Studies that reported gender differences were published; those that found no differences were not since they challenged existing, stereotypic beliefs about women and men (Sechzer and Rabinowitz 2008).

In 1974, Maccoby and Jacklin used a voting method of analysis of approximately 1,600 published studies in determining whether statistically significant differences between the sexes were reported (Maccoby and Jacklin 1974). Their goal for this research was “to sift the evidence to determine which of the many beliefs about sex differences have a solid basis in fact and which do not” (p. viii). This analysis indicated many of the presumed differences were more myth than fact, for example:

1. Girls are more responsive to auditory stimuli; boys to visual stimuli.
2. Girls are more social than boys.
3. Boys are more analytic than girls.
4. Girls excel at low-level cognitive tasks, boys at higher-level cognitive tasks.
5. Boys are more influenced by their environment; girls by heredity.
6. Girls have lower self-esteem than boys.
7. Girls are more conforming than boys.
8. Girls have less achievement motivation than boys.

Only four differences were supported by their analysis:

1. Girls have greater verbal ability than boys.
2. Boys excel in visual-spatial ability.
3. Boys excel in mathematical ability.
4. Males are more aggressive than females.

Maccoby and Jacklin (1974) reported these differences occurred during adolescence and beyond, giving support for cultural, not biological bases for differences between the sexes. For example, girls’ and boys’ verbal abilities are similar during the early school years. In high school and beyond however, girls are better in spelling, creative writing, comprehension of analogies and have a better understanding of and fluency in the complexities of language. Beginning in adolescence, boys exhibit a greater facility with math than do girls. However, in exams that use verbal processes in mathematical questions, girls perform better than boys.

Maccoby and Jacklin’s (1974) conclusions have been challenged (e.g., Block 1976; Hyde and Grabe 2008) since they simply counted the studies that found a gender difference and compared them to those that did not. Furthermore, most of the studies reviewed contained relatively few research participants, ensuring little or no statistically significant gender differences (see Hyde 1986). Most importantly for many feminist psychologists, Maccoby and Jacklin’s research continued to emphasize girls and women in relation to boys and men, in other words, to perpetuate differences.

Magnitude of Differences Between Women and Men: Meta-analysis and the Psychology of Women

Sherman (1978) and Hyde (1981) rereviewed many of the studies initially used in Maccoby and Jacklin’s study and found that while statistically significant, the magnitude of the differences between the sexes was small. According to Hyde (1981), when obtained, differences between the sexes only accounted for approximately 1–5% of the population variance. Hyde used meta-analysis to derive her conclusions, a statistical method that assists researchers in synthesizing results from several studies in order to measure the magnitude of a difference (see Hyde and Grabe 2008 for a review of

meta-analysis in the psychology of women). Meta-analytic studies have been conducted in several areas, including self-esteem (Kling et al. 1999), displaced aggression (Marcus et al. 2000), role conflict and job performance (Tubre and Collins 2000), sexuality (Hyde and Oliver 2000), malleability of automatic gender stereotypes (Lenton et al. 2009), and aggression (Eagly and Johnson 1990). Meta-analytic studies have offered revised interpretations of the data reviewed by Maccoby and Jacklin (1974). For example, Hyde et al.'s (1990) meta-analysis indicated that the conclusion Maccoby and Jacklin (1974) drew about boys excelling in mathematical ability was oversimplified. They observed that when mathematical ability is operationally defined as performance in school (as opposed to performance on standardized math tests), girls did better than boys in all grade levels.

In their review of meta-analytic studies, Hyde and Grabe (2008) concluded that meta-analyses can advance the study of the psychology of women because they can (1) indicate not only whether there is a significant gender difference but also the magnitude of the difference; (2) accept the null hypothesis; (3) investigate gender x situation interactions; (4) be used to analyze other issues, for example, race, ethnicity; (5) test theories of gender; and (6) test the Gender Similarities Hypothesis, that is, males and females are similar on most psychological variables.

One criticism of meta-analysis, however, concerns the studies that are selected to be used in the analysis. Studies that contain methodological biases are sometimes included in the analysis, sometimes they are omitted. For example, Makosky and Paludi (1990) noted that researchers may be creating the gender differences they report. This is especially true when research is done with students in introductory psychology courses. Women who take introductory psychology are majoring in the social and behavioral sciences; men typically are majoring in the natural and physical sciences. Therefore, one part of the distribution in interests, personality characteristics, and abilities are sampled for women; another for men.

In addition, meta-analysis has been criticized because of the continued emphasis on gender differences and gender similarities, which encourages researchers to exaggerate those differences they do

observe (Sechzer and Rabinowitz 2008). Similar to the early research that focused on brain size differences, the tendency persists to use research data about women to formulate social policies that would be harmful to women. Psychologists must be vigilant in their analyses as well as methodologies for this very reason.

Exaggerating Differences Between the Sexes: The Example of Moral Reasoning

"Difference" is a problematic way to construe the psychology of women. If differences are exaggerated, the findings may serve as a basis for discrimination against women, who are "different." If actual differences (e.g., in wages) are ignored or minimized, women may also be discriminated against (e.g., through inadequate child support). In both the "gender as difference" model and the "minimizing difference" model, white, middle class, heterosexual men are still the standards of comparison, the norm against which women and femininity are judged.

Proponents of the psychology of women from a gender as difference perspective view differences between the sexes as universal, essential, and enduring. This is illustrated with research on stages of moral development. We previously mentioned that Kohlberg's (1976) theory of moral reasoning was criticized because it was predicated only on boys' and men's responses. Kohlberg concluded however that his theory adequately described moral reasoning of both women and men. He also argued that women's moral reasoning is less well developed than men's.

Carol Gilligan (1982) countered Kohlberg's theory by stating that women's morality can be viewed as an "ethic of care." She argued that women view "life as dependent on connection, as sustained by activities of care, as based on a bond of attachment rather than a contract of agreement" (p. 57). Gilligan also challenged Kohlberg's theory that moral reasoning based on an ethic of justice represents the highest level of morality. However, Gilligan's theory has been criticized because it is not possible, as she theorized, to identify a universal moral reasoning that applies to all women (Cosgrove and McHugh 2000). Gilligan's theory thus has not addressed the distinctions among women but rather the moral reasoning of white, middle-class girls,

and women (Tronto 1987). There is a great deal of variability among women because of race, ethnicity, stage of family formation, socioeconomic class, sexual orientation, stage in their career development, and so on. Within group, variability is thus ignored when the focus is on “difference.”

Minimizing Differences Between the Sexes: The Example of Psychological Androgyny

Focusing on similarities between the sexes underlies the construct of psychological androgyny, introduced by Sandra Bem (1977) as a way to minimize the differences between women and men, which had previously been the focus of the psychology of women. Androgyny was defined as a personality pattern wherein an individual combined the socially valued stereotypic characteristics associated with femininity and masculinity in their behavioral repertoire. Thus individuals were not longer expected or encouraged to restrict their behaviors to traditional gender role-specific characteristics.

Lott (1981) argued however that although psychological androgyny was an improvement over the view that masculinity and femininity were opposite and mutually exclusive ends of a personality dimension, the androgynous perspective still held that personality comprises feminine and masculine elements. While the androgynous perspective implies the equivalence of femininity and masculinity, in fact the masculine traits are more highly valued in North American culture. As Hare-Mustin and Marecek (1988) noted:

- ▶ When the idea of counterparts implies symmetry and equivalence, it obscures differences in power and social value Arguing for no differences between women and men, however, draws attention away from women’s special needs and from differences in power and resources between women and men. (pp. 458, 460)

Feminist psychologists (e.g., Burger and Solano 1994; Doyle and Paludi 1997) have argued that rather than socializing individuals to express behaviors considered feminine and masculine, it would be to society’s advantage to value all positive behaviors, regardless of their appropriateness for one sex or the other. Thus, gender role transcendence is the goal, that is, the

abandoning of gender categories so that personality characteristics, social and occupational roles become independent from gender categories.

Psychology of Women as Redefining Constructs and Methodologies: Feminist Research

Several feminist researchers have recommended that psychologists redefine the constructs typically used in studies on the psychology of women so as to place value on women and women’s realities. For example, “work” needs to be redefined to include volunteer services and housekeeping; “power” needs to be changed from having power over to empowerment. In addition, feminist psychologists differ from nonfeminist psychologists in the theories used, the ways theories are applied to research problems, and the ways knowledge is constructed. For example, some feminist psychologists use qualitative research methods as one way to correct the biases inherent in quantitative methods (Sechzer and Rabinowitz 2008), to what Maracek et al. (2003) refer to as “methodological pluralism.” These methods share the following underlying values (Chrisler and Smith 2004). They:

1. Challenge dichotomous portrayals of women and men
2. Consider women’s experience within their social contexts
3. Improve women’s well-being
4. Empower women
5. Advocate for women
6. Identify sexism women experience
7. Consider reflexivity

Examples of these alternative approaches to studying the psychology of women are life narratives, content analysis, observational techniques, focus groups, field research and case studies (e.g., Hoshmand and O’Byrne 1996; Rosenwald and Ochberg 1992; Wilkinson 1999). These methods also recognize the role of values in scholarship and recommend researchers state their biases openly in the study of human behavior (Parlee 1979). According to Parlee (1979): “feminist psychologists thus have as a priority finding the best possible version of the truth about the subject matter rather than adhering strictly to a particular method” (p. 130).

McHugh et al. (1986) and Denmark et al. (1988) offered guidelines for nonsexist research, including interpreting without bias, avoiding excessive confidence in traditional methods, and examining explanatory models. These recommendations provide the beginnings for an alternative approach to the study of all of human behavior. Research is viewed as taking place within a well-defined cultural and social context, never totally free from the concerns and values of the larger society. Feminist researchers are also mindful of policy considerations of their research. The recommendations avoid androcentrism, gendercentrism, ethnocentrism, and heterosexism in all stages of the research process.

Research on Psychology of Women: International Perspectives and Values

In 2004, the American Psychological Association's Council of Representatives adopted a Resolution on Cultural and Gender Awareness that included (American Psychological Association 2004):

1. Advocate for more research on the role that cultural ideologies have in the experience of women and men across and within countries on the basis of sex, gender identity, gender expression, ethnicity, social class, age, disabilities, and religion.
2. Advocate for more collaborative research partnerships with colleagues from diverse cultures and countries leading to mutually beneficial dialogues and learning opportunities.
3. Advocate for critical research that analyzes how cultural, economic, and geopolitical perspectives may be embedded within US psychological research and practice.
4. Encourage more attention to a critical examination of international cultural, gender, gender identity, age, and disability perspectives in psychological theory, practice, and research at all levels of psychological education and training curricula.
5. Encourage psychologists to gain an understanding of the experiences of individuals in diverse cultures and their points of view, and to value pluralistic world views, ways of knowing, organizing, functioning, and standpoints.
6. Encourage psychologists to become aware of and understand how systems of power hierarchies may

influence the privileges, advantages, and rewards that usually accrue by virtue of placement and power.

7. Encourage psychologists to understand how power hierarchies may influence the production and dissemination of knowledge in psychology internationally and to alter their practices according to the ethical insights that emerge from this understanding.
8. Encourage psychologists to appreciate the multiple dilemmas and contradictions inherent in valuing culture and actual cultural practices when they are oppressive to women, but congruent with the practices of diverse ethnic groups.
9. Advocate for cross-national research that analyzes and supports the elimination of cultural, gender, gender identity, age, and disability discrimination in all arenas – economic, social, educational, and political.
10. Support public policy that supports global change toward egalitarian relationships and the elimination of practices and conditions oppressive to women.

These recommendations place women's experiences in their cultural contexts (Riger 2002). As Denmark et al. (2008) noted with respect to these recommendations, contextualizing women's experiences "encourages feminist psychologists to view women as whole beings or people who exist in a bidirectional relationship with the environment in which they live" (p. 34).

Review of Part One

While women and psychology had been independent from each other due to the androcentrism that has existed in the discipline, the field now has women as research participants and researchers, engaged in collaborative processes in a nonhierarchical relationship between researcher and participant (Sechzer and Rabinowitz 2008). Women have their voices expressed and respected in research. This has given rise to the study of topics that could not come to light in the androcentric treatment of women, for example, sexual violence against women, pregnancy, lesbian parenting, breast feeding, women's reproductive rights, feminist psychotherapy, women's friendships and romantic relationships, discrimination against women in the

workplace and women and leadership. This research is used to inform public policy, legislation and advocacy for girls and women in the courts, women's shelters, rape crisis centers, K-12, and college/university campuses. As Walsh (1985) noted, the psychology of women serves as a "catalyst for change."

In addition to topics worthy of study for and by women that were essentially omitted in the history of psychology, women psychologists themselves were omitted from discussion; their work was distorted or credited to male coresearchers.

Part Two: The Heritage of the First and Second Generations of American Women in Psychology – The Personal Is Political

The experiences of the first generation of American women psychologists have been reconstructed by several researchers, for example, Furumoto and Scarborough (1986) and Russo and Denmark (1987). In the process of restructuring their lives, issues with which the first generation of American women psychologists were dealing also have been brought to light. When compared to their male peers, women psychologists were similar in age and training. However, they were less likely to achieve equivalent professional status.

Rossiter (1982) argued that the first generation of American women psychologists were in the middle of two conflicting stereotypes. On one hand, they were stereotyped as "soft, delicate, emotional, noncompetitive, and nurturing kinds of feelings and behavior" (p. xv). On the other hand, they were scientists, who were portrayed as "tough, rigorous, rational, impersonal, masculine, competitive, and unemotional" (p. xv). Furthermore, according to the American Psychological Association (2009), with respect to the first generation of American women psychologists, "the mantle of scientific psychology was used to justify discrimination against them" (p. 1).

According to Furumoto and Scarborough (1986):

- ▶ Certain gender-specific factors profoundly affected the women's experience: exclusion from important educational and employment opportunities, the responsibility of daughters to their families, and the marriage-versus-career dilemma. (p. 39)

These issues are those in which many women in the second generation of American psychologists and modern day women psychologists face, supporting Hanisch's (1969) conclusion: "the personal is political." The personal problems faced by early women psychologists just as today are political problems, the result of systematic oppression. We discuss these issues raised by Furumoto and Scarborough (1986) in the next section, highlighting current research with experiences of the first and second generations of American women psychologists. We cite these women's firsthand accounts in order to give them their voice, thereby not perpetuating them being hidden from the history of psychology.

Gatekeepers: Exclusion of the First Generation of American Women Psychologists from Graduate Study and Academic Careers

Each of the first generation of American women psychologists experienced discrimination in her attempts to earn a Ph.D. in psychology. Margaret Washburn, Christine Ladd-Franklin, and Mary Calkins began their graduate studies as "special students" or "guests" at Columbia University, Johns Hopkins University, and Harvard University, respectively. The "special student" or "guest" status reflected the universities' exclusionary policies toward women earning graduate degrees. Gatekeepers kept women out of graduate programs in psychology; graduate school administrators and faculty who believed that women have no place in their particular profession were especially powerful gatekeepers (Betz and Schifano 2000). Gatekeepers, for example, G. Stanley Hall, the founder of the American Psychological Association, did not see themselves as discriminatory; they rationalized that their resistance to women in the profession was based on "facts."

Margaret Floy Washburn (1871–1939) had to audit graduate courses in psychology at Columbia and eventually studied at Cornell University. She stated (1930):

- ▶ Columbia had never admitted a woman graduate student: the most I could hope for was to be tolerated at a "hearer." (Floy Washburn, p. 4)

Floy Washburn is credited with being the first woman to earn the doctorate in psychology (in 1894). In addition, Washburn was the second woman

president of the American Psychological Association in 1894. She authored two texts: *The Animal Mind: A Text-Book of Comparative Psychology* (1908) and *Movement and Mental Imagery* (1916). Her research focused mainly on the relationship between motor development and mental activity.

She was denied membership in the “Experimentalists” and was denied an academic position at a research university. Floy Washburn wrote (1930):

- ▶ ...a telegram asked me to come to Wells College ... they could offer me little money, but I gladly accepted ... at a salary of three hundred dollars and home. The salary ... had by the last two years reached the maximum for women professors, seven hundred dollars and home; the men were paid fifteen hundred. (pp. 6–7)

Mary Calkins (1863–1929), a “special student” at Harvard University, was initially refused by Harvard’s administration to attend lectures by William James. However, with the intervention of both her father and the President of Wellesley College, her request was approved in 1890. Furumoto (1980) noted that Calkins’ acceptance was addressed in Harvard’s records as follows: “by accepting this privilege Miss Calkins does not become a student of the University entitled to registration.” Calkins completed the requirements for her Ph.D. from Harvard in 1895. However, she was refused the degree because she is a woman. William James had noted the following regarding Calkins’ performance at Harvard:

- ▶ It was much the most brilliant examination for the Ph.D. that we have had at Harvard. It is a pity, in spite of this, that she still lacks the degree. Your downtrodden but unconquerable sex is fairly entitled to whatever glory and credit may accrue to it from Miss Calkins’ prowess. (Reported in Scarborough and Furumoto 1987, p. 46)

Calkins was offered the Ph.D. in 1902 with one stipulation: that the degree would be under the auspices of Radcliffe College, not Harvard University. Calkins declined the degree so as to highlight the university’s refusal to recognize women and women’s accomplishments. According to Calkins:

- ▶ I ... think it highly probable that the Radcliffe degree will be regarded generally as the practical equivalent of

the Harvard degree and finally, I should be glad to hold the Ph.D. degree for I occasionally find the lack of it an inconvenience, and now that the Radcliffe degree is offered, I doubt whether the Harvard degree will ever be open to women. ... I cannot rightly take the easier course of accepting the degree.

Calkins invented the paired associate technique, created a theoretical perspective of self-psychology and founded the psychological laboratory at Wellesley College in 1981 and remained at Wellesley until her retirement 40 years later. She was the first woman president of the American Psychological Association in 1905. In 1918 Calkins was elected president of the American Philosophical Society. Calkins authored *The Persistent Problems in Philosophy* and *The Good Man and the Good*. Stevens and Gardner (1982) noted that Calkins was treated poorly in the history of psychology:

- ▶ Her major contribution to her science ... her invention of the experimental procedure she called the method of right associates, is now credited to someone else and even appears in textbooks under a different name than the one she had bestowed upon it. (p. 88)

As another example of the exclusionary practices the first generation of American women psychologists faced, *Christine Ladd-Franklin (1847–1930)* was only able to attend graduate courses at Johns Hopkins University through the intervention of mathematician James J. Sylvester. According to Jacob (1976):

- ▶ The university first announced its fellowship program in 1876, and one of the first applications to arrive was one signed “C. Ladd.” The credentials accompanying the application indicated such outstanding ability that a fellowship in mathematics was awarded to the applicant, site unseen, and was accepted. When it was discovered that the “C.” stood for Christine, several embarrassed trustees argued that she had used trickery to gain admission, and the board immediately moved to revoke the offer.

Ladd-Franklin eventually was accepted to take courses in the fall of 1878. Jacob (1976) pointed out however, that:

- ▶ Though she had a fellowship for three years, the trustees forbade that her name be printed in circulars

with those of other fellows, for fear of setting a precedent. Dissension over her continued presence forced one of the original trustees to resign.

She received the Ph.D. from Johns Hopkins 44 years after satisfying the requirements for the degree. She lectured on logic and psychology for 5 years at Johns Hopkins and was the only woman on the faculty. She also taught for 15 years at Columbia University. Ladd-Franklin published *Colour and Colour Theories*, a collection of her research on color vision.

In 1912, Ladd-Franklin wrote to E.B. Titchener concerning his exclusion of women from the “Experimentalists:”

- ▶ I am particularly anxious to bring my views up, once in a while, for hand-to-hand discussion before experts, and just now I have especially a paper which I should like very much to read before your meeting of experimental psychologists. I hope you will not say nay! (Scarborough and Furumoto 1987, p. 125)

Titchener argued that women were not allowed to attend these meetings because they could not tolerate “masculine” activities such as smoking. Ladd-Franklin responded as follows:

- ▶ Have your smokers separated if you like (tho I for one always smoke when I am in fashionable society), but a scientific meeting is a public affair, and it is not open to you to leave out a class of fellow workers without extreme discourtesy. (Scarborough and Furumoto 1987, p. 125)

Ladd-Franklin and other women were always denied membership in this association during Titchener’s lifetime. Furumoto (1994) identified this “collegial exclusion” as a major force against Ladd-Franklin and her female contemporaries. Titchener noted, regarding this association: “the select group of newcomers to the field were the men who had arrived” (cited in Furumoto 1994, p. 97). Membership in the Experimentalists provided graduate students and junior faculty with mentoring, social contexts and thus connections that are necessary for success in academia. Jandeska and Kraimer (2005) have referred to this condition as the “opportunity gap,” the factors that bar women from advancing in their careers at the same rate as men.

As Ladd-Franklin stated:

- ▶ It is evident that it is high time for us to consider seriously what steps can be taken to start these doctors of philosophy on the career which they long for and which is indeed their due. The proportion of these, who, after their brilliant preparation for the highest work, find that there is nothing in the world for them to do save the drudgery of teaching in the public schools is large, and is constantly becoming larger. . . . But, by are the most important of all, to create a few first-class women college professors who would not otherwise exist would be to make a distinct contribution toward the furthering of the rights and privileges of the sex in general. (pp. 3, 5)

The masculine bias inherent in the definition of career advancement for the first generation of American women psychologists explains why the contributions of these women to research were distorted, omitted, or trivialized. For example, Calkins spent her entire academic career at Wellesley College. Palmieri (1983) noted that Calkins and other women faculty at Wellesley had advantages since it was an all-women’s educational community. However, women faculty experienced career disadvantages as well, including: (1) heavy teaching loads, (2) inadequate resources for conducting their research, and (3) not teaching graduate students who would become the next generation of American psychologists. Thus, the definition of success used during the first generation of American psychology precluded women who were on the faculty at women’s colleges, where no graduate programs existed.

Second Generation of American Women Psychologists’ Exclusion from Graduate Study and Academic Careers

Johnston and Johnson recently (Johnston and Johnson 2008) identified the second generation of American women psychologists, those who received doctoral training before the end of World War II, who earned their doctorates between 1906 and 1945. Johnston and Johnson noted that the second generation of American women psychologists:

- ▶ . . . entered a much transformed and expanding discipline with more emphasis on applied work. They also

began their psychological careers at a time when women's status in US society was undergoing rapid change in response to the women's rights activism that had its most visible impact on women's suffrage. (p. 40)

Compared to the first generation of American women psychologists, these women had little difficulty in obtaining acceptance into graduate programs; several universities admitted many women so that the second generation of American women psychologists were not tokens in the graduate departments. However, while these women did not experience the exclusionary practice toward them entering graduate schools, they did experience discrimination after they completed their Ph.D.s. For example, many of these women were employed outside of academia in child welfare clinics, courts, and schools. In addition, those women who did enter academia did so as research fellows on short term contracts. Of the 117 second generation women who obtained academic positions, 67% held associate or full professorships. Johnston and Johnson (2008) also noted that approximately half of the women in the second generation of American psychologists taught at all women's colleges or teachers' colleges. Those in research universities found themselves to be the sole woman faculty member.

For example, *Eleanor Gibson (1910–2002)* described her experiences with being the sole woman academician in her department. According to Gibson (1976):

- ▶ I was a token woman . . . when I look around and see, yes, here I am, the only woman on a committee, again, you think: Why didn't they have some more? Sometimes there are two. There is another woman who I know quite well. She is president of the Social Sciences Research Council. We serve as the two women on many committees frequently . . . because somebody says: "Well, we have to have a woman," and her name is Eleanor too, so they say, "We should have the two Eleanors. (pp. 8–9)

Furthermore, as Johnston and Johnson (2008) noted, many of the many second-generation women who were married to psychologists were adversely affected by antinepotism laws of universities. The antinepotism rules implemented by academia impacted several

second generation women psychologists, for example, Mary Cover Jones, Eleanor Gibson, Tracy Kendler, Helen Nowlis, Anne Roe, Pauline Sears, and Thelma Thurstone (Johnston and Johnson 2008). For many women they maintained an association with academia as a part-time instructor or research assistant. They also worked in these positions for little or no salary. They attained a full time tenured position later in their lives vis-a-vis their husbands since they had to wait until academia accepted women married to male professors (Johnston and Johnson 2008).

Gatekeepers and Exclusionary Practices Toward Women Psychologists Today

Strickland (1987) noted that the field of psychology was going to become the first science to be "feminized," having more women than men. However, Hogan and Sexton (1991) identified that in the American Psychological Association, women have not attained high-level office, editorships, and significant committee posts at the same level as male colleagues. They described one 51-year-period where no women were elected to the American Psychological Association presidency. The first woman president following this period was Anne Anastasi, who was elected in 1972. Following Anastasi's election, the following women were elected president:

- 1973: Leona E. Tyler
- 1980: Florence L. Denmark
- 1984: Janet T. Spence
- 1987: Bonnie R. Strickland
- 1996: Dorothy W. Cantor
- 2001: Norine G. Johnson
- 2004: Diane F. Halpern
- 2007: Sharon S. Brehm
- 2010: Carol D. Goodheart

In its 117-year-history, 13 women have served as president of the American Psychological Association. Melba Vasquez has recently been elected to be president, with her term beginning in 2011. She is the first Latina to be elected president of the American Psychological Association.

Results from surveys by the Center for Workforce Studies of the American Psychological Association (2007) and the 2008–2009 American Psychological

Association Faculty Salaries in Graduate Departments of Psychology Survey indicated:

1. As Strickland (1987) predicted, women entering the field of psychology has increased over the past several decades. Concurrently, the percentage of men pursuing a career in psychology has slightly decreased over the same span of years.
2. In 2005, 72% of new Ph.D.s in psychology were women, an increase of 6% in the last 10 years, and 20% in the last 20 years. In 1976, the percentage of women Ph.D.s was 33.
3. The median starting salary in 2005 was \$55,206. Women reported earning a median salary approximately \$4,000 less than earned by men.
4. The majority of women Ph.D.s were on the faculty at 2-year-colleges or in hospital settings; the majority of men Ph.D.s were on the faculty of universities with graduate programs.
5. More women than men were lecturers, assistant or associate professors in academic institutions; more men were full professors.
6. More men than women achieved tenure in psychology graduate departments each selected year studied (from 1985 to the present).

Certainly great strides have been made by women and for women psychologists since the first and second generation of American women psychologists' experiences. While current statistics reflect women's individual choices concerning career/family integration, the data also reflects sexism on the part of organizations (Bernstein and Russo 2007). Handelsman et al. (2005) identified the following barriers to women in the academy: pipeline losses, chilly campus climates, lack of mentors, hidden bias among senior faculty and administrators evaluating tenure and promotion materials and glass ceiling biases.

The academy is structured by a traditional and stereotypical masculine culture which, in turn, values and rewards men who exhibit these stereotypical traits more so than women (Bailyn 2003). Women often struggle to find their place within such an organization. As Jandeska and Kraimer (2005) argued:

- This "code of conduct" in masculine cultures, while recognizable to males, can be completely alien to females and thus would be considered less hospitable

towards women's careers. For example, an "old-boy network" excludes women from centers of influence and valuable sources of information, often trivializing or ignoring their contributions. (p. 465)

Cheal et al. (2009) noted that 28% of the Fellows of the American Psychological Association are women. These statistics underscore the barriers that still exist for women psychologists.

Gatekeepers of Women of Color

Historical information about ethnic and racial minority women in psychology is relatively scarce. The first African American woman to earn a doctoral degree was Inez Prosser, who received the Ed.D. in educational psychology from the University of Cincinnati. Ruth Howard was the first African American woman to earn the Ph.D. in psychology. Martha Bernal is credited with being the first Chicana to earn the Ph.D. in psychology.

Inez Prosser (1895–1934) had taught at the secondary and college levels for nearly half of her life. Her dissertation was central to school desegregation debates leading up to *Brown v. Board of Education* decision of the United States Supreme Court in 1954. Benjamin et al. (2005) noted that when Dr. Prosser went for the fitting of her cap and gown for her doctoral graduation ceremony she was told by other degree candidates that she was in the wrong room; that the room was only for students graduating with their doctorates. Beverly (1974) indicated that Prosser's response was "Yes, I know. That's why I am here" (p. 3). Benjamin et al. (2005) also noted that Prosser's being awarded the doctorate was of such importance to the African American community that she was featured in her cap and gown on the cover of the magazine *The Crisis: A Record of the Darker Races*, the official magazine of the NAACP, in 1933.

Similar to other women faculty members in her cohort, Prosser served simultaneously as registrar, professor of education, and dean at Tillotson College for her first position. Dr. Prosser met an untimely death a year following completing her doctoral work at the University of Cincinnati.

Ruth Howard (1900–1997) earned her Ph.D. in psychology in 1934 from the University of Minnesota, where, for her dissertation, she studied the developmental history of 229 sets of triplets, ranging in age from infancy to 79 years of age. Howard completed her

internship at the Illinois Institute of Juvenile Research as well as worked at a state school for delinquent girls. Howard subsequently began a private clinical practice with her husband, Albert Sidney Beckham.

Martha Bernal (1931–2001) earned her Ph.D. in clinical psychology from Indiana University, Bloomington, in 1962. Vasquez (2003) noted that Bernal “. . . contributed to an increase in the use of empirically validated interventions in child treatment . . . she helped to advance a multicultural psychology – one that recognizes the importance of diversity in training, recruitment, and research” (p. 1). Furthermore, Dr. Bernal worked toward increasing the number of ethnic minority psychologists in the discipline and toward making the psychology curricula more inclusive. Dr. Bernal served as president of the National Hispanic Psychological Association (National Latina/o Psychological Association).

Mamie Phipps Clark (1917–1983) reported difficulty in obtaining employment following her completion of the Ph.D. in 1943 from Columbia University. Her research on identity in Negro children was instrumental in the 1954 Supreme Court ruling in *Brown v. Board of Education* that concerned desegregation of schools in the United States. She subsequently took work administering psychological tests in an agency helping homeless African American girls. In collaboration with her husband, Kenneth Clark, she founded and operated the Northside Center for Child Development in 1946. This center provided psychological services to the Harlem community. She described her experiences with the intersectionality of race and sex, and the oppressions faced by people who are simultaneous members of more than one disenfranchised group (Hill Collins 2004/1986; Hooks 2004/1990):

- ▶ Although my husband had earlier secured a teaching position at the City College of New York, following my graduation it soon became apparent to me that a Black female with a Ph.D. in psychology was an unwanted anomaly in New York City in the early 1940s. (Clark 1983, p. 271)

Gatekeepers of Women of Color Today

Results from surveys by the Center for Workforce Studies of the American Psychological Association

(2007) and the 2008–2009 American Psychological Association Faculty Salaries in Graduate Departments of Psychology Survey indicated that 80% of new Ph.D.s in 2005 are white. Latinos and Asians each comprised 6% of the new Ph.D.s. African Americans comprised 4%. De la Luz Reyes and Halcon (1988) argued that women of color have been more disadvantaged in psychology than white women as a consequence of their participation in a culture that has valued neither women nor nonwhite individuals. Beale (1970) referred to this as “double jeopardy.” De la Luz Reyes and Halcon (1988) noted that many gatekeepers operate under the “one-minority-per-pot” syndrome in academia:

- ▶ We believe that implicit in this practice is a deep-seated belief that minorities are not as qualified as nonminorities. This conviction stems from an unspoken fear that the presence of more than one minority . . . in a mainstream, traditional department might reduce the department’s . . . reputation. . . . (pp. 305–315)

Cheal et al. (2009) noted that only 7% of the Fellows of the American Psychological Association are minority individuals.

Organizations to Promote Women in Psychology

In 1968, the *Association of Black Psychologists* was established in order to eradicate the myths regarding the psychology of African American women and men and to increase their representation in the discipline of psychology.

The National Latina/o Psychological Association includes a subdivision that is: “designed to recruit, retain, and ultimately assist with the graduation and professional advancement of Latina/o students, faculty, and staff in higher education pursuing the field of psychology” (National Latina/o Psychological Association 2009).

The Asian American Psychological Association began in 1972 in order to “advance the psychological well-being of Asian American communities through affecting professional practice, research, and teaching. For our members, we offer mentoring and networking opportunities, forums to disseminate research and scholarship, structures to share information and receive support, and awards and initiatives to recognize

contributions to Asian American psychology” (Asian American Psychological Association 2009).

Division 35 of the American Psychological Association

The Division of the Psychology of Women within the American Psychological Association began in 1973 “to promote the research and study of women . . . to encourage the integration of this information about women with current psychological knowledge and beliefs in order to apply the gained knowledge to the society and its institutions” (Russo 1984). Division 35 began to be formed at the 1969 meeting of the American Psychological Association, during which members of the Association for Women in Psychology brought to the forefront discriminatory hiring practices of the organization’s employment center at the conference. According to Denmark et al. (2008):

- ▶ At that time women, but not men, were routinely asked about their marital status, spousal employment status, and intention to have children. (p. 26)

Division 35 has grown to be one of the largest divisions of the American Psychological Association. Following the formation of Division 35, three of its Fellows were elected president of the American Psychological Association: Florence L. Denmark, Janet T. Spence and Bonnie R. Strickland. As Denmark et al. (2008) concluded:

- ▶ The psychology of women . . . had a recognized voice in the formal and informal decision making of APA . . . As Division 35 grew, it functioned to provide a forum for the development of an in-depth focus on understanding both the psychological and social realities of women. (p. 27)

The Committee on Women in Psychology was formed in 1973. The goal of this committee was to “function as a catalyst, by means of interacting with and making recommendations to the various part of the Association’s governing structure . . .” (Russo 1984). All of these associations have encouraged attention to the reconstruction history of women in psychology.

Career/Family Conflict for the First and Second Generation of American Women Psychologists: Marriage, Childrearing and Elder Care

G. Stanley Hall stated that “mental women” who competed with men “in the world, would cause “race suicide” when their maternal urges were neglected by them (Shields 1975). James McKeen Cattell (1906), the fourth president of the American Psychological Association, also warned women about getting an education:

- ▶ Girls are injured more than boys by school life; they take it more seriously, and at certain times and at a certain age are far more subject to harm. It is probably not an exaggeration to say that to the average cost of each girl’s education through high school must be added one unborn child. (p. 91)

Margaret Floy Washburn taught at Wells College and then at Vassar College for 34 years. During her career as a professor and writing her first book she spent time with her parents, as she stated:

- ▶ During all those years most of my vacation time was spent with my parents. The family fortunes having declined, they were living at Newburgh, enjoying a super view of the Hudson but little variety, and I was disinclined to leave them for long . . . In December 1914, my father died and my mother came to live with me at Vassar until her death in 1924. (1930, p. 10)

Floy Washburn chose to resign from her position as review editor of the *Journal of Animal Behavior* in 1913. In her letter to the journal’s editor, Robert Yerkes, she wrote:

- ▶ I doubt if anyone else on the board is teaching eighteen hours a week, as I am. I simply must cut down my work somewhere. If I am ever to accomplish anything in psychology it must be done in the next five years, for as my parents get older, I shall have less and less command of my time. (Cited in Scarborough and Furumoto 1987)

Ethel Puffer Howes (1872–1950) taught at Simmons College, Radcliffe College, and Wellesley College concurrently. When she became engaged, she received the following letter from the President of Smith College in

1908, illustrating the negative impact marriage was believed to have on a woman's academic career:

- ▶ Dear Miss Puffer: If you really are disposed to think seriously of the position at Barnard I am sure it would be well for your friends in Cambridge to recommend you to President Butler, although I fear the rumor which reached me concerning your engagement may have also affected the recommendation which I myself sent, and that a candidate has already been selected to present to the trustees of Columbia at their next commencement. (Quoted in Seelye 1908)

Puffer Howes wrote two articles in the *Atlantic Monthly* in 1922 concerning how women can combine career and marriage. In 1929, she authored “*The Meaning of Progress in the Women Movement*,” which also dealt with the marriage versus career dilemma.

With respect to the second generation of American women psychologists, Johnston and Johnson's (2008) data also revealed that 26 of 107 of the second generation of American women psychologists remained single throughout their career life span, similar to the first generation of women psychologists. Of the women psychologists who married, 64% gave birth to children. Three of the single women had children; two adopted children and one became the guardian of her fiancée's children. As Johnston and Johnson conclude: “A significant number of second-generation women combined careers and family life, but they were not in the majority” (p. 49).

For example, *Erika Fromm (1909–2003)* retired as Professor Emeritus in psychology at the University of Chicago. She is noted as one of the nation's leading scholars of hypnosis. Fromm coauthored “*Dream Interpretation – A New Approach*” in 1964. She and her co-author, Thomas French, maintained that conflicts individuals have that are represented by their dreams are the attempts to resolve current situations. Fromm once told younger women:

- ▶ Let me say to those of you who have or contemplate having children: Don't rob yourself of the joy of having children and of being with your children. It is not an either-or: children or a career. They can be combined.

It takes some juggling, but it is possible, and why settle for the joys of one when it is possible to have both. (Fromm 1988, p. 92)

Career/Family Conflict Today

Maternal employment has increased in the past 25 years dramatically (Hill et al. 2005). Women with infants have had the fastest growth in labor-force participation of all groups in the United States (Han et al. 2001). Today, women are as likely to be employed when they have infants as they are when they have a preschool-aged child. In addition, of women who put in overtime work, 40% have children under 6 years of age (Strassel et al. 2006).

Furthermore, current research has indicated that in addition to caring for young children, many employed women in the United States are simultaneously caring for their elderly parents (Paludi et al. 2007). Lockwood (2003) and (Moen et al. 1994) noted that between 40% and 60% of women caring for elders also have child care responsibilities in addition to their careers. Lockwood (2003) further noted that women spend approximately 17 years of their lives caring for children and 18 years caring for one or both parents. The primary caregiver is the family, most likely the elderly parent's daughter or daughter-in-law (Hammer et al. 2005).

Results from surveys by the Center for Workforce Studies of the American Psychological Association (2007) and the 2008–2009 American Psychological Association Faculty Salaries in Graduate Departments of Psychology Survey also indicated:

1. Men were more likely than women to be employed full time (67% vs. 58%). Women were more likely than men to be employed part-time (9.5% vs. 58%). Ninety-two percent of women who worked part-time cited family responsibilities as the main reason for this choice.
2. Ninety-seven percent of unemployed doctorates not seeking employment were women, who cited family responsibilities for their decision.

Maternal employment has been found to benefit the woman herself; the employment is a boost to her morale and a buffer against anxieties (Hoffman and

Youngblade 1999). However, research has also identified noted costs to women who integrate careers and families, including stress-related illnesses as a consequence of the importance women place on relationships (Bainbridge et al. 2006; Karsten 2006). Furthermore, Gonzales-Morales et al. (2006) reported that employed women who experience career/family conflict are as much as 30 times more likely to experience a significant mental health problem, for example, depression, anxiety, than women who report no career/family conflicts. Karsten (2006) further noted that women integrating elder (and/or child care) with careers work longer hours than men, impacting their physical as well as emotional well-being. Mason et al. (2005), Paludi et al. (2007), and Bernstein and Russo (2007) pointed out that time demands are not the primary cause of career/family conflict, but rather it is the psychological inclusion of family life into the career and career into the family domain that causes the conflict.

Change must occur at the institutional or organizational level, not personal level if women are to ease this conflict. Such goals include reducing women's isolation in male-dominated departments or institutions, addressing women's experience as outsiders or being marginalized (Gibson 2006), and providing support for challenges particular to women's career development and advancement (Quinlan 1999). In addition, there must be a substantial number of women, especially minority women, among the faculty in psychology departments. This has been achieved in certain subfields of psychology; however, not in others, including neuropsychology, psychopharmacology, and learning (Storm and Gurevich 2001). Certainly the number of women in administrative positions in psychology and in the academy in general must be increased so as to make the psychology of women and feminist psychology central, not marginal to academia. Research by DeFour (1991) and Moses (1988) provided compelling evidence of the importance of African American faculty in the retention of African American undergraduate and graduate students. Contact with African American faculty was associated with better academic performance and psychological well-being.

Bernstein and Russo (2007) noted that "the attrition of talented women from the academy begins early on and continues at each successive step, even after

professional goals emerge and women consider graduate programs" (p. 91). One avenue of support is the provision and respect of flexible job arrangements for women graduate students and faculty who are integrating life and work roles, including career break/time off and compressed work week policies (Bernstein and Russo 2007; Paludi et al. 2007). The American Council on Education, Office of Women in Higher Education (2005) has provided several recommendations for campuses, including:

1. Creating policies for faculty to take multiple-year leaves for professional and/or personal reasons.
2. Providing tenure-track or tenured faculty to opt to take part-time positions to be used for a certain period of time as personal needs arise.
3. Providing flexible time frames for probationary periods.
4. Establishing tenure-track reentry programs for Ph.D.s who left academia full time to care for family members.

MIT and Stanford implemented an accommodation for their women graduate students (Jaschik 2005): the option of taking a 12-week-period to take care of third trimester pregnancies, delivery, and care for newborns. Women remain matriculated during this time off period and thereby receive financial support. They also are provided a one-term extension to complete their graduation requirements. Similar programs have been implemented by the National Science Foundation ADVANCE program (see Bernstein and Russo 2007), including extending tenure decisions for women wanting to start their families.

Universities, similar to businesses who implement such policies report positive ramifications for the students and faculty, including: lower absenteeism, less stress, higher morale, improved work satisfaction, lower turnover rate, staffing over a wide range of hours, child care hours that conform to work hours, and access to quality infant and child care (Frone and Yardley 1996; Paludi et al. 2007). This may be difficult to implement in some universities, considering continued biases toward women in academia and the reluctance of changing tenure and promotion decisions. Bronstein, et al. (cited in Bernstein and Russo 2007) noted that "the tenure system in the United States was set up for male faculty, whose wives provided

all the homemaking so that their husbands could devote their energies solely to academic career advancement” (cited in Bernstein and Russo 2007, p. 92).

These programs are necessary in order to deal with the incompatibility between family and work roles in the United States as is reflected in the following research findings (Heymann 2000; Paludi et al. in press; Peeters et al. 2005; Strassel et al. 2006):

Women carry more of the workload at home.
Salary inequities exist, especially for women of color.
Employed women do substantially more caregiving to children and elder parents than do men.

Conclusion: Resilience Is the Women of Psychology

What has been considered “successful” in psychology has typically had a masculine bias. Success may be represented by achievement at a prestigious university, number of peer reviewed journal articles published, academic excellence, and other accomplishments associated with masculine values. Women who manage a household and raise children and/or care for elderly relatives while in graduate school or employed as a psychologist have not typically been seen as “successful.” Women Ph.D.s who are employed in nonacademic institutions are not viewed as “successful.” Psychology must redefine achievement and achievement-related issues in a way that does not keep women’s realities and choices invisible.

Several of the first and second generation of American women psychologists faced incredible barriers to their careers. Women, especially women of color and ethnicity, were viewed as “others,” as “outsiders.” Because women were expected to conform to the gender-role stereotypes, their lack of conformity was negatively evaluated by powerful gatekeepers in the field of psychology. In addition, when women combined career and family roles they were frequently viewed negatively in at least one but usually both spheres. These experiences are shared with many modern day women psychologists. As the American Psychological Association (2009) concluded:

- ▶ Each generation must confront new challenges while protecting its gains. Inequities persist, and lessons that are not passed down must be painfully relearned. We pay a price for equity, and that price is vigilance. (p. 3, 4)

Women have all exhibited remarkable strength and resilience in their commitment to their careers and thereby served as powerful role models for subsequent generations of women psychologists. The history of women in psychology has taught us that history is not “occurring exclusively in the past; that it is an ongoing process” (Denmark et al. 2008, p. 36). We must therefore continue to help shape this history by engendering psychology through research, teaching, and advocacy, highlighting issues with which women psychologists still face and more importantly, by working toward eradicating the organizational barriers preventing women from pursuing an academic career in psychology. This will be the best tribute we can give to the first and second generation of American women psychologists.

Woolley, Helen Bradford

ASHLEY S. ROWDEN, ANGELA D. MITCHELL
Texas Woman's University, Denton, TX, USA

Basic Biography

Helen Bradford Thompson was born November 6, 1874, in Englewood, Illinois, to Isabella Perkins Faxon Thompson and David Wallace Thompson. Her parents strongly supported education for women, and all three of their daughters went on to earn college degrees. Helen Thompson graduated first in her class from Englewood High School in 1893 and was awarded

a scholarship to the University of Chicago. She received her Bachelor's degree in 1897 and continued working toward a graduate degree in psychology with James R. Angell, John Dewey, and George Herbert Mead. Thompson completed her Ph.D. in 1900. Her thesis was titled "Psychological Norms in Men and Women"; in it, Thompson compared the performance of 25 men and 25 women on various sensory and intellectual tasks. She found that sex differences seemed to be largely due to differences in social influences throughout development (Milar 2004).

After completing her degree, Thompson was awarded a European fellowship and studied in Berlin and Paris. She returned to the United States to teach at Mount Holyoke College, where she established the university's first psychological laboratory. During her time at Mount Holyoke, Thompson also completed a book chapter on philosophy and a study of after-images.

During her undergraduate studies at the University of Chicago, Thompson met and became engaged to Paul Gerhardt Woolley, who was studying medicine at The Johns Hopkins University. Woolley received his M.D. in 1900, and in 1903 he accepted a position as chief pathologist for the Bureau of Government Laboratories in the Philippines. Helen went overseas with him, and in 1905 they were married in Yokohama, Japan. After being married, the couple returned to the Philippines, where Helen worked as a psychologist for the Bureau of Investigation. During this time, children in the Philippines were only required to attend school for 3 years, and Helen was asked to determine which 3 years of age would be most optimal for learning. This proved to be a challenging feat; often, the people did not know how old they were, and ages were frequently recorded incorrectly. Woolley eventually recommended ages 9–12 as the optimal schooling years (Milar 2004).

In 1906, Paul Woolley took a position as the director of the serum laboratory in Phrapatom, Siam. Helen, who was now pregnant, returned to the United States and gave birth to Eleanor Faxon Woolley. In 1908, Paul resigned from his position in Siam and the family moved to Omaha, Nebraska, where he was employed as an associate professor of pathologic anatomy at Creighton Medical School. While in Omaha, Helen provided private psychology classes to women. During this time, she also wrote papers on color vision and the development of handedness.

A year later, the Woolley's relocated to Cincinnati, Ohio, where Paul had been appointed Professor of Pathology and director of the laboratories of Cincinnati Hospital. Helen taught philosophy at the University of Cincinnati and in 1911 she became the director of the Bureau for the Investigation of Working Children. There, she worked toward creating tests for adolescents to predict job performance. She also compared the mental and physical characteristics of children who left school to work versus children who remained in school (Ogilvie and Harvey 2000). Along with Edwin Clopper and Mary Edith Campbell, Woolley worked with the Ohio Council on Child Welfare to pass the Bing Law, which became the nation's most aggressive compulsory education attendance policy and offered the highest level of protection for working children (Burns 2009). She gave birth to her second daughter, Charlotte, in 1914.

Although Woolley is known by many for her work on sex differences, she was a strong advocate for the use of psychological batteries in public schools. In 1921, Woolley became the first female as well as the first psychologist to serve as the president of the National Vocational Guidance Association. There, she used the psychology laboratories to test children for developmental delays, behavior problems, and giftedness, and recommended that these children be placed in special classes. By this time, Paul Woolley had left to direct the National Pathologic Laboratory of Michigan and to do diagnostic work at the Detroit Clinical Laboratory. Helen joined him in 1921 and accepted a position as assistant director of the Merrill-Palmer School working with young children. Along with Elizabeth (Bess) Cleveland and Rachel Stutsman Ball, Woolley helped to develop the Merrill-Palmer Scales for Children to measure developmental changes in 3-year-olds (Ogilvie and Harvey 2000). Woolley also actively worked to promote the benefits of early education for parents and children and was an advocate for women's rights. From 1923 to 1925, she served at the vice president for the American Association of University Women (Milar 2004).

In May of 1925, Woolley was offered a position as the director of the Institute for Child Welfare Research at the Teachers College of Columbia University. There, she organized two nursery schools and used the educational clinic to conduct research on phases of child

development and parental education. Paul Woolley had moved to California by this time, where he was receiving treatment for the tuberculosis he contracted from his laboratory work in Detroit. For a while, Helen shuttled back and forth between her positions in Detroit and New York, and her physical and mental health began to deteriorate. Her friend, Bess Cleveland died of cancer in late 1925, and Helen's daughter, Charlotte noted that her mother had been losing weight and having trouble sleeping (Milar 2004). Paul Woolley also filed for divorce during this time, which was finally obtained in 1929 (he delayed the divorce when he found out that it could adversely affect Helen's position at the Teachers College). Helen also had an abdominal tumor and underwent an appendectomy and a hysterectomy. By February 1927, Helen was admitted to the Four Winds Sanitarium in Ketonah, New York, for depression and suicidal ideation. Teachers College continued to pay her salary in addition to her medical expenses, and in September of 1928, Helen Woolley returned to her position as the director of the Child Welfare Institute. Yet, Woolley's mental health problems persisted and began to impact her work and her teaching abilities and, in February 1930, Dean William Russell asked for her immediate resignation. The college agreed to pay Woolley a partial salary for a few years after her departure. Woolley initially took the news well and thanked the Dean for being so kind to her. However, over the next several years, Woolley reportedly became obsessed with proclaiming how poorly she had been treated by Russell and sent letters to colleagues and potential employers detailing what she considered his wrongdoings to no avail (Milar 2004).

Helen Woolley spent the last 17 years of her life at her daughter Eleanor's home in Havertown, Pennsylvania. She died November 24, 1947 of an aortic aneurysm at the age of 73.

Accomplishments

Although Helen Woolley was rarely able to remain in one setting for an extended period of time, she was still nationally renowned for her research in child development. Some of her more notable works include *An experimental study of children: At work and in school between the ages of fourteen and eighteen years* and *The*

mental traits of sex: An experimental investigation of the normal mind in men and women. Woolley also authored several journal articles, including "Personality studies of the three-year-olds" in the *Journal of Experimental Psychology*, "Eating, sleeping and elimination" in *A handbook of child psychology*, as well as three case studies on children written during her time at The Merrill-Palmer School. Helen Bradford Thompson Woolley played an instrumental role in the foundations of women's studies and educational psychology, and her contributions continue to have a significant impact on both fields today.

Wundt, Wilhelm

ROBERT W. RIEBER

Fordham University, New York, NY, USA

Basic Biography

Known as "The Father of Experimental Psychology," Wilhelm Wundt was born in August 1832 just outside of Mannheim, Germany. The son of a country minister, at age of 4 Wundt moved with his parents to Heidelberg. After attending Tübingen University, Wundt earned his doctorate at the University of Heidelberg, just as many of his relatives had. His career included work as a professor at Zurich and Leipzig Universities. At Leipzig, Wundt established the world's first experimental laboratory in psychology. Wilhelm Wundt died in August 1920 while still a professor at Leipzig.

Major Contributions

Discussion of Wundt usually focuses on his strict adherence to experimentation and introspection. However, the human child was also of great interest to Wundt, and a topic for which he had much to offer. Considering child psychology's lack of objectivity one of its limitations, Wundt encouraged sound observations keeping in mind influences on the child.

Just as with adults, Wundt believed children were products of learning and imitation. Willing to admit a newborn possesses inherent reflexes; Wundt theorized learning begins around 1 month. At this time, reflexes become refined and a consciousness emerges as evident by changes in mood. Physical and mental maturation enable the child to display his or her learning. During the emergence of intelligence, the child's attention becomes more focused for longer periods of time. Similarly, initially the child's associations are short-lived and last only a few hours. However, as the child grows so do the association intervals in his life span. Paralleling developments in attention and association is the emergence of self-consciousness. Impossible to observe its beginnings, Wundt felt self-consciousness functioned as early as the first few weeks after birth with the child's recognition of his or her body.

The progression in self-consciousness allows for the development of will, which distinguishes humans from animals. Wundt also argued a newborn child does not show signs of volitional acts. For example, a child does not instinctively follow visual objects. Instead this ability is gained only after improvements in attention.

Perceiving communication similarly to other volitional acts, Wundt offered an early theory on language acquisition. According to Wundt, the burgeoning of language resulted from the child's increasing ability to perceive and imitate different forms of communication in his or her environment. A child's early babbling was not equivalent to language since it lacked meaning. Babbling develops into language through social interaction with others in the child's environment, such as reciprocal imitation with parents.

Finally, it is interesting to note the impact Wilhelm Wundt had on educational systems. Many psychologists who have played a critical role in academics in America have ties with Wundt. For example, G Stanley Hall, a protégé of Wundt, worked with John Dewey. Dewey eventually became a professor at The University of Chicago where he played a very important role in developing new progressive approaches in child education.

Z

Zajonc, R. B.

JACLYN SHELDON

Pace University, Staten Island, NY, USA

Basic Biographical Information

Robert Boleslaw Zajonc (1923–2008) held many prestigious titles in his lifetime for his numerous accomplishments in the discipline of psychology. Zajonc was a professor of psychology at both University of Michigan and Stanford University. He was once the president of the Society of Experimental Social Psychology, and the president of APA Division 1 (Society for General Psychology), as well as a member of the APA Board of Scientific Affairs (Burnstein 2009). Zajonc was a recipient of the Award for Distinguished Scientific Contributions from the American Psychological Association in 1978, as well as the Distinguished Scientist Award from the Society of Experimental Social Psychology in 1986 (Burnstein 2009). Though he lost his life to pancreatic cancer (Burnstein 2009), Zajonc has made many contributions to the field that will live on.

Zajonc was born in Lodz, Poland. During the Nazi invasion of Poland, the Zajonc family fled to Warsaw,

where a bombing killed Zajonc's parents (Fox 2008). During this tumultuous time in history, Zajonc escaped imprisonment in a German labor camp but was captured and sent to a political prison in France (Fox 2008). His successful escape allowed him to join the French Resistance, where he moved toward England. Having mastered numerous languages including English, Zajonc served as a translator for the US Army in England (Burnstein 2009). He later worked for the United Nations and the Rehabilitation Administrations in Paris as the war came to an end (Burnstein 2009).

In 1948, Zajonc immigrated to the United States, where he received his undergraduate education at the University of Michigan. Despite being accepted to the university with "probation" status, Zajonc continued on to receive a bachelor's, master's, and doctoral degrees from the university (Burnstein 2009). After earning a Ph.D. in social psychology in 1955, Zajonc became an integral part of the University of Michigan faculty. Here, he began to look into the mind, a pioneering effort in this time when behavior was the core of most research (Fox 2008). Zajonc studied a number of areas, including the effects of birth order on intellectual performance. Well known for his findings of the mere exposure effect, Zajonc also studied the link between physiology and psychology. His most recent research interests have been focused on racism, terrorism, and genocide (Fox 2008).

Major Contributions

One of Zajonc's important contributions to the field of social psychology regards the effect of the presence of others on performance of a specific task. Known as social facilitation, Zajonc explored why the presence of others enhances performance in some situations but not others. He found that the presence of others enhances performance on a given task when the performer has mastered the specific skill at a high level.

On the contrary, the presence of others hinders performance on a given task when the performer has not quite mastered the specific skill (Fox 2008).

From his war-torn childhood, Zajonc was attracted to the field of psychology to provide research that may someday aid in preventing future wars (Fox 2008). Possessing both intellect and kindness, Zajonc's contributions to psychology have been plentiful. From Lodz, Poland to Palo Alto, California, Zajonc ended his career as emeritus professor of Stanford University. Zajonc influenced the field of psychology with his research but also helped inspire budding psychologists with his excellent mentoring skills (Burnstein 2009).

Zazzo, René

MOHAMED ELHAMMOUMI

College of Social Sciences, Al-Imam Muhammad Ibn Saud University, Riyadh, Saudi Arabia

Basic Biographical Information/ Major Accomplishments

A prodigious student of Henri Wallon, René Zazzo was affected by his mentor throughout his life. Zazzo sought a more Marxist interpretation to human higher mental functions than the instinct doctrine which dominates the field of psychology. In the footsteps of Wallon, Zazzo expanded his vision of psychology in Ecole Pratique des Hautes Etudes which was one of the first interdisciplinary institutes in the social sciences, and prepared the way for what was to become behavioral science in France. Zazzo did combine dialectical materialist conception of history with psychology, which was an unusual synthesis at the time. Psychology at that time was seen as a bourgeois science. It was

through Zazzo's effort that Marxist psychologists now had a language of their own to guide experimentation, empirical research, and stimulate discussion with such concepts as intelligence, human nature, higher mental functions, learning, personality, etc. To these were added over time the concepts of consciousness, cognition, dialectics, contradictions, conflicts, praxis, social production of the individual, alienation, activity, actual cognitive development, potential cognitive development, etc. Much of the development of the field along Marxist psychology lines was the extension of Wallonian conceptualization (Georges Politzer, Lev Vygotsky, Alexis Leontiev, René Zazzo, and Lucien Sève among others). Zazzo also pioneered in methodology in going beyond the laboratory to study twins in their field settings (compare the development of identical twins). Though he was the first real genetic psychologist, he did not allow himself to become a captive to a single type of technique. He sent his students into the field, schools, kindergartens, and other natural settings to observe concrete realities at first hand. He argued clearly and convincingly that the language of data should not be confused with the language of metaphor concepts. Zazzo observed that psychologists frequently resisted the attack on their favorite theories which lead in many cases as a way out or the attempt to conceptualize their concepts. Zazzo was skeptical of these strategies, because the outcome is only the growth of empirical behavioral psychology. He was known for his penetrating accounts of historical, cultural, and social factors in the shaping, formation, and structuring of human higher mental functions. Human sociality is inherited in human nature.

Zazzo spent the rest of his life trying to develop a theory of human activity (instead of behavior) that would take account of the structure of human action in an objective, concrete, and scientific manner. He was widely recognized (in Spain, South America, Africa, Eastern Europe, and Russia) for his professional and scientific contributions. He served on the board of directors of many psychological, educational, and philosophical journals. He was a great teacher, PhD mentor, and his character was as generous as the sweep of his intellect. He published over 20 books and more than 200 scientific papers in the field of child psychology, education, learning difficulties, psychometrics, philosophy, and epistemology. His works still inspire

psychologists and educators worldwide. He had a stimulating mind, a piercing wit, and was a Marxist developmental psychologist.
