5. Product made from meat and water that has been chunked, ground, chipped, wafer-sliced, etc., and formed into a roll containing a plant protein product or other binder could be labeled as a "Meat, Water, and Textured Vegetable Protein Roll." The same size lettering shall be used for the product name.
6. Product made from meat that has been chunked, ground, chipped, wafer-sliced, hydroflaked, etc., and formed in a roll containing a plant protein product or other binder shall be labeled as "Beef and Textured Vegetable Protein Roll" or "Beef and Soy Protein Concentrate Roll."

Rolls, Poultry

Only natural proportions of skin to the whole carcass or designated part may be used. If skin is in greater than natural proportions, the name must be qualified with the term "Skin Added."

See: 9 CFR 381.159.

Romano Cheese

Label must show "kind" of milk, e.g., (Caprino), "Romano Cheese made with Goat's Milk;" (Pecornia), "Romano Cheese made from Sheep's Milk;" or (Vaccino), "Romano Cheese made from Cow's Milk." The words in parenthesis are not required to be shown.

Rumaki

This product must contain at least 50% chicken livers. An hors d'oeuvre or appetizer. Rumaki is a combination of chicken livers, water chestnuts, and bacon.

Salad — Freeze Dried Ham

Antioxidants have been permitted in Freeze Dried Ham at a level of 0.01%, based on total weight of the ham.

Salad — German Style Potato Salad with Bacon

Requires at least 14% cooked bacon.

Salad Mix, Poultry

Product must contain at least 45% cooked poultry.

Salads

Standards for salads:

Meat salads must include at least 35% cooked meat or meat food product (e.g., corned beef, ham). Ingredients, e.g., "Ham water added" or "Corned Beef and water product" may be used if the formula is adjusted to account for the amount of added substances. Example: if 85% of a meat food product is meat, then 35% required meat divided by 0.85 equals 41% required meat food product in the salad.

Cobb Salad — Contains lettuce and chicken or turkey. The other ingredients that may be found include bacon, hard cooked eggs, tomatoes, Roquefort or other blue cheese or dressing. The product name must include the poultry component(s) and also identify any meat ingredient when present about 2%, e.g., "Bacon and Chicken Breast Cobb Salad."

Caesar Salad — is an acceptable product name and normally contains cheese, meat, or poultry pieces and may contain other vegetables.

Ham and Cheese Salad — Must contain at least 25% cooked ham.

Macaroni with ham or beef — Must contain at least 12% cooked meat.

Poultry Salad — Must contain at least 25% cooked poultry (natural proportions of skin and fat).

Chopped egg and ham salad — Must contain at least 12% ham.

Chopped egg and bacon salad — Must contain at least 12% bacon (9% fully cooked bacon).

Vegetable and/or fruit with poultry — Must contain at least 25% cooked poultry.

Cracker meal, bread crumbs, and similar ingredients may be included in meat or poultry salads up to 2% of the total formula. If more than 2% is used, a product name qualifier is required. Modified food starch and textured vegetable protein cannot be substituted for cracker meal and bread crumbs in salad products.

Salami

A dry sausage that requires an MPR of 1.9:1 or less. Extenders and binders are permitted. It may be cooked to shorten drying period.

Salami, Beef

A cooked, smoked sausage, usually mildly flavored, in a large casing, containing coarsely ground beef. Cereals and extenders are permitted. May contain fat. Product does not have to be labeled cooked.

Salami, Cooked

The product "Salami" must be labeled to include the word "Cooked," regardless of the type and size of its packaging, unless it is one of the following:

1. A salami with a moisture protein ratio of no more than 1:9 to 1
2. "Genoa salami" with a moisture protein ratio of no more than 2.3:1
3. "Sicilian salami" with a moisture protein ratio of no more than 2.3:1
4. Labeled, as…
   a. Kosher Salami
   b. Kosher Beef Salami
   c. Beef Salami
   d. Beer Salami
   e. Salami for Beer. Pork skins are not a permitted ingredient in cooked salami.

Salami, Cotto

A mildly flavored cooked, cured sausage, in a large casing, usually containing coarsely ground beef and pork. The product contains whole or visible pieces of peppercorns. It is cooked in dry heat.

Salami, Hard

A dry sausage with an MPR of 1.9:1. It is made with beef and pork and seasoned with garlic. Less highly flavored but usually more heavily smoked than Italian Salami. It is tied with loops or twine that gives a scalloped appearance.

Salami, Italian

This kind of dry salami is usually prepared in the San Francisco area and is easily distinguished by its covering of a white mold. This salami consists of about 80% finely chopped pork, to which a small amount of pork fat may be added. Nonfat dry milk can comprise $3\frac{1}{2}$% of the finished product. The remainder consists of chopped beef, seasoning, salt, and curing agent. The product should have an MPR not in excess of 1.9:1 to insure the fat content and dryness properties associated with a "dry salami."

Salchichon (SP)

This term, meaning "Large Sausage," This term may only be used for large casing sausage products that are 3 inches in diameter or more. Label must show a true product name.

Salisbury Steak

Finished product must contain at least 65% meat. Fat is limited to 30%. Other requirements are:

1. It is an unbreaded cooked product.
2. The meat block may contain 25% pork, with the remainder beef. Or, the meat block may contain up to 12% partially defatted chopped beef and pork.
3. Extenders are permitted up to 12%. When isolated soy protein is used, 6.8% is the equivalent of 12% of the other extenders. Those extenders include, but are not limited to: cereal, bread crumbs, cracker meal, soy flour, soy protein concentrate, isolated soy protein, and textured vegetable protein.
4. Meat byproducts are not permitted. Beef heart meat is permitted.
5. Permitted liquids include, but are not limited to: water, broth, milk, cream, skim milk and reconstituted skim milk (9 parts water to 1 part NFDM).
6. Product not cooked which conforms to the above may be labeled "Patties for Salisbury."

Salisbury Steak, Turkey

Product must contain at least 55% turkey meat in natural proportions (light and dark) or 65% turkey with skin and fat in natural proportions (skin 10%, turkey meat 55%). Maximum amount of binders and extenders is 12%.

Salpicao

A smoked sausage. The label must show a true product name, e.g., "Smoked Sausage." No more than 3% water can be added at formulation.

Salsiccia (IT)

A fresh pork sausage, highly spiced, in which paprika is permitted. It is a rope style sausage made of finely cut pork trimming.

Salt as a Cure

Dry processed hams, pork shoulders, and bacon are ordinarily cured with mixtures that contain mostly salt along with sugar and nitrates plus nitrites. However, some processors use salt alone in preparing their products. The salt in contact with the meat provides the desired cured color, taste, and necessary product protection.

Salt is an acceptable cure when used singly in the curing and salt equalization of dry processed hams, pork shoulders, and bacon. The cured products must have a 10% brine concentration.

Samosa

This product originated in India, although it is also associated with Pakistan. It resembles a "Meat Turnover" and consists of a spiced vegetable and meat mixture in a dough crust. At least 25% meat is required. Label must show a true product name, e.g., "Beef Turnover."

Samples

Free samples included along with the meat and poultry food products are not to be included in the net weight statement, and the ingredients do not need to be identified in the ingredients statement as long as the ingredients appear on sample package.

Sandalwood

According to FDA regulations, Red Saunders (red sandalwood) is not an acceptable ingredient in meat and poultry products. It is a permitted coloring and flavoring agent in alcoholic beverages only. In contrast, white or yellow sandalwood is acceptable in meat and poultry products as a flavoring agent in an amount that is "sufficient for purpose." White or yellow sandalwood extract may be labeled as "sandalwood extract" or "flavoring."

Sandwich — Closed

Product must contain at least 35% cooked meat and no more than 50% bread. Sandwiches are not amenable to inspection. If inspection is requested for this product, it may be granted under reimbursable Food Inspection Service.

Typical "closed-faced" sandwiches consisting of two slices of bread or the top and bottom sections of a sliced bun that enclose meat or poultry, are not amenable to the Federal meat and poultry inspection laws. Therefore, they are not required to be inspected nor bear the marks of inspection when distributed in interstate commerce.

Sandwich — Open

Must contain at least 50% cooked meat. Sandwiches are amenable only if they are open faced sandwiches. Product must show a true product name, e.g., "Sliced Roast Beef on Bread."

This regulatory policy in no way alters the Department's present policy with respect to caterers who include meat sandwiches in their dinners.

Sandwiches (Meat or Poultry as Components of "Dinner Products")

Dinners containing a sandwich type product, e.g., a frankfurter, hamburger, or sliced poultry meat with a bun, are amenable and subject to inspection.

Santa Fe Style

Acceptable for products that contain chilies with corn or beans and one of the following ingredients: Cheese (jack, cheddar, Mexican Style or fresh goat), bell pepper, onion, garlic, tomatoes, tomatillos, cumin, oregano or cilantro. The beans should be either black, kidney, navy, pink, pinto, red, or white beans or an indigenous variety.

Sarno

A dry smoked sausage that is air dried. The label must show a true product name, e.g., "Smoked Sausage." Coarsely chopped beef, pork, and garlic are not permitted.

Satay

This term refers more to a preparation method than to the nature of a finished product. Satay can be made from chicken, beef, lamb, pork, and other food items, and prepared in two ways:

1. Meat is cut into one inch cubes, then dipped into a spicy sauce, skewered, and roasted over an open fire (similar to "Kebobs" except no vegetables or fruit). Label must show a true product name, e.g., "Beef Cubes on Stick."
2. Meat is cut into one inch cubes, then dipped into a spicy sauce and canned. Label must show a true product name, e.g., "Beef Cubes in Spicy Sauce."

Sauce with Meat or Meat Sauce

Product must contain at least 6% ground meat.

Sauerbrauten (GR)

"Sauerbraten" must contain at least 50% cooked beef. "Gravy with Sauerbraten" must contain at least 35% cooked meat. Sauerbrauten is cooked beef in a vinegar flavored sauce. The beef is marinated in vinegar sauce, then separated from the sauce and partially cooked, and put back in the sauce and cooked completely.

Sauerkraut Balls with Meat

Product must contain at least 30% meat or meat food product.

Sauerkraut with Franks and Juice

Product must contain at least 20% franks.

Sausage Classification

1. Fresh Sausage

Made of fresh, uncured meat, generally cuts of fresh pork, and sometimes beef. Its taste, texture, tenderness, and

color are related to the ratio of fat to lean. Trimmings from primal cuts, e.g., pork, loin, ham, and shoulders are often used. When ice or water is used to facilitate chopping and mixing, it is limited to a maximum of 3% of the total formula. It must be kept under refrigeration and thoroughly cooked before serving. Bratwurst is in this class. Binders and extenders are permitted in fresh sausages except where regulations do not permit the use of such ingredients, i.e., 9 CFR 9 CFR 319.140 (Pork Sausage), 9 CFR 319.142 (Beef Sausage), 9 CFR 319.144 (Whole Hog Sausage), and 9 CFR 319.145 (Italian Sausage).

See: 9 CFR 319 Subpart E.

2. Uncooked Smoked Sausage

Has all the characteristics of fresh sausage except it is smoked, producing a different flavor and color. It must be thoroughly cooked before serving. "Smoked Pork Sausage" is included in this class. If it is a mixture of pork and other meats, regardless of size, it must be treated for trichinae.

See: 9 CFR 319 Subpart F.

3. Cooked Sausages and/or Smoked Sausages

These products are chopped or ground, seasoned, cooked and/or smoked. Added water is limited to 10% of the finished product. Meat byproducts may be used when permitted by standard. Cure is required for particular sausages, e.g., wieners or Polish sausage. These sausages come in various shapes and sizes, e.g., short, thin, long and chub. Cotto salami, liver sausage, and cooked weisswurst are included in this category. Wieners, bologna, knockwurst, etc., are also in this class but are further distinguished by a fat and moisture limitation.

See: 9 CFR 319.180.

4. Dry and Semi-Dry Sausages

Dry sausages may or may not be characterized by a bacterial fermentation. When fermented, the intentional encouragement of a lactic acid bacteria growth is useful as a meat preservative as well as producing the typical tangy flavor.

The meat ingredients, after being mixed with spices and curing materials, are generally held for several days in a curing cooler. Afterward, the meat is stuffed into casings and is started on a carefully controlled air-drying process. Some dry sausage is given a light preliminary smoke, but the key production step is a relatively long, continuous air-drying process.

Principal dry sausage products are salamis and cervelats. Salamis are coarsely cut, cervelats finely cut with few exceptions. They may be smoked, unsmoked, or cooked. Italian and French dry sausage are rarely smoked; other varieties usually are smoked.

Dry sausage requires more production time than other types of sausage and results in a concentrated form of meat. Medium-dry sausage is about 70% of its "green" weight when sold. Less dry and fully dried sausage range from 80% to 60% of original weight at completion.

Semi-dry sausages are usually heated in the smokehouse to fully cook the product and partially dry it. Semi-dry sausages are semi-soft sausages with good keeping qualities due to their lactic acid fermentation.

Although dry and semi-dry sausages originally were produced in the winter for use in the summer and were considered summer sausage, the term "summer sausage" now refers to semi-dry sausages, especially Thuringer Cervelat.

Sausage Containing Cheese

Sausages may contain cheese under the following conditions:

1. If there is a standard for that particular sausage, it must be met as though it contained no cheese.
2. The cheese must characterize the product and appear as part of the product name. Example "Italian Sausage with Cheese."

Sausage — Liquids Added

Sausages containing fluid ingredients that are expected such as fruit and juice and vinegar, are permitted at any level as long as the product is descriptively labeled. The sausage portion of the product, however, must meet any applicable standard. Vinegar is an expected ingredient in chorizos and the name does not have to indicate its presence.

Sausage — Shelf Stable

Dry sausage must have a Moisture Protein Ratio (MPR) of 1.9:1 or less, unless an MPR is cited under Moisture Protein Ratio.

Non-refrigerated, semi-dry, shelf-stable sausage must have an MPR of 3.1:1 or less and a pH of 5.0 or less, unless commercially sterilized or unless an MPR is cited under Moisture Protein Ratio. Alternately, non-refrigerated, semi-dry, shelf-stable sausages are those that:

1. are fermented to a pH of 4.5 or lower (or pH may be as high as 4.6 if combined with product water activity no higher than 0.91),
2. are in an intact form or, if sliced, are vacuum packed,
3. have internal brine concentration no less than 5%,
4. are cured with nitrite or nitrate, and
5. are smoked with wood.

Sausage Rework

This term applies to a fully or partially processed product (excluding uncooked trimmings) re-routed for reasons

other than unwholesomeness or adulteration (i.e., emulsion residue, product breakage, slicing operations, smoked meats, returns, etc.) and intended for inclusion in cooked sausage, loaves, and similar products. Rework may be used provided it does not adulterate the product, violate its standard of composition, change the order of predominance of ingredients, or perceptibly affect the normal characteristics of the product. Rework is subject to the following restrictions:

1. Cooked sausage, meat loaves may be used in similar products without limitation.
2. Except in products covered by section 9 CFR 319.180, pieces of cooked and/or smoked meat may be used without limitation if properly identified in the ingredients statement.
3. Pieces of uncooked, cured pork from primal parts may be used without limitation if properly identified in the ingredients statement.
4. Sausage products in edible collagen casings may be used in similar finely comminuted products without limitation and need not be peeled.
5. Finished cooked sausage in natural casings may be used in similar finely comminuted products without limitation, except sausages in bungs, middles, beef rounds, bladders, or stomachs, which must be stripped of the casings before use. Also, natural casings of any type that break during the stuffing operations should not be included in emulsions.

Sausage Type Products with Fruits and Vegetables

Sausage type products that contain unexpected ingredients that significantly alter the character of the product may be descriptively labeled as (characterizing ingredient) Sausage, e.g., "Cherry Pecan Sausage," "Wild Rice Sausage," or other equally descriptive names, e.g., "Sausage with Wild Rice."

The sausage portion of fresh sausage products must meet any applicable standards, including fat and added water limitations, moisture/protein ratios, and use of binders and extenders prior to the addition of any characterizing ingredient(s). For cooked, smoked, or dry sausages, the finished sausage type product must meet the sausage standard prior to the addition of any characterizing ingredients.

The unexpected ingredient must be present in sufficient quantity or form to characterize the sausage type product in flavor, texture, or other sensory attributes. However, there are no minimum use levels.

This policy applies to products containing unexpected food ingredients, e.g., fruits and vegetables, e.g., cherries, pecans, tomatoes, etc., that change the character of the product by the addition of unique flavor and other sensory characteristics. The policy does not apply to imitation products, i.e., products formulated to resemble in taste, texture, color, etc., the traditional sausage products, but which are nutritionally inferior. Sausages containing cheese are addressed Policy Memo 010, and Potato Sausages are addressed in Policy Memo 011.

Sausage with Sauerkraut in Sauce

Product must contain at least 40% sausage.

Sausage (Species)

(Species) sausages identified in 9 CFR 319.141, 319.142, 319.144, and 319.160 of the meat inspection regulations may be cooked, cured or smoked (or any combination), but must comply with the standards before being processed if the product name is to include "(species) sausage." For example, fresh beef sausage identified in 9 CFR 319.142 which is cured and cooked may be labeled "cured, cooked beef sausage." Prior to this processing, these products could not contain more than the 3% water permitted by the standard.

Cooked cured sausages or smoked cured sausages containing up to 10% added water in the finished product and prepared from one species may be labeled as "cooked cured sausage," "smoked sausage," "cooked cured sausage made with (species)," or "smoked sausage made with (species)."

Semi-dry and dry sausages made from a single species may be labeled "(species) sausage," e.g., "beef sausage."

This policy does not apply to cooked sausages identified in section 9 CFR 319.180 of the meat regulations.

Scalloped Potatoes and Ham

Product must contain at least 20% cooked ham.

Scalloped Potatoes and Sausage

Product must contain at least 20% cooked sausage.

Scalloped Potatoes Flavored with Sausage

Product must contain at least 3% sausage.

Scalloppini

Product must contain at least 35% cooked meat or poultry meat. Thin slices of cooked veal, sometimes beef or poultry, seared or fried. Label must show a true product name, e.g., "Veal Scalloppini" or "Chicken Scalloppini."

Schickenwurst (GR)

The product is made of two parts, one of which is an emulsion prepared from pork and beef cuts. The second component consists of chunks of ham measuring from 2 to 3 inches in size. The two parts are mixed, stuffed into large casings, and smoked while being cooked. The final product appears as a luncheon sausage with large pieces of red

ham meat held together by a light pink binder. The ham sections comprise at least 50% of the product and the item has a distinct smoked flavor. This product is very similar in appearance to the product sold as "Ham Bologna."

Scrambled Eggs with Bacon

Product must contain at least 10% cooked bacon.

Seaweed

The term is not an acceptable ingredient declaration. There are many types of seaweed, some are not as safe.

Select or Higher

This phrase has been extended to retail beef products that have been officially graded prime, choice or select.

Shepherds Pie (with or without Vegetables)

Product must contain at least 25% meat in total formulation. Shepherds Pie is a meat food product consisting of chopped, minced, or cubed beef or lamb, seasoned with gravy or sauce, with or without vegetables, and baked with a covering layer or surrounding border of seasoned mashed potatoes. The label must show a true product name, e.g., "Beef Shepherds Pie."

Shipping Containers

A mark of inspection and a handling statement is required on all shipping containers. Safe Handling Instructions are required with all other required features only when they shipping container is also the immediate or primary container.

See: 9 CFR 316.13.

Shu-Mai

Product must contain at least 10% meat. A Chinese product that resembles a dumpling. It is similar to a meat ravioli. The label must show a true product name, e.g., "Pork Dumpling."

Signature Line

It is not necessary to include the term "General Office" in signature lines on labels used by companies with multiple plant operations. A zip code shall appear following the address.

See: 9 CFR 317.2(g)(1) 9 CFR 381.122.

Sloppy Joe

A coined name that must be qualified by a true product name, e.g., "Barbecue Sauce with Beef." The meat content depends on the name of the product. Heart meat and tongue meat can be used but not to satisfy the minimum meat requirement.

Smoke

For imported Canadian products, e.g., bacon, which are physically smoked during processing, the word "Smoke" is acceptable in the ingredients statement. Although not required or customary, smoke can also appear in the ingredients statement of domestically produced products which are physically smoked. If included in the ingredients statement, smoke should appear as the last item.

Smoke Flavoring

The use of smoke flavoring (natural or artificial) in a component of a meat or poultry food product, e.g., ham in a ham salad, does not require that the product name be qualified to indicate the presence of the smoke flavoring. However, the smoke flavoring must be declared in the ingredients statement on the meat or poultry product labels.

Secondary product — when meat and extender product is produced using a meat product in which smoke flavoring is added, the secondary product name does not have to be qualified with a phrase as "smoke flavoring added."

When smoke flavor (natural or artificial) has been directly added to a product as part of a seasoning mix, the presence of the smoke flavor must be identified in a qualifying statement to the product name, e.g.,

1. "Chicken soup smoked flavor added," and in the ingredients statement.
2. "Beef soup smoke flavor."
3. If a product is simply sprayed with liquid smoke, it must be labeled "smoke flavoring added."

Smoked Products

The guidelines for approving labels for products prepared with natural smoke and/or smoke flavor (natural or artificial) are as follows:

1. Meat or poultry products which have been exposed to smoke generated from burning hardwoods, hardwood sawdust, corn cobs, mesquite, etc., may be labeled as "Smoked" or with terms, e.g., "Naturally Smoked" to indicate that the traditional smoking process is used.
2. Meat or poultry products which have been exposed to natural liquid smoke flavor which has been transformed into a true gaseous state by the application of heat or transformed into vapor by mechanical means, e.g., atomization, may be labeled "Smoked."
3. Meat or poultry products may be labeled "Smoked" if natural liquid smoke flavor is applied by spraying, dipping, liquid flooding,

or similar processes prior to or during heat processing. In such cases, the natural liquid smoke flavoring must be transformed into a true gaseous state by the heat of processing. If a product is simply sprayed with liquid smoke it must be labeled "smoke flavoring added."

4. Meat or poultry products to which smoke flavor (natural or artificial) has been directly applied to the exposed product surface, e.g., massaging or margination, or incorporated into the product by such means as injection, must be labeled to identify the smoke flavor as part of the product name, e.g., "Ham-Natural Smoke Flavor Added," and in the ingredients statement.
5. Meat or poultry products that are smoked, as provided for in (1), (2) and (3) above and also treated with smoke flavor as described in (4), may only be labeled "Smoked" or with terms, e.g., "Naturally Smoked," if it is clearly disclosed that the product is also treated with smoke flavor. The presence of the smoke flavor must be identified as part of the product name, e.g., "Smoked Ham-Smoke Flavoring Added" and in the ingredients statement.
6. Product may be labeled as "hickory smoked" only if the plant provides the inspector with appropriate certification that such sawdust or wood for smoking is 100% hickory.

Smoked Thuringer Links

A cooked smoked sausage made with pork only.

Snacks (Hors d'oeuvres)

Product must contain at least 15% cooked meat or 10% cooked bacon. The label must show a true product name, e.g., "Liver Pate on Toast."

Sodium Alginate

This is added as a binder in "Taquitos." Approval may be given for use at a level of less than 1% with .25% of calcium citrate to stabilize a pizza sauce or pizzas heated in household toasters.

Sodium alginate when used as glue to seal burrito and burrito like products is acceptable, if declared in the ingredients statement, or if a statement such as "sealed with sodium alginate" appears at the end of the ingredients statement.

Sodium Benzoate

Sodium Benzoate is not an acceptable ingredient for meat and poultry products, except in oleomargarine. It is accepted as an incidental additive when it is a part of a product prepared under FDA rules, e.g., sauces, gravies, and similar substances.

Sofrito with Pork

This is a sauce containing 6% smoked pork.

Soppresate (IT)

This is an acceptable name for a dry salami with an MPR of 1.9:1. This is an Italian salami that is lightly flavored with garlic and, generally, hotly seasoned with paprika and black or red peppers. It is smoked to varying degrees depending on regional tastes.

Sorbitol

This is only permitted in 9 CFR 319.180 products, cured pork products, dried beef, kielbasa and products similar to kielbasa. Do not approve when used in other products.

Souffle (Species) or (Kind)

Product must contain at least 18% cooked meat or poultry meat.

Soujouk (TK)

This is a Turkish sausage made from beef which is very dry and highly spiced with an MPR of 2.04:1. The product is usually flattened or resembles a dry salami or ring bologna. The label must show a true product name, e.g., "Dried Beef Sausage."

Soup

1. Soups that declare meat stock in the product name are meat food products and shall contain at least 25% meat stock with an MPR of not less than:
   a. Condensed soup — 67:1
   b. Ready-to-eat — 135:1
   c. Beef Bouillon — 67:1 and at least 50% beef stock
2. Soups made with meat shall contain not less than:
   a. Condensed soup — 4% cooked meat
   b. Ready-to-eat — 2% cooked meat
3. Soups containing smoked meats shall contain not less than:
   a. Condensed soup — 4.0% smoked meat
   b. Ready-to-eat — 2.0% smoked meat
4. Soups made with cooked sausages shall contain at least 4% cooked sausage.

Soup Products

Bean & Ham Shank: When soup is made from ham shanks, they must be shown in the true product name, e.g., "Bean and Ham Shank Soup."

Blood: Product must contain at least 1% blood and be made under inspection.
Chowders: Follow standard for soups.
Consomme: A broth cooked with vegetables and then strained. Must have an MPR of 135:1.
Consomme Instant: Dehydrated — not amenable.
Cream: Condensed cream soups may be made from various creams, whole milk, or dry milk powder. The amount of cream, whole milk, or dry milk powder should provide a minimum of .45% butterfat to the final product. Examples:

1. A cream containing 18% butterfat should make up the product formulation; this provides .45% butterfat to the product formulation.
2. Dry milk powder containing 27% butterfat should make up 1.67% of the product formulation.

Dried Meat Soup Mixes: Not amenable.
Italian Style Minestrone: Soup must contain zucchini. Identify meat in the true product name.
Pepper Pot: Soup must contain at least 20% scalded tripe.
Petite Marmite (FR): A soup made with meat, chicken, and vegetables.
Scotch Broth: Soup must contain at least 3% mutton in a thick mutton broth.
Vegetable: Vegetable soups made with soup stock are not considered amenable.

Souse

This is a nonspecific product that can be made with all pork byproducts. The ingredients statement directly follows the product name.

Southern Fried

Southern fried poultry cuts or patties are breaded and fried. This is not geographical.

Southwestern Style

An acceptable identification for products containing any five (5) of the following types of food ingredients:

Beans (kidney beans, black beans, pinto beans, red or pink beans), corn, chili peppers, bell peppers, cheddar cheese, cilantro, onions or onion powder, cumin, oregano, garlic or garlic powder, paprika, chili powder, either mesquite smoked, or mesquite smoke flavor added.

Soy Protein Products

Whenever soy flour, defatted soy grits, soy protein concentrate, isolated soy protein, and similar products are used as ingredients of meat and poultry products, they must be called by their common or usual name (e.g., soy flour, soy protein isolate, etc.).

Two percent isolated soy protein is equivalent to 3.5% binders.

If these products are textured, then "textured" should also be included in the name. We allow the use of the term "textured vegetable protein" when the textured soy products are mixed with spices, colorings, enrichments, etc., and the ingredients of the textured vegetable protein are listed parenthetically. "Vegetable Protein Product" is an acceptable declaration for a soy product fortified in accordance with Food and Nutrition Service regulations. The ingredients of the VPP must be listed parenthetically.

Spaghetti

Sauce with meatballs Sauce with meat with meatballs with meatballs & sauce with meat and sauce with franks and sauce.

Must contain at least 35% cooked meatballs
Must contain at least 6% meat
Must contain at least 12% meat
Must contain at least 12% franks

Spaghetti Sauce with Meat Stock

This spaghetti sauce consists mainly of tomatoes with seasoning. Product must contain 5% fresh beef and 12.5% concentrated meat stock.

Spaghettios in Cheese Sauce with Ground Beef

Product must contain at least 12% meat.

Spanish Rice with Beef

Product must contain at least 20% cooked beef.

Speckwurst

Product should conform to sausage standard (9 CFR 319.140) without the use of byproducts. Chunks of fat are usually present.

Starch

Starch, wheat starch, and cornstarch are synonymous in meaning. When "Vegetable Starch" is used as a designation, it refers to the starchy materials derived from any vegetable source, e.g., potatoes, peas, etc. Tapioca starch cannot be declared as "starch."

See: Tapioca Starch.

Steak, Chinese Pepper

Product must contain at least 30% cooked steak. A Chinese dish usually served with rice. Beef steak is cut in

thin strips, browned, and added to a sauce. Vegetables are also added to the sauce; green pepper strips are always used, and other vegetables may include celery, onions, scallions, red pepper, bean sprouts, tomatoes, or water chestnuts.

Steak, Country Style

This term is popular in the Southern region of the country. It resembles a "Gravy and Swiss Steak" product. Characteristics of this product are:

1. It is prepared from the steaking portions of beef (usually from the round) and braised.
2. The meat is mechanically "tenderized" and floured prior to browning.
3. The meat is browned by sautéing or oven browning, but not flame browned nor cooked in water.
4. When a true product name is shown as "Gravy and Beef Steak," at least 35% cooked steak must be used.
5. When a true product name is shown as "Beef Steak with Gravy," at least 50% cooked steak must be used.

Steak, Pepper

Product must meet the standard for "Fabricated Steak" in 9 CFR 319.15(d) and contain green and/or red peppers.

Sticks

There are three types of meat or poultry sticks.

1. Meat Sticks, which are an extended "pattie-like" product and are usually breaded. No more than 10% extenders and 30% breading are permitted. When whole egg, tomato, and nonfat dry milk are used, they must appear as added ingredients in the true product name, e.g., "BREADED MEAT STICK — NONFAT DRY MILK ADDED.
2. The infant finger food type of sticks is usually packed in jars. It conforms to the sausage standard and must show a true product name, e.g., "Meat Stick."
3. Nonspecific dry or semi-dry sticks that do not meet the sausage standard must be followed by the ingredients statement. If products meet the sausage standard, they may be identified as "Smoked Sausage."

Stroganoff, Meatball

Product must contain at least 45% cooked meatballs. Sauce portion shall comply with the Stroganoff Sauce standard.

Stroganoff Sauce

The sauce must contain at least 10% sour cream or a combination of at least 7.5% sour cream and 5% wine, or 2% sour cream, 2½% wine, and 9½% whole milk.

Stroganoff Sauce with/and Beef

Product must contain at least 31% beef or 21% cooked beef based on the total weight of the product, with sauce portion complying with the stroganoff sauce standard.

Stroganoff Sauce with/and Meatballs

Product must contain at least 31% cooked meatballs. Sauce portion shall comply with the stroganoff sauce standard.

Stromboli (IT)

Product is not considered a traditional sandwich. Minimum meat requirement is 25% fresh or 18% cooked meat. The label must show a true product name, e.g., "Pepperoni and Cheese Wrapped in Dough."

Stuffed Cabbage with Meat in Sauce

Product must contain at least 12% meat or at least 8% cooked poultry.

Stuffed Peppers with Meat in Sauce

Product must contain at least 12% meat or at least 8% cooked poultry.

Sukiyaki

Product must contain at least 30% beef. Sukiyaki consists of cut up vegetables, e.g., mushrooms, leeks and celery, which are cooked briefly with thin slices of beef and soy sauce.

Sulfiting Agents

The presence of sulfiting agents (sulfur dioxide, sodium sulfite, sodium bisulfite, potassium bisulfite, sodium metabisulfite, and potassium metabisulfite) must be declared on the label if their concentration in the finished meat or poultry food product is 10 PPM or higher. However, some finished meat and poultry food products may be comprised of multiple separable components, e.g., potatoes or apple cobbler in frozen dinner. For these products, if a separable component contains 10 PPM or more sulfiting agents, the sulfiting agents must be declared even though the total product contains less than 10 PPM of sulfiting agents. When sulfiting agents are required to be declared under conditions described above, their declaration shall be according to the following:

1. Sulfiting agents shall be declared by their specific name or as "sulfiting agents."

2. Declaration shall be in the ingredients statement in order of predominance or at the end of the ingredients statement with the statement "This Product Contains Sulfiting Agents" (or specific name(s)).
3. When the total product contains less than 10 PPM, but a separable component contains 10 PPM or more, the sulfiting agent must be declared as part of the component according to (1) and (2) above.

Summer Sausage

Product may be a semi-dry or cooked sausage. Meat byproducts and extenders are permitted.

Swiss Steak

Swiss Steak and Gravy: Contains not less than 50% cooked beef.

Gravy and Swiss Steak: Contains not less than 35% cooked beef.

Product labeled "Swiss Steak" must be floured or dusted before searing, or may have flour added to gravy.

Sweet and Sour Pork, Beef or Poultry

Product requires at least 25% meat or poultry meat, or 18% cooked meat or poultry meat. Product also requires sufficient traditional sweet and sour ingredients (fruit, fruit juices, vinegar, etc.) to impart sweet and sour characteristics.

Szechwan Style

Acceptable identification for any product containing one item from three or the four groups below.

1. Soy sauce
2. Spring onions, scallions or leeks
3. Garlic, ginger, ginger root
4. Chili, Szechwan peppercorn, Chili oil

Taco

Product must contain at least 15% meat.

Taco Filling

Product must contain at least 40% fresh meat. The label must show true product name, e.g., "Taco Filling with Meat," "Beef Taco Filling," or "Taco Meat Filling."

Taco Filling, Kind

Product must contain at least 40% raw poultry meat.

Tags, Tissue Strips, Brands

When tags, tissue strips, brands, etc. are used to apply ingredients statements on sausages and other products in casings or link form, the only additional marking required is the official inspection legend. However, if other features are added, e.g., the product name, all applicable required labeling features are required.

See: 9 CFR 316.10.

Tallow

Acceptable product name for the meat food product consisting of rendered beef fat or mutton fat or both.

Tamales

Product must contain at least 25% meat. Tamales prepared with meats other than beef and/or pork must include them in the product name, e.g., "Chicken Tamale" or "Chicken and Beef Tamale."

See: 9 CFR 319.305.

When inedible wrappings are used, they must be indicated:

a. In the product name, e.g., "Beef Tamale Wrapped in Corn Husk."
b. As a qualifier to the product name, e.g., "remove parchment paper prior to eating," or
c. As information in the preparation instructions, e.g., "remove the inedible covering prior to serving." The wrapper cannot be included as part of the net weight.

Filling — must contain at least 40% beef.

Pie — must contain at least 20% fresh meat. Filling must be at least 40% of the total product.

(kind) — must contain at least 6% poultry meat.

(kind) With sauce or gravy — must contain at least 5% poultry meat.

(species) — must contain at least 25% meat.

(species) With sauce or gravy — must contain at least 20% fresh meat.

If byproducts are used, their presence must be included in the product name.

Tapioca Product

Tapioca flour — can be used as a binder in some products in which "starchy vegetable flour" is permitted, as long as it is declared as tapioca flour.

Tapioca starch — can be used as a binder in some meat and poultry products in which "vegetable starch" is permitted as long as it is declared as "tapioca starch or food starch." Tapioca starch cannot be declared as "starch."

Taquitos

A Mexican dish requiring at least 15% meat. Cooked meat product is cut into strips or shredded and placed in center of tortilla. The tortilla is then rolled around the filling.

Tasajo Salted Beef (SP)

MPR not to exceed 2:1. Product is stitch pumped and cured in salt brine for 72 hours or more after which it is dried with circulated warm air for a period of at least 20 days. If the item is dipped in a tallow mixture, a statement must be shown contiguous to the product name identifying the constituents of the dipping mixture.

Teawurst or Teewurst

A cooked or uncooked product processed with or without curing and cold smoked 2 to 5 days. It is ground or coarsely chopped and is characterized by a soft spreadable texture. Typical meat ingredients include: pork, beef, pork bellies, and bacon. Fresh pork bellies may be used in place of pork fat and bacon.

Tempura

A Japanese dish consisting of shrimp, fish, vegetable, meat, poultry etc., each dipped in an egg batter and deep fried. The label must show true product name, e.g., "Chicken Tempura," "Pork Tempura," etc.

Teriyaki, Meat or Poultry

Cubes or slices of meat or poultry meat which have been marinated in a sauce containing soy sauce, some kind of sweetener, and usually ginger, garlic, or wine. When the marinated product is combined with additional sauce the product name must reflect the sauce; for example, "Beef Teriyaki with Sauce."

See: **Teriyaki Products** when product has not been cooked.

Teriyaki Products

Meat and poultry teriyaki products are not required to be cooked, provided a prominent statement is on the principal display panel informing the consumer that the product is not cooked. Example: "Ready to Cook," "Raw," and "Ready to Bake."

Tetrazzini, Poultry or Beef

Product must contain at least 15% cooked poultry or cooked beef. Made with diced cooked poultry or meat in a rich cream sauce containing sherry. This is added to cooked spaghetti or noodles in a casserole. Usually topped with bread crumbs or grated cheese.

Textured Vegetable Protein (Textured Vegetable Protein Product) for Cooked Meat and/or Poultry Meat

If the cooked meat and/or poultry meat to TVP ratio exceeds 9:1, then the TVP is declared by its common or usual name in the ingredients statement only.

If the cooked meat and/or poultry meat to TVP ratio is less than 9:1 but at least 7:1, the label must contain a qualifying phrase contiguous to the product name, e.g., "Chicken Salad, Textured Vegetable Protein Added."

If the cooked meat and/or poultry meat to TVP ratio is less than 7:1, the TVP must be shown in the product name, e.g., "Chicken and Textured Vegetable Protein Salad."

Textured Vegetable Protein (TVP) Products — Fresh Meat or Poultry Meat Ratios

The following guidelines and labeling requirements have been established regarding use of TVP in products other than patties and pizza toppings.

If the ratio of fresh meat or poultry meat to TVP is greater than or equal to 13:1, the TVP product is not considered to be characterizing or deceptive, e.g., 40% fresh meat: 3% textured soy flour = 13.3:1, and the TVP only needs to be shown in the ingredients statement only.

If the ratio of fresh meat or poultry meat to TVP product is less than 13:1 but greater than or equal to 10:1, the TVP is characterizing and must be shown contiguous to the product name, e.g., "Hot Dog Chili Sauce made with Beef Textured Vegetable Protein added."

Thai Style

Acceptable identification for products containing at least five of the following:

Basil, chilies or chili products, cilantro, coconut or coconut products, coriander, cumin, fish sauce, galangal, garlic, ginger, green onions, jasmine rice, lemon grass, peanuts or peanut products, rice noodles, shallots, or soy sauce.

Thuringer

Usually classed as a "Semi-Dry" sausage with an MPR of 3.7:1. It is usually smoked and complies with the following factors:

1. Pork fat as such may comprise up to 10% of the total ingredients.
2. Heart meat (Beef or Pork) may comprise up to 50% of meat ingredients.
3. Tongue meat (Beef or Pork) may comprise up to 10% of meat ingredients.
4. Cheek meat (Beef or Pork) may comprise up to 50% of eat ingredients.

5. No binders or extenders are allowed.
6. "Cooked Thuringer" can contain up to 10% added water.
7. Acceptable product names for uncooked Thuringer include: "Beef Summer Sausage — Thuringer Cervelat" and "Summer Sausage — Thuringer Cervelat."

Tips

Is the sub-primal of the beef round and is often referred to as the "Sirloin Tip." If the term "Tips" is used for other than from the "Sirloin Tip," it must be qualified as to the specific part of the primal such as "Beef Ribs Tips."

Titanium Dioxide

When Titanium Dioxide is used in poultry salads, a qualifying phrase should appear under the product name stating that the product has been "Artificially Whitened" or "Artificially Lightened."

Tocino

Spanish word for salt pork or bacon. Except in Puerto Rico, must show and use true product name in English, e.g., bacon, salt pork.

Tocino, Poultry

A fanciful name for a tocino product made from poultry. The fanciful name must be followed by a true descriptive product name, e.g., "Chicken Tocino, Sliced, Marinated, Cured Chicken Thigh Meat."

Tocino (Filipino or Philippine Style)

The thinly sliced piece of meat taken from either the hind leg or shoulder portion of the pork carcass. The product is treated with salt, sugar, and nitrite and/or nitrates, with optional ingredients of ascorbic acid, spices, monosodium glutamate, and phosphates. Acceptable color agents are annatto, beet powder, and paprika that must be shown as "artificially colored." A true product name must be shown on the label, e.g., "Sliced Marinated Cured Pork Shoulder Butt, followed by the solution statement."

Tocopherol

May be listed as "Topcopherol (Vitamin E)" on the label but not "Vitamin E (Tocopherol)." Tocopherol and Vitamin E are not synonyms. Also, acceptable in rendered or unrendered fat.

Tomato and Bacon Spread

Product must contain at least 25% cooked bacon.

Tongue Trimmings

Labeling terminology for the various kinds of tongue and cheek trimmings shall be as follows:

1. "(Species) tongue trimmings" shall be used to identify all tissues except cartilage and bone that are obtained by converting long-cut to short-cut tongues. This conversion is done by making a transverse cut anterior to the epiglottis, removing the soft palate and epiglottis, and cutting through the hyoid bone. Approximately $1\frac{1}{2}$ inches of the bone is left with the tongue. "(Species) tongue trimmings" may also be used to identify salivary glands, lymph nodes, and fat from which the muscle tissue has not been removed.
2. "(Species) salivary glands, lymph nodes, and fat (tongue)" must be preceded by the name of the species from which derived. Tongue meat should not include any tissues described in paragraph 2.
3. Trimmings from the tongue itself should be identified as "tongue meat" preceded by the name of the species from which derived. Tongue meat should not include any tissues described in paragraphs 2 and 3 above.
4. Trimmings with fat from tongue is acceptable ingredient in cooked sausage products covered under section 9 CFR 319.180 of the regulations. Lymph nodes and salivary glands are not acceptable ingredients.

Topping — (Species) or (Kind)

Topping is an acceptable product name for a nonspecific product containing the species or kind indicated as well as various other ingredients. The ingredients statement must follow the product name.

See: Pizza Topping Mix.

Tortellini with Meat

Product must contain at least 10% meat.

Tortilla with Meat

Product must contain at least 10% meat. Tortilla is a thin, flat unleavened masa cake which is baked on both sides.

Tostada with Meat

Product must contain at least 15% meat. A tortilla is usually topped with refried beans, meat, cheese, and fresh vegetables.

Touristen Wurst

A semi-dry type of sausage. The MPR must not exceed is 3.7:1.

"Tropic Cure" Pork Products

Pork products when ready for shipment from the official establishment must have a moisture protein ratio not in excess of 3.25:1, and a salt content not less than 6%.

Truffles

Meat food product, e.g., "Liver Pate with Truffles" or "Sandwich Spread with Truffles" would be expected to be prepared with at the least 3% truffles. Labels of product containing less than 3% truffles should indicate the amount of truffle content in the name, e.g., "Liver Pate with 2% truffles." If the name does not feature truffles and they are mentioned only in the list of ingredients, we have no minimum requirement, provided the illustration does not show truffles.

Turkey Braunschweiger

The product name must be shown on the label as "Turkey Liver Sausage." No byproducts other than liver are permitted in the product.

Turkey Chops

Turkey chops are prepared by cutting the frozen breast into slabs with each cut being made perpendicular to the long axis of the keel bone (sternum). The larger slabs are split in half through the center of the sternum, resulting in two individual servings of meat with a piece of bone on one side and a thin layer of skin on the other. The smaller pieces at each end of the breast are left intact as individual servings. The word steak is unsuitable because a turkey steak is boneless by definition.

Turkey Ham Products Containing Added Water

Product otherwise conforming to the standard for turkey ham under section 9 CFR 381.171 of the poultry products inspection regulations but weighing more than the original weight of the turkey thigh meat used prior to curing shall be descriptively labeled as follows:

1. The product name must include in addition to "Turkey Ham," words that specify the amount of the additional substances, e.g., "and % Water," "With % Water Added," or "Turkey Ham and Water Product % of Weight is Added Ingredients." (The ingredients of the added solution may be incorporated into the product name, e.g., "Turkey Ham and Water Product % of Weight is Added Water, Salt, Dextrose, Sodium Phosphate, and Sodium Nitrite.") The blank is filled in with the % determined by subtracting the original weight of the turkey thigh meat from the weight of the cooked finished product. "Turkey Ham and 12% Water" is an example.
2. In retail and non-retail size packaging, the qualifying statements described in 1 above must be shown in lettering that is either not less than three-eighths inch in height or is at least one-third the size of the letters used in the product name and in the same color and style and on the same background as the product name. Full length of the product labeling is not required.
3. The "Turkey Ham" portion of the product name must be qualified with the statement "Cured Turkey Thigh Meat" in the manner described in 9 CFR 381.171(e). This may be effected by using an asterisk as long as there is no type or other designs between the total product name and the qualifying statement. Other means of qualifying "Turkey Ham" will be evaluated based on clarity. Alternatively, the total name as described in 1 and 2 above may be qualified with a statement that includes "Cured Turkey Thigh Meat" and the amount of added water, e.g., "Cured Turkey Thigh Meat and 12% Water." The statement should be presented in the manner described in 9 CFR 381.171(e).
4. The product name shall be further qualified with the statement(s) required by section 9 CFR 381.171(f) and any other statements required in Part 381. A product complying with the standard for Turkey Ham, containing added water, and descriptively labeled as stated above, must be produced under a Partial Quality Control (PQC) program approved by the Processed Products Inspection Division (PPID) prior to the use of the approved label.

Turkey Ham and Water Products Containing Binders

Turkey ham products containing added water and binders must be labeled as "Turkey Ham and Water Products" X% of weight is added ingredients as described in Policy Memo 057a to provide freeze/thaw stability and reduce purge in packages. The binders that are acceptable for use in cured pork product can be used in these turkey ham products. The binders must be used in accordance with 9 CFR, Sections 9 CFR 319.104(d) and 424.21(c). Where several limits are listed, depending upon the cured pork product, the maximum amount permitted in the regulation is acceptable.

Turkey Ham Products Containing Ground Turkey Thigh Meat (Labeling)

Small amounts of ground turkey thigh meat may be added as a binder in turkey ham products as defined in 9 CFR

381.171 without declaration, provided the ground turkey thigh meat is made from trimmings that are removed from the turkey thighs during the boning and trimming process. The amount of ground turkey thigh meat that may be used can represent no more than the amount that was trimmed and in no case more than 15% of the weight of the turkey thigh meat ingredients when formulated. Products containing any ground turkey thigh meat not removed during the boning and trimming processes or products containing more than 15% ground turkey thigh meat must be labeled to indicate the presence of the ground turkey thigh meat, e.g., "a portion of ground turkey thigh meat added." The provision in the regulations (9 CFR 381.171(f)) regarding the required use of terminology, e.g., "Chunked and Formed," "Chopped and Formed," and "Ground and Formed" will continue to be followed.

Turkey Loaf: Cured, Chopped (Canned)

May contain seasonings, cures, and no more than 3% water at formulation. Binders and extenders are not permitted.

Turnovers

Product must contain 25% meat or 14% poultry meat. Similar to pies except the dough is folded. Cheese may be substituted for meat or poultry meat in an amount not to exceed 50% under the conditions outlined below:

1. Cheese must be part of the product name, e.g., "Beef and Cheese Turnover" or "Chicken and Cheese Turnover."
2. Imitation Cheese, substitute cheese, cheese food, and cheese spreads are not acceptable replacements for cheese.

Tzimmes

The true product name is "Beef and Vegetables" (or similar wording) when at least 50% beef is present in the product. "Vegetables with Beef" (or similar wording) is acceptable when at least 35% raw beef is used.

Ukrainian Sausage

A dry sausage made from lean pork and/or veal chunks, containing large amounts of garlic which dominates the flavor. It is cooked and smoked at high temperatures and then air dried. The water activity (Aw) of the finished product shall not exceed 0.92 or a moisture/protein ratio 2.0:1 or less.

Variety Meats in Franks

Cooked sausages with variety meats (byproducts) identified in 9 CFR 319.180(b) must contain not less than 15% red skeletal meat based on total meat block weight. The meat block includes meat, meat by-products, and if applicable, poultry.

Variety Packs — Hors d'oeuvres

Whenever FDA regulated products are included as a part of a variety pack bearing the legend (e.g., seafood hors d'oeuvres included with meat and poultry hors d'oeuvres), the labeling information must still be reviewed to assure accuracy. FDA regulated products that are found mislabeled should be corrected according to the policies of the FDA before the label can be approved.

Veal and Peppers in Sauce

Product must contain at least 30% cooked veal.

Veal Birds

Product is similar to a turnover made with meat and no more than 40% stuffing. Categories of products are as follows:

1. Veal Birds — At least 60% veal
2. Veal Birds Beef Added — At least 60% veal and beef of which 20% may be beef
3. Veal and Beef Birds — At least 60% veal and beef of which up to 50% may be beef
4. Veal Birds (made from patties) — Birds made from patties shall bear a true product name descriptive of patty used, e.g., "Veal Birds made with Veal Patties — Beef Added." The patty portion shall contain 70% meat.

Veal Cordon Bleu (FR)

The standard requires at least:

1. 60% veal;
2. 5% ham, Canadian bacon, or cooked cured pork loin; and
3. Cheese (either Swiss, Gruyere. Mozzarella, or Pasteurized Processed Swiss).

If the product is breaded, it must be shown in the product name. When the product is made with other than solid pieces of meat, "Chopped and Formed" must be shown contiguous to the product name. Beef is not permitted in this product.

Veal that has been injected with water and phosphates and used for Veal Cordon Bleu should be labeled "Veal Roll Cordon Bleu" or other descriptive names as appropriate.

Veal Drumstick, Breaded

May not contain more than 15% water or more than 10% extenders.

Veal Fricassee

Must contain at least 40% meat.

Veal Parmigiana

The following categories of products exist:

1. "Breaded Veal Parmigiana" is the product name for a solid piece of veal that is breaded and topped with cheese and tomato sauce. Breaded cooked veal must represent 40% of the finished product.
2. "Breaded Veal Parmigiana, Chopped and Formed Beef (or Beef Fat) Added" is the product name for chopped veal with up to 20% beef and/or beef fat added that is formed, breaded, and topped with cheese and tomato sauce. The chopped and formed beef added statement is shown one-third the size of "Veal" contiguous to the product name. Breaded cooked patty must represent 40% of the finished product.
3. "Breaded Veal Parmigiana made with Veal Patties, Beef (or Beef Fat) Added" is the product name for a veal patty containing at least 70% fresh meat (in unbreaded patty) of which 20% may be beef or beef fat. The patty is breaded, topped with cheese and tomato sauce. The entire qualifying statement in the product name is to be shown 1/3 size of "Veal" contiguous to product name. The breaded cooked patty represents 40% of the finished product.
4. Breaded Veal and Beef Patty Parmigiana. The patty may be prepared in proportions as governed by 9 CFR 317.2(f)(1)(v) of the regulations; the minimum meat patty requirement is 50%. If the product is breaded, the name must reflect this fact. The cheese component of the product does not have to be shown in the name of the product. A specific kind of cheese is not required, although Romano, Mozzarella, and Parmesan are the usual types used. No specific spelling of the word "Parmigiana" is required. Name applies to a "Cooked Product Assembled, Ready to Heat and Eat."

The labeling of Veal Parmigiana made from a veal patty shall include veal patty in the product name, e.g., "Breaded Veal Parmigiana made with Veal Patties" or "Breaded Veal Patty Parmigiana." The ingredients of the veal patty do not have to be part of the product name.

Veal Patties

Up to 20% beef and/or beef fat of the meat block permitted. Beef and/or beef fat must show in the true product name, e.g., "Veal Patties, beef added" or "Veal Patties, beef fat added." Beef and/or beef fat in excess of 20% of the meat block must show as "Veal and Beef Fat Patties."

Veal Scaloppini

Veal and sauce type product that must contain at least 35% cooked sliced veal.

Vegetable Declaration on Labels

1. The use of the terms onion, garlic, celery, and parsley shall mean fresh, frozen, or canned.
2. Processed onion or garlic must be qualified in a manner, e.g., "dried" or "dehydrated onion" or may be shown as "onion flakes" or "powdered."
3. It is usually not necessary to show vegetables as whole, diced, sliced, granulated, powdered, or pureed; however, whenever the name of the vegetable is necessary to describe a food, then the name of the vegetable should be modified to show the form of its degree of processing.
4. Onion or garlic juice to which water has been added shall be noted, e.g., onion juice with water added.
5. Celery seed may be listed as a spice.
6. Celery salt shall be shown as celery salt.
7. Oil of celery may be listed as a flavoring.

Vegetable Extract

The source must be identified i.e. "soy," "corn" and "beet."

Vegetable Gum

Declare common or usual name of each vegetable gum, e.g., Guar Gum.

Vegetable Pie with

"Species" meat must contain 12% meat on a raw basis. "Kind" poultry must contain 7% cooked poultry.

Vegetable Stew with: Minimum Meat Content

Vienna Sausage — Packed in Beef Broth

Meatballs	12% meat
Meat	12% meat
Meat Sauce or Gravy	6% meat
Sauce and Meat	12% meat
Poultry	6% cooked poultry meat

Product must contain 80% sausage to be in compliance prior to inclusion in can. Broth component to have a MPR

of not more than 135:1. A manufacturer holds trademark rights to the terms "Vienna" and "Vienna Beef."

Vinegar

Product must contain at least 4 grams of acetic acid per 100 cubic centimeters (approximately 4% acetic acid). This strength is referred to as 40 grain vinegar. Cider vinegar, which during the course of manufacture has developed an excess of acetic acid over 4%, may be reduced to a strength not less 4%. Cider vinegar so reduced is not regarded as adulterated but must be labeled as to its nature as "diluted" or "water added" cider vinegar. However, when vinegar of any concentration (not less than 4% acetic acid) is used in a food product, the only labeling requirement is "vinegar." Statements like "diluted" or "water added" are not required.

Vinegar Pickle

Sausage in vinegar pickle is approved with the understanding that sausage is completely covered with pickle and that the pickle has a pH level not higher than 4.5.

Water Base Solutions in Red Meat in Meat Products

Solutions intended to impart flavor (not extend the product) may be added in any amount to uncooked, cured and uncooked, uncured red meat products including those that have been chunked, ground, wafer sliced, etc., and formed/shaped. Whenever an uncooked, cured red meat product is injected, massaged, tumbled, etc., with a flavoring or seasoning solution, the product name must be qualified with a statement indicating that the addition of a solution has taken place, e.g., "Containing 6% of a Solution," "Injected with up to 12% of a Flavoring Solution." The qualifier must appear contiguous to the product name whenever it appears on the label. The ingredients of the solution may accompany the qualifier or appear in locations prescribed for ingredient statements.

For products marinated (i.e., soaked, steeped, massaged, tumbled, or injected in order to improve taste, texture, tenderness, or other sensory attributes, such as color or juiciness) and identified as "marinated," the solution added is limited to 10%. The qualifying statement must include the percentage of solution contained in the product, e.g., "Marinated with up to 8% of a Solution of Water, Salt, and Sugar."

In situations where it has been customary to coat a product by rubbing, spraying, or dipping water mixed with seasonings, flavorings, etc., onto the surface of the meat, the qualifying statement describing this treatment does not have to include the amount and a partial quality control program is not needed. If, however, these components are incorporated into the meat by excessive rubbing, massaging, or tumbling, a qualifying statement indicating the composition and the amount of any solution absorbed is needed as described herein. An approved partial quality control program is also needed.

The addition of an enzyme solution to meat products is limited to 3% of the raw meat product (green weight) by the meat inspection regulations (9 CFR 318.7(c)(4)). If a product is treated with an enzyme solution and a flavoring solution, separately or in one step, both treatments must be separately identified on the label, e.g., "Tenderized with Papain," and "Marinated with up to 7% of a Solution." No particular order is required for these qualifying statements. Combined tenderization/marination solutions are limited to 10% of the raw meat product (green weight).

For all products, the qualifying statement must be at least one-fourth the size of the largest letter in the product name. If the ingredients of the solution accompany the qualifier, they must appear in print at least one-eighth the size of the largest letter in the product name. Product name labeling prominence guidelines are found in Policy Memo 087A.

For uncooked products, the percent added substances for the label statement is determined by subtracting the fresh (green) weight of the article from the weight of the finished (total) product, i.e., after injecting, marinating, etc., dividing by the weight of the fresh article, and multiplying by 100.

In all situations where the percentage of a solution is disclosed, a partial quality control (PQC) program for the addition of solutions must be approved before the label can be used regardless of the amount of solution added.

Since the meat inspection regulations (9 CFR 319.101 and 102) allow uncooked corned beef brisket to contain 20%, and uncooked corned beef round and other cuts to contain 10% of a curing solution above the weight of the fresh, uncured (green weight) product without disclosure, the above labeling scheme does not apply until these levels are exceeded. If these levels are exceeded, the total amount of added solution, not just the level above compliance, must be indicated in the format described for other uncooked, cured products. Similarly, the labeling scheme does not apply to uncooked cured pork trimmings or uncooked cured pork products that are not labeled to indicate the presence of hams, loins, shoulders, butts, picnics, or cured pork made from parts not covered by the cured pork products regulation (9 CFR 319.104) until more than 10% added substance is present.

This policy memo does not apply to uncooked cured pork products covered by the cured pork products regulation. The labeling schemes for indicating the presence of added substances in these products are outlined in the meat inspection regulations (9 CFR 319.104 and 105) and FSIS Directive 7110.2 (Rev. 1). The percentage of the weight of added ingredients is determined as described above.

Water-Declaration

The use of water must be declared in the ingredients statement of all products with the exception of the following:

1. The water added to lactic acid starter culture (.05% or less) for the purpose of rehydration.
2. The water added to products which are freeze-dried or sprayed-dried.

Water in Canned Sausage

Water, not to exceed 8% of the total product weight, may be used in the preparation of precooked pork sausage links intended for canning. The amount of water used is for the purpose of replacing that which is lost during the processing operation that takes place prior to canning. The weight of the sausage at the time of canning shall not exceed the weight of the fresh uncured meat ingredients plus the weight of the curing ingredients and the seasoning ingredients.

Water-Misted and Ice-Glazed Meat and Poultry Products

When meat or poultry products are water-misted or ice-glazed, the net weight of the product may not include the weight of the water or ice. An acknowledgment to this effect must be indicated on the label application form. A prominent and conspicuous statement must appear on the principal display panel adjacent to the product name, describing that the product is protected with a water-mist or ice glaze (e.g., "Product Protected with Ice Glaze").

If the manufacturer can show that a water or ice glaze is sublimed from the unpackaged product during freezing so as not to compromise the integrity of the product's formulation or the standard with which it must comply, the labeling of the product need not bear the statements identified above.

Because the regulatory standard 9 CFR 319.15 precludes the addition of water — hamburger, ground beef and chopped beef patties cannot be ice-glazed and, if there is evidence of an ice-glaze on such patties subsequent to freezing, they must be labeled appropriately to be sold in commerce, e.g., as "beef patties." However, water-misting of formed hamburger, ground beef, or chopped beef patties just prior to freezing individual patties is permitted if (1) the water applied in misting acts as a processing aid to prevent shrinkage of the patties, and (2) the misted water sublimes from the surface of the patties during the freezing process such that the weight of the patty exiting the freezer does not exceed the green weight of the patty just prior to water-misting and freezing.

Weisswurst

An acceptable name for fresh sausage. It is usually made of pork or veal and must be thoroughly cooked before eating. It is of German origin, which means White Sausage-similar to Bratwurst. Weisswurst with milk should be labeled "Kalbsbratwurst." Weisswurst with milk and eggs should be labeled "Bockwurst."

Welsh Rarebit Sauce with Cooked Ham

Product must contain at least 20% cooked ham in the total formulation.

Wheat Gluten

Acceptable for use to bind fresh meat cuts, e.g., boneless loins, boneless legs, and livers together, so that they may be cooked and sliced without falling apart. The amount used should not exceed 2% of the weight of the total product. The product name shall be qualified by the phrase "Wheat Gluten Added."

Wheat gluten is not acceptable for use with chunked and/or chopped specific products as roasts, rolls, and reformed meat cuts.

Acceptable in nonspecific products and home-style meat loaves within the prescribed limits of other extenders and binders.

Whole Hog Sausage

Must contain all primal parts of a hog. Hearts and tongues, in natural proportions, are permitted ingredients in whole hog sausage when declared in the ingredients statement. Other meat byproducts are not permitted in whole hog sausage.

See: 9 CFR 319.144.

Wiener Schnitzel (GR)

A veal cutlet prepared by dipping in egg, flour, and bread crumbs and frying to a golden brown.

Wild Boar

Products prepared from wild boar from feral swine are amenable and subject to the meat inspection regulations.

"Wild Boar" is an acceptable label term for a product, provided the words "Wild Boar" are directly followed by the statement "Meat from Feral Swine." The statement "Meat from Feral Swine" must appear prominently on the principle display panel as described in 9 CFR 317.2(d)(1)(2) and (3). If the statement "Meat from Feral Swine" does not directly follow the term "Wild Boar," then an asterisk may be included with the term "Wild Boar" and the statement "Meat from Feral Swine" should appear prominently elsewhere on the principal display panel. "Wild Boar from Feral Swine," "Wild Boar Meat from Feral Swine," "Wild Boar (byproduct) from Feral Swine," are also acceptable product names.

In order to obtain approval for a product label bearing the name "Wild Boar from Feral Swine," or similar acceptable names, a statement describing and verifying the following physical and environmental characteristics typical of wild boar is required: color patterns, e.g., white stripes or spots, longer bristly haircoat, elongated snout with visible tusks, a "razorback" body shape, and wild boar males which are uncastrated. (We acknowledge both males and females under the term "Wild Boar.") The purchased hogs should be obtained from a nonrestrictive environment which permits foraging for uncultivated feed, natural selection, and breeding and farrowing without confinement. A letter should be submitted with "Wild Boar from Feral Swine" labels describing the environment where such swine live and their method of capture or entrapment. These same criteria would also apply to imported "Wild Boar Meat from Feral Swine" and arrangements should be made through foreign programs for slaughter and export from approved establishments.

In multi-ingredient products, e.g., "Beans in Sauce with Wild Boar," the "Wild Boar" part of the product name must be followed by an asterisk and a statement "(meat or meat byproduct) from Feral Swine" must appear somewhere on the principal display panel. The ingredient wild boar, wild boar meat, or wild boar byproduct must be listed as "Wild Boar [(Meat or meat byproduct) from Feral Swine]" in the ingredients statement in its proper order of predominance.

Wing Sections

First wing section is described as the wing drummette Second wing section is described as the wing portion. Wings Sections is an acceptable wing term for both wing drummette and wing portion when in natural proportions.

With Natural Juices (Poultry)

The term "With Natural Juices" may be used with poultry products to indicate the presence of cooked out juices derived solely from the liquid normally associated with the poultry prior to cooking. If liquids have been added to the poultry prior to cooking, natural can not be used.

Wraps

A ready-to-eat meat/poultry food product that may contain vegetables and seasoning ingredients and is wrapped in a dough based component, e.g., tortilla. The product name must bear the kind or species, e.g., "Ham Wraps." The minimum meat or poultry requirement is 2% cooked meat or 2% cooked poultry meat.

Yearling

The term "yearling" (e.g. yearling beef) may be used to describe an animal of either sex that is too old to be classified as a calf or lamb but less than 2 years of age. The company is required to segregate carcasses and provide product identification to insure that no commingling occurs between qualifying and nonqualifying products.

The terms "Yearling Ovine", "Yearling Mutton" and "Yearling Sheep Meat" are acceptable product names for meat derived from sheep between 1 and 2 years of age. Yearling Lamb is **not** an acceptable name for this product.

73 FDA's GMPs, HACCP, and the Food Code

Peggy Stanfield
Dietetic Resources

CONTENTS

I. INTRODUCTION

Nearly 25 years ago, the United States Food and Drug Administration (FDA) started the approach of using umbrella regulations to help the food industries to produce wholesome food as required by the Federal Food, Drug, Cosmetic Act (the Act). In 1986, the FDA promulgated the first umbrella regulations under the title of Good Manufacturing Practice (GMP) regulations (GMPR). Since then, many aspects of the regulations have been revised (1).

Traditionally, industry and regulators have depended on spot-checks of manufacturing conditions and random sampling of final products to ensure safe food. The Current Good Manufacturing Practice Regulations (CGMPR) forms the basis on which the FDA will inform the food manufacturer about deficiencies in its operations. This approach, however, tends to be reactive, rather than preventive, and can definitely be improved.

For more than 30 years, FDA has been regulating the low acid canned food (LACF) industries with a special set of regulations, many of which are preventive in nature. This action aims at preventing botulism. In the last 30 years, threats from other biological pathogens have increased tremendously. Between 1980 and 1995, FDA has been studying the approach of using Hazard Analysis and Critical Control Points (HACCP). For this approach, FDA uses the LACF regulations as a partial guide. Since 1995, FDA has issued HACCP regulations (HACCPR) (2) for the manufacture or production of several types of food products. These include the processing of seafood and fruit/vegetable juices.

Since 1938, when the Act was first passed by Congress, FDA and State regulatory agencies have worked hard to reach a uniform set of codes for the national regulation of food manufacturing industries and state regulation of retail industries associated with food, e.g., groceries, restaurants, catering, and so on. In 1993, the first document titled *Food Code* was issued jointly by the FDA and state agencies. It has been revised twice since then. This chapter discusses CGMPR, HACCPR, and the *Food Code*.

TABLE 73.1
Contents of the Current Good Manufacturing Practice Regulations (CGMPR)

Section 110.3	Definitions
Section 110.5	Current good manufacturing practice
Section 110.10	Personnel
Section 110.19	Exclusions
Section 110.20	Plant and grounds
Section 110.35	Sanitary operations
Section 110.37	Sanitary facilities and controls
Section 110.40	Equipment and utensils
Section 110.80	Processes and controls
Section 110.93	Warehousing and distribution

II. CURRENT GOOD MANUFACTURING PRACTICE REGULATIONS (CGMPR)

The Current Good Manufacturing Practice Regulations (CGMPR) cover the topics listed in Table 73.1. These regulations are discussed in detail here. Please note that the word "shall" in a legal document means mandatory and is used routinely in FDA regulations published in the U.S. Code of Federal Regulations (CFR). In this chapter, the words "should" and "must" are used to make for smoother reading. However, this in no way diminishes the legal impact of the original regulations.

A. Definitions (Section 110.3)

FDA has provided the following definitions and interpretations for several important terms.

1. *Acid food* or *acidified food* means foods that have an equilibrium pH of 4.6 or below.
2. *Batter* means a semi-fluid substance, usually composed of flour and other ingredients, into which principal components of food are dipped or with which they are coated, or which may be used directly to form bakery foods.
3. *Blanching*, except for tree nuts and peanuts, means a prepackaging heat treatment of foodstuffs for a sufficient time and at a sufficient temperature to partially or completely inactivate the naturally occurring enzymes and to effect other physical or biochemical changes in the food.

4. *Critical control point* means a point in a food process where there is a high probability that improper control may cause a hazard or filth in the final food or decomposition of the final food.
5. *Food* includes raw materials and ingredients.
6. *Food-contact surfaces* are those surfaces that contact human food and those surfaces from which drainage onto the food or onto surfaces that contact the food ordinarily occurs during the normal course of operations. *Food-contact surfaces* include utensils and food-contact surfaces of equipment.
7. *Lot* means the food produced during a period of time indicated by a specific code.
8. *Microorganisms* means yeasts, molds, bacteria, and viruses and includes, but is not limited to, species having public health significance. The term *undesirable microorganisms* includes those microorganisms that are of public health significance, that promote decomposition of food, or that indicate that food is contaminated with filth.
9. *Pest* refers to any objectionable animals or insects including, but not limited to, birds, rodents, flies, and insect larvae.
10. *Plant* means the building or facility used for the manufacturing, packaging, labeling, or holding of human food.
11. *Quality control operation* means a planned and systematic procedure for taking all actions necessary to prevent food from being adulterated.
12. *Rework* means clean, unadulterated food that has been removed from processing for reasons other than insanitary conditions or that has been successfully reconditioned by reprocessing and that is suitable for use as food.
13. *Safe moisture level* is a level of moisture low enough to prevent the growth of undesirable microorganisms in the finished product under the intended conditions of manufacturing, storage, and distribution. The maximum safe moisture level for a food is based on its water activity, a_w. An a_w will be considered safe for a food if adequate data are available that demonstrate that the food at or below the given a_w will not support the growth of undesirable microorganisms.
14. *Sanitize* means to adequately treat food-contact surfaces by a process that is effective in destroying vegetative cells of microorganisms of public health significance, and in substantially reducing numbers of other undesirable microorganisms, but without adversely affecting the product or its safety for the consumer.
15. *Water activity* (a_w) is a measure of the free moisture in a food and is the quotient of the water vapor pressure of the substance divided by the vapor pressure of pure water at the same temperature.

B. Personnel (Section 110.10)

Plant management should take all reasonable measures and precautions to ensure compliance with the following regulations.

1. Disease Control

Any person who, by medical examination or supervisory observation, is shown to have an illness, open lesion, including boils, sores, or infected wounds, by which there is a reasonable possibility of food, food-contact surfaces, or food-packaging materials becoming contaminated, should be excluded from any operations which may be expected to result in such contamination until the condition is corrected. Personnel should be instructed to report such health conditions to their supervisors.

2. Cleanliness

All persons working in direct contact with food, food-contact surfaces, and food-packaging materials should conform to hygienic practices while on duty. The methods for maintaining cleanliness include, but are not limited to, the following:

a. Wearing outer garments suitable to the operation to protect against the contamination of food, food-contact surfaces, or food-packaging materials.
b. Maintaining adequate personal cleanliness.
c. Washing hands thoroughly (and sanitizing if necessary to protect against contamination with undesirable microorganisms) in an adequate hand-washing facility before starting work, after each absence from the work station, and at any other time when the hands may have become soiled or contaminated.
d. Removing all unsecured jewelry and other objects that might fall into food, equipment, or containers, and removing hand jewelry that cannot be adequately sanitized during periods in which food is manipulated by hand. If such hand jewelry cannot be removed, it may be covered by material which can be maintained in an intact, clean, and sanitary condition and which effectively protects against their contamination of the food, food-contact surfaces, or food-packaging materials.
e. Maintaining gloves, if they are used in food handling, in an intact, clean, and sanitary condition. The gloves should be of an impermeable material.

f. Wearing, where appropriate, hairnets, headbands, caps, beard covers, or other effective hair restraints.
g. Storing clothing or other personal belongings in areas other than where food is exposed or where equipment or utensils are washed.
h. Confining the following personal practices to areas other than where food may be exposed or where equipment or utensils are washed: eating food, chewing gum, drinking beverages, or using tobacco.
i. Taking any other necessary precautions to protect against contamination of food, food-contact surfaces, or food-packaging materials with microorganisms or foreign substances including, but not limited to, perspiration, hair, cosmetics, tobacco, chemicals, and medicines applied to the skin.

3. Education and Training

Personnel responsible for identifying sanitation failures or food contamination should have a background of education or experience, to provide a level of competency necessary for production of clean and safe food. Food handlers and supervisors should receive appropriate training in proper food handling techniques and food-protection principles and should be informed of the danger of poor personal hygiene and insanitary practices.

4. Supervision

Responsibility for assuring compliance by all personnel with all legal requirements should be clearly assigned to competent supervisory personnel.

C. Plant and Grounds (Section 110.20)

1. Grounds

The grounds surrounding a food plant that are under the control of the plant manager should be kept in a condition that will protect against the contamination of food. The methods for adequate maintenance of grounds include, but are not limited to, the following:

a. Properly storing equipment, removing litter and waste, and cutting weeds or grass within the immediate vicinity of the plant buildings or structures that may constitute an attractant, breeding place or harborage for pests.
b. Maintaining roads, yards, and parking lots so that they do not constitute a source of contamination in areas where food is exposed.
c. Adequately draining areas that may contribute contamination to food by seepage or foot-borne filth, or by providing a breeding place for pests.
d. Operating systems for waste treatment and disposal in an adequate manner so that they do not constitute a source of contamination in areas where food is exposed. If the plant grounds are bordered by grounds not under the operator's control and not maintained in an acceptable manner, steps must be taken to exclude pests, dirt, and filth that may be a source of food contamination. Implement inspection, extermination, or other countermeasures.

2. Plant Construction and Design

Plant buildings and structures should be suitable in size, construction, and design to facilitate maintenance and sanitary operations for food-manufacturing purposes. The plant and facilities should:

a. Provide sufficient space for such placement of equipment and storage of materials as is necessary for the maintenance of sanitary operations and the production of safe food.
b. Take proper precautions to reduce the potential for contamination of food, food-contact surfaces, or food-packaging materials with microorganisms, chemicals, filth, or other extraneous material. The potential for contamination may be reduced by adequate food safety controls and operating practices or effective design, including the separation of operations in which contamination is likely to occur, by one or more of the following means: location, time, partition, air flow, enclosed systems, or other effective means.
c. Taking proper precautions to protect food in outdoor bulk fermentation vessels by any effective means, including:
   – Using protective coverings.
   – Controlling areas over and around the vessels to eliminate harborages for pests.
   – Checking on a regular basis for pests and pest infestation.
   – Skimming the fermentation vessels, as necessary.
d. Be constructed in such a manner that floors, walls, and ceilings may be adequately cleaned and kept clean and kept in good repair; that drip or condensate from fixtures, ducts and pipes does not contaminate food, food-contact surfaces, or food-packaging materials; and that aisles or working spaces are provided between equipment and walls and are adequately unobstructed and of adequate width to permit employees to perform their duties and to protect against contaminating food or food-contact surfaces with clothing or personal contact.

e. Provide adequate lighting in hand-washing areas, dressing and locker rooms, and toilet rooms and in all areas where food is examined, processed, or stored and where equipment or utensils are cleaned; and provide safety-type light bulbs, fixtures, skylights, or other glass suspended over exposed food in any step of preparation or otherwise protect against food contamination in case of glass breakage.
f. Provide adequate ventilation or control equipment to minimize odors and vapors (including steam and noxious fumes) in areas where they may contaminate food; and locate and operate fans and other air-blowing equipment in a manner that minimizes the potential for contaminating food, food-packaging materials, and food-contact surfaces.
g. Provide, where necessary, adequate screening or other protection against pests.

D. Sanitary Operations (Section 110.35)

1. General Maintenance

Buildings, fixtures, and other physical facilities of the plant should be maintained in a sanitary condition and should be kept in repair sufficient to prevent food from becoming adulterated within the meaning of the Act. Cleaning and sanitizing of utensils and equipment should be conducted in a manner that protects against contamination of food, food-contact surfaces, or food-packaging materials.

2. Substances Used in Cleaning and Sanitizing; Storage of Toxic Materials

a. Cleaning compounds and sanitizing agents used in cleaning and sanitizing procedures should be free from undesirable microorganisms and should be safe and adequate under the conditions of use. Compliance with this requirement may be verified by any effective means including purchase of these substances under a supplier's guarantee or certification, or examination of these substances for contamination. Only the following toxic materials may be used or stored in a plant where food is processed or exposed:
   – Those required to maintain clean and sanitary conditions;
   – Those necessary for use in laboratory testing procedures;
   – Those necessary for plant and equipment maintenance and operation; and
   – Those necessary for use in the plant's operations.
b. Toxic cleaning compounds, sanitizing agents, and pesticide chemicals should be identified, held, and stored in a manner that protects against contamination of food, food-contact surfaces, or food-packaging materials.

3. Pest Control

No pests should be allowed in any area of a food plant. Guard or guide dogs may be allowed in some areas of a plant if the presence of the dogs is unlikely to result in contamination of food, food-contact surfaces, or food-packaging materials. Effective measures should be taken to exclude pests from the processing areas and to protect against the contamination of food on the premises by pests. The use of insecticides or rodenticides is permitted only under precautions and restrictions that will protect against the contamination of food, food-contact surfaces, and food-packaging materials.

4. Sanitation of Food-Contact Surfaces

All food-contact surfaces, including utensils and food-contact surfaces of equipment, should be cleaned as frequently as necessary to protect against contamination of food.

a. Food-contact surfaces used for manufacturing or holding low-moisture food should be in a dry, sanitary condition at the time of use. When the surfaces are wet-cleaned, they should, when necessary, be sanitized and thoroughly dried before subsequent use.
b. In wet processing, when cleaning is necessary to protect against the introduction of microorganisms into food, all food-contact surfaces should be cleaned and sanitized before use and after any interruption during which the food-contact surfaces may have become contaminated. Where equipment and utensils are used in a continuous production operation, the utensils and food-contact surfaces of the equipment should be cleaned and sanitized as necessary.
c. Non-food-contact surfaces of equipment used in the operation of food plants should be cleaned as frequently as necessary to protect against contamination of food.
d. Single-service articles (such as utensils intended for one-time use, paper cups, and paper towels) should be stored in appropriate containers and should be handled, dispensed, used, and disposed of in a manner that protects against contamination of food or food-contact surfaces.
e. Sanitizing agents should be adequate and safe under conditions of use. Any facility, procedure, or machine is acceptable for cleaning and

sanitizing equipment and utensils if it is established that the facility, procedure, or machine will routinely render equipment and utensils clean and provide adequate cleaning and sanitizing treatment.

5. Storage and Handling of Cleaned Portable Equipment and Utensils

Cleaned and sanitized portable equipment with food-contact surfaces and utensils should be stored in a location and manner that protects food-contact surfaces from contamination.

E. Sanitary Facilities and Controls (Section 110.37)

Each plant should be equipped with adequate sanitary facilities and accommodations including, but not limited to:

1. Water Supply

The water supply should be sufficient for the operations intended and should be derived from an adequate source. Any water that contacts food or food-contact surfaces should be safe and of adequate sanitary quality. Running water at a suitable temperature, and under pressure as needed, should be provided in all areas where required for the processing of food, for the cleaning of equipment, utensils, and food-packaging materials, or for employee sanitary facilities.

2. Plumbing

Plumbing should be of adequate size and design and adequately installed and maintained to:

a. Carry sufficient quantities of water to required locations throughout the plant.
b. Properly convey sewage and liquid disposable waste from the plant.
c. Avoid constituting a source of contamination to food, water supplies, equipment, or utensils or creating an unsanitary condition.
d. Provide adequate floor drainage in all areas where floors are subject to flooding-type cleaning or where normal operations release or discharge water or other liquid waste on the floor.
e. Provide that there is no backflow from, or cross-connection between, piping systems that discharge wastewater or sewage and piping systems that carry water for food or food manufacturing.

3. Sewage Disposal

Sewage disposal should be made into an adequate sewerage system or disposed of through other adequate means.

4. Toilet Facilities

Each plant should provide its employees with adequate, readily accessible toilet facilities. Compliance with this requirement may be accomplished by:

a. Maintaining the facilities in a sanitary condition.
b. Keeping the facilities in good repair at all times.
c. Providing self-closing doors.
d. Providing doors that do not open into areas where food is exposed to airborne contamination, except where alternate means have been taken to protect against such contamination (such as double doors or positive air-flow systems).

5. Hand-Washing Facilities

Hand-washing facilities should be adequate and convenient and be furnished with running water at a suitable temperature. Compliance with this requirement may be accomplished by providing:

a. Hand-washing and, where appropriate, hand-sanitizing facilities at each location in the plant where good sanitary practices require employees to wash and/or sanitize their hands.
b. Effective hand-cleaning and sanitizing preparations.
c. Sanitary towel service or suitable drying devices.
d. Devices or fixtures, such as water control valves, so designed and constructed to protect against recontamination of clean, sanitized hands.
e. Readily understandable signs directing employees handling unprotected food, unprotected food-packaging materials, of food-contact surfaces to wash and, where appropriate, sanitize their hands before they start work, after each absence from post of duty, and when their hands may have become soiled or contaminated. These signs may be posted in the processing room(s) and in all other areas where employees may handle such food, materials, or surfaces.
f. Refuse receptacles that are constructed and maintained in a manner that protects against contamination of food.

6. Rubbish and Offal Disposal

Rubbish and any offal should be so conveyed, stored, and disposed of as to minimize the development of odor, minimize the potential for the waste becoming an attractant and harborage or breeding place for pests, and protect against contamination of food, food-contact surfaces, water supplies, and ground surfaces.

F. Equipment and Utensils (Section 110.40)

1. All plant equipment and utensils should be so designed and of such material and workmanship as to be adequately cleanable, and should be properly maintained. The design, construction, and use of equipment and utensils should preclude the adulteration of food with lubricants, fuel, metal fragments, contaminated water, or any other contaminants. All equipment should be so installed and maintained as to facilitate the cleaning of the equipment and of all adjacent spaces. Food-contact surfaces should be corrosion-resistant when in contact with food. They should be made of nontoxic materials and designed to withstand the environment of their intended use and the action of food, and, if applicable, cleaning compounds and sanitizing agents. Food-contact surfaces should be maintained to protect food from being contaminated by any source, including unlawful indirect food additives.
2. Seams on food-contact surfaces should be smoothly bonded or maintained so as to minimize accumulation of food particles, dirt, and organic matter and thus minimize the opportunity for growth of microorganisms.
3. Equipment that is in the manufacturing or food-handling area and that does not come into contact with food should be so constructed that it can be kept in a clean condition.
4. Holding, conveying, and manufacturing systems, including gravimetric, pneumatic, closed, and automated systems, should be of a design and construction that enables them to be maintained in an appropriate sanitary condition.
5. Each freezer and cold storage compartment used to store and hold food capable of supporting growth of microorganisms should be fitted with an indicating thermometer, temperature-measuring device, or temperature-recording device so installed as to show the temperature accurately within the compartment, and should be fitted with an automatic control for regulating temperature or with an automatic alarm system to indicate a significant temperature change in a manual operation.
6. Instruments and controls used for measuring, regulating, or recording temperatures, pH, acidity, water activity, or other conditions that control or prevent the growth of undesirable microorganisms in food should be accurate and adequately maintained, and adequate in number for their designated uses.
7. Compressed air or other gases mechanically introduced into food or used to clean food-contact surfaces or equipment should be treated in such a way that food is not contaminated with unlawful indirect food additives.

G. Processes and Controls (Section 110.80)

All operations in the receiving, inspecting, transporting, segregating, preparing, manufacturing, packaging, and storing of food should be conducted in accordance with adequate sanitation principles. Appropriate quality control operations should be employed to ensure that food is suitable for human consumption and that food-packaging materials are safe and suitable. Overall sanitation of the plant should be under the supervision of one or more competent individuals assigned responsibility for this function. All reasonable precautions should be taken to ensure that production procedures do not contribute contamination from any source. Chemical, microbial, or extraneous material testing procedures should be used where necessary to identify sanitation failures or possible food contamination. All food that has become contaminated to the extent that it is adulterated within the meaning of the Act should be rejected, or if permissible, treated or processed to eliminate the contamination.

1. Raw Materials and Other Ingredients

a. Raw materials and other ingredients should be inspected and segregated or otherwise handled as necessary to ascertain that they are clean and suitable for processing into food and should be stored under conditions that will protect against contamination and minimize deterioration. Raw materials should be washed or cleaned as necessary to remove soil or other contamination. Water used for washing, rinsing, or conveying food should be safe and of adequate sanitary quality. Water may be reused for washing, rinsing, or conveying food if it does not increase the level of contamination of the food. Containers and carriers of raw materials should be inspected on receipt to ensure that their condition has not contributed to the contamination or deterioration of food.
b. Raw materials and other ingredients should either not contain levels of microorganisms that may produce food poisoning or other disease in humans, or they should be pasteurized or otherwise treated during manufacturing operations so that they no longer contain levels that would cause the product to be adulterated within the meaning of the act. Compliance with this requirement may be verified by any effective means,

including purchasing raw materials and other ingredients under a supplier's guarantee or certification.

c. Raw materials and other ingredients susceptible to contamination with aflatoxin or other natural toxins should comply with current FDA regulations, guidelines, and action levels for poisonous or deleterious substances before these materials or ingredients are incorporated into finished food. Compliance with this requirement may be accomplished by purchasing raw materials and other ingredients under a supplier's guarantee or certification, or may be verified by analyzing these materials and ingredients for aflatoxins and other natural toxins.
d. Raw materials, other ingredients, and rework susceptible to contamination with pests, undesirable microorganisms, or extraneous material should comply with applicable FDA regulations, guidelines, and defect action levels for natural or unavoidable defects if a manufacturer wishes to use the materials in manufacturing food. Compliance with this requirement may be verified by any effective means, including purchasing the materials under a supplier's guarantee or certification, or examination of these materials for contamination.
e. Raw materials, other ingredients, and rework should be held in bulk, or in containers designed and constructed so as to protect against contamination and should be held at such temperature and relative humidity as to prevent the food from becoming adulterated. Material scheduled for rework should be identified as such.
f. Frozen raw materials and other ingredients should be kept frozen. If thawing is required prior to use, it should be done in a manner that prevents the raw materials and other ingredients from becoming adulterated.
g. Liquid or dry raw materials and other ingredients received and stored in bulk form should be held in a manner that protects against contamination.

2. Manufacturing Operations

a. Equipment and utensils and finished food containers should be maintained in an acceptable condition through appropriate cleaning and sanitizing, as necessary. Insofar as necessary, equipment should be taken apart for thorough cleaning.
b. All food manufacturing, including packaging and storage, should be conducted under such conditions and controls as are necessary to minimize the potential for the growth of microorganisms, or for the contamination of food. One way to comply with this requirement is careful monitoring of physical factors such as time, temperature, humidity, a_w, pH, pressure, flow rate, and manufacturing operations such as freezing, dehydration, heat processing, acidification, and refrigeration to ensure that mechanical breakdowns, time delays, temperature fluctuations, and other factors do not contribute to the decomposition or contamination of food.
c. Food that can support the rapid growth of undesirable microorganisms, particularly those of public health significance, should be held in a manner that prevents the food from becoming. Compliance with this requirement may be accomplished by any effective means, including:
   – Maintaining refrigerated foods at 45°F (7.2°C) or below as appropriate for the particular food involved.
   – Maintaining frozen foods in a frozen state.
   – Maintaining hot foods at 140°F (60°C) or above.
   – Heat treating acid or acidified foods to destroy mesophilic microorganisms when those foods are to be held in hermetically sealed containers at ambient temperatures.
d. Measures such as sterilizing, irradiating, pasteurizing, freezing, refrigerating, controlling pH or controlling a_w that are taken to destroy or prevent the growth of undesirable microorganisms, particularly those of public health significance, should be adequate under the conditions of manufacture, handling, and distribution to prevent food from being adulterated.
e. Work-in-process should be handled in a manner that protects against contamination.
f. Effective measures should be taken to protect finished food from contamination by raw materials, other ingredients, or refuse. When raw materials, other ingredients, or refuse are unprotected, they should not be handled simultaneously in a receiving, loading, or shipping area if that handling could result in contaminated food. Food transported by conveyor should be protected against contamination as necessary.
g. Equipment, containers, and utensils used to convey, hold, or store raw materials, work-in-process, rework, or food should be constructed, handled, and maintained during manufacturing or storage in a manner that protects against contamination.
h. Effective measures should be taken to protect against the inclusion of metal or other extraneous material in food. Compliance with this

requirement may be accomplished by using sieves, traps, magnets, electronic metal detectors, or other suitable effective means.

i. Food, raw materials, and other ingredients that are adulterated should be disposed of in a manner that protects against the contamination of other food. If the adulterated food is capable of being reconditioned, it should be reconditioned using a method that has been proven to be effective or it should be reexamined and found not to be adulterated before being incorporated into other food.

j. Mechanical manufacturing steps such as washing, peeling, trimming, cutting, sorting and inspecting, mashing, dewatering, cooling, shredding, extruding, drying, whipping, defatting, and forming should be performed so as to protect food against contamination. Compliance with this requirement may be accomplished by providing adequate physical protection of food from contaminants that may drip, drain, or be drawn into the food. Protection may be provided by adequate cleaning and sanitizing of all food-contact surfaces, and by using time and temperature controls at and between each manufacturing step.

k. Heat blanching, when required in the preparation of food, should be effected by heating the food to the required temperature, holding it at this temperature for the required time, and then either rapidly cooling the food or passing it to subsequent manufacturing without delay. Thermophilic growth and contamination in blanchers should be minimized by the use of adequate operating temperatures and by periodic cleaning. Where the blanched food is washed prior to filling, water used should be safe and of adequate sanitary quality.

l. Batters, breading, sauces, gravies, dressings, and other similar preparations should be treated or maintained in such a manner that they are protected against contamination. Compliance with this requirement may be accomplished by any effective means, including one or more of the following:
   - Using ingredients free of contamination.
   - Employing adequate heat processes where applicable.
   - Using adequate time and temperature controls.
   - Providing adequate physical protection of components from contaminants that may drip, drain, or be drawn into them.
   - Cooling to an adequate temperature during manufacturing.
   - Disposing of batters at appropriate intervals to protect against the growth of microorganisms.

m. Filling, assembling, packaging, and other operations should be performed in such a way that the food is protected against contamination. Compliance with this requirement may be accomplished by any effective means, including:
   - Use of a quality control operation in which the critical control points are identified and controlled during manufacturing.
   - Adequate cleaning and sanitizing of all food-contact surfaces and food containers.
   - Using materials for food containers and food-packaging materials that are safe and suitable.
   - Providing physical protection from contamination, particularly airborne contamination.
   - Using sanitary handling procedures.

n. Food such as, but not limited to, dry mixes, nuts, intermediate-moisture food, and dehydrated food, that relies on the control of a_w for preventing the growth of undesirable microorganisms should be processed to and maintained at a safe moisture level. Compliance with this requirement may be accomplished by any effective means, including employment of one or more of the following practices:
   - Monitoring the a_w of food.
   - Controlling the soluble solids/water ratio in finished food.
   - Protecting finished food from moisture pickup, by use of a moisture barrier or by other means, so that the a_w of the food does not increase to an unsafe level.

o. Food, such as, but not limited to, acid and acidified food, that relies principally on the control of pH for preventing the growth of undesirable microorganisms should be monitored and maintained at a pH of 4.6 or below. Compliance with this requirement may be accomplished by any effective means, including employment of one or more of the following practices:
   - Monitoring the pH of raw materials, food-in-process, and finished food.
   - Controlling the amount of acid or acidified food added to low-acid food.

p. When ice is used in contact with food, it should be made from water that is safe and of adequate sanitary quality, and should be used only if it has been manufactured in accordance with current good manufacturing practice.

q. Food-manufacturing areas and equipment used for manufacturing human food should not be used to manufacture nonhuman-food-grade animal feed or inedible products, unless there is no reasonable possibility for the contamination of the human food.

H. Warehousing and Distribution (Section 110.93)

Storage and transportation of finished food should be under conditions that will protect food against physical, chemical, and microbial contamination as well as against deterioration of the food and the container.

I. Natural or Unavoidable Defects in Food for Human Use that Present No Health Hazard (Section 110.110)

1. Some foods, even when produced under current good manufacturing practice, contain natural or unavoidable defects that at low levels are not hazardous to health. FDA establishes maximum levels for these defects in foods produced under current good manufacturing practice and uses these levels in deciding whether to recommend regulatory action.
2. Defect action levels are established for foods whenever it is necessary and feasible to do so. These levels are subject to change upon the development of new technology or the availability of new information.
3. The mixing of a food containing defects above the current defect action level with another lot of food is not permitted and renders the final food adulterated within the meaning of the Act, regardless of the defect level of the final food.
4. A compilation of the current defect action levels for natural or unavoidable defects in food for human use that present no health hazard may be obtained from the FDA for printed or electronic versions.

III. HAZARD ANALYSIS CRITICAL CONTROL POINTS REGULATIONS (HACCPR)

In 1997, FDA adopted a food safety program that was developed nearly 30 years ago for astronauts and is now applying it to seafood, and fruit and vegetable juices. The agency intends to eventually use it for much of the U.S. food supply. The program for the astronauts focuses on preventing hazards that could cause foodborne illnesses by applying science-based controls, from raw material to finished products. FDA's new system will do the same.

Many principles of this new system now called Hazard Analysis and Critical Control Points (HACCP) are already in place in the FDA-regulated low-acid canned food industry. Since 1997, FDA has mandated HACCP for the processing of seafood, fruit juices, and vegetable juices. Also, FDA has incorporated HACCP into its *Food Code*, a document that gives guidance to and serves as model legislation for state and territorial agencies that license and inspect food service establishments, retail food stores, and food vending operations in the United States.

FDA now is considering developing regulations that would establish HACCP as the food safety standard throughout other areas of the food industry, including both domestic and imported food products. HACCP has been endorsed by the National Academy of Sciences, the Codex Alimentarius Commission (an international, standard-setting organization), and the National Advisory Committee on Microbiological Criteria for Foods. Several U.S. food companies already use the system in their manufacturing processes, and it is in use in other countries, including Canada.

A. What is HACCP?

HACCP involves seven principles:

1. Analyze Hazards. Potential hazards associated with a food and measures to control those hazards are identified. The hazard could be biological, such as a microbe; chemical, such as a toxin; or physical, such as ground glass or metal fragments.
2. Identify critical control points. These are points in a food's production — from its raw state through processing and shipping to consumption by the consumer — at which the potential hazard can be controlled or eliminated. Examples are cooking, cooling, packaging, and metal detection.
3. Establish preventive measures with critical limits for each control point. For a cooked food, for example, this might include setting the minimum cooking temperature and time required to ensure the elimination of any harmful microbes.
4. Establish procedures to monitor the critical control points. Such procedures might include determining how and by whom cooking time and temperature should be monitored.
5. Establish corrective actions to be taken when monitoring shows that a critical limit has not been met — for example, reprocessing or disposing of food if the minimum cooking temperature is not met.
6. Establish procedures to verify that the system is working properly — for example, testing time-and-temperature recording devices to verify that a cooking unit is working properly.
7. Establish effective record keeping to document the HACCP system. This would include records of hazards and their control methods, the monitoring of safety requirements and action taken to correct potential problems.

Each of these principles must be backed by sound scientific knowledge such as published microbiological studies on time and temperature factors for controlling foodborne pathogens.

B. Need for HACCP

New challenges to the U.S. food supply have prompted FDA to consider adopting a HACCP-based food safety system on a wider basis. One of the most important challenges is the increasing number of new food pathogens. For example, between 1973 and 1988, bacteria not previously recognized as important causes of foodborne illness — such as *Escherichia coli* O157:H7 and *Salmonella enteritidis* — became more widespread. There also is increasing public health concern about chemical contamination of food: for example, the effects of lead in food on the nervous system.

Another important factor is that the size of the food industry and the diversity of products and processes have grown tremendously — in the amount of domestic food manufactured and the number and kinds of foods imported. At the same time, FDA and state and local agencies have the same limited level of resources to ensure food safety. The need for HACCP in the United States, particularly in the seafood industry, is further fueled by the growing trend in international trade for worldwide equivalence of food products and the Codex Alimentarius Commission's adoption of HACCP as the international standard for food safety.

C. Advantages and Plans

HACCP offers a number of advantages over previous systems. Most importantly, HACCP

1. Focuses on identifying and preventing hazards from contaminating food,
2. Is based on sound science,
3. Permits more efficient and effective government oversight, primarily because the record keeping allows investigators to see how well a firm is complying with food safety laws over a period rather than how well it is doing on any given day,
4. Places responsibility for ensuring food safety appropriately on the food manufacturer or distributor,
5. Helps food companies compete more effectively in the world market,
6. Reduces barriers to international trade.

Here are the seven steps used in HACCP plan development.

1. Preliminary Steps
   a. General information
   b. Describe the food
   c. Describe the method of distribution and storage
   d. Identify the intended use and consumer
   e. Develop a flow diagram
2. Hazard Analysis Worksheet
   a. Set up the Hazard Analysis Worksheet
   b. Identify the potential species-related hazards
   c. Identify the potential process-related hazards
   d. Complete the Hazard Analysis Worksheet
   e. Understand the potential hazard
   f. Determine if the potential hazard is significant
   g. Identify the critical control points (CCP)
3. HACCP Plan Form
   a. Complete the HACCP Plan Form
   b. Set the critical limits (CL)
4. Establish Monitoring Procedures
   a. What
   b. How
   c. Frequency
   d. Who
5. Establish Corrective Action Procedures
6. Establish a Record Keeping System
7. Establish Verification Procedures

It is important to remember that apart from HACCPR promulgated for seafood and juices, the implementation of HACCP by other categories of food processing is voluntary. However, the FDA and various types of food processors are working together so that eventually HACCPR will become available for many other food processing systems under FDA jurisdiction. Using the HACCPR for seafood processing as a guide, the following discussion for a HACCP plan applies to all categories of food products being processed in United States.

D. Hazard Analysis

Every processor should conduct a hazard analysis to determine whether there are food safety hazards that are reasonably likely to occur for each kind of product processed by that processor and to identify the preventive measures that the processor can apply to control those hazards. Such food safety hazards can be introduced both within and outside the processing plant environment, including food safety hazards that can occur before, during, and after harvest. A food safety hazard that is reasonably likely to occur is one for which a prudent processor would establish controls because experience, illness data, scientific reports, or other information provide a basis to conclude that there is a reasonable possibility that it will occur in the particular type of product being processed in the absence of those controls.

E. The HACCP Plan

Every processor should have and implement a written HACCP plan whenever a hazard analysis reveals one or more food safety hazards that are reasonably likely to occur. A HACCP plan should be specific to:

1. Each location where products are processed by that processor; and
2. Each kind product processed by the processor.

The plan may group kinds of products together, or group kinds of production methods together, if the food safety hazards, critical control points, critical limits, and procedures required to be identified and performed are identical for all products so grouped or for all production methods so grouped.

1. The Contents of the HACCP Plan

The HACCP plan should, at a minimum:

- List the food safety hazards that are reasonably likely to occur, as identified, and that thus must be controlled for each product. Consideration should be given to whether any food safety hazards are reasonably likely to occur as a result of the following: natural toxins; microbiological contamination; chemical contamination; pesticides; drug residues; decomposition in products where a food safety hazard has been associated with decomposition; parasites, where the processor has knowledge that the parasite-containing product will be consumed without a process sufficient to kill the parasites; unapproved use of direct or indirect food or color additives; and physical hazards;
- List the critical control points for each of the identified food safety hazards, including as appropriate: critical control points designed to control food safety hazards that could be introduced in the processing plant environment; and critical control points designed to control food safety hazards introduced outside the processing plant environment, including food safety hazards that occur before, during, and after harvest;
- List the critical limits that must be met at each of the critical control points;
- List the procedures, and frequency thereof, that will be used to monitor each of the critical control points to ensure compliance with the critical limits;
- Include any corrective action plans that have been developed to be followed in response to deviations from critical limits at critical control points;
- List the verification procedures, and frequency thereof, that the processor will use;
- Provide for a record keeping system that documents the monitoring of the critical control points. The records should contain the actual values and observations obtained during monitoring.

2. Signing and Dating the HACCP Plan

The HACCP plan should be signed and dated:

- Either by the most responsible individual on site at the processing facility or by a higher-level official of the processor. This signature should signify that the HACCP plan has been accepted for implementation by the firm.
- Upon initial acceptance; upon any modification; and upon verification of the plan.

F. Sanitation

Sanitation controls (3) may be included in the HACCP plan. However, to the extent that they are otherwise monitored, they need not be included in the HACCP plan.

G. Implementation

This book is not the proper forum to discuss in detail the implementation of HACCPR. Readers interested in additional information on HACCP should visit the FDA HACCP website http://vm.cfsan.fda.gov/ that lists all the currently available documents on the subject.

IV. FDA FOOD CODE

The FDA *Food Code* (the Code) (4) is an essential reference that guides retail outlets such as restaurants and grocery stores and institutions such as nursing homes on how to prevent foodborne illness. Local, state and federal regulators use the FDA *Food Code* as a model to help develop or update their own food safety rules and to be consistent with national food regulatory policy. Also, many of the over one million retail food establishments apply *Food Code* provisions to their own operations. The *Food Code* is updated every two years, to coincide with the biennial meeting of the Conference for Food Protection. The conference is a group of representatives from regulatory agencies at all levels of government, the food industry, academia, and consumer organizations that works to improve food safety at the retail level (5). A brief discussion of the Code is provided below. Further information, including access to the Code, may be obtained from the Food Safety Training and Education Alliance (www.fstea.org).

The Code establishes definitions; sets standards for management and personnel, food operations, and equipment and facilities; and provides for food establishment plan review, permit issuance, inspection, employee restriction, and permit suspension. The Code discusses the good manufacturing practices for equipment, utensils, linens, water, plumbing, waste, physical facilities, poisonous or toxic materials, compliance and enforcement. The Code also provides guidelines on food establishment inspection, HACCP guidelines, food processing criteria, model forms,

guides, and other aids. A brief introduction to the *Food Code* in this chapter is important for two reasons:

- Firstly, at the end of this book, two chapters cover retail food protection from the perspectives of food sanitation. The *Food Code* forms the backbone of these chapters.
- Secondly, although this guide is designed for retail food protection, more than half of the data included are directly applicable to food processing plants, e.g. equipment design (cleanability), CIP system, detergents and sanitizers, refrigeration and freezing storage parameters, water requirements, precautions against "backflow" (air, valve, etc.), personnel health and hygiene, rest rooms and accessories, pest control, storage of toxic chemicals, inspection forms, inspection procedures, and many more. Some of the data in the present book can be readily traced to the Code.

The Code consists of 8 chapters and 7 annexes. Some of the information found in the Code will be further explored in two chapters at the end of this book. The annex that covers inspection of a food establishment applies equally as well to both retail food protection and to sanitation in food processing. According to the Code, the components of an inspection would usually include the following elements:

- Introduction
- Program planning
- Staff training
- Conducting the inspection
- Inspection documentation
- Inspection report
- Administrative procedures by the state/local authorities
- Temperature measuring devices
- Calibration procedures
- HACCP inspection data form
- Food establishment inspection report
- FDA electronic inspection system
- Establishment scoring.

Details of these items will not be discussed here; some are further explored in various chapters in this book (please consult the index for specific topics). Instead, the next two sections trace the history and practices of food establishment inspection and how basic sanitation controls are slowly evolving into the prerequisites for HACCP plans in both retail food protection *and* food processing plants.

A. Purpose

A principal goal to be achieved by a food establishment inspection is to prevent foodborne disease. Inspection is the primary tool a regulatory agency has for detecting procedures and practices that may be hazardous and for taking actions to correct deficiencies. *Food Code*-based laws and ordinances provide inspectors science-based rules for food safety. The *Food Code* provides regulatory agencies with guidance on planning, scheduling, conducting, and evaluating inspections. It supports programs by providing recommendations for training and equipping the inspection staff, and attempts to enhance the effectiveness of inspections by stressing the importance of communication and information exchange during regulatory visits. Inspections aid the food-service industry in the following ways.

1. Serving as educational sessions on specific Code requirements as they apply to an establishment and its operation;
2. Conveying new food safety information to establishment management and providing an opportunity for management to ask questions about general food safety matters; and
3. Providing a written report to the establishment's permit holder or person in charge so that the responsible person can bring the establishment into conformance with the Code.

B. Current Applications of HACCP

Inspections have been a part of food safety regulatory activities since the earliest days of public health. Traditionally, inspections have focused primarily on sanitation. Each inspection is unique in terms of the establishment's management, personnel, menu, recipes, operations, size, population served, and many other considerations.

Changes to the traditional inspection process were first suggested in the 1970s. The terms "traditional" or "routine" inspection have been used to describe periodic inspections conducted as part of an on-going regulatory scheme. A full range of approaches was tried and many were successful in managing a transition to a new inspection philosophy and format. During the 1980s, many progressive jurisdictions started employing the HACCP approach to refocus their inspections. The term "HACCP approach" inspection is used to describe an inspection using the "Hazard Analysis and Critical Control Point" concept. Food safety is the primary focus of a HACCP approach inspection. One lesson learned was that good communication skills on the part of the person conducting an inspection are essential.

FDA has taught thousands of state and local inspectors the principles and applications of HACCP since the 1980s. The State Training Branch and the FDA Regional Food Specialists have provided two-day to week-long courses on the scientific principles on which HACCP is based, the practical application of these principles including field exercises, and reviews of case studies. State and local jurisdictions have also offered many training opportunities for HACCP.

A recent review of state and local retail food protection agencies shows that HACCP is being applied in the following ways:

1. Formal Studies — Inspector is trained in HACCP and is using the concepts to study food hazards in establishments. These studies actually follow foods from delivery to service and involve the write-up of data obtained (flow charts, cooling curves, etc.).
2. Routine Use — State has personnel trained in HACCP and is using the hazard analysis concepts to more effectively discover hazards during routine inspections.
3. Consultation — HACCP-trained personnel are consulting with industry and assisting them in designing and implementing internal HACCP systems and plans.
4. Alternative Use — Jurisdiction used HACCP to change inspection forms or regulations.
5. Risk-Based — Jurisdiction prioritized inventory of establishments and set inspection frequency using a hazard assessment.
6. Training — Jurisdiction is in the active process of training inspectors in the HACCP concepts.

Personnel of every sort of food establishment should have one or several copies of the *Food Code* readily available for frequent consultation.

V. APPLICATIONS

The sanitary requirements in the CGMPR and the *Food Code* serve as the framework for the chapters in this book. The HACCPR will be touched on when they help to clarify the discussion. Essentially, this book shows how to implement the umbrella regulations provided under the CGMPR. Each chapter handles one aspect of these complicated regulations. Most chapters discuss the regulations applicable to all types of food products being processed. Several chapters concentrate on the sanitary requirements from the perspectives of the processing of a specific category of food.

The appendix of this book reproduces the complete coverage of CGMR in Section 110.

ACKNOWLEDGMENT

The information in this chapter has been derived from *Food Safety Manual*, published and copyrighted by Science Technology System, West Sacramento, California, 2004©. Used with permission.

74 Filth and Other Foreign Objects in Food: A Review of Analytical Methods and Health Significance

J. Richard Gorham
U.S. Public Health Service

Ludek Zurek
Kansas State University

CONTENTS

I. THE FOOD, DRUG AND COSMETIC ACT

This chapter is based in large part on earlier reviews [1–3] and other contributions to the scientific literature [4, 5], but the text has been amended and expanded to include additional information.

The language of the Federal Food, Drug and Cosmetic Act (FD&C Act) seems rather unequivocal whenever acts of adulteration by filth are mentioned [6–8]. One paragraph, 301(k), prohibits any act done to a food after shipment in interstate commerce that results in the food being adulterated. Another, 402(a)(1), declares "a food shall be

deemed to be adulterated if it bears or contains any poisonous or deleterious substance which may render it injurious to health." Still another, 402(a)(3), states that a food shall be deemed adulterated if it consists in whole or in part of any filthy, putrid, or decomposed substance or if it otherwise is unfit for food. The final example, from paragraph 402(a)(4), states that a food shall be deemed to be adulterated if it has been prepared, packed, or held under unsanitary conditions by which it may have been contaminated with filth, or by which it may have been rendered injurious to health [9].

A. Enforcement and Guidance

In the United States of America, the U.S. Department of Agriculture (USDA) and the U.S. Food and Drug Administration (FDA) share responsibility for food safety. Federal drinking water standards are set, monitored and enforced by the Environmental Protection Agency. The task of enforcing the FD&C Act has been given to the FDA [10–13]. Scientists and policy managers at the FDA, along with collaborating personnel from other federal agencies and from universities, have endeavored to provide helpful guidance to the food industry by generating explanatory documents designed to spell out in detail just what FDA understands to be the meaning of these basic paragraphs of the FD&C Act [14–19].

B. Codex Alimentarius

Two United Nations agencies, the Food and Agricultural Organization (FAO) and the World Health Organization (WHO), have also issued food safety guidelines under the general title of Codex Alimentarius [20, 21] that are similar in scope and principle to the food safety guidance documents issued by the FDA and the USDA. Moreover, WHO has promulgated a global strategy for food safety [22]. The European Union has established the European Food Safety Authority (ESFA), and some European nations, such as Spain [23], have reorganized their national food safety programs to meet the EFSA guidelines.

II. ANALYTICAL METHODS FOR FILTH

This short review should in no way be construed as a technical guide to the detection of filth in food; it is meant merely to put the practice of filth analysis in its proper place in the overall arena of food safety [24]. Reliable sources of technical information are readily available [25–30].

A. History of Filth Analysis

The current edition of the *Official Methods of Analysis of AOAC International* [25] is the product of nearly 100 years of development of analytical methods. Dr. Harvey W. Wiley, who helped create the USDA-sponsored Association of Official Agricultural Chemists (AOAC) in 1894, directed the publication of the first book of official methods, a manual devoted to the analysis of agricultural fertilizers. Wiley and his group of intrepid food-tasters/testers gave much of their attention to toxic chemical adulterants [31]. However, even in those early days, around the time of the passage of the first federal food purity law in 1906 [32], some effort (apparently minimal) was made to detect filth in food. Since the detection process required some form of analysis of each kind of food, analytical methods were created out of necessity.

Over the years, the subject matter of the official methods book was expanded to include (to mention just a few among many) animal feeds, dairy products, filth, microbiological contaminants, and pesticides. Sponsorship for the Association shifted to the FDA when that arm of government was established in 1927. Because of the ever-broadening scope of analytical work, the organization's name was changed to the Association of Official Analytical Chemists in 1965. AOAC became a fully independent organization in 1979 (but still retained close ties to USDA and FDA). The ever-widening international scope of food analysis called for a more inclusive "Association of Analytical Communities" and a further name change in 1991 to AOAC International [33].

B. The Practice of Food Analysis

The practice of food analysis occurs at many different levels of sophistication. The more informal the analysis, i.e., at the lower end of the sophistication scale, the less expensive it is. The more formal the analysis, i.e., higher on the scale of sophistication, the more expensive it is. This expenditure of money and effort must be justified; in other words, there has to be some compelling reason to carry out the analysis. Generally, the more sophisticated procedures take place in a laboratory setting; the less formal procedures may occur in a wide variety of settings, including the laboratory.

C. Why Analyze Food

The reasons for performing analyses vary widely, but the basic motive of food manufacturers is to present to the consumer food that tastes good, smells good and *is* good. Achieving this maintains or enhances one's reputation, whether individual or corporate. The production and marketing of only good and wholesome food also means that the food establishment is complying with the pertinent federal, state and local laws pertaining to food purity, thus avoiding the unpleasant consequences of violating these laws: fines, prison time, and civil law suits, to mention a few [34–36].

Other reasons for conducting food analyses arise from the law enforcement side of the equation. Voluntary compliance with the laws and with good manufacturing

practices [37, 38] is very beneficial to the consumer, but the only way to know for certain the purity status, as defined by the pertinent laws and regulations, of any given food at any given time is to analyze it. Here, with regard to the Federal FD&C Act [39, 40], at least, analysts are guided by the two major filth provisions in the Act, namely that filth has no place being *in* food or being *around* food.

D. Analytical Varieties

The quick and casual observations by sight and smell that happen whenever a can or package of food is opened in the home kitchen constitute food analysis — informal but often quite telling. Similar things happen in the grocery; cans and packages are usually not opened, unless in connection with a deli operation, but cans and packages are observed for defects, and substandard items of all kinds are culled before being presented to the public. Visual inspection (read "analysis") takes place in the warehousing and distribution sectors of the food chain. Items that look bad or smell bad are discarded.

In the food-manufacturing sector, food analysis is an integral part of the operation's quality assurance protocols. Similar analyses, most informal but some involving technical expertise, happen at the places where raw materials are collected for offer as ingredients in the manufacture of foods. Analyses occur, too, at the many places where food materials are harvested.

Food materials may be visually inspected on the wharf or in the warehouse, or at the granary or flourmill. It is common for samples to be collected in all of these places by FDA and USDA investigators and sent to a government food laboratory for further examination. In the laboratory setting, the whole range of analytical techniques may be employed, from the simplest to the most technically complex.

III. ANALYSIS FOR FILTH, DECOMPOSITION AND FOREIGN MATTER

A. Heavy Filth

Although the word "filth" is in the title of this chapter, it is really just the first word in a triad of contaminants: filth, decomposition, and extraneous materials (or foreign matter) [41]. This last term covers all the others, but in common practice it refers to sand, gravel, paint chips, metal fragments, bits of glass, fruit pits, and a whole host of other hard foreign objects (these kinds of extraneous materials, often collectively called "heavy filth," are discussed below).

Visual inspection procedures and other "macroanalytical" techniques designed to detect hard or sharp foreign objects in raw ingredients or processed foods are discussed in the *Macroanalytical Procedures Manual* [42]. These hard foreign objects can be sieved out of food; or they tend to settle out of the food materials upon agitation. Analytical techniques for glass detection in infant foods packaged in glass have been developed at FDA [43].

B. Decomposition and Quality Evaluations

1. Decomposition

The detection of decomposition is a specialized kind of analysis. The process of decomposition often leads to the production of characteristic odors that a specially trained and experienced analyst can detect by *organoleptic methods* (smell, in this case, but taste is also employed in some cases). Organoleptic methods [44] have been widely used in the past to detect decomposition in seafoods and in the carcasses of meat animals and poultry. With the onset of voluntary or mandatory HACCP (Hazard Analysis and Critical Control Points) programs, organoleptic analyses have become less common.

2. Quality Evaluations

Panels of sensory analysts are often used to evaluate the quality status of dairy products, especially cheeses. The organoleptic method applied here is called *descriptive sensory analysis*. Considerable progress has been made in the development of an "electronic nose" designed to do much of the work of the human evaluation panel. The electronic nose technology has been utilized in a wide variety of applications including evaluating the microbial quality status of milk and of cereal grains, cheese and juice quality, fermentation status of sausage, and meat quality with reference to spoilage [45].

Another line of research is focused on developing an artificial tongue that mimics human taste buds [46]. These sensory elements consist of various conducting polymers embedded in an ultrathin film. Besides the basic taste categories (sweet, sour, etc.), the artificial tongue can detect slight differences among different kinds of bottled water or different batches of wine from the same winery. Toxic chemicals and extremely bitter tastes, that would be very unpleasant or dangerous for human tasters to detect, can be identified by the artificial tongue.

3. Mold as Evidence of Decomposition

Molds often occur on fruits, nuts, berries, seeds, and many other food materials. These defects may be detected by visual examination — techniques that are referred to as macroanalytical methods [42, 47, 48]. On occasion, to get an approximation of the level of moldiness, the product in question is subjected to a special sampling program that is designed to make the sample representative of the entire lot. These macroanalytical techniques are often used when

unprocessed foods are presented to the food manufacturer for use as ingredients.

In other techniques, such as the Howard Mold Count, the sample of food is prepared for analysis in such a way that the mold fragments become visible under light microscopy and that the mold count in the sample accurately reflects the level of mold contamination in the entire lot that was sampled [49].

C. Light Filth

The detection of insect fragments, feather barbules and rat hairs — all properly labeled filth but sometimes referred to as light filth — has been a major focus of food analysts for more than half a century. Basically, these kinds of analytical methods, often referred to as microanalytical methods, involve dispersing an extraction oil (usually mineral oil) into an aqueous or alcoholic mixture of the food sample. Since the bits of insect cuticle, feather barbules and hairs are oleophilic, they tend to rise with the oil to the surface. The food materials, being largely hydrophilic, tend to settle to the bottom. The analyst then simply separates the two polar opposites and examines the mineral oil fraction under the microscope [50].

This oil/water technique, frequently utilized for routine analyses in many laboratories, is the procedure that was most often used in the days when it was necessary to establish (or reexamine) a food defect action level (DAL, discussed below) for a particular product [51]. For example, in one instance in which questions were raised about filth adulterants in canned sardines, canned tuna and canned crabmeat, samples were collected, using a statistically valid sampling protocol, from many localities around the United States [52]. Before the current moratorium on new DAL development [53], other products were sampled and analyzed in a similar manner. These sample collection programs produced such huge quantities of product that it was usually not feasible for a single government laboratory to do all the analytical work. Therefore, contract laboratories in the private sector performed most of the microanalytical work.

D. Soluble Filth

In recent years there has been a trend to go beyond trying to detect merely particulate filth. These efforts have focused on identifying and quantifying the biochemical signatures left behind by food-contaminating animals (birds, bats, rodents, insects, mites) [54–60].

IV. QUALITY ASSURANCE

A. Methods of Quality Assurance

One very important aspect of filth analysis is perhaps little known and little appreciated by the general public. We refer to the great emphasis on quality assurance on the part of the analyst population. For example, when an analyst develops a new analytical technique, that technique does not simply and immediately become a standard method. The technique has to be evaluated by a panel of expert analysts to determine its reliability in the hands of several different analytical technicians. The new technique will most likely get wide exposure by its publication in a scientific periodical such as the *Journal of AOAC International*. If it survives the examination occasioned by the journal publication, the technique may eventually make it into the *Official Methods of Analysis of AOAC International* [25].

B. Analyst Quality Assurance

Most filth analysts are tested periodically to evaluate their analytical skills. Most often, this testing is done under programs sponsored by AOAC International. Test samples are sent out to the analysts and the analytical results derived therefrom are then evaluated. In this way, a high level of consistent expertise is maintained, and any deficiencies in analyst performance can be remedied.

The achievement and maintenance of a high and consistent level of skill comes by way of unending practice and the pursuit of perfection in carrying out analytical procedures. A huge body of literature [see, for example, references 61–65, as well as the other references at the end of this chapter] and a wide array of analytical techniques [25] must be mastered by the analyst.

C. Laboratory Quality Assurance

Two international bodies, the International Standards Organization and the International Electrotechnical Commission, have promulgated, as rule ISO/IEC 17025, a minimum set of standards for analytical laboratories [66]. While remaining fully functional and in compliance with internal standards, all FDA analytical laboratories (along with virtually all commercial and governmental laboratories) are in a state of transition as they strive to fully comply with ISO/IEC 17025.

D. Benefits to the Public

This emphasis on quality assurance directly benefits the general public. When any given food in found to be adulterated, the public can have confidence in that finding and reassurance in knowing that such adulterated food will not reach the dinner table. Similarly, when analysts find no filth in food and it has been certified that all applicable sanitation standard operating procedures (SSOPs) and HACCP protocols have been observed, the public can be confident that these findings reflect the actual state of the food — it is wholesome and safe to consume [67].

V. HEALTH SIGNIFICANCE OF ADULTERATION BY FILTH

A. Filth and the FD&C Act

The federal courts have never insisted that there must always be a cause-and-effect relationship between "filth" and "injurious to health" (see Section I, above). Since 1942, when District Court Judge Chestnut (sometimes spelled Chesnut) read during a trial the definition of *filth* from *Webster's International Dictionary*, the ordinary sense of the word has been used in judicial interpretations of the FD&C Act [68]. Judges and juries have rendered verdicts both for and against the government's allegations of filth in food, but always based on the practical application of this dictionary definition [35].

As used in this chapter, *filth* is defined as insect, bird, rodent, or other objectionable matter, usually of animal origin, found in or associated with food [4, 69]. The more common kinds of filth found during food inspections and analyses are whole insects and mites and fragments thereof; rodent and other mammalian hairs; feathers and feather barbules; and urine, uric acid, and feces (usually from rodents and birds); and molds.

B. Competition for Food

Human foods and animal feeds, as well as the places where these materials are stored, processed and sold, are attractive to a wide variety of opportunistic animals and fungi. Competition between "us" and "them" for nutritive substances is keen and continuous. Pests of the food industry may be counted upon to take full advantage of every opportunity to convert our foods and feeds to their own use. To prevent this, nothing less than constant vigilance is required of the food industry (or the housekeeper in the home setting) [70]. But even under the best of circumstances, it is difficult to consistently provide the consumer with foods and feeds that are completely free from contamination by food pests [69].

C. Indicators of Insanitation: Four Categories

We emphasize again that competition for food is keen. Food pests continually search for opportunities to share our food resources [71]. Commensal pests such as houseflies, cockroaches, ants and mice are considered *opportunistic* pests. They typically exhibit synanthropic behavior, that is, they are closely associated with human foods or animal feeds and with structures built by humans. *Adventive* (*facultative*) pests, such as birds, bats and various insects, sometimes utilize human-built structures for shelter and this behavior (synanthropy) may bring them into contact with foods or food-contact surfaces.

Pantry pests, such as the sawtoothed grain beetle (*Oryzaephilus surinamensis*) or the Indianmeal moth (*Plodia interpunctella*), are categorized as *obligatory* pests because they are largely dependent on human or animal foods for their own food and for shelter. All of the categories of insects noted here may also be parasitized by small wasps or flies, termed *parasitoids*; this is the fourth and final category of pests considered to be indicators of insanitation.

D. Early Ideas and Discoveries

The idea that pests might be vectors of pathogenic microbes was very slow to dawn upon the human mind. The germ theory itself had first to be thoroughly established, and that was another idea that was slow to take hold. But once the germ theory was accepted, people began to ask about the ways that germs make their way from a person who is sick to one who is well.

By the dawn of the twentieth century, it was well known that germs causing certain diseases could be transmitted directly from one person to another. This method of transmission, seemingly so simple and logical, became the overriding theory that was applied, correctly or incorrectly, to a wide variety of diseases. In some cases, the theory worked perfectly; in other cases, it seemed to work well most of the time; and in still other cases, it did not work at all.

E. Transmission Cycles

Classic studies of malaria, yellow fever, and Texas cattle fever firmly established the fact that some disease transmission cycles include an obligatory intermediary, the *vector* [72]. Moreover, the disease agents themselves were identified as belonging to a wide range of living organisms — viruses, bacteria, protists/protozoa, helminths, and fungi. The transmission cycles of these disease agents varied from the very simple to the very complex.

Before the first half of the twentieth century came to a close, a large number of vectorborne diseases had been studied to the point where their mechanisms of transmission were well understood. Two basic cycles of pathogen transmission, biological and mechanical, had been defined. In the simplest form of biological transmission, the pathogen must enter the vector, undergo at least one mandatory phase of multiplication and/or morphologic transformation, and be carried by the vector to a susceptible host. Biological transmission and the role of food pests as direct agents of disease (that is, in the production of toxins and allergens, as the cause of physical injury, or the invasion of the digestive tract by insects and mites) are not discussed is this chapter [see 72 for numerous examples], except for very brief note below regarding biological transmission. In mechanical transmission [5], the pathogen

remains on the external surface of the vector, or in its gut, or in its excretory system. The vector merely transports the pathogen from an infectious source to a susceptible host, to something that a susceptible host eats or drinks, or to a food-contact surface.

F. Mechanical Transmission

The mechanical transmission of foodborne pathogens is another idea that continues to be very slow to take hold. It seems very easy for professional health-care providers to accept the concept that a diarrheic food handler, emerging from a bathroom without washing his or her hands and immediately preparing a shrimp salad, could contaminate food with pathogenic bacteria that might cause illness in susceptible people who eat that food. This is, obviously, the classic *fecal-oral route* of transmission that every clinician and epidemiologist remembers when confronted by a case or an outbreak of foodborne illness. However, when an entomologist suggests that a housefly or a cockroach might pick up pathogens from feces and mechanically transport them to human food (or food-contact surfaces) and that people might become ill from eating that food, the traditional medical professional usually tends to look for another explanation.

1. Nosocomial Infections

A good example of this kind of tunnel-vision approach can be found in the literature on the epidemiology of nosocomial infections in which the proposition that hospital pests might be vectors is rarely considered. In spite of an extant and growing literature on the subject (some examples are given in the references cited in this chapter), the possibility of mechanical transmission by insects is typically excluded whenever environmental factors are discussed in relation to nosocomial infections [73]. Even in those hospitals, such as perhaps one in Calcutta, where one might understandably expect to have flies, ants and cockroaches as frequent visitors, usually no role is given to and no discussion is offered concerning insects as mechanical vectors [74].

In contrast to this mindset of entrenched neglect of the evidence regarding insects as mechanical vectors, infection control specialists in an Israeli hospital were quick to ban the carrying and use of cell phones by patient-care personnel when *Acinetobacter baumannii*, a multidrug-resistant, desiccation-resistant microbe that causes nosocomial infections with mortality rates in the range of 50–69%, was isolated from 12% of the phones carried by care givers [75].

2. The Housefly Menace

Before the twentieth century was even a decade old, Dr. Harvey W. Wiley, that great champion of food purity, had already made plans to study the role of houseflies (*Musca domestica*) as mechanical carriers of bacteria [76]. In the same time period, Dr. L. O. Howard [77], an entomologist, and Dr. Samuel Crumbine [78], a physician and public health administrator (to mention just two activists among many), castigated the housefly as a menace to public health (Figure 74.1) [79]. Scientists have long sought to build the case for the role of vectors in food contamination and foodborne illnesses. Several lines of thought that researchers and reviewers have applied to this question are discussed here, along with examples from the literature.

G. Examination of Pests for Microbial Pathogens

A common approach for evaluating the role of pests as vectors in the epidemiology of foodborne illnesses is to capture a pest from its natural environment and then employ microbiological culture methods to find out what microorganisms the pest carries on its body surface and/or in its gut. Hospitals have been a common venue for these pest-screening programs in which ants, cockroaches and other pests are surveyed for nosocomial and community-acquired pathogens [80–87].

Early in the twentieth century, scientists often cultured samples from flies and cockroaches to determine their bacterial associates [88, 89]. Numerous investigators have continued these vector-screening programs right up to the

present day [85, 90–96]. Various suspect vectors have been assayed for pathogenic fungi [97–99], protists/protozoans [100–102], helminths [103–105], bacteria [106, 107], and viruses [108].

1. Flies

The two groups of insects most frequently screened for foodborne pathogens are houseflies and synanthropic cockroaches. Houseflies have been reported to carry foodborne and other human pathogens including *Campylobacter jejuni* [91, 92], *Shigella* spp. [109], *Yersinia enterocolitica* [110], *Salmonella* spp. [111], *Klebsiella* spp. [112], *Aeromonas caviae* [113], *Corynebacterium pseudotuberculosis* [114], *Mycobacterium* spp. [115], *Giardia lamblia* [116], and *Cryptosporidium parvum* [117]. In Japan, houseflies have been shown to carry enterohemorrhagic *Escherichia coli* O157:H7, a pathogen that causes the sometimes fatal "hamburger disease" (hemolytic uremic syndrome and hemorrhagic colitis) [118–120].

Enterobacter sakazakii, an opportunistic pathogen sometimes found in powdered milk, causes neonatal meningitis. A possible environmental reservoir has been identified: *E. sakazakii* was isolated from the gut of larval stable flies (*Stomoxys calcitrans*) [121]. A study of the role of houseflies in the ecology of *E. coli* O157 is currently underway at Kansas State University [122].

2. Cockroaches

German cockroaches (*Blattella germanica*) were reported to carry *Salmonella* spp. in feed mills and poultry hatcheries [123]. American cockroaches (*Periplaneta americana*) have been reported to carry and disseminate *Cryptosporidium parvum*, a pathogenic protist that causes diarrhea [124]. The make up of the microbial population of the American cockroach gut, long the subject of numerous investigations, has been shown to include a variety of microorganisms: bacteria, archaeans, protists (protozoa), and nematodes [125].

H. Fate of Pathogens on and in Pests

Another common technique is to expose (either externally or orally) a "clean" potential vector, such as a fly or a cockroach, to some known pathogen and then determine how long the microbes remain viable in or on the insect, how long the insect sheds viable pathogens to its environment, and how long the pathogens remain viable and infective after being disassociated from the host insect.

Experimental work along these lines was recently carried out with laboratory populations of a free-living soil nematode, *Caenorhabditis elegans* (Rhabditidae) [126]. Colonies of non-pathogenic *E. coli* serve as the standard food medium for these nematodes. The worms, having fed readily on bacterial colonies representing four different bacterial species (all non-pathogenic surrogates of known foodborne disease pathogens), were able to transfer the ingested bacteria to sterile substrates during a three-hour period. In the case of fruits and vegetables that are in contact with soil just before harvest and are promptly consumed without further processing, there is some concern that nematodes could transport fecal pathogens to the food item while it is in or lying on soil.

1. Cockroaches

Pai et al. [100] recovered viable cysts of *Entamoeba histolytica* from the external surfaces and from the guts of cockroaches (*Periplaneta americana*, *Blattella germanica*) that had fed on cyst-laden feces. Bacteria (*Salmonella oranienburg*) fed experimentally to American cockroaches could be isolated from the fecal pellets of the roaches over a period of 140 days [127]. American, German, and Oriental (*Blatta orientalis*) cockroaches, experimentally infected with *Salmonella typhimurium*, disseminated this pathogen for at least four days and contaminated non-infected cockroaches as well as chicken eggs [123]. Bacteria (*Salmonella enteriditis*), fed experimentally to German cockroaches, were recovered from the feces for ten days and from the gut for up to 20 days after the initial exposure [128]. Virulent mycobacteria (*Mycobacterium avium avium*), recovered from cockoach nymphs (*B. orientalis*) ten days after the roaches were orally infected, caused avian tuberculosis in chickens [129].

2. Flies

Root [130] found that cysts of *Entamoeba histolytica*, ingested by flies that were subsequently drowned in water, remained viable for seven days. Houseflies, fed on broth containing pathogenic bacteria (*Yersinia pseudotuberculosis*), retained the microbes internally for about 36 hours and contaminated their environment with viable microbes for about 30 hours after ingestion [131].

Houseflies are now being considered more seriously as potential players in the ecology and transmission of *E. coli* O157:H7 [132]. Sasaki et al. [133] investigated epidemiological significance of housefly defecation and regurgitation in the dissemination of *Escherichia coli* O157:H7 to food. It was shown that this pathogen persisted in the housefly digestive tract for at least four days after the initial exposure and that frequent defecation and regurgitation enhanced the dissemination of *E. coli* O157:H7, especially during the first 24 hours. Kobayashi et al. [134] postulated that houseflies are actually biological vectors of this pathogen because the bacteria increase in numbers while ensconced within the interstices of the spongiform mouthparts of the fly.

Shane et al. [135] demonstrated experimentally that houseflies can effectively transmit *Campylobacter jejuni*,

cause of the most frequently reported foodborne bacterial illness in the Unites States and other developed countries [136].

Zimmerman et al. [137] showed that the pseudorabies virus persisted (but did not replicate) in houseflies for up to 13 hours. Under experimental conditions, houseflies can serve as transport hosts of *Cryptosporidium parvum* oocysts [138]. For up to 11 days after ingesting oocyst-laden feces, the flies regurgitated oocysts and also released them in their own feces [139].

3. Ants

House-infesting and structure-invading ants (Formicidae) have often been investigated for their potential role as mechanical vectors. Several ant species, such as the Argentine ant, *Linepithema humile* (=*Iridomyrmex humilis*), are good candidates as mechanical vectors, but the ants that attract the most attention here are Pharaoh ants, *Monomorium pharaonis*. The frequent occurrence of ants, especially Pharaoh ants, in health-care facilities [80, 140–144], food-manufacturing plants [145], restaurants, and domestic venues [146, 147], has made ants especially suspect.

This level of suspicion is heightened by the fact that representatives of several species and genera of fecal coliforms and human pathogens, such as *Escherichia coli, Streptococcus epidermidis* (=*Micrococcus pyogenes*), *Proteus vulgaris, Pseudomonas aeruginosa, Shigella flexneri, Bordetella bronchiseptica, Klebsiella pneumoniae, Streptococcus* spp., *Staphylococcus* spp., *Salmonella* spp., *Clostridium* spp., *Proteus mirabilis, Serratia marcescens, Listeria monocytogenes* and *Yersinia pestis*, have been recovered from ants [148–152].

Given that these suspect ants have all the needed characteristics to function as mechanical vectors, and the fact that some species are extremely invasive, sometimes even, in hospitals, getting into materials that are presumed to be sterile [153, 154] and foraging on the bodies of patients, further study of their significance in pathogen dissemination may result in enough evidence to elevate this group to a level comparable to that of houseflies and cockroaches as reputed mechanical vectors. Certainly, in the case of Pharaoh ants, their indiscriminant foraging habits, involving such places as floor drains, bedpans, garbage cans, food and food-preparation surfaces, sterile dressings, discarded dressings, surgical incisions, suppurative wounds, and the lips of sick infants, would be sufficient to make them suspect as mechanical vectors.

I. Role of Pest Habits in Mechanical Transmission

A third approach in evaluating the role of pests as vectors is to study the morphology, physiology and behavior of a pest to discover what attributes it possesses that make it especially accommodating to the acquisition, carriage, shedding or deposition of pathogens. Some pests make especially suitable mechanical vectors because they have morphologic features that facilitate carriage of pathogens [155]. Commensal rodents [156], cockroaches [157], ants [158], and flies [159] have habits that often take them to contaminated substrates.

1. Houseflies and Microbes

In a somewhat anthropomorphic, but nevertheless apt, comment on houseflies, West [160] notes that "If the fly were purely and simply a fecal feeder, it would not feel the impulse to spend so much time exploring the human table. This is just what makes the species so dangerous. All day long its restless nature causes it to fly back and forth between the privy and the kitchen, between a wound that is infected and a fresh incision."

Because of their anatomy, physiology and behavior, houseflies are likely the most significant insect vectors of foodborne disease pathogens. In terms of evolutionary ecology, houseflies are very closely associated with microbes; their larvae develop exclusively in decaying organic substrates (manure, compost, garbage, etc.) that harbor large and diverse microbial communities. In fact, housefly larvae cannot develop in substrates free of live microbes [161, 162]. Virtually all environments rich in decomposing organic matter harbor diverse and populous microbial communities and are, therefore, suitable substrates for development of houseflies and other filth flies [163].

2. Larval Nutrition

Housefly larvae are morphologically and physiologically adapted for the uptake and digestion of bacterial cells [164–166]. However, it is not known if the microbial cell mass serves only as a direct source of nutrients or if the microbes also play a role in chemically breaking down the substrate, making it available for larval nutrition [162]. As pupation progresses towards completion, most of the microbes in the gut are destroyed or are left behind in the discarded pupal tissues or puparium. Consequently, newly emerged housefly adults are largely free of bacteria [167, 168]. In any case, newly emerged adult flies start immediately feeding on the substrates in which they developed as larvae. Consequently, their body surfaces and digestive tracts quickly become contaminated by microbes.

Experiments conducted in Israel showed that the numbers of bacteria (*Escherichia coli*) fed to maggots (*Lucilia sericata* — sometimes used in the debridement of wounds) decreased markedly as the bacteria progressed through the alimentary canal [169]. In contrast to these findings, Fobert [170] demonstrated that flies, *Calliphora erythrocephala* (=*C. vicina*) and *Lucilia caesar*, experimentally infected

as larvae with *Salmonella montevideo*, retained the bacteria through metamorphosis to the adult stage. Some bacteria may remain viable in or on the body of the fly after it dies. For example, Fobert [170] showed that viable *Salmonella* spp. could be recovered from flies that had died two months previously.

3. Behavior of Adult Houseflies

Adult houseflies are often attracted to human dwellings (synanthropic behavior) and, once there, seem especially attracted to food and drinks. Adult flies are capable of flying long distances. They move indiscriminately between decaying substrates (where they feed and oviposit) and places where human food and animal feed are prepared and stored [160]. Thus, houseflies have great potential to transport microbes from reservoirs where they present relatively low risk (animal manure, garbage) to places where they pose a great risk (human food and food-contact surfaces) [171].

Another feature that significantly increases the potential of houseflies to disseminate foodborne disease and other human pathogens is their mode of feeding. Their sponge-like mouthparts physically limit ingested foods to only liquids or to finely comminuted solids dispersed in a liquid medium. Houseflies habitually regurgitate a portion of the contents of the foregut onto food substrates that are too large to pass through the interstices of the mouthparts [172]. This results in the deposition of digestive enzymes and bacterial decomposers (both immediately begin to liquefy the substrate or break it up into minute particles), as well as any pathogens that may have been ingested earlier [173]; thus, adult houseflies contaminate the surfaces upon which they feed or otherwise touch with their mouthparts.

4. Other Filth Flies

Other filth flies, including flesh flies (Sarcophagidae) and blowflies (Calliphoridae), also to some small extent synanthropic in behavior, develop in decaying organic matter. However, they usually do not build up to such large populations, as do houseflies. Nevertheless, all filth flies have to be considered as potential carriers of foodborne disease pathogens. For example, the Asian blowfly (*Chrysomya megacephala*) oviposits on human feces (commonly exposed in the Orient) and feeds on confections and fruits in the markets, greatly increasing the risk of contamination with fecal bacteria [174].

J. Correlation of Pest Populations and Disease Incidence

Another line of investigation is largely statistical but still requires intensive field and laboratory work. This involves correlation of pathogen occurrence in a human population (applies also to populations of domestic animals and wildlife) with that same pathogen in the population of a suspected disease vector. Sometimes a marked increase in a probable vector population is followed by an epidemic in the human population [175]. Samples for microbiological analysis must be collected from both people and suspected vectors.

A corollary approach, after an epidemic has been in progress for some time, is to dramatically reduce the suspected vector population by some control measure. If, after allowing enough time for the required incubation periods to play out, the epidemic curve subsequently slopes downward, then the implication follows that there may have been a cause-and-effect relationship between the drop in human cases and the corresponding drop in the vector population.

1. Flies and Outbreaks

In some cases, outbreaks of diarrheal diseases were observed to be closely related to seasonal peaks in filth fly numbers or dense populations of cockroaches. Outbreaks and cases of *Vibrio cholerae*, *V. fluvialis* and *Shigella* spp. in Thailand were associated with marked increases in filth fly populations [176]. Levine and Levine [109], in a review of the literature on the epidemiology of shigellosis, concluded that fly control measures tend to reduce the incidence of shigellosis in human populations. Rates of shigellosis were lower in communities where fly suppression measures were implemented than in communities without fly control programs [177].

Esrey [178] reported that the suppression of the housefly population led to a 40% reduction in frequency of diarrheal diseases among children in certain communities of Africa. West et al. [179] reported that the chance of contracting trachoma (caused by *Chlamydia trachomatis*) was 70% higher in Tanzanian preschool children in areas with high fly populations than in areas with few flies. Hyperendemicity of salmonellosis and shigellosis among infants and young children in Beirut, Lebanon, was linked to high populations of filth flies [180]. Khalil et al. [181] demonstrated that there was a correlation between the reduction of filth fly numbers and a decrease of gastroenteritis cases among infants and young children in Lahore, Pakistan.

Houseflies were postulated to be mechanical vectors of enterohemorrhagic *Escherichia coli* O157:H7 after the pathogen was collected from the flies and from patients during an outbreak of colitis in a Japanese nursery school [134]. Quantitative feeding experiments showed that the bacteria, after having apparently proliferated in the mouthparts (especially the labellum) of the fly, passed through the gut of the flies over a period of three days after the initial feeding.

2. Cockroaches and Outbreaks

Cockroaches have been implicated as probable mechanical vectors in numerous reports. The case rate during an

outbreak of infant diarrhea in a Belgian hospital dropped off shortly after the cockroaches (*Blattella germanica*) infesting the ward were exterminated. *Salmonella typhimurium* was isolated from the patients and the cockroaches [182]. An outbreak of infant diarrhea, attributed to *S. bovismorbificans*, in an Australian hospital was traced to defective sanitary practices. The pathogen was isolated from patients and from cockroaches and mice infesting the hospital [183]. *S. typhimurium* was isolated from sparrows infesting the kitchen of a mental hospital where many patients were suffering from gastroenteritis caused by the same strain of *Salmonella* [184]. *Shigella dysenteriae* was isolated from German cockroaches associated with an outbreak of shigellosis in Northern Ireland [185].

Investigators in Poland found that certain species of pathogenic bacteria collected from patients in a provincial hospital were also carried by cockroaches (*Blattella germanica*, *Blatta orientalis*) infesting the hospital [186]. In a similar situation, Indian scientists found an antibiotic-resistant strain of *Klebsiella pneumoniae* in patients and in German roaches in a New Delhi hospital [187].

K. Sampling Pathogens from Foods and Pests

Another technique in the investigation of foodborne illness is to sample suspect foods to see if there is a match between the microorganisms found in the food and those taken from suspected vectors and from people who are ill. In 1935, Staff and Grover [188] did a classic investigation of a foodborne disease outbreak, linking the patients (208, with three fatalities), the food product (a filled pastry), and the vector (*Rattus norvegicus*) to the etiologic agent (*Salmonella enteritidis*).

L. Role of Vectors in Mechanical Transmission

The last and, so far, least productive effort is to try to establish a cause-and-effect relationship between human foodborne disease and the activity of a probable vector [159, 189]. The Staff and Grover [188] investigation was exceptional; too often, the evidence is largely circumstantial. But there is at least one disease in which the route of transmission clearly involves vector contamination (via infective viruses in the urine) of food and drink: Bolivian hemorrhagic fever and the rodent transport host, *Calomys callosus* [190].

Experimental work by Klowden and Greenberg [191] unequivocally demonstrated the importance of mechanical transmission. When the mechanical transmission occurs after the final biocidal step in food processing, consumers may be at risk of ingesting viable organisms, and this may lead to foodborne illness. When bacteria (*Salmonella* sp.) were placed on the bodies of cockroaches that were subsequently killed, the bacteria survived on the dead bodies for as long as 60 days. If the cockroaches had died in a food material that was destined to be eaten without further biocidal treatment, then the consumer would have been at risk of foodborne illness.

M. Role of Pantry Pests in Mechanical Transmission

Left to themselves, the pantry pests — insects and mites that make their home in raw or processed foods and are found most often in homes, granaries, grocery stores and food warehouses — have little opportunity to become contaminated with pathogens. However, the foods in which pantry pests live are also visited by ants, flies, cockroaches, mice, rats, birds and other mobile pests, all well known for their habit of indiscriminately foraging on filthy substrates. Thus the more mobile pests bring pathogens to the home territory of the pantry pests, and they, in turn, inadvertently pick up the pathogens and disseminate them wherever they chance to travel within the food material.

1. Indianmeal Moth Larvae

Larvae of the Indianmeal moth (*Plodia interpunctella*), one of the more common insects found in the stored foods, were collected from various food sources and screened for their extracellular symbionts. Surprisingly, more than 80% of the specimens did not harbor any bacterial cells in the digestive tract that would grow on various artificial culture media [168].

2. Beetles

On the other hand, many other insect pests of stored food, including red flour beetles (*Tribolium castaneum*), lesser mealworms (*Alphitobius diaperinus*) and confused flour beetles (*T. confusum*), collected from various feed mills in the Midwestern United States, carried potentially pathogenic enterococci and aerococci [168]. Immature and adult confused flour beetles and lesser mealworms carried a fungus, *Fusarium roseum* var. *graminearum* (=*Gibberella zeae*), that produces mycotoxin F-2 (zearalenone); this fungus was also recovered from dead beetles [192].

De Las Casas et al. [193] exposed the lesser mealworm to fowl pox virus and Newcastle disease virus. Mealworms carried fowl pox virus for six hours; Newcastle disease virus was not recovered from these insects. Another avian pathogen, infectious bursal disease virus, was carried by lesser mealworms for up to 14 days after the initial exposure [194]. Harein et al. [195] isolated five different species of *Salmonella* and 48 different serotypes of *E. coli* from lesser mealworm beetles collected from poultry farms.

3. Weevils

Artificially infected rice weevils (*Sitophilus oryzae*) retained *Salmonella montevideo* for at least one week [196]. Harein and De Las Casas [197] postulated a potential role for granary weevils (*S. granarius*), collected from stored wheat, in the dissemination of several species of opportunistic pathogens including *Serratia marcescens, Streptococcus* spp., *Micrococcus* spp., and members of the *Klebsiella-Aerobacter* group.

Clearly, many species of common stored-product insect pests have significant potential as transport hosts for various pathogenic microbes; therefore, they should not be considered as merely nuisance or economic pests.

N. New Policies to Meet New Risks

1. Risks: Old and New

Disease-causing foodborne pathogens have been present throughout human history. Over past ages and right up to the present day, transmission from person to person has been effected via the fecal-oral route. The incidence of such infections has always been greater where insanitary conditions — polluted water, contaminated food, and lack of personal hygiene — prevail due to poverty or lack of education. Foodborne diseases, as most of us know from personal experience, are not limited to economically challenged populations. Affluent and well-educated people on occasion acquire foodborne infections in their own homes and in the best of restaurants.

In spite of the denial by many in the medical community, we strongly believe that a small but significant number of transmission incidents are effected through the agency of mechanical transport of pathogens by food-associated, synanthropic pests, most especially filth flies, cockroaches, ants, and rodents. We have supplied here abundant evidence to support our claim. Most people in the health-care and epidemiologic professions seem quite content to ignore the evidence. Policy makers in the food regulatory agencies of several nations have de-emphasized filth testing and terminated filth analyst and entomologist positions in government laboratories. We submit that, based on the following facts, all of which are well accepted and well known, the health of the public is not well served by these just-mentioned presuppositions and trends. There are also applications here to domestic animal and wildlife populations, but we will emphasize human populations.

a. Rapid transportation

Movement of pathogens, including food-associated pathogens, from one geographic area to another is greatly facilitated by rapid modes of transportation, as has been recently evidenced by the episodes of SARS (severe acute respiratory syndrome) in Asia and North America. Mass movements of populations between adjacent geographic regions, due to famine, civil disorders or war, may also facilitate translocation of foodborne disease pathogens, and the insanitary conditions, signaled by large populations of filth flies that often accompany such chaotic population shifts, only serve to facilitate fecal-oral transmission.

The rapid transport of food from one geographic region to another is also a factor in the epidemiology of foodborne diseases. The sanitary standards in the country or region of origin may be set at a far lower level than what would be acceptable in most of the western world. Difficult-to-clean fruits and vegetables that are usually eaten raw (e.g., raspberries, strawberries, cantaloupes) represent the greatest risks. These same foods are also often exposed to contamination by filth flies and other food pests at various stages on the journey from farm to fork: in the production fields, in transport vehicles, in distribution points for the wholesale market, at retail outlets, and in the home environment. Certain specialty food items such as smoked fish and jerky (*carne seca*) are sometimes exposed to filth flies in the early phases of production and thus to potential contamination by foodborne disease pathogens.

b. Immunocompromised people

The efficiency of the immunologic response can be underdeveloped or compromised for many reasons. The very young (with still developing immunologic systems) and the very old (with varying degrees of deterioration of the immunologic response) first come to mind. Then there are the ill for any reason, some of whom may exhibit a diminution of immunologic response in varying degrees, and the traumatized by injury or surgery (especially splenectomy and organ transplants, both involving an immediate and prolonged suppression of the immune response). Immunosuppression is the constant accessory to the radiation treatment and chemotherapy administered to cancer patients. But by far the most common sort of immunosuppression is that occasioned by the effects of the human immunodeficiency virus (HIV), the precursor to AIDS (acquired immune deficiency syndrome).

c. "Super" pathogens

Pathogens may qualify for this hyperbolic descriptor for any of several reasons. Many pathogens have acquired varying levels of resistance to the effects of certain antibiotics. This is important for anyone who contracts an infectious disease, but it is especially important for the immunocompromised. As a general rule, when a therapeutic agent is administered, cure is accomplished by the combined effects of the drug and the patient's immune system working against the pathogen population. The effectiveness of the drug becomes more crucial when the immune system is (for whatever reason) suppressed. Recovery is delayed or sometimes prevented when the pathogen has developed resistance to the antibiotic agent. Certain strains of some very common pathogens, among them some potential

foodborne pathogens, have become resistant, in varying degrees, to many of the antibiotics currently in use. A few examples are VRE (vancomycin-resistant enterococci), MRSA (methicillin-resistant *Staphylococcus aureus*), and strains of *E. coli* resistant to cephalosporin or cephamycin.

The medical journal *Emerging Infectious Diseases* is largely devoted to "new" pathogens or to "new" strains of previously recognized pathogens that often produce unexpected symptoms or exhibit unexpected virulence. Strains of the intestinal commensal, *Escherichia coli*, such as *E. coli* O157:H7, have acquired exceptional virulence, dangerous enough for healthy individuals but especially dangerous for the immunocompromised. This latter population has become especially vulnerable to opportunistic pathogens such as the non-food-associated *Babesia* recently discovered in Europe [198]. Both immunocompromised and immunocompetent populations may be susceptible to rare strains of foodborne disease pathogens, such as *Salmonella kiambu*, that "jump" unpredictably from animal to human populations.

d. Uncommon virulence

We have already stipulated that food pests play no more than an incidental role, as mechanical transport hosts, in the transmission of foodborne disease pathogens. But we submit that this "small role" is taking on greater significance because of the increasing numbers of immunocompromised people, because some of the pathogens are acquiring resistance to antibiotic drugs, and because some foodborne disease pathogens have taken on enhanced virulence, involving smaller and smaller infective doses (in amounts easily within the capabilities of mechanical vectors to deliver) to such a degree that otherwise healthy individuals, as well as the immunocompromised, may become ill.

e. Summary: why food pests are important

There may have been a time when the medical community (perhaps with some excuse) could have been nonchalant about food pests in or around food and the associated risks of mechanical transmission of foodborne disease pathogens, but now we live in a much different world. We have witnessed the emergence of foodborne pathogens possessing new virulence factors dangerous to healthy people and even more so to the immunocompromised.

A recent report, while not bearing directly on the subject matter of this chapter, does serve to underscore several points made here [198]. Careful investigation may reveal previously undiscovered pathogens or may identify microbes that have been known previously to cause only inapparent or self-limiting infections. These newly discovered pathogens can be characterized and differentiated from pathogens previously described by the application of the molecular and genetic typing techniques briefly noted below (Section VII D). These same techniques may be applied to identify and characterize microbes obtained from potential vehicles and vectors of infection, including human and vertebrate carriers, thus making it possible to establish probable chains of infection. This paper [198] also demonstrates that immunocompromised people are prime targets for opportunistic pathogens, microbes that would stand no chance of establishing infections in immunocompetent hosts.

2. Mechanical Transmission (Again)

As has been demonstrated earlier in this chapter, pathogens may be carried about by insect, rodent and bird vectors. The pathogen load borne by such vectors has traditionally (but not necessarily accurately) been thought of as very small in relation to the infective dose, that is, the minimum number of pathogenic units required to generate symptoms in a normal human host. Even if the pathogen load carried by a mechanical vector is quite small, it may be enough to produce illness in an immunocompromised host.

Some of the opportunistic pathogens, such as *Serratia marcescens* or even our ubiquitous commensal, *Escherichia coli*, isolated from various potential mechanical vectors, especially flies, cockroaches and ants, are thought to be innocuous to healthy human beings. However, for the immunocompromised, these "innocuous" bacteria may become serious, even life-threatening, opportunistic pathogens. Further, the pathogen may be one of the newly emergent "super" microbes; in that case, the "small" pathogen load, deposited by a vector, may be sufficient to make even a healthy person ill.

3. Insects and Mites in Food

The idea that eating insects and mites in our food or eating food that has been contaminated by insects and mites is harmless is becoming so pervasive that some food regulatory agencies have simply stopped doing filth inspections and filth analyses. This trend seems inconsistent with the fact of a long and continuing history of numerous successful prosecutions of filth violations in the food industry. However, consumers may still draw some assurance of safety in their food because of the fact that the policy makers still attach great importance to food pests as "indicators of insanitation."

Of course, it is true: Most of us will not suffer any ill effects from ingesting a few dead insects and mites with our food. But the occasional serious illness, such as anaphylaxis associated with ingesting mites [199–202], jars the complacency usually associated with such a benign phenomenon and justifies the establishment of regulatory action criteria [203].

4. FDA Policy on Filth in Food

Scientists and policy makers at FDA have established and defined categories of filth and extraneous matter and have

developed a flow diagram for use in evaluating the significance of these several categories within the context of a food-manufacturing operation [69].

a. Potentially hazardous

There are three categories of contaminants in the flow diagram: potentially hazardous extraneous materials, indicators of insanitation, and aesthetic defects.

A contaminant is designated as *potentially hazardous* if scientific and medical authorities recognize it as such, or if the contaminant is known to have caused injury, or if the contaminant remains in the food even though the usual processing procedures could be expected to remove it.

Hard or sharp foreign objects immediately come to mind here. When a consumer buys unpitted fruit such as cherries or prunes, the consumer is forewarned that pits are present and it is the consumer's responsibility to remove the pits before chewing the fruit. In this case, the pits are normal constituents of the food product and would not be categorized as potentially hazardous. If, however, a consumer buys pitted fruit, and it is labeled as such, any pits or fragments thereof remaining in the product could be considered as potentially hazardous because of the potential for injury or choking. Even in this instance, the consumer must be wary because FDA, in its DALs, may permit very small amounts of pit fragments in specific retail products.

Already noted above is a different, rather uncommon (and very minor, according to some [204]) sort of potentially hazardous filth: allergic reactions to certain mite-infested foods [199–202].

b. Indicators of insanitation

Another category of contaminants is represented by insects, mites, rodents and birds that are themselves not hazardous but are placed in this category because of their potential for serving as mechanical vectors of food-associated pathogens. Quite apart from any proved or suspected demonstration of pathogen carriage by these pests, their mere presence in a food-processing facility or retail food establishment causes them to be categorized as "indicators of insanitation." The presence of these pests in or around food suggests that one or more basic sanitation safeguards in the food facility have failed and that the defect or defects must be corrected.

c. Aesthetic defects

Aesthetic defects, even though generally harmless, are subject to regulatory action if they exceed the DALs. Some examples are field insects or fragments thereof accidentally carried into the food processing operation, bits of soil picked up during harvesting and not adequately removed before processing, and pieces of stems or pods that remain in the food product.

5. A New Enforcement Strategy

In any evaluation of the significance of filth and extraneous materials in food, including hard or sharp foreign objects, FDA has placed the first priority on the question, *is it a health hazard?* If the answer is yes, then HACCP immediately comes into play and corrects the problem. If the answer is no, the next question is, *does the contaminant represent a violation of good manufacturing practice?* If the answer is yes, then adherence to SSOPs [205] is reviewed for adequacy of compliance. If the answer is no, the next question to ask is, *is it an aesthetic defect?* If the answer is yes, then it must be determined whether the applicable DAL has been exceeded. Appropriate regulatory action may be taken if there is a DAL violation. However, even if there has been no technical violation of a DAL (or if, as often happens, no applicable DAL exists), regulatory action may still ensue if other factors point to deficiencies in sanitary operations.

6. End of an Era

The food defect action levels have had a long history of development in the federal food regulatory agencies of the United States [53]. At least since 1973, the DALs have been set on the basis of a large, statistically valid sample of a particular food product. The filth load in each subsample of that product was determined by standardized micro-analytical techniques. All of these individual results were then considered, along with seasonal and geographic variations, before setting a DAL.

During the last quarter of the twentieth century, entomologists, chemists and analytical technicians at the FDA Center for Food Safety and Applied Nutrition in Washington, D.C. (now located in Beltsville, Maryland), and at the various regional laboratories of the FDA, actively engaged in the development of filth detection procedures for a large variety of food products, a variety far greater than the list represented in the DAL handbook [206, 207]. Shifting priorities on the part of the decision-makers within the FDA and the USDA have resulted in the near elimination of research and development on filth detection methods. A very few modest filth methods projects are underway or planned [208, 209], but neither the expertise nor the funds remain within FDA to support the setting of any new DALs.

VI. HARD AND SHARP FOREIGN OBJECTS IN FOOD

A. Consumer Experience

Most consumers are aware of the fact that hard objects that do not belong in food are, nevertheless, sometimes present. This is because most consumers have personally found such objects. Furthermore, most such encounters are

innocuous in nature. Certain foods are so frequently endowed with physical objects (e.g., grit in spinach; bits of shell in clam chowder) that we are surprised if such objects are not found. In other instances, the encounter between the consumer and a physical object in food or drink may result in an injury, the severity of which may vary widely.

B. Literature on Hard Objects in Food

In view of the rather high frequency with which consumers encounter hard and sharp objects in food, it is surprising that the scientific literature on this subject remained remarkably scarce for so many years, the publications by Hyman et al. [210] and Gorham [211] being the first two of several to follow. Since the implementation of mandatory seafood HACCP on 18 December 1997 [212] and the installation of many voluntary HACCP programs in recent years, three general reviews [1, 213, 214] and one practical paper [215] on the subject have been published, and other numerous publications have appeared, especially regulations, guidelines, methods and didactic materials, the latter often quite redundant but useful nevertheless because they are usually tailored to meet the needs of specific audiences in the food industry [14, 16, 213, 216–220]. The USDA Food Safety and Inspection Service (FSIS) has produced a report on a technical conference on foreign material contaminants [221].

Concern for the possible adverse health effects of hard foreign objects in food and drink was evident early in the twentieth century. One might have guessed that Harvey W. Wiley, principal protagonist for the first federal pure food law [30], would have been interested in this subject, and perhaps he was. But in the record of that era, he makes only passing reference to a study of "cocoa shells in cocoa products" in his 1911 report [76]. His concern then was probably with the shells as an "economic adulterant" (in the same sense that added water was an economic adulterant of milk) rather than with the shell fragments as hard foreign objects in cocoa powder.

C. Product Tampering

Excluded from detailed discussion in this review are acts of fraud, sabotage, and product tampering. Hiding a big rock inside a bale of bay leaves to boost the weight would be considered fraud. The deliberate addition of a foreign object to a food or beverage product by an employee of the product's manufacturing company would be considered an act of sabotage. When, in an effort to cause harm to some other person or to extort money from a manufacturer, someone deliberately adds a foreign substance or a physical object such as a needle, a straight pin or bits of glass to a product offered for sale, the act would be considered product tampering [222–224]. The added object does not have to be hard or sharp to constitute product tampering: Spitting a glob of phlegm onto a fast-food hamburger before serving it to a customer would clearly be actionable.

A common type of product tampering, rarely prosecuted under the Federal Anti-Tampering Act [225] or any other statute, occurs when a consumer deliberately puts a piece of glass, a mouse, or a cockroach — to mention just a few of the possibilities — into a food or beverage, and then reports the "find" to the manufacturer, the motive being to get a free quantity of the product or money from the manufacturer.

D. Filth

Also excluded from discussion in this section on hard foreign objects are those physical objects, already noted above, usually categorized as filth [2, 69]: rodent hairs and feces; bird feathers and feces; insects and mites and their fragments; and molds and rots associated with fruits, seeds, nuts, and many other foods. The tiny metal fragments sometimes generated by opening cans with a can opener in the home or restaurant kitchen are also excluded from this present topic.

E. Hard Objects Absent from the Food, Drug and Cosmetic Act

The FD&C Act says nothing about such things as paint chips, ball bearings, or glass shards in food. When such items happen to be found in food or drink by regulatory officials, each incident is evaluated on its own merits and, if deemed actionable under the FD&C Act, it is because the foreign object has rendered the food "unfit" (402[a][3]) for human consumption due to an offensive "mouth-feel" of the adulterated food, or has rendered it "injurious to health" (402[a][4]).

An FDA Compliance Policy Guide [16] provides further regulatory details based on reviews by the FDA Health Hazard Evaluation Board of nearly 200 cases of hard or sharp foreign objects in food. The Board concluded that objects measuring less than 7 mm in length rarely cause physical injury. However, special risk consumers such as infants, the elderly, and the physically or mentally challenged may be unable to cope with objects 2 mm or less in greatest dimension.

F. Defect Action Levels

The DALs [206, 207] give no ground to physical objects that find their way into foods after the agricultural phase of production [53]. Some modest forbearance is shown in the DALs toward some of the fruits with pits (e.g. cherries, dates, olives, prunes), apparently because even the best pitting technology falls short of 100% efficacy. The DALs address these and many other unavoidable defects That the USDA permits small numbers of bone fragments in certain meats [226] is a fact many of us have discovered

to be true as we seek out a dentist to repair the damage. The DALs do not exempt from regulatory action any hard or sharp foreign object if that object has been shown to constitute a hazard for physical injury or choking or if it has been shown to cause the product to be made unfit for food.

G. The Processor's Goal

Reputable food and beverage processors prefer to produce products that are free of foreign objects. Their zeal is driven perhaps in part by the fact that there is little defense against an obvious hard foreign object, especially one that has caused injury to a consumer. No doubt, however, the overriding motive for keeping objects out of foods and beverages is to protect and preserve the company's reputation. Of course, the economic consequences of downtime on the production line and recalls of shipped products probably also play a role in a company's pursuit of zero defects in the product line, whatever that might be. Many food manufacturers use vendor certification programs to ensure that only high quality ingredients enter the food processing plant [227].

H. Quality Assurance Procedures and Devices

Many companies have invested heavily in quality assurance devices and procedures to prevent the occurrence of foreign objects in food or to discover them before the foods leave the factory [228, 229]. Glass, one of the early mass-produced commercial packaging materials, continues to be widely used. Unfortunately, glass packaging readily breaks during the manufacturing of the container and during the washing, filling, capping, labeling, and boxing of it on the production line. The problem of glass shards in foods and beverages has been reviewed in the technical literature over a span of many years beginning early in the twentieth century [1]. Reputable companies that use glass packaging strictly follow the applicable good manufacturing practice (GMP) statements [37] and carefully keep records of problems so that container-manufacturing and food-processing equipment can be fine-tuned to reduce breakage to a minimum.

Virtually all detection systems for foreign objects involve a human observer to some degree, but most production line detection systems also involve specialized machines to supplement visual observations. There are two different lines of approach to the goal of preventing hard foreign objects from getting into food and drink. One involves various screens, shakers, air blasts, filters, magnets, or other devices to remove foreign objects present in the production stream.

The second, which may sometimes be used in concert with the first, involves machines that "look" for foreign objects in product ingredients or in the finished product before or after packaging [230–236]. These machines may be very sophisticated technically and capable of detecting many kinds of foreign objects — glass, metal, bone, rocks, shell fragments (from nuts, mollusks or crustaceans) and other items.

Rigid observance of well-planned protocols for housekeeping and plant maintenance operations, with strict accountability of supplies, tools, and spare parts, serves well as a further safeguard against adulteration of food products with foreign objects [237, 238]. These protocols should include inspections of raw ingredients for hard objects and inspections of processing equipment and food packaging to detect missing parts or container fragments (Figure 74.2). The shielding of all light fixtures (to prevent broken glass lamps from falling onto the food line) is another essential preventive measure.

I. Ingestion and Inhalation of Foreign Objects

Human injury or death associated with the ingestion or inhalation of foreign objects has been reported widely in the medical literature. Many such cases have nothing to do with food. The offending object could be a coin, thumbtack, earring, marble, balloon — in other words, a vast array of small objects [239].

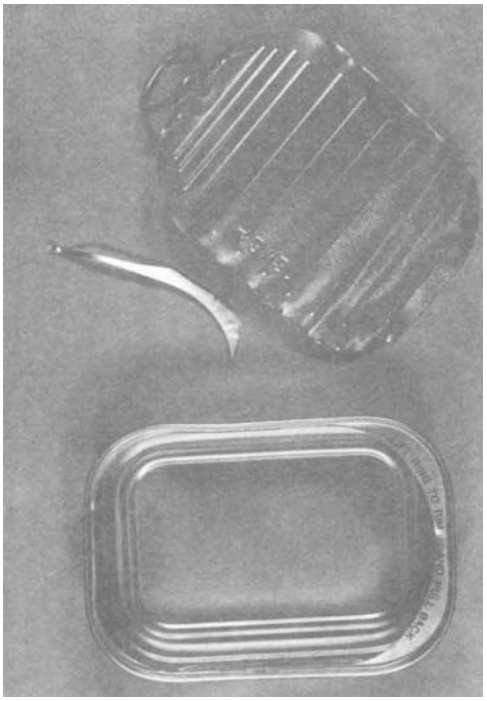

FIGURE 74.2 Metal fragment from a retail can of sardines.

1. Food-Related Items

Many other cases of injury and death have been attributed to various items of food. Hot dogs are notorious offenders, as are grapes, hard candy, nuts, chunks of meat, popcorn, beans, and many other such objects. Liquid foods may cause problems also, especially for infants.

Food regulatory agencies in England, Australia and the United States [240–242] have in recent years issued warnings about a choking hazard from a small, jelly-filled candy (Figure 74.3) made in part of konjac, a flour derived from the tuber of *Amorphophallus konjac* (Araceae) and widely used as a food ingredient in the Orient. The slippery nature of the candy, lubricated by saliva, causes it to be readily shifted, without chewing, into the back of the throat where it may block the airway, sometimes with fatal results. In the United States, a hazardous food product such as konjac candy is subject to regulatory action by both the FDA and the Consumer Product Safety Commission (CPSC) [243].

Another category of objects reported to cause injury or death consists of things that are associated intrinsically with foods: fruit pits and seeds (as in dates, grapes, apples, cherries, limes and other citrus fruits), bones (beef, pork, chicken, fish), shells (nuts, shrimp, clams, oysters), stems (raisins, string beans), pig teeth in sausage, and fish scales in canned tuna. Objects in this category sometimes are considered to be less objectionable than those in the foreign object category because it is predictable that they may occasionally filter through the normal safeguards of good manufacturing practice.

2. Hard and Sharp Foreign Objects in Food

This category consists of foreign objects in foods and beverages. Such objects are described as foreign because they are not intrinsically associated with an edible portion of a food product. Some are obviously associated with harvesting. The small stones or clumps of soil found in dried beans and peas are typical, as are the sand and grit in peanut butter and spinach (Figure 74.4).

Other objects, clearly associated with manufacturing, occur in two cases. The first is associated with the manufacturing of the food container *per se*. Glass, plastic, and metal fragments predominate here. The second occurs during food processing. Glass, plastic, and metal fragments also predominate in this phase. In earlier days, wood splinters were more common in manufactured foods because wood was then more often used in processing equipment.

FIGURE 74.3 Konjac candy (choking hazard). Courtesy of Food Standards Agency, United Kingdom. Used by permission.

FIGURE 74.4 Beans and pebbles from a retail bag of pinto beans.

Today, plastic is frequently seen on the processing lines. Due to normal wear and tear on the equipment, bits of plastic may find their way into foods and beverages.

Inadvertent contamination by foreign objects, such as wood, paper, plastic, etc., may occur during food processing. But most of these unwanted objects are already in the cans and bottles before they leave the container manufacturer. All food processors should have systems for cleaning all containers before the point at which they are filled with the food product.

a. Foreign objects associated with can manufacturing

At can manufacturing plants, small curls of plastic sometimes form on the "fingers" used to move the new cans onto pallets in preparation for shipment. On occasion, the "fingers" rub against the sharp can lip, peeling off thin curls of plastic. Quality-assurance protocols require the palletizer operators to periodically inspect the "fingers" and remove any curls; otherwise, the curls will eventually break off and drop into cans. When it is understood that on any given day, many thousands of cans are fabricated, palletized and readied for shipment, it should not be surprising that a few bits of plastic may escape notice and drop into cans. This is one of the reasons why seemingly clean cans from the can factory must be cleaned and inspected before they are filled by the processor. Glass containers must be similarly cleaned and inspected.

b. Insects associated with can manufacturing

While not bearing directly on the subject of hard foreign objects, it should be noted here that insect contamination may occur during the manufacture of cans. A relatively minor sort of "adulteration" occurs when flying insects, attracted to the lights over the finished cans on the conveyors, accumulator tables and palletizers, fall into the cans.

A far more serious kind of insect "adulteration" problem occurs during warm, humid months when conditions are favorable for the proliferation of minute mycophagous insects called psocids or booklice (Order Psocoptera). The same weather conditions that favor the production of large populations of psocids also favor the growth of fungi on the cellulose fiber (composite) slipsheets or divider boards used to separate tiers of cans in a palletized stack. This abundance of food naturally leads to large numbers of psocids. When the slipsheets are placed over the open cans on the pallet, some of the psocids fall into the cans, creating a potential violation of the FD&C Act, even though these insects have no importance as mechanical vectors.

c. Control of booklice

Two commonly used "control" measures are both uncommonly ineffective. Applying insecticidal aerosols or mists gives only minimal temporary control. The same applies to fumigation of the stacked cans or the slipsheets. In both instances, many of the dead insects remain on the slipsheets and in the cans, rendering them adulterated. Therefore, the cans must be cleaned in order to bring them back into a marketable state. In other words, the end result is the same, so it would seem to be economically prudent to avoid the purchase of ineffective "control" measures.

There is no easy or totally effective way to deal with psocids in this situation. However, the use of plastic slipsheets, instead of the traditional fiberboard slipsheets, goes a long way toward solving the psocid problem. Apparently, plastic slipsheets do not support the fungal growth required for proliferation of the booklice. Although the plastic slipsheets are more expensive than the composite board slipsheets, economy is derived from avoiding expenditures for the virtually useless measures of fumigation and spraying insecticidal mists. The use of plastic slipsheets and the practice of keeping the palletizing area scrupulously clean will minimize both the psocid problem and the incidence of unwanted foreign objects in the cans [244].

d. "Chicken a la plastique"

Plastic shards in a four-ton batch of chicken nuggets prompted a major chicken processor to initiate a recall effort. All but about 2500 pounds of the adulterated chicken were recovered. Children discovered the plastic pieces while eating lunch served at a school. This kind of hard foreign object may cause physical injury or choking; fortunately, no injuries were associated with this incident [245].

The continuing recurrence of recalls due to glass, plastic, metal and other foreign objects in food and drink indicates that, while much progress has been made, much remains to be done toward the end of preventing these unwanted objects from entering the product stream.

3. Review of Case Reports

Case reports or reviews of collections of cases involving foreign objects in the digestive or respiratory tracts typically refer to the more severe, the more unusual, or the fatal cases. The degree of severity ranges from the relative "minor" esophageal tears caused by sharp-edged, solid objects [239, 246], through partial blockages of the esophagus [247] or trachea [248], to complete and fatal obstruction of the airway [249].

A review of the medical literature readily available in the FDA foods library, covering the span of the years 1961–1990, yielded 679 cases of injury or death associated the ingestion of inhalation of foreign objects. Many of these cases (221) had nothing to do with food, but in a relatively large number (437), some kind of food material was involved. In a relatively small number of cases (28), some food-associated, hard foreign object — pit, shell, bone, stem, seed — was the culprit.

In this admittedly incomplete collection of cases from the medical literature, there was no unequivocal report of

injury, illness or obstruction caused by a hard foreign object ingested with food or drink that was not intrinsically associated the food or drink. In other words, ball bearings, wood splinters, conveyor-belt nuts and cleats (staple-like wires used to hold together sections of conveyor belt), glass shards, bits of metal or plastic, and similar extraneous hard foreign objects ingested with food or drink were in no case unequivocally implicated in obstruction of or injury to the digestive or respiratory tracts. There was one report (not included in the above informal survey) of intestinal injury caused by a wood splinter that apparently had been swallowed with food, but the patient could not recall the event [250].

4. The Food and Drug Administration Complaint Reporting System

The situation in the preceding section stands in marked contrast to that reported by Hyman et al. [210]. In a careful analysis of just one 12-month period (October 1988–September 1989), they compiled data on 10,923 complaints about food registered with FDA. Of these complaints, 25% (2726 cases) involved foreign objects in food or drink, and 14% (387 cases) of these involved illness or injury associated with foreign objects ingested in beverages or food. Most of the injuries/illnesses, as might be expected, involved cuts or abrasions in the mouth and throat, damage to teeth or dental prostheses, or gastrointestinal distress. The foreign objects were rank ordered from most to least common: glass, slime or scum, metal, plastic, stones/rocks, crystals/capsules, shell/pits, wood, and paper. Foreign object complaints involving injury or illness were associated most often with soft drinks, followed in descending order by baby foods, bakery products, cocoa/chocolate products, fruits, cereals, vegetables, and seafoods.

J. HACCP, DALs and Hard Foreign Objects

The worldwide food industry is gradually coming under the food safety program now well known as HACCP (Hazard Analysis and Critical Control Points). In the United States, HACCP programs are mandatory for the seafood [212, 251] and juice [252] industries, but many other food processing systems in the United States [253], Canada, and in numerous other countries [254] are protected by voluntary programs. The Canadian Food Inspection Agency plans to implement mandatory HACCP in all federally registered meat and poultry processing plants by mid-2005 [255].

Since HACCP focuses on microbial hazards and their prevention, reduction or elimination, the overall safety of food should be enhanced. In spite of the fact that hard foreign objects have little to do with microbial pathogens, hard foreign objects are nevertheless considered a Critical Control Point. This is because hard foreign objects may be a choking hazard or may cause injury if the consumer attempts to chew or swallow them [1, 213, 214].

The DALs [53, 206, 207] allow very small quantities of fruit pits to be present in food; at these low levels, they are considered to be natural and unavoidable constituents of food. Other hard foreign objects are considered adulterants under the provisions of the FD&C Act if they may cause injury to the mouth and digestive organs [1, 210, 214], if they simply make the food to feel gritty in the mouth, or if they may be a choking hazard for special consumers such as infants and physically challenged individuals of any age who have difficulty chewing and swallowing.

VII. CONCLUSION: HACCP, SSOPs, RESEARCH

A. HACCP

The HACCP program for food safety, when properly implemented and maintained, has the ability to protect everyone from both the traditional foodborne pathogens and parasites and from the newly-emerging ones [253, 256]. Although hard foreign objects are treated as a Critical Control Point, the other adulterants generally referred to as "filth in food" receive very little attention in the HACCP protocols.

B. SSOPs

However, this is not to say that filth is considered to be unimportant. HACCP does not deal specifically with the sources of filth in food because the whole edifice of HACCP is built (and must be built) on a foundation of thorough, persistent and dependable sanitary practices in the food industry, usually referred to as SSOPs (sanitation standard operating procedures) [229]. A substantial part of *preventing pathogens* from getting into our food is *preventing pests* from getting into our food — and this at all stages of production, harvest, storage, manufacture, distribution, retailing, and even to the home kitchen, this latter being the theater where the majority of foodborne infections are staged.

C. Foodborne Diseases

Estimates by the Centers for Disease Control and Prevention of the annual incidence of foodborne diseases in the United States range from 6.5 million to 76 million cases. Annual mortality has been estimated between 5,000 and 9,000 [257, 258]. The rates of foodborne diseases in developing countries are much higher due to poor sanitation, lack of clean water, and inadequate hygiene. With increased international travel, the risk of introduction and spread of pathogens around the world is very high.

After many years of therapeutic and preventive uses of antibiotics, many kinds of bacteria have adapted and become resistant to antibiotics. Multiple uses of antimicrobial agents in medicine, production of food animals, and crop protection have caused an increasing resistance to those agents. In addition, widespread use disinfectants in household products may also contribute to the development of resistance. As effectiveness of existing antimicrobial agents declines, it will be more difficult and expensive to treat infectious diseases and to control epidemics.

D. Research

Within the past few decades, great advances in biology (primarily biochemistry and molecular biology) have offered new and more sensitive approaches for the fields of microbial ecology and epidemiology, as exemplified in the paper by Herwaldt et al. [198]. Techniques based on biochemical analysis and amplification of nucleic acids by the polymerase chain reaction (PCR) technique, followed by genotyping by, for example, restriction fragment length polymorphism (RFLP), pulse field gel electrophoresis (PFGE), and amplified fragment length polymorphism (AFLP), allow for tracking specific pathogens (strains/serotypes/genotypes) in various clinical and environmental habitats. This leads to a better understanding of bacterial and vector ecology and consequently to formulation and implementation of more effective food safety programs.

It is clear that the need for risk assessment and surveillance programs for foodborne and other human and animal diseases, including screening for antibiotic resistance genes and their spread in the environment and an improved understanding of microbial ecology in general, is rapidly growing. Thorough assessment of the significance of mechanical and biological transmission of pathogens by arthropod and other animal vectors must be an integral and essential part of new food safety and foodborne disease prevention programs.

CONTENTS

I. INTRODUCTION

In the United States, an estimated 76 million persons, about one in every four, contract foodborne illnesses each year (1). Most cases of foodborne illness are relatively mild, with the affected individuals suffering from a few days of gastrointestinal cramping, headache, vomiting and/or diarrhea. However, some foodborne illness is much more serious, with an estimated 325,000 cases requiring hospitalization and 5000 resulting in death in the United States (1). Persons who are very young, elderly, pregnant (because of risk to the fetus) and those with weakened immune systems are especially susceptible to foodborne illness and the serious consequences that may result.

Consumers can reduce the risk of getting a foodborne illness by following safe food handling guidelines when buying, storing, preparing, cooking and serving food at home. In the United States, consumers tend to believe that food prepared at home is an unlikely source of foodborne illness, although studies indicate that many kitchen environments are contaminated with pathogens, and many consumers are unaware of or do not practice safe food handling methods (2). Many consumers clean their bathrooms more thoroughly than their kitchens, as shown in a bacterial survey of these rooms in 15 households. The kitchen was more heavily contaminated with fecal coliforms and other bacteria than was the bathroom (3). It has been shown that foods consumed in household settings are three times more likely to cause foodborne illness than foods consumed in cafeterias (2).

This chapter discusses causes and sources of common foodborne diseases encountered by consumers, and the

measures that consumers can take to prevent and control foodborne illness.

II. CAUSES OF FOODBORNE ILLNESSES

There are over 200 diseases that are transmitted through food (1), although those who work in the public arena offering food safety advice to consumers concentrate their concern on 10 to 30 of the most significant agents of foodborne disease. Most foodborne illnesses are caused by eating food that contains harmful bacteria, viruses or parasites, or a toxin produced by bacteria growing in the food; metals and prions are other sources of foodborne illness/disease, but will not be discussed here.

The U.S. Centers for Disease Control and Prevention (CDC) uses data from a number of sources to estimate the incidence of foodborne disease in the United States, including the frequency of diarrhea in the general population, and active surveillance for nine pathogens in a defined population of 20 million Americans. However, foodborne illness is underreported for a number of reasons: people who become ill may not seek medical care (and frequently do not if the illness is mild), doctors may not order diagnostic tests or sampling of patients with suspected foodborne illnesses; diagnostic tests may not be measuring the causal organism or detect low numbers of organisms; and diagnosed illnesses may not be reported to public health agencies. Sporadic illnesses, those occurring occasionally or singly, are significantly less reported than outbreak-related cases of foodborne illness, when two or more people come down with the same illness from the same contaminated food. About 81% of the 76 million foodborne illnesses projected by CDC are caused by unidentified or as yet unknown pathogens (1).

A. Viruses

Of the 13.8 million U.S. foodborne illnesses caused by identified pathogens, viruses are responsible for 9.2 million cases, or 67% (1). Viruses are extremely small pathogens that are able to reproduce only within a living host cell; they do not reproduce in foods. Some viruses (such as no rovirus and hepatitis A) can be transmitted by food and water. Other viruses (such as Human Immunodeficiency Virus, the cause of AIDS) are transmitted from person to person, but not through food or water (4). Table 75.1 provides information about the incidence, costs to society, disease severity, food sources, and the control of foodborne illness due to fourteen major foodborne pathogens, including norovirus and hepatitis A.

Norovirus is the most common cause of foodborne illness in the United States (1) because of its low infectious dose, relative resistance to sanitizers and heat, many strains, and the fact that individuals do not acquire long term immunity (5). Fortunately, the illness is usually mild. Norovirus is passed from the feces or vomit of infected persons onto the hands of food handlers or into sewage. Any food subject to human fecal contamination may cause a norovirus infection. Outbreaks are usually associated with food or contaminated water in swimming pools, lakes, or municipal supplies. Inadequately cooked shellfish or salads contaminated by food handlers have been vehicles for norovirus-caused illness. Norovirus was recently responsible for a series of troubling outbreaks of illness aboard cruise ships in the Caribbean; transmission was attributed primarily to person-to-person contact rather than through food (6). The low infective dose means that it is relatively easy for a person who has the virus to spread the disease to other people. The U.S. Food and Drug Administration (FDA) recently advised that hand washing is the best prevention against gastroenteritis (7).

Hepatitis A virus causes about 4000 foodborne illnesses annually in the United States. Similar to norovirus, hepatitis A virus is excreted in feces of infected people, and causes infection in susceptible individuals when contaminated water or foods are ingested. Controlling the spread of hepatitis A can be difficult because infected persons can shed viral particles during the long, 10 to 50 day, incubation period. The greatest danger of spreading the disease to others occurs during the middle of the incubation period, well before the first presentation of symptoms. Hepatitis A is usually mild, but can be one of the more severe foodborne illnesses (8); recovery generally requires 1–2 weeks, but can be much longer. Hepatitis A symptoms include fever, fatigue, nausea, vomiting and abdominal discomfort, followed in several days by jaundice. The infectious dose is thought to be fairly low, 10–100 virus particles (9).

B. Bacteria

Bacterial pathogens are estimated to account for about 4 million of the foodborne illnesses caused by identified pathogens annually in the United States (1). Depending on how the classification is made, there are 19 or so bacterial pathogens that cause nearly all the identified bacterial foodborne illnesses. Bacterial pathogens account for 60% of the hospitalizations attributable to foodborne illness, and 72% of the deaths (1). Bacterial pathogens can be found in virtually any environment, including food, and plants and animals produced for food. They thrive in warm, moist foods that are low in acid. Most disease-causing bacteria grow very slowly in foods at low temperatures, multiply rapidly in mid-range temperatures, and are killed at high temperatures.

Bacterial pathogens cause foodborne illness by three mechanisms: infection, intoxication or toxin-mediated infection; some employ more than one mechanism (10). Some bacterial pathogens produce a literal food poisoning

TABLE 75.1
Fourteen Common Foodborne Pathogens

Pathogen	Estimated Incidence (Foodborne)	Estimated Cost (Millions of Dollars)	Disease Severity	Common Food Sources	Food-Handling Error(s) Associated with Pathogen	Primary Control Factor
Norovirus	9,200,000	8,160	Mild to moderate	Contaminated shellfish and prepared foods handled by infected food handlers	Poor personal hygiene or infected food handlers	Personal hygiene
Shigella spp	90,000	34	Moderate to severe	Prepared foods handled by infected food handlers	Poor personal hygiene or infected food handlers	Personal hygiene
Hepatitis A	4,170	21	Moderate to severe	Contaminated shellfish and prepared foods handled by infected food handlers	Poor personal hygiene or infected food handlers	Personal hygiene
Clostridium perfringens	249,000	46	Mild, self-limiting	Meat, poultry products, and beans	Bacterial spores survive cooking; multiply when food is in danger zone	Keep food at safe temperatures
Staphylococcus aureus	185,000	85	Mild to severe (rarely)	High-protein foods handled frequently during preparation	Food handler contaminates cooked food, *S. aureus* produces toxin while food is in danger zone	Keep food at safe temperatures
Bacillus cereus	27,000	11	Mild, self-limiting	Cooked rice and pasta	Bacterial spores survive cooking; multiply when food is in danger zone	Keep food at safe temperatures
Campylobacter jejuni	1,960,000	1,798	Mild to moderate	Raw milk, poultry, beef, pork, shellfish	Inadequate cooking, fecal/environmental contamination	Adequate cooking/ cross-contamination
Salmonella spp	1,342,000	1,190	Mild to severe	Meat, poultry, raw milk, eggs fresh produce	Inadequate cooking, fecal/environmental contamination	Adequate cooking/ cross-contamination
Toxoplasma gondii	112,500	1,247	Mild to severe	Pork, ground beef, other meats	Inadequate cooking, fecal/environmental contamination	Adequate cooking/ cross-contamination
Yersinia enterocolitica	86,731	77	Mild to moderate	Pork, milk or milk products	Inadequate cooking, fecal/environmental contamination	Adequate cooking/ cross-contamination
Escherichia coli 0157:H7	62,500	205	Moderate to severe	Ground beef, raw milk, lettuce, unpasteurized apple cider	Inadequate cooking, fecal/environmental contamination	Adequate cooking/ cross-contamination
Vibrio spp.	5,218	5	Mild to severe	Raw seafood and shellfish	Inadequate cooking fecal/environmental contamination	Adequate cooking/ cross-contamination
Listeria monocytogenes	2,493	29	Mild to severe	Raw milk, soft cheeses, raw vegetables, raw-meat sausages	Inadequate cooking, post-pasteurization contamination, lengthy refrigeration	Avoid food from unsafe source
Clostridium botulinum	58	1	Severe	Home-canned or fermented vegetables, meat, fish	Inadequate processing time for low-acid food; poor fermentation	Avoid food from unsafe source

Adapted from reference 14.

by producing a toxin as they grow in food. In this case, ingestion of the toxin causes illness (*Staphylococcus aureus* and *Clostridium botulinum* are examples). Most bacterial pathogens cause an infection when ingested, burrowing into the digestive tract lining and colonizing there, increasing in number. Antibiotics are used to control bacterial infection from foodborne illnesses, but some bacterial pathogens are becoming antibiotic-resistant, resulting in illnesses that are not easily treated. Antibiotic-resistant bacteria are increasing in the food supply (11, 12), making prevention of foodborne illnesses increasingly important.

All bacteria exist as vegetative cells, which are relatively easily destroyed by heat, sanitizers and/or other controls. However, a few bacterial pathogens have the ability to form spores (for example *Clostridium botulinum* and *C. perfringens*), a structure that enables the bacteria to withstand harsh environmental conditions, such as heating and the application of sanitizers. This characteristic makes their control more difficult than that of non-spore-forming pathogens. Some bacterial pathogens (for example, *Yersinia enterocolitica* and *Listeria monocytogenes*) are psychotrophs, so refrigeration temperatures are not effective for controlling growth in food (13).

Eleven bacterial pathogens are of particular concern in consumer food safety. The illnesses caused by these pathogens are briefly discussed below in the order of the amount of foodborne disease they cause in the United States. This information is drawn primarily from the Food and Drug Administration's Center for Food Safety and Applied Nutrition's (FDA-CFSAN) *Bad Bug Book* web pages (9); this is a good source for additional information. Table 75.1 lists the estimated incidence, dollar cost to society, and disease severity of these pathogens with organisms grouped by food safety behaviors most useful in controlling each pathogen (14). *Salmonella* (nontyphoidal) and *Campylobacter* are responsible for 43% and 29% of the hospitalizations caused by known bacterial pathogens; *Salmonella* (nontyphoidal) and *Listeria monocytogenes* are responsible for 43% and 38% of the deaths caused by known bacterial pathogens (1).

- *Campylobacter jejuni* causes the most foodborne illness among bacterial pathogens. Its infective dose is small, about 400–500 bacteria may cause illness, although individual susceptibility varies. *Campylobacter* infections are frequently mild, causing diarrhea, which may be watery or sticky. Other campylobacteriosis symptoms include fever, abdominal pain, nausea, headache and muscle pain. The illness usually occurs 2–5 days after ingestion of the contaminated food or water and generally lasts 7–10 days, but relapses occur in about 25% of cases. The illness rarely can progress to further complications including reactive arthritis, hemolytic uremic syndrome, meningitis, recurrent colitis, and Guillain-Barré syndrome.
- Bacteria in the genus *Salmonella* include thousands of serotypes, most of which are pathogenic. Foodborne illness is mainly from the nontyphoidal types. As few as 15–20 bacterial cells may cause the infection, although susceptibility depends upon individual age and health, and on serotype differences. Symptoms of salmonellosis include nausea, vomiting, abdominal cramps, diarrhea, fever, and headache. The illness usually occurs 6 to 48 hours after ingestion of the contaminated food or water and lasts 1 to 2 days, but may be prolonged. Complications include post infection reactive arthritis in about 2% of cases.
- *Clostridium perfringens* is a spore-forming organism that frequently causes illness due to temperature abuse of prepared foods, which allows the spores to germinate and grow in a competition free environment. Prefringens poisoning is caused by ingestion of large numbers (greater than 100 million) bacterial cells. When the infection takes hold, toxin produced in the digestive tract is associated with sporulation of the vegetative cells. Perfringens poisoning symptoms include intense abdominal cramps and diarrhea which begin 8–22 hours after consumption of foods containing large numbers of *C. perfringens* bacteria. The illness lasts about 1 day, but residual symptoms may persist for 1 or 2 weeks.
- *Staphylococcus aureus* bacteria occur normally on human skin and in the nose and throat; about 50% of people carry this pathogen. These bacteria can be transmitted to food during handling or preparation. When potentially hazardous foods are held at temperatures where *S. aureus* can grow, any *Staphylococcus* bacteria in the food multiply and produce a heat stable toxin that is not destroyed by cooking. Staphylococcal food poisoning occurs when less than 1 μg of toxin is ingested, a toxin level produced when *S. aureus* populations exceed 100,000 per gram of food. Symptoms of staphylococcal food poisoning occur within 1 to 6 hours, depending on individual susceptibility to the toxin, the amount of contaminated food eaten, the amount of toxin in the food ingested, and the general health of the victim. The most common symptoms are nausea, vomiting, retching, abdominal cramping, and prostration. In more severe cases, headache, muscle cramping, and transient changes in blood pressure and pulse

rate may occur. Recovery generally takes two days.

- *Shigella spp.* are highly infectious bacteria that are transmitted by the fecal-oral route. As few as 10 bacterial cells can cause the gastro-intestinal infection. The symptoms of shigellosis occur within 12 to 50 hours of ingesting contaminated food or water and include abdominal pain, cramps, diarrhea, fever, vomiting and blood or mucus in the stools. Complications may include reactive arthritis and hemolytic uremic syndrome. Infants, the elderly, and the infirm are susceptible to the severest symptoms of disease, but all individuals are susceptible to some degree. Shigellosis is a very common malady suffered by individuals with acquired immune deficiency syndrome.
- *Yersinia enterocolitica* is a bacterial infection that causes fever and abdominal pain and often diarrhea and/or vomiting. Yersiniosis is more common in Northern Europe, Scandinavia, and Japan than in the United States. Complications of yersiniosis include reactive arthritis (about 2–3% frequency) and rarely bacteremia (entrance of organisms into the blood stream). Fatalities are rare.
- *Escherichia coli* is a common bacteria, but several strains have the potential to cause foodborne illness, accounting for just over 4% of known bacterial causes of foodborne illness in the United States. *E. coli* 0157:H7 causes the most serious illness, as it is responsible for 3% of total hospitalizations and 3% of total deaths from known pathogens. *E. coli* O157:H7 can cause severe bloody diarrhea. The symptoms begin to occur within one to eight days, and the illness generally lasts 5 to 10 days. About 5% of persons who are infected with *E. coli* 0157:H7 develop serious complications such as kidney failure and blood clots in the brain. Children and the elderly are much more likely to have serious complications from *E. coli* 0157:H7. In young children, *E. coli* 0157:H7 is the leading cause of acute kidney failure.
- *Bacillus cereus* is a spore forming organism that produces two types of toxins when environmental conditions permit its growth in food. These toxins cause two types of symptoms: diarrhea is caused by a large molecular weight protein, while vomiting is caused by a low molecular weight, heat-stable peptide. If the number of *B. cereus* bacteria exceeds one million per gram in a food, toxin is likely to be present. The diarrheal illness, including abdominal cramps, occurs 6–15 hours after consumption of contaminated food and persists for about 24 hours. The type of illness characterized by nausea and vomiting generally occurs more quickly, within 0.5 to 6 hours after consumption of contaminated foods, and lasts less than 24 hours.
- *Vibrio spp.* At least three species of *Vibrio* are involved with foodborne illness: *Vibrio parahaemolyticus*, *Vibrio vulnificus*, and *Vibrio cholera*. They cause somewhat different illnesses, but all are associated with seafood.
- *Vibrio parahaemolyticus* causes a usually mild to moderate infection with associated diarrhea, abdominal cramps, nausea, vomiting, headache, fever, and chills. Ingestion of greater than one million organisms causes disease, although the dose may be lowered if stomach acid is buffered by food or antacids. Illness occurs within 4–96 hours when the organism attaches itself to the small intestine and excretes a toxin. Illness usually lasts about 2.5 days.
- The ingestion of *Vibrio vulnificus* can cause serious blood infection in individuals with underlying chronic disease such as diabetes or leukemia, or those taking immunosuppressive drugs. Rapid death occurs in about 50% of cases. For healthy individuals, ingestion of this organism can result in gastroenteritis. The infective dose for gastrointestinal symptoms in healthy individuals is unknown, but for susceptible persons the infective dose is less than 100 total organisms.
- The infection caused by *Vibrio cholera*, which attaches to the small intestine and produces a toxin, creates mild to acute watery diarrhea, abdominal cramps, nausea, vomiting, dehydration, and shock. If there is severe fluid and electrolyte loss, death may occur. Human volunteer feeding studies utilizing healthy individuals have demonstrated that approximately one million organisms must be ingested to cause illness.
- *Listeria monocytogenes* bacteria rarely cause illness (an estimated 2500 foodborne cases per year), but those who get listeriosis are frequently hospitalized and about 20% of cases result in death. Pregnant women, the elderly, and those with compromised immune systems are vulnerable to *Listeria* infection. If a pregnant women gets listeriosis, the infection can be passed to the unborn child and cause death to the fetus. Listeriosis can occur within 1 day or up to 3 weeks of ingesting contaminated food.
- Botulism is a rare, but deadly food poisoning, causing an estimated 58 cases and 4 deaths per

year. This pathogen has the ability to form spores that are very resistant to heat. Ingestion of the spores or vegetative cells is generally harmless (with the exception of infant botulism), but when vegetative cells grow, they produce a toxin that is one of the most deadly agents; a few nanograms is sufficient to cause the death of an adult.

C. Parasites

Parasitic pathogens cause about 3% of known foodborne illnesses in the United States (1). Several types of parasites can be found in food and water, including *Toxoplasma gondii* (the cause of toxoplasmosis), *Trichinella spiralis* (the cause of trichinosis), *Giardia lamblia, Cryptosporidium parvum,* and *Cyclospora cayetanensis*. Parasites do not reproduce in food, and usually require more than one animal species to carry out their life cycle.

- One parasite of note, *Toxoplasma gondii* usually causes a mild, self-limiting infection. About 30% of Americans have likely been infected with *Toxoplasma*. House cats and many other animal species (including animals raised for meat), as well as humans may carry *Toxoplasma*. Pregnant women who become infected with *Toxoplasma gondii* during pregnancy may transmit the disease to their unborn child, resulting in severe illness in the child. Toxoplasmosis has been increasing in frequency due to increases in the numbers of immunocompromised individuals (15). Additional information about *Toxoplasma gondii* is in Table 75.1.

Although causes of foodborne illness like those described above have been recognized for decades, new pathogens that can cause foodborne diseases continue to be identified, and that trend is likely to continue.

III. FOOD SOURCES OF FOODBORNE DISEASE

Almost any food can be a source of foodborne pathogens, but some foods are more likely to be sources, and require more careful handling. In addition, foods which are termed "potentially hazardous" support the rapid growth of bacterial pathogens and must be kept out of the Danger Zone (40° to 140°F). Sometimes these foods are also called "perishable" foods. These foods are usually moist and low in acid and include:

- foods of animal origin such as meat, milk, cheese, poultry, eggs, fish, and seafoods
- foods of plant origin that have been heat treated, including cooked vegetables, beans, and rice
- raw sprouts
- cut melons, peeled carrots, and other peeled vegetables and fruits
- cooked pasta
- tofu and other moist soy protein products
- sauces such as Hollandaise and many other sauces (unless they are high in acid)

The Center for Science in the Public Interest, a consumer activist group that specializes in food issues, has compiled a list of foods that have caused foodborne illness from 1990 to 2001 using outbreak data reported to the CDC (16). The top six food categories linked to food-poisoning outbreaks were multi-ingredient foods, seafood, eggs, produce, beef, and poultry.

Food	Number of Outbreaks	Number of Cases
Multi-ingredient foods, such as salads, pizza, and sandwiches	337	23,142
Eggs and egg-dishes	271	10,827
Produce, including sprouts, lettuce, berries, and cantaloupe	148	9,413
Beef	134	6,089
Seafood	340	5,133
Poultry	79	4,279

Some foods are more likely to be sources of specific pathogens. The foods associated with specific pathogens are discussed below (pathogens arranged in alphabetical order).

- *Bacillus cereus*, which produces two kinds of toxins in foods, has been associated with a wide variety of foods. Meats, milk, vegetables, and cereal dishes are foods that have caused the diarrheal-type illness. The vomiting-type of illness is generally associated with starchy foods, such as rice products, potatoes, and pasta; vegetable sprouts and pasteurized cream have also been implicated (17).
- *Campylobacter jejuni* bacteria are normally found in warm-blooded animals such as cattle, poultry, and pigs. These bacteria may be present in food products that come from these animals, such as raw meat, poultry, eggs, or unpasteurized dairy products. Handling raw poultry and eating undercooked poultry is associated with many sporadic cases of campylobacteriosis (18). A majority of chicken available in the U.S. (63 to 88%) is contaminated with *Campylobacter* (19, 20).

- The bacteria that cause botulism, *Clostridium botulinum*, are indigenous in soil and water and have the ability to form spores. They become dangerous when environmental conditions of low oxygen and low acidity allow them to multiply and produce a toxin. Low-acid foods such as meat, fish, poultry, or vegetables that are improperly canned can provide a growth environment for these bacteria. The toxin also may be produced in low-acid cooked foods left too long at room temperature, such as baked potatoes or potpies. Homemade mixtures of raw garlic stored in oil at room temperature have also caused outbreaks (17).
- *Clostridium perfringens* bacteria are widely distributed in the environment (soil, water, foods) and frequently occur in the intestines of humans and many domestic and feral animals. Spores of this bacterium persist in soil, sediments, and in areas subject to human or animal fecal pollution. Meat, poultry, vegetables, beans, rice, and spices are foods in which *C. perfringens* have been identified. Meat dishes that are prepared one day and served the next day have been the source of a number of perfringens food poisoning outbreaks (17).
- *Escherichia coli* 0157:H7 can be transmitted through food and water. A wide variety of foods, including undercooked ground beef, raw (unpasteurized) milk, uncooked sprouts and unpasteurized juices as well as contaminated drinking water have been associated with *E. coli* 0157:H7 outbreaks. *E. coli* 0157:H7 also can be transmitted from person to person. This is particularly a problem in day care centers where young children are in close contact. If the bacteria are on the hands, they can be spread by touching another person or by touching food that will not be cooked before eating (21).
- *Listeria monocytogenes* has been isolated from a wide variety of foods including milk and dairy products, meat and meat products, vegetables, and seafood. Foods associated with outbreaks have generally been highly processed, capable of supporting the growth of *L. monocytogenes*, had extended shelf life at refrigeration temperature and were ready to eat. *L. monocytogenes* is able to colonize food-processing environments for long periods of time, is tolerant to sodium chloride and sodium nitrate, and can grow on a wide variety of foods at refrigeration temperatures. Thus, food manufacturers must be vigilant to prevent post-processing contamination (22). Pregnant women and others who are at risk of listeriosis are advised to either avoid or reheat paté, smoked seafood, fresh soft cheeses, luncheon meats, hot dogs, smoked fish and deli salads because these foods have been implicated in listeriosis outbreaks (23).
- *Salmonella* are normally found in warm-blooded animals such as cattle, poultry, and pigs, and foods of animal origin cause most of the *Salmonella* infections in humans. Consumers need to be aware that these bacteria may be present in raw meat, poultry, eggs, or unpasteurized dairy products. *Salmonella* outbreaks have also been associated with fresh fruits and vegetables and packaged products (17, 24).
- Since *Staphylococcus aureus* is primarily carried on human skin and in the respiratory tract, foods that require extensive handling during preparation and that are kept at Danger Zone temperatures after preparation are frequently involved in staphylococcal food poisoning. Some of the foods that are often involved in staphylococcal food poisoning include meat and meat products; poultry and egg products; salads such as egg, tuna, chicken, potato, and macaroni; bakery products such as cream-filled pastries, cream pies, and chocolate éclairs; sandwich fillings; and milk and dairy products (25).
- *Shigella* is principally a disease of the human intestinal tract and is rarely found in animals. These bacteria are found frequently in water that is polluted with human feces. The contamination of foods with *Shigella* occurs via the fecal-oral route when food handlers do not follow proper hand washing practices or when fecally contaminated water is used for irrigation or processing. Salads (potato, tuna, shrimp, macaroni, and chicken), raw vegetables, milk and dairy products, and poultry have all been involved in outbreaks (26).
- *Yersinia enterocolitica* occurs naturally in animals (pigs, birds, beavers, cats, and dogs) and in the environment (ponds, lakes). This organism has been found in meats (pork, beef, lamb, etc.), oysters, fish, and raw milk, but the exact cause of the food contamination is unknown. Poor sanitation and improper sterilization techniques by food handlers are postulated as contributing to contamination (27). Most cases are associated with pork (17).
- Infections with *Vibrio* spp. have been associated with the consumption of raw, improperly cooked, or cooked, recontaminated fish and shellfish. Improper refrigeration of contaminated seafoods will allow an increase of

pathogen numbers, which increases the possibility of infection. Infection increases during the warmer months of the year (28). Sporadic cases occur along all coasts of the U.S. (17).

IV. CONSUMER PREVENTION AND CONTROL OF FOODBORNE DISEASES

Review of the pathogens of most concern in consumer food safety indicates that the control of these pathogens requires hand washing, kitchen cleanliness, avoidance of cross-contamination and of unsafe foods, heating to appropriate temperatures, and refrigeration. Educating consumers about food safety has coalesced around four or five basic messages. The Partnership for Food Safety Education is a coalition of industry, government and consumer groups formed in 1997 to educate the public about safe food handling and reduce foodborne illness. The coalition developed the Fight BAC!® campaign to promote four steps — Clean, Cook, Chill and Separate — that consumers "can take to fight foodborne bacteria and reduce their risk of foodborne illness" (29). A recent review of the food safety literature identified and categorized common food handling messages, then used a Delphi process with a panel of food safety experts to identify the most important messages (30). They identified five pathogen control factors: 1) Practice personal hygiene, 2) Cook foods adequately, 3) Avoid cross-contamination, 4) Keep foods at safe temperatures and 5) Avoid foods from unsafe sources (1 through 4 are in concert with the Fight BAC!® steps). The pathogens shown in Table 75.1 are grouped according to these control factors needed to prevent them from causing a foodborne illness. The details associated with these messages are presented below.

A. Practice Good Personal Hygiene

The most important food safety message for consumers is adequate and frequent hand washing. Most of the foodborne illnesses that can be prevented by good personal hygiene are those that are transmitted from an infected person's intestines to another person, the fecal-oral route. These include particularly the norovirus and Hepatitis A viruses, and the bacterial pathogen *Shigella*. Consumers need to be reminded about the times to wash hands: always after using the toilet, changing a diaper, or petting an animal, and before handling food or eating food. Pathogens can be transferred to the hands from a variety of sources. Some foodborne pathogens, including norovirus and hepatitis A virus, *E. coli*, and some other types of bacteria, plus some parasites such as *Giardia*, can also be transmitted directly from person to person, often via the hands of an infected person. Animals at home, on the farm, or in a petting zoo are also sources of pathogens, as well as dirt, manure, or a sandbox. *Toxoplasma gondii*, for example, is commonly found in dirt or sand in areas where there are outdoor cats. Consumers should also be encouraged to teach and model good hand washing practices to their children. Regular hand washing can help consumers avoid transferring pathogens from raw food, the environment, or their body onto ready-to-eat foods.

Most consumers know about the need to wash hands, but do not always put knowledge into practice. A survey and observational study conducted for the American Society of Microbiology's (ASM) Clean Hands Campaign found 95 percent of men and women say they wash their hands after using a public restroom, but only 67 percent of people actually do wash before leaving the restroom (31). Hand washing studies also suggest that consumers need to be reminded about the techniques for hand washing that adequately remove pathogens from hands. Use of warm water assists in dissolving foreign materials and encourages longer washing. Soap is a surfactant and is necessary to loosen dirt and pathogens from the skin so they can be rinsed away. In spite of the prevalence of antibacterial soaps available to consumers, they are not necessary and may potentially contribute to the problem of antibacterial resistance (32). A fingernail brush helps remove dirt and feces. Hand washing research suggests that 15 to 20 seconds are necessary for adequate pathogen removal and that thorough drying of hands is necessary to prevent recontamination (33). The use of disposable paper drying towels is preferred, although frequently (daily) changing of a cloth hand towel is acceptable practice in homes.

Consumers who are sick with diarrhea should not prepare food for others. Fecal matter can contain millions of pathogenic viruses or bacteria (5), and the infectious dose is low for many pathogens. People can easily miss a few pathogens when hand washing and unintentionally infect someone else. Personal hygiene messages also need to stress that cuts and burns on hands should be covered with a bandage and disposable plastic gloves during food preparation because infected lesions can be a source of *Staphylococcus aureus.*

Specific food handling messages for consumers that focus on good personal hygiene should include:

- Wash hands after any contact with raw poultry, meat, or seafood.
- Work with clean hands, clean hair, clean fingernails, and wear clean clothing.
- Avoid using hands to mix foods when clean utensils can be used.
- Keep hands away from one's mouth, nose, and hair.
- Cover the nose and mouth with disposable tissues when coughing or sneezing, and wash hands thoroughly afterward.

- Use a clean spoon each time when tasting food while preparing, cooking, or serving.
- Wash hands after smoking.

B. Cook Foods Adequately

Cooking is an essential part of making foods safe to eat since foodborne pathogens are killed by heat. Almost all pathogens are killed when food is heated to 160°F for a few seconds; lower temperatures for longer periods of time also kill pathogens (34). The best way to be certain food has been cooked to the proper temperature is to check it with a food thermometer. However, only a small percentage of consumers use food thermometers when preparing food. For example, 12 to 24% of consumers say they use a meat thermometer (2). Only 3 to 6% use a thermometer to check endpoint temperature of hamburgers (35). Educating and motivating consumers to use instant-read food thermometers more frequently is the focus of USDA's Thermy™ Campaign (36).

Two types of instant-read food thermometers are generally available to consumers: bimetallic coil dial thermometers and thermister digital thermometers. The best kind of thermometer to use is a thermister digital thermometer. The thermister is located in the tip of the probe and is a ceramic semiconductor whose electrical resistance changes with temperature. It can be used in both thick and thin foods. Even though the temperature sensor is in the tip, the tip still must be inserted at least ½-inch deep into the middle of the thickest part of the food. Digital thermometers require about 10 seconds to register the correct temperature. When testing thin or small items for temperature, it is best to insert the thermometer from the side. Instant read dial thermometers use a bimetallic coil to sense temperature; the bimetal coil generally occupies the lower 2 to 3-inches of the thermometer stem, so for these thermometers the entire lower 2 to 3 inches of the stem must be inside the food. For thin foods, it must be inserted sideways. Instant read thermometers, dial and digital, are used to test for doneness near the end of the cooking time; they are not designed to be left in the food during cooking. Instant read thermometers should be tested for accuracy periodically using ice water or boiling water (37).

Consumers need to assume that raw (uncooked or unpasteurized) meats, poultry, fish, shellfish, milk, and eggs contain pathogens, and eating them raw or lightly cooked presents a food safety risk. Many pathogens live naturally in the intestinal tracts of food animals. Surveys of poultry cuts sold in retail food stores indicate that between 1/4 and 3/4 are contaminated with *Salmonella* and/or *Campylobacter* (20). Due to the grinding and mixing process, ground meats such as hamburger, sausage and ground poultry products may be contaminated with pathogens throughout the meat, requiring that ground meat items be cooked throughout to 160°F. Parasites such as *Toxoplasma* or *Trichinella* may be in the muscles of some animals, particularly pigs. Thus, pork also requires thorough cooking to kill parasitic as well as bacterial pathogens. Roasts and steaks from other animals usually only have pathogens on the surface of the meat unless the meat is pierced for tenderizing or pumping. Rare beef steaks and roasts are much less risky than rare pork or undercooked ground meat. Wild game may have a higher level of bacteria than commercially slaughtered meat because of the difficulty of handling game in the field, thus thorough cooking of all game meat is recommended. *Salmonella* sometimes contaminate the inside of the egg as well as the eggshell itself; about 1 egg out of every 20,000 contains *Salmonella* inside the shell (38). Shellfish may pick up bacteria and viruses from contaminated waters (13). Fish may contain parasitic worms. These microorganisms then can infect anyone who eats the shellfish or fish if they are not cooked properly.

Seventy-four to 92 percent of consumers are aware of risks associated with eating rare meats or poultry, raw or lightly cooked fish and shellfish, raw milk, and foods made with raw or lightly cooked eggs. However, 80 to 93% do not know the correct temperatures for safe heating of foods (2). Any foods likely to be contaminated with pathogens should be heated to an internal temperature of 160°F; at this temperature, most pathogens are killed very quickly (34). Safe heating temperatures for foods are shown in Table 75.2. Consumers should be advised to check the temperature with a thermometer to be certain the food is fully cooked.

C. Avoid Cross-Contamination

Caution to prevent the moving of pathogens from one food to another food is an especially critical consideration when dealing with food that is ready-to-eat. Cross-contamination is a relatively common mistake made by home food preparers. A case in point is *Campylobacter jejuni*, a common contaminant of poultry from the grocery store. *Campylobacter* is relatively easy to kill by cooking, and few people eat undercooked poultry. Yet there are about 2 million cases each year of foodborne illness resulting from *Campylobacter*, good indirect evidence that cross-contamination is common. In a United Kingdom study of consumer food handling behavior, it was found that 17% of homemade chicken salads prepared in a model kitchen were positive for *Campylobacter* as a result of cross-contamination during preparation (2).

Although it may be challenging within the confines of some small domestic kitchens, consumers can prevent cross contamination by always keeping cooked and ready-to-eat foods separate from raw foods. Food preparation surfaces need to be cleaned before and after preparing food. After any contact with raw poultry, meat, seafood, or

TABLE 75.2
Endpoint Temperatures to Control Pathogens in Specific Foods

Minimum Interior Temperature	Food Item	Details
160°F	Ground meats (including turkey and chicken)	Using visual signs to determine that ground beef is done is risky because it has been shown that 1 in 4 hamburgers appears brown before reaching 160°F.
	Pork and game meats	These meats may contain parasites. Game meats may contain more pathogens than commercially slaughtered meat due to less controlled slaughter and cutting conditions.
	Poultry	When poultry is cooked to 160°F, the meat may not look and taste 'done', although pathogens will be killed. At 170°–180°F, the flavor, texture, or appearance will be that associated with fully cooked poultry.
	Eggs	Either check the temperature with a thermometer or else cook eggs until both the yolk and white are firm. Visual cues are adequate since pathogens will be killed if the yolk and white are cooked enough to be firm.
	Food mixtures containing eggs or raw meat	Visually difficult to assess doneness; use a thermometer to check temperature.
145°F	Beef steaks and roasts, ham, lamb	Heat exterior sufficiently to kill pathogens. Interior not likely to contain pathogens.
	Fish and shellfish	Visual cues are commonly used to determine if fish and shellfish are thoroughly cooked. Cook fish until it flakes and loses its translucent or raw appearance, and cook shellfish until the shell opens and the flesh is fully cooked. Little research has been done to identify the cooking temperatures required to kill pathogens on fish and shellfish, and the cooking recommendations are based more on quality of the cooked product than on actual scientific data.
165°F	Leftovers, reheating of those to be served hot	Re-heat to kill pathogens that may have survived the first cooking or that were introduced after cooking. However, *Staphylococcus aureus* toxin is not destroyed by heating leftovers.
	Hot dogs, deli meats for some people	Pregnant women, the elderly and those with compromised immune systems should reheat before eating. Because these items have been fully cooked previously, they, like leftovers, should be heated to 165°F.

any other potentially hazardous foods, hands, knives, cutting boards, food preparation surfaces, and sink need to be thoroughly washed. For utensils and hard nonporous surfaces, washing and rinsing should be followed by sanitizing with a dilute chlorine solution and air drying. Mixing 1 tablespoon of bleach (5.25% sodium hypochlorite) to one gallon of water produces an approximately 200 ppm chlorine sanitizing solution (39, 40) that will kill most pathogens. Household bleach is easily available to consumers. For best efficacy, the chlorine solution should be left in contact with the surface for two minutes before rinsing. Storing the dilute bleach solution in a spray bottle can make sanitation more convenient. Dilute bleach solutions do lose strength over time (41) and should be re-made regularly. Kitchen countertops should be washed with soap and water before food preparation if previous use of the surface is not known; for example, if there is a cat in the house that gets on the counters.

Fresh produce should be rinsed thoroughly under running water before preparing or eating. Rinsing does not remove all pathogens, but it reduces the number present by about 90 to 99 percent (42, 43). Pathogens have been isolated from a wide variety of fresh produce, and outbreaks of foodborne illness have been associated with many types of produce, including cantaloupes, lettuce and tomatoes. If contamination is present on the skin of the fruit or vegetable, the pathogens move into the fruit when it is sliced. Removing the skin or rind reduces the risk (44).

During the preparation and storage of raw meat and poultry items it also important to avoid cross-contamination. It is best to have two cutting boards — one for raw meat, fish, and poultry, and another for food that will not be cooked before eating. Colored cutting boards, which allow boards to be more easily restricted for use with one food category, are increasingly available. A hard, nonporous cutting board such as one made of acrylic is easier to clean than a wooden board because the acrylic board can be washed in the dishwasher. In the refrigerator, raw meat and poultry should be placed on a tray or plate to prevent juices from dripping onto other food. The refrigerator "meat drawer" should be used for the storage of either raw or ready-to-eat meats, not both. All family members should be aware of refrigerator storage rules. When moving raw meats to a cooking site (such as grilling outdoors), it is important to remember to bring a clean plate or other clean container for the cooked meat in order to prevent cross contamination.

Kitchen cloths and sponges can be a major source of cross-contamination. Bacteriological surveys of kitchen dishcloths and sponges have shown the presence of many pathogens (45). Dishcloths and sponges need to be laundered frequently. Drying dishcloths in a clothes dryer aids in killing pathogens. Sponges can be washed in the dishwasher. Wet dishcloths and sponges can be sanitized by heating them in a microwave oven for one minute on high (45, 46). They also can be disinfected by soaking in a bleach solution (3 tablespoons of bleach per quart of water) for 5 minutes, then rinsed and dried (40). Paper towels should be used to clean up spilled juices from raw meat or poultry.

D. Keep Foods at Safe Temperatures

Most bacterial pathogens grow most rapidly at temperatures of 60° to 125°F. Controlling bacterial growth in potentially hazardous foods requires temperature control; the old adage "keep hot foods hot" (above 140°F) and "cold foods cold" (below 40°F) is frequently used to reinforce the message. Figure 75.1 summarizes the temperature information needed by consumers to control the growth of bacteria in foods. Temperature control recommendations for consumers differ from those used in foodservice because consumers are unlikely to keep track of the amount of time foods are kept at different temperatures.

Recommendations for consumers center around the temperatures needed for hot holding, the types of foods requiring refrigeration, proper refrigerator temperature and the limitation of time these foods are held at room temperature. Recommendations for consumer refrigerator temperature is 40°F or below (47). Prepared and leftover foods should not be at room temperature more than 2 to 3 hours, including all time involved during preparation, storage, and serving. When shopping, consumers are advised to pick up perishable foods as the last stop in the grocery store, and, especially in hot weather, get them home and into the refrigerator quickly, using an ice chest or cooler for transportation of perishable items when shopping is done more than 30 minutes from home. A recent study found that most (68%) consumers refrigerate or freeze meat within 1 hour of purchase, but 9% did not place meat purchases in cold storage until more than 2 hours (and up to 8 hours) had elapsed (48). Research indicates that about 13% of consumer refrigerators are above 40°F, and most (80%) do not have a thermometer in the refrigerator (49). Brown and colleagues (49) also reported that 78% of people did not know the correct temperature to maintain in home refrigerators. It would aid consumers in maintaining safe food if refrigerators came equipped with built in thermometers that clearly marked the temperatures recommended for cold food storage.

Foods need to be stored to prevent cross-contamination in the refrigerator. It is best to store meat, poultry and fish on a dish or tray. Refrigerators require periodic cleaning. A recent study from Ireland found that foodborne pathogens were commonly present in home refrigerators. *Staphylococcus aureus* was found in 40%, *E. coli* and *Listeria* in 6%, and *Salmonella* in 7% of the home refrigerators, indicating that some refrigerators are unclean and unsafe for food storage (50). Washing refrigerator interior surfaces with a solution of one gallon of water mixed with one-half cup of unscented ammonia is a recommended cleaning method (51).

A common consumer practice is to cool foods at room temperature prior to refrigerating in the mistaken belief that placing hot foods in the refrigerator is harmful to the appliance. Small amounts of warm or hot foods may be put into the refrigerator, but it is advisable to speed the cooling of larger quantities by cooling the container of food in a pan of ice water, stirring and replacing the ice frequently until the food has cooled to about 100°F, then refrigerating the food in shallow containers. Consumers are advised to set a timer for about 30 to 45 minutes as a reminder to check to see if the food is cooled enough to be refrigerated (52).

Planning ahead for proper cooling and reheating of food prepared in large quantities and/or prepared for transporting to other sites, such a picnics, potluck dinners, camping trips and packed lunches, requires special attention. This involves planning the amount of needed refrigerator space (to include good circulation) or ice and cooler space to keep foods at safe temperatures. If perishable foods from picnics or potlucks are not kept adequately chilled or heated during serving, they should be thrown out if in the Danger Zone for 2 to 3 hours.

Frozen perishable foods must be thawed in the refrigerator, under cold running water, or as a part of the cooking process. If food is thawed in a microwave, it should be cooked right after it thaws.

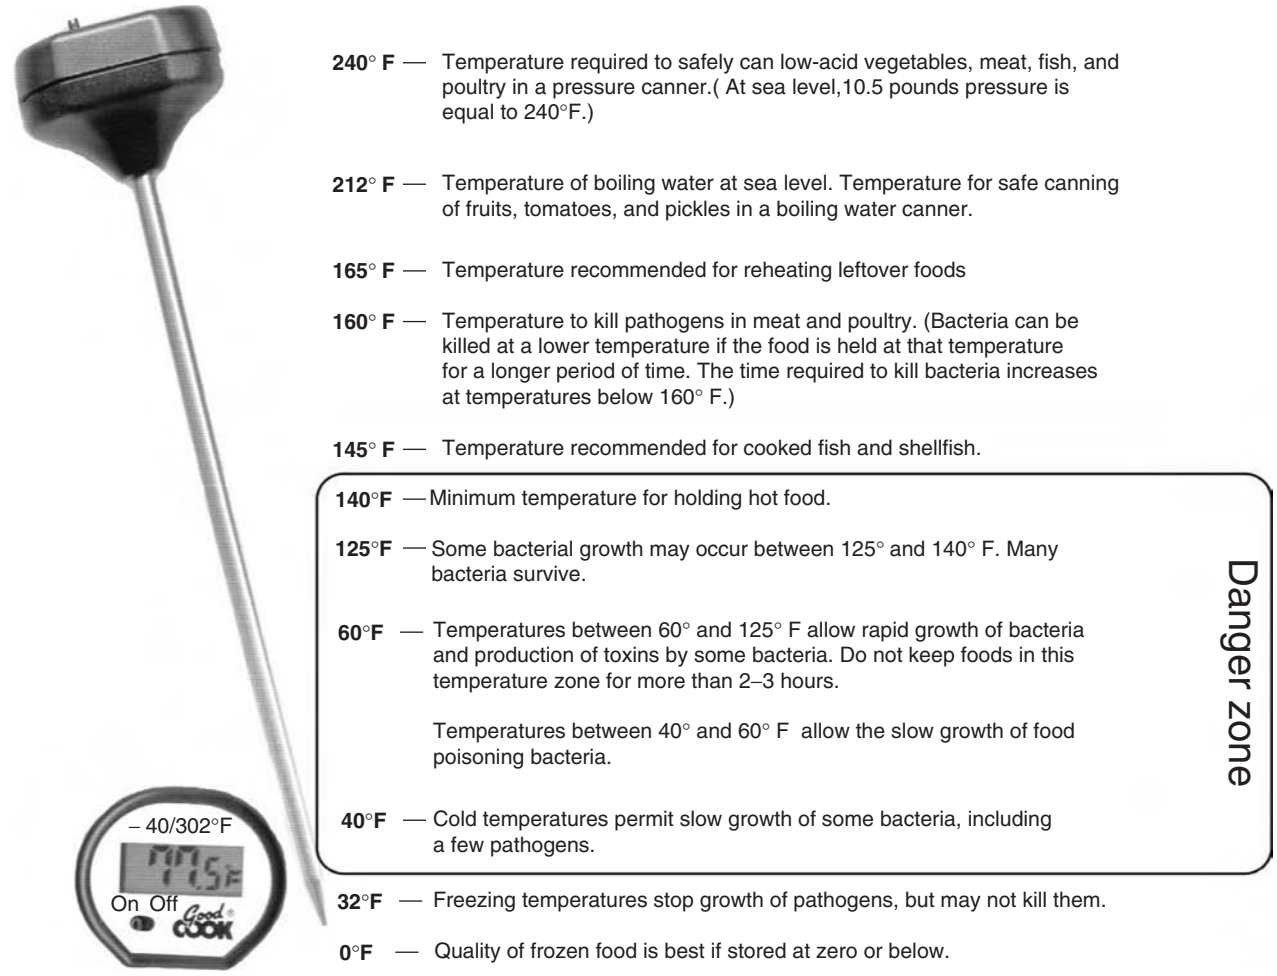

FIGURE 75.1 Safe handling food temperatures.

E. Avoid High-Risk Foods and Water

Some foods have such a high probability of being contaminated with pathogens or toxins that their consumption should be avoided by all individuals. The risk is highest for people susceptible to foodborne illness. Many of these foods are ready-to-eat and have been produced or processed in a way that does not kill pathogens. Foods frequently linked to foodborne illness include:

- Unpasteurized milk and milk products
- Raw or undercooked meats and poultry
- Unpasteurized fruit juice
- Raw sprouts of all types
- Raw seafood and fish
- Raw or undercooked eggs
- Contaminated water

Specific consumer advice for reducing the chance of contracting a foodborne illness includes:

- Drink only pasteurized milk and fruit juices.
- Avoid eating undercooked or raw meat (such as steak tartare).
- Use cheese and yogurt made from pasteurized milk.
- Cook sprouts before eating.
- Cook fish and shellfish before eating them.
- Avoid eating foods containing raw eggs. Use pasteurized eggs or egg products in food containing uncooked eggs.
- Use water from a safe water supply for drinking and for food preparation.
- Obtain shellfish from approved sources such as grocery stores (rather than from an unlicensed roadside vendor) (30).

V. SPECIAL INFORMATION FOR CONSUMERS MORE SUSCEPTIBLE TO FOODBORNE DISEASE

Some people are more susceptible to foodborne disease because of suppressed immune function. These include the very young, elderly, pregnant, people who have diseases such as AIDS, cancer or diabetes, and those whose immune

system is suppressed by other medical conditions. These groups represent 20% of the American population (23).

All food safety guidelines related to hand washing, cooking meat, seafood, poultry and eggs properly, avoiding cross-contamination and keeping foods at safe temperatures are important for control of food illnesses of all people, including those in high-risk groups. In addition to following the guidelines listed above, additional precautions are suggested for the high-risk groups. Pregnant women should be encouraged to avoid ready-to-eat foods known to be sources of *L. monocytogenes*, avoid contact with cat feces, and cook or reheat foods well before eating. Elderly and immune compromised persons should avoid raw or undercooked seafood, raw sprouts, foods that contain raw eggs, and food known to be sources of *L. monocytogenes.* For young children, use of pasteurized milk and fruit juices, avoiding raw sprouts, and washing fruits and vegetables before eating are important food safety behaviors (23).

VI. FOODS THAT CONSUMERS SHOULD HANDLE WITH EXTRA CARE

While all foods should be handled by following the basic rules (practice good personal hygiene, cook foods adequately, avoid cross-contamination, and keep foods at safe temperatures), some foods require extra care or special handling.

- **Eggs and foods containing eggs.** Fresh eggs must be handled carefully, for even eggs with clean, uncracked shells may contain *Salmonella* bacteria. Eggs should be purchased only from a refrigerated case and checked for cleanliness and intact shells. Eggs should be refrigerated promptly in their original carton and not in the rack that may be on the refrigerator door, because the temperature on the door fluctuates widely. Eggs and dishes containing eggs need to be cooked thoroughly, with both the yolk and white cooked to firmness or to 160°F. Dishes containing eggs should be cooked to 160°F as verified by thermometer. Dishes with raw or lightly cooked eggs require the use of pasteurized eggs or a modified recipe (available from the American Egg Board http://aeb.org). Cooked eggs and egg dishes should be reheated or refrigerated within 2–3 hours of their preparation, including hard-cooked eggs used for Easter egg hunts.
- **Thawing meat/fish/poultry.** Recommended thawing of frozen meat, poultry and fish includes thawing in the refrigerator (generally requires 24 hours for each five pounds of product) or submerging the frozen package in a watertight plastic bag under cold water. Since cold water thawing requires about 30 minutes per pound of frozen meat, it should not be used for very large items (10 hours would be needed to thaw a 20 lb. turkey by this method). The risk of bacterial contamination could be high if the water is not changed regularly during thawing (53).

  If meat is microwave-defrosted, it must be cooked promptly after thawing because some areas of the food become warm during microwaving. Raw meat can be thawed at room temperature for short periods of time as long as it is refrigerated or cooked while it is still cold and contains ice crystals. Cooking from the frozen state requires food to be cooked about 1½ times longer than for thawed products of the same size and shape.
- **Ground meats.** Ground meat must be handled with special care because bacteria on the surface are spread throughout the meat during grinding. Ground meats should always be cooked to 160°F, and verified with a thermometer inserted sideways into meat that has been lifted out of the pan on a spatula. Turning ground meat patties frequently assures even distribution (54).
- **Hot dogs and lunch meats.** These products are perishable and should be kept in the refrigerator. Hot dogs should be cooked before eating and luncheon meats should be heated to steaming if they are to be eaten by a person at high risk for listeriosis.
- **Stuffed meat or poultry.** When stuffing meats and poultry, stuffing should be not be tightly packed, to allow heat to penetrate throughout quickly, and these items should be stuffed just before cooking. Stuffing needs to reach a temperature of at least 165°F as verified with a thermometer. Whole, stuffed poultry should not be cooked in a microwave oven because the stuffing may not get hot enough to kill harmful bacteria.
- **Using a microwave oven to cook meat, poultry, or fish.** Cooking in a microwave oven can leave cold spots that present a food safety problem. Using meat that is the same temperature throughout aids in even cooking; if defrosted in the microwave, a rest period of 20 to 30 minutes between defrosting and cooking allows the temperature to equalize. Covering the meat item, cooking at medium power (50%), and rotating food frequently all aid in more even cooking and the elimination of cold spots. A food thermometer should be used to ensure food is cooked to the proper temperature. Letting food

stand covered for 5–10 minutes after cooking also equalizes internal temperatures.

- **Fresh produce.** The U.S. Food and Drug Administration (FDA) has offered specific consumer advice about the purchase and handling of fresh produce: buy produce that is not bruised or damaged; fresh cut produce should be refrigerated or surrounded by ice at the store; perishable produce should be promptly refrigerated; wash produce just before eating using cool tap water and reasonable agitation, and removing bruised or damaged areas (prewashed packaged vegetables labeled "Ready To Eat" do not need to be washed at home; firm produce such as melons and cucumbers should be scrubbed with a clean produce brush) (55). Some outbreaks of *E. coli* O157:H7 have been caused by apple cider; homemade apple cider should be heated to at least 160°F.
- **Honey.** Infants are susceptible to a very rare form of botulism that is caused by ingesting *Clostridium botulinum* bacteria. An infection results when these bacteria grow in the infant's intestinal tract. (In contrast, botulism in adults is caused by eating food contaminated with the toxin that the bacteria produce.) Babies with infant botulism are constipated and have difficulty holding up their heads and sucking. Because honey can contain *C. botulinum*, the U.S. Centers for Disease Control and Prevention state that children who are less than a year old should not be exposed to honey (56). (This includes foods made with honey such as honey graham crackers, muffins and jellies.) Pasteurized honey is not a solution, because the heat treatment that produces the desired crystallization is too mild to kill the spores. While only 5 percent of the nation's infant botulism cases have been traced to honey, protecting children from honey before their first birthdays is one step that parents and caregivers can actively take.
- **Home canned foods.** Low-acid foods (meat, fish, poultry, and vegetables) must be canned in a pressure canner. Boiling-water canners, ovens, steamers without pressure and open kettles do not get the food hot enough to kill the spores of *Clostridium botulinum*, so it is not safe to can vegetables, fish, meat or poultry — or mixtures containing these foods — by any method other than using a pressure canner. Tomatoes with added acid in the form of lemon juice or citric acid, pickled vegetables, and fruits can be canned safely in a boiling water canner because they are more acidic. However, overripe tomatoes or tomatoes from frost-killed vines should not be used for canning since they lose acidity as they mature or if they are frozen. Many Cooperative Extension offices have information and bulletins, and some conduct classes, with specific directions and scientific time and temperature recommendations for home canning and other food preservation methods. Research based information for home canning, the *USDA Complete Guide to Home Canning*, is available online at the National Center for Home Food Preservation (57).

VII. MOTIVATING CONSUMERS TO ADOPT SAFE FOOD HANDLING PROCEDURES

Many consumers are aware that they can reduce their risks of foodborne illness by their own actions regarding hand washing, adequate cooking, avoiding cross-contamination, refrigeration of foods and avoiding risky foods and water. However, they may not have sufficient motivation and knowledge plus the proper equipment to successfully implement all of the recommended behaviors. Some examples of barriers to adopting recommended behaviors and ways to reduce the barriers follow:

- Strong motivation is required to modify habitual behaviors. Change may occur when people participate in programs that make them aware of their actions when they wash their hands or when preparing food in a way that results in cross contamination.
- Knowledge regarding how to implement recommended behaviors may be lacking. To reduce this barrier, food safety education should be more common, including in school curricula, and emphasized in television cooking shows.
- Current recommendations may be different from what the person learned previously. For example, the current recommendation is to cook ground beef to 160°F. Previously, consumers were advised to cook ground beef until it appeared to be cooked and had no traces of pink. Extensive education about the new recommendation is necessary to replace the previous behavior.
- Equipment needed to implement the recommended behavior may not be readily available. For example, if a consumer decides to cook ground beef patties to 160°, they will need an instant-read thermometer, preferably one that has recommended endpoint internal temperatures printed on the sheath. Fortunately, these

types of thermometers are now much more commonly available to consumers.

Educational efforts are needed to increase food handlers' knowledge of correct procedures and motivation to perform recommended behaviors. Equipment should be designed to reduce opportunities to make food handling mistakes. Improvement in behaviors is likely to result in reduction in incidence of foodborne illnesses.

76 Migratory Chemicals from Food Containers and Preparation Utensils

Yvonne V. Yuan
School of Nutrition, Ryerson University

CONTENTS

I. INTRODUCTION

Plastics have revolutionized the packaging and transportation of foods, allowing foods to be packaged in light weight materials while offering excellent physical protection against mechanical damage, water vapour transmission and light oxidation. Approximately 70 to 80% of food and ingredients are packaged in polymeric materials (1). However, the use of plastic organic polymers containing functional additives such as plasticizing agents, antioxidants, U.V. light and heat stabilizers or lubricants in the manufacture, packaging and serving of common foodstuffs such as meat, cheese, margarine, bacon, vegetables and beverages may result in these polymer constituents potentially becoming indirect food additives (1, 2). This phenomenon occurs due to the potential for contact and migration or transfer of polymer components from containers or packaging films into foods during processing, packaging and storage. Plastics (e.g. polyethylene, polypropylene, polystyrene etc.) are also extremely prevalent as food service utensils and containers both inside and outside the home (3, 4). Polymer additives can fall into two functional categories: those that modify the physical properties of polymers, namely catalysts, plasticizers, lubricants and colouring agents etc. and those that have a stabilizing or protective effect on polymer degradation (antiaging additives), such as antioxidants, U.V. light and heat protection agents (5, 6). Plasticizers are synthetic organic additives characterized by low molecular weight with low melting points or low volatility with high boiling

points and high miscibility with the parent polymeric matrix (e.g. phthalic acid esters (PAEs)). They are used to improve the plasticity (e.g. flow, workability and flexibility) of polymers such as the vinyl derivatives (e.g. polyvinyl chloride (PVC), polyvinyl acetate (PVA), polyvinyl alcohol (PVAL)) and the polyolefins (e.g. polyethylene (PE), polypropylene (PP)). In this way, plastic formulations can contain up to 60% of plasticizer materials to transform an otherwise rigid polymer into a plastic with improved physical and mechanical properties such as flexibility, durability, and impact resistance (1, 2, 7). However, due to the relatively low molecular weight of residual polymeric monomers and certain additives (i.e. plasticizers and antioxidants), the migration to and absorption of these compounds by both solid and liquid foods is known to occur (8–10). This may result in off-odours or -flavours being imparted to the packaged food (11, 12) resulting in the loss of product and sales. As well, the toxicology of these substances has been the subject of intense investigation in animal models (13–17) and human subjects (18–21). These issues gain relevance due to the prevalence of microwavable convenience foods which are heated in the packaging containers, as well as the increasing interest in irradiating packaged foods for increased microbiological safety against foodborne illnesses (22–24). Gamma-irradiation of packaged foods is known to result in alterations such as crosslinking and scission of polymeric materials and component additives which may be, in turn, adsorbed by the packaged food contained therein. This chapter will discuss these issues as well as examining potential alternatives to the traditional polymeric packaging materials discussed in the recent literature.

II. MIGRATION THEORY

The investigation and mathematical modelling of the diffusion, migration and sorption of materials from food packaging materials into foods or in contrast, from foods into the packaging polymer itself, have been the subject of several recent reviews and reference book compilations (2, 5, 6, 25, 26). Generally, the movement of molecules within a packaging system reflects the motion of mass or energy from one location to another. Mass transport by diffusion will be influenced by the behaviour of the polymer itself (i.e. glassy versus rubbery state) as well as the solubility of the diffusant chemical in the polymeric matrix and the partition coefficient of the diffusing chemical between the two contact media (25). Polymers are classified as either rubbery or glassy depending on whether the temperature of the polymer is above or below the glass transition temperature (T_g) for that polymer, respectively. Above the T_g, polymer chains will be able to move more freely in space versus below the T_g, where chain mobility will cease and the polymer becomes glassy and hard. Rubbery polymers at $T > T_g$, which include polyvinylchloride (PVC, T_g = 80–100°C), polystyrene (PS, T_g = 80–100°C), polyethylene terephthalate (PET, T_g = 67–81°C) and polytetrafluoroethylene (PTFE, T_g = 115–125°C) are able to quickly establish a new equilibrium when a diffusant chemical is absorbed and transported through the rubbery matrix of the polymer (25). Conversely, glassy polymers at $T < T_g$, which comprise the various forms of the olefins PE ($T_g = -30 \pm 15$°C) and PP ($T_g = -17 \pm 5$°C) are unable to rapidly establish a homogeneous environment upon absorption of a diffusant.

In rubbery polymers, diffusion of chemicals obey *Fick's Laws of Diffusion* and can be explained on the basis of the adhesion theory, which refers to the physical interaction of two materials.

Fick's First Law of Diffusion

$$J = -D\frac{\partial C_A}{\partial X}$$

where
J = flux (i.e. moles/sec cm^2)
D = diffusion coefficient (i.e. cm^2/sec)
C = concentration of substance A (i.e. moles/cm^3)
X = distance (i.e. cm)

Fick's Second Law of Diffusion

$$\frac{\partial C}{\partial t} = D\frac{\partial^2 C}{\partial^2 x} \quad 0 < x < l$$

where
C = concentration of substance (liquid or plasticizer)
D = diffusivity in the membrane
x = space coordinate
l = length of the geometric shape in question
t = time

Fick's first law of diffusion describes steady-state diffusion wherein mass transfer from a region of high concentration to a region of low concentration occurs and eventually approaches equilibrium (26, 27). Whereas, unsteady-state diffusion is described by *Fick's second law of diffusion* wherein for a constant diffusivity, the rate of change in the concentration of the substance of interest with time is proportional to the rate at which the concentration gradient changes with distance in a given diffusion direction.

In glassy polymers, on the other hand, diffusion of compounds is more complex, in that diffusion can be:

a. Class I or Fickian, where the rate of diffusion is much less than the relaxation of the diffusant-polymer system; or
b. Class II, where the rate of diffusion is very rapid compared to the relaxation processes of the polymer system; or
c. Anomalous diffusion, where the rates of diffusion and relaxation of the polymer system are comparable to each other (25).

This non-ideal behaviour can be linked to swelling or shrinkage of the food in question, or the packaging polymer. Food components, particularly water, may influence the swelling and plasticity/mobility of the polymer chains leading to non-ideal diffusion (27).

There are two mechanisms by which adhesion plays an important role in the migration of packaging material components. The first is through the adhesion and loss of food constituents (i.e. volatiles) to the packaging material, resulting in a reduction of food sensory qualities and thus, acceptability. The second is through the adhesion of the packaging material to the foodstuff, which may introduce toxicants, unwanted flavours or odour-active substances, again resulting in the potential loss of food quality as well as safety (5, 28). The adhesion phenomena can be explained according to the conditions listed in Table 76.1 (5, 28, 29). The term migration typically refers to the movement of chemical compounds from the packaging material into the food or beverage contained therein. This migration activity would then include the movement of gases, low molecular weight compounds and water vapour from the package into the food (5). This phenomenon is distinct from sorption, which involves the movement and uptake of food constituents, such as flavour and odour components, into packaging materials (28). These processes are dynamic and can occur simultaneously by diffusion (30). At steady state, the flux can be described as a function of the concentration difference of the migrating chemical across the distance of diffusion when referring to *Fick's first law of diffusion* above (31). In general, migration and sorption are similar processes which can ultimately affect food quality. Both phenomena are influenced by the chemical and physical properties of the substrate and the receiving medium.

III. MIGRATION OF PACKAGING MATERIALS

Of primary concern to polymer and food scientists as well as the consumer are the migration and sorption processes which may impact on the organoleptic quality, nutrition and safety of packaged foods. Migration of plastic packaging constituents may result in the introduction of undesirable and/or unsafe substances into the food, thus rendering the food unsuitable for consumption. Similarly, sorption processes may result in nutrient or flavour and odour loss from the packaged food into the packaging material, giving rise to a poor quality product. Thus, sorption phenomena involve packaged foods wherein concern for product organoleptic qualities and nutrient retention are the primary focus. Packaging materials can adsorb flavour components from food systems rendering the food product unacceptable over time (i.e. during the distribution and delivery process) due to "flavour scalping" as in the case of terpenoids in juices (32). In addition, the use of heat treatment or other adhesive phenomena will contribute to weight loss or reduced volume and altered nutrient retention in packaged foods (33).

Migration of packaging materials into food is a function of the chemical composition and concentration of the packaging materials and the solubility of the migrating chemical in the polymer, or its partition coefficient between the polymer and the contact surface of the food. The fat content and more specifically, the fat-releasing properties of contact foods can greatly influence migration of low molecular weight compounds (34). For example, migration of the plasticizer stearyl 3-(3,5-di-*tert*-butyl-4 hydroxyphenyl) propionate into mayonnaise (an oil-in-water emulsion with moderate fat-releasing properties) resulted in a mean concentration of 69 μg/dm^2 compared to 792 μg/dm^2 into a

TABLE 76.1
General Tenets to Adhesion Theory Involving Migration of Food Packaging Materials[1]

Type of Adhesion Interaction	Molecular Interaction	Description of Interaction
Mechanical interlocking	Macro- and microscale	Rugosity of surface increases locking of film components.
Wetting	Liquid dispersion and surface tension	Electrodynamic intermolecular forces create dispersive and attractive forces at surfaces.
Electrostatic	Ionized substrates form electrical double layer	Double layer is positively charged while outer interface is negatively charged. Adhesive forces act by attraction through electrical double layer in films.
Chemical	Covalent bonding between surfaces and polymer components	Contact time and processing dependent.
Diffusion	Polymer and additive migration	Contact time, temperature, molecular weight, polymer type, viscosity and concentration dependent.

[1] References: 5, 28, 29.

test fat (34). Migration efficiency will also be affected by the storage or thermal processing temperature used (i.e. heating the food inside the packaging material, e.g. microwave cooking), as well as the amount of time during which the food is in contact with the package material (3). Thus, the migration of chemicals from packaging materials into foods can be mathematically modelled and predicted (4, 35, 36). Any toxicological hazard associated with the migration of food packaging materials into foods would therefore be a function of the amount of migratory material originating from the polymer which enters the food and the intrinsic toxicity of this material or its metabolites (16, 17, 37).

It is important to recognize that the conditions involved with the use of plastic packaging of foods will not be isothermal throughout the life of the polymer. Moreover, food systems are, by their nature, very complex with aqueous and hydrophobic components often co-existing in one food matrix. In order to study the extent of the migration of polymer components into foods, laboratories use established food simulants (i.e. distilled water, 3% NaCl, 3% $NaHCO_3$, 3% acetic acid, 3% lactic acid, 20% sucrose, 15–50% ethanol and olive oil or iso-octane) as model systems to estimate migration of chemicals into foodstuffs (31, 34–36). Frequently, elevated temperatures are used to simulate accelerated storage conditions and the worst-case scenario. Standard test conditions accepted by regulatory bodies in the United States (US Food, Drug and Cosmetic Act enforced by the Food and Drug Administration (FDA)), Canada (Division 23 of the Food and Drugs Act and Regulations), United Kingdom (Ministry of Fisheries and Foods (MAFF)), and European Union (EU Scientific Committee for Toxicity, Ecotoxicity and the Environment (CSTEE)) include 10 days at 40°C, 2 hr at 70°C and 1 hr at 100°C (10, 34, 38, 39). These data, used in conjunction with toxicological testing, have resulted in the establishment of regulatory allowances for food packaging components migrating into foodstuffs set at a dietary concentration of 0.5 μg/kg in the US by the FDA (36, 40, 41) and maximum total migration limits to be set at 10 mg/dm^2, or less than 60 mg/kg food by the EU (7, 42). Packaging design and construction which incorporate the concept of functional barriers (i.e. laminate films) to limit the migration of noncarcinogenic chemical components to food to a level less than the threshold of 0.5 μg/kg are regarded acceptable in the US (36). Functional barriers represent a concept whereby the specific package design and construction limit the migration of packaging materials into food in amounts regarded below this threshold level (36, 43). This is especially pertinent given the trend to use recycled materials in packaging. Quite often, a contaminated material will be co-extruded with virgin materials acting as a functional barrier against taint migration from the inner layer of recycled polymer material (36). Tripartite polyethylene terephthalate (PET) films made from core material consisting of PET contaminated with toluene and chlorobenzene sandwiched between two virgin PET layers demonstrated significant migration of the contaminants into water, 3% acetic acid and iso-octane. Migration of contaminants into 3% acetic acid (50°C over 10–131 days) from the contaminated PET into 3% acetic acid ranged from 4.1 to 33.3 $\mu g/dm^2$ and <0.1–20.7 $\mu g/dm^2$ without and with barrier layers respectively for toluene and <0.1–17.0 $\mu g/dm^2$ and <0.1–12.3 $\mu g/dm^2$ without and with barrier layers for chlorobenzene (36). Thus, the effects of diffusion of core layer contaminants in plastic films must be considered when using coextruded recycled materials.

IV. CONCERNS WITH MIGRATION OF PACKAGING MATERIALS

The classes of packaging material migrants that fall into the category of food safety concerns include the amine precursors and nitrosamines (44), plasticizers (1, 45) and polymer monomers such as vinyl chloride and styrene (17, 20). Amine precursors and nitrosamine formation have been reported from the interaction of the rubber netting used to package nitrite containing cured meats and from other foods contained in paperboard containers (5, 44, 46). The focus of the following discussion will concentrate on the polyolefin and vinyl derivative packaging materials and additives. The most commonly used plasticizers to improve the working properties of PVC, for example, are the esters of dibasic or tribasic organic acids known as phthalates which comprise as much as 60% of the market (47). Phthalic acid esters are the subject of concern due to the structural similarity of these compounds to the known teratogen thalidomide (phthalidomide) (48). Indeed, di(2-ethylhexyl) phthalate (DEHP) has been demonstrated to have fetotoxic, embryolethal and teratogenic effects in rats at a dose of 1 g/kg/day (14). Finally, vinyl chloride polymers (polyvinylchloride; PVC) are widely used in many types of packaging materials and have also been shown to migrate into foods (8, 48). PVC contains allylic chlorine atoms, which can be released from the polymer upon exposure to light or heat treatment of the packaged food. The primary concern with PVC and the monomer vinyl chloride used in the manufacture of this plastic, is due to animal and human epidemiological data from workers exposed to vinyl chloride indicating that exposure to vinyl chloride is strongly linked to hepatic carcinoma (17, 19, 20, 49).

V. SOURCES OF FOOD PACKAGING MIGRANT CHEMICALS

A. Polymers

Numerous polymers are used in food packaging to store and protect food from deterioration due to chemical or physical damage due to radiant or heat energy, while at

TABLE 76.2
Common Polymers and Migration Chemicals in Food Packaging Materials[1]

Polymer	Example of Use	Migration Chemicals
Polyethylene (PE)	Dairy product and other food containers, water pipes, food wrap films	Acetaldehyde, allyl alcohol, acrolein.
Polyvinylchloride (PVC)	Beverage and water bottles, food wrap films, water pipes	Allylic chlorine, vinyl chloride monomer, plasticizers and stabilizers.
Polypropylene (PP)	Bread packaging, bottles, frozen foods, microwavable foods	Isopropyl alcohol, methyl alcohol, formaldehyde, antioxidants and stabilizers.
Polystyrene (PS)	Microwave meals, cookie bags and syrup containers	Styrene monomers, dimers, trimers, polystyrene.
Polyethylene Terephthalate (PET)	Beverage and water bottles, box liners, boil-in-bag pouches, microwave food trays	Acetaldehyde, cyclic oligomers, ethylene glycol.
Paper and paperboard	Milk and juice cartons	Polychlorinated biphenyls (PCBs), alkyl and aryl aldehydes.
Melamine-Formaldehyde	Tableware	Melamine and formaldehyde residues.
Vulcanized rubber	Rubber nettings for packaged meats, food industry equipment	Polycyclic aromatic hydrocarbons (PAHs) including benzo[a]pyrene, nitrosamines, alkanes, alkenes, acids, antioxidants, plasticizers and sterols.

[1] References: 1, 2, 4, 5, 8, 11, 12, 35, 46, 50.

the same time enabling the consumer to view and evaluate the product. Examples of common polymers used in food packaging materials and migratory components of concern are presented in Table 76.2 and chemical formulae of plastic resin monomers and polymers provided in Tables 76.3 and 76.4, respectively.

B. Vinyl Derivatives

Polyvinyl chloride (PVC) is second only to PE in worldwide production, estimated at approximately 22×10^6 metric tons (2). PVC film is manufactured by the low pressure free radical polymerization of vinyl chloride (Table 76.3) at temperatures ranging from 50–160°C (50). PVC film is a versatile thin cling film (<25 μm or 1 mil thick) which is transparent and has high oxygen permeability but is naturally brittle and therefore requires plasticizing agents, such as the phthalic acid esters (Table 76.5), to be incorporated into the polymer (50). Plasticizer content of PVC polymers can vary from 3.0 to as high as 80% (1). A copolymer of vinyl chloride and vinylidene chloride (Table 76.3), more commonly known by its trade name, Saran™, is a high quality cling-film wrap used commercially and in the home. As plasticizers are not polymerized directly into the polymer matrix, and have high mobility associated with a low molecular weight, migration from the PVC polymer into the food product can occur. Migration is influenced by the fat content, pH and the alcohol content of the foodstuff (48). Vinyl chloride monomer (VCM) is a residue of PVC film manufacture which is removed following the polymerization reaction. However, VC has received considerable attention due to its link to angiosarcoma of the liver (ASL) (17, 19, 20). An Italian study indicated that significant quantities of VC (13 to 83 ppt) could be detected in PVC-bottled drinking water (8). Moreover, the concentration of VC in bottled water was observed to increase linearly with storage time

TABLE 76.3
Monomers and Degradation Products from Food Packaging Polymers

Compound Name	Chemical Structure

(approx. rate 1 ng/l/day), resulting in the recommendation that storage dates be placed on the labels of PVC-bottled water (8). While migration of VC into vinegar (9.4 mg/L), cooking oil (14.8 mg/kg), butter and margarine (approx. 50 µg/kg) have been reported (48), the greatest risk of health effects from VC is from occupational exposure in manufacturing plants (18, 19). Workers exposed to VC from manufacturing plants have been reported to suffer from primary nonangiosarcoma liver tumours as well as ASL (18, 19, 49). Workplace exposure to VC has also been

reported to result in the dissolution of the distal phalanges in the hands of workers as well as disturbances in the circulation of the extremities (49). Studies with cell culture and rodent animal models have demonstrated that VC is mutagenic and can induce liver, lung and brain carcinogenesis (49). Moreover, mutations to the p53 tumour suppressor gene have been observed in ASL patients in association with serum anti-p53 antibodies (20). Anti-p53 antibodies could also be detected in serum from individuals who were occupationally exposed to VC, leading these workers to suggest that serum anti-p53 antibodies may be a biomarker of individuals at risk for development of ASL.

Another vinyl derivative which is used commonly in food service utensils and dishes is the monomer styrene (Table 76.3) in the manufacture of polystyrene (PS; Table 76.4) foam articles (2, 3, 4, 9, 35, 51). Styrene is classified as a mutagen and is also known to cause irritation of the nose and eyes, drowsiness, weakness and an unsteady gait on overexposure (52, 53). Routes of exposure to styrene monomer include occupational exposure to styrene vapour during the manufacturing process and as a result of migration into food contact articles (53). Concern about styrene exposure is related to its high blood/gas phase solubility ratios whereby styrene easily enters the circulation from the lungs upon inhalation. General purpose and high impact PS are used in numerous food packaging and preparation containers including thermoset cookware, plates, cups, bowls, egg cartons, meat trays and hinged take-out containers. In most cases, foods would only be in contact with the packaging material for a short period of time at relatively mild temperatures (approx. 55°C) in a food service situation or for a longer period at refrigeration temperatures (approx. 4°C) (4). Migration of residual styrene monomer from thermoformed PS foam food contact articles into Crisco™ brand cooking oil has been reported to be proportional to the square root of the time of exposure (4). The diffusion coefficients of styrene migration into cooking oil ranged from 4.5×10^{-11} cm^2/s at 21°C to 3.4×10^{-9} cm^2/s at 65.6°C (4). Migration of styrene into 8% ethanol from egg cartons incubated over 31 days at 4°C was negligible (below the detection limit of 0.01 μg/cm^2) (4). Daily styrene exposure from the diet and inhalation has been estimated at approx. 18.2 to 55.2 μg/person for an annual exposure ranging from 6.7 to 20.2 mg/person according to a recent German survey (54). Others have evaluated the concentration and migration of styrene-7,8-oxide in food contact articles (35). Styrene-7,8-oxide is the oxidation product of styrene and is thought to be formed during the peroxide-initiated polymerization of styrene resin at 200°C. Moreover, styrene is metabolized by hepatic NADPH-cytochrome P_{450}-dependent monooxygenases to epoxides, namely its 7,8 epoxide, which can bind to cellular macromolecules (i.e. proteins, nucleic acids), resulting in cytotoxicity, mutagenicity and ultimately carcinogenicity (53). Thus, it is this styrene derivative which has been hypothesized to be responsible for the toxicity of styrene including renal, hepatic damage as well as pulmonary and cardiac abnormalities (35, 55). Finding the oxide in PS packaging materials but not in the base resin pellets indicates that the epoxides are not formed during the polymerization process but rather are formed during injection moulding or thermoforming of the plastic. However, the oxide decomposed rapidly in aqueous media at 40 and 100°C potentially making exposure levels in foods less of a risk (35).

C. Polyolefins

Polyethylene (PE) is the most wide-spread food packaging material today. Annual world production of PE polymers was 40×10^6 metric tons in the 1990's (2). This hydrocarbon polymer (Table 76.4) can be manufactured with varying amounts of branching within the linear backbone with high-density PE (HDPE) being the least branched and low-density PE (LDPE) containing the most branching (2). The ratio of LDPE to HDPE and linear LDPE (LLDPE) polymers produced was 40:40:20 (LDPE:HDPE:LLDPE) (2). The structural differences between the various forms of PE are associated with the differing uses of these polymers: HDPE has great thermal stability and as such, is used not only for films but also rigid food containers (i.e. yogurt pots) while LDPE is used for bags and cling-films due to its excellent flexibility. The related polymer, polypropylene (PP) has similar characteristics and uses in food packaging as PE. Production of PP polymers is ranked third behind PE and PVC with an annual worldwide production of 21×10^6 metric tons (2). Conditions which favour migration of chemicals from polyolefin packaging materials such as PE include elevated storage temperatures and exposure to oxygen (11, 12). The resultant reaction products (Table 76.2) can migrate into foods and cause wax-like odours that contribute to easily detected off-flavours. Vitamin E has been shown to reduce the migration of off-odour, aldehydes and ketones and hexadec-1-ene into water stored in HDPE bottles, thus reducing the development of off-flavours in stored product (11). Phenolic antioxidants were also demonstrated to reduce the release of off-odours and -tastes from HDPE bottles associated with aldehydes and ketones (low odour thresholds) although a total of 47 volatile components released from bottles could be identified by gas chromatography combined with mass spectrometry (GC/MS) (12).

D. Polyesters

The polyester polyethylene terephthalate (PET) is synthesized by the condensation of ethylene glycol and terephthalic acid and is more commonly known by its trade name Mylar™ in North America (Table 76.4). PET is often used in cola type beverage and water bottles as well as in laminated films to provide excellent strength and abrasion resistance (2). PET and polybutylene terephthalate (PBT)

are noted for the impact and wear resistance of these polymers. PET is also known to be a good barrier to gases, aroma volatiles and lipids, but less so against water vapour transmission (2). Thus, PET is used to bottle edible oils, peanut butter, dressings as well as in cereal box liners (1). In the frozen prepared-food industry, paperboard dishes are laminated with PET or PBT for use in ovens between 200–220°C. Microwavable single-serving dishes are manufactured from heat-formed PET films. Two PET monomers, mono- and di-ethylene glycol (MEG, DEG) have designated specific migration limits (SML) between 15 and 30 mg/kg food. MEG is an hygroscopic poison, more well known as antifreeze, which causes vomiting, drowsiness, coma, respiratory failure, convulsions, renal damage and ultimately death with a lethal dose of approx. 1.4 mL/kg b.wt. or 100 mL (51). DEG is also used in antifreeze solutions and has similar symptoms as MEG upon ingestion. Similar to PE and PVC, PET is also sensitive to thermal and oxidative degradation resulting in the release of acetaldehyde as the principle volatile migratory compound. Acetaldehyde concentrations in mineral water and lemonade have been reported to range between 7.5 and 11 mg/L (1). Acetaldehyde has also been associated with causing colour changes in PET as the packaging material ages. Cyclic oligomers of PET have been reported in various microwavable foods such as french fries, fish sticks, waffles and pizza at levels between 0.012 up to 7.0 g/kg (1).

E. Other Packaging Materials

Paper and cardboard are also commonly used as packaging materials. Polychlorinated biphenyls (PCBs) have been reported in foods packaged in paperboard made from recycled paper as a consequence of the recycling process or from the printing ink used in the packaging (48). In Glassine packages, a pine oil hydrogenation product is used in cereal box liners which can contribute to a pine flavour upon migration of chemical constituents (5).

VI. ADDITIVES USED IN POLYMER FORMULATIONS

A. Functionality in Polymers

There are in excess of 450 different plasticizers used in polymer formulations, of which approximately 100 are available for commercial use (5). Some common plasticizing agents, in use to decrease the rigidity and brittleness of polyolefin, vinyl derivative and polyester polymers such as PE, PVC, PS and PET, are listed along with chemical formulae in Table 76.5. Important factors in choosing an appropriate plasticizer include low volatility, miscibility with the plastic polymer and avoidance of undesirable properties such as a predisposition to induce colour alterations of the packaging material as well as adverse organoleptic or toxicological properties. Plasticizers are used primarily in

TABLE 76.5
Plasticizer Additives Used in Polymers

Classification	Compound Name	Abbreviation	Chemical Structure

	N-butyl stearate		

polymers which are characterized by a glassy or crystalline structure at room temperature (6). The rigid polymer interacts with plasticizer molecules to reduce the brittleness (brittleness temperature, T_b) as well as the glass transition temperature (T_g) allowing an increase in the temperature range of viscoelasticity for the polymer (6). Other routes of exposure to plasticizers from packaging materials include sealants of glass jar lid closures, printing inks on polymer films as well as adhesives and can lacquers (56). Other additives used in polymer manufacture include a variety of antioxidant species, namely phosphites and phenols (Table 76.6) to protect against effects from metal contaminants, photoactive dyes and pigments which may be incorporated into the polymer matrix (57, 58). Polymers are oxidized primarily by two routes: a) long-term heat aging (thermal oxidation), or b) weathering

from U.V. light (photo-oxidation) (57). Polymers are protected from thermal oxidation effects through the incorporation of phenols such as Irganox 1076™ (Table 76.6). The efficiency of the phenol antioxidants can be improved by using these antioxidants in combination with phosphites (e.g. Irgafos 168™, TNPP) which facilitate the decomposition of hydroperoxides (1). Heat stabilizers are necessary in PVC manufacture due to the low thermal

TABLE 76.6
Stabilizers Used in Polymeric Materials

Classification	Compound Name	Abbreviation	Chemical Structure
Antioxidants			
Phosphites			
	Tris(2,4-di-*tert*.butylphenyl) phosphite	Irgafos 168™		Bis(2,4-di-*tert*.butylphenyl) pentaerythritol diphosphite	Ultranox 626™ Hostanox PAR24™		Tris(nonylphenyl) phosphite	TNPP	 R = C_9H_{19}

	Tribasic lead stearate		$3PbO \cdot Pb(C_{17}H_{35}COO)_2$

stability of these polymers. Thermally aged PVC becomes discoloured due to the formation of conjugated double bonds associated with dehydrochlorination of the polymer during molding or extrusion processes. Heat stabilizers include barium, calcium or zinc fatty acid soaps and various organotin compounds (Table 76.6) (1, 57). Thermo- and light-stabilizers such as tribasic lead sulfate are often used in PVC in combination with organotin stabilizers (1). Lead stearates function as thermo-stabilizers and as a lubricant for PVC and vinyl chloride copolymers, again often in combination with organotin compounds (1).

B. Plasticizers

The commonly used phthalic acid esters (PAEs) are low molecular weight esters that consist of a cyclohexatriene ring (benzene dicarboxylic acid) core esterified to aliphatic substituents (Table 76.5). The PAEs are used in a variety of packaging materials such as PVC, PE, PS, PET, laminated aluminum-PE as well as printed fibreboard and cellophane. DEHP is the most common plasticizer incorporated into polymers with an annual worldwide production of approx. 2.7×10^6 metric tons (38). PAEs, such as DEHP and DOP, are characterized by an affinity for these polymers, low volatility, water resistance and good flexibility of products at low temperatures (6). On the other hand, DBP has a relatively high volatility and is used mainly in cellulose-based varnishes and in adhesives (6). Several other organic acids such as terephthalic acid (an isomer of phthalic acid), adipic and citric acids are the parent compounds of other plasticizers such as DOA, DEHA and ATBC. Other plasticizers include stearyl 3-(3,5-di-*tert*-butyl-4 hydroxyphenyl) propionate used in HDPE, LDPE and PP as well as *n*-butyl stearate which is used in high-impact polystyrene and PVC manufacture (6, 34). Polyepoxide plasticizers, such as ESBO, have a good affinity for the vinylic polymers and are frequently used to plasticize PVC glass jar lid gaskets (6, 56). Frequently, combinations of plasticizers will be used in formulations due to differences in plasticizing, solvation, lubrication and creep properties of finished polymer and plasticizer blends.

VII. FACTORS WHICH INFLUENCE THE MIGRATION KINETICS OF PLASTICIZERS

Over time, plastics containing low molecular weight plasticizers will lose plasticizer due to the evaporation of volatiles or migration of plasticizer during food contact (6). This will result in a change in the physical properties of the polymer (i.e. becoming hard and brittle) accompanied by a decrease in weight due to loss of the plasticizer. The migration of plasticizer from PVC films into foods is thought to follow Fickian behaviour occurring via a two-stage process involving first, the diffusion of plasticizer from the bulk phase within the polymer to the surface followed by the subsequent diffusion of the migrant compound from the polymer into the food. Transfer of the plasticizer to the surface of the film depends on the nature and properties of the film (i.e. functional barrier in a laminate) as well as barrier layer thickness (36). The migration of plasticizer into the food is facilitated by the relatively lower resistance to mass transfer within the food phase compared to that of the polymer. As a result of the differences in diffusion kinetics between the polymer and food source, both the composition (fat content and fat-releasing properties) and phase of the food, as well as the type and concentration of plasticizer used, are important variables in migration kinetics (34, 36). For example, transport of plasticizer by diffusion is expected within an immobile or solid food phase as opposed to convection kinetics if the food is in the liquid phase. In both of these situations, the migrant transportation rate will be reduced as the system approaches an equilibrium. The physico-chemical properties of the plasticizer and food simulant extraction medium will also influence the rate at which equilibrium is established (34, 36). For example, migration of stearyl 3-(3,5-di-*tert*-butyl-4 hydroxyphenyl) propionate from LDPE into distilled water after incubation at 20°C for 60 days resulted in transfer of 2.53 µg plasticizer/dm^2 whereas the transfer into olive oil was 720 µg plasticizer/dm^2 (36). These variables will also be influenced by duration and temperature of exposure of films in contact with foods (34, 36). Moreover, a lower concentration of plasticizer within a polymer will result in ultimately less migration into the foodstuff (47). Diffusion of plasticizers from a polymer will also occur more rapidly when the temperature is significantly above the T_g of the polymer material. However, if the external temperature is approximately equal to the T_g, diffusivity of the plasticizer can decrease by several fold with a change in incubation temperature in food simulant model studies. Bieber and coworkers (34) demonstrated this phenomenon with high impact PS containing *n*-butyl stearate incubated with a test fat resulting in transfer of plasticizer at a rate of 10.2 µg/dm^2 at −20°C compared to 41.7 µg/dm^2 at 20°C after 120 days incubation.

VIII. MIGRATION OF PLASTICIZER FROM POLYMER FILMS

Migration of plasticizers from PVC and PE films, PS as well as PVC-based toys and childcare articles have been studied investigating a variety of foods and food simulants modelling aqueous and fatty food systems as well as saliva extraction for the children's articles (10, 39, 42, 59, 60). Several international studies (Canadian and Danish) confirm that DEHA is present in food-contact films and as a migrant chemical in store-wrapped meat, poultry, fish, cheese and ready-to-eat prepared foods (10, 42, 59, 60).

In the Canadian study, fresh meat, poultry and fish contained up to 14 μg DEHA/g; a noteworthy observation was that smoked salmon filet contained 220 μg/g reflecting its relatively greater surface area exposed to the packaging material (10). Cheeses wrapped in polymer films contained between 2.1–310 μg DEHA/g and mean levels of 2.2 μg DEHP/g. Packaged ready-to-eat foods contained between 7.9–160 μg DEHA/g. Levels of DEHA in store-wrapped cheese were observed to reach a level of 45 mg/kg after only 2 hr at 5°C and then to increase to 150 mg/kg after 10 days of storage (59). Other workers have reported DEHA levels as high as 429 mg/kg in cheeses (60) which means that consumer intakes close to or even exceeding the EU recommended maximum tolerable daily intake (TDI) for DEHA (0.3 mg/kg body weight) are entirely possible given a 50 g portion size for cheese and a 60 kg adult. In fact, a majority of PVC cling film samples (77%) used at the various stages of food distribution (importers, wholesalers and retailers) demonstrated greater rates of overall migration (between 8.3 and 59.4 mg/dm^2) and specifically of DEHA migration into fatty foods as modelled by iso-octane (in place of olive oil) than permissible by the EU limit of overall migration of less than 10 mg/dm^2 (or $<$60 mg/kg food) as well as the specific migration limit (SML) of 3 mg DEHA/dm^2 (or $<$18 mg/kg food) (42). However, when the appropriate 'reduction factors' were applied to these migration data to take into account migration from actual fat-containing foods, overall migration was calculated to decrease to between 6.4 and 13.9 mg/dm^2. Migration of DEHA from PVC films into non-fatty foods as modelled by water was at or below the EU limit of 0.1 mg/dm^2 in this same study. It is noteworthy that while some fresh meats packaged in PVC films have contained 49 to 151 mg DEHA/kg, frozen chicken showed no detectable migration of DEHA (60).

Migration of other plasticizers including DEHP have been reported in beverages (mean 0.065 mg/kg) and foodstuffs (0.29 mg/kg) packaged in glass containers with DEHP-containing cap or lid seals (10). PVC film wrapped cheeses were observed to contain a mean of 2.2 μg DEHP/g. The UK MAFF has established TDI values for various phthalate esters as follows: DEHP 0.05 mg/kg b.wt./day; BBP 0.1 mg/kg b.wt./day; DBP 0.05 mg/kg b.wt./day and DEP 0.2 mg/kg b.wt./day (38). These TDI values relate to the EU total tolerable daily intake (TTDI) for all phthalate esters of 0.3 mg/kg b.wt./day. In an Australian survey, the most predominant plasticizers used in PE, PS, PET, cellophane, printed fibreboard and laminated aluminum-PE packaging materials were DEHP, DBP, BBP and DEHA; the greatest levels of phthalate plasticizers (up to 8160 μg/g film) were observed in printed PE films indicating the importance of printing inks on films in contributing to total phthalate esters in packaging materials (38).

Another source of phthalate ingestion unique to young children are PVC-based toys and childcare articles which may be mouthed for considerable periods of time by young infants (39). In fact, the EU CSTEE has established maximum permissable extracted amounts for several PAEs for a child weighing approx. 8 kg: all values are mg/10 cm^2 of the article mouthed over a 3 hr period, DEHP 0.3; DBP 0.8; DOP 3.0; DINP 1.2; DIDP 2.0 and BBP 1.6 (39). Using a saliva simulant solution of potassium and sodium salts in distilled water, Earls and coworkers (39) reported extractable amounts of PAEs from teethers, bath animals etc. ranging from 0.7–1.6 μg/10 cm^2/min which is less than the CSTEE migration limit of 9 μg/10 cm^2/min for DINP for example. Other plasticizers may enter a child's diet from commerically prepared and bottled baby foods (56). A Swedish study reported that ESBO migration from PVC gaskets in lids into ready cooked baby foods sold in glass jars ranged from $<$1.5–50.8 mg/kg food, with a mean of 11.9 mg/kg and a median value of 7.9 mg/kg (56). The EU CSTEE has proposed a TDI of 1 mg ESBO/kg b.wt. and a maximum total migration of 60 mg ESBO/kg food for adults. When these values are translated for an infant of approx. 8.5 kg, two servings of food containing a mean of 11.9 mg ESBO/kg results in an intake of approx. 0.38 mg/kg b.wt., which is very close to the adult TDI value above (56).

IX. METABOLISM OF PLASTICIZERS

Plasticizers in food are absorbed from the diet over a wide concentration range and can be found in several tissues, with the most concentrated amounts being found in the kidney and liver and metabolites excreted in the urine (61, 62). Studies to estimate dietary intake and excretion of DEHA reported a median intake of 23.7 mg in the United Kingdom (62). Urinary excretion of the metabolite 2-ethylhexanoic acid (EHA) acted as a useful biomarker to assess DEHA intake. Exposure to DEHP occurs not only through environmental factors such as the diet, but also from plastics used in medical settings, namely PVC medical devices such as IV bags and tubing, blood and plasma bags as well as enteral feeding and dialysis equipment (63). Average total daily exposure, excluding occupational exposure, has been estimated at 0.27 mg DEHP in the US. Exposure in the medical setting ranges from 0.01 mg DEHP/kg b.wt. from hemodialysis to a high of 140.0 mg/kg b.wt. from extracorporeal oxygenation of infants (63). There does not appear to be any significant bioaccumulation of phthalates such as DEHP in healthy higher mammals and humans (21, 61, 63). Studies in primates indicate that DEHP is rapidly and extensively metabolized to be excreted in the urine as glucuronide conjugation products of mono(2-ethylhexyl) phthalate (MEHP). DEHP is metabolized to MEHP by intestinal lipases and esterases. Another primary metabolite of DEHP is 2-ethanohexanol (2-EH), which undergoes further hepatic metabolism along with MEHP to secondary metabolites prior to excretion. The alkyl side chains are further oxidized and short chain dialkyl phthalates can be

excreted unchanged, or are completely hydrolyzed to phthalic acid (61). Longer chain DEHP is converted to polar derivatives of the monoester by oxidative metabolism prior to excretion. MEHP metabolism occurs in part by a rate limiting peroxisomal β-oxidative metabolism prior to excretion (21). For both DEHP and MEHP, excretion follows a time and dose-dependent metabolic profile in primates and man. DEHP has been estimated to have a urinary elimination half-life of approx. 6–12 hr (63). Lipoprotein bound DEHP metabolites are efficiently eliminated (e.g. peak elimination is 6 hours after ingestion) as evidenced by the 90% urinary excretion of DEHP and metabolites and 10% fecal excretion (21). Differences in DEHP metabolism between humans and rodents include the fact that rodent gut lipases are more effective in the hydrolysis of DEHP to MEHP compared to man. This results in greater intestinal absorption of MEHP by rodents, and in particular, greater absorption by young rodents compared to adults. These observations become important in the discussion of DEHP toxicity, since MEHP is thought be the active agent involved in this toxicity (63).

X. TOXICITY OF PLASTICIZERS: PHTHALATES

The potential toxicity of phthalate esters is of concern not only from packaging materials but also from the fact that PAEs are noted to leach into the environment (64). A Taiwanese study reported that PAEs such as DOP can be detected in the soil, ground water as well as vegetables grown in these environments (64). The LD_{50} for DEHP in rats has been reported to be 34 g/kg b.wt. (62). Phthalate esters have been shown to have a number of potential deleterious effects in vitro and in vivo (Table 76.7). In young male rats (110 g b.wt.), diets containing 2% (wt/wt) DEHP fed for 3 weeks resulted in decreased body weight gains associated with a decrease in energy retention and cumulative nitrogen balance (65). As mentioned above, PAEs such as DEHP, are the subject of toxicological concern due to the structural similarity of these molecules to the known teratogen thalidomide (phthalidomide) (48). In vitro studies evaluating the potential estrogenicity of various PAEs demonstrated that DBP and BBP weakly competed with 17β-estradiol for estrogen receptor binding and exhibited 36 and 42% activity, respectively, in gene expression assays using MCF-7 breast cancer cells (66). However, in vivo these PAEs did not increase uterine wet weights in the standard uterotrophic assay, nor was there any effect on vaginal epithelial cell cornification (66). Evidence of fetotoxicity, embryolethality and teratogenicity of PAEs have been reported in animal studies with DEHP and other branched PAEs fed at 1000 mg/kg diet to rat dams; no such effects were observed with DEHP fed at 200 or 40 mg/kg diet (14). DEHP at 1000 mg/kg diet, resulted in reduced numbers of live fetuses and 63% malformed fetuses, namely soft tissue malformations and skeletal malformations. Others have reported that rats dosed with 2 g DEHP or DOP/kg b.wt./day resulted in no changes in seminiferous tubular structure or Leydig cell morphology with DOP, but slight cytoplasmic rarefaction or vacuolation of Sertoli cells in seminiferous tubules with DEHP (67). Studies evaluating the developmental toxicity of 7-, 9- and 11-carbon branched PAEs have reported that doses between 500 and 1000 mg/kg b.wt. resulted in increased incidences of supernumerary lumbar ribs in pups and a significant increase in dilated renal pelves (68). Decreases in testicular weight recorded in rodents receiving MEHP at 2% of their diet has been attributed to loss of gonadal zinc. The intravenous administration of 11 mg/kg MEHP daily for 13 days to rabbits has been shown to result in 33% maternal mortality. Enlargement of liver and accompanying hypolipidemia and hepatic peroxisomal proliferation has also been reported in rats administered DEHP (16). Chronic feeding studies of DEHP at dietary intakes of 0.27–0.9 g/kg b.wt. for 2 years has resulted in a significant increase in hepatic tumours. It should be noted, however, that there is a 6,000 fold or more margin between the estimated human intake of PAEs and the dose that produced liver tumours in rodents. Thus, while PAEs have been reported to have teratogenic and fetotoxic effects in animal studies when fed at levels of 1 g DEHP/kg/day, and impaired lipid metabolism accompanied by

TABLE 76.7
Some Detrimental Effects of Phthalate Esters and their Monoester Metabolites[1]

In Vitro **Findings:**
Chromosomal aberrations in mammalian cells;
Base pair mutagenicity with/without S-9 mix (MEHP);
Genotoxicity to *B. subtilis*;
Estrogenic effects via competitive estrogen receptor binding; MCF-7 gene expression;
Inhibition of gap junctional intercellular communication (GJIC) in rat and mouse hepatocytes;
Decreased LH-stimulated secretion of testosterone from rat Leydig cells.
In Vivo **Findings:**
Decreased rat body weight gains and decreased energy and nitrogen balances;
Small or no decrease in rat litter size and pup weight;
Hepatic and pituitary hypertrophy;
Neuromuscular and skeletal deformities, i.e. increased incidence of supernumerary lumbar ribs;
Reproductive tract malformations, decreased testicular weight and sperm counts;
Hypolipidemia;
Hepatic tumorigenesis;
Fetotoxicity, embryolethality and teratogenicity in rats.

hepatomegaly at 2% DEHP in the diet, the rapid metabolism and excretion of DEHP in primates and humans suggests that this plasticizer is only a minor health risk (14, 16, 21). Indeed, the Institute of Food Technologists' Expert Panel on Food Safety and Nutrition concluded that phthalates do not represent a significant hazard to healthy humans given the relatively low rates of migration into foods (5). On the other hand, the very young and those undergoing hemodialysis and hemophiliacs with long-term exposure to higher doses of DEHP may be at risk of adverse effects including pulmonary, cardio-toxicity or increased hepatic peroxisomal proliferation (63). The risk for liver cancer in man appears to be relatively low due to the metabolism and excretion of PAE metabolites such as MEHP as well as the absence of inhibition of GJIC in human and hamster hepatocytes in culture compared to rat and mice hepatocytes (69).

XI. EFFECTS OF IONIZING RADIATION ON PACKAGING MATERIALS

Treatment of foods which represent a microbiological health risk using ionizing irradiation to improve the safety of susceptible foods such as chicken (*Salmonella sp*) and ground beef or hamburger (*Escherichia coli* O157:H7) is increasingly recommended given the potential severity of these foodborne diseases (22, 23). Irradiation must also be combined with other safe food handling or preservation techniques (i.e. refrigeration) to prevent cross- or recontamination of the irradiated product. One way to achieve this is to irradiate pre-packaged meat and poultry; however, the irradiation process should alter neither the physico-chemical properties of the packaging film nor result in the transfer of components or residues from the packaging material to contaminate the food in contact with the plastic film (71). Irradiation of plastic films may result in a combination of two basic phenomena: a) chemical cross-linking between polymer structural units ultimately resulting in a potential increase in film tensile strength, or b) fragmentation of polymeric structures resulting in decreased strength and increased permeability of packaging films (72, 73). Polymer additives such as plasticizers and antioxidants (added as stabilizers) will also be affected by the ionizing irradiation of plastic films (72–74). Radiation-induced polymer alterations will be influenced by several factors including the chemical structure and composition (i.e. additives) of the polymer, processing history and the irradiation conditions, namely the dose rate. In addition to scission and crosslinking of polymeric chains, the formation of volatile radiolysis products, which can be influenced by the presence of O_2, occur in irradiated plastics. As reviewed by Buchalla and coworkers (72), under vacuum, the main radiolysis volatiles produced are hydrogen, methane and hydrogen chloride from polymers containing chlorine molecules. In the presence of O_2, the gaseous products will also contain CO_2, CO as well as H_2, CH_4 and other hydrocarbons. The formation of reactive oxygen species as free radicals can result in the oxidation of the polymer, resulting in the formation of peroxide, alcohol and carbonyl compounds (72).

The various classes of polymers are noted to vary in their susceptibility to radiolysis. The most stable polymers include the vinyl derivative PS and the polyester PET, with the polyamides (Nylons) having intermediate stability and the polyolefins (HDPE, LDPE, PP) as the least stable polymers. When exposed to radiation doses or 25 or 50 kGy, PS samples have been reported to contain radiolysis products such as benzaldehyde, acetophenone (30–50 ppm), 1-phenylethanol ($<$10 ppm) and phenol; Nylon samples contained pentanamide (approx. 75 ppm) and caprolactam (75). Exposure of PP to heat, light or ionizing radiation is known to result in the generation of alkyl radicals (PP•) which can subsequently interact with molecular oxygen to form peroxyl radicals (PP-OO•) and ultimately, products containing hydroxyl, carbonyl or carboxyl groups (76). These volatiles can result in adverse flavour changes to irradiated foods packaged in these polymers. The intensity of off-odours is much greater upon irradiation of LDPE compared to HDPE, which in turn is greater than PS and various polyamides and polyesters (77). Moreover, the intensity of off-odours is noted to increase with the availability of oxygen in the atmosphere. Taints from PVC and PS have been reported with doses as low as 2.6 to 3.9 kGy through sensory testing (77). Odors from irradiated LDPE have been described as waxy polyolefin odor in the unirradiated control and plastic, burnt, pungent and waxy in irradiated samples (78). PET samples were described as giving off a slight plastic and a sweet plastic odor in both unirradiated and irradiated samples.

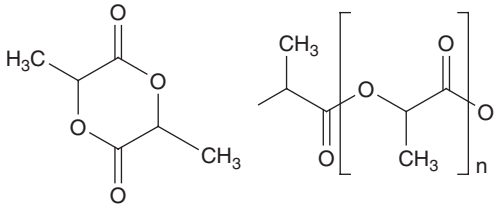
Due to the potential physico-chemical changes to polymers as a result of cross-linking or scission of polymer chains as a result of irradiation, it is necessary to investigate the permeability of irradiated films to O_2, CO_2, water vapour transmission as well as mechanical properties. Recently, Goulas and coworkers (79) reported that irradiation at 5, 10 and 30 kGy had no effect on the O_2, CO_2 permeability or water vapour transmission rates of a variety of polymers including LDPE, HDPE, PS, ethylene vinyl acetate (EVA), bi-axially oriented PP (BOPP) and an Ionomer. The low doses (5 and 10 kGy) had no effect on polymer mechanical properties such as tensile strength, % elongation at break and Young's Modulus. However, 30 kGy of irradiation resulted in decreased tensile strength in HDPE, BOPP and Ionomer and decreased % elongation at break in LDPE and Ionomer (79). There were no changes in Young's Modulus values for all polymers with the high dose irradiation. It is noteworthy that the mechanical properties of neither EVA nor PS were affected by irradiation. The overall migration into food simulants also showed variable results in that migration into distilled

water was not affected by irradiation; at 30 kGy, migration into 3% acetic acid was enhanced and decreased for BOPP and Ionomer, respectively. Similarly, migration into isooctane was increased for BOPP, but decreased for HDPE and Ionomer films (79).

The addition of antioxidants such as BHT is noted to reduce the formation of carboxylic acid derivatives in LDPE films (72). However, phenolic antioxidants such as Irganox 1076™ (Table 76.6), 1010™ and 1330™ and the arylphosphite antioxidant Irgafos 168™ which are frequently added to PVC, PE and PP polymers are susceptible to degradation following gamma irradiation, but also during melt processing and/or storage of polymers such as HDPE (58, 74). For example, low doses of irradiation of approx. 5 kGy to HDPE trays can result in the complete destruction of phosphite antioxidants such as Irgafos 168™ and Ultranox 626™ (Hostanox PAR24™) to their phosphate derivatives (58). Products of Irgafos 168™ decomposition in polymers include 1,3-di-*tert*-butylphenone and 2,4-di-*tert*-butylphenol (78). It is noteworthy that some antioxidant degradation products may become covalently linked to the matrix polymer, thereby decreasing the potential for migration into foodstuffs. This hypothesis has been validated by studies with ^{14}C-labelled packaging antioxidants indicating that following irradiation, the amount of extractable ^{14}C-labelled native antioxidant declined in irradiated polymers. This observation was associated with increases in the non-extractable radioactivity within the polymeric matrix (74). At present, little is known about the toxicity of the radiolysis products from polymers and additives given the variability in migration rates due to potential polymeric entrapment of volatiles from the different polymers into food simulants.

XII. ALTERNATIVE FOOD PACKAGING MATERIALS

Alterations in the formulation of traditional polymers are performed for several reasons including a) improvement of the biodegradability of common polymers such as LDPE once they enter the environment (80) and b) decreasing the bitterness from flavanones and terpenoids in citrus juices through the use of active packaging (enzymes immobilized on cellulose acetate films) (81). Safety concerns about the environment and the food supply with regard to the disposal of packaging materials in the environment and leaching of plasticizers into the soil and ground water (64) have been the impetus behind research into novel food packaging materials. Edible films based on carbohydrate (i.e. starches), lipids (i.e. monoglycerides) and milk protein (i.e. caseinates, whey proteins) have been investigated extensively by food technologists (82–84). However, these films have very high water vapour transmission rates (WVTR) albeit, moderate oxygen permeability, ultimately severely limiting the utility of these biodegradable or edible films in the food industry in any meaningful way (82, 83). Conn and coworkers (85) investigated the use of polylactide (PLA) as a food packaging polymer. Polylactide is a polymer resulting from the polymerization of lactic acid and its dimer lactide as shown below:



Lactide **Polylactide (PLA)**

Lactic acid has a solid history of use as a food ingredient and has had GRAS status in the US since 1984. The main physical characteristic of concern with PLA is the T_g = 60°C which limits the use of this polymer to foods which are not extensively heated. Migrant chemicals from PLA may include lactic acid, lactoyl-lactic acid (the linear dimer of lactic acid), small oligomers of PLA and lactide (85). These chemical species are however expected to be hydrolysed to lactic acid in the aqueous or acidic environment of foodstuffs or ultimately within the gastric contents. Potential applications of PLA include disposable food service items such as dishes and cutlery, packaging for fast-food applications at or below room temperature or at elevated temperatures below 60°C (85).

Other workers have investigated LDPE films which had been formulated to contain from 5 up to 40% rice, potato, wheat or soluble starch to improve the biodegradability of LDPE films when exposed to aerobic and anaerobic bioreactors (80, 86). It is noteworthy that the resultant LDPE/starch blend polymers would consist of 4 separate phases, two each of crystalline and amorphous structure from the two different polymer components. The incorporation of rice and potato starches into LDPE polymers resulted in reductions to film mechanical properties, namely tensile strength and modulus as well as % elongation; however, films retained functionality provided the starch content did not increase past 20% (80). The flexural strength and moduli of the LDPE/starch blend polymers increased with the starch proportion of the films. When evaluating gas permeability and WVTR of the LDPE/starch blends, film permeability to N_2 and CO_2 increased, as did the WVTR, with an increase in polymer starch content. As expected, biodegradability of the LDPE/starch blend polymers was enhanced at rice and potato starch contents greater than 10%, with approx. 50–60% starch removal and some early LDPE degradation observed following bioreactor incubations. Moreover, using soluble versus wheat starch improved the biodegradability of the LDPE/starch blend polymers, in that wheat starch resulted

in up to 55% starch removal, whereas soluble starch resulted in up to 80% starch removal (86). LDPE/starch blend polymers containing up to 20% starch retain mechanical barrier properties, although the susceptibility to high WVTR values and gas permeabilities would be a significant concern for most processed foods.

Active packaging is an emerging technology wherein the packaging interacts with the food inside to improve its quality, shelf-life or safety (81). Citrus juices, particularly grapefruit juice, contain bitter components, namely naringin and limonin, which may be a negative characteristic from an organoleptic perspective. Active packaging, which was comprised of fungal-derived naringinase immobilized to cellulose acetate film, reduced naringin and limonin concentrations in grapefruit juice, and thereby decreased bitterness as evaluated by paired-comparison sensory testing (81). Desorption of enzyme from the film reached only 2% following 4 weeks of storage indicating good stability compared to other acetate films.

XIII. CONCLUSION

In summary, migration of plastic polymer residues (i.e. VC, styrene), plasticizers and contaminants may adversely influence the taste, odour and safety of foods and beverages either stored or heated in specific types of storage containers (i.e. PE, PVC, paperboard etc.). Factors which influence the degree of severity of these effects include: contact surface and time, aqueous or lipophilic nature of the foodstuff, fat-releasing properties of the food, temperature of processing or storage and method of processing (i.e. ionizing radiation). Off-odours and flavours in foods packaged or stored in polymers, or conversely 'flavour-scalping' of food volatiles into packaging materials may reduce the quality and palatability of foods without affecting the health and safety of the consumer. Toxicology of plastics and plasticizers may be associated with occupational exposure as in the case of ASL in those exposed to VC, or consumption of phthalate ester plasticizers in animal studies. Exposure of consumers to the amount of phthalate esters which may migrate into foods is not considered to be a health risk. Food scientists are currently evaluating the utility of such alternate packaging materials such as edible films, polymer/starch blends, polylactide, a polymer of the dimer of lactic acid, lactide, as well as enzymes adsorbed to films as a form of active packaging which can conceivably improve a product as it interacts with its packaging. Limiting factors for the application of these novel packaging films include such problems as high rates of water vapour transmission, high gas permeability as well as glass transition temperatures close to the serving temperature of foods. However, new formulations as well as the use of laminate films may enhance the physicochemical properties of existing films and newer edible or biodegradable films.

77 Food Plant: Sanitation and Quality Assurance

Nanna Cross
Chicago, Illinois

CONTENTS

I. PART I: SANITATION

Sanitation in a food processing plant is to assure that the food product the company manufactures is wholesome and safe to eat. This usually means that the food does not contain any potential undesirable substances including:

- Biological toxins
- Chemical toxicants
- Environmental contaminants
- Extraneous substances

To achieve this goal, a food processor with products sold crossing state lines in the United States uses the following approaches:

1. Implementing a basic food plant sanitation program.
2. Compliance with good manufacturing regulations issued by the United States Food and Drug Administration (FDA).
3. Long term plan in developing a Food Hazards Critical Control Points or HACCP program for those food industries that are not mandated to have a current HACCP program.

A. Food Plant Sanitation Program

Most food processors have a sanitation program to make sure that their products are safe. Most programs have the following components, among others:

1. The product and its ingredients
2. Cleaning
3. Housekeeping
4. Personnel hygiene and safety
5. Warehousing
6. Distribution and transportation
7. Sanitation inspections

Let us use the manufacturing of bakery products as an example to study the above factors.

Bakery goods include bread cakes, pies, cookies, rolls, crackers and pastries. Ingredients consisting of flour, baking powder, sugar, salt, yeast, milk, eggs, cream, butter, lard shortening, extracts, jellies, syrups, nuts, artificial coloring, and dried or fresh fruits are blended in a vertical or horizontal mixer after being brought from storage, measured, weighed, sifted, and mixed. After mixing, the dough is raised, divided, formed, and proofed. Fruit or flavored fillings are cooked and poured into dough shells. The final product is then baked in electric or gas-fired ovens, processed, wrapped, and shipped. Loaves of bread are also sliced and wrapped.

B. Raw Ingredients and the Final Product

Sanitation considerations apply to every stage of the processing operation: raw materials, operations.

1. Critical Factors in the Evaluation of Raw Materials

1. Raw materials must come from warehouses that comply with local, county, state and federal requirements for food warehouse sanitation.
2. For certain ingredients such as egg and milk products, their sources, types, etc. should be ascertained. If frozen eggs are used, are they pasteurized and received under a Salmonella-free guarantee? Some food plants require routine testing of critical raw materials for bacterial load including Salmonella and other pathogens.
3. Are raw materials requiring refrigeration (or freezing) or refrigerated (or frozen)?
4. Is there any "blend off," mixing contaminated raw materials with clean raw materials?

2. Critical Factors in Evaluating the Sanitation of Operations

1. Room temperature, bottleneck, and bacterial contamination. During certain stages of an assembly line operation, always check sites where "bottleneck" frequently occurs. Room temperature and period of bottlenecking are related to chances of bacterial contamination.
2. Metal detection. During a production operation, always check metal detection or removal devices to make sure that they are working properly.
3. Time and temperature. Identify stages in the operation where time and temperature are major and/or critical variables. Intense education must assure that any abuses which may allow growth and possible toxin formation of microbial contaminants are strictly forbidden.
4. Equipment design. Be alert for poorly designed conveyors or equipment which might add to bacterial load through product delay or "seeding."

C. Cleaning

Imagine your kitchen. We have to wash the kitchen floor because water, oil, and other cooking ingredients are dropped accidentally or intentionally. Then there are the dishes and pots and pans. They have to be cleaned and put away.

Of course the same problems exist in a bakery processing plant, but on a much larger scale.

Almost all bakery processing plants have a written plan on plant sanitation:

- Is there water on the floor?
- Has all flour dust been removed?
- Are different and clearly identified containers used for salvaged material and returned goods? Any noncompliance may be the cause of contaminating newly produced products
- Is the distance between garbage disposal containers and the station where food ingredients are processed acceptable to avoid any potential contamination?

Those few examples are among hundreds of details that a good sanitation program will carefully identify and establish polity as to who is responsible and what the responsibility is.

Similarly, food processing equipment requires a highly structured sanitation program.

Major components or equipment in the process flow are flour bins, elevator boots, conveyor systems, sifters, dump scale apparatus, production line flouring devices, dough proofers, overhead supports and ledges, and transport vehicles. All have removal inspection ports. Schedule checks to make sure that static accumulation for insect and/or rodent infestations is acceptable. Remove them as frequently as possible.

Most companies require the inspection of equipment prior to production to determine adequacy of cleanup and sanitizing operations.

It is doubtful that a food processing company will survive long if it does not have a comprehensive and workable program to clean the equipment used to manufacture its products. The objective of cleaning any equipment that has been used in food processing is to remove any residue or dirt from the surfaces which may or may not touch any food or ingredient.

Some of the equipment may be subjected to further sanitization and sterilization. Such attempts will be questioned if there is still visible dirt or debris attached to any surface of the equipment.

The wet-cleaning process, used by all food processors, has three components: pre-rinse, cleaning, post-rinse. This can be done manually or by circulation.

- Pre-rinse. This uses water to separate loosely adhered particles (dirt, residue, etc.), using two basic considerations. Perform the cleaning after the production cycle is completed to get ready for the next work day. Predetermined criteria: method for specific surfaces (vessels, components, pipelines), period of rinsing, temperature. For both factors, most food processing plants have established appropriate policy to handle the pre-rinse.
- Clean. Under most circumstances, soaking, scrubbing and more soaking, characterize any cleaning process. The goal is to remove sticky residues or particles from the surface. Of course, cleaning detergents or solutions are used in the soaking and scrubbing. The chemical reactions are the standard: saponification, hydrolysis, emulsification, dispersion, and so on. All chemical reactions are time- and temperature-dependent.
- Post-rinse. This is no difference from rinsing cooking utensils after they have been scrubbed and soaked. This stage removes all detergents/sanitizers used and any particles left behind.

For all three stages, the water used must comply with rigid standards to avoid damage to equipment, corrosion, and status of microbiological presence.

Apart from manual cleaning, we have the Clean In Place or CIP which uses a circulation system of chemical solutions pumped through the equipment "in place." Much food processing equipment is designed to have this built-in feature. Any automatic process has inherent problems that must be dealt with in a manner dictated by circumstances.

The use of a circulatory method in cleaning is dependent on two groups of factors:

1. Substances used in the detergent or cleaning solutions.
2. The variables.

Substances used can include an array of chemicals: caustic soda, acid, etc. Obviously, the concentration of such chemicals is a critical factor. The variables include: contact temperature, contact time, flow rate between surfaces and substances in cleaning solution.

D. HOUSEKEEPING

Again, we can use our home as an example. We keep the inside clean, dusting, vacuuming, sweeping, and so on. We keep the outside of our house clean: garbage, leaves, droppings, peeling paints, and so on. It is of paramount importance that a food processing plant is clean inside and outside.

For internal housekeeping, part of the information has been discussed in the cleaning process we presented earlier. However, we still need to worry about cleaning windows, debris under counters and in the corner of a room, emptying garbage cans, and so on. Most food companies hire regular maintenance crews to do the job. Unfortunately,

the plant manager will still need to develop policy, implement and evaluate procedures.

The environment of a food processing plant has always been a problem: garbage, birds, insects, rodents, and so on. Housekeeping for the immediate vicinity outside a food plant requires close monitoring.

Many professionals consider housekeeping as "nonglamorous" and "menial." However, it is so important that it requires complete attention from management. The reason is simple. Regulatory officials from local, county, and state levels are serious about this aspect of food processing. If the company ships products across state lines, the United States FDA has the authority to issue warning letters about any unacceptable conditions, including sloppy housekeeping.

We will briefly analyze the two components of housekeeping.

1. Housekeeping inside a Food Plant

Every manufacturing company, food or otherwise, has a master schedule of cleaning. Obviously, food particles attract rodents and other undesirable animals and insects and removal is important to the plant operation. A cleaning schedule essentially has the following components:

1. Coverage: rooms, storage areas, toilets, offices, freezers, walls, ceilings, and so on.
2. Frequency: each area requires a different frequency of cleaning, days (1, 2, 3, 4, etc.), weekly, etc.

A cleaning schedule is meaningful only if the methods of cleaning are appropriate and the schedule is enforced or implemented. Also, the frequency of cleaning must be carefully evaluated with the methods of cleaning. This is because, a process of cleaning may increase the dust load in the air which may in turn contaminate other surface areas.

Some areas require frequent cleaning and others don't.

A storage room with infrequent traffic may be cleaned once a week while a storage room with frequent traffic may need to be cleaned once a day.

a. Dust

1. Most dry cleaning methods increase dust in the air, e.g., wiping with a rag, vacuum cleaners, brooms, brushes, pressurized air.
2. Since dust particles are charged electrically, they will adhere to any surfaces that are electrically or electrostatically charged. This results in contamination.
3. Dust contamination is heightened when the environment is moist, including surfaces, resulting in molds. When the molds occur on piping, back of tanks, ducts and cables, corner of ceilings and other places that are obscured from vision, the problem increases.
4. Dust moves from room to room by normal air flow from temperature differences or window and door draft. That is further contamination.
5. Dust dispersion is a risk replacing the risk that has just been removed by cleaning.

The areas to be cleaned should be evaluated with great care.

1. Although most objects, e.g., vats, holding tanks, are raised from the floor with a space for cleaning, it is still difficult to clean this part of the floor because the space is too narrow and hidden from view.
2. Corners always pose a problem for cleaning. Special devices such as suction hose are needed to keep them clean. There are places where insects, rodents, and other undesirable creatures will thrive.
3. Bottoms of most equipment always pose a problem in cleaning. Crawling on one's knees does not always solve the problem. Customized devices may be needed.

Wet-cleaning by hands or machines is acceptable. Modern technology has made available gel, foam, aerosols, and special equipment. However, the water hose is still the method of choice in most food companies. Wet-cleaning must take the following into consideration:

1. All materials that can absorb moisture, such as cardboard boxes, pallets, etc. should be removed.
2. After wet-cleaning, the surfaces must be dried carefully.
3. Proper draining systems should be in place and maintained, clean and free of debris around the openings.

II. PART II: UNITED STATES ENFORCEMENT TOOLS

A. Background Information

The FDA is charged with protecting American consumers by enforcing the Federal Food, Drug, and Cosmetic Act and several related public health laws. What does it do when there is a health risk associated with a food product?

When a problem arises with a product regulated by the FDA, the agency can take a number of actions to protect the public health. Initially, the agency works with the manufacturer to correct the problem voluntarily. If that fails, legal remedies include asking the manufacturer to recall a

product, having federal marshals seize products if a voluntary recall is not done, and detaining imports at the port of entry until problems are corrected. If warranted, the FDA can ask the courts to issue injunctions or prosecute those that deliberately violate the law. When warranted, criminal penalties — including prison sentences — are sought.

However, the FDA is aware that it has legal responsibility to keep the public informed of its regulatory activities. To do so, the FDA uses press releases and fact sheets. The FDA uses this tool before, during, and after an event of health hazard related to a food product. Some of these are briefly described below, emphasizing the sanitation deficiencies of affected food products.

1. Press Releases and Fact Sheets

FDA Talk Papers are prepared by the Press Office to guide FDA personnel in responding with consistency and accuracy to questions from the public on subjects of current interest. Talk Papers are subject to change as more information becomes available.

Below are the regulatory tools used by the FDA.

B. Data on Insanitary Practices

For the FDA to enforce its laws and regulations, it must have specific data regarding the sanitary practices of a food processing plant. The FDA has a number of ways to ascertain or determine if a food product is associated with unsanitary conditions in a food processing plant or if a food processing plant has sanitary deficiencies. They include:

1. Product monitoring
2. Activities based on reports from the public
3. Activities based on reports from other government agencies
4. Establishment inspection reports

1. Product Monitoring

Product monitoring is as old as when modern food processing first started. At present, local, county, state, and federal health authorities conduct market food product sampling and analyses to determine the wholesomeness of food. Such monitoring is restricted by the availability of allocated budget and resources. However, the FDA has the most resources and its monitoring effort produces the most results.

When products are found to be unsanitary (pathogens, rats, insects, glass, metal, etc.) by the FDA, it will implement standard procedures to warn the public, remove such products from the market and a variety of other actions it can do and which will be discussed later in this chapter.

2. Activities Based on Reports from the Public

The FDA has a website and an 800 number for the public to report health hazards including sanitation of food products. Since the establishment of such communication convenience, there is an increasing number of consumers reporting products posing health risks, such as glass in baby food, dead insects in frozen dinners, and so on. Occasionally, so-called whistle blowers, i.e., employees of food companies, inform the FDA of products with contaminants from unsanitary practices. Based on the data provided by the public, the FDA implements standard procedures to handle any potential health hazards related to the products reported.

3. Activities Based on Reports from Other Government Agencies

Health care providers frequently are the source of information that eventually lead to unsanitary practices of food companies. These include physicians, pharmacists, nurses, dentists, public health personnel, and others. Most of these reports involve injury, such as food poisoning, decomposed or spoiled product contents.

These reports become a vital source of leads for the FDA to enforce its laws and regulations.

4. Establishment Inspection Reports

Inspection of a food processing plant by a government authority is the basis on which the government can decide if the food manufactured in the plant is wholesome and poses no economic fraud. The frequency and intensity of the inspection process will depend on resources and budgets, especially for the non-federal agencies. The FDA, as a federal agency, has more authority, resources, and budget.

The framework for inspecting a plant covers the following:

1. Basics
   a. Preparation and references
   b. Inspectional authority
2. Personnel
3. Plants and grounds
4. Raw materials
5. Equipment and utensils
6. Manufacturing process
   a. Ingredient handling
   b. Formulas
   c. Food additives
   d. Color additives
   e. Quality control
   f. Packaging and labeling

After an inspection is completed, the inspector gives the plant management a copy of the report. If there are

sanitation deficiencies, the management will be expected to correct them.

The data collected from this inspectional procedure and other sources discussed earlier become the central operation base on which the FDA will enforce its legal responsibility to make sure that all deficiencies are corrected to reduce any hazard to the health of the consuming public.

The interesting part is the enforcement and compliance of the equation that concerns this chapter. We have seen the manner in which the FDA compiles data on the sanitation of a food product and a food processing plant. We will now proceed to the regulatory activities the FDA uses to assure compliance.

C. Recalls

The *FDA Consumer* magazine has published several articles on the recall of food products in this country. The following information has been compiled in these public documents.

1. Misunderstanding

Recalls are actions taken by a firm to remove a product from the market. Recalls may be conducted on a firm's own initiative, by FDA request, or by FDA order under statutory authority.

The recall of a defective or possibly harmful consumer product often is highly publicized in newspapers and on news broadcasts. This is especially true when a recall involves foods, drugs, cosmetics, medical devices, and other products regulated by FDA.

Despite this publicity, FDA's role in conducting a recall often is misunderstood not only by consumers, but also by the news media, and occasionally even by the regulated industry. The following headlines, which appeared in two major daily newspapers, are good examples of that misunderstanding:

"FDA Orders Peanut Butter Recall," and "FDA Orders 6,500 Cases of Red-Dyed Mints Recalled."

The headlines are wrong in indicating that the Agency can "order" a recall. FDA has no authority under the Federal Food, Drug, and Cosmetic Act to order a recall, although it can request a firm to recall a product.

Most recalls of products regulated by FDA are carried out voluntarily by the manufacturers or distributors of the product. In some instances, a company discovers that one of its products is defective and recalls it entirely on its own. In others, FDA informs a company of findings that one of its products is defective and suggests or requests a recall. Usually, the company will comply; if it does not, then FDA can seek a court order authorizing the Federal Government to seize the product.

This cooperation between FDA and its regulated industries has proven over the years to be the quickest and most reliable method to remove potentially dangerous products from the market. This method has been successful because it is in the interest of FDA, as well as industry, to get unsafe and defective products out of consumer hands as soon as possible.

FDA has guidelines for companies to follow in recalling defective products that fall under the Agency's jurisdiction. These guidelines make clear that FDA expects these firms to take full responsibility for product recalls, including follow-up checks to assure that recalls are successful.

Under the guidelines, companies are expected to notify FDA when recalls are started, to make progress reports to FDA on recalls, and to undertake recalls when asked to do so by the Agency.

The guidelines also call on manufacturers and distributors to develop contingency plans for product recalls that can be put into effect if and when needed. FDA's role under the guidelines is to monitor company recalls and assess the adequacy of a firm's action. After a recall is completed, FDA makes sure that the product is destroyed or suitably reconditioned and investigates why the product was defective.

The FDA has stated the following guidelines several times in its magazine FDA Consumer.

2. Categories

The guidelines categorize all recalls into one of three classes according to the level of hazard involved.

1. Class I recalls are for dangerous or defective products that predictably could cause serious health problems or death.
2. Class II recalls are for products that might cause a temporary health problem, or pose only a slight threat of a serious nature.
3. Class III recalls are for products that are unlikely to cause any adverse health reaction, but that violate FDA regulations.

FDA develops a strategy for each individual recall that sets forth how extensively it will check on a company's performance in recalling the product in question. For a Class I recall, for example, FDA would check to make sure that each defective product has been recalled or reconditioned. In contrast, for a Class III recall the Agency may decide that it only needs to spot check to make sure the product is off the market. Detailed regulations have been promulgated on FDA recalls in the U.S. Code of Federal Regulations.

Even though the firm recalling the product may issue a press release, FDA seeks publicity about a recall only when it believes the public needs to be alerted about a serious hazard. For example, if a canned food product, purchased by a consumer at a retail store, is found by FDA to contain botulinum toxin, an effort would be made to retrieve all the cans in circulation, including those in the hands of consumers. As part of this effort the Agency also

could issue a public warning via the news media to alert as many consumers as possible to the potential hazard.

FDA also issues general information about all new recalls it is monitoring through a weekly publication titled "FDA Enforcement Report."

Before taking a company to court, FDA usually notifies the responsible person of the violation and provides an opportunity to correct the problem. In most situations, a violation results from a mistake by the company rather than from an intentional disregard for the law.

There are several incentives for a company to recall a product, including the moral duty to protect its customers from harm and the desire to avoid private lawsuits if injuries occur. In addition, the alternatives to recall are seizures, injunctions, or criminal actions. These are often accompanied by adverse publicity, which can damage a firm's reputation.

A company recall does not guarantee that FDA will not take a company to court. If a recall is ineffective and the public remains at risk, FDA may seize the defective products or obtain an injunction against the manufacturer or distributor.

The recalling firm is always responsible for conducting the actual recall by contacting its purchasers by telegram, mailgram, or first-class letters with information including:

1. The product being recalled
2. Identifying information such as lot numbers and serial numbers
3. The reason for the recall and any hazard involved
4. Instructions to stop distributing the product and what to do with it.

FDA monitors the recall, assessing the firm's efforts.

3. Initiating a Recall

A firm can recall a product at any time. Firms usually are under no legal obligation to even notify FDA that they are recalling a defective product, but they are encouraged to notify the agency, and most firms seek FDA's guidance. FDA may request a recall of a defective product, but it does so only when agency action is essential to protect the public health.

When a firm undertakes a recall, the FDA district office in the area immediately sends a "24 Hour Alert to Recall Situation" notifying the relevant FDA center (responsible for foods and cosmetics, drugs, devices, biologics, or veterinary medicine) and DEEO of the product, recalling firm, and reason for the recall. FDA also informs state officials of the product problem, but for routine recalls, the state does not become actively involved.

After inspecting the firm and determining whether there have been reports of injuries, illness, or other complaints to either the company or to FDA, the district documents its findings in a recall recommendation ("RR") and sends it to the appropriate center's recall coordinator. The RR contains the results of FDA's investigation, including copies of the product labeling, FDA laboratory worksheets, the firm's relevant quality control records, and, when possible, a product sample to demonstrate the defect and the potential hazard. The RR also contains the firm's proposed recall strategy.

4. The Strategy

FDA reviews the firm's recall strategy (or, in the rare cases of FDA-requested recalls, drafts the strategy), which includes three things: the depth of recall, the extent of public warnings, and effectiveness check levels.

The depth of recall is the distribution chain level at which the recall will be aimed. If a product is not hazardous, a recall aimed only at wholesale purchasers may suffice. For more serious defects, a firm will conduct a recall to the retail level. And if the public health is seriously jeopardized, the recall may be designed to reach the individual consumer, often through a press release.

But most defects don't present a grave danger. Most recalls are not publicized beyond their listing in the weekly Enforcement Report mentioned earlier. This Report lists the product being recalled, the degree of hazard (called "classification"), whether the recall was requested by FDA or initiated by the firm, and the specific action taken by the recalling firm.

A firm is responsible for conducting "effectiveness checks" to verify — by personal visits, by telephone, or with letters — that everyone at the chosen recall depth has been notified and has taken the necessary action. An effectiveness check level of "A" (check of 100 percent of people that should have been notified) through "E" (no effectiveness check) is specified in the recall strategy, based on the seriousness of the product defect.

5. The Health Hazard Evaluation

When the center receives the RR from the district office, it evaluates the health hazard presented by the product and categorizes it as a class I, II, or III. The classification is determined by an ad hoc "Health Hazard Evaluation Committee" made up of FDA scientists chosen for their expertise. Classification is done on a case-by-case basis, considering the potential consequences of a violation.

A class I recall involves a strong likelihood that a product will cause serious adverse health consequences or death. A very small percentage of recalls are class I.

A class II recall is one in which use of the product may cause temporary or medically reversible adverse health consequences, or in which the probability of serious adverse health consequences is remote.

A class III recall involves a product not likely to cause adverse health consequences.

For class I and II, and infrequently for class III, FDA conducts audit checks to ensure that all customers have been notified and are taking appropriate action. The agency does this by personal visits or telephone calls.

A recall is classified as "completed" when all reasonable efforts have been made to remove or correct the product. The district notifies a firm when FDA considers its recall completed.

6. Planning Ahead

FDA recommends that firms maintain plans for emergency situations requiring recalls. Companies can minimize the disruption caused by the discovery of a faulty product if they imprint the date and place of manufacture on their products and keep accurate and complete distribution records.

A "market withdrawal" is a firm's removal or correction of a distributed product that involves no violation of the law by the manufacturer. A product removed from the market due to tampering, without evidence of manufacturing or distribution problems, is one example of a market withdrawal.

A "stock recovery" is another action that may be confused with a recall. A stock recovery is a firm's removal or correction of a product that has not yet been distributed.

Even though the firm recalling the product may issue a press release, FDA seeks publicity about a recall only when it believes the public needs to be alerted about a serious hazard. For example, if a canned food product, purchased by a consumer at a retail store, is found by FDA to contain botulinum toxin, an effort would be made to retrieve all the cans in circulation, including those in the hands of consumers. As part of this effort the Agency also could issue a public warning via the news media to alert as many consumers as possible to the potential hazard.

D. Warning Letters

Under FDA regulations, a prior notice is a letter sent from FDA to regulated companies about regulatory issues. One such notice is the warning letter. If the establishment inspection report includes a list of sanitary deficiencies, the FDA may send a warning letter to the food company to ask for proper correction of such deficiencies.

III. PART III: QUALITY ASSURANCE

Many college graduates in food science, food technology, and food engineering work for food processing plants. Eventually, many of them become operational managers in the company. At this stage, they realize the significance of quality assurance. They are responsible for, not only the quality of the finished product, but also its wholesomeness and safety for public consumption.

The principles and procedures for quality assurance are as applicable and beneficial to small plants as to larger plants. In many cases, quality control systems can be more efficiently administered in small plants because of a simpler organizational structure and more direct communication among employees. The term quality control is not the same as quality assurance. In general "control" refers to one aspect of "assurance." Some professionals equate quality control systems with quality assurance. To avoid this issue and for ease of discussion, we use them (quality assurance, quality control, and quality control systems) interchangeably.

A. Cost versus Benefit

Quality assurance or control is a good management tool. A quality control system specifically tailored to the volume and complexity of a plant operation can be cost-effective.

A properly designed and operated total quality control system will minimize the likelihood of mistakes during processing, give an indication of problems immediately and provide the information quickly to locate and correct the cause of problems. As a result, production delays are reduced, the need for re-processing or re-labeling is lessened, and the possibility of product recall and condemnation is reduced.

B. Product Consistency Improved

Quality control systems provide the information necessary to consistently produce a uniform quality product at a predicted cost. Some processors have questioned whether the cost of implementing a total quality control system would be recovered unless the quality of the plants product had been so poor that the plant suffered reduced sales and a high return of product.

It is true that a plant with a poor product would benefit most. In even the best plants, however, the lack of a quality control system results in a product that is more variable and not as well defined.

With organized controls and objective sampling, the plant has more extensive and precise information about its operation. As a result, management has better control and product quality is stabilized. Records from a quality control system define product quality at the time of shipment, and will aid in dealing with claims of damage or mishandling during shipment.

C. Equipment Costs

Contrary to the impression or idea that quality control systems require highly trained technicians and expensive equipment, a plant quality control system can be fairly simple and inexpensive and still be effective.

The expense of equipment is related to the type and complexity of products and operations and the volume of production. In most cases, a total quality control system in a small plant would require only inexpensive thermometers, calculators, knives, grinders, and existing testing equipment used for traditional inspection and quality assurance.

If necessary, samples may be submitted to commercial laboratories.

Technical skills in food science, mathematics and statistics necessary to establish a quality control system are available from trade associations and professional societies at a reasonable one-time charge. This assistance can be utilized to define defects, defective units, and critical control points and to establish corrective actions for the system. Once the technical details of the system are established, the system can be carried out by plant personnel familiar with the processing operation. It is not necessary to hire a quality control technician.

A critical control point is a point in the food processing cycle where loss of control would result in an unacceptable product. Such points may include the receipt of raw meat just before use, processing and storage operations, and delivery of the product to the customer.

The FDA and USDA have special programs designed to assist in identifying critical control points and setting up a quality control system in a small food processing plant. They will also provide onsite assistance in the startup of the system.

D. Elements of a Total Quality Control System

The first step in developing a plant quality control system is to outline the processes that occur in the plant. An easy way to do this is to visualize the physical layout of the plant operation. The building may be small and consist of only one or two rooms or it may be large and contain many rooms. Make a list of the rooms or areas, and draw a flow diagram of the production process, starting with the incoming or receiving area and ending with the shipping area for finished goods.

For each room or area, list the activities that occur there, making special note of those unusual or important relevant to the process or product. For each, spell out the controls that are imposed-or should be imposed- whether precise or flexible, written or not. Examples would include raw materials examined, ingredients weighed, meters used, scales calibrated, equipment cleaned, bills of lading examined, or trucks checked.

Identify the FDA or USDA inspection regulations that apply to each area of the processing plant, and these should be listed. The good manufacturing regulations promulgated by the FDA are the most appropriate.

For each processing area, designate the person responsible for the controls or inspection — the name of a plant employee or an outside contractor. How often is the control or inspection check to be done? What records are kept? This information can be compiled by a clerical or administrative employee, and the FDA or USDA inspector can assist.

When this exercise has been completed, a rough outline of a total quality control system has been developed. It can be compared, area by area, to descriptions of the elements in the sample system in the appendix of the manual that records the system. If a company does not have such a manual, it is recommended that it start one.

As each element is reviewed, note where controls may be missing. The outline that remains, with missing controls added, is another step closer to a total quality system.

The final step is to convert this outline into a written format, as though it were a set of instructions for plant employees. In reality, it can be the operating manual for the persons responsible for conducting quality control in the plant.

E. General Elements of Total Quality Control

We have just completed a discussion of the general outline of a plant quality control system. Within the system are various elements, determined by the type of operation in the plant.

In this section, the specific operations will be discussed and the elements of a good quality control system will be outlined.

F. Receiving

Examples of controls:

- Examine (and possibly sample) incoming lots
- Verify identification marks
- Check carriers
- Log deliveries

A plant's total quality control system will include written instructions for checking incoming raw materials, such as raw fruit, flour, frozen fish, spices, salt, liquid ingredients, additives and extenders, and for recording the results. These materials must be verified for wholesomeness (free from indications of mishandling, decomposition, infestation), acceptability for intended use, and approval for use.

It may also be desirable at this point — although it is not mandatory — to test for composition (fat, moisture, and so on) to assure proper blending of formulated products. It is preferable to run the most frequent tests on products likely to have the most variation. For example, biological cultures and frozen orange juice need more frequent analysis than frozen dough or dried beef. Sampling plans utilizing statistical quality control procedures are helpful in inspecting incoming lots. These plans are easy to use and may be obtained from several sources, including government booklets.

It is good practice to prepare a suppliers' or buyers' guide outlining the specifications for ingredients, additives and other products bought outside the plant.

The air temperature and product temperature in the receiving area should be checked often enough to assure

that the company's requirements are being met. This would include checks of freezers, doors, door seals, incoming railroad cars, and trucks. The quality control plan should include procedures for taking corrective action in the event a product is contaminated during shipment.

The receiving log should be checked to assure that entries are accurate and up to date and that all requirements regarding incoming products and materials are met. The log will be useful in indicating trends, so problems can be spotted early. The person who checks the log can keep a record of the dates and results of the verifications.

Lots moved from the receiving area to other areas of the plant should be periodically checked to assure that their identity is properly maintained.

In preparing written instructions for the receiving area, identify the various checks to be made, who is to make them, when they are to be made, and how and where the information will be recorded.

G. Manufacturing

Examples of Controls:

- Verifying wholesomeness
- Verifying identification, weight or volume of ingredients
- Verifying ambient temperature
- Handling of rejected ingredients or product

Although ingredients may have been checked earlier for wholesomeness and acceptability, it is a good idea to make another check just prior to actual use in the manufacturing process.

This recheck does not need to be painstaking. It should be ample to assure that unacceptable ingredients are not used, and that ingredients are correctly identified and eligible for use in the product. The frequency of these rechecks can be reduced for small, low-volume plants.

Moreover, a method for controlling the weight of each ingredient is essential in order to assure a uniform and consistent finished product that complies with the company's quality requirements for the products and FDA's good manufacturing regulations for the products.

Maintaining the correct temperature in an area is important to good quality product. Occasional checks should be made during the shift and a record kept of the findings. This will take only a small amount of time and effort on the part of a plant employee, and will identify any situations requiring correction. Inexpensive recording thermometers are useful for maintaining a record of room temperature.

Occasionally, unacceptable ingredients or materials will arrive in the manufacturing area, and procedures should be outlined for these situations. Remember, good management sets realistic and effective controls for dealing with these situations. The procedures that are outlined must be diligently followed.

In cases where a finished product must meet certain requirements, such as fat or moisture limits, consider sampling each lot. Sampling plans may be designed to fit each condition and type of analysis.

For the purpose of verifying formulation or checking wholesomeness, a lot can be each batch during each shift, several batches from the shift, or the shift's entire production. For the purpose of laboratory testing, a lot may consist of one day's production or several days' production of an item, depending on the volume and type of product.

Records of all inspections and tests must be made available to state and federal inspectors and maintained on file.

H. Packaging and Labeling

Examples of Controls:

- Verify label approval
- Verify accuracy of labeling
- Check temperatures
- Finished product sampling

Since this is one of the last steps prior to shipping, it is essential that no regulatory requirement be overlooked.

Checks must be made to assure that all labels have been approved by state and federal regulators and that proper labels are being used. Particular attention should be paid to the new nutrition labeling. It must be verified that illustrations represent the product, net weight and count declarations are accurate, and packaging meets the company's specifications. The temperatures of frozen products, as well as the condition of all containers and cases, should be checked and the findings recorded.

A net weight control program must assure that all lots leaving the plant meet with FDA's requirements for standardized foods as well as other applicable requirements. The sampling rate should be appropriate for the volume, type of product, size of package, and degree of accuracy desired. For instance, cartons of wholesale volumes need less frequent checks than retail packages.

Where applicable, routine systematic sampling, inspection, or analysis of a finished product must be part of the approved total quality control system, especially for a product going to retail outlets.

State and federal regulators in the plant, in regional offices, or in Washington can consult with processors on sampling, including rates, targets, and limits.

I. Shipping

Examples of Controls:

- "First in, first out"
- Record of shipments
- Checking order sizes and temperatures
- Checking containers and carriers

Records of the destination of products shipped from the plant are important to good quality control. In the event recall is necessary, the records will pinpoint the amount and exact location of the product.

The procedure for knowing the destination of each shipment should be explained in the quality control system. The plant may find it beneficial to have some type of container coding and dating system. This would identify the date of processing and packaging for returned goods. Occasional quality control checks should be made to verify the adequacy of the container codes and to verify order sizes, temperatures, (where applicable), and the condition of containers, rail cars, or trucks used for shipping. These controls do not need to be complicated, but adequate to assure effectiveness.

J. General Sanitation

Examples of Controls:

- Rodents and pests
- Product contamination
- Employee hygiene
- Facilities and environmental appearance

A procedure to check the overall sanitation of plant facilities and operations, including outside adjacent areas and storage areas on plant property, should be included in a total quality control system.

In a total quality control system, a designated plant official will make the sanitation inspection and record the findings. If sanitation deficiencies are discovered, a plan for corrective action is necessary. Corrective action might include re-cleaning, tagging a piece of equipment, or closing off an area until a repair is completed.

A frequent systematic sanitation inspection procedure should be used where product contamination is possible, such as packaging failure, moisture dripping, or grease escaping from machinery onto product or surfaces which come into contact with product.

Good employee hygiene should be continuously emphasized through special instruction for new employees and properly maintained, adequate toilet and welfare facilities. Clean work garments in good repair, good personal hygiene practices such as hand-washing, periodic training, and the cleaning of floors and walls in non-production areas are signs of effective sanitation. Plant management will want to use a number of techniques to assure the continued effectiveness of this phase of the quality control system.

K. Employee Training

Examples of Controls:

- New employee orientation
- Refresher training

When new employees begin work at a plant, it is useful to acquaint them with all aspects of the plant. The quality control system should provide for instruction of new employees on the plant's operations and products and on good hygiene practices.

A number of questions concerning hygiene should be addressed in this instruction. What basic things should any new employee know about food handling and cleanliness? Why is cleanliness essential? What are the standards-in other words, what does clean mean? Why are product temperatures important? What is a cooked product? What occurs if something is accidentally soiled? Which chemicals (cleaners, sanitizers, insecticides, food additives) are around? Does the new employee use or have any responsibility for any of these? How does the employee become acquainted with the operation and products? Whom does the employee consult if questions or problems arise?

Make a list of all the items that need to be covered in employee orientation, and indicate generally how and when the orientation will be performed.

Employee training should not end with orientation, but should include an ongoing program to continually remind employees of the importance of good sanitation.

How are employees continually reminded of important functions, such as personal hygiene after a visit to the restroom? Will posting a sign or poster which fades over time communicate the appropriate level of importance? There are many ways of continuing employee training and maintaining sensitivity. Plants may find that occasionally changing methods will help emphasize management's commitment.

A brief description of the methods and time schedule for assuring that employees do not become unconcerned or indifferent is helpful.

L. Completing the Total Quality Control System

When the details of the elements discussed in previous sections are compiled, the result is essentially the plant's "operating manual." It will also serve as the plant's total quality control system.

Upon completion, it should be reviewed. In some cases, a definition or description may be needed for such points as control limits, variability in weights, or number of defects per sample. Also, all critical control points should be covered.

In addition, those sections of the FDA's good manufacturing practice regulations applicable to the operations of the plant must be listed. For each, identify the specific part of the quality control system which is designated to assure compliance.

If one or more full-time quality control personnel are employed at the plant, an organizational chart should be included showing how they fit into the plant's management structure. If there are no full-time quality personnel,

identify who will assume specific responsibilities for quality control and list all other duties of that employee.

When the proposed total quality control system is completed, it is ready to be submitted to the company's management. Let us wish the best of luck to the officer who prepares the plan.

ACKNOWLEDGMENT

78 Retail Foods Sanitation: Prerequisites to HACCP

Nanna Cross
Chicago, Illinois

CONTENTS

I. BACKGROUND

When we talk about retail food protection, we include many categories of business that deal with food e.g., restaurants, cafeterias (schools, prisons, hospitals), public eating places (fairgrounds, events) and so on. As far as health agencies are concerned, delis, grocery stores, etc. are also considered as retail food business. There is no doubt that eventually all large restaurants and cafeterias will be required to implement a HACCP system. Before it can be implemented, most state regulatory agencies want to make sure that all such foodservice establishments have safety programs in place that serve as the foundation or prerequisites to a workable HACCP program. This chapter discusses such fundamental safety practices and how they can eventually be incorporated into a sound HACCP program. The information has been modified from the Food Code.

The discussion for this chapter will be much facilitated by referring to a glossary of terms frequently mentioned and provided by the Food Code as indicated in the next section.

II. GLOSSARY

Some important terms in the glossary are:

Approved source — acceptable to the regulatory authority based on a determination of conformity with principles, practices, and generally recognized standards that protect public health.

Bacteria — living single-cell organisms. Bacteria can be carried by water, wind, insects, plants, animals, and people and survive well on skin and clothes and in human hair. They also thrive in scabs, scars, the mouth, nose, throat, intestines, and room-temperature foods.

CCP — Critical Control Point.

Contamination — the unintended presence in food of potentially harmful substances, including microorganisms, chemicals, and physical objects.

Cross-contamination — the transfer of harmful substances or disease-causing microorganisms to food by hands, food-contact surfaces, sponges, cloth towels and utensils that touch raw food, are not cleaned, and then touch ready-to-eat foods. Cross contamination can also occur when raw food touches or drips onto cooked or ready-to-eat foods.

Corrective action — an activity that is taken by a person whenever a critical limit is not met.

Critical Control Point (CCP) — an operational step or procedure in a process, production method, or recipe, at which control can be applied to prevent, reduce, or eliminate a food safety hazard.

Critical limit — a measurable limit at a CCP that can be monitored to control the identified hazard to a safe level in the food.

Fish — fresh or saltwater finfish, crustaceans and other forms of aquatic life (including alligator, frog, aquatic turtle, jellyfish, sea cucumber, and sea urchin and the roe of such animals) other than birds or mammals, and all mollusks, if such life is intended for human consumption; includes an edible human food product derived in whole or in part from fish, including fish that have been processed in any manner.

Food — raw, cooked, or processed edible substance, ice, beverage, chewing gum, or ingredient used or intended for use or for sale in whole or in part for human consumption.

Food establishment — an operation at the retail level, i.e., that serves or offers food directly to the consumer and that, in some cases, includes a production, storage, or distributing operation that supplies the direct-to-consumer operation.

Foodborne illness — sickness resulting from acquiring a disease that is carried or transmitted to humans by food containing harmful substances.

Foodborne outbreak — the occurrence of two or more people experiencing the same illness after eating the same food.

HACCP — Hazard Analysis Critical Control Points.

HACCP plan — a written document which is based on the principles of HACCP and which describes the procedures to be followed to ensure the control of a specific process or procedure.

HACCP system — the result of implementing the HACCP principles in an operation that has a foundational, comprehensive, prerequisite program in place. A HACCP system includes the HACCP plan and all SOPs.

Hazard — a biological, physical, or chemical property that may cause a food to be unsafe for human consumption.

Internal temperature — the temperature of the internal portion of a food product.

Meat — the flesh of animals used as food including the dressed flesh of cattle, swine, sheep, or goats and

other edible animals, except fish, poultry, and wild game animals.
Microorganism — a form of life that can be seen only with a microscope, including bacteria, viruses, yeast, and single-celled animals.
Molluscan shellfish — any edible species of raw fresh or frozen oysters, clams, mussels, and scallops or edible portions thereof, except when the scallop product consists only of the shucked adductor muscle.
Monitoring — the act of observing and making measurements to help determine whether critical limits are being met and maintained.
National Shellfish Sanitation Program (NSSP) — the voluntary system by which regulatory authorities for shellfish harvesting waters and shellfish processing and transportation and the shellfish industry implement specified controls to ensure that raw and frozen shellfish are safe for human consumption.
NSSP — National Shellfish Sanitation Program.
Operational step — an activity in a food establishment, such as receiving, storage, preparation, cooking, etc.
Parasite — an organism that grows, feeds, and is sheltered on or in a different organism and contributes to its host.
Pathogen — a microorganism (bacteria, parasites, viruses, or fungi) that is infectious and causes disease.
Personal hygiene — individual cleanliness and habits.
Potentially hazardous food — a food that is natural or synthetic and that requires temperature control because it is capable of supporting 1) the rapid and progressive growth of infectious or toxigenic microorganisms, 2) the growth and toxin production of *Clostridium botulinum*, or 3) in raw shell eggs, the growth of *Salmonella enteritidis*.
Potentially hazardous food — includes foods of animal origin that are raw or heat-treated; foods of plant origin that are heat-treated or consists of raw seed sprouts; cut melons; and garlic and oil mixtures that are not acidified or otherwise modified at a processing plant in a way that results in mixtures that do not support growth of pathogenic microorganisms as described above.
Procedural step — an individual activity in applying this guide to a food establishment's operations.
Process approach — a method of categorizing food operations into one of three modes: 1) Process number one: Food preparation with no cook step wherein ready-to-eat food is stored, prepared, and served; 2) Process number two: Food preparation for same day service wherein food is stored, prepared, cooked, and served; or 3) Process number three: Complex food preparation wherein food is stored, prepared, cooked, cooled, reheated, hot held, and served.
Ready-to-eat food — a food that is in a form that is edible without washing, cooking, or additional preparation by the food establishment or consumer and that is reasonably expected to be consumed in that form and includes potentially hazardous food that has not been cooked; raw, washed, cut fruits and vegetables; whole, raw, fruits and vegetables that are presented for consumption without the need for further washing, such as at a buffet; and other food presented for consumption for which further washing or cooking is not required and from which rinds, peels, husks, or shells have been removed.
Record — a documentation of monitoring observation and verification activities.
Regulatory authority — a federal, state, local, or tribal enforcement body or authorized representative having jurisdiction over the food establishment.
Risk — an estimate of the likely occurrence of a hazard.
SOP — Standard Operating Procedure.
Shellfish — bivalve molluscan shellfish.
Standard operating procedure (SOP) — a written method of controlling a practice in accordance with predetermined specifications to obtain a desired outcome.
Temperature measuring device — a thermometer, thermocouple, thermistor, or other device for measuring the temperature of food, air, or water.
Toxin — a poisonous substance that may be found in food.
Verification — the use of methods, procedures, or tests by supervisors, designated personnel, or regulators to determine if the food safety system based on the HACCP principles is working to control identified hazards or if modifications need to be made.
Virus — a protein-wrapped genetic material which is the smallest and simplest life-form known, such as hepatitis A.

III. PREREQUISITE PROGRAMS

A. Food Code

The provisions of the Food Code provide a foundation on which to develop a food safety system based on the principles of HACCP. Major interventions in the Food Code demonstrate the knowledge of the person-in-charge, regarding employee health, avoiding contact with ready-to-eat food with bare hands, time and temperature control, and the use of a consumer advisory regarding the consumption of raw or undercooked animal foods. These interventions need to be addressed within the overall food safety program which may entail inclusion in SOPs (Standard Operation Procedures) which can be considered as the major frame of reference of sanitation and HACCP.

B. Standard Operation Procedures

1. Introduction

Many provisions of the Food Code address the design of food establishments and equipment as well as acceptable operational practices. Adherence to design criteria and

development of SOPs affect the food preparation environment. Both are considered prerequisite to the development of food safety systems based upon the HACCP principles. SOPs specify practices to address general hygiene and measures to prevent food from becoming contaminated during storage, preparation or service. When SOPs are in place, HACCP can be more effective because it changes the focus from the food preparation facility to the hazards associated with the food and its preparation.

SOPs specific to your operation describe the activities necessary to complete tasks that accomplish compliance with the Food Code, are documented as a written reference, and are used to train the staff who are responsible for the tasks.

Three purposes for establishing SOPs for your operation are to protect your products from contamination from microbial, chemical, and physical hazards; to control microbial growth that can result from temperature abuse; and to ensure procedures are in place for maintaining equipment.

SOP procedures ensure that:

1. Products are purchased from approved suppliers/sources
2. The water in contact with food and food-contact surfaces and used in the manufacture of ice is potable
3. Food-contact surfaces, including utensils are cleaned, sanitized, and maintained in good condition
4. Uncleaned and nonsanitized surfaces of equipment and utensils do not contact raw or cooked ready-to-eat food
5. Raw animal foods do not contaminate raw or cooked ready-to-eat food
6. Toilet facilities are accessible and maintained
7. Handwashing facilities are located in food preparation, food dispensing, warewashing areas, and immediately adjacent to toilet rooms and are equipped with hand cleaning preparations and single-service towels or acceptable hand drying devices
8. An effective pest control system is in place
9. Toxic compounds are properly labeled, stored, and safely used
10. Contaminants such as condensate, lubricants, pesticides, cleaning compounds, sanitizing agents, and additional toxic materials do not contact food, food packaging material, and food-contact surfaces
11. Food, food packaging materials, and food-contact surfaces do not come in contact with, and are not contaminated by physical hazards such as broken glass from light fixtures, jewelry, etc.

2. SOPs to Control Contamination of Food

Procedures must be in place to ensure that proper personnel health and hygienic practices are implemented including:

1. Restricting or excluding workers with certain symptoms such as vomiting or diarrhea
2. Practicing effective handwashing
3. Restricting eating, smoking, and drinking in food preparation areas
4. Using hair restraints
5. Wearing clean clothing
6. Restricting the wearing of jewelry

3. Control Microbial Growth

These procedures ensure that all potentially hazardous food is received and stored at a refrigerated temperature of 41°F (5°C) or below. Note that the Food Code makes some allowances for specific foods that may be received at higher temperatures.

4. Maintain Equipment

These procedures ensure that:

1. Temperature measuring devices (e.g., thermometer or temperature recording device) are calibrated regularly
2. Cooking and hot holding equipment (grills, ovens, steam tables, conveyor cookers, etc.) are routinely checked, calibrated if necessary and are operating to ensure correct product temperature
3. Cooling equipment (refrigerators, rapid chill units, freezers, salad bars, etc.) are routinely checked, calibrated if necessary and are operating to ensure correct product temperature
4. Warewashing equipment is operating according to manufacturer's specifications

C. The Flow of Food

The flow of food, which is the path that food follows from receiving through serving, is important for determining where potentially significant food safety hazards may occur. At each operational step in the flow, active management of food preparation and processes is an essential part of business operations. With a HACCP system, you set up control measures to protect food at each stage in the process.

The illustrations of food processes listed below are not intended to be all inclusive. For instance, quick-service, full-service, and institutional providers are major types of food service operations. Each of these has its own individual food safety processes. These processes are likely to be different from a deli in a retail food store.

Some operations may have all three types of processes or variations of the three. Identifying the flow of food processing specific to your operation is an important part of providing a framework for developing a food safety management system.

D. Food Processing with No Cook Step

1. Receive — Store — Prepare — Hold — Serve

As mentioned in the Introduction, the important feature of this type of process is the absence of a cooking step. Heating foods destroys bacteria, parasites, and viruses, and is often a CCP. But since this particular food flow does not include cooking, there is no step that will eliminate or kill bacteria, parasites, or viruses. An example is tuna salad that is prepared and served cold. Control in this process will focus on preventing:

1. Bacterial growth (e.g., storage under refrigeration)
2. Contamination from employees (e.g., restriction of employees ill with diarrhea, proper handwashing, preventing bare hand contact with ready-to-eat foods, etc.)
3. Cross-contamination from other foods (e.g., raw to ready-to-eat)
4. Cross-contamination from soiled equipment (e.g., cleaning and sanitizing)
5. Obtaining foods from approved sources (e.g., a supplier of raw fish for sushi who adequately freezes fish to control parasites)

You should also think about some other factors.

1. Are there any ingredients or menu items of special concern? (see Food Code)
2. Is this a potentially hazardous food requiring specific temperature controls?
3. How will it be served? Immediately? On a buffet?
4. Does this food have a history of being associated with illnesses?
5. Will this menu item require a great deal of preparation, making preparation time, employee health, and bare hand contact with ready-to-eat food a special concern?
6. How will an employee ill with diarrhea be restricted from working with food?
7. Are you serving food to a population that is known to be highly susceptible to foodborne illness (e.g., residents of health care facilities, persons in child or adult day care facilities, etc.)?

E. Food Preparation for Same Day Service

1. Receive — Store — Prepare — Cook — Hold — Serve

In this process, a food is prepared and served the same day. The food will be cooked and held hot until service, such as chili. Generally, the food will pass through the temperature danger zone only once before it is served to the customer, thus minimizing the opportunity for bacterial growth.

The preparation step may involve several processes, including thawing a frozen food, mixing in other ingredients, or cutting or chopping. It is important to remember that added ingredients may introduce additional contaminants to the food. Cutting or chopping must be done carefully so that cross contamination from cutting boards, utensils, aprons, or hands does not occur. Control points at this operational step include good sanitation and handwashing.

During cooking, food will be subjected to hot temperatures that will kill most harmful bacteria, parasites, and viruses that might be introduced before cooking, making cooking a CCP. It is the operational step where raw animal foods are made safe to eat, and therefore, time and temperature measurement is very important. Temperature of foods during hot holding must be maintained until service so that harmful bacteria do not survive and grow.

F. Complex Processes

1. Receive — Store — Prepare — Cook — Cool — Reheat — Hot Hold — Serve

Failure to adequately control food product temperature is the one factor most commonly associated with foodborne illness. Foods prepared in large volumes or in advance for next day service usually follow an extended process flow. These foods are likely to pass through the temperature danger zone several times. The key in managing the operational steps within the process is to minimize the time foods are at unsafe temperatures.

In some cases, a variety of foods and ingredients that require extensive employee product preparation may be part of the process. A sound food safety management system will incorporate SOPs for personal hygiene and cross contamination prevention throughout the flow of the food.

Before you set up a management system for your operational steps, there are several factors you should consider. Multiple step processes require proper equipment and facilities. Your equipment needs to be designed to handle the volume of food you plan to prepare. For example, if you use a process that requires the cooling of hot food, you must provide equipment that will adequately and efficiently lower the food temperature as quickly as possible. If you find that a recipe is too hard to prepare safely, you may want to consider purchasing pre-prepared items from a reputable source.

IV. GETTING STARTED

The most effective way to get started is to use a team approach to design and implement a plan based on the HACCP principles. A team could be comprised of the owner and the chef or cook. Although managers are responsible for designing the system, implementation involves the efforts and commitment of every employee. Education and training of both management and employees in their respective roles of producing safe foods are important. You may consider working with outside consultants, university extension services, and regulatory authorities to ensure your HACCP system is based on the best available science and will control identified hazards.

V. PROCEDURAL STEP 1: GROUP MENU ITEMS

To get started, review how your menu items flow through your operation, note whether they undergo a cook step for same day serving, receive additional cooling and reheating following a cook step, or have no cook step involved. Refer to the Food Code for organizing your menu items by Process 1, 2, and 3.

Looking at your menu, place each menu item or similar menu items (like "hot soups" or "cold salads") into the appropriate group. You may discover that more than one food process is conducted within your operation. These menu items may pose special hazards that are not always readily apparent. To accomplish the first procedural step in developing your food safety management system, identify the food processes specific to your menu items.

A. Process-Specific Lists

List your menu items that belong to one of the three processes.

Chart 1: Process-Specific Lists

Process #1	Process #2	Process #3
List menu foods:	List menu foods:	List menu foods:
Examples:	Examples:	Examples:
Salad greens	Hamburgers	Soups
Fish for sushi	Soup du jour	Gravies
Fresh vegetables	Hot vegetables	Sauces
Oysters or clams served raw	Entrees for "special of the day"	Large roasts
Tuna salad	Cooked eggs	Chili
Caesar salad dressing		Taco filling
Coleslaw		Egg rolls
Sliced sandwich meats		
Sliced cheese		

Process number 1
Food preparation with no cook step — ready-to-eat food that is stored, prepared, and served.

Process number 2
Food preparation for same day service — food that is stored, prepared, cooked, and served.

Process number 3
Complex food preparation — food that is stored, prepared, cooked, cooled, reheated, hot held, and served.

VI. PROCEDURAL STEP 2: CONDUCT HAZARD ANALYSIS

In developing a food safety system, you need to identify the hazards that exist in the flow of foods in your operation from receiving to serving. Hazards include:

1. Pathogens or toxins present in food when you receive them
2. Pathogens that may be introduced during preparation (e.g., using a raw animal food as one ingredient)
3. Pathogen growth or toxin production during storage, preparation, or holding
4. Pathogens or toxins that survive heating
5. Contaminants (i.e., pathogens, chemicals, physical objects), that are introduced to food by food workers or equipment

Since you have grouped your menu items, including ingredients, into the three processes on Chart 1, you can identify hazards that are associated with each process. You will see that the more complex the process is, the greater are the opportunities for hazards to occur.

In consultation with your regulatory authority, you need to identify the hazards associated with various foods and ingredients, such as:

1. *Salmonella* and *Campylobacter jejuni* in raw poultry
2. *E. Coli* O157:H7 in raw ground beef
3. *Staphylococcus aureus* toxin formation in cooked ham
4. *Bacillus cereus* spore survival and toxin formation in cooked rice
5. *Clostridium perfringens* spore survival and subsequent growth in cooked foods
6. Hazards specific to seafood (see Food Code)

This list is only a brief sample of hazards associated with specific foods. By identifying the hazards, you will be able to determine CCPs and critical limits on the worksheet. Another way of fulfilling the hazard analysis step is to understand the hazards associated with your specific menu items and to adhere to the critical limits established in the Food Code. Those critical limits are based on the anticipated hazards.

A. Food Safety Management Worksheets and Summaries for Operational Steps

Worksheets and summaries are provided to enable you to:

1. Identify those operational steps in the food flow that are specific to your operation
2. Write in your SOPs which are the general procedures that cross all flows and products
3. Reference the CCPs and critical limits pertaining to those process steps
4. Develop monitoring procedures and corrective actions which are customized to fit your operation
5. Consider the type of record keeping you need to document you are controlling significant food safety hazards

HACCP allows the flexibility for you to customize a food safety management system specific to your operations. The worksheets are provided to assist you in developing procedures to:

1. Monitor CCPs
2. Take corrective actions when critical limits are not met
3. Establish a verification procedure
4. Establish a record keeping system

Review the following worksheets and the summary page for each operational step. Determine the ones that are applicable to your operation and make copies of them so you can fill in your groupings of menu items (which you did preliminarily in Procedural Step 1). Then continue to use the forms and complete the information as you work through Procedural Steps 3 through 9.

1. Receiving

At receiving, your main concern is contamination from pathogens and the formation of harmful toxins. Obtaining food from approved sources and at proper temperatures are important purchase specifications for preventing growth and contamination during receiving. Approved sources are suppliers who are regulated and inspected by appropriate regulatory authorities.

Ready-to-eat, potentially hazardous food is a special concern at receiving. Because this food will not be cooked before service, microbial growth could be considered a significant hazard for receiving refrigerated, ready-to-eat-foods. Having SOPs in place to control product temperature is generally adequate to control the hazards present at receiving of these products. Besides checking the product temperature, you will want to check the appearance, odor, color, and condition of the packaging.

Federal regulations require that processors of seafood and seafood products for interstate distribution have a HACCP plan. These establishments are approved sources for seafood, and you may ask your interstate seafood supplier for documentation that the firm has a HACCP plan in place. Processors of seafood and seafood products that are sold or distributed only within a state may or may not be required to have a HACCP plan, depending on the state, local, or tribal regulations.

Special consideration should be given to certain species of finfish and raw molluscan shellfish. Molluscan shellfish (oysters, clams, mussels, and scallops) that are received raw in the shell or shucked must be purchased from suppliers who are listed on the FDA Interstate Certified Shellfish Shippers' List or on a list maintained by your state shellfish control authority. Shellfish received in the shell must bear a tag (or a label for shucked shellfish) which states the date and location of harvest, in addition to other specific information.

Finfish harvested from certain areas may naturally contain a certain toxin that is not readily apparent. This toxin is called ciguatera. Other finfish may develop toxins after harvest if strict temperature control is not maintained. This toxin is called scombrotoxin. Temperature control is important at receiving because this toxin can not be eliminated by cooking. For more information on toxins in reef finfish, histamine formation in certain species, and parasites in raw finfish requiring control, refer to the Food Code.

Operational Step 1: Receiving

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 1	Examples: Salads Sushi	Microbial contamination Bacterial growth Parasites Scombrotoxin Ciguatera or other toxin contamination Chemical contamination	Yes _____ or No _____	Receive at 41°F or below Approved source Seafood HACCP plan Proper chemical storage/use				

(*Continued*)

Operational Step 1: Receiving
(*Continued*)

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 2	Examples: Hamburgers Mahi-mahi	Microbial contamination Bacterial growth Scombrotoxin Ciguatera or other toxin contamination Chemical contamination	Yes _____ or No _____	Receive at 41°F or below Approved source Seafood HACCP plan Proper chemical storage/use				
Process 3	Example: Soups	Microbial contamination Bacterial growth Ciguatera or other toxin contamination Scombrotoxin Chemical contamination	Yes _____ or No _____	Receive at 41°F or below Approved source Seafood HACCP plan Proper chemical storage/use				

2. Storage

When food is in refrigerated storage, your management system should focus on preventing the growth of bacteria that may be present in the product. This is primarily achieved through temperature control. Special attention needs to be given to controlling and monitoring the temperatures of potentially hazardous ready-to-eat foods.

When determining the monitoring frequency of product storage temperature, it is important to make sure that the interval between temperature checks is established to ensure that the hazard is being controlled and time is allowed for an appropriate corrective action. For example, If you are storing potentially hazardous ready-to-eat foods under refrigeration, you may decide to set a critical limit for the refrigeration units to operate at 41°F (5°C) or below. You may also want to set a target, or operating limit, of 40°F (4.4°C) for example, in order to provide a safety cushion that allows you the opportunity to see a trend toward exceeding 41°F (5°C) and to intervene with appropriate corrective actions.

Monitoring procedures for ready-to-eat food ideally include internal product temperature checks. You need to assess whether it is realistic and practical for you to do this, depending on the volume of food you are storing.

You may choose to base your monitoring system on the air temperature of the refrigerated equipment as an SOP. How often you need to monitor the air temperature depends on:

1. Whether the air temperature of the refrigerator accurately reflects the internal product temperature — (remember, your food safety refrigeration temperature must be based on the internal product temperature of the food stored within a refrigeration unit, not the air temperature)
2. The capacity and use of your refrigeration equipment
3. The volume and type of food products stored in your cold storage units
4. The SOPs that support monitoring this process
5. Shift changes and other operational considerations

Standard operating procedures can be developed to control some hazards and assist in implementing a food safety system that minimizes the potential for bacterial growth and contamination. The control of cross contamination can be done by separating raw foods from ready-to-eat products within your operation's refrigeration and storage facilities.

Special consideration should be given to the storage of scombroid fish due to the potential formation of histamine, a chemical hazard. To control histamine formation in scombroid toxin-forming fish, it is recommended that storage be a CCP with the critical limit not to exceed 41°F (5°C), as stated in the Food Code, unless you can show through scientific data that the food safety hazard will not result.

3. Preparation

Of all the operational steps in food processes, preparation has the greatest variety of activities that must be controlled,

Operational Step 2: Storage

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 1	Example: Salads Sushi	Bacterial growth Cross contamination Parasites Chemical contamination	Yes _____ or No _____	Store at 41°F or below Separate raw from ready-to-eat food Freeze fish to be consumed raw @ −4°F for 7 days or −31°F for 15 hours Proper chemical storage/use				
Process 2	Example: Hamburgers Mahi-mahi	Bacterial growth Scombrotoxin Cross contamination Chemical contamination	Yes _____ or No _____	Store at 41°F or below Separate raw from ready-to-eat food Proper chemical storage/use				
Process 3	Example: Soups	Bacterial growth Scombrotoxin Cross contamination Chemical contamination	Yes _____ or No _____	Store at 41°F or below Separate raw from ready-to-eat food Proper chemical storage/use				

monitored, and in some cases documented. It is impossible to include in this model a summary guide that covers the diversity in menus, employee skills, and facility design that impact the preparation of food. The preparation step may involve several processes, including thawing a frozen food, mixing together several ingredients, cutting, chopping, slicing, or breading.

At the preparation step, SOPs can be developed to control some hazards and assist in implementation of a food safety system that minimizes the potential for bacterial growth and contamination from employees and equipment.

Front-line employees will most likely have the greatest need to work with the food. A well-designed personal hygiene program that has been communicated to all employees will minimize the potential for bacterial, parasitic, and viral contamination. Your program must include instructions to your employees as to when and how to wash their hands. Procedures need to be in place that either eliminate employee hand contact with ready-to-eat foods, or implement an alternative personal hygiene program that provides an equivalent level of control of bacterial, parasitic, and viral hazards. It is also very important to identify and restrict ill employees from working with food, especially if they have diarrhea.

Procedures must be in place to prevent cross contamination from utensils and equipment. Designated areas or procedures that separate the preparation of raw foods from ready-to-eat foods minimize the potential for bacterial contamination. Proper cleaning and sanitizing of equipment and work surfaces are an integral SOP to this operational step.

Batch preparation is an important tool for controlling bacterial growth because limiting the amount of food prepared minimizes the time the food is kept at a temperature that allows growth. Planning your preparation ahead assists in minimizing the time food must be out of temperature at this operational step. Batch preparation also breaks the growth cycle of bacteria before they can reach dangerous levels.

When thawing frozen foods, maintaining proper product temperature and managing time are the primary controls for minimizing bacterial growth. Procedures need to be in place to minimize the potential for microbial, chemical, and physical contamination during thawing.

Use of prechilled ingredients to prepare a cold product, such as tuna salad, will assist you in maintaining temperature control for this process.

Special consideration should be given to disallowing bare hand contact in the preparation of ready-to-eat foods. You need to control the introduction of hazards during preparation. How will you accomplish controlling the hazard presented by hand contact with ready-to-eat food? You should review your operation to determine whether this operational step will be controlled as a CCP or an SOP.

4. Cooking

This operational step only applies to those foods that you have listed in Processes #2 and #3. Cooking foods of animal

Operational Step 3: Preparation

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 1	Example: Salads	Bacterial growth Cross contamination Contamination from employees Chemical contamination	Yes _____ or No _____	Store at 41°F or below or use time to control growth Separate raw from ready-to-eat food Restrict ill employees; control bare hand contact Proper chemical storage/use				
Process 2	Examples: Hamburgers Mahi-mahi	Bacterial growth Cross contamination Contamination from employees Chemical contamination	Yes _____ or No _____	Store at 41°F or below or use time to control growth Separate raw from ready-to-eat food Restrict ill employees; control bare hand contact Proper chemical storage/use				
Process 3	Example: Soups	Bacterial growth Cross contamination Contamination from employees Chemical contamination	Yes _____ or No _____	Store at 41°F or below or use time to control growth Separate raw from ready-to-eat food Restrict ill employees; control bare hand contact Proper chemical storage/use				

origin is the most effective operational step in food processes for reducing and eliminating biological contamination. Hot temperatures will kill most harmful bacteria and with relatively few exceptions, such as cooking plant foods, this is a CCP. It is at this step that food will be made safe to eat. Therefore, product temperature and time measurements are very important. If the appropriate product temperature for the required amount of time is not achieved, bacteria, parasites, or viruses may survive in the food.

Critical time and temperature limits vary according to the type of food. Employees should view ensuring proper cooking temperatures as an essential element in producing an acceptable product. A final cooking time and temperature chart for specific foods is included for your review. Simply reference the foods specific to your food establishment and incorporate the appropriate critical time and temperature limits into your management system.

You will need to determine the best system for you to use that will ensure that the proper cooking temperature and time are reached. Checking the internal product temperature is the most desirable monitoring method. However, when large volumes of food are cooked, a temperature check of each individual item may not be practical. For instance, a quick service food service operation may cook several hundred hamburgers during lunch. If checking the temperature of each hamburger is not reasonable for you to do, then you need to routinely verify that the specific process and cooking equipment are capable of attaining a final internal product temperature at all locations in or on the cooking equipment.

Once a specific process has been shown to work for you, the frequency of record keeping may be reduced. In these instances, a record keeping system should be established to provide scheduled product temperature checks to ensure that the process is working.

Special consideration should be given to time and temperature in the cooking of fish and other raw animal foods. To control the pathogens, it is recommended that cooking be a CCP, based upon the critical limits established by the Food Code, unless you can show through scientific data that the food safety hazard will not result.

5. Cooling

This operational step is only used for those foods that you have listed in Process #3. One of the most labor intensive operational steps is rapidly cooling hot foods to control microbial growth. Excessive time for the cooling of potentially hazardous foods has been consistently identified as one of the factors contributing to foodborne illness. Foods

Operational Step 4: Cooking

Process 1	Example: Salads Sushi	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply
Process 2	Examples: Hamburgers Mahi-mahi	Bacterial, parasitic, or viral survival or growth	Yes ___ or No ___	Cook to Product Internal Temp Time See Chart 2				
Process 3	Example: Soups	Bacterial, parasitic, or viral survival or growth	Yes ___ or No ___	Same as Process #2				

Chart 2: Food Code Cooking Temperatures and Times

Product	Final Internal Temperature	Time
1a. Poultry Wild Game Animals Stuffed Fish Stuffed Meat Stuffed Pasta Stuffed Poultry Stuffed Ratites or Stuffing containing Fish Meat Poultry or Ratites	1a. 165°F	1a. 15 seconds
1b. Animal foods cooked in a microwave oven	1b. 165°F; food rotated, stirred, covered	1b. Cover and allow to stand for 2 minutes
2a. Pork, ratites, or injected meats	2a. 155°F	2a. 15 seconds
2b. Ground meat, fish, or game animals commercially raised for food	2b. 155°F	2b. 15 seconds
2c. Game Animals under a voluntary inspection program	2c. 155°F	2c. 15 seconds
2d. Raw shell eggs that are NOT prepared for immediate service	2d. 155°F	2d. 15 seconds
3a. Raw shell eggs broken and prepared in response to consumer order and for immediate service	3a. 145°F	3a. 15 seconds
3b. Fish and Meat including Game Animals except as specifically referenced on this chart	3b. 145°F	3b. 15 seconds
4a. Fruit and vegetables cooked for hot holding	4a. 140°F or above	4a. Instantaneous
4b. Ready-to-eat food from a commercially sealed container for hot holding	4b. 140°F or above	4b. Instantaneous
4c. Ready-to-eat food from an intact package (from a food processing plant inspected by the regulatory authority with jurisdiction over the plant) for hot holding	4c. 140°F or above	4c. Instantaneous

(*Continued*)

Chart 2: Food Code Cooking Temperatures and Times (*Continued*)

Product	Final Internal Temperature	Time
5a. Beef Roast/Corned Beef Roasts Preheated Oven Temperatures	5a. LESS THAN 10 lbs. (i) Still dry: 350°F or more (ii) Convection: 325°F or more (iii) High Humidity: 250°F or less MORE THAN 10 lbs (i) Still dry: 250°F or more (ii) Convection: 250°F or more (iii) High Humidity: 250°F or less	
5b. Beef Roast/Corned Beef Roasts Internal Food Temperature for Specified Amount of Time	5b. ACHIEVE ONE OF THE FOLLOWING: (i) 130°F for 121 Minutes (ii) 132°F for 77 Minutes (iii) 134°F for 47 Minutes (iv) 136°F for 32 Minutes (v) 138°F for 19 Minutes (vi) 140°F for 12 Minutes (vii) 142°F for 8 Minutes (viii) 144°F for 5 Minutes (ix) 145°F for 3 Minutes	

Operational Step 5: Cooling

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 1	Examples: Salads Sushi	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply
Process 2	Examples: Hamburgers Mahi-mahi	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply
Process 3	Example: Soups	Bacterial growth Cross contamination Contamination from employees or equipment	Yes ___ or No ___	Cool food from 140°F to 70°F within 2 hours and from 70°F to 41°F within 4 hours Separate raw from ready-to-eat foot Restrict ill employees; control bare hand contact				

that have been cooked and held at improper temperatures provide an excellent environment for the growth of disease causing microorganisms that may have survived the cooking process (spore-formers). Recontamination of a cooked food item by poor employee practices or cross contamination from other food products, utensils and equipment is a concern at this operational step.

Special consideration should be given to large food items, such as roasts, turkeys, thick soups, stews, chili, and large containers of rice or refried beans. These foods take a long time to cool because of their mass and volume. If the hot food container is tightly covered, the cooling rate will be further slowed down. By reducing the volume of the food in an individual container and leaving an opening for heat to escape by keeping the cover loose, the rate of cooling is dramatically increased.

Commercial refrigeration equipment is designed to hold cold food temperatures, not cool large masses of food. Some alternatives for cooling foods include:

1. Using rapid chill refrigeration equipment designed to cool the food to acceptable

temperatures quickly by using increased compressor capacity and high rates of air circulation.
2. Avoiding the need to cool large masses by preparing smaller batches closer to periods of service.
3. Stirring hot food while the food container is within an ice water bath.
4. Redesigning your recipe so that you prepare and cook a smaller or concentrated base and then add enough cold water or ice to make up the volume that you need. This may work for some water-based soups, for example.

Whatever cooling method you choose, you need to verify that the process works. Once again if a specific process has been shown to work for you, the frequency of record keeping may be reduced. A record-keeping system should be established to provide scheduled product temperatures checks to ensure the process is working.

6. Reheating

This operational step applies only to those foods that you listed in Process #3. If food is held at improper temperatures for enough time, pathogens have the opportunity to multiply to dangerous numbers. Proper reheating provides an important control for eliminating these organisms. It is especially effective in reducing contamination from from Staph toxin. Along with personal hygiene, preventing cross contamination through the use of cleaned and sanitized equipment and utensils is an important control measure.

Special consideration should be given to the time and temperature in the reheating of cooked foods. To control the pathogens, it is recommended that reheating be a CCP, based upon the critical limits established by the Food Code, unless you can show through scientific data that the food safety hazard will not result.

7. Holding

All three processes may involve holding. Proper temperature of the food while being held is essential in controlling the growth of harmful bacteria. Cold temperature holding may occur in Processes 1, 2, or 3. Hot temperature holding occurs primarily only in Processes 2 and 3. Where there is a cooking step as a CCP to eliminate pathogens, all but the spore-forming organisms should be killed or inactivated. If cooked food is not held at the proper temperature, the rapid growth of these spore-forming bacteria is a major food safety concern.

When food is held, cooled, and reheated in a food establishment there is an increased risk from contamination caused by personnel, equipment, procedures, or other factors. Harmful bacteria that are introduced into a product that is not held at proper temperature have the opportunity to

Operational Step 6: Reheating

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 1	Examples: Salads Sushi	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply
Process 2	Examples: Hamburgers Mahi-mahi	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply	Does not apply
Process 3	Example: Soups	Bacterial, parasitic or viral survival or growth	Yes _____ or No _____	Reheat to 165°F within 2 hours				

bacterial spore-formers which survived the cooking process and may have multiplied because foods were held at improper temperatures.

Although proper reheating will kill most organisms of concern, it will not eliminate toxins, such as that produced by *Staphylococcus aureus*. If microbial controls and SOPs at previous operational steps have not been followed correctly and Staph toxin has been formed in the food, reheating will not make the food safe.

Incorporating a comprehensive personal hygiene program throughout the process will minimize the risk multiply to large numbers in a short period of time. Once again management of personal hygiene and the prevention of cross contamination impact the safety of the food at this operational step.

Keeping food products at 140°F (60°C) or above during hot holding and keeping food products at or below 41°F (5°C) is effective in preventing microbial growth. As an alternative to temperature control, the Food Code details actions when time alone is used as a control, including a comprehensive monitoring and food marking system to ensure food safety.

Operational Step 7: Holding

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 1	Examples: Salads Sushi	Bacterial, parasitic, or viral introduction, survival, or growth	Yes _____ or No _____	41°F				
Process 2	Examples: Hamburgers Mahi-mahi	Bacterial, parasitic, or viral introduction, survival, or growth	Yes _____ or No _____	140°F or 41°F				
Process 3	Example: Soups	Bacterial, parasitic, or viral introduction, survival, or growth	Yes _____ or No _____	140°F or 41°F				

How often you monitor the temperature of foods during hot holding determines what type of corrective action you are able to take when 140°F (60°C) is not met. If the critical limit is not met, your options for corrective action may include evaluating the time the food is out of temperature to determine the severity of the hazard and based on that information, reheating the food, if appropriate, or discarding it. Monitoring frequency may mean the difference between reheating the food to 165°F (74°C) or discarding it.

When determining the monitoring frequency of cold product temperatures, it is important to make sure that the interval between temperature checks is established to ensure that the hazard is being controlled and time is allowed for an appropriate corrective action. For example, If you are holding potentially hazardous ready-to-eat foods under refrigeration, such as potato salad at a salad bar, you may decide to set a critical limit at 41°F (5°C) or below. You may also want to set a target, or operating limit, of 40°F (4.4°C) for example, in order to provide a safety cushion that allows you the opportunity to see a trend toward exceeding 41°F (5°C) and to intervene with appropriate corrective actions.

Special consideration should be given to the time and temperature in the hot or cold holding of potentially hazardous foods to control pathogens. It is recommended that hot or cold holding be a CCP, based upon the critical limits established by the Food Code, unless you can show through scientific data that the food safety hazard will not result.

8. Setup and Packing

Setup and packing is an operational step used by some retail food establishments including caterers (e.g., restaurant/caterer or interstate conveyance caterer), commissaries, grocery stores (for display cases), schools, nursing homes, hospitals, or services such as delivery of meals to home-bound persons. Setup and packing can be controlled through an SOP and may involve wrapping food

Operational Step 8: Setup and Packing

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 1	Examples: Salads Sushi	Bacterial Growth Microbial contamination from employees	Yes _____ or No _____	41°F No bare hand contact or equivalent alternative				
Process 2	Examples: Hamburgers Mahi-mahi	Bacterial Growth Microbial contamination from employees	Yes _____ or No _____	140°F or 41°F No bare hand contact or equivalent alternative				
Process 3	Example: Soups	Bacterial Growth Microbial contamination from employees	Yes _____ or No _____	140°F or 41°F No bare hand contact or equivalent alternative				

items, assembling these items onto trays, and packing them into a transportation carrier or placing them in a display case. An example would be an airline flight kitchen where food entrees are wrapped, assembled, and placed into portable food carts which are taken to a final holding cooler. Hospital kitchens would be another example where patient trays are assembled and placed into carriers for transportation to nursing stations. Food may be placed into bulk containers for transportation to another site where it is served.

This operational step might not be considered a CCP, but it is a special consideration when setting up your program. This process can be controlled by strict adherence to SOPs to minimize the potential for bacterial contamination and growth, to eliminate bare hand contact with ready-to-eat foods, to ensure proper handwashing, and to ensure food comes into contact with cleaned and sanitized surfaces.

Following final assembly into either individual trays or into bulk containers, the food may be held for immediate service or for transportation to another site for service. This hot holding or cold holding operational step needs to be evaluated in the same manner as other holding operational steps on the worksheet. Temperature control or using time as a control measure during transportation, and holding and serving at a remote site must be evaluated and managed as part of your food safety system.

Special consideration should be given to time/temperature controls and the prevention of cross contamination from equipment and utensils and contamination from employees' hands. This process may be adequately controlled through an SOP; however, holding and transportation should be considered CCPs.

9. Serving

This is the final operational step before the food reaches the customer. When employees work with food and food-contact surfaces, they can easily spread bacteria, parasites, and viruses and contaminate these items. Managing employees' personal hygienic practices is important to controlling these hazards. A management program for employee personal hygiene includes proper handwashing, the appropriate use of gloves and dispensing utensils, and controlling bare hand contact with ready-to-eat foods.

Minimizing the growth of bacteria is also a concern at hot and cold holding customer display areas. Maintaining food products at proper temperature within these display units will control the growth of microorganisms. Refer to the HOLDING worksheet for additional information.

Special consideration needs to be given to minimizing contamination from the customer. Customer self-service displays, such as salad bars, require specific procedures to protect the food from contamination. Some suggestions for protecting food on display include:

1. The use of packaging
2. Counter, service line, or salad bar food guards
3. Display cases
4. Suitable utensils or effective dispensing methods
5. Not mixing an old product with fresh
6. Having employees monitor self-serve stations

Preventing cross contamination from soiled utensils and equipment will minimize the potential for bacterial contamination of ready-to-eat foods.

VII. PROCEDURAL STEP 3: IDENTIFY CCPs AND CRITICAL LIMITS

The CCPs column identifies places in the flow of food where you can have a significant impact in controlling food safety hazards. A measurable critical limit has been identified for each of these CCPs. These critical limits provide the baseline for measuring the effectiveness of your food safety procedures.

For each of your operational steps, within your operation, review the CCPs and critical limits needed to minimize or eliminate significant food safety hazards. Does

Operational Step 9: Serving

Process	Menu Item	Hazard	CCP	Critical Limits	Monitoring	Corrective Actions	Verification	Records
Process 1	Examples: Salads Sushi	Bacterial, parasitic, viral, or physical contamination	Yes _____ or No _____					
Process 2	Examples: Hamburgers Mahi-mahi	Bacterial, parasitic, viral, or physical contamination	Yes _____ or No _____					
Process 3	Example: Soups	Bacterial, parasitic, viral, or physical contamination	Yes _____ or No _____					

your operation currently have control measures in place that are at least equivalent to these critical limits?

On the worksheet, you will need to decide whether the operational step is a CCP or whether the hazard is controlled by your SOPs that address the prerequisite program elements discussed in the Food Code.

In some operational step worksheets, such as the cooking step, the Guide recommends that the step be considered a CCP, because there is no practical alternative to ensure control of the hazard. In other operational steps, you may have a choice as to how you will control the hazard. For example, in the preparation step for ready-to-eat foods, you will identify contamination from employees' hands as a hazard. When controlling that hazard as a CCP, you must also identify the critical limits, establish monitoring and corrective actions, verification procedures, and records. Alternatively, you may choose to control that hazard by instituting an SOP that disallows bare hand contact with ready-to-eat food. You will need to decide the most effective method of controlling the hazard, i.e., as a CCP or through use of an SOP.

VIII. PROCEDURAL STEP 4: MONITOR CRITICAL CONTROL POINTS

Use the worksheet to develop procedures, customized to your operation, for monitoring your CCPs. Consideration should be given to determining answers to the following questions.

1. What critical limit at the CCP are you measuring?
2. How is it monitored?
3. When and how often will the CCP be monitored?
4. Who will be responsible for monitoring it?

Monitoring is observing or measuring specific operational steps in the food process to determine if your critical limits are being met. This activity is essential in making sure your critical food processes are under control. It will identify where a loss of control occurs or if there is a trend toward a loss of control of a critical food process. Needed adjustments will then become obvious.

In your food safety management system, certain processes have been identified as CCPs. What you are going to monitor depends on the critical limits you have established at each CCP. Minimum critical limits for many CCPs have been established by the Food Code. For example, cooking hamburger (which is the CCP) to 155°F (68.3°C) for 15 seconds (which is the critical limit) will kill most harmful bacteria. Therefore, final temperature and time measurements are very important and you need to determine how you will effectively monitor the critical limits for each CCP.

Is monitoring equipment needed to measure a critical limit? The equipment you choose for monitoring must be accurate and routinely calibrated to ensure critical limits are met. For example, a thermocouple with a thin probe might be the most appropriate tool for measuring the final product temperature of hamburger patties.

When deciding how often you need to monitor, make sure that the monitoring interval will be reliable enough to ensure the hazard is being controlled. Your procedure for monitoring should be simple and easy to follow.

Individuals chosen to be responsible for a monitoring activity may be a manager, line-supervisor, or a designated employee. Your monitoring system will only be effective if employees are given the knowledge, skills, and responsibility for serving safe food. Train your employees to carefully follow your procedures, monitor CCPs, and take corrective action if critical limits are not met.

IX. PROCEDURAL STEP 5: DEVELOP CORRECTIVE ACTIONS

Decide what type of corrective action you need to take if a critical limit is not met.

1. What measures do you expect employees to take to correct the problem?
2. Is the corrective action understood by your employees?
3. Can the corrective action be easily implemented?
4. Are different options needed for the appropriate corrective actions, depending on the process and monitoring frequency?
5. How will these corrective actions be documented and communicated to management so the system can be modified to prevent the problem from occurring again?

Whenever a critical limit is not met, a corrective action must be carried out immediately. Corrective actions may be simply continuing to heat food to the required temperature. Other corrective actions may be more complicated, such as rejecting a shipment of raw oysters that does not have the required tags or segregating and holding a product until an evaluation is done.

In the event that a corrective action is taken, you should reassess and modify if necessary your food safety system based upon the HACCP principles. Despite the best system, errors occur during food storage and preparation. A food safety system based upon the HACCP principles is designed to detect errors and correct them before a food safety hazard occurs. It is a benefit to industry and regulators to be able to show that immediate action is taken to ensure that no food product that may be injurious

to health is served to or purchased by a customer. It is important to document all corrective actions in written records.

X. PROCEDURAL STEP 6: CONDUCT ONGOING VERIFICATION

A. Description

Because HACCP is a system to maintain continuous control of food safety practices, implementation of the plan needs to be audited or verified. Verification is usually performed by someone other than the person who is responsible for performing the activities specified in the plan. That person might be a manager, supervisor, designated person, or the regulatory authority.

There is ongoing verification, which is conducted frequently, such as daily, weekly, monthly, etc., by designated employees of the establishment. It is important to note that routine monitoring should not be confused with audit or verification methods or procedures.

There is long-term verification, which is done less frequently. This will be discussed in Procedural Step 8.

Verification is an oversight auditing process to ensure that the HACCP plan and SOPs continue to:

1. Be adequate to control the hazards identified as likely to occur
2. Be consistently followed (i.e., a comparison is made regarding observed, actual practices and procedures with what is written in the plan)

Ongoing verification activities include:

1. Observing the person doing the monitoring: is monitoring being done as planned?
2. Reviewing the monitoring records:
   a. Are records completed accurately?
   b. Do records show that the predetermined frequency of the monitoring is followed?
   c. Was the planned corrective action taken when the person monitoring found and recorded that the critical limit was not met?
   d. Do records of the calibration of monitoring equipment indicate that the equipment was operating properly?

B. Procedures

Procedures may include the following activities:

1. Observe the person conducting the activities at the CCPs and recording information
2. Check monitoring records
3. Check corrective action records
4. Periodically review the total plan
5. Test product in process or finished product
6. Review equipment calibration records
7. Review recording thermometer accuracy (large operations and some processes such as large quantity cook and chill operations or smokers, etc.)

C. Frequency

Verification should occur at a frequency that can ensure the HACCP plan is being followed continuously to:

1. Avoid adulterated/unsafe product getting to the consumer
2. Be able to take corrective action without loss of product
3. Ensure prescribed personnel practices are consistently followed
4. Ensure personnel have the tools for proper personal hygiene and sanitary practices (e.g., handwashing facilities, sanitizing equipment, cleaning supplies, temperature measuring devices, and sufficient gloves, etc.)
5. Follow/comply with the control procedures established
6. Conduct calibrations as needed depending upon the type of equipment (some may be verified daily and others annually)

D. Observations/Documentation — Examples

1. System Verification

a. Receiving

The manager reviews temperature logs of refrigerated products at various intervals such as daily or weekly. An operation may want its HACCP Plan to specify that the manager checks the monitoring records daily if:

1. Receiving constitutes a high volume, or
2. Products include particular items such as fresh tuna, mahi-mahi, mackerel, etc. (scombrotoxin-forming species).

b. Chill step

Weekly, the production manager checks the "chilling log" that is maintained for foods that are either left over or planned for later service. Recorded on the log sheet are the time the food is placed into the cooler, its temperature, the type of container used (depth per SOP), and measurements of the time and temperature involved in cooling the food.

c. Handwashing facilities and practices

Daily, the manager checks the log maintained at the handwashing facilities and corrections made in areas where

ready-to-eat food is prepared. Less frequent checks are made in other areas of the operation.

2. Process Verification

The manager checks daily or weekly, the time/temperature monitoring records at all CCPs (receiving, holding, preparation before cooking for scombrotoxin-forming seafood; cooking time/temp for hamburgers, etc.)

XI. PROCEDURAL STEP 7: KEEP RECORDS

In order to develop the most effective record-keeping system for your operation, determine what documented information will assist you in managing the control of food safety hazards. Some recorded information should already be part of your food safety system, like shellfish tags, and an additional record may not be needed. Your record-keeping system can use existing paperwork, such as delivery invoices, for documenting product temperature. Another method could be maintaining a log to record the temperatures. A record-keeping system can be simple and needs to be designed to meet the needs of the individual establishment. It can be accomplished many different ways that are customized to your operation as long as it provides a system to determine that activities are performed according to the HACCP plan.

Accurate record keeping is an essential part of a successful HACCP program. Records provide documentation that the critical limits at each CCP were met or that appropriate corrective actions were taken when the limits were not met. Records also show that the actions performed were verified.

Involve your employees in the development of your management system. Ask them how they are currently monitoring CCPs. Discuss with them the types of corrective actions they take when a critical limit is not met. Employees are an important source for developing simple and effective record keeping procedures. Managers are responsible for designing the system, but effective day-to-day implementation involves every employee.

The simplest record-keeping system that lends itself to integration into existing-operations is always best. A simple yet effective system is easier to use and communicate to your employees.

Record-keeping systems designed to document a process rather than product information may be more adaptable within a retail food establishment, especially if you frequently change items on your menu. Accurately documenting processes like cooking, cooling, and reheating, identified as CCPs, provides active managerial control of food safety hazards. Consistent process control by management reduces the risk of foodborne illness.

Simple logs for recording refrigeration equipment temperature are perhaps the most common SOP records currently maintained. However, product temperature records are commonly CCP records.

Other records may include:

1. Writing the product temperature on delivery invoices
2. Keeping a log of internal product temperatures of cooked foods
3. Holding shellstock tags for 90 days

Some retail establishments have implemented comprehensive HACCP systems where records are maintained for each CCP. These records may be quality control logs, but they can also constitute CCP records if they are designed to monitor activities that are, in fact, CCPs. The level of sophistication of record keeping is dependent upon the complexity of the food operation. For example, a cook–chill operation for a large institution would require more record keeping than a limited menu, cook–serve operation.

Once a specific process has been shown to work for you, such as an ice bath method for cooling certain foods, the frequency of record keeping may be reduced. In these instances, a record keeping system provides a scheduled check (verification) of the process to ensure that it effectively controls the risk factor. This approach is extremely effective for labor-intensive processes related to:

1. Cooking large volumes of food where a temperature check of each individual item is impractical
2. Implementing a verified process will allow employees to complete the procedure within the course of a scheduled work day
3. Cooling foods or leftovers at the end of the business day
4. Maintaining cold holding temperatures of ready-to-eat potentially hazardous foods in walk-in refrigeration units

XII. PROCEDURAL STEP 8: CONDUCT LONG-TERM VERIFICATION

Once your food safety system is implemented, you will need to confirm that it is effective over time, an activity referred to in this document as long-term verification. You may benefit from both internal (quality control) verifications and external verifications that may involve assistance from the regulatory authority or consultants.

Long-term verification is conducted less frequently (e.g., yearly) than on-going verification. It is a review or audit of the plan to determine if:

1. Any new product/processes/menu items have been added to the menu
2. Suppliers, customers, equipment, or facilities have changed
3. The SOPs are current and implemented

Procedural Step 8: Long-Term Verification

Name of person responsible for long-term verification: _____ Title: _____
Frequency at which the long-term verification is done: _____ _____
Reason, other than frequency, for doing a long-term verification: _____ _____

Date of last long-term verification: _____

The length of time this record is kept on file: _____

1. (a) Has a new product, process, or menu item been added since the last verification?	No ___			
	Yes ___ Go to Question #2	Does this change necessitate a change on the worksheet? No ____ Yes ____		
(b) Has the supplier, customer, equipment, or facility changed since the last verification?	Yes ___ No ___ Go to Question #2			
2. Do the existing worksheets contain accurate and current information?	No ___ >	Worksheet information updated:	Date: _____	Name: _____ _____
	Yes ___ Go to Question #3			
3. Are the existing CCPs correctly identified?	No ___ — >	CCP's updated:	Date: _____	Name: _____
	Yes ___ Go to Question #4			
4. Are the existing critical limits appropriate to control each hazard?	No ___ — >	CL's updated:	Date: _____	Name: _____ _____
	Yes ___ Go to Question #5			
5. Do the existing monitoring procedures ensure that the critical limits are met?	No ___ — >	Monitoring procedures updated:	Date: _____	Name: _____ _____
	Yes ___ Go to Question #6			
6. Do existing corrective actions ensure that no ensure that no injurious food is served or purchased?	No ___	Corrective actions updated:	Date: _____	Name: _____ _____
	Yes ___ Go to Question #7			
7. Do the existing on-going verification procedures ensure that the food safety system is adequate to control hazards and is consistency followed?	No ___	On-going verification procedures updated:	Date: _____	Name: _____ _____
	Yes ___ Go to Question #8			

(*Continued*)

8. Does the existing record keeping system provide adequate documentation that the critical limits are met and corrective actions are taken when needed?	No ___	Record keeping procedures updated:	Date: _____	Name: _____ _____
	Yes ___ Go to Question #9			
9. Are the existing SOPs current and implemented?	No ___	Does this necessitate a change in your plan? If so, start again with number 1.		
	Yes ___			
The long-term verification procedure is now complete. The next long-term verification is due _____. The changes made to the food safety management system were conveyed to the line supervisor or front-line employees on _____.				
	Completed by:	Name _____ Title _____ Date _____		

4. The worksheets are still current
5. The CCPs are still correct, or if new CCPs are needed
6. The critical limits are set realistically and are adequate to control the hazard (e.g., the time needed to cook the turkey to meet the Food Code internal temperature requirement)
7. Monitoring equipment has been calibrated as planned

Long-term verification helps the operator:

1. Ensure the food safety management system is implemented and the HACCP plan is being followed
2. Improve the system and HACCP plan by identifying weaknesses
3. Eliminate unnecessary or ineffective controls
4. Determine if the HACCP plan needs to be modified or updated

79 Seafood Processing and U.S. HACCP QMP

Nanna Cross
Chicago, Illinois

CONTENTS

I. INTRODUCTION

This chapter discusses HACCP (Hazard Analysis Critical Control Point) program management for the seafood industry as recommended by the U.S. National Marine Fisheries Service (NMFS).

HACCP is a nontraditional, noncontinuous inspection technique recommended by the National Academy of Sciences as a more scientific, analytical, and economical approach than that provided by traditional inspection and quality control methods. HACCP, which focuses on problem prevention and problem solving, relies heavily on proper monitoring and record keeping by the industry. One of the primary economic benefits of HACCP is that it provides for reduced destructive sampling of the finished product as compared to the end-product sampling required under traditional inspection systems. The application of HACCP principles to seafood inspection has been adopted by several countries, including Canada, Iceland, and the European Union, and is becoming more broadly recognized by the international community as a mechanism to apply uniform inspection procedures.

Hazard Analysis Critical Control Point (HACCP) is a management system in which food safety is addressed through the analysis and control of biological, chemical, and physical hazards from raw material production, procurement and handling, to manufacturing, distribution and consumption of the finished product. For successful implementation of a HACCP plan, management must be strongly committed to the HACCP concept. A firm commitment to HACCP by top management provides company employees with a sense of the importance of producing safe food. In July 1992, the U.S. National Marine Fisheries Service (NMFS) announced the availability of a new seafood inspection program based on (HACCP) principles. This program is in addition to the Integrated Quality Assurance (IQA) Program that also uses HACCP principles. However, the IQA program, having unique methods for the inspection and grading of products, will continue as an option for applicants to the program. The guidelines for the HACCP Quality Management Program (QMP) have been compiled to inform interested parties that the NMFS is offering an alternative inspection program in addition to what is presently available. Participation in one program over the other is a decision, which must be made by the company's management. Under the Quality Management Program, the company takes on the responsibility of documenting and implementing a quality system. NMFS will then ensure that the quality system in place is adequate to control the critical functions by regular inspections of the system, known as audits. These audits will evaluate the quality system by examining product, processes, and records.

This document includes sections, which explain the specifications or requirements of the QMP program for documenting a quality system that will meet NMFS requirements. The document is also a guide manual for use by interested parties in developing their own quality manual. The HACCP Quality Management Program will allow participants an opportunity to apply their existing quality systems more efficiently, receive the management benefits of producing safe, wholesome, and properly labeled products more consistently and obtain the marketing benefits of using marks associated with the program. In summary, the HACCP-based service is consistent with global activities to harmonize inspection protocols. In addition, NMFS believes that the service will enhance the safety, wholesomeness, economic integrity, and quality of seafood available to consumers, as well as improve seafood industry quality assurance and regulatory oversight.

NMFS policy is to encourage and assist interested parties in the development and implementation of HACCP-based quality management systems to facilitate consistent distribution of safe, wholesome, and properly labeled fishery products of desired uniform quality. The development and implementation of HACCP-quality management systems is optional. However, their use should result in more efficient use of NMFS resources to inspect, grade, and certify fishery products.

NMFS has issued a document "NOAA HACCP Quality Management Program (HACCP QMP). Program Requirements." The latest revision was dated January 1, 2000. This document is designed to provide guidance for the development, implementation, and operation of HACCP-quality management systems, which will meet NMFS approval. All information in this chapter has been modified from this document.

When studying this document, please note the following premises:

1. The data have been obtained from a document issued by the NMFS. Data have been slightly modified for ease of reading. Therefore, for details, users should obtain a copy of the original document from the NMFS.
2. The user is assumed to know the abbreviations.
3. In the U.S., the word "shall" is a legal requirement and is used where applicable.
4. The legal numerical citation is maintained.
5. Although the information in this document is designed for seafood processors in the United States, it can be easily modified to fit foreign producers who may be interested to apply HACCP in a proper manner.

II. DEFINITIONS

1. Auditee: The organization being audited.
2. Auditor: A person qualified to perform audits.

3. Contamination: The occurrence of a contaminant in fish due to microbial pathogens, chemicals, foreign bodies, spoilage, objectionable taints, unwanted or diseased matter, which may compromise fish safety or suitability.
4. Control measure (preventive measure): Action performed to eliminate a hazard or reduce it to an acceptable level. For the purposes of this guide a control measure is also applied to a defect.
5. Control Point: Any step in a process whereby biological, chemical, or physical factors may be controlled.
6. Corrective Actions: An action taken to eliminate the causes of an existing nonconformity, defect, or other undesirable situation in order to prevent recurrence.
7. Critical Control Point (CCP): A point, step, or procedure in a food process at which control can be applied, and a food hazard can as a result be prevented, eliminated, or reduced to acceptable levels.
8. Critical Deficiency: A hazardous deviation from plan requirements such that maintenance of the safety, wholesomeness, and economic integrity is absent; will result in unsafe, unwholesome, or misbranded product.
9. Critical Limit: The maximum or minimum value to which a physical, biological, or chemical parameter must be controlled at a critical control point, or defect action point, to prevent, eliminate, or reduce to an acceptable level the occurrence of the identified food hazard.
10. Decision Tree: A sequence of questions applied to each process step with an identified hazard to identify which process steps are CCPs. For the purpose of this Program this also applies to a Defect Action Point.
11. Decomposition: A persistent and distinct objectionable odor or flavor including texture breakdown caused by the deterioration of fish.
12. Defect: A condition found in a product which fails to meet essential quality, composition and/or labeling provisions of the appropriate product standards or specifications.
13. Defect Action Point (DAP): A point, step or procedure at which control can be applied and a defect can be prevented, eliminated or reduced to acceptable level, or a fraud risk eliminated.
14. Food Safety Hazard: Any biological, chemical, or physical property that may cause a food to be unsafe for human consumption.
15. HACCP Plan: A document prepared in accordance with the principles of HACCP to ensure control of hazards which are significant for food safety and control of defects which are significant for essential quality, composition, and/or labeling provisions in the segment of the food chain under consideration.
16. Hazard: A chance for, or the risk of, a biological, chemical, physical, or economic property in a food product that could violate established program criteria or cause the consumer distress or illness.
17. Hazard analysis: The process of collecting and evaluating information on hazards and conditions leading to their presence to decide which are significant for food safety and therefore should be addressed in the HACCP plan.
18. High risk products: Seafood that may pose a significant danger to the health of the public when prepared for consumption by conventional or traditional means. For example, ready-to-eat; heat and/or brown and serve products; products which may contain a microbial pathogen, biotoxin, or physical or chemical contaminant which may pose an unacceptable health risk at the time of consumption.
19. Low risk products: Seafood that poses no significant risk to the health of the public when prepared for consumption by conventional or traditional means.
20. Major Deficiency: A significant deviation from plan requirements, such that maintenance of safety, wholesomeness, or economic integrity is inhibited.
21. Minor Deficiency: A failure of the part of the HACCP-based system relative to facility sanitation which is not likely to reduce materially the facility's ability to meet acceptable sanitation requirements.
22. Monitoring Procedures: Scheduled testing and/or observations recorded by the firm to report the findings at each CCP or DAP.
23. NUOCA (Notice of Unusual Occurrence and Corrective Action): The record that outlines the incident and the corresponding corrective action implemented by the facility.
24. Objective Evidence: Information, which can be proved true, based on facts, obtained through observation, measurement, test, or other means.
25. Prerequisite Program: Procedures, including Good Manufacturing Practices that address operational conditions providing the foundation for the HACCP system.
26. Preventive Measure(s) (control measure): Physical, chemical, or other factors that can be used to control an identified food safety hazard. For the purposes of this program, this also applies to a DAP.

27. Process: One or more actions or operations to harvest, produce, store, handle, distribute, or sell a product or group of similar products.
28. Quality: Totality of characteristics of an entity that bear on its ability to satisfy stated and implied needs. The inherent properties of any processed product which determine the relative degree of excellence of such product, and includes the effects of preparation and processing, and may or may not include the effects of packing media, or added ingredients.
29. Quality Audit: A systematic and independent examination to determine whether quality activities and related results comply with planned arrangements and whether these arrangements are implemented effectively and are suitable to achieve objectives.
30. Record: A document that furnishes objective evidence of activities performed or results achieved.
31. Serious Deficiency: A severe deviation from plan requirements such that maintenance of safety, wholesomeness, and economic integrity is prevented; and, if the situation is allowed to continue, may result in unsafe, unwholesome, or misbranded product.
32. Severity: The seriousness of the effect(s) of a hazard or defect. Specification: A document stating requirements. A detailed document describing the materials, dimensions, and workmanship requirements of a product.
33. Systems Audit: On-site NMFS evaluation of the firm's effectiveness in following the plan after validation.
34. Validation: That element of verification focused on collecting and evaluating scientific and technical information to determine if the Quality Management Plan, when properly implemented, will effectively control the hazards and defects.
35. Verification: Those activities performed by the firm, other than monitoring, that determine the validity of the Quality Management Plan and that the system is operating according to the plan.

III. APPLYING TO ENTER THE PROGRAM

Firms who wish to participate in the Program may apply orally or in writing to the appropriate Regional Inspection Branch of the NMFS. The Regional Inspection Branch will provide the applicant with all necessary materials to inform them of the program and its requirements. This material will also include the requirements and any policies necessary for development and submission of a Quality Management Plan. The firm develops its Quality Management Plan and submits it for review according to the plan review procedures described further in this document. There may be a cost for the application.

IV. EDUCATION AND TRAINING

The success of a HACCP system depends on educating and training management and employees in the importance of their role in producing safe foods. This should also include information concerning the control of food borne hazards related to all stages of the food chain. It is important to recognize that employees must first understand what HACCP and quality management is and then learn the skills necessary to make it function properly. Specific training activities should include working instructions and procedures that outline the tasks of employees monitoring each CCP or DAP. Management must provide adequate time for thorough education and training. Personnel must be given the materials and equipment necessary to perform these tasks. Effective training is an important prerequisite to successful implementation of a HACCP or quality plan.

Each facility must employ a NMFS-certified person knowledgeable in the program's principles to be present during all processing times. The certification must be kept on file and available to NMFS at all times.

NOTE: Retail establishments of significant size do not require the certification of an individual at each store or facility location. However, they must have demonstrated sufficient control of the training of all pertinent individuals and have a sufficient number of management personnel trained and certified in their system to maintain proper control of the concepts and the HACCP plan.

V. PLAN REVIEW AND DESK AUDIT

Each applicant must submit a QMP plan in accordance with this document. At the request of the firm, NMFS will provide consultation toward the development of the HACCP Quality Management Program plan on a fee basis. Plans are submitted to the servicing Regional Inspection Branch for desk review. Reviews of the plan may require requests for changes, clarifications, deletions, etc., from the firm. The servicing region will work with the firm to finalize the development of the QMP Plan. A written review is sent to the firm indicating what changes, if any, are necessary prior to scheduling the site visit. All work of the assigned CSO and the Regional Inspection Branch is performed on a fee basis at established rates.

VI. LABEL REVIEW PROCEDURES AND APPROVAL

All applicable labels must be approved prior to use in accordance with regulations.

The firm should begin following their plan as soon as possible. The firm must adhere to the plan's provisions and keep all records associated with the approved QMP plan for at least five (5) consecutive production days. The firm will contact the Regional Inspection Branch as soon as they believe the approved plan is functioning successfully and when they have records covering the minimum production days. The Regional Inspection Branch will schedule a site visit with the firm. The firm must verify through end-product examination that the process controls result in a product which complies to all regulations and applicable quality standards or specifications. If documentation has not been previously provided, the firm must collect data prior to the site visit, which will be sufficient to demonstrate this relationship. Firms attempting to document this relationship must collect data on not less than 20 percent of their lots using sampling plans comparable in statistical confidence to those in 50 CFR Part 260, with at least one lot representing each product form.

The inspection records must be available to NMFS personnel upon request. Although not required, NMFS recommends that the firm submit end-item verification records with their QMP Plan. This will allow the firm to test their controls, provide plan reviewers more information, and possibly reduce the time and cost of the site visit.

The audit performed on site will determine whether all of the hazards/defects and CCPs/DAPs have been identified, the quality management plan is being followed and monitored by the firm, and is effectively controlling the identified hazards/defects. The site visit will be conducted on a fee basis by a team of personnel assigned based upon the needs of the audit and the expertise available. The number and structure of the team will be determined by the size and complexity of the firm's process and nature of hazards associated with the products covered under the QMP Plan. The audit will include conducting document and record reviews, evaluating sanitation and in process observations and product verification.

All reviews will be performed using accepted auditing practices based on the current standards of ISO 10011. Conducting a combination of statistical reviews of records and finished product sample inspections will complete product verifications. At least one lot for each product form will be verified by inspecting samples of finished product. NMFS inspection personnel may, for cause, sample and verify product in excess of this guideline. Firms will be evaluated using the QMP System Evaluation Criteria. If the firm is determined to be acceptable it will qualify as a participant in the program and may finalize a contract for services with NMFS. If the audit at the firm is favorable, all products under review during the audit, including the previous five (5) production days, are eligible to bear the appropriate official marks or advertising claim.

Note for Vessels: Due to logistical factors, only one NMFS Consumer Safety Officer will perform the site visit. The NMFS Consumer Safety Officer will accompany the vessel, if determined necessary, for an appropriate time period during a fishing season, performing the background checks of critical control points and auditing the plan at one time. The officer may assist the quality assurance/management group on board the vessel in any alterations to make to their QMP Plan to work toward plan approval and a successful audit. Once the QMP plan is approved, the officer is taken off the vessel as soon as is practicable. These procedural accommodations are made in recognition of possible space restrictions and to reduce the numbers of transfers at sea.

VII. QMP PLAN CHANGES

After the QMP plan has been approved, modifications may be made under the following conditions. The firm must notify the servicing Regional Inspection Branch, in writing (Faxes are acceptable), of any modifications in their QMP plan before implementing the changes. However, any changes to address a health or safety issue may be made without prior approval, but must be documented in a corrective action plan. The Regional Inspection Branch must be notified of these immediate changes within one working day.

As the QMP Plan outlines the basic foundation and policies of the firm's quality program, changes to the plan must be approved in advance with Program management. However, the specific work procedures may change as necessary without prior approval, as long as they meet the NMFS Program Quality System Standard found at the end of this document. Prior to signing the contract, it will be determined what of the firm's document requires preapproval.

VIII. SYSTEMS AUDITS

Only with a valid contract and continued demonstrated compliance with all applicable laws and regulations and policies may (1) the firm be eligible to use official marks or other related statements and (2) firm-collected data be used by NMFS towards issuing official certification of the firm's products or facility compliance. After the firm's QMP Plan is approved, NMFS will conduct Systems Audits at a frequency listed below to determine the firm's continued adherence to their QMP Plan.

A. VESSELS

Firms must provide the appropriate NMFS Regional Inspection Branch with their tentative season schedules and off-loading schedules and sites as soon as they are known. Firms must give the servicing Regional Inspection Branch notice prior to each port arrival, providing

sufficient time for auditors to verify and audit the vessel when required. Failure to do so could result in the removal of the vessel from the Program. Vessels will be visited once every other trip, with at least one visit per year. A visit will be composed of a maximum of ten (10) percent of the scheduled fishing days for the trip in question. For example, if a trip is scheduled to last 30 days, the Systems Audit will be performed over approximately three days. Additional days may be necessary if the Consumer Safety Officer has encountered a problem during the audit. Audits may not require the auditor to be on board during fishing, but will require the auditor to be present during offloading.

NOTE: Samples of finished product may be pulled while the NMFS Consumer Safety Officer is on board or at dockside. If samples are pulled while on board, they will be evaluated immediately for compliance.

B. Processing Establishments

NMFS will conduct unannounced Systems Audits to determine the firm's continued adherence to their plan. Facilities will be visited at least once every month.

C. Retail and Food Service Establishments

NMFS will conduct unannounced Systems Audits to determine the firm's continued adherence to their plan. Facilities will be visited at least once every three months.

NOTE: NMFS is interested in providing this program with a minimum possible burden to retail participants. Record keeping should not be so grand as to cause undue hardship on the retailer. Records should be of a precision only to show what products were received by what supplier on a particular day.

D. Procedures for Retail and Food Service Operations with Multiple Outlets and with an Established Quality Assurance Program

Firms which operate a chain of stores may have the stores under the program sampled as outlined in the chart below (provided they have an established approved Quality Assurance System).

In addition, the following criteria apply:

1. All firms will enter the Program at the Tightened level of sampling. After two successive audits at this level, the firm will move to the Normal level of sampling. After two successive audits at the Normal level, the firm will move to the Reduced level of sampling.
2. No stores in the sample may be considered unreliable. If a store in the sample is deemed unreliable (Five Serious deficiencies or One Critical deficiency), the Firm's Quality Assurance System is suspect. NMFS will then perform an audit on the Quality Assurance System of the firm for the next thirty days. This audit will include the sampling of additional stores. During this 30 day period, the stores may continue to use all advertisement claims.
3. If after this audit the Quality Assurance System is deemed to be under control, the firm will be sampled at the Tightened level and the system begins again as described above.
4. If the Quality Assurance System is deemed to not be performing as designed, Regional management and the Quality Team will evaluate the firm's entire program and suggest the necessary changes to continue in the Program. This evaluation could include each store being audited and/or removed from the Program or may result in a permanent or temporary removal of the firm from the Program.
5. During this thirty day period the stores may continue to use all advertisement claims.
6. If the sample of stores does not meet the above requirements, then each store in the chain must be audited on its own until such time as the Quality Assurance System has been re-approved.

E. Tightened Frequency Audit Procedures

A firm at the tightened frequency has demonstrated difficulties in administering their QMP Plan and has rated the facility as unreliable. If a Consumer Safety Officer rates a facility unreliable, he/she will rate the facility and immediately contact his/her Supervisor. The decision to rate a facility unreliable will be made prior to the Consumer Safety Officer performing the exit interview. Once the rating is confirmed, the Chief Quality Officer of the Seafood Inspection Program is to be informed and provided with all documentation, including but not limited to: Final Audit Report, score sheets, supporting documentation, etc. Facilities who are rated unreliable have a period of thirty days to remove the unreliable status. Failure to do so will result in the facility's removal from the NMFS HACCP Quality Management Program, or the EU HACCP Program. A firm who is deemed unreliable may continue to use the mark or other applicable advertising privileges if consent by NMFS is given for daily auditing of the firm. Consent will be on a case by case basis and granted only if NMFS believes the nature of the condition which caused the firm

to become unreliable warrants daily auditing. Daily auditing will be acceptable to NMFS under the following conditions:

1. The firm must submit a corrective action plan to the NMFS Consumer Safety Officer detailing how they will correct the problem (Faxes are acceptable). The corrective action plan must include, at a minimum, detailed descriptions of the following:
   a. A statement of the problem
   b. Identification of the person or persons
   c. Handling the situation
   d. The methods to be used to correct the problem
   e. A schedule which details the time frame to correct the problem
   f. A statement with signatures of top management attesting to their commitment to correct the deficiency The corrective action plan must be written in sufficient detail to provide NMFS with all necessary information for its approval or disapproval.
2. The NMFS Consumer Safety Officer will review the corrective actions identified by the firm and will approve or disapprove the corrective actions and notify his/her Supervisor. Daily auditing will continue until the issue is corrected for a maximum of thirty calendar days.
3. Products may be certified during daily auditing. However, if any condition(s) exists that is considered critical, no product certification will occur until the condition is corrected to the satisfaction of NMFS.
4. At the inspector's discretion, product compliance will be verified by end-item inspection. No products covered by the QMP plan will leave the firm without NMFS approval.
5. Firms deemed unreliable twice in a 12-month period will be removed from the HACCP Quality Management Program or the EU HACCP Program.
6. Firms who have been removed from the HACCP Quality Management Program or the EU HACCP Program may submit a request for reapplication into the program after a period of three calendar months. Application will be accepted by NMFS only if evidence of a change in management philosophy can be provided.
7. Firms who have been removed from the NMFS HACCP Quality Management Program or EU HACCP Program may still be eligible to enter into the traditional Inspection Program.

F. Appeal Procedures

If a facility wishes to appeal this decision, they are to contact, in writing, the Chief Quality Officer in NMFS Seafood Inspection Program headquarters. The facility must provide, in writing, all pertinent information as to why it is believed the rating was determined in error and what the facility expects to be a proper correction. Once the Chief Quality Officer receives all information, he/she will investigate the matter and make a determination. The decision will be communicated to the Regional Inspection Branch and the facility as soon as it is made. A written report will follow.

G. Use of Marks

Participating firms are responsible for using the marks in accordance with the regulations set forth in 50 CFR Part 260 and the Policy and Guidelines for Advertising and Marking Products Inspected by the U.S. Department of Commerce. Facilities who have received official stamping devices must have written procedures in place securing the device and protecting from its abuse.

H. Analytical Testing and Product Verification

The firm must perform periodic end-item verification of product compliance to program requirements. Both the firm and NMFS must agree upon the firm's frequencies of testing and end-item product requirements; however, product samples for analytical testing must be collected and analyzed at least once per year as part of the firm's verification procedures. The level of analytical sampling per lot must also be comparable to that found in the Hazards and Controls Guide of the Food and Drug Administration. Records of all analytical findings will be made available to NMFS inspectors during Systems Audits and at other times as necessary. As part of the product verification discussed below, NMFS will have product tested analytically throughout the year. Six lots will be tested based upon the information found in the FDA Hazards and Controls Guide. Three lots will be tested for any criteria that is considered quality or economic integrity in nature, such as moisture content of scallops. Variation in the described sampling frequency may occur if evidence warrants. However, any changes to the frequency (and their effects) will be discussed with the applicable parties prior to their implementation.

To determine whether the product produced at the firm meets specification and/or U.S. grade standard requirements, NMFS will routinely perform a product audit on up to three (3) lots produced by the firm since the last Systems Audit. This information will be used to guide the auditor in his/her audit of the system. Product audits

will be completed by conducting records reviews and finished product sample inspections. Additional lots may be sampled if the situation warrants. Lots must be defined by the firm in their QMP plan and approved by NMFS.

IX. QMP SYSTEM EVALUATION CRITERIA

A. General Requirements

1. 21 CFR Part 123

a. Hazard analysis not performed

Every processor shall conduct, or have conducted for it, a hazard analysis to determine whether there are food safety hazards that are reasonably likely to occur for each kind of fish and fishery product processed by that processor and to identify the preventive measures that the processor can apply to control those hazards. Such food safety hazards can be introduced both within and outside the processing plant environment, including food safety hazards that can occur before, during, and after harvest. A food safety hazard that is reasonably likely to occur is one for which a prudent processor would establish controls because experience, illness data, scientific reports, or other information provide a basis to conclude that there is a reasonable possibility that it will occur in the particular type of fish or fishery product being processed in the absence of those controls. The hazard and defect analysis is the foundation of the quality plan. If the analysis is not performed, the entire plan and its efficacy is suspect. Firms must provide this analysis to the requesting Consumer Safety Officer in writing. If it is not provided and evidence suggests that it was performed but a written document is not available, a Serious deficiency will only be assessed. Otherwise, a Critical deficiency will be assessed. [Deficiency: Serious/Critical].

b. No written HACCP plan when one is required

Every processor shall have and implement a written HACCP plan whenever a hazard analysis reveals one or more food safety hazards that are reasonably likely to occur. Firms must provide this plan to the requesting Consumer Safety Officer. [Deficiency: Serious].

c. Plan is not location and/or fish species specific

A HACCP plan shall be specific to:

1. Each location where fish and fishery products are processed by that processor; and
2. Each kind of fish and fishery product processed by the processor. The plan may group kinds of fish and fishery products together, or group kinds of production methods together, if the food safety hazards, critical control points, critical limits, and procedures required to be identified and performed in paragraph are identical for all fish and fishery products so grouped or for all production methods so grouped.

[Deficiency: Major]

d. Hazard(s) is not listed in the plan

The HACCP plan shall, at a minimum list the food safety hazards that are reasonably likely to occur and that thus must be controlled for each fish and fishery product. Consideration should be given to whether any food safety hazards are reasonably likely to occur as a result of the following:

1. Natural toxins
2. Microbiological contamination
3. Chemical contamination
4. Pesticides
5. Drug residues
6. Decomposition in scombroid toxin-forming species or in any other species where a food safety hazard has been associated with decomposition
7. Parasites, where the processor has knowledge or has reason to know that the parasite-containing fish or fishery product will be consumed without a process sufficient to kill the parasites, or where the processor represents, labels, or intends for the product to be so consumed
8. Unapproved use of direct or indirect food or
9. Color additives
10. Physical hazards

[Deficiency: Serious]

e. Hazard(s) is not controlled

Firms may not have met the requirements of performing the hazard analysis or writing a required HACCP plan. However, controls may still be in place for the hazards identified by the Consumer Safety Officer. If it is determined that the controls are not in place, a Critical deficiency will be assessed. [Deficiency: Critical]

f. CCPs are not properly identified in the plan

The HACCP plan shall, at a minimum list the critical control points for each of the identified food safety hazards, including as appropriate:

1. Critical control points designed to control food safety hazards that could be introduced in the processing plant environment; and

2. Critical control points designed to control food safety hazards introduced outside the processing plant environment, including food safety hazards that occur before, during, and after harvest.

[Deficiency: Serious]

g. Appropriate critical limit(s) is not listed in the plan

The HACCP plan shall, at a minimum list the critical limits that must be met at each of the critical control points. If evidence is present that the critical limits were improperly identified but those identified were followed, the deficiency will be assessed here. [Deficiency: Serious]

h. Monitoring procedure(s) in the plan is inadequate

The HACCP plan shall, at a minimum, list the procedures, and frequency thereof, that will be used to monitor each of the critical control points to ensure compliance with the critical limits. [Deficiency: Serious]

i. Corrective action listed in plan is not appropriate

Whenever a deviation from a critical limit occurs, a processor shall take corrective action by following a corrective action plan that is appropriate for the particular deviation. [Deficiency: Serious]

j. Verification procedure(s) stated in plan is inadequate

The HACCP plan shall list the verification procedures, and frequency thereof, that the processor will use. Every processor shall verify that the HACCP plan is adequate to control food safety hazards that are reasonably likely to occur, and that the plan is being effectively implemented.

Verification shall include, at a minimum:

1. Reassessment of the HACCP plan. A reassessment of the adequacy of the HACCP plan whenever any changes occur that could affect the hazard analysis or alter the HACCP plan in any way or at least annually. Such changes may include changes in the following: Raw materials or source of raw materials, product formulation, processing methods or systems, finished product distribution systems, or the intended use or consumers of the finished product. The reassessment shall be performed by an individual or individuals who have been trained in accordance with Sec. 123.10 of 21 CFR Part 123. The HACCP plan shall be modified immediately whenever a reassessment reveals that the plan is no longer adequate to fully meet the requirements.
2. Ongoing verification activities. Ongoing verification activities including:
   - A review of any consumer complaints that have been received by the processor to determine whether they relate to the performance of critical control points or reveal the existence of unidentified critical control points
   - The calibration of process-monitoring instruments
   - At the option of the processor, the performing of periodic end-product or in process testing
3. Records review. A review, including signing and dating, by an individual who has been trained in accordance with Sec. 123.10, of the records that document:

   The monitoring of critical control points. The purpose of this review shall be, at a minimum, to ensure that the records are complete and to verify that they document values that are within the critical limits. This review shall occur within 1 week of the day that the records are made. The taking of corrective actions. The purpose of this review shall be, at a minimum, to ensure that the records are complete and to verify that appropriate corrective actions were taken in accordance with Sec. 123.7. This review shall occur within 1 week of the day that the records are made; and the calibrating of any process control instruments used at critical control points and the performing of any periodic end product or in-process testing that is part of the processor's verification activities. The purpose of these reviews shall be, at a minimum, to ensure that the records are complete, and that these activities occurred in accordance with the processor's written procedures. These reviews shall occur within a reasonable time after the records are made.
4. Processors shall immediately follow corrective action procedures whenever any verification procedure, including the review of a consumer complaint, reveals the need to take a corrective action. (See Corrective Action sections listed below.)
5. Reassessment of the hazard analysis. Whenever a processor does not have a HACCP plan because a hazard analysis has revealed no food safety hazards that are reasonably likely to occur, the processor shall reassess the adequacy of that hazard analysis whenever there are any changes that could reasonably affect whether a food safety hazard now exists. Such changes may include, but are not limited to changes in: raw materials or source of raw materials, product formulation, processing methods or

systems, finished product distribution systems, or the intended use or consumers of the finished product. The reassessment shall be performed by an individual or individuals who have been properly trained in accordance with 21 CFR 123.10. (See 2.3.1)
6. Recordkeeping. The calibration of process monitoring instruments, and the performing of any periodic end-product and in-process testing shall be documented in records that are subject to record keeping requirements listed below.

[Deficiency: Serious]

k. Sanitation standard operating procedures not present

Each processor should have and implement a written sanitation standard operating procedure (SSOP) or similar document that is specific to each location where fish and fishery products are produced. The SSOP should specify how the processor would meet those sanitation conditions and practices that are to be monitored. [Deficiency: Serious].

l. Sanitation not monitored

Each processor shall monitor the conditions and practices during processing with sufficient frequency to ensure, at a minimum, conformance with those conditions and practices specified in 21 CFR Part 110 that are both appropriate to the plant and the food being processed and relate to the following:

1. Safety of the water that comes into contact with food or food contact surfaces, or is used in the manufacture of ice
2. Condition and cleanliness of food contact surfaces, including utensils, gloves, and outer garments
3. Prevention of cross-contamination from unsanitary objects to food, food packaging material, and other food contact surfaces, including utensils, gloves, and outer garments, and from raw product to cooked product
4. Maintenance of hand washing, hand sanitizing, and toilet facilities
5. Protection of food, food packaging material, and food contact surfaces from adulteration with lubricants, fuel, pesticides, cleaning compounds, sanitizing agents, condensate, and other chemical, physical, and biological contaminants
6. Proper labeling, storage, and use of toxic compounds
7. Control of employee health conditions that could result in the microbiological contamination of food, food packaging materials, and food contact surfaces
8. Exclusion of pests from the food plant [Deficiency: Serious]

2. Program Requirements

a. Defect action plan is not adequate to control product quality characteristics

Every processor, as applicable, shall have and implement a written Defect Action Plan and a quality defect analysis for products that will either bear an inspection mark or will be advertised as under the NMFS Seafood Inspection Program. Firms must provide this plan to the requesting Consumer Safety Officer. [Deficiency: Critical]

b. Quality manual is inadequate

Every processor, as applicable, shall have and implement a written quality manual which covers each of the elements delineated in the Quality System Requirements. Firms must provide this plan to the requesting Consumer Safety Officer. [Deficiency: Serious]

c. Labels and/or specifications are inadequate

Title 50 of the Code of Federal Regulations (CFR) requires that establishments contracting for fishery product inspection service obtain NMFS approval of labels prior to use on products packed under Federal inspection, regardless of whether or not they bear official inspection or grade marks. Additionally, the "Policy for Advertising Services and Marks" identifies additional labeling and advertising of marks and services that must be approved prior to use. The Regulations Governing Processed Fishery Products require that specifications for all products for which U.S. Standards for Grades are not available be approved by the Secretary of Commerce and that end-product samples, when requested, be evaluated to determine their compliance with approved specifications prior to NMFS inspection and certification of such products. [Deficiency: Serious]

B. Adherence to HACCP-Based Plan

1. Procedures

The procedures outlined in a firm's QMP plan must be followed as written. The plan was approved by NMFS as a whole, not procedure by procedure. Not following a procedure could affect the entire critical control point.

a. Monitoring procedures not followed

Monitoring procedures must be followed to maintain control of the process. If any monitoring procedure has not been followed and a corrective action report is not filed, the firm is not in compliance with this item. [Deficiency: Serious]

b. Critical limits not followed
Self Explanatory. [Deficiency: Critical]

c. Corrective action not taken
Whenever a deviation from a critical limit, sanitation, verification, or quality plan occurs, a processor shall take corrective action. Processors may develop written corrective action plans, which become part of their QMP plans by which they predetermine the corrective actions that they will take whenever there is a deviation from a critical limit. A corrective action plan that is appropriate for a particular deviation is one that describes the steps to be taken and assigns responsibility for taking those steps, to ensure that:

1. No product enters commerce that is either injurious to health, is otherwise adulterated as a result of the deviation, or does not meet Program requirements; and
2. The cause of the deviation is corrected. A firm is provided room for error in their plan through a system of corrective actions.

If an error or problem arises in the conducting of the QMP plan, the firm must file a corrective action report (Notice of Unusual Occurrence and Corrective Action — NUOCA). All other deficiencies may possibly be averted in this checklist if corrective action reports are filed for each problem or situation. Failure to file a corrective action report will be considered a failure to take a corrective action and the firm will then not be in compliance with this item.

When a deviation from the QMP occurs and the processor does not have a corrective action plan that is appropriate for that deviation, the processor shall:

1. Segregate and hold the affected product.
2. Perform or obtain a review to determine the acceptability of the affected product for distribution. The review shall be performed by an individual or individuals who have adequate training or experience to perform such a review.
3. Take corrective action, when necessary, with respect to the affected product to ensure that no product enters commerce that is either injurious to health or is otherwise adulterated as a result of the deviation or does not meet other program requirements.
4. Take corrective action, when necessary, to correct the cause of the deviation.

Perform or obtain timely reassessment by an individual or individuals who have been properly trained to do so, to determine whether the plan needs to be modified to reduce the risk of recurrence of the deviation, and modify the plan as necessary. [Deficiency: Critical]

d. Verification procedures not followed
Verification procedures are those that provide for management to determine the overall effectiveness of the plan. Not following these procedures could ultimately cause the plan to fail or misidentify a hazard, defect, or control procedure. Since failure of these procedures will likely not immediately cause the plan to fail, it is rated at a Serious level. This item should be checked on a trend basis, not based on isolated incidences unless they are of such severity to warrant action. Firms must reassess their hazard and defect analyses when information or other evidence indicates the need and at least yearly. The plan must be signed and dated by a management official responsible for the operation of the facility. The plan must be signed upon implementation and at least once each year. [Deficiency: Serious]

e. Sanitation standard operating procedures not followed
This deficiency will be assessed if it is determined that the firm did not follow their written SSOPs, whether or not specific sanitation deficiencies were observed. [Deficiency: Serious]

f. Defect action plan/quality manual not followed
This deficiency will be assessed if the firm did not follow the policies outlined in their Quality manual or did not follow the procedures listed in their defect action plan. This deficiency will be assessed whether or not it was determined that product was affected. [Deficiency: Serious]

2. Records

a. Inadequate information on records (facility name and location, etc.)
Self Explanatory
Based on the required information stated in 21 CFR Part 123. All records required by this part shall include:

1. The name and location of the processor or importer
2. The date and time of the activity that the record reflects
3. The signature or initials of the person performing the operation
4. Where appropriate, the identity of the product and the production code, if any. Processing and other information shall be entered on records at the time that it is observed [Deficiency: Major]

b. Record data is missing
All records must be kept up-to-date. Entries must be made as they are measured. The records shall contain the actual values and observations obtained during monitoring or

measurement. All time schedules outlined in the QMP plan must be maintained. Examples of non-compliance include: measurement observed to be taken but not entered on record; partial entry of information from monitoring procedures; initials for QA verification not recorded in a timely manner; etc. If record data is missing, a Major deficiency will be assessed.

All labels must be up-to-date. All labels must be kept on file by the firm. If labels are not up-to-date, a Serious deficiency will be assessed. The maintenance of records on computers is acceptable, provided that appropriate controls are implemented to ensure the integrity of the electronic data and signatures. [Deficiency: Major (Serious for Labels)]

c. Records are inaccurate

All entries must be accurate or the record is meaningless. If calculations, time test measured, etc., are not correct, the box for this deficiency should be checked. This deficiency will also be used for the compliance of product leaving the firm. [Deficiency: Serious/Critical]

d. Records are not available for inspection

If the firm for any unreasonable amount of time does not surrender the applicable record for inspector review, they are not in compliance with this item. If portions of a record are not available, the firm is not in compliance with this item. All required records shall be retained at the processing facility or importer's place of business in the United States for at least 1 year after the date they were prepared in the case of refrigerated products and for at least 2 years after the date they were prepared in the case of frozen, preserved, or shelf-stable products. Records that relate to the general adequacy of equipment or processes being used by a processor, including the results of scientific studies and evaluations, shall be retained at the processing facility or the importer's place of business in the United States for at least 2 years after their applicability to the product being produced at the facility.

If the processing facility is closed for a prolonged period between seasonal packs, or if record storage capacity is limited on a processing vessel or at a remote processing site, the records may be transferred to some other reasonably accessible location at the end of the seasonal pack but shall be immediately returned for official review upon demand. [Deficiency: Critical]

e. Documents or records are falsified

This item is self-explanatory. However, intent on the part of the firm or its representatives must be shown. For example, if an item on a record was shown to be corrected with correction fluid or other means of obliteration, the inspector must show that someone with, full knowledge, changed the entry to reflect a value that was not the value measured or observed. Otherwise, this will be considered an inaccurate entry. [Deficiency: Critical]

3. Other Requirements

a. Program trained personnel not available

Hazard analysis, reassessment or modification of HACCP plan, or records review performed by untrained personnel. Each firm must employ a person who has been certified by NMFS for this program. At least one NMFS HACCP-certified person is required to be present during production. In addition, copies of all certified personnel's certificates must on file with the firm. Per 21 CFR part 123, these duties are assigned only to properly trained personnel. For the QMP Program, properly trained will be any person who has passed the NMFS Certification Exam. However, failure of this element will not likely cause an immediate hazard or defect. Therefore, it is rated as a Serious deficiency. Per 21 CFR part 123, these duties are assigned to only properly trained personnel. Failure of this element could lead to an immediate hazard or defect. At a minimum, the following functions shall be performed by an individual who has successfully completed training in the application of HACCP principles to fish and fishery product processing at least equivalent to that received under standardized curriculum recognized as adequate by the U.S. Food and Drug Administration or who is otherwise qualified through job experience to perform these functions. Job experience will qualify an individual to perform these functions if it has provided knowledge at least equivalent to that provided through the standardized curriculum.

Developing a HACCP plan, which could include adapting a model or generic-type HACCP plan, that is appropriate for a specific processor, in order to meet the requirements of Sec. 123.6(b); Reassessing and modifying the HACCP plan in accordance with the corrective action procedures specified in Sec. 123.7(c)(5), the HACCP plan in accordance with the verification activities specified in Sec. 123.8(a)(1), and the hazard analysis in accordance with the verification activities specified in Sec. 123.8(c); and Performing the record review required by Sec. 123.8(a)(3). The trained individual need not be an employee of the processor. [Deficiency: Serious]

b. Modification to QMP plan without approval

Any change in procedures whether they are written or not will be considered non-compliance by the firm for this item. This includes all procedures at critical control points, sanitation procedures, recall procedures verification procedures, and consumer complaint procedures. Exceptions will be allowed for those procedures the firm can justify that were necessary to avert or control a public safety or health situation provided a corrective action report is on file for the incident and a request for plan modification is filed with the servicing NMFS Regional Inspection Branch within a 24-hour period. [Deficiency: Serious]

C. Facility Sanitation

1. Safety of Process Water

Process water must be of very high quality as it directly interfaces or becomes part of the product being manufactured. Therefore, no filth, deleterious chemicals, bacteria, or other contaminants may be present in solution as it will directly affect the safety of the product. Available water must pass potability standards established by federal, state, and local authorities. Water that is supplied to the plant must meet certain minimum standards. However, processing water must also be reasonably protected in the facility. Conditions that allow contamination to occur cannot be allowed. These may include cross-connection of plumbing, backsiphonage, or back flow from a contaminated source to the supply system or open vessels of water.

a. Unsafe or unsanitary water supply

The water supply, including seawater, will be in compliance when by certification or direct testing the supply is found to meet the federal standards set forth by the Environmental Protection Agency. Private supplies shall have testing performed at a minimum of every six (6) months. Certification of municipal or community systems should be secured at a minimum of once per year. [Deficiency: Critical]

b. No protection against backflow, back-siphonage, or other sources of contamination

A facility will be in compliance when all cross connections are eliminated, backflow prevention devices are installed wherever backflow or siphonage may occur, or where other possible forms of contamination may be present. [Deficiency: Serious]

c. Inadequate supply of hot water

Hot water is necessary for many cleaning techniques. In addition, a hot water supply is necessary to provide a comfortable means for employees to wash their hands. If the tap is on and a luke-warm supply of water is present in sufficient quantities for the tasks it will perform in the facility, the plant is in compliance. The supply must also be easily accessible for its proper use. [Deficiency: Minor]

d. Ice not manufactured, handled, or used in a sanitary manner

A facility will be in compliance when potable water is used for manufacturing, when the manufacturing equipment is clean, and the ice only touches impervious surfaces; the ice holding containers are clean and made of appropriate impervious material; handling equipment is clean and appropriate for food contact; and ice is not reused on ready-to-eat product. For facilities receiving ice from an outside supply, a certificate of conformance will be necessary to ensure that the ice being received meets the standards set forth in this document. In addition, potability checks must be made at a minimum of every six (6) months on ice received. [Deficiency: Critical]

2. Food Contact Surfaces

a. Equipment and utensils' design, construction, location, or materials cannot be readily cleaned and sanitized; does not preclude product adulteration or contamination

Any equipment used in the manufacturing or handling of the food product must be designed or constructed so that it can be easily taken apart for regular cleaning and inspection. Failure to do so will cause the facility to be out of compliance. In addition, if the materials used are not of a material suitable for its intended purpose or there is reuse of single-service items, then the facility is also out of compliance. [Deficiency: Major]

b. Equipment, primary packaging materials, and utensils not maintained in proper repair or removed when necessary. (Product-contact surfaces)

All product contact surfaces must be kept in good repair. If the contact surface cannot be repaired, then the piece of equipment or utensil should be removed so as not to allow for its use. Primary packaging materials should be adequately covered when stored or not in use. Failure to provide these conditions will result in non-compliance. [Deficiency: Major (Serious for products at a high risk stage of processing)]

c. Product contact surfaces not cleaned or sanitized before use, after interruptions, or as necessary

Product contact surfaces must be cleaned using proper techniques to remove dirt and debris. Sanitizers must be used before product contacts the surface. Sanitizing without cleaning is insufficient. Any violation will be considered noncompliance. [Deficiency: Serious (Critical for products at a high risk stage of processing)]

d. Processing or food handling personnel do not maintain a high degree of personal cleanliness

All persons, while in food preparation or handling areas shall wear clean outer garments, use clean cloths, and conform to hygienic practices while on duty, to the extent necessary to prevent contamination or adulteration of food. This includes occasional workers or visitors to the area. [Deficiency: Major/Serious]

e. Processing or food handling personnel do not take necessary precautions to prevent adulteration or contamination of food

All persons, while in a food preparation or handling area, shall:

1. Wash their hands thoroughly to prevent contamination by undesirable microorganisms before starting work, after each absence from the work station, and at any other time when the hands may have become soiled or contaminated. After washing, the hands must be sanitized using the company-provided hand dip stations.
2. Remove all insecure jewelry, and when food is being manipulated by hand, remove from hands any jewelry that cannot be adequately sanitized.
3. If gloves are used in food handling, maintain them in an intact, clean, and sanitary condition. Such gloves shall be of an impermeable material except where their usage would be inappropriate or incompatible with the work involved. If gloves are used they will be washed and sanitized at the same frequency as employees' hands as described in number one of this list.
4. Wear hairnets, caps, masks, or other effective hair restraint. Other persons that may incidentally enter the processing areas shall comply with this requirement.
5. Not expectorate; nor store clothing or other personal belongings; not eat food or drink beverages; nor use tobacco in any form in areas where food or food ingredients are exposed, or in areas used for food processing, storage of food ingredients and/or packaging materials, washing of equipment and utensils, or in production areas.
6. Take other necessary precautions to prevent contamination of foods with microorganisms or foreign substances including, but not limited to perspiration, hair, cosmetics, tobacco, chemicals, and medicants. [Deficiency: Serious/Critical]

3. Prevention of Cross Contamination

a. Grounds condition can permit contamination to enter the facility

There shall be no conditions on the grounds such as dusty roads or parking lots, mud puddles, chemical spills, etc., that can cause contamination to be carried into the plant through such means as wind drafts, personnel foot traffic, adherence to personnel clothing, flooding, etc. Design of the facility structure should be such that access is easily obtained to all areas. This is necessary for proper cleaning and sanitizing of floors, walls and ceilings, as well as for visual inspections. [Deficiency: Minor]

b. Facility

Design, layout of materials used cannot be readily cleaned and sanitized; does not preclude product adulteration or contamination

If the rooms (including restrooms and employee break rooms) in the facility are laid out or designed in such a way that they cannot be readily cleaned or sanitized, then the facility is not in compliance. This would include improper materials for walls, ceilings, etc., as well as hard-to-reach rooms or corners even when the equipment is removed from the room. [Deficiency: Major]

Insufficient separation by space or other means allows product to be adulterated or contaminated

There must be sufficient separation between different activities in the processing, packaging and handling of food products. This includes the complete separation of living/sleeping quarters or heavy maintenance areas from food-handling areas. The food product should flow easily from one stage to another and not be allowed to come into contact with non-food surfaces if exposed. In addition, the layout of the facility should not be such that product contamination is likely due to heavy employee traffic through work areas. Retail product displays should be arranged so that there is sufficient separation to assure that no cross-contamination can occur between raw, cooked, and live product. [Deficiency: Serious (Critical for products at a high risk stage of production)]

c. Condition of roof, ceilings, walls, floors, or lighting not maintained; lights not protected

Areas directly affecting product or packaging material

For those areas that will directly affect product or primary packaging materials, (packaging immediately surrounding product), the roof, ceiling, walls, floors, and lighting fixtures must be maintained as designed and lights must be protected. Failure to do so causes the facility to be out of compliance. [Deficiency: Critical]

Other

For areas in the facility other than in section above (Areas directly affecting product or packaging material), the roof, ceilings, walls, floors, or lighting fixtures must also be maintained as designed. This does not include those areas designated as offices and in which food products or primary packaging materials in any stage of production will not be handled or stored. [Deficiency: Minor (Major for products at a high risk stage of production)]

d. Cleaning methods permit adulteration or contamination

Employees must take care to use methods that will not adulterate or contaminate the product. Any cleaning or sanitizing procedures or techniques that may cause the

product to become adulterated or contaminated will caused the facility to be in non-compliance. Examples of non-compliance include but are not limited to inadvertent touching of product or product surfaces with wash water, detergent, sanitizers, etc., during production. [Deficiency: Serious (Critical for products at a high risk stage of production)]

e. Finished product not properly covered or protected

Finished product must be either packaged, covered or protected so as to not permit contamination or adulteration prior to shipment. [Deficiency: Major (Serious for products at a high risk stage of production)]

f. Equipment and utensils not maintained in proper repair or removed when necessary (Non-product contact surfaces)

All non-food contact surfaces should also be maintained in good repair. The facility is in noncompliance when the maintenance of all additional equipment or areas of equipment and utensils not referred to in item 3.2.a above is insufficient and may allow indirect product contamination or adulteration. [Deficiency: Minor (Major for products at a high risk stage of production)]

g. Non-product contact surfaces not cleaned before use

Non-product contact areas must also be cleaned prior to use. However, sanitizing is not required. This includes wall, ceilings, floors, and other room areas as well as equipment. [Deficiency: Major]

4. Handwashing, Hand Sanitizing, and Toilet Facilities

a. Hand washing and hand sanitizing stations not present or conveniently located

Hand washing and hand sanitizing stations must be present and located conveniently and in sufficient numbers to provide employees ease of their use. [Deficiency: Serious (Critical for products at a high risk stage of production)]

b. Improper disposal of Sewage

A facility is in compliance when sewage systems drain properly, are vented to the outside, and are connected to an approved private septic system or a public septic and/or sewerage system. [Deficiency: Critical]

c. Inadequate supplies

The restrooms must provide supplies such as toilet paper, soap, etc., sufficient enough to meet employees' needs. [Deficiency: Major]

d. Insufficient number of functional toilets

The facility must have one operable, in good repair, conveniently accessible toilet per fifteen (15) employees, per gender. For men, urinals may be substituted for toilet bowls, but only to the extent of one-third (1/3) of the total number of bowls required. [Deficiency: Minor]

5. Protection from Adulteration

a. Condensation

Areas directly affecting product or primary packaging material

If any condensation, overhead leaks, or water splash is found in areas in the facility where the condensation has the potential to come in contact with product or primary packaging material, the facility is in non-compliance. [Deficiency: Serious (Critical for products at a high risk stage of production)]

Other

Any areas other than those noted above where food is stored, handled, processed, packaged, or displayed shall be condensation-free. If condensation is noted in these areas, the facility shall be in non-compliance. [Deficiency: Major]

b. Adequate air exchange does not exist

A facility is in compliance when adequate air exchange exists to preclude the development of foul odors.

[Deficiency: Minor (Only for products at a high-risk stage of production)]

6. Proper Labeling, Use, and Storage of Toxic Compounds

Plant chemicals are cleaners, sanitizers, rodenticides, insecticides, machine lubricants, etc. They must be used according to manufacturer's instructions, have proper labeling, and be stored in a safe manner or they may pose a risk of contaminating the food product that the establishment is handling or manufacturing. A facility will be in compliance when the chemicals are used according to manufacturer's instructions and recommendations and stored in an area of limited access away from food handling or manufacturing. All chemicals must be labeled to show the name of the manufacturer, instructions for use, and the appropriate EPA or USDA approval.

a. Chemical(s) improperly used or handled

[Deficiency: Critical]

b. Chemical(s) improperly stored

[Deficiency: Serious]

c. Chemical(s) improperly labeled

[Deficiency: Major]

7. Control of Employee Health Conditions

a. Facility management does not have in effect measures to restrict people with known disease from contaminating the product

No person affected by disease in a communicable form, or while a carrier of such disease, or while affected with boils, sores, infected wounds, or other abnormal sources of microbiological contamination, shall work in a food plant in any capacity in which there is a reasonable possibility of food or food ingredients becoming contaminated by such person. Plant management shall require employees to report illness or injury to supervisors. [Deficiency: Serious]

8. Exclusion of Pests

The presence of rodents, insects, and other animals in the facility must not be allowed because they are sources for the contamination of food with foreign material, filth, and bacteria, etc.

a. Harborage and attractant areas present

The facility and grounds are free of harborage areas. These include but are not limited to: uncut weeds, brush or tall grass; improper storage of unused equipment or materials; presence of litter, waste and refuse; or standing or stagnant water. All garbage and refuse containers are rodent/insect-resistant and outside storage areas are properly constructed. [Deficiency: Major]

b. Pest control measures not effective

Exclusion

Openings to the outside of or within the facility may allow vermin or other pests to enter. Openings and cracks should be screened or otherwise sealed. Screens must be of a mesh not larger than 1/16th of an inch in order to exclude insects. Cracks or holes should be sealed and doors and windows should close tightly (no opening larger than 1/4″) to exclude rodents or other animals. Air curtains and strip curtains must be effective. Air curtains shall comply with National Sanitation Standard Number 37 for Air Curtains for entranceways in food establishments. Strip curtains must run the entire width of the opening with sufficient overlap between flaps (1/2 inch). In addition, every effort should be made to keep birds from areas of the plant where food is transferred or processed. [Deficiency: Major]

Extermination

Birds — Nesting areas must be eliminated. Insects — There should not be a significant number of insects present in the facility. Insect electrocution devices, when used, must be located near the entranceway. Approved insecticides should be used whenever insect populations become noticeable.

Rodents — There should not be evidence of rodent activity. Evidence of rodents includes, but is not limited to: fecal droppings present; urine stains on bags or walls; slide marks along rodent runways; or feeding areas around stored dry goods bags that may be excessive. The facility should have appropriate rodent control measures in place. If not, the facility is not in compliance. [Deficiency: Serious]

c. Inadequate disposal of processing waste

A facility is in compliance with regard to processing wastes when they are placed in proper containers, placed at appropriate locations throughout the plant, and removed frequently. [Deficiency: Serious]

d. Inadequate housekeeping

Any excess clutter in production areas, employee areas, or other areas of the facility will cause the facility to be in non-compliance. This does not include those areas designated as office areas. [Deficiency: Minor]

80 Workers Safety and Types of Food Establishments

Nanna Cross
Chicago, Illinois

CONTENTS

I. STANDARD INDUSTRIAL CLASSIFICATION (SIC) OF FOOD ESTABLISHMENTS

Food and kindred products may be classified according to the "Standard Industrial Classification Manual" (Occupational Safety and Health Administration). This manual is revised periodically by using supplements. Ever since the introduction of the Internet, the use of this manual has increased tremendously.

In this manual, food and kindred products are placed under Major Group 20. This major group includes establishments manufacturing or processing foods and beverages for human consumption, and certain related products, such as manufactured ice, chewing gum, vegetable and animal fats and oils, and prepared feeds for animals and fowls. Table 80.1 describes the industrial establishments according to categories of food and kindred products, and the group number for each category is also given.

Table 80.2 describes food establishment categories, operations, and product examples.

II. POTENTIAL OCCUPATIONAL HAZARDS IN A FOOD PROCESSING PLANT

The potential hazards associated with the manufacturing process in the nearly 50 subdivisions of food and kindred

TABLE 80.1
Classification of Industrial Establishments According to Categories of Food and Kindred Products

Group Number	Establishments of Manufacturing or Processing
201	Meat products
202	Dairy products
203	Canned and preserved fruits and vegetables
204	Grain mill products
205	Bakery products
206	Sugar and confectionery products
207	Fats and oils
208	Beverages
209*	Miscellaneous food preparations and kindred products

*This group includes canned and cured fish and seafoods, fresh or frozen packaged fish and seafood, roast coffee, manufactured ice, macaroni, spaghetti, vermicelli, and noodles, and food preparations not elsewhere classified**.

**This category includes baking powder, yeast, and other leavening compounds; chocolate and cocoa products except confectionery, made from purchased materials; peanut butter, packaged tea (including instant); ground spices; potato, corn, and other chips; and vinegar and cider. There are others.

TABLE 80.2
Food Establishment Categories, Operations, and Product Examples

Food Establishments (SIC)	Operations Product Examples	Product Examples
Packing houses (201)	Slaughtering	Dressed meat and fowl
	Dressing	Meat products
	Packing	Processed meat
	Processing	
Dairies and creameries (202)	Churning	Fluid milk
	Cheese making	Butter
	Condensing	Cheeses
	Freezing	Evaporated milk
		Ice cream
Canneries and preserving (203)	Canning	Canned fruit and vegetables
	Drying	Dried products
	Pickling	Pickled products
	Freezing	Frozen products
Grain mills (204)	Flour milling	Wheat, corn, and rye flour
	Corn meal	Corn products
	Rice milling	Rice
	Wet corn	
	Milling	Prepared foods
	Prepared foods	
Bakeries (205)	Baking	Bread
	"Dry" baking	Cookies
		Crackers
Sugar refineries and confectioneries (206)	Extracting concentrating, and crystallizing cane and beet sugar	Cane and beet sugars
		Molasses
	Processing confectioneries	Syrup
		Candies
		Chewing gum
Fat and oil (207)	Extracting vegetable oils and animal oils by pressing, heating the solution	Vegetable oils
		Animal and fish
	Hydrogenating	Shortening
		Margarine
		Edible oils
Beverages (208)	Alcoholic	Beer, wine, and spirits
	Brewing	
	Fermenting	
	Distilling	
	Nonalcoholic	Bottled and canned soft drinks
	Extracting	
	Carbonating	Carbonated drinks
	Canning	
Miscellaneous prepared foods (209)	Cooking	Canned and frozen seafoods
	Canning	Roasted coffee
	Drying	Noodles
	Curing	Macaroni
	Roasting	Ice
	Ice making	

products are primarily safety hazards (Table 80.3). The following safety hazards were generally common to all the processes:

1. Extensive manual handling of feed and in-process materials and of finished products
2. Extensive exposure to slippery floors and supports
3. Extensive use of sharp implements such as cutting hand tools, saws and knives
4. Exposures to microorganisms, chemicals, allergens, viruses, molds, and dusts on substances in the feed materials

TABLE 80.3
Food Processes, Safety Hazards and Controls

Controls Process	Occupational Condition	Potential Hazard	Control
Meat processing, SIC 201	Handling live, immobile, and slaughtered animals	Strains, contusions	Mechanization, training
	Cutting and use of sharp tools	Lacerations, loss of body members	Protective clothing, gloves, guards, training
	Wet flooring, platforms, decks	Falls, sprains	Drains, shields
	Steam	Burns, scalds	Shields, reliefs
	Animal borne microorganisms	Brucellosis, dermatitis	Inspection
Dairy processes, SIC 202	Handling churns, homogenizers, plasticizers, evaporators, freezers	Lacerations, contusions, etc., from moving machine parts	Guards, shields, layout, clothing, insulation
	Handling in-process materials, products	Strains and contusions	Mechanization, training
Food preservation processes, SIC 203	Cleaning, cutting, screening, peeling raw fruit and vegetables	Lacerations, bruises, pinches in operating and maintaining the tools and machines	Guards, shields, clothing layout, training
	Blanching, cooking, pasteurizing, curing, freezing products	Burns, scalds, extreme temperatures	Insulation, shields
	Storing, packaging, shipping	Cuts, bruises from packaging machines, sprains	Guards, gloves, shields, mechanization
Grain mill processes, SIC 204	Operating and servicing breaking rolls, sieves, conveying and elevating equipment, man-lifts	Bruises, contusions, pinches, lacerations, falls	Guards, barriers, training
	Handling feed, in-process material products	Body strains	Mechanization, training
	Dust, noise, vibration	Respiratory effects, hearing	Ventilation, insulation
Bakery processes, SIC 205	Mixing, kneading, and forming machinery-conveyors	Injuries from moving parts	Guards, shields, layout
	Baking ovens	Burns, hot working environments	Insulation, clothing, air conditioning
	Handling in-process materials, products	Strains	Mechanization, training
Sugar and confectionery processes, SIC 206	Cleaning, grinding, shredding, and extraction machinery	Lacerations, contusions from moving machine parts	Guards, protective clothing, layout, ventilation, drains, overflows
	Purifiers and chemicals	Lime, sulfur dioxide, chlorine dioxide, formaldehyde	Controls, ventilation
	Concentrators, crystallizers		
	Centrifuges, filters, dryers under operating and maintenance conditions	Burns, spills, leaks	Overflows, drains
		Lacerations, contusions, burns	Controls, maintenance, insulation-sizing
Fat and oil recovery processes, SIC 207	Extracting oil and fat from animal and vegetable processes by steam distillation, mechanical expression, solvent extraction	Burns and scalds from steam and liquor leaks, spills; breaks and leaks from presses; vapors and gases from extractors	Insulation, barriers, layout, controls against overloads, spills, ventilation and monitoring
	Cleaning, grinding, shredding feeds	Machine injuries	Guards, training
	Purification, hydrogenation processing	Chemical effects	Ventilation
Beverages, SIC 208	Handling in-Processing materials	Body straining from lifting	Increasing mechanization, training
	Broken glass	Lacerations	Protective clothing, gloves

5. Seasonal operating schedules, reflecting time of harvesting, that influence safety training effectiveness

Specifically, particularly high rates are associated with the meat processing, food preservation, sugar and confectionery, fat and oil recovery, and beverage processes. In general, average rates are associated with the dairy, grain mill, and bakery processes.

The high injury and illness rates in the meat processing and fat and oil recovery processes appear to result primarily from hazards associated with cutting and hand tools, slippery floor conditions, and batch handling. There is little specific information that explains the elevated rates associated with the food preservation and sugar and confection processes, but the seasonal schedules and temporary, untrained work forces employed to meet harvest requirements are important factors. In the

beet and cane sugar industry, contusions and bruises to hands and feet, especially to maintenance workers, are a frequent cause of injury; scalds from hot water are considered to be another important factor. The foremost potential hazards associated with the beverage processes, particularly the bottled and canned soft drink processes, are body strains and sprains arising from the manual handling of the products.

Outbreaks of diseases of bacterial origin in meat processing facilities appear to be foremost among the reported nonsafety related potential health problems associated with that industry. Reports of brucellosis and skin sepsis in slaughtering and rendering plants, psittacosis in a turkey processing plant, and antibodies to *E. coli* enterotoxin in beef and swine meat-packing workers were encountered. Respiratory illness resulting from exposure to polyvinyl chloride pyrolysis fumes is a potential health hazard for meat wrappers.

Brucellosis is an acute or subacute infectious disease with variable manifestations. It is characterized by attacks of irregular fever, chills, sweating, and pain in muscles and joints, which may last for months. The disease shows remissions and although relapses are frequent, brucellosis does produce substantial immunity to reinfection. Because it can be confused with almost any febrile episode, diagnosis is very difficult unless blood cultures are positive. The *Brucella* species that are classically infective for man are found in dairy cattle (*B. abortus*), hogs (*B. suis*), and sheep and goats (*B. melitensis*). Each of these species may occasionally infect the other animals. Brucellae are distributed throughout the infected animal and may remain viable for 21 days in a refrigerated carcass. The tissues, blood, placenta and fetus, milk, and urine may be infectious. They may survive the curing of ham, but are killed by smoking, cooking, and pasteurization. Brucellae may invade through the eye, nasopharynx, genital tract, and gut, but unbroken skin is resistant. Contact with swine is the probable source of infection.

An outbreak of psittacosis among workers in a turkey processing plant had been reported. Cases occurred in employees working in the kill and pick, evisceration, and packaging departments, and inhalation of infectious sprays of poultry blood and other tissues was considered to be the primary route of infection. The results of the investigation suggested, however, that workers having both frequent contact with turkey tissues and skin injuries were more likely to be infected than other processing workers. Psittacosis is a disease of bacterial origin (*Chlamydia psittaci*), which usually takes the form of a pneumonia accompanied by fever, chills, headaches, body aches, cough, and often splenomegaly. Respiratory tract illness has been reported in meat wrappers exposed to polyvinyl chloride (PVC) pyrolysis fumes while working with hot wire cutting machines. From the data available, it appears that the major emissions from the meat wrapping film are di-2-ethylhexyladipate and hydrogen chloride. Meat wrapping, however, is usually performed in the meat departments of retail super-markets. Respiratory distress has also been reported in some meat cutters following exposure to heat-activated price labels; emissions from heated price labels have recently been found to include phthalate anhydride, 2,5-di-tert-amylquinone, and dicyclohexyl phthalate.

The rates for injury and illness in the industry's processes are considerably above the average for U.S. manufacturing and one of the highest in all manufacturing.

Design features that may reduce employee exposure to hazards basically involve factors that ensure steady and uninterrupted equipment operation, such as sizing, strength, capacity corrosion, and wear-resistance properties. Overloading, spills, breakdowns, and failures are major causes of potentially hazardous exposures. Engineering controls should also provide adequate space for easy and safe access to the equipment by production and maintenance workers, and means for sensitive, reliable, and accurate monitoring of process conditions.

In addition to those basic design controls, engineering controls apply to specific working conditions. Adequate and reliable ventilating, scrubbing, and monitoring systems should be provided to ensure good air in working areas. Vents for storage tanks and closed areas may also be required, as well as comprehensive safety guarding systems for cutting tools and moving machine parts, and proper electrical grounding. Insulating and isolating barriers for excessive temperature, noise, or vibration may be appropriate in certain instances. Maintenance tends to increase the potential for hazardous exposures because of the unusual conditions that may develop, and the special procedures that may be involved.

Table 80.3 describes food processes, safety hazards, and controls.

III. AN EXAMPLE OF WORKERS SAFETY IN A BAKERY ESTABLISHMENT

A. Identification

Industry: Bakery products. Sub-group: Bread, cake and related products; cookies and crackers. Standard Industrial Classification: 2051, 2052.

B. Process Description

Bakery goods include bread, cakes, pies, cookies, rolls, crackers and pastries. Ingredients consisting of flour, baking

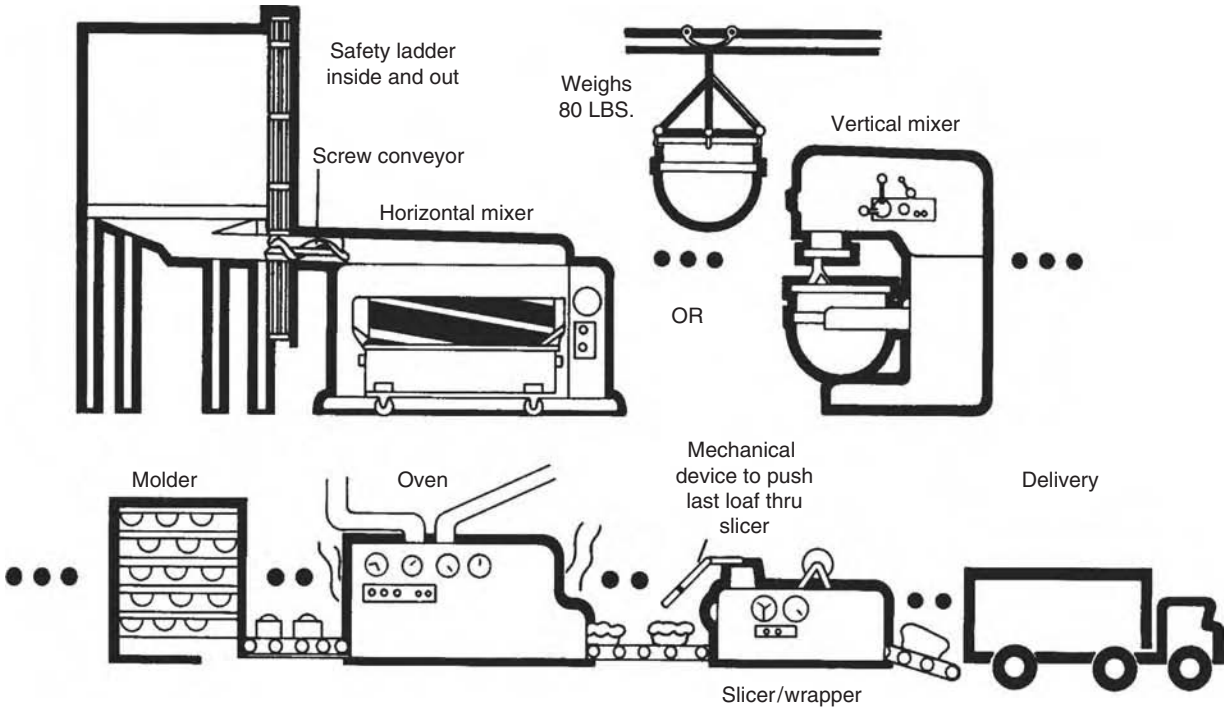

FIGURE 80.1 Process flow for a bakery establishment.

powder, sugar, salt, yeast, milk, eggs, cream, butter, lard, shortening, extracts, jellies, syrups, nuts, artificial coloring, and dried or fresh fruits are blended in a vertical or horizontal mixer after being brought from storage, measured, weighed, sifted, and mixed. After mixing, the dough is raised, divided, formed, and proofed. Fruit or flavored fillings are cooked and poured into dough shells. The final product is then baked in electric or gas-fired ovens, processed, wrapped, and shipped. Loaves of bread are also sliced and wrapped.

Figure 80.1 presents a simple outline of the process flow in this category of food establishments.

C. Injury Type and Sources

In bakery products, most of the injured employees are struck by or struck against some object, fell or slipped or were caught in, under or between objects. These injuries most commonly encountered are dislocations, sprains and strains and often involve machines and working surfaces as sources of injury.

D. Inspection Analysis

When a company officer inspects the bakery establishment for safety concerns, he or she should do the following analysis. The inspection should begin in the receiving and storage areas where bins must be checked for safety ladders of non-splintering material. Any OSHA Class II hazardous locations must have approved electrical fixtures. Mixers should then be checked for interlocks, along with agitator guards, size of openings, and cranes for moving bowls over 80 lbs. Bread rollers must have in-running rollers guarded and the slicing machine must have a device to push the last loaf of bread through and be interlocked. Employees must be checked for personal protective equipment at hot fat kettles. Machines must be grounded and have power transmission and guarded throughout. Any hot water or steam pipe must be guarded, especially in mixing and oven areas. Any conveyor passing over an aisle must have a lower guard to protect employees passing underneath baking machinery. Dividers, dough breaks, biscuit and cracker equipment, sugar and spice pulverizers, cheese and fruit cutters, and dough sheeters shall have guards to protect nip points and points of operation. Aisles must be clear of all tripping and slipping hazards particularly at open fat kettles. High noise areas must be surveyed or referred to an Industrial Hygienist.

E. OSHA Hazards Analysis

Table 80.4 presents the types of hazards, their causes and their occurrence in the bakery processing plant.

TABLE 80.4
OSHA Hazards Analysis

	Activities or Equipment	Location
Major Hazards		
Amputation and mangled limbs from contact with gears, shafts, pulleys, belts, chains and sprockets	Mechanical power transmission apparatus	Throughout plant
Slipping, tripping and falling hazards	Housekeeping	Throughout plant
Amputation and mangled limbs from nip points and sharp blades	Point of operation	Throughout plant
Electrocution from inadequate grounding	Electrical connections	Throughout plant
Burns from hot pipes and hot fat splashes. Inhalation of carbon monoxide	Ovens and open fat kettles	Throughout plant
Other Hazards		
Broken chain links and pulleys causing mixing bowls to fall on employees	Cranes and hoists	Mixing
Back strains and pulled muscles	Lifting	Mixing and baking areas
Explosion or fire	Combustible dusts	Storage

F. Other Pertinent Information

An Industrial Hygienist referral must be made for flour dust, which can cause rhinitis, buccopharyngeal disorders, bronchial asthma and eye diseases. There is a high incidence of pulmonary tuberculosis among bakers.

81 Animal Food (Feed) Product Safety

Nanna Cross
Chicago, Illinois

CONTENTS

I. INTRODUCTION

The safety and economic integrity of animal feeds for domestic animals, e.g., beef cattle and pet foods, are regulated by the U.S. Food and Drug Administration (FDA). This chapter discusses the regulatory guidelines issued by the FDA.

The use of food products is governed by the provisions of the Federal Food, Drug, and Cosmetic Act (FFDCA), and the regulations issued under its authority. These regulations are published in the Code of Federal Regulations (CFR). The FFDCA defines food as "articles used for food or drink for man or other animals…." Therefore, any product that is intended to be used as an animal feed ingredient, to become part of an ingredient or feed, or added to an animal's drinking water is considered a "food" and thus, is subject to regulation. FDA's Center for Food Safety and Applied Nutrition (CFSAN) is responsible for the regulation of

human food products. FDA's Center for Veterinarian Medicine (CVM) is responsible for the regulation of animal food (feed) products.

- Premarket Approval
- Labeling and Claims
- Regulatory Discretion

The FFDCA sets forth requirements for "foods" in the Sections 402 and 403. Failure to meet these requirements can result in a product being deemed adulterated or misbranded. Adulteration includes, among other things, food packaged or held under unsanitary conditions, food or ingredients that are filthy or decomposed, and food that contains any poisonous or deleterious substance. A food may be considered misbranded if its labeling is false or misleading in any way or fails to include required information.

The Dietary Supplement and Health Education Act (DSHEA) of 1994, has affected the way FDA regulates "food for humans," i.e., among other things, it restricts substances from being food additives or drugs if the product meets the definition of a dietary supplement. However, the agency's assessment of the law is that it was not intended and does not apply to animal feed, including pet food. This assessment was published in the Federal Register on April 22, 1996 (61 FR 17706). Thus, products marketed as dietary supplements or "feed supplements" for animals still fall under the FFDCA prior to DSHEA, i.e., they are considered "foods," "food additives," or "new animal drugs" depending on the intended use (see below). The regulatory status of a product is determined by CVM on a case-by-case basis, using specific criteria.

FDA carries out its responsibility for the regulation of animal feed in cooperation with state and local partners through a variety of mechanisms: cooperative agreements, contracts, grants, memoranda of understanding and partnerships. For instance, FDA cooperates with the Association of American Feed Control Officials (AAFCO) and the States for the implementation of uniform policies for regulating the use of animal feed products. This includes the establishment of uniform feed ingredient definitions and proper labeling to assure the safe use of feeds. The ingredient definitions are important because animal feeds and feed ingredients must be correctly and truthfully labeled when they enter commerce. Although FDA has the responsibility for regulating the use of animal feed products, the ultimate responsibility for the production of safe and effective animal feed products lies with the manufacturers and distributors of the products.

A. Premarket Approval

The FFDCA does not require pre-market approval of "food." Foods that animals consume, e.g., grains, hays, etc., are considered safe. Most mineral and vitamins are generally recognized as safe (GRAS) as sources of nutrients; however, some ingredients added to an animal feed must be used in accordance with a food additive regulation (21 CFR 573). Further, a substance that does not become a component of feed but that is used, for example, in preparing an ingredient of the food to give it a different flavor, texture, or other characteristic may be a food additive.

The basis for a food additive regulation is an approved food additive petition. Use of a food ingredient that is neither GRAS nor an approved food additive can cause a "food" to be adulterated, which cannot be legally marketed in the United States. Section 409 of the FFDCA sets forth the statutory requirements for approval of a food additive.

Under Section 409(c)(3) of the FFDCA, FDA is not to approve a food additive petition if a fair evaluation of the data fails to establish that the proposed use of the food additive, under the conditions of use to be specified in the regulation, will be safe. Only if the petitioner meets this burden can the food additive be approved. Regulations, which apply specifically to food additives in feeds, are published in Title 21, Part 570 of the CFR. Part 571 prescribes the kinds of data that should be submitted by the petitioner and the required format for the petition itself. While the actual content may vary from petition to petition, depending primarily on the composition of the food additive and its intended use, each of the following subject areas should be addressed: a) Human food safety; b) Target animal safety; c) Environmental impact; d) Utility (intended physical, nutritional or other technical effect); e) Manufacturing chemistry; f) Labeling (cautions, warnings, shelf life, directions for use); and g) Proposed regulation.

A list of approved food additives for use in animal feed is found in Part 573 and a partial list of GRAS substances for use in animal feed is found in section 582 of Title 21 of the CFR. Substances affirmed as GRAS for use in animal feeds are listed under 21 CFR 584. Copies of the CFR may be obtained by fax: 202-512-2233 or by mail: Superintendent of Documents, Government Printing Office, Washington, D.C. 20402.

B. Labeling and Claims

A feed label should contain information describing the feed product and any details necessary for the safe and effective use of the feed. The federal regulations concerning the labeling of animal feeds are published in Part 501 of the 21 CFR. The FFDCA defines "labeling" as all labels and other written, printed or graphic matter upon any article or any of its containers or wrappers, or accompanying such articles. The courts have interpreted labeling to include promotional brochures, promotional pamphlets, testimonials, product information sheets, books, etc. Also, promotion of an animal product on the Internet for unapproved drug claims can cause the product to be misbranded under the

FFDCA, if the product label fails to bear adequate directions for the uses promoted on the Internet.

In addition to meeting the federal labeling requirements, animal feed products are also subject to individual state laws. Under many state regulations, the feed label must include the following information:

- Brand Name, if any
- Product Name
- Purpose Statement
- Guaranteed Analysis
- List of Ingredients
- Directions for Use
- Warning or Caution Statements
- Name and Address of Manufacturer
- Quantity Statement

Under the FFDCA, expressed or implied claims that establish the intended use to cure, treat, prevent or mitigate disease, or affect the structure/function of the body in a manner other than food (nutrition, aroma, or taste), identify an intent to offer the product as a "drug." Unless the "drug" product has been shown to be safe and effective for its intended use via approval of a New Animal Drug Application (NADA), it could be subject to regulatory action as an adulterated drug. It is noted that, on a case-by-case basis, CVM has allowed references to "nutritional support" for specific organs or body functions. Further, CVM has incorporated the philosophy of the Nutrition Labeling Education Act (NLEA) in its policies to permit meaningful "health" information on the label of some animal food products. For example, the use of "urinary tract health" and "dental health" claims on cat food diets falls under this policy. Feed manufacturers provide substantiation that the desired statement is truthful and not misleading. CVM review and acceptance of the claim is needed before the claim is utilized on product labeling.

C. Regulatory Discretion

The use of regulatory discretion to allow specific products to be marketed is done to conserve agency, state and industry resources, without jeopardizing human or animal health or subjecting the consumer to fraud. If a problem is found with a product, which is allowed on the market under regulatory discretion, FDA can quickly act to remove it from the marketplace. Decisions concerning the use of regulatory discretion are made on a case-by-case basis by the Center.

II. FEED INGREDIENTS AND ADDITIVES

A. Biotechnology Products

Biotechnology products are a growing proportion of the feed components regulated by the Center for Veterinary Medicine. We anticipate that "new" biotechnology will become an even greater source of products in the future. The spectrum of products being presented to CVM for regulation includes biotechnology products from plants, microbes and animals.

B. Feed Contaminants

There are two classes of feed contaminants. The first is a toxic or deleterious substance that is an inherent, naturally occurring constituent of an animal food and is not the result of environmental, agricultural, industrial or other contaminations. Examples of this class include some of the mycotoxins, such as aflatoxin and fumonisin, the glucosinolates, and the heavy metals, like lead and cadmium. The second class is made up of industrial toxic or deleterious substances, which are not naturally occurring and are increased to abnormal levels in the animal food through mishandling or other intervening acts. Examples of this class are the polychlorinated biphenyls (PCBs) and certain pesticides, like DDT (1,1′-(2,2,2-Trichloroethylidene) bis[4-chlorobenzene]). CVM may prohibit any detectable amount of a contaminant or establish a regulatory limit for the contaminant, taking into account the protection of the public health, the extent to which the presence of the contaminant cannot be avoided, and other ways in which the consumer may be affected by the presence of the contaminant.

C. Feed Ingredients

A feed ingredient is a component part or constituent or any combination/mixture added to and comprising the feed. Feed ingredients might include grains, milling byproducts, added vitamins, minerals, fats/oils, and other nutritional and energy sources. Animal feeds provide a practical outlet for plant and animal byproducts not suitable for human consumption. The Official Publication of the Association of American Feed Control Officials (AAFCO) contains a list of feed ingredients with their definitions. Many of these ingredients are not approved food additives and may not meet the criteria needed to be recognized as GRAS (21 CFR 570.30). Nevertheless, FDA has not objected to the listing of certain ingredients (e.g., those used as sources of nutrients, aroma, or taste) in the AAFCO Official Publication or their marketing in interstate commerce, provided there were no apparent safety concerns about the use or composition of the ingredient.

Federal regulations require ingredients be listed on the product label by their common or usual name in descending order of predominance according to weight (21 CFR 501.4). A common or usual name is one that accurately identifies or describes the basic nature of the ingredient (21 CFR 502.5). FDA has recognized the definitions as they appear in the Official Publication of AAFCO as the common or usual name for animal feed ingredients including pet food

(Compliance Policy Guide 7126.08). There is only one exception to the requirement to list the common or usual name on the label — when the ingredient is part of a collective name. Regulation 21 CFR 501.110 describes the use of collective names. The following are acceptable collective names: animal protein products, forage products, grain products, plant protein products, processed grain byproducts and roughage products. These collective names may be used in the ingredient list for livestock and poultry feeds, but not pet foods.

1. Association of American Feed Control Officials (AAFCO)

AAFCO is composed of state, federal, and international regulatory officials who are responsible for the enforcement of state laws regulating the safe production and labeling of animal feed, including pet food. FDA and AAFCO work together in the area of feed regulation, particularly in the establishment of definitions to describe new feed ingredients. Each year AAFCO publishes its Official Publication which includes a model feed bill for states to adopt in regulating feed products and a list of accepted feed ingredients. Most states have adopted all or part of the model feed bill and allow feed ingredients listed in the publication to be used in their respective territories.

D. Food Additives (Food Additive Petitions)

Any substance intentionally added to an animal feed, including pet food, must be used in accordance with a food additive regulation unless it is generally recognized as safe (GRAS) among qualified experts for its intended use. The basis of a food additive regulation is an approved food additive petition. The food additive petition should include an adequate factual basis to establish that the food additive is safe for its intended use, under the conditions of use specified in the petition. If the petitioner meets this burden of proof, the food additive can be approved for use in animal feed.

There are several types of food additives based on its composition and intended use. A food additive generally provides one or more of the following, i.e., nutrient, aroma/flavor, taste, soluble or insoluble fiber, stabilizer, emulsifier, sequestrant, chemical preservative, anti-oxidant, anti-caking agent, etc.

Section 571 of Part 21 of the Code of Federal Regulations (CFR) prescribes the kinds of data that must be submitted by the petitioner and the format which the food additive petition must follow when sent to FDA. While the actual content may vary from petition to petition, depending primarily on the food additive's composition and intended use, each of the following subject areas must be addressed: human food safety, target animal safety, environmental impact, utility, labeling, proposed regulation, assay methodology, and manufacturing process and controls. Subsequently, when the FDA concludes that the available data for a food additive are sufficient to meet current criteria, the FDA issues a regulation permitting the petitioned use of the additive.

III. PET FOODS

A. General

The FDA regulates that can of cat food, bag of dog food, or box of dog treats or snacks in your pantry. The FDA's regulation of pet food is similar to that for other animal feeds. The Federal Food, Drug, and Cosmetic Act (FFDCA) requires that pet foods, like human foods, be pure and wholesome, safe to eat, produced under sanitary conditions, contain no harmful substances, and be truthfully labeled. In addition, canned pet foods must be processed in conformance with the low acid canned food regulations to ensure the pet food is free of viable microorganisms (see Title 21 Code of Federal Regulations (CFR), Part 113).

There is no requirement that pet food products have premarket approval by the FDA. However, FDA ensures that the ingredients used in pet food are safe and have an appropriate function in the pet food. Many ingredients such as meat, poultry, grains, and their by products are considered safe "foods" and do not require premarket approval. Other substances such as mineral and vitamin sources, colorings, flavorings, and preservatives may be generally recognized as safe (GRAS) or must have approval as food additives. (See Title 21 CFR, Parts 73, 74, 81, 573 and 582.) For more information about pet foods and marketing a pet food, see FDA's Regulation of Pet Food and Information on Marketing A Pet Food Product.

Pet food labeling is regulated at two levels. The FDA regulations require proper identification of the product, net quantity statement, name and place of business of the manufacturer or distributor, and a proper listing of all the ingredients in order from most to least, based on weight. Some states also enforce their own labeling regulations. Many of these regulations are based on a model provided by the Association of American Feed Control Officials (AAFCO). For more information about AAFCO, please visit its website. There are two informational documents on CVM's web site that provide more details about labeling requirements: Interpreting Pet Food Labels and Interpreting Pet Food Labels — Special Use Foods.

FDA also has put into place policies for making health claims on pet food, such as "maintains health of urinary tract," "low magnesium," "reduces plaque and tartar," and "reduces hairballs in cats." Guidance for collecting data to make a urinary tract health claim is available in Guideline 55 on the CVM internet site.

B. BSE (Bovine Spongiform Encephalopathy) and the Safety of Pets

With the exception of cats, no pets (companion animals) are known to be susceptible to the infectious agent that causes BSE (Mad Cow Disease) in cattle. No evidence of BSE has ever been found in dogs, horses, birds, or reptiles.

However, cats are susceptible. Approximately 90 cats in the UK and several cats in other European countries have been diagnosed with the feline version of BSE. Before it was recognized that they were susceptible to the BSE agent, cats were exposed to the infectious agent through commercial cat food and through meat scraps provided by butchers.

Currently in the U.S., rendered products that are prohibited from cattle feed are acceptable for use in pet food. Such products include meat and bone meal, for example. However, FDA believes that the safeguards it has put into place to prevent BSE in the U.S. have protected cats. FDA continues to review these safeguards to be sure they are adequate, especially in light of the BSE case found in Washington State.

Rendered material from the BSE positive cow in Washington State did not pose a risk to cats in the U.S. because none of it was released into distribution. All firms involved with the incident in Washington State were found to be in compliance with the BSE rules.

In addition, when the BSE positive cow was found in Canada in May 2003, the FDA stopped imports of all pet foods made from material derived from mammalian sources, and the pet food manufacturer recalled the food it had manufactured that was thought to contain material from the infected cow.

CVM does not recommend one product over another or offer guidance on individual pet health issues that are normally provided by the pet's veterinarian. Questions regarding your pets' health and/or the specific use of any veterinary drug, pet food, or other product should always be referred to your veterinarian.

C. An Example of a State Regulation for Pet Foods

To illustrate how states regulate pet food, the regulations used by Pennsylvania are presented here. The data have been modified from Pennsylvania Codes, Title 7, Chapter 72, sections 1–13. All legal citations and languages have been removed for easy reading. The original document must be consulted for details.

1. Definitions

Immediate container — The unit, can, box, tin, bag or other receptacle or covering in which a pet food is displayed for sale at retail.

Ingredient statement — A complete listing on the label of the ingredients of which the pet food is composed.

Principal display panel — That part of a label on an immediate container that is most likely to be displayed or examined under normal and customary conditions of display for sale at retail.

2. Label Format

The following information should be shown on the principal display panel:

1. Statement of net content
2. Product name
3. The words "Dog Food," "Cat Food" or similar designations

The following information should be shown either on the principal display panel or elsewhere on the label and should be sufficiently conspicuous as to render it easily read by the average purchaser under ordinary conditions of sale:

1. Guaranteed analysis
2. Ingredients list
3. Listing of artificial color, drugs, and other additives, if any
4. Directions for use, if a limited purpose food
5. Name and address of the manufacturer, packer or distributor

3. Statement of Net Content

The declaration of net content should be made in conformity with the federal regulations.

4. Guaranteed Analysis

The guaranteed analysis should be stated in the following order:

1. Crude protein (minimum)
2. Crude fat (minimum)
3. Crude fiber (maximum)
4. Moisture (maximum)
5. Any additional guarantees

The sliding scale method of expressing a guaranteed analysis, such as "protein 15–18%," is prohibited.

The label of a pet food which is formulated as, and represented to be, a mineral supplement should include a guarantee of all the minerals contained in the ingredient statement.

Pet foods containing 5.0% or more mineral ingredients should include in the guaranteed analysis the minimum and maximum percentage of calcium (Ca) and salt (NaCl) and the minimum percentage of any added phosphorus (P)

and iodine (I). Minerals (except salt NaCl) should be stated in terms of percentage of the element when quantitatively guaranteed.

The label of a pet food which is formulated as, and represented to be, a vitamin supplement should include a guarantee of the minimum content of each vitamin contained in the ingredient statement.

Vitamin guarantees should be stated in units or milligrams per pound or parts per million, with the following exceptions:

1. Vitamin E should be stated in U.S.P. or International units.
2. Vitamin A, other than percursors of vitamin A, should be stated in U.S.P. units.
3. The compounds pyridoxine hydrochloride, choline chloride and thiamine need not be stated in true vitamin units.

Oils and concentrates containing vitamin A or vitamin D or both may be additionally labeled to show vitamin contents in units per gram. The term "d-pantothenic acid" may be used in stating the pantothenic acid guarantee. The vitamin potency of pet foods distributed in container smaller than one pound may be guaranteed in approved units per ounce.

If the label of a pet food does not represent the product to be either a vitamin or a mineral supplement, but does include a table of comparison of a typical analysis of the vitamin, mineral or nutrient content of the product with levels recommended by a recognized animal nutrition authority, such comparison may be stated in the units of measurement used by such recognized authority. The statement, in a table of comparison, of the vitamin, mineral or nutrient content should constitute a guarantee and need not be repeated in the guaranteed analysis.

5. Ingredients Statement

Each ingredient of the pet food should be listed in the ingredient statement in descending order of predominance by weight and names of all ingredients in the ingredient statement should be shown in letters or type of the same size. Any ingredient for which the Association of American Feed Control Officials has established a name and definition should be identified by the name so established. Any ingredient for which no name and definition has been so established should be identified by the common or usual name of the ingredient. Brand or trade names should not be used in the ingredient statement.

The term "dehydrated" should precede the name of any ingredient in the ingredient list that has been artificially dried.

No reference to quality or grade of an ingredient should appear in the ingredient statement of a pet food product label.

6. Brand and Product Names

No flavor designation should be used on a pet food label unless the designated flavor is detectable by a recognized test method, or is one the presence of which provides a characteristic distinguishable by the pet. Any flavor designation on a pet food label must either conform to the name of its source as shown in the ingredient statement or the ingredient statement should show the source of the flavor. Distributors of pet food employing such flavor designation or claims on the labels of the product distributed by them should, upon request, supply verification of the designated or claimed flavor to the Secretary.

The designation "100%" or "All" or words of similar connotation should not be used in the brand or product name of a pet food if it contains more than one ingredient. Water sufficient for processing, required decharacterizing agents, and trace amounts or preservatives and condiments should not be considered ingredients for the purpose of this subsection.

The terms "meat" and "meat byproducts" should be used on a pet food label only if the meat and meat byproducts are from cattle, swine, sheep and goats.

The name of the pet food should not be derived from one or more ingredients of a mixture to the exclusion of other ingredients and may not be one representing any components of a mixture of a pet food product unless all components or ingredients are included in the name except as specified in subsection (a), (e) or

If any ingredient or combination of ingredients is intended to impart a distinctive characteristic to the product which is significant to the purchaser, the name of the ingredient or combination of ingredients may be used as a part of the name of the pet food provided the following conditions exist:

1. The ingredient or combination of ingredients is present in sufficient quantity to impart a distinctive characteristic to the product.
2. It does not constitute a representation that the ingredient or combination of ingredients is present to the exclusion of other ingredients.
3. It is not otherwise false or misleading.

When an ingredient or a combination of ingredients derived from animals poultry or fish constitutes 95% or more of the total weight of all ingredients of a pet food mixture, the name or names of such ingredients may form a part of the product name of the pet food. Where more than one ingredient is part of such product name, then all such ingredient names should be in the same size, style and color printing.

If an ingredient or a combination of ingredients derived from animals, poultry or fish constitutes at least 25% but less than 95% of the total weight of all ingredients of a pet

food mixture, the name or names of such ingredient or ingredients may form a part of the product name of the pet food only if the product name also includes a primary descriptive term, such as "meatballs" or "fishcakes," so that the product name describes the contents of the product in accordance with an established law, custom or usage or so that the product name is not misleading. All such ingredient names and the primary descriptive term should be in the same size, style and color printing.

Contractions or coined names referring to ingredients should not be used in the brand name of a pet food unless it is in compliance with subsection (a), (d), (e), or (f).

7. Balanced and Complete Rations

The label of a pet food should not contain an unqualified representation or claim, directly or indirectly, that the pet food there in contained, or a recommended feeding there of, is or meets the requisites of a complete, perfect, scientific, or balanced ration for dogs or cats unless such product or feeding meets one of the following requisites:

1. It contains ingredients in quantities sufficient to provide the estimated nutrient requirements for all stages of the life of a dog or cat, as the case may be, which have been established by a recognized authority on animal nutrition, such as the Committee on Animal Nutrition of the National Research Council of the National Academy of Sciences.
2. It contains a combination of ingredients which when fed to a normal animal as the only source of nourishment will provide satisfactorily for fertility of male and female gestation and lactation, normal growth from weaning to maturity without supplementary feeding, and will maintain the normal weight of an adult animal whether working or at rest and has had its capabilities in this regard demonstrated by adequate testing.

To the extent that the ingredients of the product provide nutrients in amounts which substantially deviate from those nutrient requirements estimated by a recognized authority on animal nutrition, or in the event that no estimation has been made by a recognized authority on animal nutrition of the requirements of animals for one or more states of these animals lives, the represented capabilities of the product in this regard should have been demonstrated by adequate testing.

8. Limited Purpose Pet Foods

The label of a pet food product which is suitable only for intermittent or supplemental feeding or for some other limited purpose should either bear a clear and conspicuous disclosure to that effect or contain specific feeding directions which clearly state that the product should be used only in conjunction with other foods. (b) Labels for products which are compounded for or which are suitable for only a limited purpose may contain representations that the particular pet food product or a recommended feeding thereof is or meets the requisites of a complete, perfect, scientific, or balanced ration for dogs or cats only in conjunction with a statement of the limited purpose for which the product is intended or suitable, for such as "a complete food for puppies." Such representations and the required qualifications of purpose should be juxtaposed on the same panel and in the same size, style and color printing.

Qualified representations for limited purpose pet food products may appear on labels only if one of the following conditions exist:

1. The pet food contains ingredients in quantities sufficient to satisfy the estimated nutrient requirements established by a recognized authority on animal nutrition, such as the Committee on Animal Nutrition of the National Research Council of the National Academy of Sciences for such limited or qualified purpose.
2. The pet food product contains a combination of ingredients which when fed for such limited purpose will satisfy the nutrient requirements for such limited purpose and has had its capabilities in this regard demonstrated by adequate testing.

9. Moisture Limitation

The maximum moisture in all pet foods should not exceed 78% or the natural moisture content of the constituent ingredients of the product, whichever is greater. Pet foods such as those consisting principally of stew, gravy, sauce, broth or juice which are so labeled, may contain moisture in excess of 78%.

10. Drugs and Additives

An artificial color may be used in a pet food only if it has been shown to be harmless to pets. The permanent or provisional listing of an artificial color by the United States Food and Drug Administration at 21 CFR Parts 8 and 9 as safe for use, together with the conditions, limitations and tolerances, if any, incorporated there in, should be deemed to be satisfactory evidence that the color is, when used, under the regulations, harmless to pets.

Prior to approval of a facility registration for pet foods which contain additives, including drugs, other special purpose additives or non nutritive additives, the distributor may be required to submit evidence to prove the safety and efficacy of the pet food, when used according to

directions furnished on the label. Evidence of the safety and efficacy of a pet food is not required under the following conditions:

The additives used are legal.
The pet food is a drug and approved by the FDA.
The medicated labeling format recommended by Association of American Feed Control Officials should be used.

11. Misrepresentations

A vignette, graphic or pictorial representation of a product on a pet food label should not misrepresent the contents of the package. The use of the word "proven'' in connection with label claims for a pet food is prohibited unless scientific or other empirical evidence establishing the claim is first submitted to the Secretary for review.

No statement may appear upon the label of a pet food which makes false or misleading comparisons between that pet food and another pet food. Personal or commercial endorsements are permitted on pet food labels where said endorsements are factual and not otherwise misleading.

12. Identification of Producer

The label of a pet food should specify the name and address of the manufacturer, packer or distributor of the pet food. The statement of the place of business should include the street address, if any, of the place unless the street address is shown in a current city directory or telephone directory.

If a person manufactures, packages or distributes a pet food in a place other than his principal place of business, the label may state the principal place of business in lieu of the actual place where each package of the pet food was manufactured or packaged or is to be distributed, if the statement is not misleading in any particular.

13. Outer Containers or Wrappers

When a pet food is enclosed in an outer container or wrapper which is intended for retail sale, the required label information should appear on the outside wrapper or container unless all of the required label information is readily legible through apertures or transparencies in the outside container or wrapper.

82 Bioterrorism and Protecting Food Supply in the United States

Nanna Cross
Chicago, Illinois

CONTENTS

I. INTRODUCTION

Since the terrorist attack in U.S. soils on September 11, 2001, this country is tightening its security in all fronts. Food and drinking water are considered major weak points susceptible to attack by terrorists. The government considers this as part of bioterrorism. This chapter is not meant to be a comprehensive reference source on the topic. Rather, it is confined to one small aspect of protecting our food supply from enemy attack, preparedness and responses.

For ease of discussion and the lack of a reference standard, the approach to protect our food supply from terrorist attack can be divided into six components listed in the table below, using botulism as an example.

Components	Meaning	U.S. Knowledge Level	Sources of Information
Risks analysis	For example: What food, what beverages, what risks, how significant, etc.?	The best our experts can offer.	Information available from government, industry, and academia. ***Some early data are presented in this chapter.***
Science	The basic scientific information about pathogens, e.g., botulism.	The best our scientists can offer.	Information available from government, industry, and academia.
Delivery (Technology & Engineering)	How to package the pathogen for distribution to cause maximal damage to U.S. population?	The best our technologists and engineers can offer	Information available from government, industry, and academia.
Public health and medicine	How to investigate and treat the public if the attack occurs?	The best our public health officials and physicians can offer	Information available from government, industry, and academia
Threats and strikes	Exactly when, where, how, and so on?	An unknown factor handled by U.S. government?	No one knows at any moment in time.
Preparedness and response	What can be done now?	Preliminary steps have been started	Laws, regulations, guides, etc., issued by responsible U.S. government agencies. ***Some early data are presented in this chapter.***

The next section presents the risk assessment and food terrorism.

II. RISK ASSESSMENT FOR FOOD TERRORISM AND OTHER FOOD SAFETY CONCERNS

A. Introduction

On October 13, 2003, the Food and Drug Administration (FDA) issued the following information about risk assessment for food terrorism.

The events of September 11, 2001, and the subsequent anthrax incidents gave rise to concerns about unconventional terrorist attacks, including the threat of attacks on the U.S. food supply. Those events also heightened international awareness that nations could be targets for biological or chemical terrorism — a threat that had long concerned military and public health officials.

In the aftermath of those incidents, the FDA took steps to improve its ability to prevent, prepare for, and respond to, incidents of food sabotage. Though motivated by the concerns about deliberate contamination, those activities built upon and expanded the agency's continuing efforts to protect consumers from foods that have been unintentionally contaminated (e.g., through processing failures or handling errors).

As part of those activities, FDA assessed the risk to, and vulnerability of, the U.S. food supply to an act of terrorism. However, most of those assessments contain classified information. To promote transparency, FDA prepared this publicly available assessment of the risks to public health of a terrorist attack on the food supply and of serious illness due to inadvertent food contamination.

The Risk Assessment follows the generally accepted framework for risk assessments endorsed by the Codex Alimentarius Commission, the U.S. National Academy of Sciences, and other authoritative bodies. The framework divides risk assessment into four components: (1) hazard identification, (2) hazard characterization (or dose-response assessment), (3) exposure assessment, and (4) risk characterization. Unlike traditional risk assessments, however, which focus on one hazard, this assessment addresses the broad range of hazards available to terrorists intending to sabotage food, as well as hazards that accidentally are introduced into food.

This Risk Assessment uses scientific evidence on food terrorism to the extent that it exists and is available, but balances this disclosure with the need to maintain the integrity of classified information. Thus, this assessment is based solely on unclassified information. In addition, the very nature of "bioterrorism" and the fact that it is a relatively new and evolving threat present challenges in quantitatively evaluating the associated risks. FDA has prepared a qualitative risk assessment that presents various risk scenarios, as well as discusses the quality of information available for, and the uncertainties associated with, the assessment. The agency has determined that this qualitative risk assessment, which discusses prior incidents of food contamination and available unclassified information on prior acts of food sabotage, is appropriate to the circumstances.

B. Risk Assessment

1. Hazard Identification

Even before the September 11 attacks, the U.S. Centers for Disease Control and Prevention (CDC) had developed a strategic plan on biological and chemical terrorism. The CDC plan identified and ranked several foodborne pathogens as critical agents for possible terrorist attacks. Among the high-priority biological agents ("Category A" agents) were *Bacillus anthracis* (anthrax) and *Clostridium botulinum* (botulism), both of which are deadly pathogens and may contaminate food. Most of the foodborne biological agents identified by CDC were classified as "Category B" agents because they are moderately easy to disseminate and cause moderate morbidity and low mortality. The Category B biological agents include *Salmonella* spp., *Shigella dysenteriae, E. coli* O157:H7, and ricin. Notably, several of the pathogens identified by CDC as critical biological agents also are known to pose a significant threat due to unintentional contamination of food.

In addition, the CDC identified certain chemicals as possible agents for a terrorist attack. Those included heavy metals, such as arsenic, lead, and mercury, and pesticides, dioxins, furans, and polychlorinated biphenyls (PCBs), all of which may be used to contaminate food. These toxins also have been introduced inadvertently into foods and linked to human health effects.

The CDC further warned:

> … [P] ublic health agencies must prepare also for the special features a terrorist attack probably would have … Terrorists might use combinations of these agents, attack in more than one location simultaneously, use new agents, or use organisms that are not on the critical list (e.g., common, drug-resistant, or genetically engineered pathogens).

Acts of deliberate food contamination have already occurred in the U.S. In 1984, for example, the members of a religious cult contaminated salad bars with *Salmonella typhimurium* in order to disrupt a local election. This incident caused 751 cases of salmonellosis and resulted in the hospitalization of 45 of the victims. In another incident, in 1996, a disgruntled laboratory worker deliberately infected food to be consumed by co-workers with *Shigella dysenteria* type 2, causing illness in 12 people. Four of the victims had to be hospitalized and five others were treated in hospital emergency rooms. Furthermore, in May 2003, a supermarket employee pleaded guilty to intentionally

poisoning 200 pounds of ground beef with an insecticide containing nicotine. Although the tainted meat was sold in only one store, 111 people, including approximately 40 children, were sickened.

Examples of food sabotage can be drawn from other countries' experiences, as well. In September 2002, nearly 40 people died and more than 200 were hospitalized near Nanjing, China after the owner of a fast-food outlet poisoned a competitor's breakfast foods with rat poison. One year earlier, 120 people in China were sickened when the owners of a noodle factory reportedly laced their food with rat poison. A dozen children in Holland and West Germany were hospitalized in 1978 after citrus fruit from Israel was deliberately contaminated with mercury. Finally, in Canada in 1970, a postgraduate student tainted his roommates' food with the parasite *Ascaris suum*. Four of the victims became seriously ill; two of these suffered acute respiratory failure.

The incidents discussed above illustrate a few of the possible agents for food terrorism. The range of such agents is broad, and their characteristics varied; they may include:

- Biological and chemical agents
- Naturally occurring, antibiotic-resistant, and genetically engineered substances
- Deadly agents and those tending to cause gastrointestinal discomfort
- Highly infectious agents and those that are not communicable
- Substances readily available to any individual and those that are more difficult to acquire
- Agents that must be weaponized and those that are accessible in a useable form

This assessment addresses the risk to public health not only of deliberate contamination of the food supply, but also of hazards that are inadvertently introduced into foods that FDA regulates.

2. Hazard Characterization

The hazard characterization analyzes the magnitude of the risk (i.e., the severity and duration of adverse effects), using reports of foodborne disease caused by unintentional contamination. Such reports are relevant to an analysis of both inadvertently and deliberately introduced hazards, because many of the pathogens that historically have been linked to unintentional food contamination, such as *E. coli* O157:H7 and *Salmonella* spp., were identified by the CDC as "critical" agents for food terrorism. Moreover, the risk to consumers and the public health response to these known pathogens would be comparable, regardless of whether the contamination was deliberate or accidental. Officials responding to an outbreak of foodborne illness probably would not know whether the contamination was accidental or intentional until an investigation was performed to determine the source of the outbreak. Even then, officials might never be able to conclusively determine whether the food was deliberately sabotaged or inadvertently contaminated. For all of these reasons, the risk assessment uses incidents of unintentional food contamination as the basis for a characterization of hazards that could be either deliberately or unintentionally introduced into food.

a. Illnesses and deaths

The World Health Organization (WHO) estimates that microbiologically contaminated food and water cause approximately two million children worldwide to die from diarrhea each year. Even in industrialized countries, WHO estimates that one person in three suffers from a foodborne disease annually. Recognizing that foodborne illnesses "significantly affect people's health and well-being," the World Health Assembly in 2000 adopted a resolution stating that the assembly was "[d]eeply concerned that foodborne illness associated with microbial pathogens, biotoxins and chemical contaminants in food represent a serious threat to the health of millions of people in the world."

In the U.S., the CDC estimates that 76 million illnesses, 325,000 hospitalizations, and 5,000 deaths occur annually due to food that has been inadvertently contaminated by pathogens. Based on current population data, this roughly translates to an estimate that, each year, one out of every four Americans will develop a foodborne illness.

Major outbreaks of foodborne illness occur all too frequently, sometimes affecting hundreds of thousands of people. Among the largest reported outbreaks caused by unintentional biological contamination was an outbreak of *Salmonella typhimurium* infection that sickened approximately 170,000 people in 1985 and was linked to post-pasteurization contamination of milk from a U.S. dairy plant. An outbreak of hepatitis A caused by tainted clams affected nearly 300,000 people in China in 1991 and may be the largest foodborne disease incident in history. In 1994, an outbreak of *Salmonella* Enteritidis infection linked to a contaminated ice cream pre-mix sickened an estimated 224,000 people in 41 states in the U.S. In 1996, about 8,000 children in Japan became ill, and some died, after eating *E. coli* 0157:H7-tainted radish sprouts served in school lunches.

Illnesses from pesticides, mycotoxins, heavy metals, cyanide, and other acutely toxic chemicals also have been reported. In one deadly incident, over 800 people died and a chemical agent present in cooking oil sold in Spain in 1981 injured about 20,000. In 1985, nearly 1,400 people in the U.S. reported becoming ill after eating watermelon grown in soil treated with the pesticide aldicarb. In Iraq in 1971–1972, more than 6,500 people were hospitalized with neurological symptoms and 459 died after eating bread made from mercury-contaminated wheat. Additionally, in the 1960's, more than 200 people in Japan suffered from mercury poisoning after eating highly contaminated fish caught in polluted waters.

In today's global marketplace, the contamination of food in one country can have a significant effect on public health in other parts of the world. In 1989, approximately 25,000 people in 30 states in the U.S. were sickened by *Salmonella* chester in cantaloupes imported from Mexico. In 1996 and 1997, 2,500 people in 21 states in the U.S. and two Canadian provinces developed *Cyclospora* infections after eating tainted Guatemalan raspberries.

If an unintentional contamination of one food, such as clams, can affect 300,000 individuals, a concerted, deliberate attack on food could be devastating, especially if a more dangerous chemical, biological, or radionuclear agent were used. It would be reasonable to assume that a terrorist using the food supply as a vehicle for attack would use an agent that would maximize the number of deaths associated with the contamination. Many of these agents are the same pathogens that have been linked to significant outbreaks of foodborne illness due to unintentional contamination.

b. Economic effects

Deliberate or accidental contamination of food also may have enormous economic implications in the U.S., where one out of every eight Americans is estimated to work in an occupation directly linked to food production. Indeed, food terrorists may have economic disruption as their primary motive. For example, the sabotage of Israeli citrus fruit exports, discussed above, was allegedly intended to damage Israel's economy.

At least three types of economic effects may be generated by an act of food terrorism: direct economic losses attributable to the costs of responding to the act; indirect multiplier effects from compensation paid to affected producers and the losses suffered by affiliated industries, such as suppliers, transporters, distributors, and restaurant chains; and international costs in the form of trade embargoes imposed by trading partners.

Though the costs associated with the food sabotage discussed above are unavailable, reports from unintentional contamination incidents demonstrate the tremendous costs of responding to such events. In 1998, a company in the U.S. recalled nearly 16,000 metric tons of frankfurters and luncheon meats potentially contaminated with *Listeria monocytogenes*, at a total cost of $50 million to $70 million. The company reported spending more than $100 million in the following two years to improve food safety and convince consumers that its products were safe. Indirect costs can be staggering as well. The U.S. Department of Agriculture estimates that foodborne illnesses linked to five pathogens costs the economy $6.9 billion annually. The outbreak from *Salmonella*-contaminated ice cream, discussed above, was estimated to have cost the U.S. economy about $18.1 million in medical care and time lost from work. In addition, costs arise from the disruption of international trade, as was demonstrated when Belgium's dioxin incident caused the recall of food products distributed globally.

c. Social and political implications

The response to the 2001 anthrax incidents showed that limited dissemination of biological agents by simple means could cause considerable disruption and public anxiety, even if only a few cases of illness result. The potential magnitude of the social impact arising from a food terrorism incident may be best illustrated by examining the effects of the Bovine Spongiform Encephalopathy (BSE) (also known as "mad cow disease") crisis in Great Britain in the 1990's. When researchers first discovered BSE in British cattle in 1986, some speculated that BSE could be spread to humans. However, for the next decade British authorities consistently reassured citizens that BSE was only an animal disease. When, in 1996, authorities acknowledged that BSE could be linked to human disease and announced that ten people in the U.K. had been infected or died from a human form of mad cow disease, widespread panic erupted.

Even though the toll of human fatalities — 137 deaths to date — was lower than the death toll from many other diseases, the effects of this public health crisis were widespread and long lasting. Bans on imports of British beef lasted for several years. Furthermore, the public's shattered confidence in government forced the creation of a new food regulatory authority, the Foods Standards Agency. The slaughter of millions of cattle and other BSE control measures, together with depressed markets for British beef, crippled the country's cattle industry. Some key issues from the BSE crisis are unresolved. In addition, BSE has been identified in cattle in both Canada and the U.S.

Fear and anxiety may contribute to reduced confidence in the political system and government, and may result in political destabilization, as was seen in Great Britain during the mad cow crisis.

3. Exposure Assessment

As discussed above, the CDC estimates that unsafe food causes 76 million illnesses, 325,000 hospitalizations, and 5,000 deaths each year in the U.S. This roughly translates to an estimate that, each year, one in every four Americans will develop an illness due to the accidental food contamination.

Although the CDC has identified certain pathogens as critical agents for food terrorism, it is difficult for FDA to predict with any certainty the likelihood that an act of food terrorism will occur. Indeed, Codex has recognized that uncertainty may be prevalent in the risk assessment process:

Many sources of uncertainty exist in the process of risk assessment of food related hazards to human health. The degree of uncertainty and variability in the available scientific information should be explicitly considered in the risk analysis.

FDA further recognizes that the potential impact of a food terrorism event is influenced not only by the likelihood of occurrence, but also by the specific target and agent selected by a terrorist.

Despite these uncertainties, the WHO has warned that "the malicious contamination of food for terrorist purposes is a real and current threat." The CDC's infectious disease experts similarly have concluded that sabotage of food and water is the easiest means of biological or chemical attack largely because such attacks (albeit on a small scale) have been successful in the past. In addition, the CDC experts explain, the relative centralization of food production in the U.S. and the global distribution of food products give food a "unique susceptibility," and many points of vulnerability to sabotage intended to affect a large number of people exist in the food production and food distribution processes.

The threat to the U.S. food supply is more than theoretical. When U.S. troops entered the caves and safe houses of members of the al Qaeda terrorist network in Afghanistan in the months following the September 11th attacks, they found hundreds of pages of U.S. agricultural documents that had been translated into Arabic. A significant part of the group's training manual was reportedly devoted to agricultural terrorism — specifically, the destruction of crops, livestock, and food processing operations.

Moreover, recent threats of food sabotage from known terrorist groups have been reported. Specifically, the U.S. Central Intelligence Agency stated in January 2003 that it was investigating whether one of al Qaeda's leading experts on chemical and biological warfare was involved in a plot to poison food intended for British troops. The investigation stemmed from the discovery of ricin in a London apartment linked to suspected militants, one of whom worked for a catering company. The suspects were believed to have been in contact with people who worked on at least one British military base.

In early September 2003, the U.S. Federal Bureau of Investigation (FBI) issued a bulletin warning that terrorists might use two naturally occurring toxins, nicotine and solanine, to poison U.S. food or water supplies. The FBI noted that terrorist manuals and documents recovered in Afghanistan refer to the use of these substances as poisons. Citing the supermarket employee that deliberately contaminated ground beef with an insecticide containing nicotine, FBI officials advised: "Such lone offenders, whether al-Qaida [*sic*] sympathizers or domestic criminals, are a concern to FBI because they are so difficult to detect."

The U.S. is not alone in its concern about a food terrorist event. The WHO Secretariat noted last year that several countries have reported heightened states of alert for a biological or chemical attack on air, water, or food. The events of September 11, 2001, and evidence from al Qaeda validate concerns about threat of terrorism against the United States.

4. Risk Characterization

This Risk Assessment addresses a broad range of hazards that may be deliberately or accidentally introduced into the food supply that FDA regulates. Despite the difficulty of developing a quantitative risk assessment of cumulative risk in the present circumstance, FDA notes that the public health impact of unintentionally contaminated food has been documented by the CDC estimate that 76 million illnesses, 325,000 hospitalizations, and 5,000 deaths from foodborne illness occur annually in the U.S. Other journal articles and risk assessments, referenced here, also provide data on risk of illness from the accidental introduction of pathogens into food. For example, the government's quantitative risk assessment for *Salmonella* Enteritidis (SE) in shell eggs and egg products estimated, based on modeling, that an average of 660,000 illnesses occur each year in the U.S. due to SE-contaminated eggs. The predicted average risk is 3.5 SE illnesses per one million egg servings per year.

It is more difficult for FDA to characterize the risk of food terrorism, largely because of uncertainties associated with estimating the likelihood of occurrence — even though documented incidents of sabotage have occurred and recent reports have surfaced of al Qaeda plots to poison food supplies. Traditional risk assessments for acute hazards, particularly those using modeling, often generate estimates of risk on an annual basis, as was done in the SE risk assessment. In the present circumstance, the agency has determined that the magnitude of the risk of food terrorism, and the uncertainty associated with that risk characterization, depend on the temporal basis of the risk estimate. Specifically, if a small increment of time, such as one day, is used to estimate the risk of an act of deliberate contamination, then the likelihood of occurrence would be low. If, however, a larger increment of time, such as the period of one month, is used, then the risk would be greater, and if the agency considers the likelihood of occurrence over the period of one year, then the risk of an act of food terrorism is significantly higher. To ensure that this assessment is useful for planning purposes, FDA has determined that it is appropriate to characterize the risk of occurrence of an act of food sabotage or a significant incident of unintentional food contamination on an annual basis.

The agency has considered, for the purposes of risk characterization, the known exposure to food that has been inadvertently contaminated and the past incidents of deliberate contamination, as well as the evidence that terrorists have targeted our food supply. In light of this information and the uncertainties attendant to characterizing the risk of an act of food terrorism, FDA has concluded that there is a high likelihood, over the course of a year, that a significant number of people will be affected by an act of food terrorism or by an incident of unintentional food contamination that results in serious foodborne illness.

C. Conclusion

The CDC's strategic planning workgroup on biological and chemical terrorism warned, more than a year before the September 11th attacks and the anthrax incidents.

An act of biological or chemical terrorism might range from dissemination of aerosolized anthrax spores to food product contamination, and predicting when and how such an attack might occur is not possible. However, the possibility of biological or chemical terrorism should not be ignored… Preparing the nation to address this threat is a formidable challenge, but the consequences of being unprepared could be devastating.

Though the likelihood of a biological or chemical attack on the U.S. food supply is uncertain, significant scientific evidence documents the risk to public health of food that has been inadvertently contaminated. Notwithstanding the uncertainties described in this risk assessment, and given the broad range of agents that may contaminate the food supply that FDA regulates, the agency concludes that there is a high likelihood, over the course of a year, that a significant number of people will be affected by an act of food terrorism or by an incident of unintentional food contamination that results in serious foodborne illness.

FDA has determined that this qualitative risk assessment, which discusses prior incidents of food contamination and available unclassified information on prior acts of food sabotage, is appropriate to the circumstances.

Using the above information as a premise, there are two types of preparedness and response we can do at this stage: tracing the sources of domestic food supply; and tracing the sources of imported foods from foreign countries. The importance of the information is based on one assumption. When any stage of a food chain is attacked by an enemy, the authority wants an answer to one question. What is the source of the food being attacked, a manufacturing plant, a truck doing the transport, a warehouse, a grocery store? Advance information is vital. So, the FDA has issued regulations and guidelines to achieve two goals: registration of domestic food facilities and registration of foreign manufacturing plants that export foods to the United States.

III. REGISTRATION OF FOOD FACILITIES

A. Background Information

The information is this section is presented under the following premises:

1. At time of writing, some of the data are laws and regulations and some are general guidelines. Their legal status may be different in the foreseeable future.
2. All legal citations and languages have been modified to facilitate reading. Always obtain the original document for details.

The Public Health Security and Bioterrorism Preparedness and Response Act of 2002 (the Bioterrorism Act) directs the Secretary of Health and Human Services to take steps to protect the public from a threatened or actual terrorist attack on the U.S. food supply. To carry out the provisions of the Bioterrorism Act, FDA published, on October 10, 2003, an interim final regulation, *Registration Of Food Facilities*, which requires domestic and foreign facilities that manufacture/process, pack, or hold food for human or animal consumption in the United States to register with the FDA. In the event of a potential or actual bioterrorism incident or an outbreak of food-borne illness, facility registration information will help FDA to determine the location and source of the event and permit the agency to notify quickly facilities that may be affected.

This new regulation pertains *only* to facilities that manufacture/process, pack, or hold food, as defined in the regulation, for consumption in the U.S. Examples of "food" include:

- Dietary supplements and dietary ingredients
- Infant formula
- Beverages (including alcoholic beverages and bottled water)
- Fruits and vegetables
- Fish and seafood
- Dairy products and shell eggs
- Raw agricultural commodities for use as food or components of food
- Canned and frozen foods
- Bakery goods, snack food, and candy (including chewing gum)
- Live food animals
- Animal feed and pet food

Food contact substances and pesticides are not "food" for purposes of the interim final rule. Thus, a facility that manufactures/processes, packs, or holds a food contact substance or a pesticide is not required to register with FDA.

B. Questions and Answers

Let us look at some questions and answers about the registration of food facilities that are usually made available when a new law is initiated.

FDA's guidance documents, including this guidance, do not establish legally enforceable responsibilities. Instead, guidance describes the Agency's current thinking on a topic and should be viewed only as recommendations, unless specific regulatory or statutory requirements

are cited. The use of the word *should* in Agency guidances means that something is suggested or recommended, but not required.

1. Who Must Register?

The owner, operator, or agent in charge of a domestic or foreign facility that manufactures/processes, packs, or holds food for human or animal consumption in the U.S., or an individual authorized by one of them, must have registered that facility with FDA by December 12, 2003. A domestic facility must register whether or not food from the facility enters interstate commerce. A foreign facility must designate a U.S. agent (for example a facility's importer or broker), who must live or maintain a place of business in the U.S. and be physically present in the U.S., for purposes of registration.

2. What Types of Facilities Do Not Need to Register?

- *Private residences of individuals*, even though food may be manufactured/processed, packed, or held there.
- *Non-bottled water drinking water collection and distribution establishments and structures*, such as municipal water systems.
- *Transport vehicles that hold food only in the usual course of their business as carriers*.
- *Farms*, i.e., facilities in one general physical location devoted to the growing and harvesting of crops, the raising of animals (including seafood), or both. Washing, trimming of outer leaves, and cooling of produce are considered part of harvesting. The term "farm" also includes facilities that pack or hold food, provided that all food used in such activities is grown, raised, or consumed on that farm or another farm under the same ownership, and facilities that manufacture/process food, provided that all food used in such activities is consumed on that farm or another farm under the same ownership. A farm-operated roadside stand that sells food directly to consumers as its primary function would be exempt from registration as a retail food establishment.
- *Restaurants*, i.e., facilities that prepare and sell food directly to consumers for immediate consumption, including pet shelters, kennels, and veterinary facilities that provide food directly to animals. Facilities that provide food to interstate conveyances, such as commercial aircraft, or central kitchens that do not prepare and serve food directly to consumers are not restaurants for purposes of the rule.
- *Retail food establishments*, such as groceries, delis, and roadside stands, that sell food directly to consumers as their *primary function*, meaning that annual sales directly to consumers are of greater dollar value than annual sales to other buyers. An establishment that manufactures/processes, packs, or holds food and whose primary function is to sell food directly to consumers, including food that the establishment manufactures/processes, from that establishment is a retail food establishment and is not required to register.
- *Nonprofit food establishments*, which are charitable entities that meet the terms of §501(c)(3) of the Internal Revenue Code and that prepare or serve food directly to the consumer or otherwise provide food or meals for consumption by humans or animals in the U.S. Central food banks, soup kitchens, and nonprofit food delivery services are examples of nonprofit food establishments.
- *Fishing vessels* that harvest and transport fish. Such vessels may engage in practices such as heading, eviscerating, or freezing fish solely to prepare the fish for holding on board the vessel and remain exempt.
- *Facilities regulated exclusively and throughout the entire facility by the U.S. Department of Agriculture*, that is, facilities handling only meat, poultry or egg products.

3. Questions and Answers about "Private Residences"

1. *Q*: If a person has a business in his/her home that involves manufacturing/processing, packing, or holding food, does that person need to register his residence as a food facility?
   A: No. A private residence is not a facility as defined in the Interim Final Rule (21 CFR 1.227(b)(2)) and thus, need not be registered. [CFR = U.S. Code of Federal Regulations].

2. *Q*: If a person is selling food from his or her private residence through the Internet, does that person need to register his residence as a food facility?
   A: No. A private residence is not a facility as defined in the Interim Final Rule (21 CFR 1.227(b)(2)) and thus, need not be registered.

3. *Q*: Is a private residence in which low acid canned food is produced exempt from the regulations for low acid canned food (21 CFR Part 113)?
   A: No. Although such a residence is not required to be registered as a food facility under

21 CFR Part 1, Subpart I, it is not exempt from any other requirements established by any other laws or regulations (21 CFR 1.240).

4. Questions and Answers about "Farms"

4. *Q*: Is a facility that manufactures/processes and sells seed to farmers required to be registered if the seed is intended for cultivation? What if the seed is an ingredient that will be included in animal feed?
   A: FDA requires registration of any facility that manufactures/processes, packs, or holds food for consumption in the U.S. As noted in a response to a comment in the Interim Final Rule (Comment 62), FDA will consider a product as one that will be used for food if the owner, operator, or agent in charge of the facility reasonably believes that the substance is reasonably expected to be directed to a food use. Therefore, if the owner, operator, or agent in charge of the facility in this question reasonably believes that the seed is reasonably expected to be used as an ingredient for animal feed, the seed is considered "food" and thus, the facility is required to be registered. However, if the seed is reasonably expected only to be cultivated, the facility is not required to be registered.

5. *Q*: Is a farm that grows tomatoes and sells them directly to consumers from a roadside stand located on the farm exempt from registration?
   A: Yes. Assuming that the farm on which the tomatoes are grown otherwise satisfies the definition of farm (21 CFR 1.227(b)(3)), it is exempt from registration. If the primary activity of the roadside stand is selling food (including the tomatoes) directly to consumers, it is exempt as a retail food establishment (21 CFR 1.227(b)(11)).

6. *Q*: If a farm located in a foreign country ships food directly to the U.S., is it required to register?
   A: No. Assuming that the farm otherwise satisfies the definition of farm (21 CFR 1.227(b)(3)), the farm is exempt from registration if it ships food directly to the U.S. However, if prior to export to the U.S., food grown on the farm is shipped to a foreign facility that manufactures/processes, packs, or holds the food, the second facility must register unless the food subsequently undergoes further manufacturing/processing of more than a *de minimis* nature at another foreign facility (21 CFR 1.226(a)). The *de minimis* provision is discussed further in question 21 of this guidance and in the preamble to the Interim Final Rule (responses to comment 17, 21, 25, and 26).

7. *Q*: Is a mixed-type facility, such as a farm that grows oranges and processes them into orange juice for sale to a distributor, required to register?
   A: Yes. FDA uses the term "mixed-type facility" in the preamble to the Interim Final Rule (response to Comment 46) to refer to an establishment that engages in both activities that are exempt from registration and activities that require the establishment to be registered. In this example, the farm is required to be registered because its processing activities are not covered by the farm definition (21 CFR 1.227(b)(3)).

8. *Q*: Is applying pesticides on a farm considered a "traditional farming activity" within the scope of the farm definition and exemption? Does this include applying a pesticide, for example, on bananas in the field or in the packing station just prior to packing?
   A: Whether the application of a pesticide to a crop is an activity covered by the farm definition depends upon whether the application is prior to or post-harvest. Section 1.227(b)(3) defines a farm as "a facility in one general location devoted to the growing and harvesting of crops, the raising of animals (including seafood), or both." FDA considers application of pesticides to a crop prior to harvest as an integral part of growing crops. Such application generally does not involve close manipulation of the food being grown because the application is usually directed at the entire plant. Therefore, an establishment devoted to the growing and harvesting of crops that applies a pesticide to its crops prior to harvest is a "farm" within the meaning of the Interim Final Rule. However, post-harvest application is necessarily directed at the food, not the entire plant, and thus, is considered to be manufacturing/processing under §1.227(b)(6). Therefore, a farm that treats a crop against pests post-harvest must register with FDA unless it satisfies the conditions of §1.227(b)(3)(ii).

9. *Q*: Is use of chlorinated water to wash lettuce on a farm considered "processing," necessitating registration of a farm?
   A: If the farm is using water directly from a public or other water supply that is chlorinated for other purposes, FDA will consider this activity "washing" within the meaning of 21 CFR 1.227(b)(3). Accordingly, an establishment using chlorinated water in this manner is a "farm" and is not required to be registered. In addition,

FDA's Good Agricultural Practices guidance document (section 2.2) (http://www.foodsafety.gov/~dms/prodguid.html) notes that chlorine is commonly added to water at 50–200 parts per million (ppm) total chlorine, at a pH of 6.0–7.5, for post harvest treatment of fresh produce, with a contact time of 1–2 minutes. FDA recognizes that chlorination at these levels is the only way many growers and packers can raise the microbiological quality of the water they use to a level that is safe and suitable. Addition of chlorine to water at these levels, therefore, does not constitute "manufacturing/processing" within the meaning of 21 CFR 1.227(b)(3)(ii).

In contrast, if water used as a wash on harvested foods on a farm contains added chlorine above levels of 200 ppm to create a specific wash, FDA considers this activity as "treating" food within the meaning of 21 CFR 1.227(c)(6), which is a manufacturing/processing activity that would require the farm to register, unless it falls under another exemption (e.g., foreign facility exemption).

10. *Q*: Does placing stickers on fruit on a farm amount to "manufacturing/processing" and therefore require registration of the facility in which the application of the stickers occurs?
A: A farm that places stickers on produce grown or consumed on the farm is not required to register as long as the farm otherwise satisfies the definition of farm (21 CFR 1.227(b)(3).) Under §1.227(b)(3)(i), FDA considers on-farm facilities that pack or hold food as meeting the farm definition, if all food used in such packing or holding is grown, raised, or consumed on that farm or another farm under the same ownership. As stated in the response to comment 41 in the Interim Final Rule, FDA considers certain activities to be "packing," such as sorting, grading, wrapping, or boxing harvested food for the sole purpose of transporting this food off the farm. FDA also considers placing stickers on produce grown or consumed on a farm part of "packing."

5. Questions and Answers about "Retail Facilities"

11. *Q*: Does a warehouse club that sells to both consumers and businesses need to be registered?
A: A warehouse club is exempt from registration as a retail food establishment (21 CFR 1.227(b)(11)) if it sells food products directly to consumers as its primary function. A retail food establishment's primary function is to sell food directly to consumers if the annual monetary value of sales of food products directly to consumers exceeds the annual monetary value of sales of food products to all other buyers. Businesses are not considered consumers.

12. *Q*: If a supermarket has a bakery on the premises that bakes bread and sells it to other stores in the same chain, is the supermarket required to be registered?
A: The supermarket is exempt from registration as a retail food establishment (21 CFR 1.227(b)(11)) if its primary function is to sell food products directly to consumers from the supermarket. As noted, an establishment's primary function is to sell food directly to consumers if the annual monetary value of sale of all food products directly to consumers exceeds the annual monetary value of sales of food products to all other buyers.

6. Questions and Answers about "Nonprofit Food Facilities"

13. *Q*: Are exporters of food for charity exempt from the registration requirements?
A: Yes. A facility, including a non-profit facility, is not required to be registered if all food manufactured/processed, packed, or held at the facility is not for consumption in the U.S. (21 CFR 1.225 and 1.227(b)(7)).

7. Questions and Answers about "Facilities Regulated Exclusively, Throughout the Entire Facility, by USDA"

14. *Q*: Are facilities that process deer, elk, and bison required to register with FDA?
A: Yes. These facilities are required to be registered with FDA because they are not regulated exclusively by the United States Department of Agriculture (USDA) (21 CFR 1.226(g)).

8. Questions and Answers about Some "Definitions"

a. Holding

15. *Q*: Are local collecting facilities for grains exempt from the registration requirement?
A: All establishments at which food is manufactured/processed, packed, or held are required to be registered, unless otherwise exempt. FDA understands the term "collecting facilities" to refer to facilities that store or hold food, such as silos or grain elevators. Such a facility must be registered with FDA because food (grain) is held by the facility (21 CFR 1.225; 1.227(b)(5)).

16. *Q*: If a facility receives packaged produce for shipping and holds it in cold storage, is it required to register?
A: Yes. The facility in this example is holding food and therefore, must be registered (21 CFR 1.225; 21 CFR 1.227(b)(5)).

17. *Q*: If finished food products for consumption in the U.S. are held at a third party facility before consolidation for import into the U.S., must this facility be registered?
A: Yes, if the finished products are held at a third party facility prior to export to the U.S., the facility is required to be registered (21 CFR 1.225; 1.227(b)(5)).

18. *Q*: In a lessor–lessee relationship, such as a food-producing business that rents space from a landlord, who is legally obligated to register the facility?
A: Either the lessor or the lessee may register the facility as follows. The Bioterrorism Act and the Registration Interim Final Rule place the duty to register a facility on the owner, operator, or agent-in-charge of the facility. Each of these persons has an independent obligation to comply with the registration requirement, and any one of them may satisfy the obligation for the other two. On the other hand, if a facility is not registered, FDA could proceed with an enforcement action against one or all of the three. A facility is defined as "any establishment, structure, or structures under one ownership at one general physical location, or, in the case of a mobile facility, traveling to multiple locations, that manufactures/processes, packs, or holds food for consumption in the United States." Thus, for a public warehouse, either the owner of the entire warehouse may register the warehouse and satisfy the obligation for all lessees, or an individual lessee, functioning as the operator or agent-in-charge of the portion of the warehouse he/she leases, may register that portion of the facility.

19. *Q*: Post offices and similar facilities owned or operated by express couriers may have packages containing food on their premises as part of the shipment process. Are these types of establishments required to be registered with FDA as food facilities?
A: No. For purposes of the registration Interim Final Rule, post offices and express courier facilities are not required to be registered with FDA as food facilities. The activities of both postal services and express courier services are focused on the transport of goods; their facilities generally serve only as a point of transfer of packages and other freight, including packages containing food. Thus, it is appropriate to view both types of facilities as part of the transportation process. The definition of "facility" in the Interim Final Rule (21 CFR 1.226(b)(2)) does not include transportation vehicles "if they hold food only in the usual course of business as carriers." Although the registration Interim Final Rule does not define "transportation vehicles," the proposed rule on the establishment and maintenance of records (68 FR 25188 at 25238; May 9, 2003) defines "transporter" as "a person who has possession, custody, or control of an article of food — for the sole purpose of transporting the food." FDA believes that it is appropriate to apply this same rationale to exclude from registration facilities that house food only because they are part of the process of transporting it from one location to another. This analysis is also consistent with the definition of "facility" in 21 CFR 1.227(b)(2). Thus, for the purpose of the registration Interim Final Rule, post offices and express courier facilities operating in a manner comparable to post offices that are part of the transportation network and have possession, custody, or control of food for the sole purpose of transporting it are not required to be registered with FDA.

20. *Q*: Truck terminals and freight forwarders may have food on their premises as part of the shipment process. Are these types of establishments required to be registered with FDA as food facilities?
A: No. Truck terminals and other stationary facilities that serve merely to assist transportation vehicles in the process of transporting food are not required to be registered with FDA. The analysis for post offices and similar facilities is also applicable here. Thus, for the purpose of the registration Interim Final Rule, truck terminals and freight forwarders that are part of the transportation network and have possession, custody, or control of food for the sole purpose of facilitating its transport are not required to be registered with FDA.

FDA acknowledges that this response is not completely consistent with certain prior guidance (Response to Comment 36; 68 Fed. Reg. 58894 at 58904; October 10, 2003). The agency has further considered this issue, as well as related ones, resulting in a revision of the earlier guidance.

b. Manufacturing/processing

21. *Q*: Is fumigation (such as of bagged cocoa beans) considered *de minimis* processing?
A: No. The Interim Final Rule states that "treating" food is a manufacturing/processing activity (21 CFR 1.227(b)(6); also see the response to Comment 41 in the rule). Therefore, a foreign facility that performs fumigation of food that is for consumption in the U.S., is required to be registered unless another foreign facility conducts further manufacturing/processing of more than a *de minimis* nature before the food is shipped to the U.S. FDA notes that even if fumigation were considered to be a *de minimis* activity, the facility at which the fumigation occurs would be required to be registered. The Bioterrorism Act *de minimis* provision is relevant to whether a particular foreign facility that manufactures/processes, packs, or holds food prior to the "*de minimis* facility" is required to be registered. The response to comment 17 in the preamble of the Interim Final Rule also discusses fumigation of cocoa beans.

22. *Q*: Is it necessary for a facility housing cotton gins to register if the cotton gins separate cotton from its seeds and hulls and the facility then sells these seeds or hulls to a manufacturer who then further processes the seeds and hulls into feed for sale to livestock operations?
A: FDA notes that the answer to this question depends in part on whether the cotton by-products are "food" as defined in the interim final rule (21 CFR 1.227(b)(4)) and whether the establishment housing the cotton gins is domestic or foreign.

In the preamble to the Interim Final Rule, FDA responded to a comment (Comment 62) regarding facilities that manufacture/process, pack, or hold multi-use substances. (68 Fed. Reg. 58894 at 58910; October 10, 2003.) The agency believes that discussion is relevant to this question. In the Interim Final Rule, the agency stated that "a product is one that will be used for food if the owner, operator, or agent in charge of the facility reasonably believes that the substance in question is reasonably expected to be directed to a food use." In this example, the facility containing the cotton gins is a food facility because the owner, operator, or agent in charge of the facility knows or should know that the cotton by-products are reasonably likely to be used as components of animal feed.

If the cotton gin establishment is located in the U.S., the establishment is required to be registered because it is manufacturing/processing food (components of animal feed), and the facility does not appear to satisfy any exemption from registration. FDA notes that any subsequent facility that processes the cotton seed and hulls into animal feed is also required to be registered.

However, if the cotton gin establishment and the establishment that processes the cotton seed and hulls into animal feed are both located in a foreign country, the cotton gin establishment would not required to be registered because a subsequent foreign facility (the feed manufacturer) conducts further manufacturing/processing of the cotton by-products prior to export to the U.S. The foreign feed manufacturing/processing facility must be registered unless, before the feed is exported to the U.S., the feed undergoes further manufacturing/processing of more than a *de minimis* nature at a third foreign facility (21 CFR 1.226(a)).

c. US agent

23. *Q*: For foreign facilities, may the U.S. agent for the facility also serve as the facility's emergency contact?
A: Yes. The U.S. agent will be considered the emergency contact for a registered foreign facility unless another name is provided in the facility's registration as the emergency contact (21 CFR 1.227(b)(13); 1.233(e)).

24. *Q*: Some U.S. law firms are charging fees to serve as a foreign facility's U.S. agent. Some of these firms have the word "FDA" in their name. Must a foreign facility use one of these firms as its U.S. agent?
A: No. A foreign facility's U.S. agent may be an individual, partnership, corporation, or association; the only requirement for such an agent is that the agent must have a place of business or residence in the U.S. and be physically present in the U.S. For example, a foreign facility may use its U.S. importer as its U.S. agent. FDA does not recommend or endorse any particular firm, organization, persons, or company to serve as a foreign facility's U.S. agent. FDA is not affiliated with any firm offering its services as a U.S. agent.

25. *Q*: May a foreign government official residing in the U.S., such as a representative from the foreign country's embassy, act as a foreign facility's U.S. agent for purposes of food facility registration?
A: In the preamble to the Interim Final Rule (Comment 90), FDA noted that the agency has concerns that acting as a U.S. agent may conflict with the duties of foreign government

representatives. Whether it is proper for a foreign government representative to act as a U.S. agent is a fact-specific inquiry, depending on the title and status of the foreign government representative and the functions that the representative assumes as a U.S. agent. FDA will consider such situations on a case-by-case basis in consultation with the U.S. State Department.

26. *Q*: I am a foreign facility that does business with several different brokers. May I use more than one of these as my U.S. agent?
A: No. The Interim Final Rule requires that each foreign facility have only one U.S. agent for food facility registration purposes. However, having a single U.S. agent for FDA registration purposes does not preclude a facility from having multiple brokers for other business purposes. FDA notes that a foreign facility is not required to conduct all of its business in the U.S. through the U.S. agent designated for purposes of registration. 21 CFR 1.227(b)(13)(iii) and the response to comment 86 in the preamble to the Interim Final Rule further discuss this issue.

27. *Q*: Is the U.S. agent legally liable in the event something goes wrong with food manufactured/processed, packed, or held at the foreign facility for which he serves as U.S. agent?
A: FDA generally does not intend to hold a foreign facility's U.S. agent responsible for violations of the Bioterrorism Act that are committed by the foreign facility. FDA, however, would consider legal action against a U.S. agent where the agent knowingly submits false information to FDA or the U.S. agent and the foreign facility are effectively the same entity. Liability issues between the facility and its U.S. agent must be resolved between the private parties (i.e., the facility and its U.S. agent), most likely through the terms of their contractual relationship.

d. Owner, operator, agent in charge, parent company

28. *Q*: How does FDA define "owner," "operator," and "agent in charge?"
A: The owner, operator, or agent in charge is a person (21 U.S.C. 321(e)) who has an ownership interest in, or management authority of, a facility or a portion of a facility (e.g., a lessee of a part of a public warehouse).

29. *Q*: How does FDA define "parent company?"
A: The term "parent company" is used in 21 CFR 1.232(b) and is intended to have the meaning it has in the corporate context. If a facility is part of a company that is owned by another corporation, then the corporation would be the parent company. For example, if a facility is owned by Company X, and Company X is a subsidiary of Corporation Y, then the owner of the facility is Company X and the parent company is Corporation Y.

9. Other Questions

a. Do all foreign facilities that manufacture/process, pack, or hold food for consumption in the U.S. need to register?

No. If a foreign facility that manufactures/ processes, packs, or holds food sends it to another *foreign* facility for further manufacturing/processing or packaging before the food is exported to the U.S., only the *second* foreign facility is required to register. However, if the second foreign facility performs only a *de minimis* activity, such as putting on a label, *both* facilities would be required to register. Also, any foreign facility that *packs or holds* food after the last foreign manufacturer/processor of the food must register.

b. How often must you register?

Registration is required only once for each food facility. However, required registration information must be updated if it changes.

c. What does the registration number mean?

It means that the owner of the facility has complied with this rule by registering with FDA. Assignment of the number does not convey FDA approval or endorsement of the facility or its products.

d. Is there a fee for registration?

There is no fee for registration or for updates of any registration.

e. Is there a mechanism for registering multiple food facilities at one time?

FDA will accept multiple registrations.

f. What information is required?

Each registration must include the name, address, and phone number for the facility and its parent company (if applicable); the name, address, and phone number of the owner, operator, or agent in charge; all trade names the facility uses; applicable food product categories as identified in FDA's regulation, 21 CFR 170.3; a statement certifying that the information submitted is true and accurate and that the person submitting the registration, if not the owner, operator, or agent in charge, is authorized to submit the registration. A foreign facility must also provide the name, address, and phone number of its U.S. agent. The foreign facility must also provide the emergency contact phone number for its

U.S. agent unless the facility designates another person to serve as the emergency contact. A domestic facility must also provide an emergency contact phone number.

g. Is additional information requested?

FDA is asking for, but not requiring, certain *optional* information on the registration form. The optional information will help us communicate more effectively with facilities that may be the target of an actual or potential terrorist threat or other food-related emergency. For example, some food products are not identified in the list of food categories at 21 CFR 170.3, such as certain dietary supplements, infant formula, and animal feed, but foods in these categories may be the focus of a food-related emergency.

h. Is registration information available to the public?

No. Neither the list of registered facilities, any registration documents submitted under this regulation, nor any information derived from the list or the documents that would reveal the identity or location of a specific registered person is subject to disclosure under the Freedom of Information Act (FOIA).

i. What if the submitted registration information changes?

When a required element of a facility's registration information changes, e.g., change of operator, agent in charge, or U.S. agent, the owner, operator, or agent in charge, or an individual authorized by one of them, must submit an update to the facility's registration within 60 days of the change through the Internet at http://www.access.fda.gov/ or through the paper update process.

j. What if a facility goes out of business?

When a facility goes out of business, its registration must be canceled.

k. What if a new owner acquires an already-registered facility?

The former owner must cancel the facility's registration within 60 days of the change, and the new owner must re-register the facility.

l. What happens if a facility does not register?

Failure of a domestic or foreign facility to register, update required elements, or cancel its registration in accordance with this regulation is a prohibited act under the Federal Food, Drug, and Cosmetic Act. The Federal government can bring a civil action to ask a Federal court to enjoin persons who commit a prohibited act, or it can bring a criminal action in Federal court to prosecute persons who are responsible for the commission of a prohibited act. If a foreign facility is required to register but fails to do so, food from that foreign facility that is offered for import into the U.S. is subject to being held within the port of entry for the article unless otherwise directed by FDA or the Bureau of Customs and Border Protection (CBP). FDA plans to issue enforcement guidance regarding the agency's policies regarding refusals of imported food under section 801(m)(1) or holds of imported food under section 801(l). This guidance document will be available to the public, and FDA will publish a notice of its availability in the Federal Register.

IV. PRIOR NOTICE OF IMPORTED FOODS

A. Introduction

On October 10, 2003, the Food and Drug Administration (FDA) published an interim final rule in the Federal Register requiring submission to FDA of prior notice of food, including food for animals, that is imported or offered for import into the United States (68 FR 58974). The prior notice interim final rule implements section 801(m) of the Federal Food, Drug, and Cosmetic Act (the FD&C Act) (21 U.S.C. 381(m)) which was added by section 307 of the Public Health Security and Bioterrorism Preparedness and Response Act of 2002 (the Bioterrorism Act) (Public Law 107–188), which requires that FDA receive prior notice of food imported into the United States. This guidance document provides a list of questions that have frequently been asked about the requirements of the prior notice regulation, and the answers to those questions. This document is being issued to help the food industry and others comply with the legal requirements established by the prior notice interim final rule. We intend to issue additional guidance as new questions arise. FDA's guidance documents, including this guidance, do not establish legally enforceable responsibilities. Instead, guidances describe the Agency's current thinking on a topic and should be viewed only as recommendations, unless specific regulatory or statutory requirements are cited. The use of the word should in Agency guidances means that something is suggested or recommended, but not required.

B. Background

a. What is prior notice?

Prior notice is notification to the FDA that an article of food, including animal feed or pet food, is being imported or offered for import into the United States in advance of the arrival of the article of food at the U.S. border (68 FR 58974; October 10, 2003).

b. Why is prior notice required to be submitted to FDA?

Prior notice is required by new section 801(m) of the Federal Food, Drug, and Cosmetic Act (the FD&C Act)

(21 U.S.C. 801(m)). Section 801(m) requires advance notification to FDA prior to the arrival of food imported or offered for import into the United States.

How can the industry learn how to comply and submit prior notice through the U.S. Bureau of Customs and Border Protection (CBP) Automated Broker Interface of the Automated Commercial System (ABI/ACS) or FDA Prior Notice System Interface (PNSI)?

Since publication of the Prior Notice and Registration interim final rule on October 10, 2003, FDA has conducted extensive domestic and international outreach and education about the new rule. FDA and CBP held a satellite downlink public meeting on October 28, 2003, and a series of public meetings across the U.S. to discuss the prior notice and registration interim final rules. Public meetings are announced on FDA's web site at http://www.fda.gov/. In addition, we have prepared several tools, such as tutorials, instructions, and question-and-answer documents, to help importers and other affected persons to submit prior notice under either through ABI/ACS or PNSI. These are available on FDA's web site at http://www.fda.gov/. CBP continues to issue instructions to ABI/ACS filers and brokers on complying with the prior notice regulation.

c. Where can I get more information about FDA's prior notice regulation?

Information on the prior notice regulation may be found on FDA's web site at http://www.fda.gov/. Many of your questions can be answered by reading the prior notice interim final rule or by reviewing the tutorials, fact sheet, and other materials that are posted on the web site. If your questions are not answered by information on that web site, you can send an email to the following address: http://www.cfsan.fda.gov/~furls/helpf2.html. FDA plans to periodically issue guidance documents to answer those questions that are not directly addressed in the prior notice interim final rule or its preamble. Thus, you will not receive an individual response to your email. You should check our web site at http://www.fda.gov/oc/bioterrorism/bioact.html periodically to obtain a copy of these guidance documents.

d. Where can I get more information about CBP's procedures under the Bioterrorism Act and the prior notice regulation?

For additional information on the U.S. Bureau of Customs and Border Protection's (CBP's) procedures for prior notice, you may want to consult the CBP website at http://www.customs.treas.gov/.

e. Is information about prior notice available in languages other than English?

Yes. Information about prior notice to FDA is available in other languages. Translations available are indicated at the top of the English version of documents located on the Internet at http://www.cfsan.fda.gov/~dms/fsbtact.html

C. Definitions

1. Food

a. For the purposes of the prior notice regulation, what is food?

Food is defined in the prior notice regulation by reference to section 201(f) of the FD&C Act, which defines food as articles used for food or drink for man or other animals, chewing gum, and articles used for components of any such articles (21 U.S.C. 321(f)). However, for purposes of prior notice, the definition of food does not include food contact substances or pesticides (21 CFR 1.276(b)(5)(i)). Examples of food subject to prior notice include: fruits, vegetables, fish, including seafood, dairy products, eggs, raw agricultural commodities for use as food or as components of food, animal feed (including pet food), food and feed ingredients, food and feed additives, dietary supplements and dietary ingredients, infant formula, beverages (including alcoholic beverages and bottled water), live food animals, bakery goods, snack foods, candy, and canned foods.

b. Is a bulk commodity like raw cane sugar "food" that is subject to prior notice?

Yes, if a bulk commodity like raw cane sugar is food under the definition if it is for use as food, including for use as a component of food. Raw agricultural commodities for use as food or as components of food are food for prior notice purposes (21 CFR 1.276(b)(5)(ii)). FDA will consider an article as one that will be used for food if any of the persons involved in importing or offering the product for import (e.g., submitter, transmitter, manufacturer, grower, shipper, importer, owner, or ultimate consignee) reasonably believes that the substance is reasonably expected to be directed to a food use.

c. Are live animals "food" for prior notice purposes?

Live animals are food for purposes of prior notice (21 CFR 1.276(b)(5)(ii)) if any of the persons involved in importing or offering the live animal for import (e.g., the submitter, transmitter, manufacturer, grower, shipper, importer, owner, or ultimate consignee) reasonably believes that the live animal is reasonably expected to be directed to a food use (21 CFR 1.276(b)(5)). Note that live food animals are not excluded from prior notice under section 801(m)(3)(B) of the FD&C Act and 21 CFR 1.277(b)(4) or (5) because live food animals do not fall within the exclusive jurisdiction of USDA under the Federal Meat Inspection Act or Poultry Products Inspection Act.

If USDA's Animal Plant and Health Inspection Service (APHIS) inspects the live animals when they are imported into the U.S., are the live animals "food" for prior notice purposes?

Yes. Live food animals that are subject to border inspections by APHIS are also subject to FDA's prior notice requirements: FDA and APHIS may both have jurisdiction over live animals. Note that the requirement for prior notice to FDA for live food animals does not alter the role of APHIS in, or any APHIS requirements relating to, inspection of live animals imported into the U.S.

d. Are game animals "food" for which prior notice must be given?

Yes, if any person involved in importing the animal reasonably believes the animal is reasonably expected to be directed to a food use, the animal is food for which prior notice is required (21 CFR 1.276(b)(5)). So, for example, elk imported to stock a ranch where the elk are hunted and used for food would be food under the prior notice definition. By contrast, elk imported for repopulating a national park where hunting the elk is not permitted would not be food for which prior notice is required. Note that live food game animals are not excluded from prior notice under section 801(m)(3)(B) of the FD&C Act and 21 CFR 1.277(b)(4) or (5) because neither these live food animals nor the products derived there from, fall within the exclusive jurisdiction of USDA under the Federal Meat Inspection Act or Poultry Products Inspection Act.

e. Are chemicals used to manufacture food additives included in the definition of food for prior notice purposes?

Yes, chemicals that are used for food or drink or are used for components of any such articles are food and are subject to the prior notice rule. However, if the chemicals are used for food contact substances or components of food contact substances or pesticides, prior notice is not required (21 CFR 1.276(b)(5)).

f. What are some examples of food contact substances?

Food packaging materials, empty food packages, ceramic dinnerware, brass drinking vessels, and corn husks to be used as tamale wrappers, are examples of food contact substances. Even though these foods are excluded from prior notice requirements in section 801(m) of the FD&C Act, they are still subject to other provisions of the FD&C Act, including section 801(a), and FDA will still make admissibility decisions about them.

g. Are secondary direct additives, many of which are processing aids, exempt from prior notice as "food contact substances"?

The term "secondary direct food additive" is not a defined term. Under 21 CFR 1.276(b)(5), "food" excludes "food contact substances" and "pesticides." Thus, if the "secondary direct food additive" is a food contact substance or a pesticide, it is not included in the definition of food, for purposes of prior notice, and prior notice is not required.

2. FDA Country of Production

a. What is the FDA Country of Production and how does it differ from CBP's Country of Origin?

For food that is in its natural state, the FDA Country of Production is generally the country where the food was grown or collected, including harvested and readied for shipment to the U.S. Articles of food grown, including harvested or collected and readied for shipment, in U.S. territories are considered to be grown in the U.S. (21 CFR 1.276(b)(4)(i)). However, for wild fish, including seafood, that is caught or harvested outside U.S. waters by a vessel that is not registered in the U.S., the FDA Country of Production is the country in which the vessel is registered. (21 CFR 1.276(b)(4)(i)).

For food that is no longer in its natural state, the FDA Country of Production is generally the country where the food was made or processed. However, if the article is made from wild fish aboard a vessel, the FDA Country of Production is the country in which the vessel is registered. If food that is no longer in its natural state was made in a Territory, the FDA Country of Production is the United States (21 CFR 1.276(b)(4)(ii)).

The FDA Country of Production may be different from the CBP Country of Origin. For example, the CBP Country of Origin for beans that are grown and dried in the U.S., then rehydrated and canned in the Dominican Republic would be the U.S. The FDA Country of Production would be the Dominican Republic. However, for purposes of the prior notice provisions of the FD&C Act, the "article of food" is canned beans, not dried beans. From a food safety standpoint, FDA is most interested in knowing where the article of food was processed and canned. To avoid confusion between FDA's prior notice requirements and CBP requirements, the interim final rule uses the term "FDA Country of Production" instead of the term "originating country" or "country from which the article originates." "FDA Country of Production" is already familiar to customs brokers and self-filers using ABI/ACS interface with OASIS.

3. International Mail

a. Are express carriers, such as Federal Express, considered "international mail"?

The term "international mail" only covers foreign national mail services. Express carriers, such as Federal Express, as well as express consignment operators, or other private delivery services are not considered international mail under the prior notice rule (21 CFR 1.276(b)(7)).

4. Port of Arrival/Port of Entry

a. What is the "port of arrival" and how does it differ from the "port of entry?"

The port of arrival is the water, air, or land port at which the article of food is imported or offered for import into the U.S., i.e., the port where the article of food first arrives in the U.S. (21 CFR 1.276(b)(9)). Port of entry is given the same definition the CBP regulations use, which "refer[s] to any place designated by Executive order ..., by order of the Secretary of the Treasury, or by Act of Congress, at which a Customs officer is authorized to accept entries of merchandise, to collect duties, and enforce the various provision of Customs and navigation laws ..." (19 CFR 101.1).

b. Can the port of arrival differ from the port where entry is made?

Yes. The port of arrival is the port where the articles first arrive in the U.S. A consumption or warehouse entry or foreign trade zone admission documentation may be presented to CBP at a different port than the port of arrival. This port is often referred to as the "port of entry" or "port where entry is made." Note that timeframes for submission of prior notice are tied to the time of arrival in the port of arrival, not arrival in the so-called port of entry.

5. United States

a. Is prior notice required for foods that are imported into Puerto Rico?

Yes. The prior notice interim final rule defines the United States to be the 50 states, the District of Columbia, and the Commonwealth of Puerto Rico, but not the U.S. Territories (21 CFR 1.276(b)(13)). Therefore, prior notice is required for food that comes from outside the U.S. into Puerto Rico, but not for food shipped from Puerto Rico into the 50 states or the District of Columbia.

b. Is prior notice required for foods that are imported into the U.S. Territories?

No. The prior notice interim final rule defines the United States to be the 50 states, the District of Columbia, and the Commonwealth of Puerto Rico, but not the U.S. Territories (21 CFR 1.276(b)(13)). Therefore, prior notice is not required for food shipped into a U.S. Territory. However, prior notice is required for food coming from a U.S. Territory (e.g., Guam, the U.S. Virgin Islands, and the Northern Mariana Islands) into the 50 states, the District of Columbia or the Commonwealth of Puerto Rico.

c. Is prior notice required for shipments originating in another NAFTA country?

Yes. Because the "United States" is defined for purposes of prior notice to be the Customs territory of the United States (21 CFR 1.276(b)(13)), food that is imported into the 50 states, the District of Columbia, or the Commonwealth of Puerto Rico from a country that is a signatory to the North American Free Trade Agreement (other than the United States) is subject to prior notice.

D. Scope

1. General

a. What is the scope of prior notice regulation? What shipments of food imported or offered for import into the United States require prior notice?

If the article that is shipped to the United States is food within the meaning of 21 CFR 1.276(b)(5), then prior notice is generally required, even if the item is intended for further processing, is not intended for consumption in the United States, or is not intended for commercial distribution. Thus, prior notice is required for all food for humans and other animals that is imported or offered for import into the United States for use, storage, or distribution in the United States, including food for gifts and trade and quality assurance/quality control samples, food for transshipment through the United States to another country, food for future export, and food for use in a U.S. Foreign Trade Zone.

b. Are there any exceptions from the prior notice requirements?

Yes. Prior notice is not required for:

- Food for an individual's personal use (i.e., for consumption by the individual, family, or friends, and not for sale or other distribution) when it is carried by or otherwise accompanies the individual when arriving in the United States;
- Food that was made by an individual in his/her personal residence and sent by that individual as a personal gift (i.e., for non-business reasons) to an individual in the United States;
- Food that is imported then exported without leaving the port of arrival until export; and Meat food products, poultry products, and egg products that are subject to the exclusive jurisdiction of the U.S. Department of Agriculture (USDA) at the time of importation (21 CFR 1.277(b)).
- Prior notice also is not required under FDA requirements for food brought into the United States in a diplomatic pouch. (The Vienna Convention on Diplomatic Relations (1961) provides: "The diplomatic bag shall not be opened or detained." Art. 27(3) Any baggage or cargo marked "diplomatic bag" or "diplomatic pouch" is immune from search, including by electronic devices, and thus its contents are not subject to FDA's prior notice requirements.)

b. Are there exceptions from prior notice for any of the following:

- Food items of small value or quantity;
- Food samples for research and development or for testing purposes only and not for consumption; or
- Food samples for test marketing?

There are no exemptions from prior notice requirements for:

- Food based on the size or value of the shipment (68 FR 58993);
- Samples of food (including animal feed) for research and development. (However, if the samples are items that are in such early stages of research and development that they cannot yet be considered food under 21 CFR 1.276(b)(5), they would not be subject to prior notice requirements. An example of such an item is a substance being tested for possible preservative qualities before being tested in any food); or
- Samples of food, including animal feed, for test marketing.

2. Shipments from Farms

a. Is prior notice required for tomatoes from a foreign farm that packs and exports tomatoes to the U.S. since farms don't have to register?

Yes. The requirement for prior notice is not based on whether registration is required. FDA registration requirements (21 CFR 1.266(b)) apply to facilities that manufacture/process, pack, or hold food for consumption in the United States. The prior notice requirements apply to articles of food imported or offered for import into the United States. Although registration of farms is not required, the articles of food grown, harvested, or collected on farms are not exempt form prior notice requirements. Thus, generally, the food that a foreign farm exports to the U.S. is subject to the prior notice requirements (21 CFR 1.277).

3. Shipments for Charities

a. Is there an exemption for food imported for charity?

No. Food intended for charity is not exempt from prior notice. Although the registration interim final rule exempts nonprofit food establishments in which food is prepared for, or served directly to, the consumer from the requirements to register their facilities, (21 CFR 1.266(e)), the prior notice interim final rule does not exempt food imported for use by those nonprofit food establishments. Thus, imported food that is imported for or by a U.S. charity is subject to prior notice (21 CFR 1.277).

4. U.S. Goods Returned

a. Is prior notice required for "reimported" food product that was produced in the U.S., shipped to a foreign country, and then shipped back to the U.S. without further processing?

Yes. FDA has determined that, for the purposes of section 801(m) of the FD&C Act, the phrase "imported or offered for import into the United States" applies to articles of food of U.S. origin that are "reimported" back into the U.S. (68 FR 58990; 21 CFR 1.277). These reimportations are most often referred to as American Goods Returned or U.S. Goods Returned.

5. Food Not for Consumption in the U.S.

a. If the food is not for consumption in the U.S., is prior notice required?

Yes. Prior notice requirements apply even when the food is not for consumption in the United States. You must submit prior notice for food for that is for transshipment, further processing and export, or storage and export. In contrast, the requirement to register facilities applies only to food facilities that manufacture/process, pack, or hold food for consumption in the U.S.

b. Is prior notice required for food transiting the U.S. for exportation to another country, e.g., for a Transportation and Exportation (T&E) entry?

Yes. Prior notice is required for food for transshipment through the U.S. to another country and food for future export (21 CFR 1.277(a)).

6. Foreign Trade Zones

a. Will food being admitted into a Foreign Trade Zone need to have prior notice?

Yes. Food for admission into a Foreign Trade Zone is subject to the requirements of the prior notice regulation (21 CFR 1.277). However, prior notice is not required when the food is withdrawn from the FTZ, either as an export or for use within the United States. However, if the food is withdrawn from the FTZ for consumption entry into the United States, FDA will be notified and make the admissibility decision about the consumption entry at that time.

7. Gifts

a. Does prior notice apply to food sent as gifts from family living outside the U.S.?

If the food was made by an individual in his/her personal residence and sent by that individual as a personal gift (i.e., for non-business reasons) to an individual in the United States, prior notice is not required (21 CFR 1.277(b)(2)). Other food products sent as gifts are subject to the prior

notice requirement (21 CFR 1.277). FDA recognizes that, in these circumstances, the sender who purchased the food as a gift may not have the manufacturer/producer registration number. Thus, the sender can use the name and address of the firm that appears on the label. A registration number need not be provided (21 CFR 1.281(a)(6)).

8. Airline Food

Is aircraft food exempt from prior notice, since any excess is incinerated at the U.S. airport? Is in-flight food, imported in bulk and moved in-bond to U.S. caterers, for use on export flights exempt?

If the aircraft food is consumed on the flight or discarded and is not entered into the U.S. for use, storage, or distribution, it is outside the scope of the regulation and prior notice is not required (21 CFR 1.277(a)). By contrast, prior notice is required for in-flight food that is moved to U.S. caterers for use on export flights (21 CFR 1.277).

9. Personal Baggage

a. I am bringing food from a foreign country in my luggage and for my personal use. Do I need to submit prior notice to FDA?

No. Prior notice is not required for food that is carried by or otherwise accompanies an individual entering the United States (e.g., is in his or her carry-on or checked baggage) when the food is for that individual's personal use (21 CFR 1.277(b)(1)). Personal use means that the food is for consumption by the individual or by the individual's family and friends and is not for sale or other distribution.

10. Food Shipped by Express Carriers or Express Consignment Operators

a. Is an article of food that is shipped by an express carrier or express consignment operators like Fed Ex exempt from prior notice?

No. Imported food transported into the U.S. via express carriers or express consignment operators is not exempt from the requirements of the prior notice regulation. Articles imported via these private delivery services are subject to prior notice, which must be submitted within the timeframe for the applicable mode of transportation (21 CFR 1.279).

11. Food Shipped by International Mail

a. Is food imported into the U.S. by international mail exempt from prior notice?

No. Food sent to the U.S. via international mail is not exempt from the requirements of the prior notice regulation. Articles imported via international mail are subject to prior notice, which must be submitted before the article is sent to the U.S. (21 CFR 1.279(c)).

12. Personal Shipments

a. Is prior notice required for food for personal use that is shipped by the individual while overseas and, therefore, does not accompany the individual when returning to the U.S.?

Yes. Food purchased abroad and sent to the U.S. (i.e., does not accompany the individual when arriving in the U.S.) is subject to prior notice (21 CFR 1.277).

a. I have ordered food for my personal use that is being shipped to me through international mail. Do I need to provide prior notice to FDA?

Yes. Prior notice must be provided. The exception for food for "personal use" applies only when the food is carried by or otherwise accompanies an individual when arriving in the U.S. (21 CFR 1.277(b)(1)). This exception does not apply when the food is shipped to the U.S. Although you or any other person with knowledge of the required information may submit prior notice (21 CFR 1.278), it would make sense for the foreign shipper to provide prior notice because the PN Confirmation Number, which indicates that FDA has received and confirmed the prior notice for review, must accompany an article of food that is sent to the U.S. via international mail (21 CFR 1.279(e)).

b. What if my order is shipped by an express carrier or express consignment operators like Fed Ex?

Prior notice is still required. Food transported to the U.S. via express carriers or express consignment operators is not exempt from the requirements of the prior notice regulation. Articles imported via these private delivery services are subject to prior notice, which must be submitted within the timeframe for the applicable mode of transportation (21 CFR 1.279).

14. Trade Samples

a. Is food that is a trade sample and that I carry with me into the United States exempt from prior notice?

No. The exclusion for good carried by an individual applies when the food is for the individual's personal use when it is carried by or otherwise accompanies the individual when arriving in the United States (21 CFR 1.277(b)(1)). However, trade samples are imported or offered for import to generate sales, which is a commercial, not personal, use.

15. Food Moved with Household Goods

a. Are foods included with my household goods subject to prior notice when I move to the U.S.?

Yes.

16. Food Subject to USDA/FSIS Requirements

a. Is prior notice required for meat, poultry, or eggs that are under the jurisdiction of the U.S. Department of Agriculture (USDA)?

If, at the time the food is imported or offered for import, the food is subject to the exclusive jurisdiction of the USDA's Federal Meat Inspection Act (21 U.S.C. 601 et seq.), the Poultry Products Inspection Act (21 U.S.C. 451 et seq.), or the Egg Products Inspection Act (21 U.S.C. 1031 et seq.), the food is not subject to the requirements of prior notice. (21 CFR 1.277(b) (4)-(b)(6)).

E. Requirements to Submit Prior Notice of Imported Food

1. Submitters and Transmitters

a. Who may submit prior notice to FDA?

Any person with knowledge of the required information may submit prior notice for an article of food. This person is the submitter. The submitter may also use another person to transmit the required information on his or her behalf. The person who transmits the information is the transmitter. The submitter and transmitter may be the same person (21 CFR 1.278).

b. May I submit a prior notice on behalf of another person?

Yes. Note that if you transmit the required information on behalf of a submitter, you are the transmitter.

c. Is it possible for the submitter to have his/her legal residence in the country of origin and for the transmitter to have his/her legal residence in the U.S.?

Yes. There are no geographic restrictions on the location of the submitter or the transmitter (21 CFR 1.278).

2. Deadlines for Prior Notice

a. When must prior notice be submitted?

Prior notice must be submitted and the submission must be confirmed by FDA no more than 5 days before arrival, except for food arriving by international mail, and no less than:

2 hours before arrival, if the food is arriving by land by road;
4 hours before arrival, if the food is arriving by land by rail
4 hours before arrival, if the food is arriving by air; and
8 hours before arrival, if the food is arriving by water (21 CFR 1.279(a) and (b)).

For article of food sent by international mail, prior notice must be submitted and confirmed by FDA before the food is sent (21 CFR 1.279(c)). The Prior Notice (PN) Confirmation Number must appear on the Customs Declaration that accompanies the package (21 CFR 1.279(e)).

If you are carrying an article of food or if it otherwise accompanies you (i.e., the food is in your checked baggage), and the food is not for personal use, you must submit prior notice according to the timeframe established for the mode of transportation you are using. You must receive confirmation from FDA and provide a copy of the confirmation, including the PN Confirmation Number, to CBP or FDA when arriving in the U.S. (21 CFR 1.279(f).

3. Submitting Prior Notice

a. How is prior notice submitted to FDA?

You must submit prior notice to FDA electronically either through the U.S. Bureau of Customs and Border Protection's (CBP's) Automated Broker Interface of the Automated Commercial System (ABI/ACS) or FDA's Prior Notice System Interface.

CBP's ABI/ACS allows prior notice to be submitted to FDA through the existing ABI/ACS interface (21 CFR 1.280(a)(1)); and FDA's Prior Notice System Interface (PNSI) is available through FDA's website at http://www.access.fda.gov/ (21 CFR 1.280(a)(2)).

Both ABI/ACS and the FDA PNSI are available 24 hours a day, 7 days a week for information submission.

b. Do I have to submit prior notice information to both FDA and CBP?

No. Prior notice must be submitted to FDA. If you are an authorized user of CBP's ABI/ACS you may submit prior notice to FDA through the ABI/ACS interface or through FDA's Prior Notice System Interface (PNSI) at http://www.access.fda.gov/. If you are not an authorized user of CBP's ABI/ACS, you may arrange for prior notice submission by an authorized user or submit prior notice through PNSI. Except, however, prior notice for the following, must be made through FDA's PNSI:

Articles of food shipped through international mail;

Transaction types that cannot be transmitted through ABI/ACS; and Articles of food that have been refused admission under section 801(m)(1) of the FD&C Act (21 CFR 1.280(a)(2)).

c. I am an authorized user of CBP's ABI/ACS. Can I use FDA's Prior Notice System Interface (PNSI) to submit prior notice?

Yes. You may submit prior notice through either system.

d. I am shipping food by international mail. How do I provide prior notice?

You provide prior notice to FDA through PNSI (21 CFR 1.280(a)(2)). Prior notice must be submitted and confirmed by FDA before the food is sent (21 CFR 1.279(c)). The Prior Notice (PN) Confirmation Number must appear

on the Customs Declaration that accompanies the package (21 CFR 1.279(e)).

e. What happens if the CBP or FDA system is not working?

If CBP's ABI/ACS is not available or if your broker's or your self-filing system is not working, you must submit prior notice through the FDA Prior Notice System Interface at http://www.access.fda.gov/. (21 CFR 1.280(b)).

If we determine that our Prior Notice System Interface is not working, we will issue notification on our website (http://www.fda.gov/) and on the Prior Notice System Interface, as well as through messages in ABI/ACS. If you do not use ABI/ACS, and the PNSI is down, you must submit prior notice by e-mail or fax to FDA.

If FDA determines that its automated import system (OASIS) is not working, FDA will issue notification on our website (http://www.fda.gov/) and on the Prior Notice System Interface and all prior notices must be submitted to FDA by e-mail or by fax. The e-mail address and fax number, as well as more information on how to submit prior notice if FDA or CBP systems are not working, will be available at http://www.fda.gov/.

f. What happens if my computer system is not functioning or I don't have electricity for a period of time?

If your computer is not functioning or there is no electricity to operate your computer but the Prior Notice System Interface and ABI/ACS are functioning, you must arrange to use a functioning computer to submit the required prior notice.

If I have problems submitting prior notice through the Prior Notice System Interface (PNSI), how can I get help?

Tutorials on use of PNSI are available on FDA's website at http://www.fda.gov/. If you are already familiar with how to use PNSI and you are having problems win an online submission through PNSI, in the U.S call toll-free 1-800-216-7331. From elsewhere, call 301-575-0156. You may send a fax to 301-210-0247. These phone numbers will be staffed on business days from 7 AM until 11 PM U.S. Eastern Time. Requests for assistance also may be emailed to http://www.cfsan.fda.gov/~furls/helpf2.html. For assistance with ABI/ACS transmission, contact your CBP client representative.

g. Can I submit the prior notice to the Prior Notice System Interface in a language other than English?

You must submit all prior notice information in the English language, except that an individual's name, the name of a company, and the name of a street may be submitted in a foreign language. All information, including these items, must be submitted using the Latin (Roman) alphabet (21 CFR 1.280(a)).

h. If you are not comfortable with English, you may choose to use a transmitter to enter the information for you. Can anyone submit prior notice through ACS/ABI?

No. CBP allows submissions through ACS/ABI only by brokers or filers that are recognized by CBP, e.g., licensed brokers and filers. Individuals can contract with a broker to transmit prior notice for them. In this case, the submitter is the person responsible for providing the information, but the broker is the transmitter.

Brokers are licensed private individuals or companies that are regulated by CBP and who aid importers and exporters to move merchandise through CBP. Brokers provide the proper paperwork and payments to CBP for clients and charge a fee for this service. Before brokers apply for a license, they must pass the Customs broker examination. See:http://www.customs.gov/xp/cgov/import/broker_management/brokers.xml

Filers are licensed carriers and self-filers who submit entries on their own behalf. Filers are required to submit a written request to CBP port personnel for a filer code, which is subsequently assigned by CBP headquarters. See: http://www.cbp.gov/ImageCache/cgov/content/import/brokers/broker_5fhandbook_2epdf/v1/broker_5fhandbook.pdf

Individuals who choose not to use a broker or who chose not to become recognized by CBP as a filer can submit their prior notice only through the FDA PN System Interface (PNSI).

i. Do I have to submit prior notice if I do not have to file a consumption entry with CBP?

Yes. The requirement to submit prior notice to FDA is different from the requirement to file a consumption entry with CBP. Some foods arriving in the United States do not require a CBP consumption entry at the time of arrival, such as entries that move under bond (in-bonds) from the port of arrival to an inland port and shipments into a Foreign Trade Zone. However, any article of food imported or offered for import into the United States requires prior notice, unless the food is specifically excluded from the requirement to submit prior notice (21 CFR 1.277).

j. Can I submit any CBP entry or admission for food without prior notice?

No, not if the entry or admission contains food subject to prior notice requirements. You can not submit a CBP import entry or admission if you have not submitted prior notice to FDA for an article of food that requires prior notice, because the Harmonized Tariff Schedule (HTS) codes have been flagged to indicate foods that require or may require prior notice. You must submit prior notice either through the ABI/ACS (along with the CBP entry information) or through the FDA Prior Notice System Interface at http://www.access.fda.gov (21 CFR 1.280(a)).

When you submit prior notice through the FDA Prior Notice System Interface, you will receive a Prior Notice (PN) Confirmation Number (21 CFR 1.279(d)). If you subsequently submit import entry or admission information through ABI/ACS, you must enter the PN Confirmation Number for that submission as an Affirmation of Compliance when the CBP entry or admission is filed. The PN Confirmation Number will allow CBP to confirm that prior notice was submitted to FDA.

k. I cannot or do not want to use CBP's ABI/ACS. What other way can I submit prior notice?

If you cannot or do not want to use ABI/ACS, you must submit prior notice through the FDA Prior Notice System Interface at http://www.access.fda.gov/ (21 CFR 1.280(a)). You will receive a confirmation number when you complete the prior notice through the Prior Notice System Interface (21 CFR 1.279(d)). The PN Confirmation Number must accompany the food when the article arrives in the U.S. (21 CFR 1.279(g)).

l. How do I submit prior notice for foods that are covered by immediate transportation or transportation and exportation entries?

The U.S. Bureau of Customs and Border Protection (CBP) has modified the Automated Broker Interface of the Automated Commercial System (ABI/ACS) interface to allow for submission of prior notice to FDA for IT and T&E entries. Prior notice for such entries also may be made through FDA's Prior Notice System Interface.

m. I regularly ship food to the United States in a truck, under bond, to St. Louis. When and how do I need to file prior notice?

The time frame for submitting prior notice is based on the mode of transportation and the port of arrival, i.e., the port where the food first arrives in the United States. This port may be different from the port where the entry documentation is presented to CBP. Prior notice for food arriving by truck (by land by road) must be confirmed by FDA for review at least 2 hours before the truck arrives at the port where it is crossing the border into the United States (21 CFR 1.279).

If you are entering under bond and want to file your CBP entry in St. Louis, you can file your prior notice either through FDA's Prior Notice System Interface or through CBP's ABI/ACS interface (21 CFR 1.280(a)). If you submit the prior notice through the FDA Prior Notice System Interface, you will receive a Prior Notice Confirmation Number (21 CFR 1.279(d)). This Prior Notice (PN) Confirmation Number must be made available to CBP when entering the United States, and must be entered as an Affirmation of Compliance when you file your CBP entry information (21 CFR 1.279(g)).

n. Is there a filing fee for prior notice?

No. FDA does not charge a fee for filing prior notice or for using FDA's Prior Notice System Interface. However, if you chose to use a broker to file the prior notice through the ABI/ACS interface, the broker may charge a fee for providing that service. The collection of duty by CBP is not affected by FDA's prior notice regulation.

4. Prior Notice Data Elements

a. What information must be included in the prior notice?

The information required for prior notice varies, based on the type of entry, mode of transportation for the entry, and whether the food is in its natural state. You should refer to the interim final rule (21 CFR 1.281) for details on the required information. The preamble to the interim final rule includes a chart that summarizes the information requirements (68 FR 58980). The interim final rule is available on FDA's web site http://www.fda.gov/. Tutorials on the FDA Prior Notice System Interface (PNSI) also are available on FDA's website to help guide you through the process for providing the required information when you submit prior notice through PNSI.

b. How does the information required for prior notice of imported food shipments differ from information submitted to the CBP before December 12, 2003?

Most of the information required by 21 CFR 1.281 also is entry data required by CBP before December 12, 2003. The key differences are the information required about the identity of manufacturer, grower, owner, and submitter and the identification of the country from which the article is shipped.

c. What time do I enter for anticipated time of arrival?

For prior notice, anticipated time of arrival is the local time when the food will arrive at the border (21 CFR 1.281(a)(11)(iii)). For vessels, this would be when the vessel will dock in the port where the shipment is offloaded. For planes, this would be when the plane is scheduled to land. For land vehicles, such as trucks, buses, and trains, this would be when they will cross at the border.

5. Changes to Prior Notice Submissions

a. Do I have to resubmit prior notice if the anticipated time of arrival changes?

No. Prior notice does not need to be resubmitted if the anticipated arrival information changes (21 CFR 1.282(a)(2)(ii)). Although a new prior notice submission is not required, FDA staff may need time to respond to the changes in arrival information.

b. What should I do if information changes after I submit prior notice?

The interim final rule requires that if required information (except estimated quantity, anticipated arrival information, and planned shipment information) changes after FDA has confirmed prior notice for review, the prior notice must be resubmitted (21 CFR 1.282(a)(2)).

If the prior notice was submitted as part of a multi-line ABI/ACS entry, and information about one or more of the products changes, the entry must be deleted and resubmitted. Prior notice for the new product can be submitted as part of a new entry. If you submitted the prior notice via the FDA Prior Notice System Interface, you should cancel the prior notice via the FDA Prior Notice System Interface (21 CFR 1.282(b)).

c. Which changes require me to resubmit prior notice and which changes don't?

Changes in the estimated quantity, anticipated arrival information, or planned shipment do not require resubmission of prior notice after FDA has confirmed your prior notice submission for review (21 CFR 1.282(a)(1)(i)-(iii)). For all other changes, e.g., if the identity of the manufacturer changes, you should cancel the prior notice and you must resubmit prior notice if you still intend to import or offer the food for import into the U.S. (21 CFR 1.282).

6. Changes to Shipments

a. May I add another article of food to an existing prior notice after the prior notice has been submitted to FDA?

No. Each article of food requires a separate prior notice (21 CFR 1.281(a)(5) and 1.281(b)(4)) and receives a unique confirmation number (21 CFR 1.279(d)). However, FDA is allowing prior notices to be grouped in an ABI/ACS entry, or in an "envelope" for the FDA Prior Notice System Interface (PNSI) entries and In-Bonds submitted through ABI/ACS, in order to reduce data entry for transmitters and to simplify CBP review at the border. For submissions through PNSI, no articles of food can be added to an envelope after the Prior Notice Confirmation Number(s) has been received. For submissions through ABI/ACS, no additional lines may be added after the entry is accepted by ACS.

b. What can I do if I want to add another article of food to a shipment after prior notice was submitted to the FDA?

New articles of food cannot be added to an entry, or prior notice envelope, after it has been submitted to FDA (21 CFR 1.282). If a new article of food is being added to a shipment for which prior notice(s) has already been submitted and confirmed, a separate prior notice must be filed for that article under a new entry/envelope (21 CFR 1.281(a) and (b)). The submission time for the new prior notice will be different from that of the rest of the shipment, and this may have an effect on the ability of the shipment to enter the United States (21 CFR 1.279). For example, if you add another food to a truck at 9:00 am, that food is not covered by timely prior notice until 11:00 am. The rest of the food on that same truck may be covered by prior notices submitted at 8:00 am and deemed timely at 10:00 am. It is recommended that the time for arrival be anticipated on the last article of food submitted and confirmed by FDA for review.

c. What can I do if I want to remove an article of food from the information provided for a shipment?

If the prior notice was submitted through ACS, you can delete the prior notice using the existing entry delete procedures. If you submitted the prior notice via the FDA Prior Notice System Interface, you should cancel the prior notice via the Prior Notice System Interface (21 CFR 1.282(b)).

7. PNSI and ACS/ABI Features

a. If I need to revise some information on a prior notice, will some of the fields be filled in by the computer automatically or will I need to start from the beginning?

The answer depends on how the prior notice submission is being made. If submitting through the CPB Automated Broker Interface of the Automated Commercial System (ABI/ACS), the ability to pre-fill or otherwise support submission will depend on the functionality of the software used by the filer. The ABI/ACS interface is concerned with the validity of the information in the submission, not with how it was generated.

If submitting through FDA's Prior Notice System Interface, the answer varies with the status of the submission. The Prior Notice System Interface will allow a transmitter to pre-enter information and save the draft until the time of actual submission. Before the draft is submitted, changes can be easily made to the draft because information previously entered will be pre-filled.

After the prior notice has been submitted to FDA, no changes can be made unless requested by FDA to correct an error found during the review process before a Prior Notice (PN) Confirmation Number issues to the transmitter (21 CFR 1.282).

8. Confirmation

a. Will I receive confirmation that FDA has received the prior notice I submitted?

Yes. FDA will notify the transmitter that the prior notice has been confirmed for review with a reply message that

contains a Prior Notice (PN) Confirmation Number. For prior notice submissions through the CPB ABI/ACS, the PN Confirmation Number together with the "PN received" message will be made available to the transmitter (broker or filer) through the ABI/ACS. For prior notice submissions through the FDA Prior Notice System Interface (PNSI), a PN Confirmation Number will be provided to the transmitter through PNSI as soon as FDA confirms your prior notice for review.

b. Is a copy of the prior notice required to accompany the food?

To ensure that entry proceeds as smoothly as possible, the carrier or individual should consider having a copy of the reply message that contains a PN Confirmation Number in his/her possession upon arrival.

For food carried by or otherwise accompanying an individual that is not for personal use, the individual must provide a copy of the PN confirmation to FDA or CBP. Food covered by prior notice submitted through the FDA Prior Notice System Interface must be accompanied by a copy of the reply message that contains the PN Confirmation Number.

For international mail packages, the confirmation number must accompany the package.

c. Does receipt of a PN Confirmation Number mean that the food will not be examined or sampled?

No. Receipt of a PN Confirmation Number is evidence only that a prior notice has been received for FDA review. Based on review of the prior notice, FDA may determine that an article of food should not be allowed to proceed into the United States without further inspection and sampling at the border. The food may be refused under the prior notice regulation and section 801(m) of the FD&C Act and held if the prior notice is inaccurate or if it is untimely and FDA has not had sufficient time to receive, review, and respond to the prior notice information. In addition, FDA may examine or sample the food for food safety and security concerns and for determining whether the food is subject to refusal under section 801(a) of the FD&C Act.

d. If receipt of the Prior Notice (PN) Confirmation Number does not mean the FDA has determined that timely prior notice was submitted or that the information submitted is accurate, what is the value of the PN Confirmation Number?

The Prior Notice (PN) Confirmation Number is FDA's notice to you that that your prior notice was submitted to and received for review by FDA. It is the signal to you that the time frame for prior notice for the food covered by that prior notice submission has started. In addition, the PN Confirmation Number provides a mechanism for prior notice data, submitted to FDA, to be matched with an entry submitted to CBP. The timeliness of prior notice can not be assessed until the food actually arrives in the United States and, often, the accuracy of the prior notice can not be fully determined until the food is examined upon arrival.

F. Consequences

1. Inadequate Prior Notice

a. What does FDA consider to be inadequate prior notice?

Inadequate prior notice is when:

1. There is no prior notice submitted for an article of food imported or offered for import into the United States; and/or
2. The information submitted in the prior notice is inaccurate; and/or
3. The prior notice is not submitted in concurrence with the required timeframes.

FDA's enforcement policies on inadequate prior notice are being set out in a separate guidance document. This Compliance Policy Guide will be available on FDA's website at http://www.fda.gov/ora/compliance_ref/cpg/default.htm

b. What are some examples of inadequate prior notice?

The following examples of inadequate prior notice are for 5 articles of food (foods A, B, C, D, and E) arriving at the border by truck:

1. Prior notice was submitted for only 4 of the 5 articles of food (foods A, B, C, and D). Inadequate prior notice, e.g., no prior notice, was provided for food E.
2. Prior notice for food A was submitted and confirmed for FDA review with PN Confirmation Number 999. Food B arrives associated with PN Confirmation Number 999. Inadequate prior notice, e.g., inaccurate prior notice, was provided for food B.
3. Prior notice for food A was submitted and confirmed for FDA review at 9:00 am on February 2, 2005. Food A arrives at the port of arrival at 9:30 am on February 2, 2005, but CBP has not received an examination decision response from FDA. Inadequate prior notice, e.g., untimely prior notice, was provided for food A.

FDA's enforcement policies on inadequate prior notice are being set out in a separate guidance document. This

Compliance Policy Guide will be available on FDA's website at http://www.fda.gov/ora/compliance_ref/cpg/default.htm

c. What happens to food that is imported or offered for import without adequate prior notice?

Articles of food arriving with no prior notice, inaccurate prior notice, or untimely prior notice may be refused admission and, other than food arriving by international mail or carried by or otherwise accompanying an individual, if refused, will be handled in one of the following ways:

1. Immediately exported, with CBP concurrence, from the port of arrival; or
2. Held within the port of entry, unless directed by CBP or FDA (21 CFR 1.283(a)(1)(i)-(iii) and (b)).
3. Refused food is considered general order merchandise under section 490(a) of the Tariff Act (19 U.S.C. 1490(a)) and may move only under appropriate custodial bond (21 CFR 1.283(a)(2)). If the refused article is moved, the submitter must notify FDA of the hold location within 24 hours of refusal. The refused food may not be delivered to the importer, owner, or ultimate consignee (21 CFR 1.283(a)(2)(ii)).

For food that is carried by or accompanies an individual arriving in the U.S. and the food is not for personal use, if adequate prior notice is not submitted or if the PN confirmation number cannot be provided to FDA or CBP, the food is subject to refusal. If before leaving the port, the individual does not arrange to have the food held at the port or exported, the article may be destroyed (21 CFR 1.283(b)).

For food arriving by international mail, if prior notice is inadequate or if the PN Confirmation Number is not affixed, the article will be held for FDA inspection and disposition. If refused and there is a return address, the parcel may be returned to sender. If there is no return address or the food in the shipment appears to present a hazard, FDA may dispose of or destroy the parcel at its expense. If FDA does not respond within 72 hours of the CBP hold, CBP may return the parcel back to the sender or, if there is no return address, destroy the parcel, at FDA expense.

FDA's enforcement policies on inadequate prior notice are being set out in a separate guidance document. This Compliance Policy Guide will be available on FDA's website at http://www.fda.gov/ora/compliance_ref/cpg/default.htm.

d. Will my food be held if it arrives earlier than the anticipated time of arrival I submitted?

If arrival occurs before the anticipated arrival time, the food could be refused and held until the prior notice timeframe has elapsed (21 CFR 1.279) or until processing is complete, which ever comes first. However, if the prior notice has been fully processed by FDA, the food will not be refused because the anticipated arrival time has not yet come (21 CFR 1.283(a)(1)(ii)). However, if FDA plans to examine the food, it may be held to allow time for FDA staff to arrive.

e. What does it mean if, after I receive a Prior Notice (PN) Confirmation Number, FDA later refuses the same article of food?

The PN Confirmation Number only confirms that the submission is complete and facially valid. If FDA's review process determines that the prior notice is inaccurate after receipt of the prior notice is confirmed by issuance of the PN Confirmation Number, the article of food is still subject to refusal under 21 CFR 1.283(a)(1)(ii).

f. Does meeting all the requirements of prior notice mean that the article of food will not be held or examined further?

No, the food must meet the requirements of all other applicable regulations as well. If FDA decides to take no prior notice action for an article of food under 21 CFR 1.283 or 1.285(a), this decision has no bearing on whether the article of food is admissible or will be granted admission under other provisions of the FD&C Act or other U.S. laws. Thus, for imported food or food offered for import, FDA will continue its normal investigative and enforcement activities for food safety and security concerns and for determining whether the food is subject to refusal under section 801(a) of the FD&C Act.

g. Who will be notified if FDA determines that a food needs to be held for examination when it arrives at the border?

FDA will communicate the decision to examine articles of food to CBP.

Functional Food Ingredients

83 Food Additives

Laszlo P. Somogyi
Kensington, California

CONTENTS

I. INTRODUCTION

The broadest definition of a food additive is any substance that becomes part of a food product, either directly or indirectly, during some phase of processing, storage, or packaging. The universe of food additives encompasses.

Direct food additives, those that are intentionally added to food for a functional purpose, in controlled amounts, usually at low levels (from parts per million to 1–2%, by weight), and

Indirect or incidental food additives, those entering into food products in small quantities as a result of growing, processing, or packaging.

The difference between food ingredients and additives is mainly in the quantity used in any given formulation. Food ingredients can be consumed alone as food (e.g., sucrose), while food additives are used in small quantities (usually less than 2%) relative to the total food composition but which nonetheless play a large part in the production of desirable and safe food products.

Food additives may be looked upon as minor ingredients incorporated into foods to affect their properties in some desired way. Most commonly, the effects desired relate to color, flavor, texture, nutritive value, or stability in storage. There is no rigorous definition that meets all needs.

The *Codex Alimentarius*, which dominates actions in international circles, considers an additive as an ingredient "not normally consumed as a food by itself and normally used as a typical ingredient." This obviously leaves great latitude for judgment by the committee. The U.S. Food, Drug, and Cosmetic Act has a complex definition of food additives that comes close to any component of food introduced into U.S. commerce after 1957 and it will be addressed in the section dealing with government regulations.

II. FUNCTIONS OF FOOD ADDITIVES

Direct food additives serve several major functions. Many additives, in fact, are multifunctional (Table 83.1). The basic functions of direct food additives include the following:

A. Preservation

Food preservation techniques have advanced in the past 100 years and now include thermal processing, concentration and drying, refrigeration and freezing, modified atmosphere, and irradiation. However, the use of chemical preservatives frequently augments these basic preservation techniques and represents the most economical way for food manufacturers to ensure a reasonable shelf life for their product. Antioxidants and antimicrobial agents perform some of these functions as well.

B. Processing

Food processors are increasingly using food additives to ensure the integrity and appeal of their finished products. Emulsifiers maintain mixtures and improve texture in breads, dressings, and other foods. They are used in ice cream when smoothness is desired, in breads to increase shelf life and volume and to distribute the shortening, and in cake mixes to achieve batter consistency. Stabilizers and thickeners assist in presenting an appealing product with consistent texture. Sorbitol, a humectant and sweetener, is used to retain moisture and enhance flavor. With the removal of sugar from many foods for dietetic reasons, a substitute bulking agent is needed.

C. Appeal and Convenience

The changing eating habits of consumers, partly brought about by the large increase in the number of women who work outside the home, is creating a growing need for convenience foods. In many of these types of foods, it is essential that a variety of additives be used to provide the taste, color, texture, body, and general acceptability that are required. This need for convenience, while maintaining aesthetic appeal and taste, is becoming extremely important. Most food additives such as gums, flavoring agents, colorants, and sweeteners are included by food processors because consumers demand that food look and taste good as well as be easy to serve.

D. Nutrition

There have been tremendous advances in the knowledge of human nutrition, and consumers are increasingly aware of the value of good nutrition. Vitamins, antioxidants, proteins, and minerals are added to foods and beverages as supplements in an attempt to ensure proper nutrition for those who do not eat a well-balanced diet. In addition, additives such as antioxidants are often used to prevent deterioration of natural nutrients during processing. Recently more importance has been attributed to disease prevention through proper nutrition, as well as to increasing performance through sport nutrition products. On the other hand, the desire for good nutrition through a balanced diet may adversely affect consumer demand for some food additives such as fat substitutes.

Adopted from the National Academy of Sciences/National Research Council national survey of food industries, the following terms describe the physical and technical effects of various food additives:

- Anticaking agent or free-flow agent: substance added to finely powdered or crystalline food products to prevent caking, lumping, or agglomeration.
- Antimicrobial agent: substance used to preserve food that prevents the growth of microorganisms and subsequent spoilage, including fungistats, mold and rope inhibitors, antimicrobial agents, antimyotic agents, preservatives, and mold preventing agents (indirect additives).

TABLE 83.1
Food Additives and Their Functions

Food Additive	Preservation	Process Improvement	Appeal Modification	Nutrition
Anticaking agents		X	X	
Antioxidants	X		X	X
Colors			X	
Emulsifiers		X	X	X
Enzymes		X	X	
Fat substitutes				X
Flavors			X	
Humectants			X	
Leavening agents		X	X	
pH control agents	X	X		
Preservatives	X			
Processing aids		X		
Sweeteners (sugars only)	X	X	X	
Sweeteners, high intensity				X
Thickeners and stabilizers	X		X	X
Vitamins and minerals				X

- Antioxidant: substance used to preserve food by retarding deterioration, rancidity, or discoloration due to oxidation.
- Boiler water additive: substance used in a steam or boiler water system as an anticorrosion agent to prevent scale or to effect steam purity.
- Color or coloring adjunct: substance used to preserve or enhance the color or shading of a food including color fixatives and color-retention agents.
- Curing or pickling agent: substance imparting a unique flavor and/or color to food, usually producing an increase in shelf-life.
- Dough strengthener: substance used to modify starch and gluten, thereby producing more stable dough.
- Drying agent: substance with moisture-absorbing ability used to maintain an environment of low moisture.
- Emulsifier or emulsifier salt: substance which modifies surface tension in the component phase of an emulsion to establish a uniform dispersion or emulsion.
- Enzyme: used to improve food processing and the quality of finished food.
- Firming agent: substance added to precipitate residual pectin, thus strengthening the supporting tissue and preventing its collapse during processing.
- Flavor enhancer: substance added to supplement, enhance, or modify the taste and/or aroma of a food without imparting a characteristic taste or aroma of its own.
- Flavoring agent or adjuvant: substance added to impart or help impart a taste or aroma in food.
- Flour treating agent: substance added to milled flour to improve its color and/or baking qualities, including bleaching and maturing agents.
- Formulation aid: substance used to promote or to produce a desired physical state or texture in food, including carriers, binders, fillers, plasticizers, film-formers, and tableting aids, etc.
- Freezing or cooling agent: substance that reduces the temperature of food materials through direct contact.
- Fumigant: volatile substance used for controlling insects and pests.
- Humectant: hygroscopic substance incorporated in food to promote retention of moisture.
- Leavening agent: substance used to produce or stimulate production of carbon dioxide in baked goods in order to impart a light texture, including yeast, yeast foods, and calcium salts.
- Lubricant or release agent: substance added to food contact surfaces to prevent ingredients and finished products from sticking to them (direct additives), including release agents, lubricants, surface lubricants, waxes, and antiblocking agents (indirect additives).
- Malting or fermenting aid: substance used to control the rate of nature of the malting or fermenting process, including microbial nutrients and suppressants and excluding acids and alkalis.
- Masticatory substance: substance that is responsible for the long-lasting and pliable property of chewing gum.
- Nonnutritive sweetener: substance having less than 2% of the caloric value of sucrose per equivalent unit of sweetener.

- Nutrient supplement: substance necessary for the body's nutritional and metabolic processes.
- Nutritive sweetener: substance having greater than 2% sucrose per equivalent unit of sweetening capacity.
- Oxidizing or reducing agent: substance which chemically oxidizes or reduces another food ingredient, thereby producing a more stable product.
- pH control agent: substance added to change or maintain active acidity or basicity, including buffers, acids, alkalis, and neutralizing agents.
- Processing aid: substances used as a manufacturing aid to enhance the appeal or utility of a food or component, including clarifiers, clouding agents, catalysts, flocculents, filter aids, crystallization inhibitors, etc.
- Propellant: gas used to supply force to expel a product or to reduce the amount of oxygen in contact with the food in packaging.
- Sequesterant: substance which combines with polyvalent metal ions to form a soluble metal complex to improve the quality and stability of products.
- Solvent or vehicle: substance used to extract or dissolve another substance.
- Stabilizer or thickener: substance used to produce viscous solutions or dispersions, impart body, improve consistency, or stabilize emulsions, including suspending and bodying agents, setting agents, and bulking agents.
- Surface-active agent: substance used to modify surface properties of liquid food components for a variety of effects, other than emulsifiers. Including solubilizing agents, dispersants, detergents, wetting agents, rehydrating enhancers, foaming agents, defoaming agents, etc.
- Surface finishing agents: substance used to increase palatability, preserve gloss, and inhibit discoloration of foods, including glazes, polishes, waxes, and protective coatings.
- Synergist: substance used to act or react with another food ingredient to produce a total effect different from or greater than the sum of the effects produced by the individual ingredients.
- Texturizer: substance which affects the appearance or feel of the food.
- Tracer: substance added as a food constituent (as required by regulation) so that levels of this constituent can be detected after subsequent processing and/or combination with other food materials.
- Washing or surface removal agent: substance used to wash or assist in the removal of unwanted surface layers from plant or animal tissues.

III. FOOD ADDITIVE CATEGORIES

Substances that come under the general definition of direct food additive number in the thousands and include

Inorganic chemicals (e.g., phosphates, sulfiltes, calcium chloride, etc.)

Synthetic organic chemicals (e.g., dyes, benzoates, aroma chemicals, vitamin A, etc.)

Extraction products from and derivatives of natural sources (e.g., pectin, essential oils, vitamin E, etc.)

Fermentation-derived products (e.g., enzymes, citric acid, xanthan gum, etc.)

Most food additives have a long history of use; others are the result of recent research and development to fill particular requirements of modern food processing. Some are common chemicals of industry that are upgraded in terms of purity to allow their use in food.

Major categories of food additives include preservatives, colorants, antioxidants, flavors, thickeners and stabilizers, emulsifiers, acidifiers and buffers, enzymes, and sweeteners. Examples of major products in each category are shown in Table 83.2. Within this same category, products may belong to several chemical classes and offer specialized functionality (e.g., water- and oil-soluble antioxidants that include ascorbic acid and hindered phenols, respectively, and water-soluble azo dyes and water-dispersible carotenoids as food colors). Basic foodstuffs are excluded from the definition, although ingredients added to foods (e.g., high fructose corn syrup, MSG, and protein concentrates) are often included among food additives.

Certain food additives, such as colors, flavors, gums, emulsifiers, and preservatives may find use also in pharmaceutical products and in toiletries and cosmetics (e.g., toothpaste, lipstick, etc). The same Food Chemical Codex (FCC) grade as in food is typically used in these applications, however, the combined value of the additive for these other applications does not exceed 10% of food use.

Indirect food additives have no purposeful function in food and may be divided into the following categories:

- Components of adhesives (e.g., calcium ethyl acetoacetate 1,4-butanediol modified with adipic acid)
- Components of coatings (e.g., acrylate ester copolymer coatings and polyvinyl fluoride resins)
- Components of paper and paperboard (e.g., slimicides, sodium nitrate/urea complex, and alkyl ketone dimers)
- Basic components of single- and repeated-use food contact surfaces (e.g., cellophane, ethylene-acrylic acid copolymers, isobutylene copolymers, and nylon resins)
- Components of articles intended for repeated use (e.g., ultrafiltration membranes and textiles and textile fibers)

TABLE 83.2
Selected Major Food Additives

Thickeners and Stabilizers	Vitamins
Agar	Vitamin A
Alginates	Vitamin A acetate
Carageenan	Vitamin B_1
Carboxymethyl cellulose (CMC)	Thiamin hydrochloride
Casein	Vitamin B_2
Gelatin	Thiamin mononitrate
Gellan gum	Vitamin B_6
Guar gum	Pyridoxine hydrochloride
Gum Arabic	Vitamin B_{12}
Locust bean gum	Cyanocobalamin
Modified starches	Vitamin C
Pectin	Ascorbic acid
Xanthan gum	Vitamin D
	Ergocalciferol, cholecalciferol
	Vitamin K
	Menadione
Sweeteners	**Antioxidants**
Acesulfame-K	Ascorbic acid/sodium ascorbate
Aspartame	Erythorbic acid/sodium erythorbate
Dextrose	BHA (butylated hydroxyquinone)
Lactitol	BHT (butylated hydroxytoluene)
Mannitol	PG (propyl gallate)
Sorbitol	TBHQ (tert-butyl hydroquinone)
Saccharin	Tocopherols
Xylitol	Sulfur dioxide/sulfite salts
Colors	**Preservatives**
Certified food colors	Benzoic acid/benzoates
Dyes	Propionic acid/propionates
Lakes	Parabenes
Noncertified colors	Sorbic acid/sorbates
Caramel	Sulfites
Plant extracts	
Synthetic carotenoids	
Fat replacers	**Emulsifiers**
Partially or nonmetabolizable	Mono- and diglyercides
Sucrose polyester (Olestra)	Lactylated esters
Medium-chain triglycerides	Lecithin
Fat mimetics	Polysorbates
Carbohydrate based products	Propylene glycol esters
Protein based products	Sorbitan esters
Emulsifiers	Sucrose esters
Flavors	**Anticaking agents**
Aroma chemicals	Aluminum calcium silicate
Vanillin	Calcium silicate
Essential oils/natural extracts	Salts of fatty acids (stearates)
Menthol	Silicon dioxide
Flavor compositions	Tricalcium silicate
Strawberry flavor	Yellow prussiate of soda
Enzymes	**pH control agents**
Amylases (alpha-amylase, etc.)	Citric acid
Glucose isomerase	Malic acid
Pectinases	Phosphoric acid/phosphates
Proteases	Sodium citrate
Rennin	Sodium hydroxide

- Compounds controlling growth of microorganisms (e.g., sanitizing solutions)
- Antioxidants and stabilizers (e.g., octyltin stabilizers in vinyl chloride plastics)
- Certain adjuvants and production aids (e.g., animal glue, hydrogenated castor oil, synthetic fatty alcohols, and petrolatum)

In many countries, these materials are defined and regulated as contaminants. In the United States, these materials are food additives under the law. They are commonly classed as indirect food additives, but the FDA handles them in the same way as direct additives. Just as with direct additives, they may be generally recognized as safe (GRAS) substances and thereby escape explicit regulation because that status makes them, in fact, not food additives. In general, however, regulation of these materials is more extensive and more rigorous in the United States than in other counties. As might be expected, packaging materials which have been used for a long time, such as glass, receive less close scrutiny than more newly introduced materials and those materials just being proposed for introduction.

IV. FOOD ADDITIVE SUPPLY INDUSTRY

Food additive suppliers are an important part of the food manufacturing system, supplying products to both commodity processors and food processors (Figure 83.1). Practically every food manufacturing operation depends to some degree on the use of food additives, but the range of additives necessary for the formulation varies (Table 83.3).

Overall, the food additive industry appears to be highly fragmented, consisting of more than 500 companies supplying a variety of chemically and functionally different products that serve a common end-use market — the food industry. However, suppliers tend to be either highly specialized participants in the major product categories (e.g., Novozimes with enzymes, Sensient Colors, Inc. with certified food colors, etc.) or large chemical companies that offer food-grade versions of a few industrial products (e.g., Lonza's emulsifiers, FMC Corp.'s cellulose derivatives). Manufacturers are typically involved in supplying additives in a limited number of product categories (e.g., colors, vitamins, or enzymes) or servicing selected food sectors (e.g., processed meats, dairy-based products, or bakery products). While a company or group or companies may tend to dominate sales in each of the specific categories (e.g., Novozimes with enzymes, or Rhodia with vanillin), no single company or small group of companies dominates the entire food additive industry.

Forty years ago it was relatively easy and lucrative for chemical companies to stumble into the role of food additive supplier and reap profits by upgrading the purity and quality of chemicals originally developed for other industrial

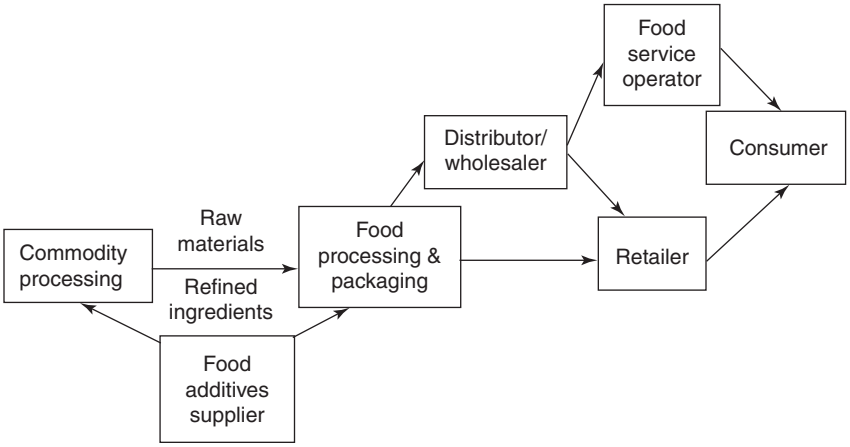

FIGURE 83.1 Integrated view of the U.S. food manufacturing system.

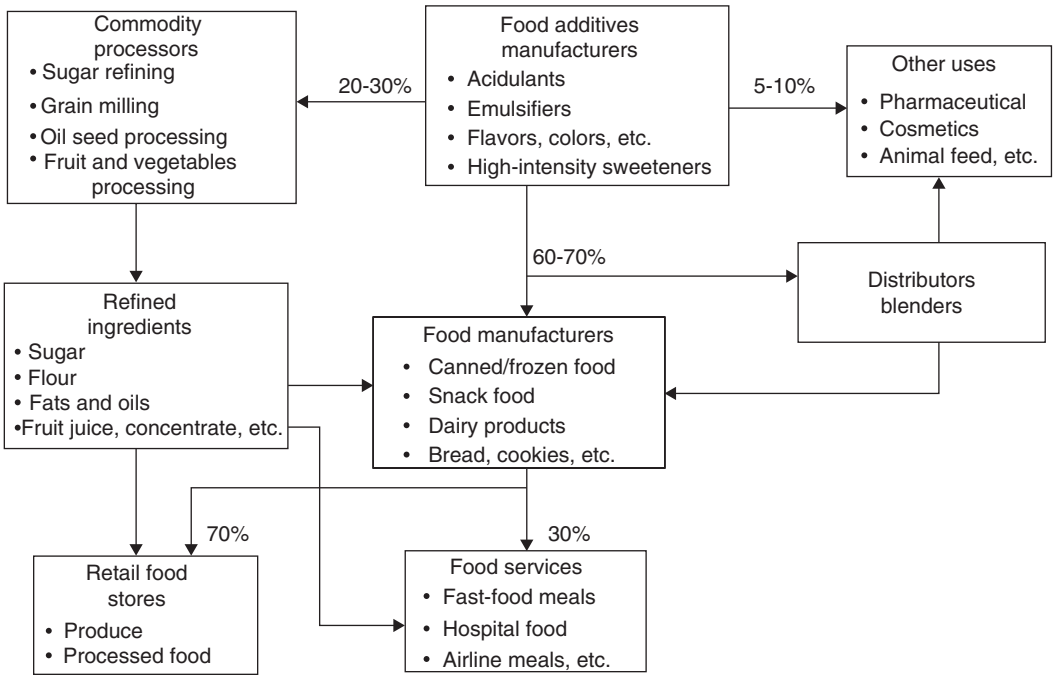

FIGURE 83.2 Food additives, pattern of use in food, and other applications.

markets. Today, however, the long time and high costs associated with gaining regulatory approval (estimated 5–10 years and $15–$40 million) have taken away the incentive to commercialize products from basic research. As a result, food additives represent only a minor portion of large chemical companies' overall business. Most large chemical companies that supply food additives, such as FMC, Monsanto, Lonza, Hoffman-La Roche, Degussa, BASF, Rhoclia, Nutrinova, and Eastman Chemicals, have diversified chemical operations, with perhaps only 5% or less of total sales generated by food additives.

Figure 83.2 depicts the food additive industry structure and the flow of its products. Some 60–70% of food additives are used in the manufacture of food: about 20–30% are used in commodity processing operations such as flour milling, meat packing, oilseed crushing and refining, vegetable packaging, animal feeds, and fruit juice processing; and the remaining 5–10% are used for things such as pharmaceuticals and cosmetics. In addition to basic additive producers, the food additives industry includes companies that specialize in compounding of specialty product mixes, and national and local distributors (Figure 83.2). Specialty compounders formulate mixed products for the food industry such as dairy ingredients, baker's mixes, curing blends, thickener and emulsifier blends, cheese aids, ethnic flavors, total seasoning packages, and spice blends. They are generally very knowledgeable about additive and ingredient properties and are experienced in food technology overall. Compounding companies are often relatively small, sell directly to a food processor, are highly service oriented, and market product lines that have a high level of perceived differentiation. Their formulations offer convenience and enjoy higher gross profit margins than single food additive sales.

Distributors also play an important role in the distribution of food additives. Additive producers typically use distributors to service their smaller accounts or for warehousing and servicing of accounts that geographically the producers cannot cover effectively or economically.

V. RESEARCH AND DEVELOPMENT

Because there are so many dissimilar and unconnected segments of the food additives industry, the participating companies exhibit different approaches to research and development (R&D). Many stress applications research to uncover new niches for existing additives or modifications of currently FDA-approved additives. Some emphasize innovative research or new, high-value products, but these are very few because of the cost and time for basic research, development, regulatory approval, and market acceptance of a new food additive product. For example, NutraSweet's aspartame product took more than 11 years to gain FDA approval; acesulfame-K took 6 years for FDA approval and a total of 21 years since development. The total costs of research, development, and approvals for aspartame were close to $25 million.

Procter & Gamble's Olestra™ was in research and development for 20 years, yet wasn't submitted to the FDA until June 1987. After spending over $200 million

in development costs and waiting for more than 8 years for FDA approval, the fat substitute received approval in January 1996. Approval of the food additive is limited to snacks such as potato chips and tortilla chips. Moreover, it has a special regulatory constraint: Olestra™-containing products require fortification with vitamins A, D, E, and K to compensate for the limited absorption of these fat-soluble vitamins, and the products must be labeled with the statement. "This product contains Olestra. Olestra may cause abdominal cramping and loose stools. Olestra inhibits the absorption of some vitamins and other nutrients. Vitamins A, D, E, and K have been added."

In general, only large, well-financed companies can afford the R&D efforts necessary to bring a new food additive product to market. Small companies simply are unable to deal with the complexity, costs, and required time. Personnel staffing requirements for R&D of food additives vary significantly. Because statistics for the food additives business of most producing companies are not reported separately, only estimates can be made. R&D expenditures as a percentage of sales typically range from 1% or less for products such as preservatives, to 5–6% for more technically oriented products such as fat substitutes and certain natural colors, and 5–10% for flavors.

VI. MANUFACTURING

Manufacturing processes for food additives vary widely in their nature and technological sophistication. Some of the specific processes for the more important food additives are described in later sections of this report. A common characteristic of all food additives manufacturing, however, is that the products must be made to a high degree of purity and under sanitary conditions similar to those of food processing plants. Production equipment must be dedicated to food additive products and cannot be used for other industrial production. Plants producing food additives are subject to periodic inspection by the regulatory agencies. Typically chemical additives made by synthesis (e.g., BHT, saccharin) or by fermentation (e.g., aspartame, microbial enzymes, xanthan and gellan gums) require a high level of capital investment. The former additives have industrial uses and are likely to share their basic production costs with the industrial-grade material; a small portion of the total production is then upgraded and purified to food-grade quality in separate dedicated plant units. Accurate long-term market forecasts for products are essential in order to minimize the risk associated with capital investment decisions in single-purpose plants. Other participants in the food additives business that are not involved in chemical production on a large scale for the extraction and purification of natural products, small-scale synthesis of aromatic chemicals, and for flavor and ingredient compounding have much lower capital requirements.

VII. GOVERNMENT REGULATIONS

A. United States

The application of food additives is highly regulated worldwide, although regulatory philosophy, the approval of specific products, and the level of enforcement differ from country to country. Basic regulations in the United States, Western Europe, and Japan are described below. These three major industrial regions are the largest consumers of food additives. With only 13% of the world's population, these countries account for more than two-thirds of the food additive market.

The U.S. Food and Drug Administration (FDA) is the principal U.S. regulatory body controlling the use of food additives. It does so through the 1958 Food Additives Amendment to the Food, Drug & Cosmetic (FD&C) Act of 1938. The amendment was enacted with the threefold purpose of

1. Protecting public health by requiring proof of safety before a substance can be added to food.
2. Advancing food technology.
3. Improving the food supply by permitting the use of substances in food that are safe at the levels of intended use.

According to the legal definition, food additives that are subject to the amendment include "any substance the intended use of which results or may reasonably be expected to result directly or indirectly in its becoming a component or otherwise affecting the characteristics of any food." This definition includes any substance used in the production, processing, treatment, packaging, transportation, or storage of food.

If a substance is added to a food for a specific purpose it is referred to as a direct additive. For example, the low-calorie sweetener aspartame, which is used in beverages, puddings, yogurt, chewing gum, and other foods, is considered a direct additive.

Indirect food additives are those that become part of the food in trace amounts due to its packaging, storage, or other handling. This class includes all materials that would not usually become part of food if man could completely control food production. In practice, indirect food additives are found in agricultural produce in quantities well within acceptable and legal tolerances. For example, minute amounts of packaging substances may find their way into foods during storage. A variety of chemicals, including plastic monomers, plasticizers, stabilizers, printing ink, and other substances, migrate at extremely low levels into foods. Lead and tin are perhaps the main concerns associated with packaging materials. The storage of acidic foods in inappropriate containers can result in the leaching of toxic heavy metals, such as zinc and copper, into the food. Food packaging manufacturers therefore must prove to

the FDA that all materials coming in contact with food are safe before they are permitted for use in such a manner.

A wide variety of chemicals are used in modern agricultural practice. Residues of these chemicals can linger in raw and processed foods, although federal regulatory agencies evaluate the safety of such chemicals, and regulate and monitor their use on food products. The major categories of agricultural chemicals include insecticides, herbicides, fungicides, fertilizers, and veterinary drugs, including antibiotics.

Industrial and/or environmental pollutants may migrate into foods in small amounts. On rare occasions, hazardous levels of polychlorinated biphenyls (PBCs) and polybrominated biphenyls (PBBs) have been found in foods.

For regulatory purposes, all food additives fall into one of three categories:

1. Generally recognized as safe (GRAS) substances
2. Prior sanctioned substances
3. Regulated direct/indirect additives

GRAS substances (approximately 700 compounds) are a group of additives regarded by qualified experts as "generally recognized as safe." These substances are considered safe because their past extensive use has not shown any harmful effects. Prior sanctioned substances (approximately 1400 compounds) are products that were already in use in foods prior to the 1985 Food Additives Amendment and are therefore considered exempt from the approval process. Some prior sanctioned substances also appear on the GRAS list. This is the grandfather clause of the amendment.

The FDA is involved in an ongoing review of the GRAS and prior sanctioned substance lists to ensure that these substances are tested by means of the latest scientific methods. Likewise, the FDA also reviews substances that are not currently included on the GRAS list to determine whether they should be added.

All other additives are regulated — that is, a specific food additive petition must be filed with the FDA requesting approval for use of the additive in any application not previously approved. A food or color additive petition must provide convincing evidence that the proposed additives perform as intended. Animal studies using large doses of the additive for long periods are often necessary to show that the substance will not cause harmful effects at expected levels of human consumption.

In deciding whether an additive should be approved, the agency considers the composition and properties of the substance, the amount likely to be consumed, its probable long-term effects, and various other safety factors. Absolute safety of any substance can never be proven. Therefore the FDA must determine if the additive is safe under the proposed conditions of use, based on the best scientific knowledge available. In addition, the FDA operates an Adverse Reaction Monitoring System (ARMS) to help serve as an ongoing safety check of all additives. The system monitors and investigates all complaints by individuals or their physicians that are believed to be related to specific foods, food additives, or nutrient supplements.

Color additives for food represent a unique and special category of food additives. They have historically been so considered in legislation and regulation. The current legislation governing the regulation and use of color additives in the United States is the Food, Drug & Cosmetic Act of 1938, as amended by the Color Additive Amendment of 1960. Colors permitted for use in foods are classified either as certified or exempt from certification. Certified colors are man-made, with each batch being tested by the manufacturer and the FDA (certified) to ensure that they meet strict specification for purity.

Color additives that are exempt from certification include pigments derived from natural sources. However, color additives exempt from certification also must meet certain legal criteria for specifications and purity. One of the features of the Color Additive Amendment of 1960 was the equal treatment of synthetic colors and the so-called natural colors in respect to pretesting requirements. Moreover, currently all color additives, certified and uncertified ("natural"), are designated on the label as artificial color.

Flavor substances are regulated somewhat differently, and the rules are less restrictive. However, the use of aroma chemicals as flavor ingredients is regulated under laws that may differ from country to country. Following the lead of the United States, inclusion on a positive list that spells out which chemicals are permitted for food use has become the prevalent legislation for regulating flavor chemicals worldwide. The United States has a list of flavor substances that are deemed GRAS based on the history of use, review of available toxicology, and the opinion of experts. These GRAS lists (through GRAS 20) have been compiled since 1977 by the expert panel of the Flavor Extracts Manufacturers Association of the United States (FEMA). Over the years, more than 1800 materials appeared on FEMA lists. Formed in 1909, FEMA is an industry association that originally started pursuing voluntary self-regulation and later was granted quasi-official status on regulatory matters regarding flavor chemicals by the FDA. The FEMA expert panel was formed in 1960. This independent panel, composed of eminently qualified experts recruited from outside the flavor industry, has expertise in human nutrition, physiology, metabolism, toxicology, and chemical structure-activity relationships. Most industrial countries more or less follow the U.S. system.

Although the FDA has primary jurisdiction over food additives, clearance for use of additives in certain products must be obtained from other government agencies as well. For example, the U.S. Department of Agriculture (USDA) through the Meat Inspection Division (MID) exercises jurisdiction over additives and ingredients for meat and poultry; the Bureau of Alcohol, Tobacco, and

Firearms (BATF) of the U.S. Department of the Treasury controls the ingredients used in alcoholic beverages.

The standards of identity specify in detail what can and cannot be packaged under a given product name. Standards of identity exist for milk, cream, cheese, frozen dessert, bologna products, cereal products, cereal flours, pasta, canned and frozen fruits and vegetables, juices, eggs, fish, nuts, nonalcoholic beverages, margarine, sweeteners, dressings, and flavorings. An approved food additive in the United States may be precluded from use in certain foods characterized by the standards of identity unless the additive is specifically required by or is listed as an optional ingredient in the standards. The standards of identity establish the ingredient composition of a given food, which can then be labeled by its common name. If the manufacturer does not adhere to the standard composition, the food must be labeled "imitation."

The Federal Insecticide, Fungicide and Rodenticide Act (FIFRA), which was issued in 1972 and amended in 1988, covers pesticides used on raw agricultural products. The FDA, however, is responsible for enforcing tolerances for pesticide residues that end up in food products.

In the United States, label disclosure of food additives is mandated with few exceptions. Under FDA, USDA, and BATF regulations, the ingredients of a food or beverage must be stated on the product label in decreasing order of predominance. For many direct additive categories, chemical constituents must be identified by their common names and the purpose for which they were added.

One of the recent regulations involving the food industry, as well as food additive manufacturers, came with the passing of the Nutrition Labeling and Education Act of 1990 (NLEA), which amends the Federal Food, Drug & Cosmetic Act, to make nutrition labeling mandatory for most FDA-regulated foods. The nutrition labeling regulations issued by the FDA and the USDA Food Safety and Inspection Service (FSIS) required compliance by August 8, 1994.

The FDA's nutrition labeling regulations focus on nutrients currently accepted as significantly affecting consumer health. The serving size is the basis for reporting each food's nutrient content. Serving sizes are defined for most foods reflecting the amount people actually eat and are shown in both common household and metric measures. The amount per serving of the following nutrients are required to be included on labels: total calories, calories from total fat, total fat, saturated fat, cholesterol, total carbohydrates, complex carbohydrates, sugars, dietary fiber, protein, sodium, vitamin A, vitamin C, calcium, and iron. Listing other essential vitamins and minerals such as thiamin, riboflavin, and niacin, among other nutrients, is optional. A simplified nutrition label format is allowed for foods containing insignificant amounts of more than half the required nutrients. The minimum label includes total calories, total fat, total carbohydrates, protein, and sodium.

The FDA regulation requires the nutrition content be based on amounts of the product customarily consumed, and expressed in both common household and metric measures (e.g., 1 cup and 240 ml). Serving size reference amounts are based on food consumption survey data on amounts of food commonly consumed per eating occasion by persons 4 years of age and older. Manufacturers must follow the procedures to convert the reference amounts to serving sizes appropriate for their specific products. Any package containing less than two servings is considered a single-serving container.

Nine terms are presently allowed by the FDA to describe a food, including free, low, high, source of, reduced, light/lite, less (or, for calories, fewer), more, and fresh. Claims for cholesterol are tied to levels of saturated fat in the food. Meal-type products are not allowed to use the terms reduced.

Health claims are allowed for only the following nutrient/disease relationships:

- Calcium and osteoporosis
- Sodium and hypertension
- Unsaturated fats, low cholesterol intake, and cardiovascular disease
- Dietary lipids and cancer
- Fiber-containing grain products, fruits and vegetables, and cancer
- Fruits, vegetables, and grain products that contain fiber and risk of coronary heart disease
- Fruits and vegetables and cancer
- Folic acid and neural tube defect
- Sugar alcohols and dental caries
- Psyllium-containing foods and the risk of heart disease (when consumed as part of a diet low in saturated fat and cholesterol
- Soy protein and reduced risk of coronary heart disease

Changing dietary recommendations and labeling requirements impact food additive producers both positively and negatively. Products used for fat-sparing/substitution (e.g., hydrocolloids, starches, other fat substitutes) and low-calorie sweeteners fare well, as food manufacturers strive to lower the caloric and saturated fat content of their products. Natural colors (provided they can be substituted), as well as other natural or seemingly natural products will also be in higher demand so as to provide consumers with a more healthy and nutritious product (or at least one with a more healthy-sounding label).

The Food Additives Amendment also contains what is known as the Delaney clause, which mandates the FDA to ban any food additive found to cause cancer in man or animals, regardless of dose level or intended use. The clause applies not only to new food additives but also to those in use prior to 1958. The Delaney clause is totally inflexible

in that it does not recognize any threshold level below which the additive might not present a health hazard. Thus it has caused a number of problems for the food industry and for food additives. Certain additives (e.g., the sweetener cyclamate, etc.) have been banned after they were found to be potential carcinogens — even though feeding tests in animals at massive dose levels may not bear any correlation to the potential risk to man of chronic ingestion at very low levels. Were it not for a moratorium mandated risk to man of chronic ingestion at very low levels. Were it not for a moratorium mandated by Congress, saccharin would also have been banned in the United States several years ago by the FDA in compliance with current U.S. food laws. Although congressional sentiment has been running for some time in favor of repealing the Delaney clause, to date, attempts to replace it with a more practical and realistic law and have been unsuccessful.

1. Approval Process

A new substance gains approval for food use through the successful submission of a food additive petition that must document the following:

- Safety, including chronic feeding studies in two species of animals.
- Intended use.
- Efficiency data at specific levels in the specified food system.
- Manufacturing details and product specifications.
- Methods for analysis of the substance in food.
- Environmental impact statement.

Quite frequently, this process can be lengthy — up to 10 years in the case of aspartame and Olestra™ — and costly in terms of man-hours and dollars. There is little doubt that every level of the U.S. food additives business is affected by regulations, and operates with a constant awareness of the importance of FDA decisions. Not only is the introduction of a new food additive impossible without FDA approval, but the additives in use are under constant scrutiny by the regulatory agency and remain vulnerable to new unfavorable toxicology findings. While the barring of an additive may create opportunities for suppliers to develop new or substitute materials, the potential market is often too small to create sufficient incentive, and the loss of the ingredient may cause havoc within affected sectors of the food industry. For example, the ban on cyclamates, followed by the close call on saccharin, almost caused the demise of the diet soft-drink industry. The well-recognized need for alternative safe sweeteners undoubtedly was a stimulus for G.D. Searle (now Monsanto's NutraSweet Kelco division) to engage in a 10-year effort to have aspartame cleared for food use.

B. European Union (EU)

Food additives intended for human consumption are regulated by the member states as described in Directive 89/107/EEC of December 21, 1988. The EU food additive law recognizes 106 food additives. Later, several amendments and adaptations of the directive were introduced or proposed including

- A list of additives the use of which is authorized to the exclusion of all others.
- The list of foodstuffs to which these additives may be added, the conditions under which they may be added and, where appropriate, a limit on the purpose of their use.
- The rule on additives used as carrier substances and solvents, including their purity criteria.
- In 1990 the commission proposed a first specific directive relating to sweeteners and food additives other than colors and sweeteners. The Sweetener Directive took effect on July 30, 1994.

Efforts have been toward a uniform registration process so that a registration obtained in one country would be valid in all EU member countries. The new EU food additive law, however, will not prevent individual countries from asking for additional or country-specific requirements for new product registrations. At the EU level, several institutions and groups are involved in the development of food additives law, including the Scientific Committee for Food (SCF), one of the institutions of the European Commission which deals with safety issues, representatives from different national professional organizations, representatives from the food industry, retailers, etc. The Standing Committee on Foodstuffs ensures close cooperation between the commission and the member states.

The EU rules for the evaluation, marketing, and labeling of novel food such as genetically modified foods are also being developed. The new marketing rules would also oblige manufacturers to obtain permission before placing new foods or ingredients on the market, with the exception of products that are substantially equivalent to existing foods. The new rules have still to be cleared by the European Parliament, which has the power to veto under the new co-decision procedure introduced in 1995.

In many countries, additives must be declared in the labeling. Within the EU, some additive groups have been uniformly codified with "E" numbers for the orientation of consumers. Some countries, such as Germany, have gone further, adopting regulations on an acceptable daily intake (ADI) basis that build on the latest toxicological knowledge. Some examples of "E" numbers are presented in Table 83.4.

Under EU food law, any claim that a food has the property of preventing, treating, or curing a human disease

TABLE 83.4
Selected EU Food Additives and Codes

Colorants	
E100	Curcumin
E101	Riboflavin
E102	Tartrazin
E110	Yellow no. 6
E120	Carmin
E150	Caramels
E160	Annatto
E160a	Beta-carotene
E160c	Paprika
E162	Beetroot red (betanin, betanidin)
E163	Enocyanin (grape-skin extract)
Preservatives	
E200	Sorbic acid
E201	Sodium sorbate
E202	Potassium sorbate
E203	Calcium sorbate
E210	Benzoic acid
E211	Sodium benzoate
E212	Potassium benzoate
E281	Sodium propionate
E282	Potassium propionate
E283	Calcium propionate
Antioxidants	
E300	L-ascorbic acid (vitamin C)
E307	Synthetic alpha-tocopherol (vitamin E)
E311	Propyl gallate (PG)
E320	Butylhydroxyanisole (BHA)
Thickeners and stabilizers	
E401	Sodium alginate
E415	Xanthan
E420	Sorbitol
E440a	Pectin

E322	Lecithin
E471	Mono- and diglycerides of fatty acids
E475	Polyglycerol esters of fatty acids
E481	Sodium steroyl-2 lactilate

or condition, or any implication of such properties, is prohibited. This aspect of the law has been strictly enforced in all member states of the EU. As early as 1980, the European Commission recognized that the area of food claims required harmonization and circulated the first proposal for a directive. By the end of 1998, this approach had not succeeded.

Recently the introduction of genetically modified (GM) corn and soy into Europe has caused considerable activity within governments and consumer organizations. European Parliament and Council Regulation no. 258/97 on novel foods and novel food ingredients requires prior approval of foods and food ingredients containing or consisting of a GM organism, and food and food ingredients produced from, but not containing GM organisms. More recently, Council Regulation 1139/98 came into force, requiring that any product containing GM soy or corn, or derivatives of GM soy or corn containing protein or DNA, must be labeled with the statement "produced from genetically modified soy" or "produced from genetically modified maize." However, refined oils or lecithin that are very unlikely to contain GM protein or DNA are exempt from such labeling statement requirements.

A further labeling change that came into force in February 2000 is the quantitative declaration of ingredients (QUID). This applies to foods and beverages with more than one ingredient, with very few exceptions. The quantity of ingredients, expressed as a percentage of the food or drink, must appear in or immediately next to the name of the food or in the list of ingredients next to the ingredient concerned.

C. JAPAN

In Japan, the Food Chemistry Division of the Ministry of Health and Welfare (MHW) has jurisdiction over food additives through the Food Sanitation Law. It was in 1948 that the term "food additive" appeared in the law (in the Food Sanitation Law) and a positive list of food additives was created in Japan. It was the first positive list created in the world, and it did not distinguish between synthetic or natural additives. Several amendments were adopted later. Amendments to the regulations, as well as additions or deletions to *Kohetisho* (the Japanese Codex of Food Additives), were mostly influenced by two major objectives: protection of food sanitation and customer safety, and harmonization with international regulatory requirements.

In the Food Sanitation Law, the term "additive" means anything added to, mixed into, permeating, or otherwise put in or upon food for the purpose of processing or preserving it. Most discussions on regulating food additives in Japan have been related to defining what food additives should be under legal restriction and on labeling requirements. Very often in these discussions, differentiating "synthetic" and "natural" food additives had been at issue. In Japan, those two generally used terms have often misled customers into a blind belief in natural food additives. However, regulatory bodies, as well as the food additive industry, no longer distinguish additives with these terms. The latest amendment of the law (May 24, 1995) includes deletion of the term "chemically synthesized substances." Thus "natural" food additives are regulated under the amended law (being enacted from May 24, 1996), unless they are listed as "existing food additives." The MHW then disclosed the list of "existing food additives" on August 10, 1995.

Under the amended Japanese Food Sanitation Law (1995), substances that are permitted for use as food additives fall into four categories listed below:

- Substances that are generally recognized as food (about 70 substances).
- Natural-based flavors (about 580 substances).

- Natural-based substances that are recognized as safe to human health on the basis of actual results for use as food additives (about 490 substances).
- Synthetic substances that are recognized as safe to human health on the basis of the results of safety evaluations (about 350 substances).

The amended law requires that any new substances, regardless of whether they are natural-based or synthetic, be verified to be safe to human health through safety evaluations and then approved by MHW before being used as food additives. Also, it is required, that the type of substance and the intended purpose of addition be labeled on the surface of food containers or packaging.

However, in general, data requirements for natural additives are still not as strict as those for chemical substances. Natural food additives reported to the MHW are listed in a table separate from the conventional positive list for chemical food additives. There are about 1200 items in the natural additive list, while the conventional list contained 349 compounds as of 1992.

VIII. TRENDS AND ISSUES

While there are many differences in food tastes and preferences among consumers, the major trends driving the food additives industry appear to be very similar:

Concern for health, nutrition, naturalness, quality.
Food safety, free of contaminants.
Desire for convenience.
Price-value relationship.

Growing awareness of the connection between diet and diseases such as cancer and heart disease has caused consumers to reexamine their diets and lifestyles and seek healthier alternatives. Consumer desire for healthier, more nutritious foods favors natural additives and ingredients (and those that are perceived as natural), as well as those that reduce calories, sodium, cholesterol, and the overall fat in foods. Fortification with the "right level" of vitamins, amino acids, and trace minerals is important, and additives that sound natural (e.g., gelatin, pectin, vitamins, etc.) versus chemical (e.g., potassium benzoate, butylated hydroxyanisole, etc.) have a more favorable consumer image.

The shift away from commodity to more processed, higher-value food products favors an increased use of additives in processing. Additives that are perceived favorably by consumers as healthy or natural foods are likely to grow faster. Finally, demands are high for fat replacers, high-intensity sweeteners, low-calorie bulking agents, certain gums, freeze/thaw stabilizers, and natural flavors.

Sales of ingredient and additive blends will dominate in the future. The synergistic effects that enhance the functionality of these materials, while reducing the quantity needed, will play an ever-more significant role in formulated foods. Information on these blends will be scarce, because they will be developed in house by food additive suppliers and food manufacturers wishing to maintain confidentiality in order to optimize exclusive commercial benefit. Other issues affecting the growth and broadening of the food additives industry include increasing government regulatory activity; increasing R&D and legal expenses; and the great length of time needed to perfect, gain approval for, and market a new food additive product.

In addition to traditional processed food products, a variety of health-related products known as "functional foods" and "nutraceuticals" have appeared on the market. Functional foods are food products that improve performance or provide a health benefit beyond meeting the basic nutritional needs of humans. Although functional foods are consumed for their taste, aroma, or nutritional value, they are also consumed by health conscious adults for their perceived benefits in preventing the onset of degenerative diseases such as arthritis, cancer, or heart disease.

Nutraceuticals are specific vitamins, minerals, amino acids, herbs and other botanicals, or constituent parts thereof that are taken in oral form to promote natural ways of preventing or treating various degenerative disease conditions. Nutraceuticals differ from functional foods in that they are only consumed for their health benefits rather than for taste, aroma, or nutritive value. In the United States nutraceuticals will have to overcome regulatory constrained before they can gain a large market. In contrast, in Japan and several countries in Europe the concept of nutraceuticals is well established, both in terms of regulations and consumer acceptance.

The safety of the food supply continues to receive a great deal of attention from the press, the public, and the governments. In 1993, an outbreak of food poisoning in the United States, eventually traced to undercooked beef, caused fundamental changes in regulatory policies and demonstrated to food processors the need for increased caution against food pathogens. The recent European outbreaks of bovine spongiform encephalopathy (BSE), known as "mad cow disease," have created more serious and worldwide concerns about cattle-derived food products, including some dietary supplements (e.g., gelatin capsules) and personal care products.

Fast-paced lifestyles will continue to drive the demand for savory, high-quality convenience foods. Microwaveable and shelf-stable products that are tasty and healthy require additives such as specialized flavors, colors, and stabilizers to enhance/maintain quality and will result in continuing growth of the market for these additives.

The concept of value-added products is also of great interest to food processors as foods with added value, or at least perceived added value (e.g., low-fat, low-calorie, vitamin fortified, more convenient form/package, perceived prevention against particular diseases), garner higher margins.

Therefore consumption of additives that can aid in adding value to processed foods will continue to increase.

Following trends in the United States, the European market shows increased interest in ethnic foods and vegetarianism. The motivation in both cases is to promote health. Also, more products are being introduced which are aimed at very specific groups. These include children, teenagers, women, and in particular the growing population of elderly persons.

IX. DESCRIPTION OF MAJOR FOOD ADDITIVES

Direct food additives comprise more than 30 types. With about 3000 food additives, including more than 1800 flavoring substances currently approved for use in the United States (and more petitioning for approval), it would be difficult in a chapter such as this to discuss each and every substance. Ten major food additives were selected for discussion in this chapter.

A. Sweeteners

Sweeteners are used in formulated foods to impart sweetness and to perform several other functions. They render certain foods palatable and mask bitterness; add flavor, body, bulk, and texture; change the freezing point and control crystallization; control viscosity, which contributes to body and texture; and prevent spoilage. Certain sweeteners act as preservatives by binding moisture in food that is required by detrimental microorganisms. Alternatively, some sweeteners can serve as food for fermenting organisms that produce acids that preserve the food, thus extending shelf life by retaining moisture. These auxiliary functions must be kept in mind when considering applications for artificial sweeteners.

Sweeteners can be classified in a variety of ways:

- Nutritive or nonnutritive. Materials either are metabolized and provide calories, or are not metabolized and thus are noncaloric.
- Natural or synthetic. Commercial products that are modifications of a natural product, for example, honey or crystalline fructose, are considered natural.
- Regular or low-calorie/high-intensity. Although two sweeteners may have the same number of calories per gram, one may be considered low-calorie or high-intensity if less material is used for equivalent sweetness.
- As foods. For example, fruit juice concentrates can impart substantial sweetness.

Sweetness is measured via sensory methods by taste panels. It is a subjective perception influenced by a multitude of variables including the temperature of the food being tasted, pH, other flavors and ingredients in the food, physical characteristics of the food sweetener, concentration, rate of sweetness development, and permanence of sweetness and flavor. Also, results can vary depending on the foods consumed prior to testing (even several hours before testing), the flavors to which the taster is accustomed, tasting experience of the panelist, time of day, and the physical surroundings in the test room.

Sucrose, commonly known as table sugar (or refined sugar), is the standard against which all sweeteners are measured in terms of quality of taste and taste profile. It is consumed in the greatest volume of all sweeteners. Sucrose, high-fructose corn syrup (HFCS), and other natural sweeteners (e.g., molasses, honey, maple syrup, and lactose) are food commodities and are not considered as food additives, therefore they will not be covered here. The discussion that follows is limited to the polyol alternative sweeteners and the high-intensity sweeteners.

1. Polyols

Polyols (sugar alcohols or polyalcohols) are chemically reduced carbohydrates. These compounds are important sugar substitutes that are utilized where their different sensory, special dietary, and functional properties make them desirable. Also polyols are utilized in low-calorie food formulations. The sweetness of polyols relative to sucrose and their caloric values are shown in Table 83.5. Moreover, because polyols are absorbed more slowly from the digestive tract than is sucrose, they are useful in certain special diets. When consumed in large quantities (in excess of 25–50 g/day), however, they have a laxative effect, apparently because of the comparatively slow intestinal absorption. In the EU countries, if a food product contains more than 10% by weight of a polyol, a warning statement must be added to the label stating that excessive consumption may induce a laxative effect.

In the United States food products sweetened with polyols and containing no sucrose can be labeled as "sugarless," "sugar free," or "no sugar" but must also bear the

TABLE 83.5
Relative Sweetness and Calorie Value of Polyols

	Relative Sweetness	Caloric Value
Polyol	(sucrose = 100)	(U.S. allowance; kcal/g)
Erythritol	60–70	0.2
Hydrogenated starch Hydrolysates	25–50	3.0
Isomalt	45–65	3.0
Lactitol	40	2.0
Maltitol	90	3.0
Mannitol	70	1.6
Sorbitol	50–70	2.6
Xylitol	100	2.4

statement "Not a reduced calorie food," "Not a low calorie food," or "Useful only for not promoting tooth decay."

Sorbitol occurs naturally many edible fruits and berries including pears, apples, cherries, prunes, and peaches. Its nontoxic nature has long been recognized. In 1974 the FDA included sorbitol as one of the first four chemicals in its revised list of GRAS substances.

Sorbitol is only 70% as sweet as sucrose. However, it has many functional properties desirable in a sweetener, such as bulking agent ability, high viscosity (contributing to body and texture), hygroscopicity (resulting in its humectant as well as its softening nature), cool taste, sequestering ability, and crystallization modification (retardation). Because sorbitol can be digested without insulin and is also noncarinogenic, it is used as a sugar substitute in diabetic and sugarless foods and candies.

In general, sorbitol is used in foods to aid retention of product quality during aging, or to provide texture or other product characteristics to the formulation. In its major applications — sugarless chewing gum, candies, and mints — liquid sorbitol is used primarily as a bulking agent and not for its sweetness. Sorbitol's noncariogenic nature and the fact that it does not promote tooth decay may account for its wide use in these applications.

Mannitol is only about 70% as sweet as sucrose and is also noncariogenic. Because of its nonhygroscopic nature, mannitol is used as a dusting powder and anticaking agent, besides its special dietary food application. The highest demand for mannitol is in sugarless chewing gum and sugar-free chocolates. However, mannitol has a more serious laxative effect than sorbitol and a warning label is required when consumption is likely to exceed 20 g/day.

Xylitol is a five-carbon polyol with sweetness similar to sucrose. It is found in small amounts in a variety of fruits and vegetables, and is formed as a normal intermediate in the human body during glucose metabolism.

Xylitol has good solubility, blends well with foods, and has a lower melting point than sucrose, an advantage in the manufacture of confectionery products. There is also evidence that xylitol is not only noncariogenic but reduces tooth decay when used as a replacement for sucrose. It is mainly used in compressed candies, chewing gum, and over-the-counter pharmaceutical products. Xylitol is expensive, therefore it is usually used in small amounts in combination with other sweeteners. In a blend with aspartame, the two compounds have an excellent synergistic effect. Also, xylitol is blended with other polyols to minimize undesirable properties, such as hygroscopicity or the laxative effect of sorbitol, or to improve the solubility of mannitol.

Lactitol monohydrate, a sugar alcohol, has physicochemical properties different from those of sugars. It has a sweetness value approximately one-third of that of sucrose and is therefore suitable where bulking with low sweetness is required. To increase the sweetness it can be blended with high-intensity sweeteners. It is derived from milk sugar and used as a sweetener in Japan, Israel, and Switzerland. In the United States a self-affirmation GRAS statement petition has been submitted to the FDA for its use in chocolate, confections, and baked goods.

Erythritol is about 70% as sweet as sucrose. Like other polyols, it does not promote tooth decay and is safe for diabetics. However, it is distinctive for its caloric content (the lowest of the polyols — 0.2 calories/gram) and its high digestive tolerance. Studies have shown that, due to its small molecular size and structure, more than 90% of ingested erythritol is absorbed and excreted unchanged through the kidneys within 24 hours, so that the laxative side effects sometimes associated with polyol consumption are unlikely. As a result, foods containing substantial amounts of erythritol are very unlikely to cause gaseous and laxation side effects. A recent clinical study showed that daily consumption of 1 gram per kilogram of body weight is well tolerated by adults and compared to sucrose-containing foods.

Maltitol, approximately 0.9 times as sweet as sucrose with similar sweetness and body, has application in products such as chewing gum, dry bakery mixes and chocolate. It is said to behave similarly to sucrose in chocolate making. Some believe that maltitol has the best flavor of the polyol family and it has been particularly successful as an alternative to mannitol in the manufacture of sugar-free chocolates. Also because of its heat stability and good handling properties, it is suitable for use in sugar-free baked goods. Maltitol is also increasingly being used in dairy products.

Hydrogenated Starch Hydrolysates (HSH), also known as maltitol syrup and hydrogenated glucose syrup. Hydrogenated starch hydrolysates are a mixture of sorbitol, maltitol and hydrogenated oligosaccharides. Depending on the sorbitol and maltitol content, the sweetness of HSH can vary from 0.25 to 0.5 times that of sucrose. HSH serve a number of functional roles, including use as bulk sweeteners, viscosity or bodying agents, humectants, crystallization modifiers, cryoprotectants and rehydration aids. They also can serve as sugar-free carriers for flavors, colors and enzymes. HSH have been used by the food industry for many years, especially in confectionery products.

Isomalt, approximately 0.45–0.65 times as sweet as sugar. Isomalt can be used in candies, gums, ice creams, jams and jellies, fillings and frostings, beverages and baked products. As a sweetener/bulking agent, it has no off-flavors and works well in combination with other sweeteners. Isomalt is made from sucrose and looks much like table sugar. It lacks the "cooling" effect characteristic of some other polyols. It is white, crystalline and odorless, and is more stable chemically and enzymatically than sucrose.

2. High-Intensity Sweeteners

High-intensity sweeteners, once used mainly for dietetic purposes, are now used as food additives in a wide variety

TABLE 83.6
Regulatory Status and Sweetness Relative to Sugar[a]

	Sweetness (Sucrose = 1)	U.S.	Canada	European Community	Japan
Cyclamate, Na salt	30	P	A	A	N
Aspartame	200	A	A	A	A
Acesulfame K	200	A	A	A	P
Saccharin	300	A	N[e]	A	A
Sucralose[b]	600	A	A	A	N
Thaumatin (talin)	3000	A	A	A	A
Alitame[c]	2000	P	P	P	P
Neohesperidin DC	2000	N	N	A	N
Stevioside	300	N	N	N	A
Glycyrrhizin	300	N[d]	N	N	A
Neotame	7000–13000	A	N	N	N

[a] A = approved; P = petition filed; N = not approved.

[b] Sucralose is approved in Australia, Russia, Brazil, New Zealand, Quasar, Romania, and Mexico.

[c] Alitame is approved in Australia, New Zealand, People's Republican of China, Indonesia, Colombia, and Mexico.

[d] Glycyrrhizin is approved as a flavoring, but not as a sweetener in the United States.

[e] Saccharin in Canada is limited for use in personal care products and pharmaceutical, but it is banned in foods and beverages.

of products. They are termed high-intensity because they are many times sweeter than sucrose. But because of their very low use levels, high-intensity sweeteners cannot perform other key auxiliary functions in food and often must be used in conjunction with other additives such as low-calorie bulking agents. High-intensity sweeteners are also used in pharmaceuticals, cosmetics, animal feed, and biocides. The regulatory status and sweetness relative to sugar of high-intensity sweeteners are shown in Table 83.6.

Aspartame was approved in the United States in 1981 for use in prepared foods, dry beverage mixes, and as a tabletop sweetener, and in 1983 for use in liquid soft drinks. It gained instant popularity and has become the sweetener in virtually all diet soft drinks in the United States. Aspartame has impacted not just the dietetic soft drink market but also many other sweetener markets. Its success has encouraged R&D, and FDA approval is currently being sought for its use in baked products, since aspartame can now be made heat-stable through an encapsulation process.

Aspartame first appeared in the U.S. diet soft drink market in combination with saccharin (30% aspartame and 70% saccharin). Presently about 98–99% of canned or bottled diet sodas contain 100% aspartame. However, aspartame may be replaced in many products because in 1998 other high-intensity sweeteners were approved for beverages.

Aspartame can be used in many diverse applications. It is approved for use in more than 100 countries worldwide, and more than 5000 products contain aspartame. In the United States, FDA approval is being given to more and more applications. In 1981 it was approved for use in prepared foods, dry beverage mixes, and as a tabletop sweetener and for carbonated liquid products in 1983. More recently, in 1993, FDA approval was extended to many other products, and the list of approved products now includes the following categories:

- Nonalcoholic beverages and ready-to-serve nonrefrigerated, pasteurized, aseptically packaged fruit juice beverages, including sport drinks
- Frozen desserts (dairy and nondairy)
- Refrigerated, flavored milk beverages
- Fruit and wine beverages containing less than 7% alcohol
- Yogurt-type products in which aspartame is added after pasteurization and culturing
- Refrigerated, ready-to-serve gelatin desserts
- Confectionaries (hard and soft candies)
- Baked goods, including baking mixes
- Low-alcohol beer (containing less than 3% alcohol)

Aspartame is about 200 times sweeter than sucrose. Unlike many other low-calorie sweeteners, aspartame is digested by the body to amino acids, which are metabolized normally. However, because of its intense sweetness, the amounts ingested are small enough that aspartame is generally considered noncaloric. Aspartame has a sugar-like taste, and enhances some flavors.

Before aspartame was approved by the FDA, it underwent the most rigorous review the agency ever gave a food additive. The process took approximately 10 years to complete. In early 1984, aspartame's safety in beverages was again brought into question by researchers at the University of Arizona and the Community Nutrition Institute. The FDA, however, rejected a request for further hearings, saying it was satisfied that aspartame is safe in soft drinks. More recently, some research reports show that artificial sweeteners have had no effect on lowering weight levels and suggest that artificial sweeteners may actually increase appetite and thirst. To date, these findings have not appeared to affect the American consumer's perceived benefit of low-calorie sweeteners. A few cases relating aspartame consumption to severe medical reactions have been reported in medical journals. About 4000 consumer health complaints of headaches and other reactions have been received by the FDA, allegedly due to the consumption of aspartame. The clinical validity and resultant outcome of these claims are not known at the present time.

Saccharin was discovered in 1879 and has been used as a food additive since the early 1900s. Saccharin is approximately 300 times as sweet as sucrose. Because it is acidic

and not very soluble in water, it is used primarily as its sodium salt. Saccharin combines well with other sweeteners and has an excellent shelf life. Its main disadvantages are a bitter, metallic aftertaste and concern over its safety. Saccharin is the most widely used nonnutritive sweetener worldwide and is the least expensive on a sweetness basis.

The FDA took saccharin off the GRAS list in the early 1970s as a result of a study suggesting is caused cancer in rats. A ban on saccharin used in the United States was proposed by the FDA but was stayed by Congress in 1977 because of the ensuing public uproar fueled by the fact that there was then no noncaloric sweetener to replace it. However, saccharin has now been cleared of the possibility of causing bladder cancer by a number of studies. It is banned in Canada.

Saccharin has been used primarily in soft drinks, but also as a tabletop sweetener and in a wide range of other beverages and foods. A drop in the demand for saccharin for use in soft drinks occurred in early 1985 after Coca-Cola and Pepsi-Cola substituted a major portion of their saccharin use with aspartame. However, it is still used in other products in the rapidly growing dietetic soft drink market.

In July 1988, the FDA approved the use of Hoechst AG's (now Nutrinova) acesulfame K (Sunette™) for use in chewing gum, dry beverage mixes, instant coffee and tea, gelatins, puddings, and nondairy creamers. In 1998, the FDA approved its use in nonalcoholic beverages. Acesulfame K has a rapidly perceptible sweet taste 200 times that of sucrose. It has a good shelf life and is relatively stable across temperature and pH ranges associated with the preparation and processing of foods. Baked goods, candies, and dry mixes are believed to be the most viable markets for this low-calorie sweetener. A limitation is an unusual taste detected at levels required for adequate sweetness, which will no doubt prevent its widespread use in diet soft drinks. No toxicity problems have been reported in a multitude of studies to date.

Sucralose is the only low-calorie sweetener made from sugar. Since 1991 it has been authorized for use in foods and beverages in more than 30 countries worldwide, including the USA, Canada, EU, Mexico, Brazil, Australia, New Zealand, Argentina, Lebanon, Russia, and Romania, and it received FDA approval in April 1998. Developed by Tate & Lyle (UK), sucralose is a chloroderivative of sucrose, 600 times sweeter than sucrose, made by altering the sucrose molecule. Unlike sugar, sucralose is not converted into energy by the body, and therefore contains no calories. In addition, sucralose does not promote tooth decay, and is stable in a wide range of pH and thermal process conditions. Its uses include soft drinks, dairy products, baked and extruded products, puddings, breakfast cereals, jams and jellies, canned fruit, and chewing gum.

Neotame, formed through a modification of aspartame's dipeptide base, is approximately 7,000 to 13,000 times sweeter than sugar. It is a free-flowing, water soluble, white crystalline powder that is heat stable and can be used as a tabletop sweetener as well as in cooking applications. Examples of uses for which neotame has been approved include baked goods, nonalcoholic beverages (including soft drinks), chewing gum, confections and frostings, frozen desserts, gelatins and puddings, jams and jellies, processed fruits and fruit juices, toppings and syrups. In determining the safety of neotame, FDA reviewed data from more than 113 animal and human studies.

Other high-potency sweeteners not approved for use in the United States but used elsewhere include the following compounds:

Cyclamate is 30 times sweeter than sucrose. It has a sugarlike taste, a good shelf life, and a synergistic effect when combined with saccharin or aspartame. Cyclamate was introduced as a food sweetener in the 1950s, but was banned in 1970 because of its suspected carcinogenic potential. Since then, Abbott Laboratories, the developer and main producer of cyclamate, has undertaken further studies and submitted petitions to the FDA that demonstrate its safety. In June 1985, the National Academy of Sciences concluded that cyclamate was not a carcinogen. The FDA, however, has not reapproved use of the sweetener. Cyclamate use is currently permitted in more than 40 countries, including Canada and the EU (excluding the United Kingdom). Cyclamate is used as a tabletop sweetener, in beverages, and in low-calorie foods, particularly in combination with saccharin. The use of cyclamate with saccharin gives a better taste to beverages than saccharin alone. Thus saccharin producers would welcome reintroduction of cyclamate in view of competition from aspartame.

Developed by Pfizer in 1979 (prior to selling its food business), alitame is a dipeptide made of two amino acids, L-aspartic and D-alanine. It is 2000 times as sweet as sugar, with the same taste as sugar; thus its use level would be 25–400 ppm. Composition and use patents had been issued in 32 countries. The U.S. patent expired in 2000. Alitame is approved in Australia, New Zealand, the People's Republic of China, Indonesia, and Mexico for use in food, beverage, and tabletop applications. Approval is still pending in the United States, Japan, Canada, and the EU. Potential market applications for alitame include bakery products, snack foods, candies and confectionaries, ice cream, and frozen dairy products. A reported advantage of alitame over aspartame is lower loss during cooking and heating, since it is heat-stable.

Thaumatin, a mixture of sweet-tasting proteins from the seeds of *Thaumato coccusceus daniellii*, a West African fruit, is about 2000–2500 times sweeter than sucrose. Its taste develops slowly and leaves a licorice aftertaste. Thaumatin acts synergistically with saccharin, acesulfame K, and stevioside. Potential applications include beverages and desserts; it cannot be used in baked products. Thaumatin is generally recognized in the United States as

safe for chewing gum, and the supplier. Tate & Lyle, is seeking GRAS extensions for other foods. Thaumatin has been permitted in Japan as a natural food additive since 1979. Although it is approved for use as a sweetener in the United Kingdom and Australia, it is used primarily as a flavor enhancer.

Stevia rebaudiana, a plant native to South America, is the source of the stevia extract, which is a natural sweetener. Stevia can be used in food products that require baking or cooking because of its stability in high temperatures. This product is approved for use as a sweetener in Japan, but is not approved for use in the United States. There is currently a proposal in Brazil that the sweetener be included in any sugar-free soft drink in that country. Brazil is believed to be the third-largest soft drink market in the world, after the United States and Mexico.

Dihydrochalcones (DHCs) are derived from bioflavonoids of citrus fruits and are 300–2000 times sweeter than sucrose. They leave a licorice aftertaste and give a delayed perception of sweetness. Currently DHC that is 2000 times sweeter than sucrose is produced from bitter Seville oranges by hydrogenation of natural neohesperidin (the main flavone of some oranges). In low concentration in combination with other sweeteners, it has potential uses in chewing gum, candies, some fruit juices, mouthwash, toothpaste, and pharmaceuticals. It is approved for use in Spain, the Netherlands, Germany, Belgium, and Zimbabwe.

Several other high-potency plant constituents (in addition to stevia and thaumatin) that have been considered as food sweeteners include monellin from the African "serendipity berry"; glycyrrhizin, also discussed as a flavor enhancer and extracted from the licorice root; and hernandulcin, an oil extracted from a Mexican plant. Such sweeteners could potentially be used in addition to or as substitutes for synthetic sweeteners that are now used to sweeten low-calorie or dietetic foods and beverages.

B. Thickeners and Stabilizers

Thickeners and stabilizers (also called hydrocolloids, gums, or water-soluble polymers) provide a number of useful effects in food products. The technical base for these effects results from the ability of these materials to modify the physical properties of water. Most food and beverage products largely consist of water. Water-soluble materials function as rheology modifiers, affecting the flow and feel (mouth) of food and beverage products; act as suspension agents for food products containing particulate matter; stabilize oil/water mixtures; act as binders in dry and semidry food products; and create both hard and soft gels in food products that require this physical form.

During the 1990s, fat replacement (discussed in detail in a later section) became a major application for modified starches and gums as these additives provide unique texturizing, bulking, and emulsifying properties. Moreover, natural gums have been preposed as good sources of dietary fiber. Thickeners and stabilizers are generally used in very small amounts in most food products (e.g., 0.15% in jam, 0.35% in ice cream, and 1–2% in salad dressings). Table 83.7 indicates the primary functions of many food thickeners.

Two principal classes of these materials are recognized: natural materials obtained from plants and animals, and semisynthetic materials that are manufactured by chemical derivatization of natural organic materials, generally based on a polysaccharide on microbial fermentation-based substances. A third class known as "synthetic polymers," obtained from petroleum or natural gas precursors, is not used as a food additive. Figure 83.3 shows the sources and the various hydrocolloids used by the food processing industries.

Unmodified or natural corn starch, produced by the wet milling of field corn, supplies the majority of thickening material for the American food and beverage market. Other natural starches of significance include potato, tapioca, arrowroot, and sago starches. Unmodified cornstarch, commonly called pearl starch, is used in the food processing industry in the preparation of sauces, gravies, and fillings. It is the choice thickening ingredient in many formulated food products because of its modest price. It is modestly priced in comparison to modified starch, but even more so compared with additives such as cellulose ethers, guar, xanthan, and alginates. Major use categories for unmodified starch include

- Meat gravies
- Cooked puddings
- Cream-style sauces
- Pie fillings
- Barbecue sauces
- Salad dressings
- Baked good fillings

Modified starches used in food products or food processing have been modified to

Extend the bodying or gelling effect of normal starches
Improve resistance to acid or heat degradability and to low temperature and freeze/thaw (eliminating aggregation)
Improve texture
Modify gelling tendencies as desired
Increase viscosities at high temperature without gelling on cooling
Provide instant solubility and gelling in cold water

Modified or derivatized starches are generally designed for more selective food applications than unmodified starch.

TABLE 83.7
Major Food Thickeners and Stabilizers and Their Functions

	Thickening	Emulsion Stabilization	Suspending Properties	Gelation	Crystallization Control	Water Binding	Mouth Feel	Foam Stabilization	Flavor Fixation	Protective Film Forming	Synergistic Effect	Fat Substitution

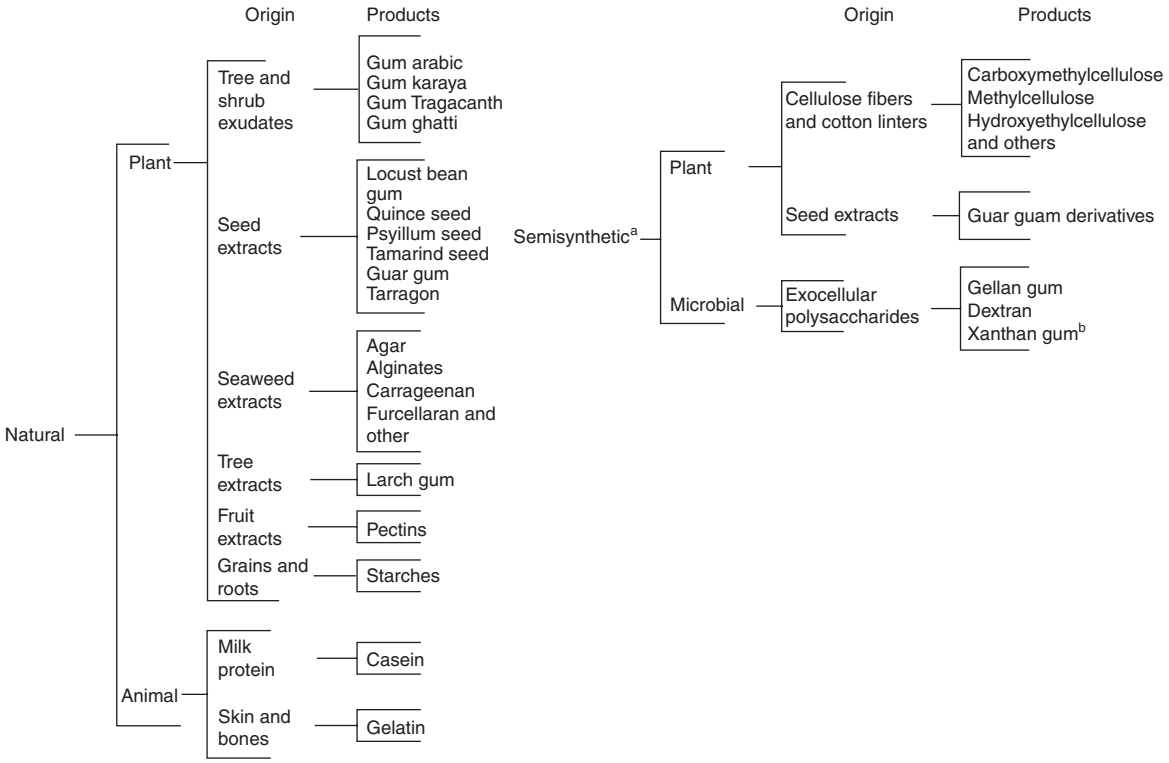
Agar				X								



[a] Natural-based, but highly derivatized and commercially significant products.

[b] Although xanthan gum is sourced from a natural product (grain), it is classified as a semisynthetic polymer because it is manufactured by fermentation in a chemical plant. Some industry sources disagree with this classification.

FIGURE 83.3 Natural and semisynthetic hydrocolloids used as food additives.

Modified starches are used in a wide variety of products, including baby foods, purees, candy (e.g., bonbons and butter creams), jellies, cake mixes, dough, various soup powders and liquids, instant noodles, puddings, pie fillings, batter mixes, sauces, salad dressings, dairy desserts, snack foods, and canned foods. In meat products such as sausage, ham, and luncheon meat, modified starches serve as a binder as well as thickener. Recently, modified starches have been used as fat substitutes in margarine-like spreads, salad dressings, cookies, and baked products.

Casein is a protein occurring naturally in, and obtained from, milk; it is the main ingredient in cheese. Casein is marketed as sodium, calcium, potassium, or magnesium caseinate and is used in confections, puddings, bakery fillings and frostings, coffee whiteners, and whipped toppings. In 1970 only five protein products were available from milk. Since then, numerous advances have been made used in the methods to isolate and modify proteins. As a result, most suppliers now offer multitudes of specialty casein products.

Gelatin is obtained from pork skin and bones (type A), or beef skin and bones (type B). Type A is mostly used for confectionery products and type B for dairy applications. Gelatin is about 97% protein, but it has no beneficial value to human nutrition. Food applications for gelatin includes dairy products such as yogurts, confectionary products such as gummy animal chewables, meats such as canned hams, and gelatin desserts. Gelatin is hygroscopic, capable of absorbing up to 10 times its weight in water. Under refrigeration it forms a thermally reversible gel of high strength.

Gelatin seems to exhibit little synergy with other thickeners and stabilizers. Therefore it appears to be of little benefit to blend gelatin with other gums to produce custom formulations.

Carboxymethylcellulose (CMC) is the primary cellulose ether consumed in food and beverage applications, mainly in pet foods, frozen dairy products, beverages, bakers' goods, dry drink mixes, syrups, glazes, icings, and toppings. The current search for microwave-compatible food additives makes CMC a candidate for this rapidly growing formulated food market. CMC, a nonnutritive substance, is also popular in diet food formulations requiring thickeners and stabilizers. Methylcellulose (MC) and hydroxypropylcellulose (HPC) are also used in specialized food and beverage applications, but their relatively high market prices preclude them from large volume applications.

Guar gum is the galactomannan derived from the endosperm of guar seeds (*Cyamoposis tetragonolobus*)

grown in India and Pakistan since ancient times. It is one of the most economical and widely used gums, with extensive use in a variety of food applications since the 1950s. In spite of several attempts by major domestic guar concerns to encourage domestic production of guar in Texas and other arid agricultural areas of the American Southwest, most of the guar gum consumed in the United States is derived from imported degermed guar beans (splits), mostly from India. Because of changing supplies due to weather and harvest conditions, as well as the demand for guar gum for industrial applications, the price of guar gum tends to shift dramatically. However, guar is expected to remain one of the most cost-effective thickeners on the market. Major uses for guar gum include ice cream, dessert toppings (e.g., Cool Whip®), frozen and refrigerated prepared meals, cheese, imitation bakery jellies and dry-mix bakery formulations, fruit drinks, soups, gravy and sauce mixes, water-based frozen desserts, salad dressings, and instant hot cereal.

Alginates are extracted from different types of seaweeds, mainly from brown seaweed, *Macrocytis pyrifera* and *Laminaria sp.* The alginates include the various salts of alginic acid and propylene glycol alginate (PGA). Sodium alginate is used primarily as a binder in frozen desserts, reconstituted onion rings, crab and shrimp analogs, instant pudding mixes, fabricated puddings, sauces and gravies (particularly those containing milk or requiring the low "weep" property of alginates), and re-formed meats.

Propylene glycol alginate (PGA) is used in the United States as a foam stabilizer in beers and ales. In addition, PGA is used by major food manufacturers in salad dressing formulations. The nonsodium light metal salts of alginic acid are used as sodium alginate alternatives in low-sodium and dietary food specialties.

Xanthan gum, a fermentation product, is used in salad dressings, relishes, syrups, sauces, bakery fillings, prepared puddings, glazes and toppings, processed cheese products, dry cake and beverage mixes, and fruit and carbonated beverages. A significant use is in dairy products, where it prevents the separation of the contained whey from the rest of the food product. Xanthan does not exhibit any reactivity with milk proteins and therefore is often used in combination with other hydrocolloids, particularly carrageenan. Moreover, the stability of xanthan gum to acid and high salt content makes it very useful for many types of foods.

Gellan gum is the latest hydrocolloid approved for food use, produced with a fermentation process like that used for the fermentation of xanthan gum by the organism *Auromonas elodea.* The FDA approved gellan gum for use in icings, frostings, bakery fillings, and low-solids jams and jellies and confections. It is also approved for food use in Japan. Gellan gum can be used at levels substantially below those required by conventional hydrocolloids. There are two forms of gellan gum. The first is a high-acetyl gum, which is partly acetylated and provides thermoreversible gels. The second is a low-acetyl gum forming a firmer and more brittle gel.

Pectin is a fruit extract from the peel of citrus fruits and apple pomace. The main commercial types used in foods are pectin itself and potassium pectinate, sodium pectinate, and amidated pectin. Commercial products include high ester [degree of esterification (DE) of 50] or low ester (DE of less than 50) pectins. Traditional food uses of pectins are in jellies and jams. Newer applications include gummy candies and fruit-flavored juices and carbonated drinks. In gummy candies and jellies, it is replacing starch for improvement of fruity flavor. In fruit-flavored drinks, it stabilizes the constituents and makes the product more appealing. A constraint on the supply of pectin is the approval required by the EPA to start up a new plant. Because of the high costs of compliance to dispose of the large volume of waste generated during pectin production, the last North American pectin production plant was relocated from Florida to Mexico.

Locust bean gum is obtained from the carob tree. The major source of locust bean gum is the Mediterranean countries. The size and quality of the crop is directed related to climatic conditions, producing periodic shortages of supply and great fluctuations of price. Chemically locust bean gum is similar to guar gum. Anionic, cationic, and hydroxyalkyl derivatives are also produced commercially. Locust bean gum swells in cold water, but heating is necessary for maximum solubility. Locust bean gum is widely used in frozen dairy products, in conjunction with guar gum and carrageenan, and is used for preventing syneresis in cream cheese. In addition, locust bean gum is used in many nonemulsified sauces and dressings as a thickener, in prepared meals, and in bakery products as a moisture retention aid. Much of the locust bean gum is supplied in a blended form to the dairy industry.

Gum arabic is obtained from various trees of the genus *Acacia*, primarily from *A. senegal.* It is highly soluble in water (up to 50%), and its solutions are of relatively low viscosity. Other advantages of gum arabic as a food additive are its nontoxicity and lack of odor, color, and taste. These properties are especially useful in systems requiring emulsifying properties, such as high solid suspensions. It is used as an emulsifier in beverages for citrus oil and flavors, a foam stabilizer in beer, as a crystallization retarder and emulsifier in confectionaries, and as a stabilizer in dairy and bakery products. Since the source of supply has sometimes been unreliable because of political and social events in the Middle East, many U.S. users have turned to substitutes, including starch derivatives.

Carrageenan is extracted from Irish moss (*Chondrus* and *Gigartina* species) that is harvested off the Atlantic shores of New England, the Canadian Maritime Provinces, and several European countries. Carrageenan is readily soluble in water to form an inelastic gel and is commonly used with other gums. Its most unique property is a high

degree of reactivity with certain proteins, such as casein. The largest application of carrageenan in food use is in dairy products (e.g., frozen desserts, flavored milk powder, nondairy creamers). For example, coca can be suspended in milk with the use of about 0.025% carrageenan.

One of the most significant recent developments for carrageenan suppliers has been its widespread use in poultry applications for moisture retention. The product serves to retain moisture before and during cooking and allows the poultry to be pumped with large amounts of water.

In 1990, the FDA decided to allow an unrefined seaweed extract known as Philippine Natural Grade (PNG) to be sold under the carrageenan heading. Traditionally, refined carrageenan is made in a 10-step process in which carrageenan is extracted from the seaweed and then filtered to remove the cell walls, or cellulose, the other substances from the seaweed. PNG carrageenan is prepared in a five-step process that extracts the unwanted substances from the seaweed, leaving both carrageenan and about 10–14% cellulose, as opposed to the less than 1% found in traditionally refined product. PNG is currently being used in the meat, cheese, and pharmaceutical markets.

Agar (also called agar-agar) is obtained from various red-purple seaweeds of the class *Rhodophycae*. Agar is used primarily in baked foods (icings, toppings, meringues) and in confectionary products. Because agar is the most expensive of the seaweed extracts, there have been efforts to substitute with other gums such as carrageenan.

A number of other thickening agents are used by the food industry, but the represent a very minor portion of the food additives market. Most are higher priced, in erratic supply, and face increasing competition from the principally used thickeners. Such other thickening and stabilizing agents and their principal uses include

- Ghatti gum. Obtained from India and Sri Lanka; no other functional properties are known than thickening and emulsion stabilization.
- Tragacanth gum. Obtained from the Middle East and used in salad dressings and sauces.
- Karaya gum. Obtained from India and used for extreme thickening to pastelike gels.

C. Colors

Colors are additives used to improve the overall appearance of foods and influence the perception of texture and taste. Products are derived from either natural origins or produced synthetically. In the United States, colors are divided into two types: certified (FD&C) and natural (exempt from certification) colors. Food colors are listed in the *Code of Federal Regulations* (CFR) Title 21 parts 70–82. If an additive is not specifically included in these sections, it may not be used for coloring food, drug, or cosmetic products that will be sold in the United States.

There is some confusion about the term "natural" colors. The definition of "natural" varies between the United States, Europe, and Japan. This section will concentrate on the U.S. regulations, with occasional reference to others. In the United States, from a regulatory point of view, there is no definition for natural colors, only "certified dyes" and "color additives exempt from certification." Certified colors are synthetic materials whose purity is checked by the FDA. Colors, obtained from animal, plant, or mineral origins are not certified because they often contain complex mixtures of many components. The exact composition of natural color varies from plant variety to plant variety, from region to region, and from season to season. Users depend on the integrity of their suppliers to ensure product quality.

The certification process concerns only batch purity, it does not guarantee the safety of the color molecule. There is no inherent reason why certified colors are either more safe or less safe than natural colors (colors exempt from certification). In order to market their products, U.S. producers must submit product samples from each batch of material and pay a certification fee. The materials are analyzed in an FDA laboratory to ensure that they meet specific purity specifications. In other parts of the world, only self-certification exists, except in Japan where certification of synthetic colors has been required since 1994. Certified food colors, both primary and blends, are produced in a variety of forms including powder, liquid, granules, plating blends, nonflashing blends, pastes, and dispersion; the least expensive form is powder.

A number of formerly certified FD&C colors have been banned under the provisions of the Delaney clause of the Food, Drug & Cosmetic Act, either because they were found to be carcinogenic or because there was no assurance that they could be made free from carcinogenic impurities. These actions have steadily reduced the number of certified dye colors available to the U.S. food industry from more than 22 in 1950 to 7 in 2003. (In addition FD&C citrus red no. 2, is permitted for coloring the skins of oranges that are not intended or used for processing, but it has not been produced in the United States in recent years; and orange B may be used for coloring the casings or surfaces of frankfurters and sausages.) Certified food colorants can be divided into dyes and lakes. Dyes are chemical compounds that exhibit their coloring power or tinctorial strength when dissolved in a solvent. Lakes are insoluble colored materials that color by dispersion. Table 83.8 shows the physical properties of these seven certified food colorants.

Color regulations specify a legal minimum of 85% pure dye for primary colors, but most dye lots contain from 90–93% pure dye. Certified dyes fall into several chemical classes: azo-dyes (yellow no. 5, yellow no. 6, red no. 40, citrus red no. 2), triphenylmethane dyes (blue no. 1, green no. 3), xanthine type (red no. 3), and sulfonated indigo (blue no. 2).

TABLE 83.8
Physical and Chemical Properties of Certified U.S. Food Colorants

FD&C Name	Common Name	Light	Stability to Oxidation	pH Change	Compatibility with Food Components	Tinctorial Strength	Hue	Water Solubility
Red no. 3	Erythrosine	Fair	Fair	Poor	Poor	Very good	Blue	9
Red no. 40	Allura red AC	Very good	Fair	Good	Very good	Very good	Yellow	25
Yellow no. 6	Sunset yellow FCF	Fair	Fair	Good	Good	Good	Red	19
Yellow no. 5	Tartrazine	Good	Fair	Good	Good	Good	Lemon yellow	20
Blue no. 1	Brilliant blue FCF	Fair	Poor	Good (unstable in alkali)	Good	Excellent	Green-blue	20
Blue no. 2	Sodium indigo disulfonates	Very poor	Poor	Poor	Very poor	Poor	Deep blue	1.6
Green no. 3	Fast green FCF	Fair	Poor	Good	Good	Excellent	Blue	20

FD&C dyes are also used in the production of lakes, which are pigments prepared by combining a certified dye with an insoluble alumina hydrate substratum. Lakes are both water and oil insoluble and impart color through dispersion in food. Thus they are suitable for coloring foods that cannot tolerate water and products in which the presence of water is undesirable. Examples include bakery products (icings, fillings, cake and doughnut mixes), confections, dairy products (hard fat coatings for ice cream novelties, wax coatings for cheese, yogurt with fruit syrups), dry pet foods, dry beverage bases, and dessert powders. The FD&C lakes do not have a legally specified minimum dye content; manufacturers use formulations of from 11% (standard) to 42% pure dye (concentrated).

Noncertified colors can be from either natural origins (primary sources), such as vegetables and fruits, or produced synthetically. Traditional markets for noncertified food colors include lipid-based, high-fat food systems such as butter, margarine, shortening, popcorn oil, processed cheeses and spreads, salad dressing, and snack foods. Water-soluble forms are also available and are used in beverages, baked goods, confections, and dairy products. Food color additives exempt from certification, their colors and sources are listed in Table 83.9 and described in more detail below.

Annatto extract (Bixin, Norbixin, etc.) is an extract of a seed from a shrub called *Bixa orellana L.* that grow in South America, East Africa, and the Caribbean. Oil- and water-soluble forms exist depending on the method of extraction. Annatto extracts exhibit various yellow shades, and are commonly used in cheddar cheese and bakery products, often in combination with turmeric or paprika oleoresin.

Beet juice/powder (betanin, beet-root red, etc.) is a water-soluble color found as the predominant pigment in red beets (*Beta vulgaris*). Several forms exist, including dried ground beets, or dehydrated beet powder; beet juice concentrate, the liquid obtained by concentrating the expressed juice from mature beets; and beet powder, made by spray drying beet juice concentrate onto a carrier of maltodextrin.

TABLE 83.9
Food Color Additives Exempt from Certification[a]

Additive	Color	Source
Annatto extract	Yellow	Vegetable
Beet juice	Red	Vegetable
Dehydrated beets	Purple	Vegetable
Canthaxanthin[b]	Red	Synthetic
Caramel	Brown	Semi-synthetic
Apocarotenal[c]	Orange	Synthetic

Corn endosperm oil[d]	Yellow	Vegetable
Dried algae meal[d]	Yellow	Plant
Ferrous gluconate[e]	Black	Synthetic
Ferrous lactatee	Black	Synthetic
Fruit juice (grape and cranberry)	Red	Fruit
Grape skin extract (enocianina)[f]	Red	Fruit
Paprika	Red	Vegetable
Paprika oleoresin	Red	Vegetable
Riboflavin	Yellow	Synthetic
Saffron	Yellow	Vegetable
Titanium dioxide[g]	White	Synthetic
Turmeric	Yellow	Vegetable
Turmeric oleoresin	Yellow	Vegetable
Vegetable juice	Red	Beet and red cabbage juice

[a] Under the Code of Federal Regulations, Title 21. No color additive may be used in foods for which standards of identity have been promulgated under Section 401 of the Federal Food, Drug & Cosmetic Act, unless the use of added color is authorized by such standards.
[b] May not exceed 66 mg/kg of solid, or pint of liquid, food.
[c] May not exceed 33 mg/kg of solid, or pint of liquid, food.
[d] To enhance yellow color of chicken skin and egg yolk.
[e] To color ripe olive.
[f] Used only in beverages.
[g] May not exceed 1% by weight of the food.

Canthaxanthin (Roxanthin) is a synthetically prepared carotenoid that is commercially available as a water-dispersible powder. It exhibits reddish orange to dull violet shades.

Caramel (burnt sugar) color results from the controlled heat treatment of food-grade carbohydrates. Often catalysts are added to drive the reaction to the desired color end point. Caramel colors exhibit a colloidal charge and a variety of shades from yellow brown to reddish brown, and is available in powder and liquid forms. Caramel has a very large market in cola beverages. It is also used in bakery products and confectionaries.

Apocarotenal (beta-apo-8′-carotenal) is a red-orange synthetically prepared carotenoid that is oil soluble. The pigment is found in oranges and tangerines and is commonly used in products such as cheese spreads and snack foods. In the United States, a usage restriction of 15 mg/lb of semisolid or solid food exists.

Commercial products of natural beta-carotene exist from several sources, including the alga *Dunaliella salina* and palm oil. Beta-carotene can be also synthesized. It is oil soluble and exhibits a characteristic butter to egg-yolk shade. It is commonly used in baked goods, beverages, and confections.

Cochineal extract, or carmine, the lake pigment of cochineal extract, is an extract of a female cochineal insect *Dactylopius coccus*, or *Coccus cacti.* It is a stable colorant used since antiquity. At pH 4 and below it is orange, at pH 4–6 it is magenta-red color, and at pH greater than 6, it has a blue-red shade. The insect is commonly cultivated in Peru, Ecuador, and the Canary Islands. Approximately 70,000 insects are required to produce one lb of 50% carminic acid lake. It is commonly used in beverages, sausage products, aperitifs, and confections. Cochineal extract is not kosher.

Fruit juices that typically contain carotenoid- or anthocyanin-type pigments are often used in concentrated or single-strength forms as coloring agents. In the United States, fruit juices must be expressed from mature varieties of edible fruits or a water infusion of the dried fruit. Fruit juices that are used for coloring include cranberry, cherry, raspberry, elderberry, grape, orange, and tomato.

Grape skin extract (enocianina) is obtained by an aqueous extraction of fresh, deseeded marc remaining after grapes have been pressed to produce grape juice or wine. It contains the common components of grape juice but not in the same proportion. During the steeping process, sulfur dioxide is added, and most of the extracted sugars are fermented to alcohol. The extract is concentrated by vacuum evaporation, during which practically all of the alcohols are removed. A small amount of sulfur dioxide may be present. In the United States, grape skin extract is permitted only for use in coloring beverages.

Paprika is the ground form of sweet red peppers (*Capsicum annum*). Paprika oleoresin is a solvent extract of the coloring principles of sweet red peppers. Extraction of the peppers is carried out with several permitted solvents, including hexane, ethylene dichloride, and various alcohols. Oil is commonly added to the extract to standardize the strength, with typical designations in American Spice Trade Association (ASTA) units and color value units (CVU). Paprika oleoresins are oil soluble, reddish orange shades. Typical applications include coloring salad dressings, snack foods, cheese product, baked goods, breading, and crackers.

Riboflavin, a bright yellow color, is also referred to as lactoflavin and vitamin B_2. It is a naturally occurring yellow pigment isolated from milk, and it can also be synthesized. It has limited solubility, a bitter taste, and is light sensitive, therefore it has limited use.

Saffron is the dried stigmas or extract or *Crocus sativus.* The predominant pigments are crocin and crocetin. Saffron is limited in its application due to its very high cost; approximately 165,000 blossoms are required to produce 1 kg of colorant. Saffron is commonly used as a spice and colorant in rice products. Its bright lemon-yellow color is also used in applications such as soups, baked goods, and certain dairy products.

Titanium dioxide is a white pigment that is reacted product from a mineral oxide called ilmenite, a type of iron ore. The crystal form, anatase, is the form of choice as a colorant for food. In the United States, purity of 99% or greater is required. Titanium oxide is the only white pigment currently permitted as a color additive in the United States. It is often used to opacify systems such as low-fat/no-fat salad dressings and dairy products, pet foods, baked goods, sugar-coated candies, and other confections. It colors by dispersion, as it is not water or oil soluble.

Turmeric and turmeric oleoresin is a bright yellow pigment from the rhizome *Curcuma longa*, which is grown predominantly in India. The principle coloring agent is curcumin. The oleoresin form is extracted by solvents, such as alcohol and acetone. It is available with or without flavor components.

Some vegetable juices, typically in a concentrated form, are used as coloring agents. In the United States, vegetable juices must meet the criteria of the federal regulation, which describes juice expressed from mature varieties of edible vegetables. An example of a commercially available vegetable juice colorant is red cabbage juice, which contains anthocyanins. Most other vegetable juice concentrates contain chlorophyll pigments and are often not of sufficient color concentration nor stable enough to be used commercially. In addition, the flavor impact is often undesirable.

Eight synthetic dyes are permitted for use in the EU countries. Red no. 4 (Ponceau 4R) was banned in the US in 1970, but it is still approved for food use in the EU countries. At the same time Red no. 40 (Allura Red AC) the most widely used red color in the United States has not been approved yet in the EU countries. Twelve water-soluble dyes and eight of their lake colors are allowed in Japan for foods. Compared to American consumers, European and Japanese consumers are more prone to demand that their food products contain natural colorants.

There is a growing body of evidence that many natural colorants perform additional functions. They also act

as vitamins, antioxidants, and antimicrobial and antiviral agents. Natural colorants also may have anticancer properties and can be used to treat vascular disease and improve night vision. This information was discovered in recent years.

D. Fat Replacers

Although fats are essential for a healthy diet, excessive consumption of fat has been related to health problems. Ft replacers are those ingredients that can help to reduce a food's fat and calorie levels while maintaining some of the desirable qualities fat brings to food, such as "mouth feel," texture, and flavor. Fat replacers can be carbohydrate, protein, or fat based.

Three alternative approaches are being pursued in this area:

- Fat substitutes. There are partially or fully nonmetabolizable compounds that possess fatlike properties and can replace fats on a one-for-one basis. Most fat substitutes are synthetic compounds that possess fatlike properties and can replace fat in a broad range of applications.
- Fat mimetics. These are nonfat ingredients that mimic the mouth feel and other functional properties provided by fat, but have fewer calories than fat. In recent years, numerous approaches have been undertaken to partially replace or to eliminate fats in food by using FDA-approved traditional nonfat food ingredients such as novel carbohydrates and gums, as well as other innovative ingredients, including microparticulated milk and egg proteins, and modified oat fibers. These products are capable of duplicating many of the functional properties of fats, such as lubricity, tenderization, opacity, flavor release, slipperiness, melt, and plasticity. These products cannot substitute for fats on a one-to-one replacement basis. Moreover, these ingredients are suitable as fat replacements only in foods that do not require extensive heat processing (e.g., salad dressings, frozen desserts, margarine-like spreads, etc.)
- Emulsifiers are fat- or fatty acid-derived compounds that have the ability to modify the surface properties of solids or liquids and possess many of the properties of a fat or an oil. The caloric value of most emulsifiers is similar to that of triglycerides. However, depending on the degree of esterification and polymerization, some emulsifiers such as polyglycerol esters may have a lower calorie content. Polyglycerol esters contribute only 6 kcal/g. Typically 2% fat in a formula can be replaced with 1% emulsifier with no loss of functionality. However, due to regulatory constraints and flavor considerations, emulsifiers are usually used at 1% concentration or less in formulated foods.

1. Low and Noncaloric Lipids

Olestra (brand name Olean™), developed by Procter & Gamble Co. (P&G), was approved by the FDA in January 1996 for use in preparing potato chips, tortilla chips, and other savory snacks. Olestra is a sucrose polyester made from sucrose backbone and six to eight fatty acids. The number and type of fatty acids vary depending on the performance characteristics desired. The fatty acids are derived from vegetable oils found in soy, corn, and cottonseed oils. Olestra molecules are much larger than those of ordinary fats, so the body's digestive enzymes cannot break it down. Thus Olestra is neither digested nor absorbed, passing straight through the body. It is noncaloric and nonsweet.

Olestra was discovered about 25 years ago. Its submission to the FDA was withdrawn numerous times as the information on it was refined. At the time of its approval, more than 300 volumes covering more than 100 laboratory studies on seven species and 98 clinical investigations involving 2500 humans comprised the body of knowledge on this compound. P&G spent more than $200 million for the development and regulatory approval process of olestra.

There are some concerns about olestra because it blocks the absorption of fat-soluble vitamins consumed with it. Therefore the FDA requires that fat-soluble vitamins A, D, E, and K be added to foods made with olestra. Also it is reported to cause abdominal discomfort and may act as a laxative in some cases. Therefore products with olestra have to carry a warning label that these effects are possible. Approval of olestra brought a range of responses from scientists and consumer advocates who disapprove of its use, as well as endorsements by groups such as the American Dietetic Association, which identifies olestra as "one more choice for consumers in the war against fat."

Medium-chain triglycerides (MCT) are esters of fractional coconut oil fatty acids. These compounds provide 8.3 kcal/g, only slightly less than conventional fats. However, recent physiological studies suggest that MCTs are burned readily for energy and have little tendency to be incorporated into tissue lipids that are not deposited as fat. MCTs are GRAS compounds, have been used in medical and infant feeding products for more than 30 years, but have not been used in consumer food products because of their high cost. More recently, their use has been expanded into sport/nutrition foods.

2. Fat Mimetics

a. Carbohydrate-based substitutes

Nearly 40 different products based on starch have been recommended for fat replacement. Some of these exist as

products with other uses, although several have been developed specifically as fat mimetics. Most of the materials in this category are used to form a gel containing modified starch and water. The gel is then substituted for fat in the formula on an equal-weight basis. Starch-based fat mimetics have many different properties depending on the parent starch and on the degree of cross-linking, substitution, and acid modification. In many instances, two or more starches must be used together to give the desired effect, or they can be combined with other polymers and emulsifiers.

Maltodextrins are products of the acid hydrolysis of starch, and act as bulking agents, giving the mouth-feel qualities of fat. One of the first on the market, in 1984, was N-Oil, a hydrolyzed tapioca maltodextrin. The substance forms a thermoreversible gel in aqueous foods, and therefore creates the mouth feel of fat, N-oil and several similar products are used in frozen desserts, salad dressings, margarine-type spreads, dips, baked products, and snacks. Several other starch-based maltodextrin fat replacers are available.

One of the most widely used fat mimetics is Avicel™, a cellulose derivative used in frozen desserts, salad dressings, and baked goods. Methocel, a food gum, is made of cellulose ethers for use in bakery products, fried foods, and salad dressings.

Pectin is a gum that forms a gel. It has a large water-holding capacity and therefore helps to overcome some of the dry impression of fat-free foods. A gum is a soluble fiber, so it must be counted as a carbohydrate (4 kcal/g) in the calculation of calories for labeling purposes. In 1991 Splenda, a specialty pectin, was introduced as a fat replacer. Another gum fat replacer, carrageenan, that was used in low-fat hamburger, failed to achieve wide consumer acceptance.

Other hydrocolloids and gums are frequently promoted as fat-sparing agents. Xanthan, gelatin, carrageenan, algin, guar konjak, locust bean gums, etc., can be utilized as well for their fat-sparing function.

Polydextrose — "Litesse™" and "Veri-Lo™" — is recommended for replacement of fats. Polydextrose is a water-soluble, reduced-calorie polymer is dextrose that contains small amounts of sorbitol and citric acid. It provides 1 cal/g as it is only partially metabolized by the human body.

Oatrim, developed in the USDA laboratory in Peoria, Illinois, is an amylodextrin with 5% β-glucan extracted from oat flour. It is used as a fat replacer in baked products.

b. Protein-based substitutes

Lita is based on zein, a microencapsulated protein from corn. Like other protein-based fat replacers, it contributes less than 2 kcal/g. It is used in frozen desserts, whipped toppings, and mayonnaise.

c. Emulsifiers

Emulsifiers are fat-based substances that are used with water to replace all or part of the shortening content in cake mixes, cookies, icings, and vegetable-dairy substitute. Most emulsifiers provide the same calories as fat, but less is used, resulting in fat and calorie reductions. Many emulsifiers simply play a "fat-sparing" role. However, polyglycerol esters may have a lower caloric content than triglycerides, depending on the degree of esterification and polymerization.

The commonly used food emulsifiers that have applications as fat replacers include lecithin, mono- and diglycerides, and derivatives such as acetylated, succinylated, and diacetyl tartaric esters of distilled monoglycerides, polyglycerol esters, polysorbates, and sucrose esters.

More information on specific compounds can be found in the emulsifier section of this chapter.

While fat replacement is still very important to consumers in the United States, over the last years the interest in low- and non-fat products has begun to weaken. Even the advent of olestra in snack-food products has not provided the solution. Still, the fastest growth for fat substitute-containing products is expected to be in the United States, where diets have historically been higher in fat and sugar and consumers appear to have more problems with obesity/weight control and associated diseases. In Europe, consumer preference for low-fat, low-calorie foods perceived as natural, rather than artificial, has tended to limit acceptance of fat substitutes. On the regulatory side, fat substitutes face more daunting approval challenges in Europe than do other types of food additives. In Japan, and other Asian countries the market for fat substitutes is currently very small.

E. Enzymes

Enzymes are catalysts used during food processing to make chemical changes to the food. They are biological catalysts that make possible or greatly speed up chemical reactions by combining with the reacting chemicals, bringing them into the proper configuration for the reaction to take place. They are not affected by the reaction. All enzymes are proteins and become inactive at temperatures greater than about 40°C or in unfavorable conditions of acidity or alkalinity. Some of the specific functions food enzymes perform include:

- Speed up reaction
- Reduce viscosity
- Improve extractions
- Carry out bioconversions
- Enhance separations
- Develop functionality
- Create/intensify flavor
- Synthesize chemicals

Food enzymes are usually classified into the following categories:

- Carbohydrates and amylases are commercially the most important subgroup, hydrolyzing 1,4-glycosidic bonds in carbohydrates
- Proteases, hydrolyze peptide bonds in proteins
- Lipases, split hydrocarbons from lipids
- Pectic enzymes and cellulases, hydrolyze plant cell wall material
- Specialty enzymes

These enzyme categories can be divided further into 15–20 subgroups. The traditional roles of enzymes in the food industry have been in the processing of bakery goods, alcoholic beverages, and starch conversion. But interest is now focused on newer and more varied applications, such as hydrolysis of lactose, the preparation of modified fats and oils, the processing of fruit juices, and other processes where newer enzymes are being identified.

Today many food processes utilize enzymes. Food-grade enzymes encompass a wide variety of commercial products that are employed in the production, conversion, and modification of foods because of their highly efficiency and selective catalytic functions. Table 83.10 lists many of the major food enzymes and gives some applications in foods and food processing. The largest application of enzymes in the food industry is the use of alphaamylase, glucoamylase, and glucose isomerase for starch conversion and production of high fructose corn syrup.

Rennin, a protease enzyme used in cheese making, is also of significant value, followed by a host of other enzymes, including pectinases, invertase, lactase, and maltase (used for the modification of starches and sugars), catalase, pepsin, glucose oxidase (an antioxidant for canned foods), and bromelin, ficin, and papain (plant proteases used for tenderizing meat and producing easily digestible foods). Enzymes are highly specific and can act only on a single class of chemicals, such as proteins, carbohydrates, or fats. These same enzymes are also used in nonfood applications such as pharmaceuticals, textiles, detergents, and waste treatment.

Enzymes are produced from animal tissues (e.g., pancreatin, tripsin, lipase), plant tissues (e.g., ficin, bromelin), and most frequently by microorganisms (e.g., pectic, starch enzymes). Microbial production from a variety of species of molds, yeasts, and bacteria is increasingly becoming the predominant source of enzymes.

Application of genetic engineering to the development of enzymes has already made a significant impact. The first food additive produced by genetic engineering was chymosin, "Chy-Max,™" a microbial rennet that has been approved by regulatory agencies in the United States, Canada, the United Kingdom, Australia, Italy, and several other countries. Advantages of the bioengineering product are increased yields, relative ease of manufacture, lower price, and the ability to label the product as kosher.

TABLE 83.10
Applications for Enzymes in the Food Industry

Food Processing	Enzyme	Application
Alcohol production	Amylases	Starch liquefaction
Analytical testing	Cellulase, pectinase, amylases	Testing for dietary fibers, sugars
Baking	Fungal proteases	Dough conditioning, flour bleaching, malting, and antistaling
Brewing	Microbial proteases, papain, pectinase	Low-calorie beer, chill proofing, barley, alternative adjunct liquefaction, and saccharification
Confections	Invertase	Cream candy centers
Coffee processing	Pectinases, cellulase	Removal of burnt flavor in UHT (ultra-heat-treated) milk Separation of bean, viscosity control of extracts
Dairy	Rennins, lactase, lipase	Cheese making, accelerated cheese ripening, natural cheese flavor concentrations, whey utilization, lactase intolerance
Fats and oils	Lipase, phospholipase	Coca-butter substitutes, flavor-ester synthesis
Flavors	Protease, lipase	Synthesis of savory flavors, natural flavor esters
Fruits and vegetables	Cellulase	Breakdown of cellulose structure
Fruit juice and wine	Pectinases	Mash treatment, depectinization, starch/araban haze removal, citrus pulp wash viscosity reduction, natural cloud production
Protein	Bromelin, papain, pepsin, pancreatin	Rendering, soy milk production, egg white replacement emulsifier production, functional hydrolysates
Sugar processing	Amylases, cellulase	Removal of undesirable starches and polysaccharides in the processing of cane sugar
Starch conversion	Glucose isomerase	High fructose corn syrup, maltose, and dextrin syrups
Waste treatment	Proteases, cellulases, lipase	Breakdown of cellulose, lignins, oil residues and other solid waste material
Other	Proteases	Meat tenderizing, coffee soluble-extract viscosity reduction

Approximately, 60% of food enzymes used globally are now sold as recombinant proteins.

F. Vitamins

Vitamins are nutritive substances required for normal growth and maintenance of life. They play an essential role in regulating metabolism, converting fat and carbohydrates into energy, and forming tissues and bones. Vitamins can be used as functional ingredients in foods. Vitamin E (tocopherol) and vitamin C (ascorbic acid) protect foods by serving as antioxidants to inhibit the destructive effects of oxygen. This helps protect the nutritive value, flavor, and color of food products. In addition, ascorbic acid enhances the baking quality of breads, increases the clarity of wine and beer, and aids color development and inhibition of nitrosamine formation in cured meat products. Beta-carotene and beta-apo-8′-carotenal are vitamin A precursors, which are brightly pigmented and may be added to foods such as margarine and cheese to enhance their appearance. The roles of these substances outside their nutritional functions are discussed elsewhere in this chapter (see Antioxidants, Preservatives, and Color).

Thirteen vitamins are recognized as essential for human health, and deficiency diseases occur if any one is lacking. Because the human body cannot synthesize most vitamins, they must be added to the diet. Most vitamins are currently consumed as pharmaceutical preparations or over-the-counter vitamin supplements. Some, like vitamins B, C, D, and E are added directly to food products. Ready-to-eat breakfast cereals are a good example of fortification. Because the primary use of these cereals is as a complete breakfast entrée, they are commonly formulated to provide 25% or more of the daily value (% DV) per serving of the 10–12 important vitamins and minerals common to cereals. Another important example is the fortification of fruit drinks with vitamin C. Other foods that typically have added vitamins include margarine, infant formula, meat replacements, and breakfast bars (Table 83.11).

Vitamins are added to processed foods for several reasons:

- To restore vital nutrients lost during processing — this is important with dried milk, dehydrated vegetables, canned foods, and refined and processed foods.
- To standardize nutrient levels in foods when these fluctuate because of seasonal variations, soil differences, and methods of preparation.
- To fortify fabricated foods that are low in nutrients and promoted as substitutes for traditional products; this includes complete breakfasts, breakfast drinks, meat extenders, and imitation products such as eggs, milk, cheese, and ice cream.

TABLE 83.11
Fortified Food Groups

Food	Vitamin	Use Level	Remarks
Milk	Vitamin D	420 IU/1	Optional, but generally added
Beverages (noncarbonated)	Vitamin C	15–100% of U.S. RDI per serving	Optional; also added as an antioxidant
Cereals	Most essential vitamins	25–100% of U.S. RDI per serving	Optional; added to 90% of cold cereals
Flour	Thiamin, Riboflavin, Niacin	8–15% of U.S. RDI per 2 oz. serving	Mandatory
Margarine	Vitamin A	33,100 IU/kg	Optional, but generally added
Miscellaneous foods (e.g., instant breakfast, energy bars, etc.)	Most essential vitamins		Added to position food as complete meal replacement

- To fortify a major staple, such as bread, with a nutrient known to be in short supply.
- For the preparation of functional foods (nutraceuticals) containing vitamins that are shown to be useful in preventing chronic diseases.

Vitamins are typically divided into two groups: fat soluble and water soluble. Fat-soluble vitamins are usually measured in international units (IUs) and consist of vitamins A, D, E, and K. The water-soluble group, usually measured in units of weight, consists of vitamin C (ascorbic acid) as well as the B vitamins. Humans need eight nutritive B-complex vitamins: niacin, riboflavin, panthotenic acid, pyridoxine, folic acid, thiamin, biotin, and vitamin B_{12}. Table 83.12 outlines synonyms for and the most commonly marketed forms of the major vitamins consumed in the United States as food additives.

In 1993 the FDA introduced reference daily intakes (RDI) [formerly recommended daily allowance (RDA)] for the labeling of foods and vitamin supplements. The RDI was designed to spell out the nutritional requirements of an average American. Those with greater than average needs (young woman, the elderly, and cigarette smokers, for example) are responsible for knowing their additional requirements and supplementing their diet, RDI values for vitamins established by FDA regulations are listed in Table 83.12.

Vitamin A is generally added to margarine and milk. Much of the vitamin A content of milk is obtained by feeding cows supplements of the vitamin. In addition, vitamin A is frequently added to instant breakfast foods, granola bars, and quick preparation or energy bar food products to better position those foods as complete meal replacements.

TABLE 83.12
Vitamins Consumed as Food Additives and U.S. RDI Values

Vitamin	Principal Synonyms	Major Market Form	U.S. RDI Value
Vitamin A			5000 IU
A_1	Retinol	Vitamin A acetate Vitamin A palmitate	
A_2	Dehydroretinol		
Vitamin B			
Niacin	Vitamin B_3	Nicotinic acid	20 mg
Thiamin	Vitamin B_1	Thiamin hydrochloride	1.5 mg
Riboflavin	Vitamin B_2	Riboflavin	1.7 mg
Pantothenic acid	Vitamin B_5	Calcium pantothenate	10 mg
Pyridoxine	Vitamin B_6	Pyridoxine hydrochloride	2 mg
Cyanocobalamin	Vitamin B_{12}		6 µg
Folic acid	Vitamin B_c	Folate	0.4 mg
Biotin			0.3 mg
Vitamin C	Ascorbic acid	Ascorbic acid Sodium ascorbate Calcium ascorbate	60 mg
Vitamin D			400 IU
D_2	Ergocalciferol		
D_3	Cholecalciferol		
Vitamin E	Tocopherols	DL-alpha tocopherol acetate D-alpha tocopherol D-alpha tocopheryl acid succinate	30 IU
Vitamin K			
K_1	Phytonadione	Phylloquinone	65 µg
K_3	Menadione		

Most natural vitamin A is derived from fish oils or carotenoid pigments found in chlorophyll-containing plants. These carotenoid pigments are the source of several provitamins, of which alpha- and beta-carotene are the most important. Important commercial forms include beta-carotene, retinol, retinol acetate, and retinol palmitate. Practically all the vitamin A used today is obtained by synthesis from the chemical intermediate, beta-ionone.

Thiamin (vitamin B_1) is found in all plants, but cereal grains, milk, legumes, nuts, eggs, and pork contain large amounts. Thiamin is essential for the proper functioning of the central nervous system. Important commercial products include thiamin hydrochloride and thiamin mononitrate. Thiamin is obtained synthetically by several different routes, including linking chlorate-thylpyrimidine with 4-methyl-5-(hydroxy-ethyl)thiazole. Another method is the conversion of 4-amino-5-cyano-pyrimidine into a thioformylaminomethyl derivative via catalytic hydrogenation and reaction with sodium dithioformate.

Riboflavin (vitamin B_2) occurs in plant and animal cells. Important dietary sources include organ meats, yeast, and dairy products. Riboflavin is produced synthetically from D-ribose and fermentation processes.

Pantothenic acid (vitamin B_3) occurs in all animals and plants and in some microorganisms. Natural sources of pantothenic acid include liver, eggs, broccoli, cauliflower, tomatoes, and molasses. Commercially available forms include the liquid D-pantothenyl alcohol (panthenol), as well as calcium D-pantothenate and racemic calcium pantothenate. It is produced commercially by condensation of D-pantolactone with beta-alanine.

Niacin (vitamin B_4) is a generic term that includes both niacin (nicotinic acid) and niacinamide (nicotinamide). Poultry, meats, and fish are the most important sources of niacin. Both niacin and niacinamide are important commercial forms. Niacin is produced synthetically by the oxidation of quinoline, or 2-methyl-5-ethyl-pyridine. Niacinamide is produced by amidation of niacin.

Pyridoxine (vitamin B_6) refers to naturally occurring pyridine derivatives that have vitamin B_6 activity. Most forms of the vitamin occur in plant and animals, but chemical synthesis is a far more efficient and economical method of production than natural isolation. Pyridoxine hydrochloride is produced by the condensation of ethoxyacetylacetone with cyanoacetamide.

Cyanocobalamin (vitamin B_{12}) is found in dairy and meat products. Cyanocobalamin and hydroxocobalamin are the important commercial forms, produced by fermentation using either *Streptomycetes griseus* or *S. aureofaciens.* Vitamin B_{12} is essential for bone marrow cells, the nervous system, and the gastrointestinal tract, as well as for normal blood function.

Folic acid, a member of the vitamin B complex, is a yellow-orange crystalline powder found in brewer's yeast, wheat, nuts, legumes, and liver tissues. Folic acid and the calcium salt of folic acid can be obtained synthetically by a number of routes from triaminohydroxypyridine and para-aminobenzoylglutamic acid. Folic acid functions as a coenzyme in the synthesis of nucleic acid, purine-pyrimidine metabolism, and other systems.

Recently folic acid gained importance because of its role in reducing the chances of neural tube birth defects and its role of controlling homocysteine, a risk factor in atherosclerosis. Medical studies indicate that folic acid and pyridoxine (vitamin B_6) can reduce high levels of homocysteine, an amino acid, in the blood. A high level of blood homocysteine was found to be an independent factor from cholesterol leading to increased risk of heart attack and stroke. Therefore folic acid and possibly vitamin B_6 use in nutraceuticals and other fortified food products (e.g., breakfast cereals, cereal bars, calorie control and fitness food products, etc.) will increase substantially in the next few years.

Vitamin C (ascorbic acid) is the most important vitamins used as a food additive in terms of volume. Primary applications include fruit juices, still beverages, juice-added

sodas, and dry cocktail or beverage powder mixes. Ascorbic acid is also used as a food preservative. Fruit juice makers, in particular, are applying the vitamin to preserve and protect against color change in fruit ingredients. By doing so, they can also promote the high vitamin content of juices.

Vitamin D_2 (ergocalciferol) and vitamin D_3 (cholecalciferol) are produced synthetically by the irradiation of the provitamins ergosterol and 7-dehydrocholesterol, respectively. Vitamin D_3 can also be isolated from fish liver oils. Although vitamins D_2 and D_3 are both important commercial products, most of the vitamin D is synthesized by the photochemical conversion of 7-dehydrocholesterol to D_3.

Vitamin E is found widely throughout nature, but the main dietary sources include vegetable fats and oils, dairy products and meat, eggs, cereals, nuts, and leafy green and yellow vegetables. The role of tocopherol as an antioxidant that can reverse the damaging effects of free radicals and therefore prevent certain chronic diseases has received increasingly wide attention in recent years. Naturally occurring vitamin E can be obtained from vegetable oil sources by distillation, and recently two major vegetable oil processors initiated the commercial production of natural tocopherols. However, large quantities of tocopherols are synthetically derived.

Vitamin K, found in green leafy vegetables, tomatoes, cauliflower, egg yolks, soybean oil, and liver, is essential for the formation of prothrombin and other blood-clotting factors in the liver. Menadione and its sodium bisulfite and diphosphoric acid ester derivatives are the most common commercial forms of the vitamin K group of compounds. Menadione (vitamin K_3) is produced synthetically by treating 2-methylnaphthalene with chromic acid in the presence of sulfuric acid.

G. Antioxidants

Antioxidants are food additives that retard atmospheric oxidation and its degrading effects, thus extending the shelf life of foods. Examples of food oxidative degradation include products that contain fats and oils in which the oxidation would produce objectionable rancid odors and flavors, some of which might even be harmful. Antioxidants are also used to scavenge oxygen and prevent color, flavor, and nutrient deterioration of cut or bruised fruits and vegetables.

Recently, definitive studies have shown and been widely publicized in the news media that antioxidant nutrients such as ascorbic acid (vitamin C) and tocopherols (vitamin E) can protect against harmful cell damage and thus prevent certain human diseases. Foods formulated with antioxidants and other vitamins are now recommended to prevent and cure cancer, cardiovascular diseases, and cataracts. The same antioxidants that are used to prevent oxidative deterioration of food may be used in functional foods (nutraceuticals, designer foods, etc.) to create products that prevent or cure certain chronic diseases. In this section, however, only the food preservation function of antioxidants will be discussed.

To improve the performance of antioxidants, two other types of food additives, sequestrants (e.g., EDTA, citric acid) and synergists (e.g., mixtures of antioxidants and lecithin), are frequently used with them. Antioxidants may also be present in food packaging as indirect food additives, but such use is not covered in this chapter.

Food antioxidants can be divided into water-soluble and oil-soluble compounds and also classified as natural or synthetic, as shown in Table 83.13. The most frequently used natural antioxidants are ascorbic acid (vitamin C), its stereo isomer erythorbic acid, and their sodium salts, plus the mixed delta and gamma tocopherols. While ascorbic acid finds its major use as a nutritive supplement or in pharmaceutical preparations, smaller amounts are intentionally used for antioxidant purposes. Erythorbic acid (isoascorbic acid) is virtually devoid of vitamin C activity (only 5% that of ascorbic acid). Citric acid and tartaric acid are also natural antioxidants (and antioxidant synergists), but are predominantly added to foods as acidulants.

Synthetic antioxidants used as direct food antioxidants include butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), tert-butyl hydroquinone (TBHQ), and propyl gallate (PG). These antioxidants are effective in very low concentrations (0.01% or less in animal fact) and not only retard rancidity but also protect the nutritional value of the food by minimizing the breakdown of vitamins and essential fatty acids. At one time, safety

* Major products.

questions were raised about several synthetic antioxidants. These have largely been resolved, although the impact on the market for synthetic antioxidants still exists.

The major applications of antioxidants in foods are listed in Table 83.14. The fats and oils industry and the snack/fast food/convenience food industries are the major users of food antioxidants.

While the growth of fat-containing foods is declining because of consumer concerns related to the adverse effects of fat and high caloric intake to health, the increasing preference for "healthier" unsaturated fats will increase demands for oil-soluble antioxidants because these fats require more protection against rancidity.

Butylated Hydroxyanisole (BHA) was introduced commercially in foods in 1948. The major applications for BHA are in frying fats and oils, salad oils, and shortenings. BHA can be used in blends with BHT, TBHQ, or PG to optimize performance. For example, blends of BHA and propyl PG are used as stabilizers in edible lard and tallow.

BHA is approved by the FDA as a GRAS substance, but the use is limited to a maximum 0.02% of the total fat and oil content of the product. Past developments have had a detrimental effect on the demand for BHA. In 1982, the Japanese government reported that, according to feeding studies done in Japan with BHA at 2% of the entire diet, BHA was found to be carcinogenic. Consequently BHA would not be allowed in food products sold in Japan after July 1982. Various governments, including the United States, Canada, and the United Kingdom, requested a delay in the implementation date until further studies could be done. The date was then deferred to February 1, 1983, and the ban was never implemented. Subsequently the World Health Organization's Food and Agriculture Organization studies showed that BHA dosage levels would have to be high (e.g., about 2% of the oil or fat content of the food) before any carcinogenic effects would become apparent. (The normal BHA content level is 200 ppm of the fat or oil content of the food). However, because of Japan's announcement of its initial study, BHA was removed from some of the food and food packaging sold in the United States and Japan. The findings of the Japanese study relative to BHA were surprising since several other studies conducted worldwide had found BHA to be noncarcinogenic. The original Japanese researcher has now agreed that BHA is not carcinogenic; however, irreparable damage to BHA as a food antioxidant has occurred, and the product's unhealthy image is unlikely to be reversed in the future.

Butylated hydroxytoluene (BHT) was approved for use as a food antioxidant in 1954. BHT is often used in blends with BHA or BHA/PG in vegetable oils and in edible animal fats to take advantage of the synergism obtained. Although BHT was never removed from the FDA's GRAS list, demand for BHT as a direct food additive declined throughout the 1980s. That proposal, as well as the general trend toward the use of all-natural ingredients in foods, has negatively impacted BHT use in foods.

Producers of both BHA and BHT have petitions filed with the FDA to recognize the existence of "prior sanctions" for the use of the chemicals as food antioxidants at levels not to exceed 0.02%. Such recognition would eliminate the necessity of classifying the chemicals as food additives.

Tertiary-butyl hydroquinone (TBHQ) is related to BHA and has good heat stability. It was first introduced for food applications in 1972. TBHQ shows exceptional ability in protecting unsaturated vegetable oils and animal fats from rancidity. One of its largest applications is in soybean oils. Although mostly used by itself, TBHQ can be used in combination with BHT and BHA. TBHQ is often used as a replacement product for PG.

Propyl gallate (PG) has been used as a food antioxidant since the 1950s. Its current primary use is more as a synergist in combination with BHA and BHT. The active part gallic acid, can be extracted from natural sources and can be synthesized. Propyl gallate is effective in vegetable oils as well as animal fats, but it is not heat stable, even at cooking temperatures. Total consumption of PG is very small because of its relatively high price and competition from TBHQ.

Ascorbic acid (vitamin C) and sodium ascorbate are widely used as natural antioxidants and vitamin supplements. As an antioxidant, ascorbic acid is used primarily in prepared foods (canned fruits and vegetables, juice drinks, applesauce, potatoes) and in processed meats (sausages). Manufacturers use it if for its protective function in soft drinks, for example, but declare it as "added vitamin C." Ascorbic acid is insoluble in fats and oils, and its almitoyl

TABLE 83.14
Food Applications for Antioxidants

Oil-Soluble Antioxidant Applications (to Retard the Onset of Rancidity)	Water-Soluble Antioxidant Applications (to Prevent Oxidative Deterioration of Color, Flavor, and Nutrients)
Edible fats	Fresh fruits and vegetables
Vegetable oils	Dried fruits
Nuts	Fruit juices and drinks
Shortenings	Frozen fruits and vegetables
Margarine	Frozen entrees
Salad oils	Confectionery products
Fast food frying oils	Flavoring compositions
Bakery products	Frozen potatoes
Processed meat	Meat and poultry spreads
Cheeses	Processed cheese
Processed chicken	Thermally processed fruits in nonmetallic containers
Canned meat and poultry	
Pancake/cake mixes	
Breakfast cereals	
Dehydrated potatoes	
Chewing gums	

ester is synthesized to impart some lipid solubility. Used alone, the ester is not very effective in fats and oils, and it is normally used in combination with tocopherol.

Erythorbic acid (iso-ascorbic acid) and sodium erythorbate are used primarily as antioxidants in cured meats (e.g., bacon, sausages) and by salad bars as an oxygen scavenger. They are also used in frozen fruits, vegetable fats and oils, and frozen fish and seafood. Erythorbic acid (and its salts) has benefited significantly from the FDA's ban on the use of sulfites for fresh or uncooked vegetables in salads. Approximately 80% of the total U.S. consumption is estimated to be in the form of sodium erythorbate. The greatest use is in cured meat to minimize the formation of nitrosamines during the curing or cooking process. USDA regulations governing the maximum level of nitrite permitted for curing bacon require the use of 500 ppm of ascorbates or erythorbates. Other food uses of erythorbates are in fresh cut meat, frozen fruits and vegetables, and raw fresh cut vegetables. In Europe, erythorbic acid use has been permitted since 1995.

Tocopherols are the fastest growing antioxidants used in the United States. Because the United States trades heavily with Japan, where synthetic antioxidants are banned, U.S. food exporters are reformulating products using natural antioxidants. Mixed tocopherols appear to be the product of choice.

Although the isomeric forms (alpha, gamma, and delta) of tocopherol show antioxidant activity, the 80% gamma/20% delta mixture of natural tocopherols has the best antioxidant activity. Mixed natural tocopherol products can be used to protect a variety of food products, including dehydrated and processed vegetables, pasta and noodles, animal fats, salad dressings and oils, snacks, meats, and baked foods.

Residues from vegetable refining contain a small but significant level of tocopherols. Using techniques such as molecular distillation, these can be concentrated to give a brown oily product with good antioxidant properties. The composition varies with the origin (type of vegetable oil), and both gamma-rich and delta-rich versions are used.

Sulfites serve multiple functions in foods: (1) inhibition of enzymatic and nonenzymatic browning, and (2) control of microbial growth. For years, sulfur dioxide and sulfite salts have been widely used to help preserve the color of dried fruits and vegetables. Sulfites are used in wine making and the wet milling of corn to prevent the browning of fresh produce with the use of sulfites. But because of the allergic reactions of some consumers (especially asthmatics) to sulfites, regulations were issued and alternatives sought. In July 1986, six sulfiting agents — sulfur dioxide, sodium sulfite, sodium bisulfite, potassium bisulfite, sodium metabisulfite, and potassium metabisulfite — were banned by the FDA for use in raw vegetables and fruits on salad bars. In July 1987, the FDA ruled that all packaging foods containing 10 ppm or more of sulfur dioxide equivalents must disclose on the label that sulfiting agents are present. In 1990, the use of sulfites on fresh potatoes was banned.

Treatment of fruits and vegetables with sulfites is the most effective means available today to control browning. However, because sulfites have been banned in certain food categories and their regulatory status in other categories is in question, alternative treatments to retard enzymatic browning and other oxidative reactions have been investigated. To date, however, alternatives to sulfites are not equivalent to sulfites in their effectiveness, cost, or functionality.

The promising antioxidant/preservative alternatives generally contain ascorbic acid or erythorbic acid in combination with one or more adjuncts, such as citric acid or some other acidulant, a calcium salt, a phosphate, sodium chloride, cysteine, or a preservative such as potassium benzoate or sorbate. The ascorbic acid derivatives, ascorbic acid 2-phosphate and ascorbic acid-6-fatty acid esters, are also reportedly effective. Another suggested substitute (which functions in water but not with fats and oils) is the sequesterant and chelating agent ethylenediaminetetraacetic acid (EDTA), which has been widely used in processed potatoes, salad dressings, sauces, and beverages.

Cyclodextrin is another sulfite alternative that can be used to prevent browning. Finding a good substitute for sulfites, however, has not yet been realized. This is because sulfites not only act as antioxidants to prevent browning, but also perform preservative functions in preventing unwanted microbial spoilage. The above chemicals are ineffective against microbes.

Ethoxyquin is included in the FDA regulation but limited to specific applications only. It is cleared for retarding oxidation of carotene, xanthophylls, and vitamins A and E in animal feed and fish food, and as an aid in preventing the development of organic peroxides in canned pet food.

Gum guaiac is an approved antioxidant for natural flavoring substances and other natural substances used in conjunction with flavors. It is also approved for addition to animal feed and food-packaging materials.

H. Preservatives

Preservatives (antimicrobial agents) are capable of retarding or preventing the growth of microorganisms such as yeast, bacteria, molds, or fungi and subsequent spoilage of food. The principal mechanisms are reduced water availability and increased acidity. Sometimes these additives also preserve other important food characteristics, such as flavor, color, texture, and nutritional value. Important food preservatives used include sorbic acid and its potassium salt, calcium and sodium propionates, sodium and potassium benzoates, and parabens.

Sulfur dioxide and sulfites are also used extensively for controlling undesirable microorganisms in soft drinks, juices, wine, beer, and other products. Salt, organic acids,

TABLE 83.15
Major Uses of Preservatives by Use Sector

Preservative	Application
Sorbates	Mold and yeast inhibition in processed cheese and spreads, other low-acid foods, and dried fruits. Effective in the acidic pH range up to pH 6.5
Benzoates	Antibacterial use in beverages, fruit juice, pickles. Effective in pH range 2.5–4.0
Propionates	Mold and rope inhibitors in bread and baked goods
Parabens	Antibacterial for use in low-acid foods (pH greater than 5.0) such as meat and poultry products

sugar, alcohol, spices, essential oils, and herbs also inhibit the growth of microorganisms, but usually their primary function is different when added to food.

Chemical preservatives play a very important role in the food industry, from manufacture through distribution to the ultimate consumer. The choice of a preservative takes into consideration the product to be preserved, the type of spoilage organism endemic to it, the pH of the product, the shelf life, and the ease of application. No one preservative can be used in every product to control all organisms, and therefore combinations are often used. In certain foods, specific preservatives have very little competition. In the concentrations used in practice, none of the preservatives discussed here is lethal to microorganisms in foods. Rather, their action is inhibitory. Major uses for preservatives by food industry sector are listed in Table 83.15.

In general, increased demand by consumers for lightly processed, lightly prepared foods (as people tend to do less cooking at home but at the same time are looking for products that are fresh, such as prepared salads) has stimulated use of antimicrobial preservatives over the past several years. At the same time, however, media and consumer reaction to chemical preservatives has stymied or limited the growth of several preservatives in favor of "all natural" and "no preservatives added" food products. However, significant displacement of traditional preservatives with naturally derived new products is not expected in the near future.

Important areas for preservatives are in fruit beverages and convenience foods. For example, low fat/low calorie salad dressings require a preservative, while the traditional high oil-containing products had lower water activity and therefore an acceptable shelf life without chemical preservatives.

Potassium sorbate and sorbic acid are used as preservatives in a great variety of foods and can be used as direct additives, as sprays or dip baths, and as coatings on wrapping materials, inhibiting yeasts, molds, and bacteria. Potassium sorbate is used where high water solubility is desired. Because sorbates have no effect on the microorganisms that produce lactic acid, they can be utilized to prevent yeast and mold spoilage of foods, such as most cultured dairy products and pickles, without interfering with the desired bacterial cure. Potassium sorbate solutions may also be used for spray and dip bath applications on cheese, dried fruits, smoked fish, and similar products.

The effectiveness of potassium sorbate is based on its ability to depress fatty acid metabolism in the microorganisms. Use of sorbic acid is limited because of its low solubility in water. Therefore potassium sorbate is the primary form used in foods. It is effective against microbes at pH 6.5 or less. As the pH decreases, the antimicrobial activity of this preservative increases. On an equal weight basis, potassium sorbate has 74% of the activity of sorbic acid.

Sorbic acid and potassium sorbate are GRAS additives. Normal use levels are in the range of 0.05–0.01%. Sorbates are used in cheeses, baked goods, spreads, margarine, dried fruits, jams, and jellies.

Because of its corrosive nature, propionic acid, a liquid, is rarely used in the food industry. Its sodium and calcium salts are used in its place, yielding the free acid within the food at low pH. They are highly effective mold inhibitors, but have essentially no effect against yeast. They have negligible activity against bacteria, except for their effectiveness against the rope-causing *Bacillus mesentericus.*

Propionic acid occurs naturally in Swiss cheeses at levels as high as 1%. Its calcium salt, and to a lesser extent its sodium salt, have been used for more than 30 years as an inhibitor of mold growth in bread. The main market for propionate salts is in bakery products, chiefly because these salts do not inhibit yeast action (they also have almost no activity against bacteria).

The propionates have GRAS status for use in foods and have no upper limits imposed except for breads, rolls, and cheese, which come under the Standards of Identity. They can be used up to 0.3% in cheese products and to 0.32% by weight of the flour in white bread and rolls.

Benzoic acid is one of the oldest chemical preservatives used in foods, having been described as a preservative in the 1800s. It has been used in foods since the early 1900s. Benzoic acid occurs naturally in some fruits and spices, such as cranberries, prunes, cinnamon, and cloves. Sodium or potassium benzoates are most effective in the pH range of 2.5–4.0. Benzoates have activity against yeasts, molds, and bacteria. However, benzoates are not recommended for bacterial control because their antimicrobial activity is poor above pH 4, where bacteria are the greatest problem. As benzoates are very efficient in controlling yeasts, they cannot be used in dough or in other yeast-raised bakery products.

The most important uses for benzoates are in fruit juices and carbonated beverages, jams and jellies, and condiments. In carbonated drinks, 0.03–0.05% is used; in noncarbonated drinks, up to 0.1% is used. Benzoates are also used for fats and oils, gravies, frostings, puddings, and gelatins. Potassium benzoate became in many of the above food products. It is also useful in margarine, potato salad,

fresh fruit cocktails, and pickles. Although the amount of sodium added with the benzoate salt is nutritionally insignificant, the potassium salt was developed specifically for use in reduced or low-sodium food products to avoid sodium declaration on the label.

The potassium or sodium salts of benzoic acid are more soluble in water than is benzoic acid and consequently are preferred for use in many food products. They do not destroy yeasts or molds but instead retard further growth of organisms already present, provided the degree of contamination is not too high. Benzoic acid and benzoates are GRAS substances and are permitted for use in foods up to a maximum of 0.1% concentration.

Parabens are esters of para-hydroxybenzoic acid. A combination of methyl and propyl esters and sodium benzoate is most often used, but the ethyl and butyl esters also have utility. Parabens are the only phenols approved for microbiological preservation of foods. Parabens are effective against molds and yeasts and are relatively ineffective against bacteria, especially the gram-negative bacteria. Their antimicrobial activity extends up to pH 7.0, making the parabens the only antimicrobial agents effective at higher pH values.

The methyl and propyl parabens are GRAS ingredients, but their use is limited to 0.1% (combined). *n*-Heptyl paraben is permitted in beer at a minimum concentration of 12 ppm. Parabens are used in baked goods, beverages, fruits, jams and jellies, and olives and pickles, but not in dairy products. Because parabens are the most expensive of the available preservatives and have some technical problems associated with their use in foods, use by the food industry remains limited.

About 10 years ago, sodium nitrite and sodium nitrate were used in curing bacon and other meats to prevent the growth of bacteria that cause botulism. The nitrate and nitrite were linked to the formation of nitrosamines in the meat, which were considered carcinogenic in experimental animals. Though the public outcry has largely subsided and nitrites continue to be used in smaller amounts, the continued use of these preservatives probably stems from the absence of suitable alternatives. Sodium ascorbate and sodium erythorbate are effective catalysts in the curing process, and the addition of one of these antioxidants to bacon makes it possible to reduce the quantity of sodium nitrite used.

Most chemical preservatives in use today have specialized uses and established niche markets in the food industry. A great amount of interchangeability does not exist because of specific inhibitory actions toward bacteria, molds, or yeasts. Blends of antioxidants and preservatives (some natural and some synthetic chemicals) can provide multiple functions for multiple food products. One such combination of ingredients is a blend of erythorbic acid, citric acid, and potassium sorbate as an antioxidant and antimicrobial substitute for sulfites on fresh vegetables.

I. EMULSIFIERS

Emulsifiers are additives that allow normally immiscible liquids, such as oil and water, to form a stable mixture. They are widely used in foods in order to achieve the texture, taste, appearance, fat reduction, and shelf life desired in foods. Bread and bakery products is the largest food segment utilizing emulsifiers. In this application, they soften the bread and strengthen the dough by distributing the fat within the product so less fat (shortening) needs to be added. Emulsifiers are utilized as fat-sparing agents in salad dressings and bakery and dairy products. Visible fats and oils routinely need emulsifiers for food-product processing, appearance, maintenance of shelf life, texture, and taste uniformity. They are also included in low-fat formulations (e.g., frozen desserts, bakery products), often more so than in formulations with normal fat levels. In addition, food emulsifiers are widely used in convenience, snack, and microwaveable food products. The multiple applications and functions of food emulsifiers are shown in Table 83.16, and several of the more prominent food uses of emulsifiers are shown in the following listing:

Breads
Frozen desserts
Icings
Cream fillings
Chocolate milk
Whipped toppings
Coffee creamers
Instant breakfasts
Infant formula
Dessert mixes
Rolls
Cake mixes
Fresh cakes
Donuts
Cereals
Food coatings
Instant potatoes
Pastas
Snack foods
Ice cream
Dips
Shortenings
Margarine and diet spreads
Peanut butter
Candy
Caramels
Chewing gum base
Chocolate
Toffees

The most common and commercially important emulsifiers are monoglycerides and diglycerides of fatty acids and their esters (e.g., glyceryl monostearate), lactylated esters (e.g., sodium stearoyl lactylate), propylene glycol mono- and diesters (e.g., propylene glycol monostearate), lecithin, sorbitan esters (e.g., sorbitan monostearate), and polysorbates (e.g., polyoxyethylene 80 sorbitan monolaurate). With the exception of lecithin, few emulsifiers are used as a single additive. Most food emulsifiers are used as blends of emulsifiers, water, fats, and other classes of food additives such as gums. These products are formulated for specific applications (or specific customers) so that the combination provides both enhanced performance and ease of use. Emulsifiers are regulated as food additives in most countries. The FDA classifies lecithin, monoglycerides and diglycerides, diacetyl tartaric acid ester (DATEM), and triethyl citrate as GRAS substances.

TABLE 83.16
Functions of Emulsifiers

Function	Typical Application	Process
Emulsifying	Margarine, creamy salad dressing, coffee whiteners, frozen desserts	Disperses small droplets of immiscible substances
Antistaling	Most baked goods	Complexing action on starch reduces firming of crumbs
Modifying texture	Bread, cakes, macaroni	Complexing action on starch reduces clumping, improves consistency and uniformity
Wetting	Coffee whiteners, drink mixes, instant breakfasts	Reduces interfacial tension between liquid and solid
Solubilizing	Color and flavor systems	Improves solubility
Crystal modification	Shortenings, margarine, peanut butter	Modifies mode and rate of crystal formation
Preventing agglomeration	Ice cream, frozen desserts	Controls coagulation of fat particles
Foaming	Whipped toppings, icings, cakes, convenience desserts, ice cream	Controls dispersion of a gas in a liquid
Defoaming	Processing of syrups, yeast	Breaks emulsions
Reducing tackiness	Candies, chewing gums	Assures texture
Fat sprang	Baked products, frozen desserts, whipped toppings, margarine, spreads, imitation sour cream	Reduces size of fat globules, resulting a wider dispersion and reduced fat levels
Improving palatability	Icings, confectionary coatings	Improves mouth feel

The other emulsifiers have specific regulations that permit their use in specific products at set levels.

Monoglycerides and diglycerides are used in the largest amounts (more than 50% of the total volume for emulsifiers), mainly because of their low cost. Important applications are in the preparation of shortenings, in bread and other bakery products, and in ice cream.

Lecithin. Commercial lecithin is usually a by-product from the refining of crude soybean oil. The term lecithin describes a complex mixture of phospholipids, triglycerides, fatty acids, and other components that occur naturally in soybean oil. The major phospholipids of lecithin are phosphatidylcholine (PC), phosphatidylinositol (PI), phosphatidylethanolamine (PE), and phosphatidic acid (PA). The unique structure of these phospholipids and other minor constituents gives lecithin its emulsification properties. Lecithin is often modified to improve its effectiveness as an emulsifier. The common modified lecithins that are commercially available are the hydroxylated, acetylated, and enzyme-modified lecithins. The result is more hydrophilic, water-dispersible lecithin with enhanced oil-in-water emulsion properties. The primary applications for lecithin are in baked products, dairy blends, baby foods, nutritional drinks, margarines, chocolates, chewing gums, and confectionaries.

Polysorbates are a group of emulsifiers that contain sorbitans, various types and amounts of fatty acids, and polyoxyethylene chains. Heating sorbitol with stearic acid in the presence of a catalyst cyclizes sorbitol and forms an ester to produce sorbitan monostearate and tristearate. Other sorbitan esters of importance are monooleate and tristearate. Any of the three esters may be reacted with ethylene oxide to give polyoxyethylene derivatives, which are much more hydrophilic than sorbitan esters. The monostearate derivative is known as polysorbate 60, the tristearate is polysorbate 65, and the monooleate is polysorbate 80. Polysorbates and sorbitol esters are used chiefly in ice cream, imitation dairy products, and in baking applications.

Polyglycerol esters contain polymerized glycerol and various types and amounts of fatty acids. The polyglycerol portion is synthesized by heating glycerol in the presence of an alkaline catalyst. The polyglycerol backbone is then esterified either by direct reaction with a fatty acid or by interesterification with triglyceride fat.

Sucrose esters are manufactured by adding fatty acids to a sucrose molecule. Sucrose has eight free hydroxyl groups that are potential sites for esterification with fatty acids. Derivatives containing one to three fatty acid esters are emulsifiers and are approved for food use.

There are a large number of other emulsifiers used in the food industry, but their volumes are negligible. Examples include lactylated esters, used in direct baking (not the shortening) and in imitation dairy products, and propylene glycol esters, used in various prepared mixes, shortening, and baking.

J. Flavors

Flavors consist of concentrated preparations, with or without solvents and carriers, used to impart a specific taste to food. Flavor ingredients are the largest single group of direct food additives utilized by the food industry. They also represent the highest value among the food additives segments. Flavoring substances are classified as

- Natural flavoring substance — obtained by physical separation, enzymatic processes, or microbial processes from vegetable or animal sources, either in the raw state or after processing (including drying, torrefaction, and fermentation).

- Nature-identical flavoring substance — obtained by synthesis or isolated by chemical processes and chemically identical to substances naturally present in the vegetable or animal sources (this classification is used in Europe but not allowed in the United States).
- Artificial flavoring substance — obtained by chemical synthesis and not found in nature.
- Flavoring preparation — products other than natural substances, whether concentrated or not, with flavoring properties, obtained by physical separation or enzymatic or microbial processes from material of vegetable or animal origin, either in the raw state or after processing (including drying, torrefaction, and fermentation).
- Process flavorings — products obtained by heating to a temperature not exceeding 180°C for a period not exceeding 15 minutes using a mixture of ingredients, not necessarily having flavoring properties themselves, of which at least one contains nitrogen (amino) and another is a reducing sugar.
- Smoke flavorings — smoke extracts used in traditional foodstuff smoking processes.
- Flavor enhancers — some amino acids and nucleotides, as well as sodium salts (such as monosodium glutamate, sodium inositate, and sodium guanylate), have only a weak taste by themselves but have the power to considerably enhance the taste sensation caused by other ingredients in savory flavors.

The flavor industry is not a single homogeneous entity, but a composite of closely interrelated and somewhat overlapping sectors including essential oils and natural extracts, aroma chemicals, and compounded flavors. The first two sectors provide the raw materials used for compounding flavors.

Essential oils are usually defined as the volatile aromatic material obtained from botanical or animal sources by the process of distillation, expression, solvent extraction, or maceration. The most common physical process used for removal of essential oils is steam or water distillation.

The term "extract" refers to a material that has been removed from a plant by a solvent, after which the solvent is evaporated to concentrate the oil. Absolutes, which are alcohol-soluble liquids, and concentrates, which are usually waxy solids, are both extracts.

Oleoresins are thick, viscous products obtained by extraction of plant material with a nonaqueous solvent (e.g., hydrocarbon) that is subsequently removed. Extracts of vanilla beans and other fruit extracts are the most important product examples of this class.

Essential oils and natural extracts represent complex aroma mixtures containing hundreds of chemical constituents. They may be used for imparting scent or aroma to consumer products or may be used as raw materials for compounding flavor and fragrance compositions, or they may be the source of isolated aroma chemicals, also used in compounding. Essential oils can be classified into three chemical groups: straight hydrocarbons, oxygenated compounds, and benzene derivatives.

Aroma chemicals comprise organic compounds with a defined chemical structure that are isolated from microbial fermentation, plant or animal sources, or produced by organic synthesis. Isolation consists of the physical removal of the flavor compound of interest from a natural source that contains it (e.g., L-menthol isolated from cornmint oil). Isolates may be further chemically modified.

Aroma chemical used to compound flavors are of two types: (1) isolates, which have been physically removed from natural sources that contain them and which may be further chemically modified; and (2) synthetic aroma chemicals that duplicate the structure and aroma characteristics of their counterparts found in nature. Synthetic aroma chemicals that duplicate the structure and aroma characteristics of their counterparts found in nature are known as "nature identical." Those that are not know to occur in nature but display an aroma reminiscent of known natural products with unrelated chemical structure are defined as "artificial." However, the legal definition of natural and artificial varies, depending on each country's legislation. Aroma chemicals are used as raw materials for flavor compositions. While technical merits are not at issue, naturally occurring aroma chemicals may enjoy preferential status for their use in certain countries because of labeling regulations.

More than 80% of aroma chemicals in use contain only carbon, hydrogen, and oxygen in their structure, the large majority being esters, ketones, aldehydes, and alcohols. A few contain nitrogen (nitro and nitrile groups, pyrazines) and/or sulfur (mercaptane, thiazoles). About 4% of the chemicals are unsaturated hydrocarbons, primarily with cyclic and acyclic terpene structures (e.g., limonene, pinenes, etc.). Most of the aroma chemicals are oil-soluble, water-insoluble liquids.

Aroma chemicals of commerce can be broadly classified according to their chemical structure and are grouped into three categories as follows:

1. Benzenoids (including naphtalenoids): chemicals containing a benzene or naphthalene ring, including alcohols, acids, esters, aldehydes, ketones, phenols, phenol esters, and lactones.
2. Terpene and terpenoids: chemicals with (or closely related to) characteristic terpene structures, both acyclic and cyclic, having two or more isoprene (C_5H_8) moieties and oxygenated derivatives of the terpene hydrocarbons, including alcohols, aldehydes, ketones, and esters.

TABLE 83.17
Commercial Flavor Compositions

Type of Flavor	Classification	Manufacturing Process	Raw Materials	Product Form
Compounded flavors	Natural or synthetic	Blending, mixing	Essential oil, natural extracts, fruit juice concentrates, aroma chemical	Liquid, spray-dried, encapsulated
Natural extracts	Natural	Extraction, enzymatic treatment	Food substrates (e.g., plants, fish, meat, etc.)	Liquid, paste
Reaction flavors (thermally processed)	Natural	Heating/pressure cooking	Amino acids and sugars, hydrolyzed proteins	Paste, powder
Enzymatically modified flavors	Natural	Enzymatic/microbial reaction	Food substrates (e.g., cheese)	Paste, powder

3. Other aroma chemicals: includes aliphatic, alicyclic, and heterocyclic compounds and esters of lower fatty acids.

Of the thousands of aroma chemicals included in compounded flavors, the following compounds are used in very large quantities: 3-phenetyl alcohol and esters, vanillin, ethyl vanillin, esters of lower fatty acids, benzyl acetate, alpha-hexyl-cinnamaldehyde, 1-menthol (synthetic), geraniol/nerol and esters, and anethol.

The universally applicable definition of flavor compositions is that of mixtures of aromatic materials that are added to foods and beverages in order to improve palatability. Flavor compositions consist of complex mixtures of various aromatic materials from few to 100 or more constituents. Compounded flavors may contain aroma chemicals, natural extracts, essential oils, solvents, and in some cases other functional additives (e.g., antioxidants, acidulants, emulsifiers, etc.). Certain raw materials that can be used directly as flavors without compounding (e.g., vanilla, peppermint) and those products with a taste of their own, such as sweeteners, acidulants, and salts, are not included in the above definition.

Flavors serve all sectors of the food processing industry, including carbonated and still beverages, processed foods, confectionary, and dairy foods, and are added to foods and beverages for the following reasons:

- To create a totally new taste
- To enhance, extend, round out, or increase the potency of flavors already present
- To supplement or replace flavors to compensate for losses during processing
- To simulate other more expensive flavors or replace unavailable flavors
- To mask less desirable flavors — to cover harsh or undesirable tastes naturally present in some foods

The types of flavor compositions, their manufacturing process and the starting materials for manufacturing them, and their common product form are summarized in Table 83.17.

X. ADVERSE EFFECTS OF FOOD ADDITIVES

The practice of adding chemicals (e.g., salt, spices, herbs, vinegar, and smoke) to food dates back many centuries. In recent years, however, the ubiquitous presence of chemical additives in processed foods has attracted much attention and public concern over the long-term safety of additives to man. Although the safety issue is far from subsiding, there is scientific consensus that food additives are indispensable in the production, processing, and marketing of many food products. Moreover, the judicious use of chemical additives — typically in the range of a few parts per million (ppm) to less than 1% by weight of the finished food — contributes to the abundance, variety, stability, microbiological safety, flavor, and appearance of food. While food additives offer a major contribution to the palatability and appeal of a wide variety of foods, their level of use is relatively insignificant in the total human diet. For the most part, the permitted food additives are safe, highly effective, and have been in continuous use for a long time.

There is much discussion about whether a food additive or food product is natural or synthetic. The fact is that this classification, in many instances, has become somewhat arbitrary. Many food additives synthesized in chemical laboratories are also naturally occurring in normal food. Monosodium glutamate, a flavor-enhancing food additive, is the sodium salt of glutamic acid, an amino acid found in many foods such as mushrooms and tomatoes and metabolized by the human body using the same biochemical pathways of digestion. Synthetic vitamin C (ascorbic acid) and its isomer, erythorbic acid, are the same chemicals that are found in citrus fruits. Similarly, citric acid, which is today produced commercially by enzymatic fermentation of sugars, is the same chemically as the naturally occurring chemical that has been found to make lemons and limes tart.

Much of the worldwide public concern about the use of food additives relates to fears about safety and has generated some sort of regulatory structure in every major country, as well as in international bodies, to monitor this aspect of the field. There is a Joint Experts Committee on Food

Additives, set up by the Food and Agriculture Organization and the World Health Organization, to consider the safety of additives and set specifications and limits for them. These limits take the form of an acceptable daily intake (ADI). The Codex Committee on Food Additives is required to follow the safety guidelines of the Joint Express Committee. Its safety criteria are generally not very different from those used in the United States, although they are not codified. In the United States, criteria for food additives are stated in 21 CFR §170.22, "Safety factors considered," and 21 CFR §170.20, "General principles for evaluating the safety of food additives." The key sentence, which also runs through the decisions in other countries, says, "A food additive for use by man will not be granted a tolerance that will exceed 1/100th of the maximum amount demonstrated to be without harm to experimental animals."

It should be remembered, however, that in the United States, these criteria apply only to substances that are legally food or color additives and, by interpreting regulation, to those substances that are GRAS on the basis of "scientific procedures." For those substances that are GRAS because of "experience based on common use in food," there are no rules. Decisions of safety depend on the knowledge and judgment of the "experts qualified by scientific training and experience to evaluate its safety."

One other aspect of the safety question deserves discussion. In the United States only, there is a special provision, known as the Delaney clause, that says "no additive shall be deemed to be safe if it is found to induce cancer when ingested by man or animal." This means that an additive is not to be permitted at any level, no matter how low, if it induces cancer at any level, no matter how high.

The risks posed to the consumer by the food supply are rated in decreasing order of severity as follows:

1. Microbiological hazards (food poisoning from bacteria or bacterial toxins salmonellosis, botulism, etc.).
2. Nutritional hazards (excessive consumption of sodium, saturated fat, etc.).
3. Environmental pollutants (mercury in fish, lead from car exhaust, etc.).
4. Natural toxicants (mushroom poisoning, solanine in potatoes and other solanaceous plants, shellfish toxins, etc.).

TABLE 83.18
Food Additives Prohibited from Use in Human Food

Food Additive	21 CFR Section	Date of Ruling	Functionality
Calamus and its derivatives	189.110	May 9, 1968	Flavoring compound
Cinnamyl anthranilate	189.113	Oct 23, 1985	Flavoring compound
Cobaltous salts and its derivatives	189.120	Aug. 12, 1966	Foam stabilizer
Coumarin	189.130	March 5, 1954	Flavoring compound
Cyclamate and its derivatives	189.135	Oct. 21, 1969	High-intensity sweetener
Diethylpyrocarbonate (DEPC)	189.140	Aug. 2, 1972	Ferment inhibitor in beverages
Dulcin	189.145	Jan. 19, 1950	High-intensity sweetener
Monochloroacetic acid[a]	189.155	Dec. 29, 1941	Preservative in beverages
Nordihydroguaiarectic acid (NDGA)	189.165	Apr. 11, 1968	Antioxidant
P-4000 (5-nitro-2-n-propoxyaniline)	189.175	Jan. 19, 1950	High-intensity sweetener
Safrole	189.180	Dec. 3, 1960	Flavoring compound
Thiourea (thiocarbamide)	189.190		Antimycotic preservative
Chlorofluorocarbon	189.191	Mar. 17, 1978	Propellant
Flectol H (1,2-dihydro-2,2,4-tri-methylquinoline	189.220	Mar. 15, 1977	Food packaging adhesive
Lead solders	189.240	June 27, 1995	Can solder
Mercaptoimidazoline and 2-mercaptoimidazoline	189.250	Nov. 30, 1969	Packaging material
4,4′-methylenebis (2-chloroanaline)	189.280	Dec. 2, 1969	Packaging adhesive and polyurethane resin
Hydrogenated 4,4′-isopropylidene-diphenolphosphite ester resins	189.300	Feb. 17, 1989	Antioxidant and stabilizer in vinyl chloride resins
Tin-coated lead foil capsules for wine bottles	189.301	Feb. 8, 1996	Capsule for wine cork

[a] Permitted in food package adhesives with an accepted migration level up to 10 ppb under §175.105.

5. Pesticide residues (maximum residue levels are enforced in the United States but may exceed federal limits in imported produce).
6. Food additives (documented cases of poisoning due to food additives are rare and were due to noncompliance with federal regulations).

Although the risk to human health from food additives ranks the lowest among food hazards, some potential risks from food additives to exist.

A. Food Additives Banned from Use

In the United States, the FDA prohibited the use of a number of chemicals in foods for human consumption because they either present a risk to public health or have not been shown to be safe by adequate scientific data. Table 83.18 lists the food additives that are presently prohibited from addition to food. Use of any of these substances causes the food to be in violation of FDA regulations.

In the years since 1970, food colors, especially the synthetic dyes, have received tremendous publicity — nearly all of it bad. Color additives for food represent a unique and special category of food additives. They have historically been so considered in legislation and regulation. The current legislation governing the regulation and use of color additives in the United States is the Food, Drug & Cosmetic Act of 1938, as amended by the Color Additives Amendment of 1960. This amendment allowed for the provisional or temporary listing of food colorants, pending completion of scientific studies determining the suitability of these colorants for permanent listing. Pharmacological testing of synthetic "certified" colors was initiated in 1957. Many of the synthetic colors that had been approved for use at some time in the past have been removed from the approved list as a result of new toxicological test results. This has steadily reduced the number of certified dye colors available to the U.S. food industry from more than 22 in 1950 to 7 in 2003. Table 83.19 provides a history of the status of synthetic colorants in the United States. Another eight dyes are permitted in the EU, but are not permitted in foods in the United States.

The EU works on a positive list system using EU Directive no. 95/2/EC, which is the general directive on food additives (other than colors and sweeteners that are covered in separate directives). This law recognizes 106 food additives. If the additive is mentioned in the doctrine then it is allowed, if not it is forbidden. However, the directive includes a list of substances that cannot be used in flavorings (Table 83.20).

TABLE 83.19
Chronological History of Certified Food Colors in the United States

Year Listed for Food Additive	Name of Certified Food Color	Year Delisted
1970	Red no. 1	1961
1907	Red no. 2	1976
1907	Red no. 3	*
1907	Orange no. 1	1956
1907	Yellow no. 1	1959
1907	Green no. 2	1966
1907	Blue no. 2	*
1916	Yellow no. 5	*
1918	Yellow no. 3	1959
1918	Yellow no. 4	1959

1959	Citrus red no. 2	**
1966	Orange B	**
1971	Red no. 40	*

* Currently permitted.

** Currently permitted with certain restrictions.

B. Industrial Chemicals

Polychlorinated biphenyls (PCBs) and polybrominated biphenyls (PBBs) are toxic industrial chemicals. Because of their widespread, uncontrolled industrial applications, they have become a persistent and ubiquitous contaminant in the environment. As a result, certain foods, principally those of animal and marine origin, contain PBCs and PBBs as environmental contaminants.

PCBs are transmitted to the food portion (meat, milk, and eggs) of food-producing animals ingesting PCB-contaminated animal feed. In addition, a significant percentage of paper food-packaging materials contain PCBs, which may migrate to the packaged food. Therefore temporary tolerances for residues of PCBs as unavoidable contaminants are established by the FDA (21 CFR §109.15 and §109.30). The temporary tolerances for residues of PCBs are as follows:

- 1.5 ppm in milk (fat basis)
- 1.5 ppm in manufactured dairy products (fat basis)
- 3 ppm in poultry (fat basis)
- 0.3 ppm in eggs
- 0.3 ppm in finished animal feed for food-producing animals
- 2 ppm in animal-feed components of animal origin, including fish meal and other by-products of marine origin and in finished animal feed

TABLE 83.20
European Union List of Food Additives Prohibited for Use in Flavorings (Directive 95/2/EC)

EU Number	Compound
E230	Biphenyl, diphenyl
E231	Orthophenyl phenol
E232	Sodium orthophenyl phenol
E233	Thiabendazole
E234	Nisin
E235	Natamycin
E239	Hexamethylene tetramine
E242	Dimethyl dicarbonate
E249	Potassium nitrite
E250	Sodium nitrite
E251	Sodium nitrate
E252	Potassium nitrate
E280	Propionic acid
E281	Sodium proprionate
E282	Calcium proprionate
E282	Potassium proprionate
E284	Sodium tetraborate (Borax)
E311	Octyl gallate
E312	Dodecyl gallate
E315	Erythorbic acid
E316	Sodium erythorbate
E579	Ferrous gluconate
E620	Glutamic acid
E621	Monosodium glutamate
E622	Monopotassium glutamate
E623	Calcium diglutamate
E624	Monoammonium glutamate
E625	Magnesium diglutamate
E626	Guanylic acid
E627	Disodium guanylate
E628	Dipotassium guanylate
E629	Calcium guanylate
E630	Inosinic acid
E631	Disodium inosinate
E632	Dipotassium inosinate
E633	Calcium inosinate
E634	Calcium 5′-ribonucleotides
E635	Disodium 5′-ribonucleotides
E912	Montan acid esters
E914	Oxidized polyethylene wax
E927b	Caramide
E950	Acesulfame K
E957	Thaumatin
E1105	Lysozyme

concentrates, supplements, and premixes intended for food-producing animals
- 2 ppm in fish and shellfish (edible portion)
- 0.3 ppm in infant and junior foods
- 10 ppm in paper food-packaging material intended for use with human food or finished animal feed

Cereals containing gluten (wheat, rye, barley, oats)
Crustacea and products
Eggs and egg products
Fish and fish products
Peanuts and products
Milk and milk products
Tree nuts and nut products
Soybeans and products

C. Food Allergies and other Adverse Reactions to Food Additives

Food allergies and other food sensitivities are individualistic adverse reactions to foods. These food-related illnesses are individualistic because they affect only a few people in the populations; most consumers can eat the same food with no ill effects. Many different types of reactions are involved in these individualistic adverse reactions to foods. Adverse food reactions can include IgE (immunoglobulin E) and non-IgE-mediated primary immunological sensitivities, non-immunological food intolerances, and secondary sensitivities. While these various types of reactions are often considered collectively as food allergies, true food allergies represent only a fraction of the individualistic adverse reactions to foods.

True food allergies are abnormal responses of the immune system to components of certain foods. The components of food that elicit these abnormal immune responses are typically naturally occurring proteins in foods, although some may be polysaccharides (Table 83.21).

Certain foods can elicit adverse reactions that resemble true food allergies. These foods contain elevated levels of histamine, one of the principal mediators of allergic reactions in the body. When large doses of histamine are ingested with foods, the body's protective mechanism can be overwhelmed resulting in histamine poisoning.

Food intolerances are abnormal reactions to foods or food components that do not involve the immune system. Lactose intolerance is an example of a metabolic food disorder resulting from a defect in the metabolism of a food component. Favism is an example of a metabolic disorder resulting from food-born substances that interfere with normal metabolic processes. Sulfite-induced asthma is an example of an idiosyncratic reaction that occurs among certain consumers, although the mechanism remains unknown.

Although food allergy rarely constitutes a serious, life-threatening concern, it may result in chronic illness. As complete avoidance of the incriminated food is the best defense against adverse reactions, information is of foremost importance. Consumers with various types of food allergies and intolerances must alter their lifestyles on a continuing basis to avoid the offending food or food ingredient.

Symptoms. The most common manifestations of food-allergic reactions are gastrointestinal, dermal, and respiratory, and they represent interaction of released mediators with receptors on those tissues. Gastrointestinal symptoms are common, especially in infants and young children. These include nausea, vomiting, cramping, and diarrhea. Skin reactions can include itching and swelling of the lips, tongue, gums, oral mucosa and pharynx. A topic dermatitis, a chronic inflammatory skin disease, is characterized by dry, easily irritated, intensely pruritic skin. Urticaria (hives) and dermatitis are the most common skin manifestations, and can be a general or localized nature.

The reactions are very individualistic and diverse; initially some individuals may experience immediate contact reactions on their lip and tongue, while others do not experience a reaction until the offending food has moved farther down the gastrointestinal tract. Respiratory symptoms can include upper airway distress, produced as a consequence of bronchoconstriction, with resulting swelling and mucus production. Asthma has been associated with allergies to certain foods. Anaphylactic shock, the most severe manifestation of a food allergic reaction, is a rare, acute, and potentially fatal response.

Despite the multitude of additives used in foods, only a small number have been associated with adverse reactions. Table 83.22 provides a list of the food additives that have been associated with adverse reactions.

Burning of sulfur-containing coal has been used for centuries to preserve food. In addition, sulfite salts (sodium and potassium sulfite, bisulfite, or metabisulfite) are used as a sanitizing agent for fermentation containers and are added to a wide variety of food products, including dried fruits and vegetables, wine, shrimp and other seafood, and citrus beverages. Because of complaints about severe allergic reactions from asthmatic consumers, in 1986 the FDA banned the use of sulfites in fresh cut fruits and vegetables and sulfites must be listed on the label if a food product contains in excess of 10 ppm sulfite. The FDA estimates that about 1% of the U.S. population may be sulfite sensitive. However, among the asthmatic patient population, the sensitivity to sulfites is more prevalent, ranging from 2% to 5%.

The antimicrobial food preservatives benzoate and paraben are believed to cause adverse reactions, such as asthmatic reactions in some individuals. Benzoates occur naturally in certain berries and are used in beverages, and their use is limited to 0.1% concentration. Parabens are effective antioxidants in low-acid products. However, they are primarily used in cosmetic and pharmaceutical products and rarely in food. They have been implicated as a cause of eczematous or contact dermatitis reactions.

Butylated hydroxyanisole (BHA) and butylated hydroxytoluene (BHT) have been linked to adverse reactions in a small number of individuals. These antioxidants are frequently used in fats and oils and in cereal products to retard rancidity.

TABLE 83.22
Food Additives Suspected of Causing Adverse Reactions

Antioxidants
Sulfur dioxide
Sodium sulfite
Sodium bisulfite
Sodium metabisulfite
Potassium bisulfite
Potassium metabisulfite
Preservatives

Potassium nitrite
High-intensity sweetener
Aspartame (aspartic acid and methylphenylalanine)
Flavor enhancer
Monosodium glutamate (MSG)
Certified food colors (dyes)
Tartrazine (FD&C yellow no. 5)
Sunset yellow (FD&C yellow no. 6)
Brilliant blue (FD&C blue no. 1)
Indigotin (FD&C blue no. 2)
Erythrosine (FD&C red no. 3)
Ponceau (Red no. 4, permitted in Europe and Japan)
Amaranth (Red no. 5, permitted in Europe)

Aspartame (L-aspartyl-L-phenylalanine methyl ester), a widely used artificial sweetener, is a dipeptide. Humans metabolize it. Aspartame has been cited as the most frequently complained-about product. Soft drinks have been mentioned most often as the aspartame-containing product, and headaches are the common reaction reported. In the United States, the FDA requires that aspartame-containing products include the following label declaration: "Phenylketonurics: contains phenylalinine." Also, in the EU countries, the label declaration "contains a source of phenylaniline" is required.

Monosodium glutamate (MSG) is used as a food additive because of its flavor-enhancing properties. The most commonly reported adverse reaction associated with MSG consumption is Chinese restaurant syndrome. Symptoms of the Chinese restaurant syndrome include nausea, headache,

Xanthan gum

sweating, thirst, facial flushing, and abdominal pain. These symptoms typically occur 15–30 minutes after consuming food containing a large amount of MSG. A Chinese food meal may contain from 5 to 10 g of MSG.

Among the coloring agents used in the food industry, tartrazine (FD&C yellow no. 5) has most often been implicated as a cause of allergies, especially urticaria and asthma. Respiratory problems subsequent to tartrazine ingestion have been reported by several sources. Tartrazine produces a bright yellow color and it is used in a variety of beverages, baked products, confectionaries, dessert mixes, etc. Tartrazine is also used to produce other food colors such as green, maroon, and rust. Lack of yellow color, therefore, is not a guarantee of tartrazine's absence. Thus the FDA requires that FD&C yellow no. 5 be specifically stated by name on food ingredients labels. Food colorings other than tartrazine (listed in Table 83.23) have also been implicated as causing adverse reactions in some individuals.

D. Food Additives Derived from Allergenic Foods

A few foods are responsible for the majority of allergic reactions. In adults, these foods include nuts, peanuts, fish, and shellfish. In children, the main culprits include eggs, milk, peanuts, soy, wheat, and fish. Elimination of these foods from the allergic individual's diet is essential. However, many food additives are derived from these basic food items, and the allergen compound may be carried over even into highly refined derivatives. Recognition of the presence of such potentially allergenic compounds is sometimes difficult.

In Table 83.23, selected food additives derived from allergenic natural food sources are listed. Recognition of these additives is crucial to avoid potential health hazards to consumers sensitive to certain foods.

The industry must provide these consumers with the information necessary for them to practice such avoidance effectively. Ingredient labeling statements are the key to implementation of safe and effective avoidance diet. FDA regulation exempts specific substance declaration of flavors, spices and colorings. However, the agency strongly encourages specific declaration of an allergenic ingredient if present among these exempt ingredients (e.g. FD&C Yellow No. 5). Also, manufacturers must be aware that certain processing practices such as the use of shared equipment can result in undeclared residues of allergenic foods existing in other products. These situations can be hazardous for allergic consumers especially if larger quantities of the allergenic foods are present on an undeclared basis.

84 Food Processing Biofilms and Antimicrobial Agents

Balamurugan Sampathkumar, George G. Khachatourians, and Darren R. Korber
Department of Applied Microbiology and Food Science, University of Saskatchewan

CONTENTS

I. INTRODUCTION

While more than two decades have passed since the term "biofilm" was coined, the effect of surface contamination by attached bacteria has long been known in the food processing industry. It has only been over the past 10 years, during which time the production of food, and especially meat products, has come under increasing pressure to improve sanitation and reduce the incidence of foodborne pathogens, that biofilms have been targeted as a major concern to food processing operations. Most food processing operations now use HACCP to closely monitor and record critical food processing steps to ensure that high standards of plant and employee hygiene are maintained, and that the potential for health hazards in the final product is minimized. However, biofilms continue to pose a serious problem in many facilities despite efforts to control the situation. The solution to this problem in part lies with improved education about what biofilms are and how they form, as well as proven and novel control strategies for their removal and killing.

Most foods are a source of pioneer bacterial flora, and as such represent a major source of contamination and recontamination in food production facilities. Cleaned or

new surfaces in a plant rapidly become fouled with spoilage and/or pathogenic bacteria soon after processing operations begin, and if unchecked, a surface fouling, or biofilm, problem may result. Once established, biofilms are difficult to dislodge and completely kill, features evidenced by their rapid regrowth following typical cleaning and sanitization operations. Much is already known of the ecology and nature of biofilms despite the fact that specific studies haven't always been performed in food processing environments; hence, extrapolation of this knowledge to food systems is possible in many instances. For example, it is known that biofilms are different, in terms of physiology, gene expression and behaviour, from pure cultures grown in planktonic culture (the traditional approach to the study of bacteria). Biofilm bacteria express different genes, up- or down-regulate production of various proteins, undergo physiological changes that impact their ability to survive imposed stress factors such as antimicrobial agents, and become integrated within complex assemblages of different microbial species rather than just a single species. The condition of these sessile bacteria is very far removed from that experienced by a pure culture of bacterial cells suspended in liquid growth medium.

No universally effective control strategy or antimicrobial agent presently exists for biofilms; hence, research for developing and testing new approaches for biofilm control is ongoing. The most common strategy for controlling biofilms involves the application of antimicrobial agents to vulnerable surfaces, typically in conjunction with other agents as well as surface sanitation techniques. Development of new chemical agents and/or techniques, especially in light of new revelations of the distinct physiological and molecular status of biofilm bacteria, is an obvious goal of those researchers in the discipline. This review is intended to provide key foundational information describing biofilms, as well as biofilm control measures currently in use or under development that are relevant to food processing.

II. BIOFILMS DEFINED

Other than Antonie van Leeuwenhoek, who used a handmade single lens microscope to view microbial populations from his teeth back in the late 1600s, the first individual credited with speculating that significant populations of attached bacteria existed was Zobell, who in 1943 examined surfaces associated with oligotrophic aquatic systems (1). It is now known that virtually any surface over which liquid flows, including contact lenses, ship hulls, dairy equipment, teeth, water distribution systems, petroleum pipelines, rocks in streams, heat exchangers and all varieties of biomedical implants and transcutaneous devices are all prone to colonization by biofilm bacteria over time. While biofilms may be either beneficial or detrimental, the detrimental effects are best characterized.

Exactly what is a biofilm tends to vary in the scientific literature; however, they are consistently described as bacterial cells attached to a surface and enmeshed in an extracellular exopolysaccharide (EPS) matrix. A more descriptive explanation of how these elements are arranged is useful, however, if one is to appreciate the complexity and organization exhibited by most microbial biofilms. Thus, biofilms are the result of a variety of different bacteria and their EPS material forming a highly-hydrated matrix positioned at a solid liquid interface, which will eventually develop to include extraneous particulate matter, proteins, nucleic acids, lipids, enzymes, etc. The structural arrangement of cells and polymer has been described as "architectural," due to the high degree of apparent organization in three-dimensional space; given time, embedded microcolonies and cellular aggregates become separated by channels, voids or tunnels. A number of review articles have addressed the topic of biofilm architecture and its importance to biofilm nutritive and metabolic processes (2–4).

III. THE FORMATION OF BIOFILMS

Biofilm development is a complex process that includes the following "phases"; i) molecular film adsorption, ii) bacterial attachment, iii) biofilm growth, spread or maturation, and iv) biofilm dispersion or cell shedding. It is useful to view the events governing biofilm formation in terms of a particular time frame involved (e.g., either relatively short or very long), as these events may then be considered in light of the sanitation and operation of a typical food processing operation.

A. Early Events

When biofilm research intensified during the 1980's, much effort was focused on bacterial attachment, as cells must first attach to surfaces before they form a biofilm. The adsorption of a molecular film from the liquid phase is significant in that any clean surface placed in an impure liquid will rapidly accumulate a molecular film. This process starts immediately following the immersion of a surface in liquid, and where there is an abundance of complex organic materials and exudates such as in a meat processing plant, the accumulated film can be significant. Molecular films rapidly modify the chemistry of the surface to reflect that of the solution, and consequently impact surface physicochemical properties. For example, surface charges and zeta potentials, contact angles, and surface tensions can be expected to vary as a function of the properties of the liquid as well as that of the once-clean substratum (5–9). The adsorption of this film has been documented to have measurable effects on bacterial attachment. Meadows (10) demonstrated that sorption of casein and gelatin enhanced attachment processes whereas Fletcher (11) determined that precoating polystyrene

surfaces with albumin, gelatin, fibrinogen, and pepsin all inhibited the attachment of a marine Pseudomonad. Chemotactic bacteria have also been shown to respond to the presence of organic molecules, providing an explanation for the directed movement and preferential positioning of many bacterial species on solid substrata (12–15).

While sanitizing protocols in food processing settings are unable to eliminate all surface organic and inorganic molecules (or even all bacteria for that matter), they should be effective enough to prevent the surface from acting as a major source of nutrients for bacteria. As soon as the next production shift begins, a new film will accumulate fairly rapidly; thus, the daily challenge is to minimize the amount of surface soil remaining following cleaning along with any bacteria that may have become established or grown during the preceding shift, thereby preventing the uncontrolled growth of attached microorganisms for any longer than the time required for a single shift.

The actual attachment of bacteria involves close cell-surface interactions at solid liquid interfaces. Non-motile bacteria initially contact attachment surfaces via gravitational settling, convection, or Brownian motion/diffusion (16, 17). In contrast, motile organisms migrate either chemotactically or randomly to surface attachment sites. The process of adhesion has been described by Marshall et al. (18) to involve two phases, a theory that still sees extensive use. The first, or reversible attachment, phase is a non-specific process involving the association of cells near ($\geqslant$50 nm), but not in actual contact with, the substratum. Adhesion is reversible as only weak bonds (Van der Waal's forces, hydrogen bonding, hydrophobic interactions, or electrostatic interactions) secure the bacterium to the surface; thus, any significant shear force will remove the cells. At these distances, the microbial and solid surfaces are too far apart for molecular recognition of most surface features. Once the cell is positioned 10 to 20 nm from a solid surface, interplay between attractive Van der Waal's and repulsive electrostatic forces (while most bacteria and surfaces carry a net-negative charge; non-uniform, oppositely charged, ion clusters exist on the cell surface) now occurs. For attachment to occur, attractive forces must exceed repulsive forces. The presence of pili and/or flagella (pili are ~4–7 nm in diameter and up to 1000 nm in length) that penetrate the repulsive barrier from long range both enable bacterial cells to become stably attached. Overall, reversible attachment is rapid and may occur within a fraction of a second following a bacteria-surface contact.

Other factors also affect attachment of bacteria. For example, surface composition (e.g., plastic, metal, or wood), surface condition (e.g., whether it is new or has scratches or pits), and surface charge and hydrophobicity all contribute to microbial attachment success. Other factors like solution ionic strength, liquid shear forces and viscosity, and temperature have been shown to play roles of varying importance (5, 19). Lastly, bacteria-specific parameters, such as the type of organism, growth phase and prior growth conditions, flagellum and motility factors, and specific cell–cell coaggregation events all affect attachment success (20–24). These factors not only impact initial attachment success of bacteria but also the tenacity of long-term attachment by various organisms — conditions that result in stronger adhesion translate into increased difficulty of bacterial removal during plant sanitation. While perhaps self-evident, the condition of the surface is especially important, not only because it may contribute to cellular adhesion, but because surface imperfections like scratches and corrosion provide refuge for biofilms and subsequently shield cells from the effects of antimicrobial agents (25). Work on bacterial attachment continues today, reflect the fact that this phenomenon is both complex and pervasive.

B. Late(r) Events

Once reversibly attached, stronger cell-surface interactions may cause the cell to become permanently, or irreversibly, attached (the second phase in Marshall's (18) two stage attachment description; see above). The key to this process is the production of extracellular polysaccharides (EPS), a substance that bridges the bacterial cell surface and the solid substratum. Bacterial EPS are high molecular weight polymers that are highly hydrated (26, 27); thus, food processing surfaces with a biofilm contamination problem often have a "slimy" feel. Biofilm EPS constituents includes, in addition to polysaccharides, globular glycoproteins, amino acids and sugars, nucleic acids, lipids, phosphates, organic acids and ions. While EPS does not form strong bonds with the substratum, it does form a large number of weak bonds that collectively immobilize bacterial cells within the biofilm and more importantly, secure the biofilm to the substratum.

Specific EPS moieties also play important adhesive roles. For example, glycoproteins contain positive charges that ionically cross-bridge the EPS and substratum. Other EPS related factors that influence bacterial adhesion include EPS age, complexation of EPS with other molecules, chemical makeup of the EPS, and the types of organisms present. Biofilm EPS, like the EPS produced by planktonic bacteria, vary greatly in terms of their physical and chemical properties and it has been reported that EPS from different bacterial species actually function synergistically to strengthen overall biofilm adhesion (26). Another effect of an aging cell-EPS matrix is a reduction in diffusional transport, a factor tending to make biofilms more substrate- and oxygen-limiting. This alters the physiological status of the cells trapped within, and embedded cells typically have decreased rates of growth and metabolism. The role of EPS is greater than that of simple adhesion, and biofilm EPS is widely thought to participate in nutrient capture and uptake, maintaining an optimal biofilm microenvironment,

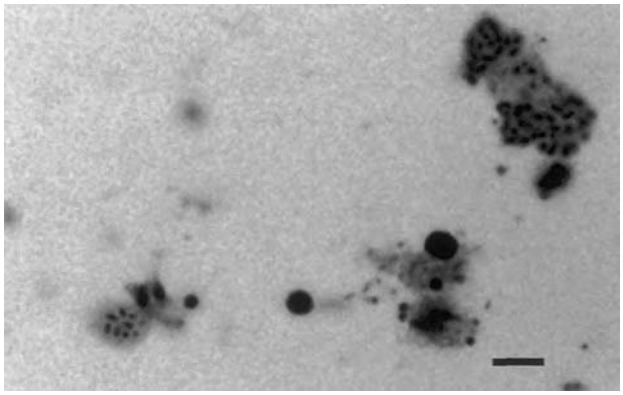

FIGURE 84.1 Confocal laser microscope image of negatively stained (0.1% fluorescein solution) mixed species biofilms showing microcolonies surrounded by dense EPS material. Note that the EPS material tends to exclude the low molecular weight fluorescein (289 MW) in regions immediately adjacent to the cells. Scale bar = 10 μm.

and protecting biofilm inhabitants from predators, desiccation and antimicrobial agents (27, 28). The contribution of EPS in the protection of food processing biofilms from antimicrobial agents is discussed further below (see section on *Biofilm resistance to sanitizing and antimicrobial agents*). Figure 84.1 shows bacterial microcolonies enmeshed in dense EPS material.

Factors like flagella, pili and adhesins have also been shown, using adaptation-minus mutants, to play important roles during adhesion and subsequent biofilm formation. The primary function of flagella in biofilm formation is assumed to be in transport and in initial cell-surface interactions (see above). However, the presence of a functional flagellum has also been shown to act as a adhesion factor during the colonization of potato and wheat surfaces by *Pseudomonas* species (29, 30), whereas pili-associated adhesins are known to be important during the colonization of epithelial surfaces of mammals (31–34).

C. Microcolonies, Maturation and Architecture

The colonization of surfaces by bacteria may be based on either solitary or colonial strategies (3). Single cell strategies are employed by budding bacteria like *Rhizobium* or *Caulobacter* spp. These cells attach to surfaces either in a polar or non-polar manner and then release their progeny into the aqueous phase (35). Budding organisms most commonly exist in oligotrophic waters systems or are associated with plant roots and are typically slow growing and non-pathogenic; hence, they are of limited importance to food processing. Of greater significance are colonial cells, of which *Pseudomonas aeruginosa* or *P. fluorescens* provide examples. Soon after these cells attach to surfaces, they proliferate and develop into microcolonies. The formation of microcolonies are considered to represent primitive behavioural patterns, and follow a defined (often species-specific) developmental pathways or colonization strategy (3). These organisms attach as single cells, multiply on the surface into packed, or dense, microcolonies, and then release progeny as single cells to recolonize new surfaces (19). The majority of food processing pathogens colonize surfaces in this manner.

Microcolony formation patterns considered "behavioural" have been shown to vary with the physical, chemical and biological environment; thus, flow velocity and substratum type, nutrient status and Eh, and presence of competing or communal organisms affect microcolony developmental kinetics and appearance. Wolfaardt et al. (36) and Moller et al. (37) showed that by changing to a labile carbon source from a recalcitrant carbon source resulted in a different biofilm appearance. While biofilms are the dominant mode of growth in many environments, specific examples exist of bacterial adaptation to both the planktonic and biofilm modes of growth. *Vibrio parahaemolyticus* clearly shows this trait; a short, polarly flagellated variant is adapted for migration within low viscosity environments such as the open ocean, whereas an elongated, laterally flagellated variant is suited for colonization of high viscosity environments (e.g., mucus layers of fish) (38). Switching between these two phenotypes ensures the organism is poised for success in either system. Based on other adaptations like motility and chemotaxis, it is clear that the free swimming or suspended versions of bacteria are key parts of their life cycle. For more information on the bacterial surface colonization behaviour, readers are referred to a review by Lawrence et al. (1996).

Prior to the advent of confocal scanning laser microscopy (CSLM), biofilm models were based on electron microscopic observations and thus described as homogeneous layers of cells on surfaces. After the first examination of native, fully-hydrated biofilms using CSLM (39) it was revealed that biofilms exhibited considerable organization and variability of cells and their extracellular products in three-dimensional space. The organization exhibited by many pure cultured and mixed species biofilms in large part contribute to the description of biofilms as having a "primitive circulatory system." A number of biofilm models have subsequently been described, including mushroom structures interspersed by a network of channels, mounds, aggregates, clusters, channels, void spaces, holes, bridges, etc. (40, 41). The variables controlling architecture are equally diverse, and include the organism or organisms involved, nutrient status, predation, flow velocity and substratum type and condition. Figure 84.2 shows a series of optical thin sections of a positively-stained *Salmonella enteritidis* biofilm where voids and cell aggregates (or mounds) may clearly be seen.

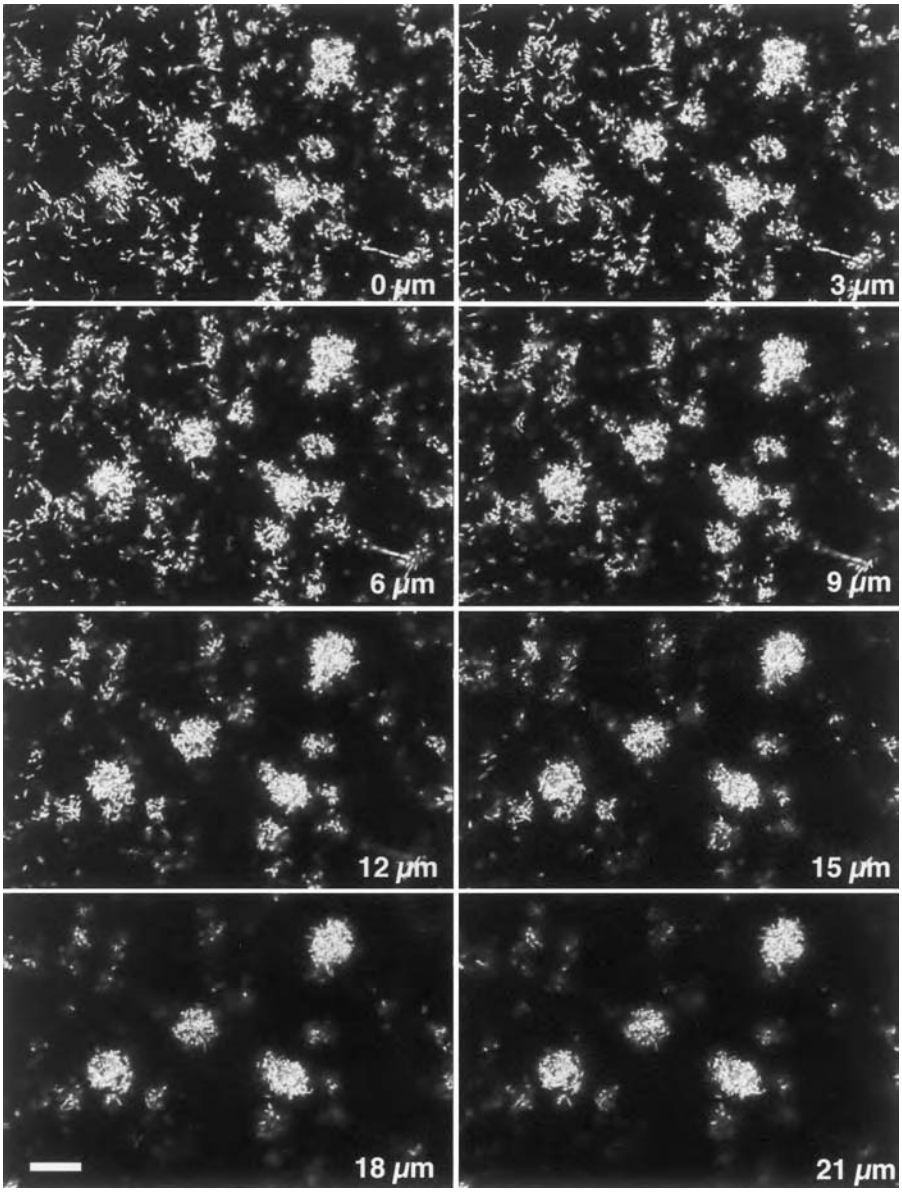

FIGURE 84.2 Confocal laser microscope images showing cell aggregates and channels in a *Salmonella enterica* serovar Enteritidis biofilm grown in a model flow cell system. Optical thin sections from the 0, 3, 6, 9, 12, 15, 18 and 21 μm section depths are shown. Cells were positively stained using Syto 9. Scale bar (lower left) = 20 μm.

D. Biofilm Maturation

Biofilm bacteria are quite different from their planktonic counterparts, as judged by gene expression, cellular physiology and increased resistance to antibiotics and antimicrobial agents (40, 42, 43). These differences involve not only the proliferation of attached cells into microcolonies and biofilm along with the production of EPS, but also the establishment of a biofilm structure (architecture; as described above) along with the creation of distinctive physical and chemical zones, or microenvironments (44).

The biofilm microenvironment is physically and chemically distinct from the macroenvironment and is the consequence of metabolic activity of microorganisms themselves (consumption of O_2, production of CO_2, acid and end product formation) in conjunction with the physical characteristics of the cells and EPS polymer matrix. Biofilm microenvironments tend to be diffusion-dependent, and thus gradients of all chemical parameters may be encountered. For example, *in situ* CSLM work with molecular probes has directly confirmed the existence of zones of hindered diffusion, gradients of pH, dense polymer and varied cell metabolic activity. The depths of actively growing heterotrophic biofilm such as *P. aeruginosa* rapidly become oxygen limiting, with the highest O_2 concentrations located near the biofilm-liquid interface, and the most

oxygen depleted regions located at the biofilm-substratum interface (the attachment surface) (40). As the exchange of nutrients and end products into and out of the biofilm are diffusion-dependent, the velocity of the overflowing liquid also impacts nutrient exchange.

The consequences of the formation of the chemical microenvironment are two-fold: 1) establishment of a spatial gradient of growth conditions for biofilm organisms, altering their rates of growth and ability to carry out metabolic reactions, and 2) creation of a gradient of growth conditions for different organisms with different growth requirements. It is widely believed that the formation of the microenvironment is a key factor in resistance of biofilm bacteria to antimicrobial agents (see discussion below). The integration of pathogens within a non-pathogenic biofilm is obviously of the greatest concern with respect to food processing biofilms. Thus, as biofilms "mature," the capacity to harbor pathogenic organisms, like *E. coli* and *Listeria monocytogenes*, may increase (45). More research is needed for a better understanding of how different microbial species become integrated into complex communities.

Recently, gene and protein expression patterns have demonstrated genetic and physiological differences between biofilms and planktonic cells, as well as between biofilms at different developmental stages. Brözel and coworkers monitored global protein expression patterns in attached *P. aeruginosa* cells and observed as many as 11 proteins whose levels became altered during various stages of attachment (46). Similar studies revealed fairly high levels of gene expression existed for certain proteins (35% of total) of *E. coli* following transition from the planktonic to biofilm growth state (47). More recently, Sauer et al. (43, 48) reported the regulation of as many as 30 genes and 40 gene products became altered in *P. putida* within 6 h following attachment, and using direct microscopic observation were also able to characterize five stages of biofilm development in *P. aeruginosa*. The varied physical and chemical conditions experienced in the biofilm microenvironment would also result in differences in the expression of genes and production of proteins.

In *P. aeruginosa*, changes in gene expression following bacterial attachment include the surface-induced gene activation of *algC*, a gene involved in lipopolysaccharides core biosynthesis, as well as the biosynthesis of the exopolysaccharide alginate (49, 50). Others have linked the down-regulation of flagellar synthesis with the alginate up-regulation (51). As cells adjust to an immobile life on a surface, they lose their flagella and increase the production of EPS.

A seemingly important step in the maturation of biofilms is the formation of characteristic biofilm architecture. While the advent of CSLM was a pivotal tool in revealing the complexity of the different biofilm architectures, until recently it wasn't clear how the development of these structures was regulated. The observation that a mutant of *P. aeruginosa* unable to synthesize the quorum-sensing molecule acylhomoserine lactone (acyl-HSL) developed a radically altered biofilm architecture, suggested that architecture was indeed regulated. As published in the journal Science, a *lasI* mutant (defective for production of acyl-HSLs) formed a biofilm without the typical well-spaced microcolonies (attaining heights of over 100 μm) and lacked resistance to SDS treatment typically seen in the wild-type strain (52). This study suggested that cell-cell communication was essential for *P. aeruginosa* to establish structured biofilms. However, more recent work using similar *P. aeruginosa* AHL mutants have found contradictory results (53, 54). The role of quorum sensing in the development of biofilm architecture is therefore unclear for the time being. This continues to be an enticing research area with potential for benefits in the area of biofilm control. One interesting study approach would use furanone AHL analogs, produced by *Delisea pulchra* (a macroalga that naturally resists biofilm formation), to disrupt or block AHL communication, and hence biofilm formation.

Overall, post-attachment events are considered by some to culminate in the "maturation" of the biofilms into a thick layer of organized cell material interspersed by channels within a matrix of EPS material. While it is useful in theory to envision biofilms developing sequentially (e.g., molecular film, attachment phases, microcolony development, biofilm formation, and biofilm sloughing and progeny dissemination), and there is evidence to indicate that this indeed is the way things occur for *P. aeruginosa* (43), these models are based on sterile laboratory systems that are "inoculated" after which biofilm formation is monitored over time. In real-world situations, it is altogether more likely that many phases (e.g., attachment, detachment, shedding/sloughing, microcolony formation, etc.) of biofilm formation will be occurring concurrently, and would involve different bacterial species.

IV. BIOFILM DETECTION

Detection of biofilm contamination depends on rinsing or swabbing surfaces, followed by dilution and plating of the samples on agar media. While some modifications to the sampling methods exist (e.g., spray gun samplers, sonication-assisted removal of cells), these are essentially the same culture-based techniques. Owing to the complexity and variable geometry of surfaces and equipments (e.g., pipelines) within a processing plant it may be desirable to perform "in line" surface sampling. The Modified Robbin's Device (MRD, Tyler Research, Edmonton, Canada) permits the removal of plugs that mount flush with a surface or a fluid delivery pipeline. These plugs or coupons may be removed at defined intervals, with the biofilm stained and

observed directly, and/or disrupted and enumerated using culture based methods. One obvious advantage of culture-based methods is that various selective and differential growth media are readily available. Their main shortcoming is the time to obtain a result, since most organisms require 24 or more hours of cultivation. As in other disciplines, molecular methods like polymerase chain reaction (PCT) and real-time PCT can be used to identify and estimate the number of specific pathogens that may be plaguing a facility. Use of ATP-sensitive luciferase assay kits can also provide a measure of biofilm buildup. ATP-bioluminescence is a non-culture based commercially-available method that relies on the ATP-dependent production of light from the luciferin-luciferase system. Surfaces are sampled with sterile cotton swabs and are then reacted with kit reagents. After reaction, light generation is read in a hand-held luminometer. ATP bioluminescence may provide an index of plant surface hygiene that can then be used to estimate microbial contamination. Since it is a rapid method it can be used on-site providing results in as little as 5–10 minutes. However, it is important to note that non-microbial sources of ATP cannot be differentiated from those of microbial origin, thus ATP associated with meat exudates can affect the readings. It is important to remember that the biofilm sampling methods described above are to be performed in addition to routine plant cleaning and sanitation, and not as a diagnostic step to prescribe cleaning. Lastly, there are numerous model systems and approaches for the study of biofilms. Many of these are highly applicable to the food processing situation, and thus many techniques and methods are directly transferable. Reviews describing these culture systems are available (55, 56).

V. PREVENTION AND REMOVAL OF BIOFILMS IN FOOD PROCESSING FACILITIES

Microbial attachment and biofilm formation may be beneficial (vinegar production, enzyme production); however, it is far more common for biofilm formation to be detrimental to food production. Fouling of food processing equipment and foods by spoilage or pathogenic bacterial biofilms is the main concern, however damage to metal surfaces (pitting and corrosion) and breakdown of plastics are other possible outcomes. Biofilms also contribute to decreased heat transfer, lost sensor sensitivity, and plugging of filters. Low pressure, large diameter pipes do not always fill and thus are prone to biofilms and are hard to clean without disassembly. Pathogens known to form biofilms include *Salmonella*, *Klebsiella*, *Pseudomonas*, *Campylobacter*, enterohaemorrhagic *E. coli* and *Listeria*. These organisms are of special significance where ready-to-eat and minimally-processed meat products are produced as they aren't controlled in a terminal processing step.

Those areas of food processing plants where biofilms become problematic are often non-food contact surfaces with high humidity or moisture levels. Machine shrouds, overhead structures, floor drains and walls are examples. These surfaces do not directly contact foods; however, indirect transfer of biofilm bacteria may occur as a consequence of moisture dripping onto food contact surfaces below, worker activity, and especially during cleaning where aerosolized bacteria in water droplets may be propelled many meters during pressure washing.

Other areas where even the best efforts may fail to control biofilms include conveyor surfaces, brine injectors, belts, gaskets, damaged steel cutting surfaces, floor drains, elbows or dead-ends in pipelines, pumps, valves, and food or liquid storage tanks. Injectors for brining or tenderizing meats have been identified as a location for recurrent *L. monocytogenes* biofilms. Czechowski (57) reported finding biofilms in dairies and breweries on bends in pipes, rubber seals, conveyor belts, waste water pipes, floors, etc. Teflon® and Buna-n® seals were determined to be excellent sites for biofilm formation and when cracked provide reservoirs for microbes which are difficult to inactivate or kill during cleaning. *Listeria monocytogenes* persists on the rubber fingers of poultry pluckers and the trolleys that carry the carcasses after cleaning (58), as does *S. aureus* (59). Notermans and co-workers (60) have observed biofilms in poultry slaughterhouses by scanning electron microscopy. They found that after several weeks of operation the whole surface of the rubber plucker finger was pitted, trapping microorganisms in places like surface scratches and metal welds so that microorganisms become protected from routine cleaning and disinfection. Such biofilms represent a recurrent source of contamination to foods coming in contact with them, potentially with health consequences.

Because of the sensitive nature of certain foods, the occurrence of food processing biofilms has the potential to impact both food shelf-life and safety. During the processing of meats and minimally processed meat products, persistent biofilms may cause significant reductions in product quality and consumer safety. Most of the problem associated with biofilms is associated with the inability or failure to adequately clean the affected surface; hence, the age and design of the facility, as well as the design of the equipment, play important roles in providing cleaning access to vulnerable sites in the processing stream. Routine inspections of potential sites for biofilm formation, as well as scheduled replacement of problem surfaces (gaskets and cutting boards) will assist in limiting problems of this nature.

VI. BIOFILM RESISTANCE TO SANITIZING AND ANTIMICROBIAL AGENTS

The fact that biofilm bacteria have greater resistance to antimicrobial agents than planktonic cells has received

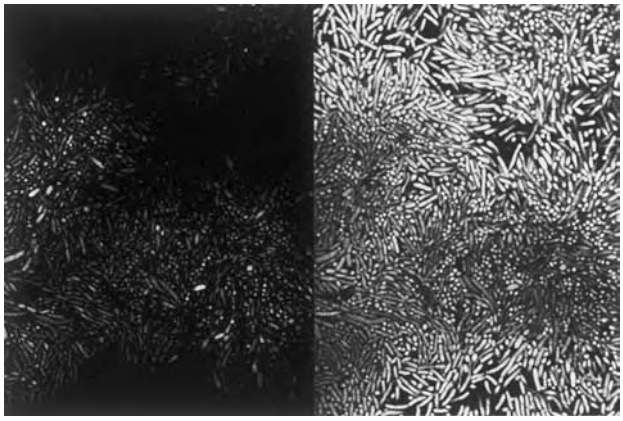

FIGURE 84.3 Dual-channel confocal laser microscope image showing *E. coli* biofilm bacteria after treatment with 0.625% trisodium phosphate (TSP) and staining with the BacLight™ Live/Dead Viability probe. Cells in the right hand panel have been killed by the treatment and thus fluoresced in the red wavelengths. Cells in the left hand panel have not been killed and thus fluoresced green. It is suggested that incomplete penetration of the antimicrobial agent, in combination with interaction of the agent with cells and EPS material, resulted in a reduction of TSP efficacy.

considerable attention over recent years. Specific reports detailing this phenomenon are regularly published. For example, Williams et al. (61) reported that cells of *S. aureus* biofilms on silicon surfaces were 10 times more resistant to vancomycin than were their planktonic counterparts. Ceri and coworkers (62) reported that *P. aeruginosa* required as much as 1,024 μg of imipenem and *E. coli* required a much as 512 μg of ampicillin as the minimal biofilm eradication concentrations compared to just 1 and 2 μg, respectively, for their planktonic counterparts. A similar increase in resistance was reported against ceftazidime and doxycycline in both *P. pseudomallei* and *Streptococcus sanguis* biofilms, respectively (63, 64). Investigators have also observed increases in resistance of biofilms and attached microorganism on food contact surfaces to various sanitizing agents (65–69). Frank and Kofi (66) found that attached microcolonies of *L. monocytogenes* were resistant to prolonged treatment (~20 min) with the anionic acid sanitizer, benzalkonium chloride, whereas cell suspensions were killed by a 30 sec exposure to the same concentration of sanitizer. Results of work conducted by Mustapha and Liewen (70) and Wirtanen and Matti-la-Sadholm (71) suggest that the age of a biofilm affects the resistance of microorganisms to sanitizers. Sodium hypochlorite and quaternary ammonium compounds were effective against a 24 h biofilm of *L. monocytogenes* on food contact surfaces. Biofilms of *P. fluorescens*, *L. monocytogenes*, and *Bacillus subtilis* challenged with 0.1% and 1.0% chlorine at 25°C were shown to become more resistant with biofilm age. Figure 84.3 shows a confocal laser microscope dual channel image where *E. coli* biofilm bacteria have been treated with trisodium phosphate (a foodgrade antimicrobial) but surviving cells exist at the base of the biofilm.

VII. MECHANISMS OF BIOFILM RESISTANCE TO ANTIMICROBIAL AGENTS

At least three mechanisms have been proposed to account for the increased resistance of biofilm bacteria to antimicrobial agents: (i) delayed penetration of the antimicrobial agent, (ii) altered growth rate of biofilm organisms, and (iii) physiological changes due to the biofilm mode of growth.

Bacterial cells enmeshed in an EPS matrix present a diffusion barrier for these molecules by influencing either the rate of transport of the molecule (hindered diffusion) to cells in the biofilm interior or the reaction of the antimicrobial material with the matrix material. Suci and coworkers (72) demonstrated the delayed penetration of ciprofloxacin into *P. aeruginosa* biofilms; what normally required 40 s for a sterile surface required 21 min for a biofilm-fouled surface. DuGuid and coworkers (73) examined *Staphylococcus epidermidis* susceptibility to tobramycin and concluded that the organization of cells within biofilms could in part explain the resistance of this organism to this antimicrobial agent. Studies examining antimicrobial penetration and interaction with the EPS of biofilms have revealed reduced efficacy due to poor diffusion of the antimicrobial agent through the biofilm matrix. Hatch and Schiller showed that a 2.0% suspension of alginate, a key EPS component, from *P. aeruginosa* inhibited diffusion of gentamicin and tobramycin, and this effect was reversed by using the enzyme alginate lyase (74). Souli and Giamarellou (75) demonstrated that *S. epidermidis* slime hindered the antimicrobial efficacy of *B. subtilis* against a large number of agents.

The rate of cell growth has also been shown to influence the resistance of biofilms to antimicrobial agents. Biofilm-associated cells grow significantly more slowly than planktonic cells in logarithmic growth (the common target of previous antibiotic susceptibility tests). Many antibiotics depend on inhibiting a key component of cell biosynthesis (e.g., cells walls, protein synthesis, DNA replication), and thus tend to have a greater effect on actively growing cells. Using a method of cell culture designed to determine the effect of growth rate apart from other biofilm processes, Evans et al. (76) found that the slowest growing cells of *E. coli* were most resistant to cetrimide. Eng et al. (77) controlled the growth rate of bacteria through nutrient limitation and demonstrated that only fluoroquinolone antibiotics produced bactericidal effects against stationary-phase gram-negative organisms. However, increasing the

growth rate of target biofilm cells was followed by an increase in antimicrobial efficacy. Anwar and coworkers (78) also demonstrated age-related differences in the response of *S. aureus* biofilms to antimicrobial therapy; 4-day-old biofilms exposed to tobramycin and/or cephalexin caused a rapid decrease in the numbers of viable cells, whereas biofilms developed over a 13-day period demonstrated marked resistance to either drug or a combination of both. Korber et al. (79) provided indirect evidence of a gradient of cell growth rates through *P. fluorescens* biofilms, using the antimicrobial agent fleroxicin (which inhibits DNA gyrase and causes growing cells to elongate) and confocal scanning laser microscopy. Cells nearest the biofilm-liquid interface elongated significantly more than those cells near the biofilm-substratum interface and were more susceptible to fleroxacin.

Other physiological factors may also play a role in biofilm resistance. For example, Gram-negative bacteria respond to nutrient limitations and other stresses by synthesizing sigma factors. In *E. coli*, those sigma factors that are under the control of the *rpoS* regulon regulate the transcription of genes whose products mitigate the effects of stress. By studying *E. coli* biofilms formed by strains with or without *rpoS* genes, Adam and McLean (80) found that the *rpoS*$^+$ *E. coli* biofilms were more dense and had higher number of viable cells. Since *rpoS* is activated during slow growth of this organism, it appears that conditions that elicit the slowing of bacterial growth, such as nutrient limitation or build-up of toxic metabolites, favor the formation of biofilms. Nutrient limitation and increase in toxic metabolite concentrations might be particularly acute within the depths of established biofilms, and therefore slow growth and cell physiology are likely linked. Tresse et al. (81) found that agar-entrapped *E. coli* cells were more resistant to an aminoglycoside as oxygen tensions were decreased. They suggested that the effect was due to lowered uptake of the antibiotic by the oxygen-starved cells. It is also thought that at least some of the cells in a biofilm adopt a distinct and protected biofilm phenotype. This phenotype is not a response to nutrient limitation, but is thought to be a biologically programmed response to growth on a surface. This phenotype is likely the consequence of the expression and translation of unique genes and proteins (see earlier discussion on biofilm maturation). Our group has identified a number of differentially expressed proteins found in *Campylobacter jejuni* and *Salmonella enterica* that are likely to play roles in this regard (82, 83).

Thus, multiple factors likely play additive or combinatorial roles in the resistance of biofilms to antimicrobial compounds. It follows that a key element of any surface sanitation program is to first use methods and compounds sufficient to dislodge cells and their EPS from the food processing surfaces, as physical removal of biofilm material is not dependent on their killing *per se*. This will, in turn, enhance the efficacy of any antimicrobial treatment that is then applied. For more details on the resistance of biofilms to antimicrobial agents, the reader is directed to the following review articles (4, 84).

VIII. CONTROL OF FOODBORNE BACTERIA

Bacteria may become associated with foods because of their presence in the raw materials or their introduction during processing. Control of foodborne bacteria is essential to hazard free and acceptable food for consumption. In the absence of appropriate controls, bacteria present in foods will change the quality or devalue the product and in extreme cases cause spoilage and become serious source of hazard to the consumers.

A. Foodgrade Surface Agents/Novel Agents

Food surfaces are the prime areas of exposure to air, processing instrument, and human and animal contact. Surfaces in general and food surfaces in particular, pose exceptional challenge because they may be uneven and contain cracks (both macro- and nano-sizes) and be inaccessible to removal of microorganisms. Additionally, many foods are prepared in contact with various surfaces (tables, cutting knives, handlers, etc.). Due care in the sanitation of the processing environment, instruments and personnel become critical issues in the manufacture of bacteria free foods. A number of chemical treatments allow for cleaning or disinfecting foods undergoing processing or the surfaces with which they come in contact. The types of agents used for this purpose vary.

Surface active agents such as wetting agents or surfactants are non-polar, long chain organic molecules with a polar head. They aid cleaning by reducing water surface tension and their ability to be suspended in fats, including bacterial membranes and cause disruptions. Other agents such as organic alkalies, inorganic and organic acids, at critical concentrations are bactericidal. Other options include the use in combination of e.g., sucrose laurate (SL) ethylenediaminetetraacetate (E), and butylated hydroxyl anisole (B) (SLEB) as an effective antimicrobial agent against both gram-negative (aerobes) and gram-positive (facultative anaerobes) foodborne bacteria (85).

B. Trisodium Phosphate

Trisodium phosphate (TSP) is an orthophosphate salt of phosphoric acid. It has a minimum of 41.5% P_2O_5 and a pH of approximately 11.8 in a 1% solution (86). Uses of TSP include as a food additive, dietary supplement, paint remover, and detergent or industrial cleaner. The beneficial effects of phosphates on food products include: (i) water binding, (ii) retardation of oxidative rancidity,

(iii) emulsification, and (iv) color development and stabilization (87). The ability of phosphates to enhance microbial safety and stability of certain food has been discussed by Wagner (87).

The AvGard™ process is an USDA-approved process where TSP solution is applied to reduce the incidence of Salmonella contamination during poultry processing (88). The AvGard™ process was the first commercial process for which a claim of successfully reducing Salmonellas (2 to 5 log decrease) on processed carcasses can be made (86). The process has been patented for poultry (86), specifically covering solutions of trialkali metal phosphate in concentration of 4% (Wt./Vol.) or greater with the pH values of 11.5. TSP in solution results in an alkaline pH which contributes to its antimicrobial action. Exposure of *Salmonella enterica* serovar Enteritidis ATCC 4931 to different concentrations of TSP resulted in membrane damage and leakage of cellular contents leading to cell death in a concentration dependent manner (89). The antimicrobial action of TSP treatment has been reported to successfully reduce numbers in *E. coli*, *Campylobacter jejuni* and *L. monocytogenes* (90). The treatment with TSP is as effective as alkali treatment without the adverse effects on the meat or skin associated with inorganic alkali treatments (90). The process was also found to have little or no effect on the taste, texture, and appearance of poultry (91). The phosphate residue can therefore be left on the poultry surfaces to provide reduced bacterial activity and improved shelf life (86). Efforts to extend the efficacy of TSP, using combinatorial or sequential approaches (i.e., EDTA and TSP) have been performed. Korber et al. (92) examined a process termed plasmolysis-deplasmolysis, where cells were plasmolyzed in the absence of the antimicobial agent using high salt solutions, and then deplasmolyzed in the presence of TSP. This approach did reduce the TSP concentrations required against a panel of pathogen and spoilage organisms in model systems, but failed to universally enhance TSP efficacy on meat tissues.

C. Biological Antibacterial Products

There are several naturally synthesized antibacterial products that are efficient, and often effective means for the control of foodborne bacteria. The choice for the type of agents may depend on several factors including cost, availability, compatibility and safety for human consumption. Certain plant synthesized products, e.g. tannins (93) in addition to having antimicrobial properties carry other properties such as antinutritional factors and antiinfective agents. Tannins are water-soluble polyphenols found in many plant foods. Tea polyphenols and many tannin components were suggested to be anticarcinogenic. The antimicrobial activities of tannins are well documented. The growth of many fungi, yeasts, bacteria, and viruses was inhibited by tannins and tannic and propyl gallate are inhibitory to foodborne bacteria and off-flavor-producing microorganisms. Their antimicrobial properties seemed to be associated with the hydrolysis of ester linkage between gallic acid and polyols hydrolyzed after ripening of many edible fruits. Tannins in these fruits thus serve as a natural defense mechanism against microbial infections. Tannic acid is used in food processing to increase the shelf life of certain foods, such as catfish fillets. Tannis also play a role in detaching attached bacteria from surfaces, and thus act by both removing bacteria and by killing the bacteria.

D. Lactic Acid Bacteria Derived Peptides

Nisin is an antibacterial peptide (35 kDa) produced by the dairy fermentation bacterium *Lactococcus lactis* subsp. *lactis*. It exhibits a broad spectrum of inhibitory activity against gram-positive microorganisms such as *L. monocytogenes*, *S. aureus* and *Clostridium botulinum* (94). Although nisin was once thought to inhibit only gram-positive bacteria, researchers have found that the spectrum of nisin activity can be extended to gram-negative bacteria, including a variety of pathogens. Stevens et al. (95) reported that when gram-negative cells were treated with a combination of 20 mM EDTA and 50 μg/ml of nisin in a complex buffer and incubated at 37°C for 60 min, populations of *Salmonella* sp., *Enterobacter aerogenes*, *Shigella flexineri*, *Citrobacter freundii*, and *E. coli* O157:H7 were reduced by 3 to 6 log. In this process, EDTA is thought to chelate magnesium ions from the lipopolysaccharide (LPS) layer of the outer membrane of gram-negative bacteria. This causes the outer cell surface to be more permeable, thereby allowing the bacteriocin access to the cytoplasmic membrane where nisin-mediated inactivation occurs (95). Compounds such as 1% sodium hexametaphosphate or 500 mM lactate, as well as EDTA (50 mM) or citrate (100 mM), have been reported to enhance nisin activity against gram-negative pathogens *in vitro* (96). Synergistic effects between nisin and thymol on antimicrobial activities in *L. monocytogenes* has also been shown to be useful in certain traditional fermented dairy and cultured-milks. There is an additional need for methods to substantially reduce or inhibit food-borne and biofilm bacteria using food-grade compounds. These methods would be of considerable interest to the food industry.

E. Lactoferrin

Lactoferrin is an iron-binding glycoprotein present in milk and many exocrine secretions that bathe the mucosal surface. Lactoferrin contains 703 amino acids and has a molecular weight of 80 kDa. Lactoferrin co-ordinately binds to metal ions and occurs in divergent biological milieu including saliva, tears, seminal fluids, mucins, and the secondary granules of neutrophils. Lactoferrin is

considered a multifunctional or multi-tasking protein. It appears to play several biological roles. Owing to its iron-binding properties, lactoferrin is thought to play a role in iron uptake by the intestinal mucosa of the suckling neonate. Lactoferrin also appears to have antibacterial, antiviral, antifungal, anti-inflammatory, antioxidant and immunomodulatory activities. A number of laboratories have identified lactoferrin as a broad spectrum antimicrobial and reported a variety of inhibitory mechanisms on both Gram-positive and Gram-negative bacteria (97). Lactoferrin occurs naturally as iron saturated, iron free and immobilized/activated forms. The iron free and immobilized forms of lactoferrin have the highest antibacterial ability. However, the current processes used to isolate lactoferrin from cow's milk alter the protein structure so that the majority of lactoferrin that is extracted is in the less effective, iron saturated state. "Activated" lactoferrin is a term used to describe a unique combination of natural ingredients that mimic the optimum environment necessary for lactoferrin to have maximum antimicrobial activity. Activation biases lactoferrin to its iron free and immobilized forms, in effect returning lactoferrin to its most natural and functional state. Activated lactoferrin has been approved by the FDA and USDA for use on meat to prevent contamination by a number of foodborne pathogens, such as *E. coli* O157:H7. Activated lactoferrin is sprayed onto a beef carcass as one of the final steps on a multiple-intervention system. Activated lactoferrin reacts with pathogenic bacteria that are already attached to the meat surface and binds with them causing their detachment. Once the activated lactoferrin has been applied, it is followed by a final rinse, allowing for the detached bacteria to be washed away safely. Activated lactoferrin protects meat from pathogenic bacteria in three ways: 1) detachment of adherent pathogens, 2) prevention of pathogen attachment by rendering bacterial attachment structures non-reactive, and 3) inhibition of pathogen growth through the binding of iron required by bacteria for growth (98). Sing et al. (99) showed that lactoferrin can reduce bacterial colonization and biofilm development in a dose-dependent manner. This suggests that lactoferrin could be used as an antimicrobial agent to maintain hygiene on food processing equipments. Exploring the potential of such methods is clearly of interest to those striving to maintain and improve processing plant hygiene and sanitation.

F. Antibacterial Plant Peptides

Antibacterial plant peptides are short peptides that are produced by plants to defend themselves through restricting attack or invasion of bacteria. Several hundred peptide antibiotics are produced by a broad range of plant species as defense molecules. Plant antimicrobial peptides are approximately 50 amino acids in length and contain cysteine residues that allow for the formation of disulfide bonds, which contribute to their high stability (100–102).

TABLE 84.1
Known *In Vitro* Antibacterial Activity of Different Plant Antimicrobial Peptides. IC50 Equals the Concentration Required for 50% Growth Inhibition of the Test Organism

	Amount of AMP Needed for 50% Growth Inhibition	
Test Bacteria	***M. jalapa* (AMP2)**	***I. balsamina* (Ib-AMP4)**
Bacillus megaterium	2	—
Bacillus subtilis	—	20
Clavibacter michiganensis	—	<10
Erwinia amylovora	—	>100
Erwinia carotovora	>500	—
Escherichia coli	>500	>500
Micrococcus luteus	—	5
Proteus vulgaris	—	>500
Pseudomonas solanancearum	—	>100
Sarcina lutea	50	—
Staphylococcus aureus	—	20
Streptomyces faecalis	—	5
Xanthomonas campestris	—	6
Xanthomonas oryzae	—	15

Plant-based antimicrobial peptides are classified into three groups, antifungal peptides, factors against microbial toxins (e.g., tablotoxin), and those determining the need for synthesis of other natural defense products. The genetic expression of plant antimicrobial peptides can be adaptive or constitutive. The constitutive ones are found in herbs and spices, e.g. phenolics, essential oils (allicin) and various thiocyanates. The most abundant source of these products appears to be the seeds; however, they have been isolated and purified from the seeds, kernels and roots. Table 84.1 shows the antibacterial potency of these proteins *in vitro.* Biotechnology should not only help in our understanding of the mechanisms of action, but also in application of these molecules in the production and processing of foods. A large number of AMPs have not yet been evaluated against organisms of concern to the food processing sector, thus there is potential for these compounds as antimicrobial agents.

G. Surface Antimicrobial Agents

Newer types of food-packaging material, which uses combinations of food-packaging materials (plastic and rubber articles, paper-based materials, textile fibrils, and a low-density polyethylene film with triclosan and chitosans as a choice antimicrobial substance is being used to control microbial surface contamination of foods. This strategy can be used for vacuum packaged meat, fish, poultry or

cheese. Many classes of antimicrobial compounds have been evaluated in both synthetic polymer and edible film states, including organic acids and their salts, enzymes, bacteriocins, and miscellaneous compounds such as triclosan, chitosan, silver zeolites, and fungicides. In the adoption of antibacterial agents in wrapping material, special consideration is needed as the presence of fatty acids or adipose tissues may diminish the antimicrobial activity of certain compounds on meat surfaces. Chitin and chitosan matrices are known for their adsorptive capacities, however their potential as antimicrobial coatings has only recently been considered. While these results are preliminary, edible chitosan coatings (e.g., hotdogs or deli-products) may offer some protection against food-borne pathogens like *L. monocytogenes*. At this time, antimicrobial packaging materials cannot legally be used in the EU. The state of this technology for its particular commodities and use of different types of antimicrobial concepts is under research and development (103, 104).

H. Surface Sanitizing for Biofilm Control

The general approach for cleaning food processing surfaces should be inherently the same. First to be addressed is the problem of surface soil or fouling. Following an initial rinse, surface fouling is best addressed by physical cleaning or pressure washing using either an acidic or alkali based detergent — acidic detergents dissolve fats and mineral buildup, whereas alkali based detergents dissolve microbial polymeric substances. This wash step must be followed by a rinse which will remove any residual detergent that might interfere with subsequent sanitizing steps. The surface is then treated with a sanitizing agent, which typically involves use of chlorine-based or peroxyacetic acid (POAA) treatments. The POAA treatment may be left on as peroxide and acetic acid are food grade additives, whereas chlorinated compounds must be rinsed off — this is important not only because of food flavor effects, but also because strong alkaline compounds tend to corrode even food grade stainless steels. All the rinsing steps should use potable water. The incorporation of novel antimicrobial agents such as surface-incorporated polychlorinated compounds (triclosan) is a somewhat different approach — it would tend to prevent initial colonization and growth by biofilm forming bacteria. However, both advocates of this type of antimicrobial approach insist that this doesn't eliminate the need for proper sanitation and/or hygiene, but rather must be complimentary. Such considerations are best made during the planning stage of processing plant construction; the appropriate type of material or equipment design should be selected to prevent microbial adhesion and facilitate cleaning. In cases where an existing facility is of concern, a suitable starting point involves a microbiological audit in order to determine where biofilms are likely to occur followed by strict HACCP implementation.

IX. CONCLUSION

Microorganisms have been observed to adhere and aggregate on surfaces, grow into microcolonies, form complex 3-dimenisonal structures and communal relationships, resulting in complex biofilm. Our knowledge of biofilm comes from studies of nutrient limited environments or simulations of these environments. However, very little understanding regarding the kind of biofilm found in the food industry is available because of a lack of direct observation of biofilms in these facilities or research using appropriate model systems. Foodborne pathogens and spoilage organisms can form biofilm on many food contact and environmental surfaces and can coexist with other environmental flora leading to contamination of food that come in contact with them. This challenges the plant hygiene as well as safety of the food product and can lead to significant loss to business and public health. Biofilms on food processing surfaces are difficult to control due to the problem associated with cleaning complex food processing equipment, and also because biofilms are quite resistant to antimicrobial agents in general. Thus, biofilm control relies on the implementation of effective cleaning and sanitation procedures employed in processing facilities specifically designed for effective and thorough cleaning.

Currently, there is an increased interest in methods to monitor biofilm development on surfaces, as well as to develop surfaces with functional antimicrobial coatings to inhibit bacterial colonization. There is also a seemingly prosperous research direction involving the design and engineering of novel antimicrobial agents. As much of this research is ongoing, there is no universal measure to control biofilms. At present, education and vigilance are the best tools for ensuring food safety and plant hygiene.

I. INTRODUCTION

A. General

This review covers the chemistry, in particular the mode of action, the analysis and the evaluation of the efficacy of antioxidants. It briefly touches on synergism in antioxidant mixtures and the legal implications of addition of antioxidants to foodstuffs. At the outset it should be noted that the medical and economic aspects are scarcely mentioned as it falls outside the expertise of the authors.

The word antioxidant is not found in English dictionaries of the first half of the last century. One of the earliest definitions of an antioxidant appears in the 1966 edition of the *Random House Dictionary of the English Language* that reads "Any of a group of substances that inhibit the deterioration of rubber, gasoline, soaps, etc." It is noteworthy that at that time no mention was made of the deterioration of foodstuffs although the prevention of this now occupies the energy and ingenuity of many scientists. The *Cambridge Encyclopaedia* of 1990, however, gives the following definition: "Substances which slow down the oxidation of others, often by being oxidized themselves. The term is usually applied to additives in foods and plastics" clearly illustrating the shift in emphasis from rubber, gasoline, and soaps to foods and plastics.

B. Chemistry of Action

Upon exposure to atmospheric oxygen, lipids (fats and oils) are slowly oxidized to peroxides. This reaction is of immense practical importance as it leads to the spoilage of foodstuffs and deterioration of tissues in living organisms (ageing) (1,2). Even freeze-dried foods can be spoilt by peroxides formed during cold storage. These peroxides are the reaction products of free radicals and atmospheric oxygen. Free radicals are uncharged, highly reactive chemical entities with a lone electron that are initially formed by the loss of a hydrogen atom from a lipid fatty acid moiety induced by ultraviolet light or heat. Once generated, these reactive free radicals propagate themselves by a theoretically endless chain reaction involving oxygen unless halted by an antioxidant. Antioxidants act sacrificially by donating a hydrogen atom to the reactive free radical and regenerating the original molecule. In the process, the chain reaction is terminated and the antioxidant itself becomes a free radical. The difference, however, is that this free radical is unreactive as antioxidants possess structures capable of delocalizing the lone electron, thus rendering it unreactive, and no further damage to the lipid or tissue is done. This is illustrated in the following simplified reaction scheme:

1. Initiation
   $RH \longrightarrow R^{\bullet} + H^{\bullet}$
2. Propagation
   $R^{\bullet} + O_2 \longrightarrow RO_2^{\bullet}$
   $RO_2^{\bullet} + RH \longrightarrow ROOH + R^{\bullet}$
3. Termination
   $\left.\begin{array}{l} R^{\bullet} + R^{\bullet} \\ RO_2^{\bullet} + RO_2^{\bullet} \\ RO_2^{\bullet} + R^{\bullet} \end{array}\right\}$ products

In the propagation step ROOH is a hydroperoxide and $\dot{R}\ddot{y}$ is either another reactive free radical as in the initiation step, or an unreactive free radical if RH is the antioxidant. The primary reaction products, hydroperoxides ROOH and peroxides ROOR then decompose further into secondary products such as aldehydes, ketones, alcohols and carboxylic acids. These secondary oxidation products are responsible for the unpleasant taste and odours of spoilt foods, variously described as "rancid," "tallowy" or "fishy." But it is not only the oxidation of the fat itself which is important; other vulnerable components in the foods such as vitamins, pigments and even proteins are liable to be destroyed as a consequence of lipid oxidation. Vitamins and pigments are normally minor components of foods but they are important in determining its appearance, palatability and nutritional value thus damage to them can easily make the food unacceptable. This deterioration is not confined to foods of high fat content, it can also occur in cereals that contain relatively little fat, vegetables such as unblanched frozen peas, and potato chips. This is because the flavour threshold of the aldehydes and ketones that are formed is often less than 1 part per million (ppm), sometimes as low as 1 part per billion (ppb). Such traces, that can wreak havoc to the economy of food companies, are readily detectable by the human senses of taste and smell (3). It must also be realized that research on antioxidants is never straightforward: antioxidants are anomalies in that they do not follow rules and nothing is ever predictable, but it is precisely this unpredictability which constitutes the challenge and attraction of this field of research. Much has been learned over the years by empirical methods of trial and error and we are now able to protect valuable foodstuffs much more effectively than half a century ago.

C. Chemical Structures

The question may now be asked: "What are the structures of those compounds, small amounts of which are capable of stabilizing foodstuffs?" Several structures are known and occasionally new structures are discovered, as for instance those incorporating the indole and indoline chromophores (4). However, because of the very stringent safety requirements of the United States Food and Drug Administration (FDA), it is doubtful whether these novel antioxidants will eventually be approved for the use in foodstuffs. Most antioxidants both synthetic and natural possess an aromatic ring.

D. Synthetic Antioxidants

Structures such as hydroquinone [1,4-dihydroxybenzene; **1**], *t*-butylhydroquinone [TBHQ; 1,4-dihydroxy-2-*t*-butylbenzene; **2**], butylated hydroxytoluene [BHT; 3,5-di-*t*-butyl-4-hydroxytoluene; **3**], butylated hydroxyanisole [BHA; a 9:1 mixture of 3-*t*-butyl-4-hydroxyanisole and 2-*t*-butyl-4-hydroxyanisole; **4**] and ethoxyquin [EQ; 1,2-dihydro-6-ethoxy-2,2,4-trimethylquinoline; **5**] (Figure 85.1) are examples of synthetic antioxidants. These antioxidants do not occur naturally and they act in very small doses, typically ppm. Since the parent compound, hydroquinone, is a suspected carcinogen it is not permitted as an antioxidant in food. However it is used as an antioxidant in rubber and in the preparation of methyl esters of highly unsaturated lipids (5,6). TBHQ [**2**] and BHT [**3**] are pure chemical compounds, properly characterized with sharp melting points of 128–129° and 69–70°C respectively. Food grade BHA [**4**] is normally a 9:1 mixture of the 3- and 2-isomers and shows a melting range of 48–55°C. The ratio in which they are produced from 4-hydroxyanisole and isobutene is 9:1 and it appears uneconomical to separate the two. The bulky *t*-butyl groups greatly enhance the antioxidant character of these compounds by inhibiting other molecules from approaching

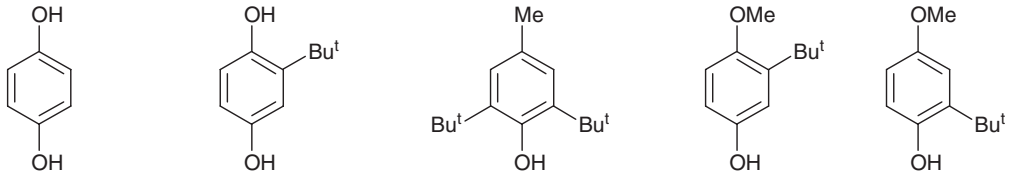

FIGURE 85.1 Synthetic antioxidants.

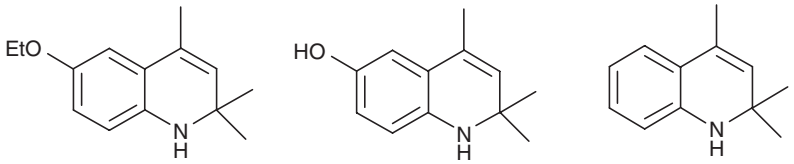

FIGURE 85.2 Ethoxyquin and two analogues.

the active site. Other examples of unreactive hindered free radicals are known, for example, the triphenylmethyl radical (7) and 2,2,6,6-tetramethyl-1-piperidinyloxy free radical (TEMPO) of melting point 36–40°C that can even be purified by sublimation and is listed in various commercial catalogues. TBHQ is the latest and also the best phenolic antioxidant for oils and is often used for prolonging the shelf life of potato crisps (8). However, it is a poor antioxidant for fish meal (A.J. de Koning, unpublished work). BHT, prepared from 4-hydroxytoluene and isobutene, was originally an antioxidant in the petroleum industry and as a result suffers from a slight stigma. In spite of this it is very effective in protecting animal fats and is used often in combination with BHA, resulting in an antioxidant mixture that shows synergism (see below) (8). BHA, on the other hand has no stigma and is normally the antioxidant of choice in the food industry, where it finds extensive use in oils for deep-fat frying. Both BHT and BHA are volatile in steam, which is a disadvantage when using them at high temperatures. These phenolic antioxidants have degradation products that act as powerful antioxidants in their own right, some possessing greater efficacy than the parent compound. Japanese workers in particular have extensively investigated these products (9,10,11). This, however, was found to depend on the substrate used for testing the degradation products.

EQ [**5**], an antioxidant used in spice blends, as a postharvest dip for apples and to prevent spontaneous combustion in fish meal, also has a benzene ring and its structure is reminiscent of vitamin E [**9**]. Its antioxidant activity centres on the NH grouping which donates its hydrogen atom forming an unreactive free radical stabilized by delocalization in the benzene ring assisted by the ethoxy group in position 6.

TABLE 85.1
Efficacy Values of a Number of Antioxidants Relative to Ethoxyquin in Fish Meal and Fish Oil

	Efficacy Value (%)	
Antioxidant	**Meal**	**Oil**
Ethoxyquin (**5**)	100	100
Butylated hydroxytoluene (**3**)	65	75
Hydroxyquin (**6**)	74	350
Hydroquin (**7**)	101	52
Methoxyquin (**11**)	105	100
Propoxyquin	n.d.*	100
i-Propoxyquin	n.d.	100

* n.d. means not determined.

Analogues of EQ have been prepared and their efficacies compared to EQ (12,13,14). It was found that the efficacies in oil and meal were, for unknown reasons, often markedly different. One analogue, hydroxyquin [1,2-dihydro-6-hydroxy-2,2,4-trimethylquinoline; [**6**] (Figure 85.2), where a hydroxyl replaces the ethoxy group, was 3.5 times as effective in fish oil as EQ, while in fish meal it had only three quarters of its activity. On the other hand, hydroquin [1,2-dihydro-2,2,4-trimethylquinoline; **7**] the simplest analogue, was equally effective as EQ in meal but in oil it showed only half its efficacy. BHT only showed about 75% and 65% of the efficacy of EQ in oil and meal respectively. This is recorded in Table 85.1. Oxidation of EQ gives rise to two products that have been detected in aged fish meals originally treated with EQ. These products, a dimeric oxidative coupling product and a quinolone, both showed antioxidant activity; the dimer

having about 30% and the quinolone about 75% of the activity of EQ (15).

E. Natural Antioxidants

The naturally occurring antioxidants, vitamin C or ascorbic acid [**8**] and vitamin E or tocopherol [**9**] (Figure 85.3), are generally preferred by the public due to negative perceptions surrounding the use of synthetic chemicals in foodstuffs. The efficacy of these natural antioxidants is, however, sometimes far less than that of their synthetic counterparts. For example, 2% vitamin E gave much less protection of the polyunsaturated fatty acids [PUFA] in dietary fish oil capsules than 100 ppm of synthetic dodecyl gallate (16). This observation seems to contradict the results of Burton and Traber who claim that vitamin E is superior to phenolic antioxidants (17). However, this only seems to be a contradiction as Burton and Traber refer to the *in vivo* efficacy of vitamin E whereas in the protection of fish oil capsules the *in vitro* efficacy was measured.

Vitamin C [**8**] is a pure chemical compound with a sharp melting point of 190–192°C, and it is water-soluble in contrast to the above mentioned oil-soluble antioxidants. It is abundantly present in citrus fruits and a variety of vegetables. It has no aromatic benzene ring to delocalize a lone electron, however careful scrutiny of its structure shows two enolic hydroxyl groups (which are responsible for its acidity), similar to a phenolic hydroxyl group in TBHQ, BHT and BHA. Removal of a hydrogen atom from an enolic hydroxyl group creates a free radical which can be stabilized by delocalization, albeit not as extensively as in a benzene ring. Vitamin C is used to prevent browning in fruits and vegetables, to preserve the aroma and colour of fruits and to improve the shelf-life of beer. This form of spoilage is due to oxidation of phenolic substances under the catalytic influence of traces of copper. It can therefore also act as a chelating agent and enhance the action of other antioxidants (18,19). In living organisms vitamin C acts as a back-up of vitamin E which it regenerates after this has been used up by oxidation (20). To render vitamin C more soluble in oil the semi-synthetic derivative, ascorbyl palmitate has been made and this is frequently used to stabilize oils and fats. For instance 0.01% ascorbyl palmitate has been shown to be more effective than BHT or BHA in stabilizing vegetable oils (21).

Vitamin E or tocopherol [**9**] has four different isomers α, β, γ and δ. These isomers have different antioxidant activities, the α isomer being the most potent and also the most naturally abundant. Foods of both animal and vegetable origin contain tocopherols, but it is mainly in vegetable foods, in particular seeds, that substantial amounts occur. Seed oils are a rich source of tocopherols, with the α isomer occurring at a level of approximately 600 ppm in refined sunflower seed oil, whereas the δ isomer is often not detectable (22). Large amounts (between 30 and 70%) of the tocopherols are lost during refining of these seed oils, especially in the vacuum steam deodorizing process (23). The distillate thus becomes a rich source of tocopherols but extensive purification is required to isolate them (24). In the body vitamin E is present in the lipid bilayers of biological membranes where it plays a structural role. It used to be "the vitamin in search of a disease" but it is now known as a powerful *in vivo* antioxidant to prevent the oxidation of unsaturated lipids to peroxides (25). Peroxides can cause extensive damage to cells when insufficient vitamin E is present. Increasing the polyunsaturated fatty acid (PUFA) content of a diet, which is frequently suggested by medical practitioners, should ideally be accompanied by a simultaneous increase in vitamin E and at least 0.6 mg of vitamin E per g of linoleic acid is recommended (26). Vegetable oils having high concentrations of linoleic and linolenic acid fortuitously also have sufficiently high levels of vitamin E to give adequate protection.

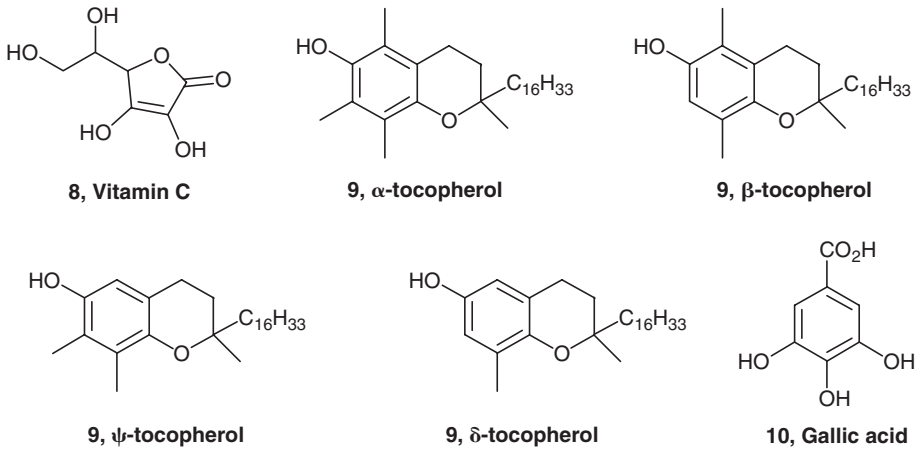

FIGURE 85.3 Natural antioxidants.

However, consuming fish oil capsules as a dietary supplement with high levels of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) without an additional dosage of vitamin E might lead to cell damage. It is recommended therefore that for each gram of DHA in a fish oil dietary capsule at least 1.8 mg of vitamin E should be added (27).

Propyl, octyl and dodecyl gallate are esters of 3,4,5-trihydroxybenzoic acid [**10**] or gallic acid (Figure 85.3), a naturally occurring substance abundantly present in tannins; for instance tea leaves contain about 10% gallic acid derivatives. Gallic acid itself acts as an antioxidant, but it is not used as such because of its insolubility in oils and fats. The esters do not occur naturally and must be prepared by esterification of gallic acid with the appropriate alcohol. They are therefore neither synthetic nor natural but hybrids, similar to ascorbyl palmitate. No bulky *t*-butyl groups are present in these gallates, nevertheless they act as powerful antioxidants for the protection of fats, oils and margarine in snack foods, for instance (8).

II. ANALYSIS OF ANTIOXIDANTS

A. General

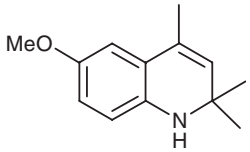
Food laboratories mostly have their own in-house methods for the analysis of antioxidants. These normally originate from procedures of the American Oil Chemists' Society (AOCS), the Association of Official Analytical Chemists (AOAC), the International Union of Pure and Applied Chemistry (IUPAC), or the British Pharmacopoeia. It should be emphasized, however, that procedures of these professional societies are not necessarily the best and most convenient for a particular analysis in a laboratory. A literature search can sometimes unearth a more suitable procedure, or a novel method may even be devised by an enterprising scientist. A few selected procedures will be briefly discussed, mainly concentrating on the principles involved.

B. TBHQ, BHT, BHA, and Gallates

The phenolic antioxidants and the gallates are usually determined by High Performance Liquid Chromatography (HPLC). The food sample is extracted with hexane and the antioxidant in the hexane is quantitatively extracted into multiple volumes of acetonitrile, which is immiscible with hexane. The acetonitrile is concentrated, an aliquot injected into the chromatograph and the antioxidants eluted with a mixture of acetonitrile and aqueous acetic acid. A standard mixture of antioxidants is treated in the same manner, and each one quantified by UV detection at 280 nm. Excellent separation of the antioxidants can be achieved by selecting the correct HPLC column and eluting solvent (28). However, the accuracy of this analysis could be much improved and time and energy saved if a suitable internal standard were adopted. Replacing the *t*-butyl group with an *i*-propyl group in the three phenolic antioxidants seems to provide an ideal internal standard and it is suggested that suppliers of fine chemicals prepare these analogues with the prediction that they will find a ready market. Recently, a convenient and rapid gas chromatographic method for the determination of TBHQ, BHT and BHA in fats and oils was developed in Taiwan. The sample is simply dissolved in diethyl ether, the internal standard 8-hydroxyquinoline (oxine) is added and the mixture injected into a gas chromatograph fitted with a capillary column. As the fats and oils are injected together with the antioxidants the capillary column will undoubtedly need frequent replacement (29). Earlier determinations of BHT and BHA were based on the volatility of these phenolic antioxidants in superheated steam. After separation from the non-volatile food residues with superheated steam, the antioxidant in the distillate is determined spectrophotometrically at 515 nm using the ferric chloride-2,2-dipyridyl reagent for BHT and at 620 nm using the 2,6-dichloroquinonechloroimide reagent for BHA. This method is still the official IUPAC procedure (30).

C. Ethoxyquin

Ethoxyquin (EQ) can be determined in foodstuffs and fish meals by gas chromatography making use of the internal standard methoxyquin (MQ; 1,2-dihydro-6-methoxy-2,2,4-trimethylquinoline [**11**]) (Figure 85.4) (15). An accurate amount of MQ is added to the weighed sample, which is then treated with hexane and filtered. The hexane extract is subsequently washed with 1M HCl, separating the EQ and MQ into the aqueous phase, as EQ and MQ are organic bases and thus soluble in aqueous HCl. The HCl solution is made alkaline and the EQ and MQ extracted back into hexane. This solution, after concentration, is injected into the gas chromatograph. Gas chromatography on almost any column perfectly separates both compounds and EQ is quantified by comparing peak areas. Earlier methods separated EQ from other components by liquid chromatography over a column of alumina. The EQ is eluted with a mixture of hexane: diethyl ether (9:1, by vol.), while the progress of the elution is followed with an UV lamp, as EQ is fluorescent, and the EQ is collected in a volumetric flask. The absorbance of the solution is read at 362 nm and using its molar absorptivity of



11, MQ

FIGURE 85.4 Internal standard in EQ analysis.

3254 moles^{-1} l.cm^{-1} the EQ content of the sample is calculated (14,15). Other methods make use of the fluorescing characteristic of EQ and minute residual quantities (of the order of 0.05 ppm) of EQ in chicken tissues and eggs were determined in this manner (31).

D. Vitamin C

Vitamin C is a mild reducing agent and can be determined simply and inexpensively in, for instance, fruit juices by titration in strong aqueous acid (>3M HCl) with the oxidizing agent potassium iodate using starch and a small amount of chloroform as indicator. Initially iodate is reduced to iodine by the vitamin C, but when this is consumed, oxidation of iodine to ICl takes place. The end point of the reaction is signalled by complete disappearance of the iodine shown by decolorization of the purple starch-iodine colour of the chloroform phase (32). A more recent method relies on the fluorescence of vitamin C on reaction with *o*-phenylenediamine (1,2-diaminobenzene). The fluorescence is read on a fluorometer and standard solutions of vitamin C are used to quantify the results (33). This sophisticated analysis yields results for the vitamin C content of fruit juices comparable to the simple titration procedure just mentioned.

A gas chromatographic procedure making use of the volatility of the tetra-*O*-trimethylsilyl ether derivative of vitamin C using octadecane as internal standard has also been described (34). This method does not elaborate on the difficulty of identifying vitamin C amongst the multiplicity of carbohydrate peaks present when determining it in food stuffs. A similar gas chromatographic method also determines vitamin C in food products by extraction in 95% ethanol followed by precipitation with lead acetate, addition of the internal standard glutaric acid, and conversion into its tetra-*O*-trimethylsilylether. This publication shows a chromatogram illustrating the multitude of peaks accompanying the vitamin C and glutaric acid signals (35).

E. Vitamin E or Tocopherol

A vast amount of work has been done on the analysis of tocopherols, as shown in a recent review (36). The IUPAC, the AOAC and the AOCS have published their own methods (37,38,39), all of which rely on the fact that tocopherols end up in the non-saponifiable fraction of the substance to be analysed. For example in the IUPAC method (37), tocopherols are determined in the non-saponifiable material by capillary gas chromatography of their respective trimethylsilyl ethers at a temperature of 250°C. The internal standard squalane (a high molecular weight hydrocarbon) is used to quantify them. However, it must be realized that squalane, which is not an isomer of vitamin E, is only added at the final stage of the analysis. This means that all chemical manipulations prior to the chromatographic separation must be carried out quantitatively. As with the phenolic antioxidants, if a suitable isomer of vitamin E were to become available (for instance, the ethyl analogue of tocopherol) a great deal of time and energy could be saved by using it as an internal standard. An alternative IUPAC procedure determines vitamin E in the non-saponifiable material by thin layer chromatography on silica gel. The spots, after visualization under UV light, are cut out, extracted into ethanol and the tocopherols determined colorimetrically at 520 nm with the ferric chloride-2,2-dipyridyl reagent (37). Other methods combine HPLC separation with fluorescence detection of vitamin E (40,41).

III. EVALUATION OF THE EFFICACY OF AN ANTIOXIDANT

A. General

The efficacy of an antioxidant depends, for as yet unknown reasons, not only on the antioxidant but also on the substrate that it is meant to protect. For instance, the efficacies of analogues of EQ are totally different in fish oil and fish meal (14). The selection of an antioxidant should ideally be based on its efficacy in a realistic situation using subjective criteria such as taste and smell. Unfortunately, time constraints often necessitate accelerated tests at higher than storage temperatures, which then serve as a guide. There are many methods for assessing the efficacy of an antioxidant and the Journal of the American Oil Chemists' Society has numerous papers dealing with ancient and modern methods. Marco, for example, lists eight different methods and then proceeds to add another one (42). A few selected procedures will be discussed in some detail.

B. Procedures for Evaluating Antioxidants

A frequently used method for determining the efficacy of oil-soluble antioxidants is the Active Oxygen Method (AOM) (43). In this method air is blown simultaneously into several oil samples held in glass tubes in a water bath maintained at a constant temperature, typically 50°C. The air flow is kept constant at 5 ml/second. Oxidation of the oil is followed by determining peroxide values of the oil at predetermined intervals, i.e. every 4 hours. A control oil together with a number of other oils containing the antioxidants to be tested is included in the run. The oil is normally a refined vegetable or animal oil, free of natural antioxidants. The efficacy of an antioxidant is obtained by determining the time taken for the antioxidant-treated oil to show a rapid increase in peroxide value compared to the control. This time is known as the induction time. The efficacy of the antioxidant is expressed as a difference (or a ratio) of the induction time of the control and the antioxidant-treated oil. There are a number of variables in this test which can be altered to suit almost any requirement, such

as the temperature of the water bath, the rate of air flow, and the level at which the antioxidant is tested. It is an accelerated test and often criticised for not being realistic. The test has the characteristics of a three-stage oxidation process, firstly, an induction period during which the peroxide value remains low and increases slowly over time, this is followed by a period in which the peroxide value increases sharply and finally a period in which the peroxide value decreases. It is, of course, only necessary to complete the first and second stages to obtain the efficacy of the antioxidant. Fully automated instruments have been marketed under the name Rancimat, rendering antioxidant assessment a routine matter. These Rancimats use either peroxide values or titration of volatile fatty acids formed during oxidation, to measure the efficacy of an antioxidant. A more realistic procedure for testing antioxidants in fish meal has recently been described (44). This test measures the remaining polyunsaturated fatty acids (PUFA) in the extracted meal lipids over a one-year storage period at 25°C. The efficacies of the different antioxidants are assessed by periodically determining the amount of PUFA in the residual meal lipids and calculating their average daily decrease. A control fish meal is included in the test. Lipid extractions are done at approximately bi-monthly intervals over a total period of about 12 months. At the end of the experiment, regression lines and correlation coefficients are calculated using at least 6 data points. Several analogues of EQ have been tested by this procedure. It was found that efficacies of the antioxidants in fish meal were entirely different from those in fish oil. Some comparisons are shown in Table 85.1. A rather interesting and rapid method for evaluating antioxidants is described by scientists from Monsanto. It involves the preservation of the yellow colour of β-carotene in a mineral oil film at 75°C. The preservation of the β-carotene colour, compared to a control, serves as an index of the efficacy of the antioxidant (45). A total of forty quinoline derivatives, including both ethoxyquin (**5**) and hydroquin, (**7**) were tested by this procedure. However, it failed to recognize hydroquin (**7**) as a potentially viable alternative to ethoxyquin (**5**) for the protection of the PUFA in fish meal (44,45), illustrating the importance of the substrate when testing antioxidants.

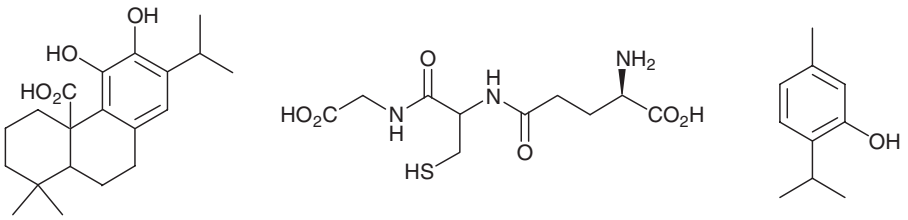
IV. SYNERGISM

The dictionary defines synergism as "the joint action of agents, such that the total effect is greater than the sum of the two effects taken independently," in other words "one gets something for nothing." Mixtures of antioxidants sometimes show synergism and have a higher efficacy than expected from the individual components. A 1:1 combination of BHT and BHA shows this and is very effective in stabilizing animal fat (8). However, it is prudent to carefully investigate every claim of a superior antioxidant mixture on the grounds of synergy, as frequently an expensive antioxidant is merely diluted with a cheaper one. For instance, no synergy was found between EQ and the less expensive BHT when tested with the active oxygen method in Marinol (a bleached and refined fish oil) (46), and neither was the proprietary mixture Oxiquin Super (EQ mixed with BHT and soyabean lecithin) found to be superior to EQ (47).

A curious fact emerges from the study of synergism. Since mixtures of antioxidants display synergism, a random occurrence, it follows logically that other mixtures will display antagonism, i.e. the joint action being less than the sum of the two effects thus offsetting the mysterious gains of synergism and, as it were, "balancing the books." One comes across it in the medical field where the public is warned that certain drugs are antagonistic towards each other. However, it appears that cases of antagonism remain unreported in the food world (no doubt due to the expense involved in reporting it). This is unfortunate, as it inhibits scientists from trying to unravel the as yet unexplained mystery of synergism, where seemingly the laws of thermodynamics are broken: "in synergism one gets something for nothing." Examples of chelation (sequestering or complexing) of metal ions are sometimes wrongly classified under the heading of synergism. Small amounts of metal ions such as copper and iron (as low as 0.02 ppm) often cause off-odours in milk and butter. These off-odours are due to the formation of minute amounts of complex ketones and aldehydes from the milk lipids under the catalytic influence of metal ions. Milk and milk products are particularly vulnerable as milk is deficient in natural antioxidants and therefore easily develops a "soapy," "fishy," or "metallic" taste. Complexing agents such as citric acid or ethylenediaminetetra-acetic acid (EDTA) are used to combat this type of spoilage (48,49,50,51). Another method to protect milk products is to mix them with cocoa butter, which has sufficient vitamin E to stabilize the butter fat (52). Instances of phospholipids acting as both chelating and solubilizing agents are reported and often an antioxidant mixture will contain phospholipids for this very purpose. The chelating action of the phospholipids seems to be confined to the phosphatidylethanolamine fraction while its solubilizing property is a characteristic of the whole phospholipid (53).

V. ANTIOXIDANT CONCOCTIONS

Modern consumers frequently shun synthetic antioxidants and demand natural ones. This had led to the proliferation of plant extracts claiming to have antioxidant properties similar or superior to synthetic ones. The chief difference between the natural antioxidants mentioned earlier and these concoctions is that the latter are not properly defined and are therefore not reproducible. If a plant extract shows antioxidant properties, the active ingredient should be isolated and characterized. This has been done for rosemary extracts



12, Carnosic acid **13, Glutathione** **14**

with the identification of carnosic acid (**12**) (54,55) and for broccoli, parsley and spinach with glutathione (**13**), a tripeptide, as the active ingredient (56). Similarly, thymol (3-hydroxy-4-*i*-propyltoluene) (**14**) has been identified as the main antioxidant in the volatile components of eucalyptus leaves (57) (Figure 85.5). In other cases, however, this identification is sadly lacking. A brief glance at recent titles in food journals will confirm this, and a cursory look on the Internet identified more than 482,000 publications dealing with these concoctions. It is the proliferation of these publications, which is the real danger. It is impossible to keep up with these claims, therefore those with real potential are in danger of being drowned in a flood of unverifiable claims.

VI. ANTIOXIDANTS AND THE LAW

Government regulations concerning the use of food antioxidants differ from country to country and are liable to be modified continually. Travelling through this maze of regulations is a lawyer's job, not a scientist's, although the scientist cannot escape the legal implications of work carried out in the laboratory. Antioxidants to be used in the food industry all aspire to receive GRAS (Generally Recognised As Safe) status. This is the brainchild of the U.S. FDA, and it has given GRAS designation to antioxidants in use prior to January 1, 1958, based on common knowledge accumulated through years of usage. Clearly it was not the intention of the FDA to ban all food antioxidants until they were shown to be safe, as this would have virtually halted the production of many foodstuffs. New antioxidants, however, must now undergo years of rigorous testing to ensure freedom from harmful effects. The European Union also evaluates antioxidants and, if approved, grants them *E numbers*, which must appear on food labels. Many of these *E number* antioxidants are the naturally occurring substances such as vitamins C [**8**] and E [**9**], which are often prepared using a synthetic route; others are not naturally occurring such as BHT [**3**] and BHA [**4**] (58). It appears that the practice of granting *E numbers* is gaining ground and is set to become the international standard.

A vast amount of work has been done to establish the toxicity of antioxidants. The results are surprising, as it was found that in large doses antioxidants, including BHT and BHA, might be the cause of cancer in animals. Evidently a number of antioxidants become pro-oxidants when used in large concentrations; even vitamins C and E are potentially toxic at high doses (59,60). The regulatory authorities, however, decided to permit the use of BHT [**3**], BHA [**4**] and the gallates [**10**] whilst keeping the situation under review as new research results become available (59). Since little is known of the long term toxicity of TBHQ [**2**], the latest and also the best phenolic antioxidant for oils and fats, it has been banned as antioxidant in foods in a large number of countries, including the U.S. (59). The European Union has followed suit and has not assigned an *E number* to it (58). Predictably, neither EQ (**5**) nor any of its analogues have received either GRAS or *E number* status. In spite of this, it is allowed in foodstuffs in many countries up to a certain maximum level differing from country to country. For instance, in Belgium, Denmark, Greece, Italy, Luxembourg, the Netherlands, and Spain it is not allowed in any food for human consumption. Sweden and the U.S., however, allow it at levels of as high as 100 ppm in spice blends and spice extracts, while in the United Kingdom only 3 ppm is allowed as a pesticide on apples and pears (14). This is just one example illustrating the complexity of the regulations governing food antioxidants with which some scientists are forced to familiarize themselves.

VII. CONCLUDING REMARKS

In our opinion, the cost of introducing new synthetic antioxidants still outweighs any potential benefits due to the stringent testing criteria that have to be met. This is in all probability the main reason for the phenomenal surge in research in the field of natural antioxidants and their mixtures. So far the results of these natural antioxidants have fallen dismally short of expectations, as they are unable to compete in efficacy and price with synthetic ones. However, as antioxidants are compounds that continue to surprise it is probably prudent to remain optimistic and say "in antioxidant research nothing is ever predictable."

On the other hand, in the medical arena great strides have been taken in the elucidation of the protection afforded by antioxidants *in vivo*, and this seems to be the area of research yielding the largest dividends in the future.

86 Synthetic Colorants

M. Beatriz A. Glória

CONTENTS

I. INTRODUCTION

Color is one of the most important quality attributes of foods. No matter how nutritious, flavorful, or well textured, a food is unlikely to be eaten unless it has the right color. Color affects the overall judgments on the worth of food from both aesthetic and safety point of view. It plays an important role in taste thresholds, flavor identification, food preference, pleasantness, acceptability and, ultimately, food choice (10, 15, 28, 32, 47).

Specific colors of foods are often associated with freshness or ripeness. Redness of raw meat is associated with freshness, while brownish-red meat as not fresh. A green apple, tomato, or peach may be judged as unripe, although some apples are green when ripe (32, 44).

Colors also influence flavor perception. The consumer expects red drinks to be strawberry, raspberry, or cherry flavored, yellow to be lemon, and green to be lime flavored. The impact of color on sweetness perception has also been demonstrated (6, 40, 44).

Color in foods is due to naturally occurring pigments, which are normal constituents of cells. Many pigments are, unfortunately, unstable during processing and storage. Depending on the pigment, stability is affected by factors such as light, oxygen, heavy metals, oxidizing or reducing agents, temperature, water activity, and pH (6, 30, 44).

Colorants are added to foods to help preserve the identity or character by which foods are recognized; to intensify the natural color of food; to correct for natural variations in color; to ensure uniformity of color from batch to batch due to natural variations in color intensity; to restore the original appearance of the food when natural colors have been altered during processing and storage; and to enhance colors naturally occurring in foods in less intensity than the consumer would expect. They are also used to give an attractive appearance to certain colorless foods, such as imitation foods, and to help protect flavor and light-sensitive vitamins during storage via sunscreen effect. But it has also been used for adulteration purposes — to disguise food of poor quality, to mask decay, to redye food, to mask effects of aging or to simulate a higher biological value (4, 14, 32, 40).

II. HISTORY

The practice of coloring foods dates back to very early times. It is known from Pliny, that wine was colored through the use of smoke or aloe as far back as 200–300 BC. Pliny also noted the practice of adding seawater to wine to increase the color's brightness. As early as 1396, an edict was issued in Paris that forbade the coloring of

butter (5, 40, 46). The increasing use of colorants and other adulterants led Frederick Accum to publish in 1820 a treatise on adulteration of food and culinary poisons, in which he described, among other practices, the coloring of hedge leaves with verdigris to resemble green tea and the artificial greening of pickles and candies with copper salts (40).

Until the middle of the nineteenth century, the only coloring matters available were derived from natural sources of animal, vegetable and mineral origin (10, 46). The first synthetic organic colorant, mauve, was discovered in 1856 by Sir William Henry Perkin from the coal-tar derived methylanaline. This synthetic purple dye sparked not only the birth of the modern organic chemical industry, but also the quest for synthetic colorants (40). Soon after that, new and different colorants were available in a wide range of shades, higher tinctorial value and stability, more uniform, and more permanent than natural organic dyes and, in the opinion of some, were safer for use in foods than many of the mineral colorants in use at that time. These colorants were applied to foods immediately (5, 10, 27).

Accum's book initiated a flurry of investigations and reports on food adulterations and a number of treatise were published to prompt state government increasingly into legislating the safety of the food supply (40). The United States first legalized the use of synthetic organic dyes in foods by the act of Congress that authorized the addition of coloring matter to butter in 1886. The second came ten years later when Congress officially recognized coloring matter as a legitimate constituent of cheese. By 1900, Americans were eating a wide variety of artificially colored products, including ketchup, jellies, cordials, butter, cheese, ice cream, candy, sausage, noodles and wine. The rapid growth in the use of color additives was prompted not just by the availability of these new colorants but also by the numerous changes that were taking place in food technology. The development of food substitutes or imitation products such as margarine for butter, jellied glucose for jam, soft drinks for fruit juices, etc., created needs for colorants. Furthermore, the increased use of food preservatives, refrigeration, canning and large-scale food processing, all of which tended to alter the natural color of food products, demanded new approaches to restore the normal appearance of food products (27).

The abundant use of color additives was soon recognized as a threat to the public's health. Of particular concern was the fact that substances known to be poisonous were often incorporated into food and the colorants were frequently used to hide poor quality, to add bulk and weight to certain products and to pass off imitation foods as real. Another concern, besides the misuses of colorants, was that little or no control was exercised over the purity of the colorants added to foods. Towards the end of the 1800s, concern began over some of the dangerous and deceptive ways colorants were being used in foods and so a number of legal steps were taken. In the early 1900s, several European countries wrote laws that either outlawed the use of certain colorants in foods, or limited the colorants that could be used. At about the same time, state and municipal governments in the United States moved to control the use of colors in foods, too. American food manufacturers also moved to stop misuse of colorants in food. A circular was issued on 1899 by the executive committee of the National Confectioners' Association that enumerated 21 coal-tar colorants which were considered harmful and therefore unfit for adding to foods (10, 27).

Eventually, it became obvious that the individual efforts of industry and state and local governments were not enough to restrain the misuse of colorants in foods, and that some form of national government control was needed if the public's health was to be protected. The beginning of this control in the United States was probably 1862, when the Congress established the Department of Agriculture (USDA) and its Division of Chemistry, later named the Bureau of Chemistry (27, 40).

The Food and Drug Act of 1906 banned the addition of poisonous colors to confectionery products and prohibited the addition of colorants to foods for the purpose of concealing inferiority. That same year, Dr. Bernhard C. Hesse was hired to determine which colorants could be safely added to food and which restrictions should be placed on their use. Hesse began his work by examining the chemistry and the physiology of 695 colorants then known to be in use throughout the world for foods and by reviewing the laws of numerous countries that controlled their use. After much study, Hesse and the Bureau concluded that coal-tar dyes should not be used indiscriminately. They also concluded that only specific colorants that were proven to be safe should be permitted in foods, and that each batch of colorant intended for use in food should be tested and certified as pure before allowing its use (27, 31).

Based on these principles and taking into consideration recommendations of the National Confectioners' Association, the current needs of industry and suggestions by the German and American dye manufacturers, seven colorants, among them, amaranth, ponceau 3R, orange I, erythrosine, naphthol yellow S, light green SF yellowish and indigo disulfo acid sodium salt were permitted through the Food Inspection Decisions (FID 76, July 13, 1907). Furthermore, procedures for certification of these colorants were established (FID 77, September 25, 1907) and made it clear that each batch of dye had to be certified (27, 40).

Soon after Hesse published the list of permitted colorants, pleas began to expand it. In response to the appeals, testing began in 1915 and soudam I, butter yellow OB, and yellow AB were added to the list (FID 175, April 23, 1918). However, soudam I and butter yellow were delisted (FID 180, June 7, 1919) for causing severe contact dermatitis in workers handling the colorants (31). During the 1920s, the number of colorants on the list continued to grow, with the addition of guinea green B (FID 184, July 10, 1922),

fast green FCF (FID 207, April 9, 1927) and brilliant blue FCF, ponceau SX and sunset yellow (1929) (27).

The Food, Drug and Cosmetic Act of 1938, resulted in a number of important changes for color additives. It made certification mandatory for three specific certified categories: colors suitable for foods, drugs, and cosmetics (FD&C), colors suitable for drugs and cosmetics (D&C) and colors suitable for externally applied drugs and cosmetics (Ext. D&C). It made it clear that certification had to be on a batch-wise basis at the expenses of the industry. It also allowed manufacturers to add harmless diluents to colorants. In 1939, Food and Drug Administration (FDA) added orange SS, dipotassium salt of naphthol yellow S and oil red XO to the list and proposed a new systematic method for naming certified colorants — FD&C colorants (27, 40).

In January of 1950, FD&C violet No. 1 was added to the list. In the same year, three incidents involving excessively applied colorants in popcorn and candies prompted FDA to begin a more rigorous toxicological testing program (31). FDA ordered a complete retesting of all FD&C colorants, including two-year chronic oral toxicity experiments. While all the testing was going on, another event was taking place that would have significant effects on color additives — the hearings of the House Select Committee to investigate the use of chemicals in food products, whose chairman was James Delaney. These focused on the numerous chemicals being added to foods, including colorants which raised the public's concern regarding the safety of the food supply. In 1953, results of the new round of animal testing indicated that FD&C orange No. 1 and FD&C red No. 32 could cause adverse effects (18, 27). As a consequence, FD&C orange Nos. 1 and 2 and FD&C red No. 32 were delisted in 1958 and FD&C yellow Nos. 1, 2, 3 and 4 were delisted in 1959. In this same year, the Department of Health, Education, and Welfare submitted the Color Additives Amendment, which was approved in 1960. This amendment allowed for the continued use of existing color additives pending the completion of investigations to ascertain their suitability for listing as permanent colorants, and authorized the Secretary of Health, Education, and Welfare to establish limits of use for colorants, thus eliminating the harmless-per-se interpretation formerly employed. A special provision, commonly known as the Delaney Clause, specifically directed the Secretary not to list a color additive for any use if that colorant could be shown to induce cancer in humans or animals. Another feature of the Color Additives Amendments gave the FDA jurisdiction over all color additives by eliminating any distinction under the law between coal-tar colors and any other color additives, regardless of their source or method of manufacture. The Amendments also addressed the issue of the need to certify colorants such as beta-carotene by empowering the Secretary to decide which colors must be certified and which could be exempt from certification (27).

III. DEFINITIONS AND CLASSIFICATION

Color refers to the human perception of colored materials. Foods have color because of their ability to reflect different quantities of energy at wavelengths which stimulate the retina in the eye. The energy range to which the eye is sensitive is referred to as visible light. Depending on the individual's sensitivity, it encompasses wavelengths of approximately 380 to 770 nm, which is a portion of the electromagnetic spectrum. The perception of color results from differences in absorption of radiant energy at several wavelengths. If the shorter wavelengths of 400–500 nm are reflected to a greater extent than other wavelengths, the color is described as blue. Maximum reflection in the medium wavelength range results in green or yellow color, and maximum reflection at longer wavelengths 600−700 nm indicates red objects (8, 27).

According to the 1938 Act, a color additive is defined as "a dye, pigment or other substance made or derived from a vegetable, animal, mineral or other source and that, when added or applied to a food, is capable of imparting a color thereto" (15, 40). Even though colorants have been classified as natural or synthetic, the FDA does not recognize any category of colorant as being natural, as the addition of any colorant to food (natural source or nature-identical) results in an artificially colored product (32). Naturally occurring colorants or pigments are described in another chapter. Synthetic colorants or dyes are attractive to the food industry because they are superior to natural colorants in tinctorial power, consistence of strength, range and brilliance of shade, hue, stability and ease of application (2, 8). Synthetic colors provide a larger spectrum of colors. They also have lower prices and higher availability (32, 35).

IV. CHEMICAL AND PHYSICAL PROPERTIES

The synthetic food colors are categorized in different ways. The E or EEC references are the numbers allotted in the European Economic Community Directive of 23/10/62 to the coloring matters listed in Annex I of that Directive. The FD&C No. is a systematic method for naming certified colorants permitted in the United States. The CI Food Color Numbers are the Color Indexes established by the Society of Dyers and Colourists (United Kingdom) and the Society of Dyers Colorists of the United States (8).

Synthetic food colorants are also classified according to their chemical structures into the classes: azo, triarylmethane, xanthene, quinoline and indigoid compounds (39, 44). The chemical structures of some synthetic food dyes are shown in Figures 86.1 and 86.2.

The azo colorants comprise the largest group. They are characterized by the presence of the azo group (-N=N-) in association with one or more aromatic systems. There may be one or more azo groups present in the molecule. They are synthesized by the coupling of a diazotized

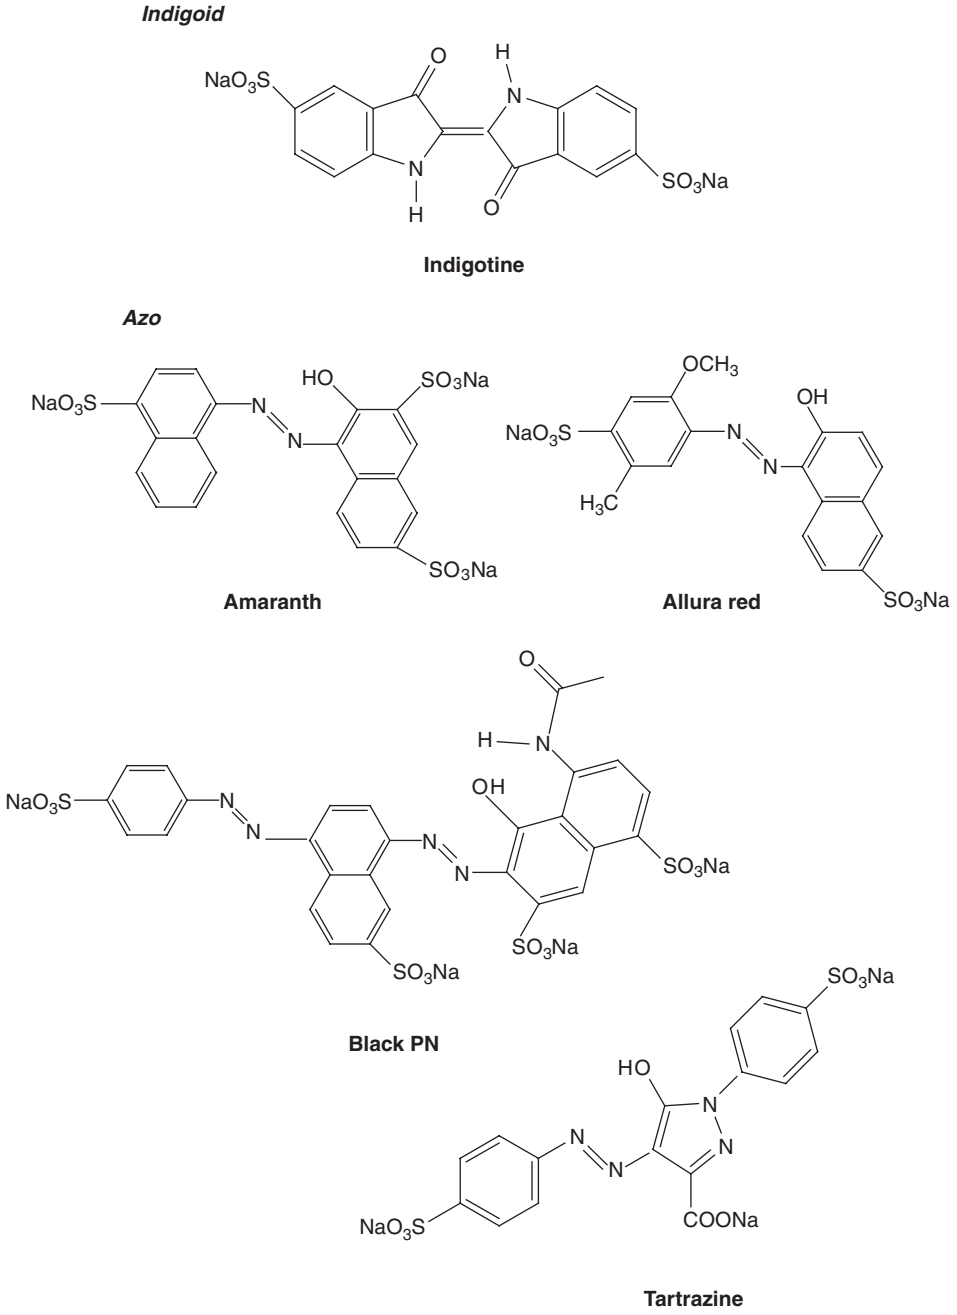

FIGURE 86.1 Chemical structures of azo (amaranth, allura red, black PN, and tartrazine) and indigoid (indigotine) colorants.

primary aromatic amine to a component capable of coupling, usually a naphthol. The soluble azo dyes can contain one or more sulfonic acid groups. Their degree of solubility is determined by the number of sulfonic groups present and their position in the molecule. The azo dyes give rise to colors in the yellow, orange, red, blue, violet, brown and black range. Amaranth, allura red, black PN and tartrazine (Figure 86.1) belong in this class (8, 27, 44).

There are colorants of the indigoid type, including indigotine (Figure 86.1), which is the water-soluble disodium sulfonate derivative of indigo, one of the oldest known and most extensively utilized natural pigments. The pigment is derived from various species of the indigo plant found in India. It is made by sulfonating indigo, yielding 5,5′-indigotine disulfonate. The color, which results from the resonance hybrid of structures, is a deep blue, compared to the greenish-blue of brilliant blue FCF. It has the lowest water solubility of any of the FD&C colorants and it is highly susceptible to oxidation by ultraviolet light and fades rapidly (8, 27, 44).

The triarylmethane or triphenylmethane colorants consist of three aromatic rings attached to a central carbon

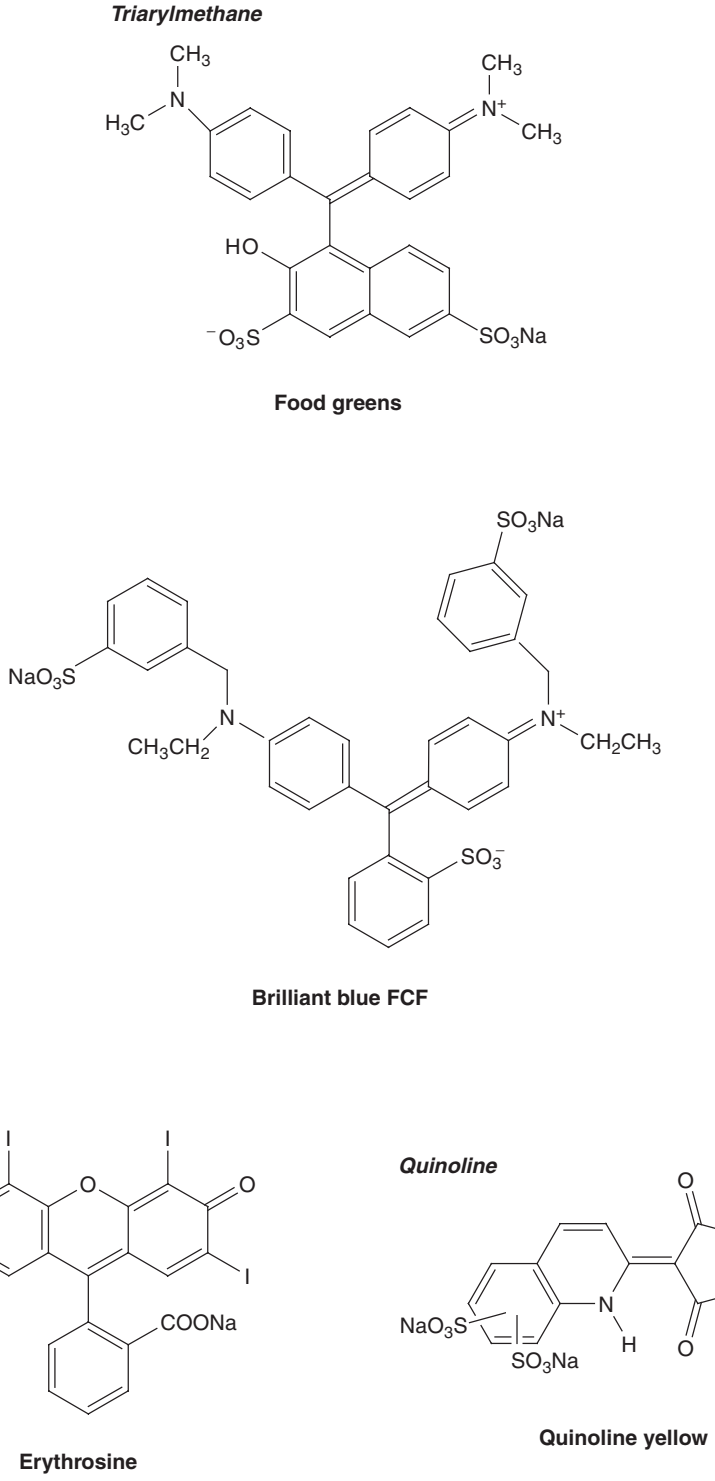

FIGURE 86.2 Chemical structures of triarylmethane (Food green S and brilliant blue FCF), xanthene (erythrosine) and quinoline (quinoline yellow) colorants.

atom (Figure 86.2). They are water soluble, anionic, sulfonated compounds. They are distinguished by their brilliance of color and high tinctorial strength, but they have poor light-fastness properties. They are characteristically bright green or blue. Alkali decolorization of a triphenylmethane colorant involves formation of a colorless carbinol base. The ortho-substituted sulfonic acid group sterically hinders access of the hydroxyl ion to the central

carbon atom, thus preventing formation of the carbinol base. Substitution of a sulfonic group for a hydroxyl group in these colorants improve the resistance to alkali and also the stability to light (8, 44).

In the xanthene group, the chromophoric system is the xanthene or dibenzo-1,4-pyran heterocyclic ring with amino or hydroxyl groups in the meta position with respect to the oxygen bridge. The xanthenes are usually water-soluble. Erythrosine (Figure 86.2) is insoluble in acids and it is quite stable to alkali. The chromophoric group imparts a brilliant red shade to erythrosine. It also exhibits fluorescence (8, 27, 44).

The quinolines are derived from quinaldine by condensation with phthalic anhydride. The chromophoric system is the quinophthalone or 2-(2-quinolyl)-1,3-indandione heterocyclic ring. Bright greenish yellow shades with poor light fastness are characteristic of the group. Quinoline yellow (Figure 86.2) is the only dye in this group of importance for use in food coloration (8, 14, 39, 44).

The generic and chemical names, the chemical classes, and color identification according to the International Numbering System (INS) or European Economic Community (EEC or E number), United States Food, Drug and Cosmetic Act, Color Index Constitution Number, and the Chemical Abstract Service Register Number of some synthetic colorants are shown in Table 86.1. The chemical formulas, molecular and milliequivalent weights, color shade, maximum absorbance wavelength, and extinction coefficients of some synthetic food colorants are indicated on Table 86.2.

It is the bond conjugation within the organic molecule which is responsible for color. Delocalization of the π-bonding electrons lowers their excitation energies, allowing them to absorb light. Extensive conjugation, or the presence of electron donor and acceptor groups within the molecule, serves to shift the absorption of light to the lower energies (longer wavelengths) comprising the visible spectrum. The tinctorial strength is an intrinsic property of the dye's chemical structure, i.e., the extinction coefficient. The coloring power is thus best manipulated through optimization of the physical form of the dye used and the carrying vehicle (40).

The chemical and physical properties of some colorants, as summarized in Tables 86.3 to 86.6, confer advantages and disadvantages, and thus fulfill a specific application need (8, 9, 32, 43). However, the chemical and physical properties desired in a food coloring material are not easy to achieve. Furthermore, many factors can contribute to the instability of colorants.

Water solubility is conferred by the presence of at least one salt-forming moiety (-SO_3H, -CO_2H). These dyes are usually isolated as their sodium salts. They have colored anions and are known as anionic or acid dyes. Dyes containing basic groups, such as -NH_2, -$NHCH_3$ and -$N(CH_3)_2$ form water soluble salts with acids. These are the cationic or basic dyes, and the colored ion is positively charged. Some dye molecules have both acidic and basic groups, giving rise to an internal salt or zwitterion structure. Indigotine, in particular, has many possible zwitterionic structures besides that shown in Figure 86.1 (39).

Azo and triarylmethane dyes are susceptible to discoloration or precipitation during processing and storage in the presence of reducing agents (monosaccharides, aldehydes, ketones, and ascorbic acid), heavy metals, metal packaging, exposure to light, excessive heat, or exposure to acid or alkali (Tables 86.4 and 86.5). Azo dyes give rise to colored subsidiary products and to the colorless hydrazo forms or sometimes to the primary amine.

Azo dyes are also subject to SO_2 decolorization through HSO_3 addition to the nitrogens, resulting in the colorless hydroazo sulfonic acids. Triarylmethane dyes are reduced to the colorless leuco base (11, 40, 44).

Free trace metals, including zinc, tin, aluminum, iron, and copper are known to cause fading of some additives (27). Of most concern are iron and copper. The presence of calcium and magnesium can also result in the formation of insoluble salts and precipitates (44). Azo dyes in particular are troublesome in that they often react with food cans at a rate proportional to their concentration, causing corrosion of the container and a corresponding loss in the food's dye content. Some colorants lack stability in retorted protein foods, whereas others are affected by peroxides (27).

The stability of a colorant toward light, either by itself or in solution, is not necessarily the same as its stability toward light in a product. Various ingredients, including aldehydic flavors, reducing sugars, and oils, are known to enhance the effects of light on some colorants, whereas, others prove to be more light stable in a product than alone. Several methods are used to minimize the effects of light on colorants in products, including packaging in light-proof packing, the incorporation of ultraviolet absorbers into the products, the use of color lakes, and the careful selection of the other ingredients used in the product. In general, the most stable colorants to light are tartrazine, carmoisine, amaranth, allura red, chocolate brown HT and brilliant blue FCF. Erythrosine and indigotine are the least stable (8, 27).

The pH value must also be considered when choosing a colorant, since not everyone of them can be used at all pH values. Indigotine fades rapidly in acid or alkaline media, while erythrosine precipitates from acid solution, whereas fast green FCF turns blue under alkaline conditions. Other colors exhibit important pH related changes in their properties, including shifts in shade, variations in shelf life, changes in solubility, and loss of tinctorial strength (8, 27).

The stability of synthetic food colors towards the conditions prevailing in food processing depends upon a number of factors. These include the medium in which the color is used, the concentration of the color and of the various food additives used and the temperature and time of exposure. Changes that occur as a result of these factors vary for each color used so that all of the components of a blend of food colors will not fade at the same rate. The resulting shade may, therefore, be entirely different from the original blend (8).

Temperatures used in cooking can be detrimental to food colors. The most stable of the commonly used synthetic colorants to average boiling and baking temperatures of 100 and 200°C, respectively are ponceau 4R, allura red, sunset yellow, tartrazine, chocolate brown HT and brilliant blue FCF. Indigotine is not stable to processing heat. At very high temperatures some carbonization may occur which will cause color loss or change of shade. All colors should be added at the lowest possible temperature, and as late as possible in the food manufacturing process, when little further heating will take place (8).

The synthetic colorants are stable to the levels of benzoic acid generally used as a preservative in foodstuffs, except patent blue V, quinoline yellow and indigotine. Erythrosine is precipitated from the solution in the presence of benzoic acid. The addition of sulphur dioxide as a preservative in fruit based-products causes color loss in patent blue and indigotine (1, 8).

Vitamins and antioxidants are added to a wide range of processed foods and vitamin C is frequently used to perform both functions. Sunset yellow, tartrazine, fast green FCF, and brilliant blue FCF are moderately stable to levels up to 160 ppm, while amaranth is stable in the presence of 70 ppm of ascorbic acid (1, 8).

When subjected to higher processing temperatures, particularly at above atmospheric pressure while retorting, color loss can occur as a result of reaction with proteins. This applies particularly in fish and meat processing but may also occur in processed milk products. In view of the varying protein contents of each product, it is important to carry out small-scale tests on each type of raw material to be used. Amaranth is the most susceptible food color to this type of action, while erythrosine is the most stable (8).

V. COLORANTS USE IN FOODS

Colors are added to foods to make them recognizable and pleasing to the consumer. What consumers want in the color of a food depends on a variety of factors, including cultural background, geographic, and sociological aspects of the population, past experiences, desire for color coordination, esthetic appeal, local customs, among others (6, 27).

The reason for coloring any particular food depends on a number of factors. The major use is in products containing little or no color of their own. These include many liquid and powdered beverages, gelatin desserts, candies, ice creams, sherbets, icings, jams, jellies, and snack foods. Without the addition of colors to some of these products, all flavors of the product would be colorless, unidentifiable and probably unappealing to the consumer (27).

The process used to prepare foods results in the formation of a color which depends largely on the time, temperature, pH, air exposure and other parameters experienced during processing. Therefore it is necessary to supplement the color of the product to ensure its uniformity from batch to batch. Foods that fall into this category include certain beers, blended whiskies, brown sugars, table syrups, toasted cereals, and backed goods. The storage of foods can also be a problem because natural pigments often deteriorate with time due to exposure to light, heat, air and moisture or because of interactions of the components of the products with each other or with packaging material. The color of maraschino cherries, for example, changes so easily with storage that they are bleached and colored artificially (27).

The problems of the citrus fruit industries are typical of those encountered with products produced in different areas of the country or at different times of the year. Most varieties of Florida oranges tend to be green, suggesting unripeness, even though they contain the proper ratio of solids to acid for fully nutritious, ripened fruit. Therefore, there is a need to color these oranges to make them comparable in appearance and thus of commercial acceptability as naturally colored fruit from other areas of the country. The percentage of the total crop colored varies from year to year and depends largely on the weather. However its use is not permitted for oranges intended for processing (27).

The problems associated with dairy products are more complex. Approximately 90% of the yellow color in milk is due to the presence of beta-carotene, a fat-soluble carotenoid extracted from feed by cows. Summer milk is more yellow than winter milk. This is largely due to seasonal feeding practices in which cows grazing on lush pastures consume much higher levels of carotenoids than do cows barn-fed on hay and grain in the fall and winter. Furthermore, various breeds of cows and even individual animals differ in the efficiency to extract beta-carotene from feed and in the degree to which they convert it into colorless vitamin A. The differences in the color of milk are more obvious in products made from milk fat. Thus, unless standardized though the addition of yellow colorant, products like butter and cheese can show a wide variation in shade and in many cases appear unsatisfactory to the consumer. It is also frequently necessary to use various amounts of blue or green colorants when making gorgonzola, provolone, blue and other cheeses to neutralize the yellow of the curd used to prepare them (27).

Other products whose natural color varies enough to make standardization desirable include the shells of certain kinds of nuts, the skins of red and sweet potatoes and ripe olives (27, 40).

Ink used by inspectors to stamp the grade or quality on meat must, by law, be made from food-grade colors. Dyes used in packaging materials that come in direct contact with a food must also be food-grade or, if not, it must be established that no part of the colorant used migrates into the food product (27).

There are numerous restrictions on the use of color additives. They cannot, for example, be employed to deceive the public by adding weight or bulk to a product or by hiding quality. In addition, special permission is needed to use colorants or products containing them in foods for which standards of identity say so. Other restrictions pertaining to the areas of use and the quantities of colorants allowed in products are specified in regulations for particular additives. Citrus red No. 2, for example can only be used to color the skins of oranges not intended for processing (27).

The amount of color additive allowed in a product depends on both the colorant and the food being colored. When numerical limits for use of food colorants are not specified, the amount allowed is controlled by "good manufacturing practices," e.g., one cannot use more colorant in a product than it is needed to achieve the desired effect. Today, the excessive use of colorants is rarely a problem since manufacturers are not likely to waste costly additives and, at the same time, run the risk of making their products appear unnatural (27).

VI. FORMS OF COLORANTS AVAILABLE

Food colors are available as straight colors, referred to as primaries. They are also available as blends of two or more straight colors, with or without diluents, referred as blends, mixtures, secondaries or secondary blends. The blends are standardized in strength by mixing the colors with approved diluents such as sucrose, salt, caramel, flour, etc. Mixtures of just one straight color with one or more diluents are also provided on special order for color users. However, mixtures must be made only from previously certified straight colors (23).

Typical forms of certified primary food colors are powder, ultra-fine powder, plating grade powder, granules,

dry blends, wet-dry blends, solutions, pastes and dispersions. The latter three preserved forms are used less frequently because of the added costs incurred in their preparation (23).

Secondary blends are the forms used for creating a wide variety of shades ready for immediate use in food preparations, such as grapes, raspberry, lime and various chocolates. The processing of secondary blends is dictated by the needs of the consumer. Many blends can be combinations of all dry ingredients. Some blends, especially those containing blue or green, must be combined in a wet state, then redried in order to prevent flashing at the time the consumer combines the product with water or milk. The dried products are ground, blended and standardized in strength within carefully controlled limits as required by the product specifications (23).

In manufacturing any colorant, the major difficulty is to meet the specifications of purity given for certification. However, the color manufacturing industry not only meets these purity specifications, but most manufacturers exceed them. The pure colorant content of a typical certified colorant is 86–96%. Variation of 2–3% in total colorant content of a colorant is of little practical significance since such variation has no significant effect on the ultimate color of a product. The moisture content of the colorant powder is between 4 and 5% and the salt (ash) content is approximately 5%. The high ash content comes from the salt used to crystallize (salt out) the colorant (44).

Where water-insoluble colorants are desired, the lakes are useful as insoluble pigments. Lakes were first approved for use in 1959. They are a special kind of color additive prepared by precipitating a straight color as aluminum salts on a substratum of alumina hydrate. To make a lake, the alumina substrate is first prepared by adding sodium carbonate or sodium hydroxide to a solution of aluminum sulfate. Next, a solution of colorant is added to the resulting slurry, the aluminum chloride is added to convert the colorant to an aluminum salt, which adsorbs onto the surface of the alumina. The slurry is filtered, and the cake is washed, dried, and ground to an appropriate fineness, typically 0.1 to 40 μm (8, 23, 27).

Lakes are available with pure dye contents ranging from less than 1% to more than 40% and with moisture levels of 6–25%. Typical use levels are 0.1 to 0.3%. Griding or mixing a lake in oil or fat achieves a result which, for some applications, is superior to coloring the product with a water-soluble dye. Lakes are marketed individually or mixed with other lakes or approved diluents, or dispersed in various edible vehicles such as hydrogenated vegetable oil, coconut oil, propylene glycol, glycerin, or sucrose syrup, or dispersed in other approved media that make the mixtures appropriate for printing food packagings (10, 23, 27).

Although lakes are insoluble in water, some bleeding or leaching may be observed in hot water, in strongly acid (pH <3.5) and alkaline (pH >9.0) conditions, or in solvents in which the unlaked dye is soluble. Lakes often show amphoteric properties with both acid and alkali tending to solubilize the inorganic substrate releasing free colorant (23, 27).

Properties of lakes that enhance their usefulness include opacity, ability to be incorporated into products in the dry state, relative insolubility, and superior light, chemical and thermal stability (40). Such properties have made possible the more effective and more efficient preparation of candy and tablet coatings and often eliminate the need to remove moisture from dry products before coloring them. Lakes have also made possible the coloring of certain products that, because of their nature, method of preparation, or method of storage, cannot be colored with ordinary color additives (23, 27). Lakes have proven particularly valuable for coloring water-repelling foods such as fats, gums, waxes, and oils, and for coloring food packaging materials including lacquers, containers, plastic films and inks from which soluble dyes would be quickly leached out (10, 27).

Unlike dyes that color objects through their adsorption or attachment from solution to the material being colored, lakes impart color by dispersing them in the medium to be colored. As a consequence of this pigment-like character, both the shade and the tinctorial strength of lakes are highly dependent on the conditions used in their manufacture as well as their physical properties, including their particle size and crystal structure (27, 40).

Lakes are considerably more expensive than the water-soluble colorants, however, there are several specialty uses where their application is practical (23). Some specific products in which lakes are used include icings, fondant coatings, sandwich cookie fillings, cake, doughnut mixes, decorative sugar crystals, coated and compression tablets, hard candy, candy wafers, chewing gums, wax coatings for cheese, yogurts, dry beverage bases, dessert powders, snack foods, spice mixes, printing inks, plastic films, decorative coatings, can linings, meat trays, produce containers, and margarine tubs (27).

When selecting a colorant for food use, several requirements must be attended. First of all, it should posses a desirable hue range and should have a high tinctorial strength. The tinctorial strength or coloring power of a colorant determines the amount and thus the cost of the colorant that must be added to a product to achieve a particular effect. A colorant's tinctorial strength is an inherent property of its chemical structure and cannot be changed, although maximum use can be made of it by selecting the physical form, vehicle, and conditions under which it is used (27).

The colorant must not impart any offensive property to the product. Offensive properties that can be transferred to a product include taste and odor, which can originate from the colorant itself or from trace impurities (27).

The colorant must be stable in the presence of light, oxidation and reduction, pH change, and microbial attack. Furthermore, it must be nonreactive with the products and the containers in which it is used. Tables 86.4 to 86.6 describe the performance of some colorants. An even more serious problem can result from the instability of a colorant, whether it is inherent or caused by reaction with a product or a product's container. Generally, color additives have shown excellent stability when stored in the dry state. For example, most food colors show little degradation after storage periods of 15 years or more. However, the stability of a colorant stored neat is no guarantee of its stability in a product. Consequently, use tests must still be performed and on an individual product/colorant basis (27).

The dye must also be easy to apply to products and should be highly soluble (Table 86.3) in water and in other inexpensive acceptable polar food grade solvents (e.g., alcohol, propylene glycol); it might need to be soluble in edible fats and oils, and if it is not soluble, it should be easily dispersed (27).

The colorant should also be inexpensive. The cost per pound of colorants is affected by the cost of the raw materials, equipment, and labor needed to produce it, as well as the supply and demand of the colorant. To these expenses, the additional cost needed to ensure the ultrahigh purity required must be added as well as the cost of certification. These factors make certified colors more expensive than typical technical dyestuffs. The saving feature is that in most cases, relatively little colorant is needed to achieve the desired depth of shade in a product, and, thus, the cost of the colorant adds relatively little to the cost of the finished product (27).

Although all of these factors should be considered when selecting the colorant for food use, the safety criteria, e.g. its safety for humans and the levels allowed are of extreme importance and should be fully satisfied, while the other factors are seldom completely met.

VII. TOXICOLOGICAL ASPECTS

The safety of food colorants has been a matter of concern. Most synthetic colors have been extensively tested in conventional toxicity studies. However, divergent views have often been expressed on the significance of the same toxicity data (11). Most of the questions have been associated with the azo dyes with respect to hypersensitive reactions. Some individuals show allergic reactions, such as urticaria (hives), asthma, and rhinitis, after ingestion of tartrazine (15, 17, 26, 29, 37). Tartrazine was observed to provoke bronchospasms in asthmatics and aspirin-intolerant persons. Newer studies indicated that the incidence of tartrazine hypersensitivity was rare (fewer than 1 out of 10,000 people being susceptible) and that tartrazine responses in asthmatic or aspirin-sensitive were exceptional and idiosyncratic (20). However, a double-blind, placebo-controlled study linked tartrazine ingestion with irritability, restlessness, and sleep disturbance in some children (38). Therefore, the use of tartrazine in a food product should be declared on the label (44).

Carcinogenic potential has been confirmed for some colorants, such as, ponceau 3R, butter yellow, methyl red, soudam R brown, soudam 7B red, orange SS and crisoidine (11, 41). Studies by FDA in 1972, evidenced that amaranth is embryophatic to rats. Allura red was observed to cause no significant and consistent adverse effect. However, there is concern about the presence of impurities, such as *p*-cresidine, which has been proven to be carcinogenic (36). However, recent studies have indicated that tartrazine, indigotine and erythrosine are potent inhibitors of skin tumor promotion in mice treated with 7,12-dimethylbenz[*a*]anthracene and with 12-*O*-tetradecanoylphorbol-13-acetate (24).

Erythrosine has been regarded as probable adventitious source of iodine, and toxicological studies confirmed its carcinogenic action on thyroid of male rats (11, 34, 41, 44). Although erythrosine is permanently listed, its long term toxicity is questionable. The lake of this colorant is no longer permitted for use in foods because of toxicological concerns (44).

The most publicized and controversial food color is amaranth. It had been used in the US since 1908. However, two Russian studies alleged that it was both carcinogenic and embryotoxic. While FDA discounted the charges of carcinogenicity, it was concerned about the teratogenic and reproduction effects. After several studies, ADI was reduced to 0–0.5 mg/kg body weight. The US prohibited the use of amaranth, however Canada, after studies of their own, observed that amaranth was not organ specific and allowed its use in foods together with the European Community, Japan, among others (19, 41). Amaranth has been recently delisted in Canada (7).

Many azo colors are not stable under certain conditions. Therefore, they undergo fading giving rise to colorless and colored subsidiary products whose toxic properties are not known. Indigotine is unstable in aqueous solution giving isatin-5-sulphonic acid and 5-sulphoanthranilic acid which are less clearly defined toxicologically than the parent molecule (11).

The International Life Sciences Institute, Nutrition Foundation's Catalog of Food Colors reports on the regulatory status of colorants in use throughout the world and on the safety assessment data, including international expert committee evaluations (21). The Joint Expert Committee on Food Additives Safety (JECFA), FAO, WHO, also reports on the regulatory status of colorants in use throughout the world and on safety assessment data (11, 41). JECFA also evaluates and provides updated information (22) on acceptable daily intakes (ADI) of colorant in mg per kg of body weight, making it accessible as it is evaluated (Table 86.7).

TABLE 86.7
Acceptable Daily Intake of Some Synthetic Food Colors

Food Color	ADI (mg/kg Body Weight) (Last Evaluation)
Carmoisine	0–4 (1983)
Ponceau 4R	0–4 (1983)
Amaranth	0–0.5 (1984)
Erythrosine	0–0.1 (1990)
Allura red	0–7 (1981)
Sunset yellow	0–2.5 (1982)
Tartrazine	0–7.5 (1964)
Quinoline yellow	0–10 (1984)
Indigotine	0–5 (1974)
Brilliant blue FCF	0–12.5 (1969)
Patent blue V	not allocated (1982)
Fast green FCF	0–25 (1986)
Chocolate brown HT	0.25 (1979)
Brilliant black PN	0–1 (1981)

ADI = Acceptable daily intake in mg/kg body weight.

According to JECFA (22), it is important to constantly gather information on the levels of synthetic colorants in foods to assess where the dietary intake stands compared to the ADI. Therefore, each country, and even regions within a country, should verify periodically the dietary intake of colorants, and additives in general, to make sure that intake does not exceed the ADI. In 1992, Toledo et al. (42) investigated the potential weekly intake of synthetic colorants by 3–14 years-old children from Barão Geraldo, Brazil. Results indicated that male children, especially from lower classes were most exposed to artificial colors. Comparison of estimated potential intakes with the ADI showed that consumption of amaranth, sunset yellow, indigotine and tartrazine represented ca. 24, 3, 0.05 and 0.4% of the actual ADI values, respectively.

VIII. LEGISLATION

Legislation on the use of colors in foods arose from the need to protect the consumer from harm and from fraudulent practices. The regulations promulgated by various countries world-wide differ in detail rather than in concept, as all have the same ultimate goal. Today, the food colors permitted in most countries are allowed only when a need has been demonstrated and their safety assured. Before these colors are authorized for food use, they have been subjected to rigorous toxicological testing and numerous debates between government officials, scientists, and representatives from the industry and consumer associations. Furthermore, the colors have been manufactured to exacting standards resulting in a high degree of purity (33).

Previously, several different colorants were used in foods. There was a great deal of research into the safety of food colors in the past years. Even thought results of those studies were often ambiguous and open to interpretation, there has been a decrease on the number of synthetic colorants permitted in many countries. However, differences in interpretation accepted by the various countries have led to the situation in which a color can be considered safe and acceptable in one country, but prohibited in another (12, 33).

Today, the types of colorants allowed varies greatly among countries, which reflects the different opinions about their toxicity (Table 86.8). However, there is a trend toward using fewer synthetic colorants. It is hoped that the trend to international standardization of food colorants will gain momentum (12, 44).

In the United States seven synthetic colorants are permitted for general food use, while in Canada and Japan, eight and nine colorants, respectively, are allowed (7). In Brazil and Mercosur (common trade among Brazil, Uruguay, Paraguay and Argentine), eleven synthetic colorants are allowed for food use (3). The European Economic Community allows much more than that (seventeen). Norway, however, prohibits the use of any synthetic colorant in the manufacture of foods. Lake pigments and dispersions are also permitted (10, 14).

In order to prevent indiscriminate use, many countries limit the types, uses and amounts of colorants permitted by groups or specific foods (11, 25). Since different countries allow the use of specific food colorants, it is possible that foodstuffs may be imported into a country, which forbids the coloring agent present in the product. Therefore,

the importer country legislation must be known in order to comply with regulations (4, 13, 16).

Colors used in the food products, like other additives, must be declared in the ingredients list, either the name of the color or the number, E number for the European Union and the FD&C number for the U.S. (10). The amount of colorants added to any food today is small. Furthermore, it is self-limiting due to good manufacturing practices and also by the fact that the certified colors in use today possess high tinctorial strength, thus only an extremely small amount is needed to color a product properly (4, 13, 16).

IX. CONCLUSIONS

Throughout time there was a significant reduction in the availability of colorants (23). This reduction resulted from several reasons, among them, the advances in the science of toxicology which enabled the access of more subtle effects; the excessively high use levels on the part of a few uninformed users; the unwarranted conclusion sometimes drawn from less than the best toxicology work (FD&C red no. 4); toxicology studies using a test substance probably not meeting purity standards (FD&C violet no. 1); political pressure (FD&C red no. 2); and lack of market demand (FD&C green no. 1 and green no. 2).

Although today's list is much shorter than in some other times, the safety in use of these products rests on more firm grounds. This is due to the fact that these synthetic organic colors have been more thoroughly tested than almost all other food additives.

Many advances in the development of food colorants have been made over the last 25 years, particularly in terms of harmonized legislation and advances in processing and formulation technology. However, there is still room for future development, specially on customized blends and technical support as well as improved handling properties.

87 Biosynthesis of Natural Aroma Compounds

Tzou-Chi Huang
Department of Food Science, National Pingtung University of Science and Technology

CONTENTS

I. INTRODUCTION

In recent years, the consumers' demand for natural food flavor has increased continuously. This trend can be attributed to increasing health- and nutrition-conscious lifestyles. As a consequence, the demand for natural ingredients has risen from 10% of the food company requests to 80% within the last decade. The comparison of the costs for natural flavor compounds and their synthetic counterparts show that the chemically produced compounds are by a factor of 100–400 cheaper than the natural ones (1).

Three flavor categories exist in Europe: Natural, nature-identical and artificial flavors. In the US, natural flavors are defined as: essential oil, oleoresin, essence or extractive, protein hydrolysate, distillate, or any product of roasting, heating or enzymolysis, which contains the flavoring constituents derived from a spice, fruit juice, vegetable or vegetable juice, edible yeast, herb, bud, bark, root, leaf or similar plant material, meat, seafood, poultry, eggs, dairy products or fermentation products thereof whose significant function in food is flavoring rather than nutrition (2). The definition of naturals in Europe is almost identical to the US guidelines. Materials (mixture or single substances) are called natural if they are obtained exclusively by physical, microbiological, or enzymatic processes from material of vegetable or animal origin, either in the raw state or after processing for human consumption by traditional food preparation process (including drying, roasting, and fermentation) (3). Flavors and fragrances that can be labeled "natural" both in the United States and Europe have to be produced from natural sources by physical,

enzymatic or microbiological processes (US Food and Drug Administration 2001). Biotechnologically produced flavors are also covered by the term natural. The major advantage of biotechnologically produced products is attainment of the natural status and the ability to make such a claim on the product label and the ingredient list. Duplicating plant secondary metabolism in microbial systems ("fermentative processes") leads to aroma compounds that are classified as natural by the European and US food legislation. Aroma chemicals, such as vanillin, benzaldehyde (bitter almond, cherry) and 4-decanolide (fruity-fatty) are marketed on a scale of several thousand tons per year. Their production by single-step biotransformations, bioconversions and de novo synthesis using microorganisms, plant cell or isolated enzymes has been studied intensively (4).

Metabolic engineering strategies that involve inactivation of undesired genes and/or over-expression of existing or novel ones have been used to create rerouting of the metabolic fluxes by changing the energy metabolism, or the concentration of metabolic intermediate, or of existing or completely new end-products (5). Three sources for the biotechnological production of flavors are plants, enzymes, and microorganisms. Plants cells used for the production of flavors can either be manipulated by conventional plant breeding methods such as intraspecific crossing, hybridization and nonspecific mutagenesis by chemicals or irradiation, or by novel plant breeding methods such as tissue culture techniques, protoplast fusion techniques and recombinant DNA techniques. Microorganisms have the advantage that they can use relatively inexpensive substrates such as carbohydrates and amino acids to form complex flavor mixtures. Screening for highly productive strains and genetic engineering is necessary to obtain reasonable amounts. The use of enzymes on industrial scale is now a common practice. The enzyme transformation produces extremely pure products. However, of the 1500 chemicals that are used by the US flavor industry only 20 has been produced commercially by fermentation routes (6).

II. AMINO ACID-DERIVED FLAVORS

A. 2-Phenylethanol

2-Phenylethanol (2-PE) is an important flavor and fragrance compound with a rose-like odor. Most of the world's annual production of several thousand tons is synthesized by chemical means but, due to increasing demand for natural flavors, alternative production methods are being sought. Characterized by a delicate fragrance of rose petals, 2-phenylethnol is the main commercial alcohol following ethyl alcohol. It is the most used fragrance in the food, cosmetic, and perfume industries. In addition to presenting interesting sensory characteristics which influence the quality of alcoholic beverage or fermented food, it is also widely used to modify certain flavor compositions of food stuffs such as fruit formulas, ice cream, candy, pudding, and chewing gum (7). 2-PE occurs naturally in the essential oils of many flowers and plants, such as hyacinths, jasmine, narcissi, and lilies. In most cases, concentrations are too low to justify extraction. One exception is rose oil, which can contain up to 60% 2-PE. Both 2-PE and its ester, especially phenylethyl acetate (GRAS 2857), are valuable flavor and fragrance compounds (8).

Like many other higher alcohols, 2-PE is a metabolite of microbial fermentation, thus synthesis by microorganisms is an obvious option. The commonly accepted route for 2-PE formation is by conversion of phenylanine through deamination, decarboxylation and reduction, first described by Ehrlich and consequently named after him. It is assumed that for industrial purposes, only yeast strains improved by conventional screening, selection, and mutagenesis rather than by genetic engineering have been used so far (9). Various organisms including *Cladosporium cladosporioides, Kluyveromyces lactis, Saccharomyces cerevisiae, Hansenrula anomala*, and *Kluyveromyces marxianus* have been reported to be capable of producing 2-phenylethnol. 2-Phenylethanol and 2-phenylethylacetate are obtained in substantial amounts when *Hansenula anomala* CBS 110 and *Kloeckera saturnus* CBS 5761 are grown with L-phenylalanine as sole nitrogen source. While in the first microorganism the alcohol predominates, in the second the acetate is formed almost exclusively (10). Production of 2-phenylethnol increases almost in parallel with the growth of *Pichia fermentans* during the initial stage of fermentation (11).

B. Vanillin

Vanillin (4-hydroxy-3-methoxybenzaldehyde) is one of the most important aromatic flavor compounds used in foods, beverages, perfumes, and pharmaceuticals and is produced on a scale of more than 10,000 tons per year by the industry through chemical synthesis. Vanillin is the major component of vanilla flavor extracted from the fermented pods of *Vanilla* orchids. Alternative biotechnology-based approaches for the production are based on bioconversion of lignin, phenolic stilbenes, isoeugenol, ferulic acid, or aromatic amino acids, and on de novo biosynthesis, applying fungi, bacteria, plant cells, or genetically engineered microorganisms (12).

Phenylalanine is known as the starting point of flavonoid, coumarine, stilbene, and ferulic acid biosynthesis in plant. The shikimate pathway was discovered as the biosynthetic route to the aromatic amino acids phenylalanine, tyrosine, and tryptophan. This pathway has been found only in microorganisms and plants. All phenylpropanoids are derived from cinnamic acid, which is formed from phenylalanine by the action of phenylalanine ammonia lyase (PAL, EC 4.3.1.5) (13). The enzyme phenylalanine

ammonia lyase (PAL) catalyzes the first metabolic step from primary metabolism into phenylpropanoid metabolism, which is the deamination of phenylalanine to produce cinnamic acid (14).

One of the most intensively studied biotransformations to produce natural vanillin is the conversion of ferulic acid. Ferulic acid is an extremely abundant cinnamic acid derivative found in the cell walls of woods, grasses, and corn hulls (15). A novel CoA-dependent, non-β-oxidative pathway for ferulic acid cleavage was identified in *Pseudomonas fluorescens* (16). Ferulic acid is activated to the CoA thioester, catalyzed by feruloyl-CoA synthetase (FCS, EC 6.2.1.34). The gene *fcs* of *Pseudomonas* encoding this enzyme has been cloned and expressed in *Escherichia coli* (17). Feruloyl-CoA is subsequently hydrated and non-oxidatively cleaved to vanillin and acetyl-CoA. Both reactions are catalyzed by one distinct enzyme, designated as enoyl-CoA hydratase/aldolase (EC 4.2.1.17). This function was confirmed with the purified enzyme and by cloning and expressing the corresponding genes of *Pseudomonas* in *E. coli*. Cloning of *fcs* of *Pseudomonas* in *E. coli* resulted in a recombinant strain that was able to convert ferulic acid to vanillin at a rate of 0.022 mole per min per ml (18).

C. Benzaldehyde

In quantity, benzaldehyde is the second most important flavor molecule after vanillin. Natural benzaldehyde is produced by microbial degradation of natural phenylalanine. This process is added by a plentiful, cheap supply of natural L-phenylalanine, which has become available as an intermediate of the synthesis of aspartame (19). L-phenylalanine was almost completely converted to the flavor compounds benzaldehyde and 3-phenylpropanol following two different degradation pathways of submerged cultured *Ischnoderma benzoinum* (20). The oxidative degradation pathway to benzaldehyde was also found in bacteria and subsequently patented (21).

D. 4-Vinylguaiacol

Vinylphenols (4-vinylphenol and 4-vinylguaiacol) are natural constituents of wine and can play a role in wine aroma. 4-Vinylguaiacol (PVG) is an important aroma in soy sauce. However, 4-Vinylguaiacol (PVG), a major off-flavor in citrus products, was detected in stored model solutions of orange juice containing ferulic acid, and its amount increased with time and temperature (22). These volatile phenols have a distinct flavor that is evaluated as smoky, pharmaceutic, clove, or leather, and impart a phenolic characteristic to wine. High levels of 4-vinylphenol and 4-vinylguaiacol were detected in wines made from grape juice initially treated with some enzyme preparations. Two enzyme activities, which operate successively, are responsible for this formation. First, the cinnamoyl esterase (feruloyl esterase, ferulic acid esterase, hydroxycinnamoyl esterase, EC 3.1.1.73) activity from enzyme preparation liberates cinnamic acids from their corresponding tartaric acid esters. Second, cinnamic acids are transformed into 4-vinylphenol and 4-vinylguaiacol by decarboxylase activity provided by the yeasts (23).

Bacillus pumilus PS213 isolated from bovine ruminal fluid was able to transform ferulic acid and *p*-coumaric acid to 4-vinylguaiacol and 4-vinylphenol, respectively, by nonoxidative decarboxylation. The enzyme responsible for this activity has been purified and characterized. The purified enzyme shows a single band of 23 kDa; the molecular mass calculated by size exclusion chromatography is 45 kDa. Enzyme activity is optimal at 37 degrees C and pH 5.5 (24). Seven strains of *Lactobacillus* isolated from malt whisky fermentations and representing *Lactobacillus brevis*, *L. crispatus*, *L. fermentum*, *L. hilgardii*, *L. paracasei*, *L. pentosus*, and *L. plantarum* contained genes for hydroxycinnamic acid (*p*-coumaric acid) decarboxylase. With the exception of *L. hilgardii*, these bacteria decarboxylated *p*-coumaric acid and/or ferulic acid, with the production of 4-vinylphenol and/or 4-vinylguaiacol, respectively. It seems likely that the combined activities of bacteria and yeast decarboxylate *p*-coumaric acid and then reduce 4-vinylphenol to 4-ethylphenol more effectively than either microorganism alone in pure cultures (25).

E. 2-Acetyl-1-Pyrroline

2-acetyl-1-pyrroline has been reported as a potent flavor component of an aromatic rice (26). 2-acetyl-1-pyrroline was synthesized naturally in Pandan (*Pandanus amaryllifolius* Roxb.) leaves (27), bread flowers (*Vallaris glabra* Ktze) (28) and pearl millet (*Pennisetum americanum*) (29). In addition to plant materials, microorganisms, especially, *Bacillus cereus* (30), and bakers' yeast (31) biosynthesizes 2-acetyl-1-pyrroline as well.

Proline apparently plays an important role in formation of 2-acetyl-1-pyrroline. Increases in concentration of 2-acetyl-1-pyrroline occurred when proline, ornithine, and glutamate were added to the medium for seeding and callus of rice. Results of tracer experiment using ^{15}N-proline, ^{15}N-glycine, proline-1-^{15}C indicated that the nitrogen source of 2-acetyl-1-pyrroline was proline. 2-acetyl-1-pyrroline was formed in the aromatic rice at temperature below that of thermal generation in bread baking, and formed in the aerial part of aromatic rice from proline as the nitrogen precursor (32).

Previous investigations concluded that this trait of rice underwent monogenic inheritance, whereas others stated that two or three recessive or dominant genes controlled the construction of the trait (33). Lorieux et al. (34) reviewed the genetics of aromatic fragrance and concluded that a single recessive gene was responsible for the production

of fragrant rice plants. This single recessive fragrance gene (*fgr*) was linked to the RFLP clone RG28 on chromosome 8, at a genetic distance of 4.5 cM. They confirmed the close linkage between RG28 and *fgr* (5.8 cM) and also identified two quantitative trait loci for fragrance, one on chromosome 4 and the other on chromosome 12. Fragrance can be detected by tasting the associated flavor in individual seeds or assessing the aroma of leaf tissue or grains after either heating in water or reacting with solutions of KOH or I 2-KI. PCR-based molecular marker for the fragrance gene detection in rice (*Oryza sativa*. L.) has been developed (35). The genomic DNA clone RG28, linked to the major fragrance gene of rice (*fg*r), was assessed for polymorphism in order to produce a PCR-based marker for fragrance. A small mono-nucleotide repeat, that was polymorphic between a pair of fragrant and non-fragrant cultivars, was identified and developed into a co-dominant PCR-based marker. The polymorphism-information-content determinations for three microsatellite markers, that have been genetically mapped near RG28, are also presented. These PCR-based markers were used to distinguish fragrance-producing alleles from non-fragrance-producing alleles at the *fgr* locus.

The arginine deiminase or dihydrolase (ADI, EC 3.5.3.6) pathway for arginine degradation is comprised of three enzymes: ADI (EC 3.5.3.6), which degrade arginine into citrulline and ammonia; ornithine transcarbamoylase (OTC, EC 2.1.3.3), which cleaves citrulline into carbamoyl phosphate and ornithine; and carbamate kinase (CK, EC 2.7.2.2), which produces ATP, ammonia, and carbon dioxide through dephosphorylation of carbamoyl phosphate. A fourth membrane transport protein, which catalyzes an electroneutral exchange between arginine and ornithine, is also fundamental for this pathway. Sequence analysis of the genetic organization of the ADI pathway has been studied largely either with gram-negative bacteria or with gram-positive bacteria such as *Clostridium perfringens*, *Bacillus licheniformis*, *Streptococcus sanguis*, *Lactobacillus sakei*, and *Oenococcus oeni*. High similarities among species and revealed that genes are clustered to form the operon arcABCTD and encode ADI(*arcA*), OTC(*arcB*), CK(*arcC*), and the membrane transport protein (*arcD*)(36). Oxygen, carbohydrate metabolism, arginine concentration, pH, repression by glucose, and intracellular ATP, NADH, or other intermediate metabolites seemed to be signals for ADI expression, with an influence which depended on bacterial species (37).

The cytoplasmic extracts of 70 strains of the most frequently isolated sourdough lactic acid bacteria were screened initially for arginine deiminase (ADI), ornithine transcarbamoylase (OTC) (EC 2.1.3.3), and carbamate kinase (CK) (EC 2.7.2.2) activities, which comprise the ADI (or arginine dihydrolase) pathway. Only obligately heterofermentative strains such as *Lactobacillus sanfranciscensis* CB1; *Lactobacillus brevis* AM1, AM8, and 10A; *Lactobacillus hilgardii* 51B; and *Lactobacillus fructivorans* DD3 and DA106 showed all three enzyme activities. The three enzymes were purified from this microorganism to homogeneity by several chromatographic steps. ADI, OTC, and CK had apparent molecular masses of ca. 46, 39, and 37 kDa, respectively, and the pIs were in the range of 5.07 to 5.2. The OTCs, CKs, and especially ADIs were well adapted to pH (acidic, pH 3.5 to 4.5) and temperature (30 to 37°C) conditions which are usually found during sourdough fermentation. ADI, OTC, and CK of *Lactobacillus sakei. L. sanfranciscensis* CB1 expressed the ADI pathway either on MAM broth containing 17 mM arginine or during sourdough fermentation with 1 to 43 mM added arginine. Cell survival during storage at 7°C, and tolerance to acid environmental stress and favored the production of ornithine, which is an important precursor of crust aroma compound, 2-acetyl-1-pyrroline (38).

F. Pyrazine

Alkylpyrazines are heterocyclic, nitrogen containing molecules found in wide variety of foods. They are responsible for different flavors, according to the nature of the alkyl substituents. Many products were formed with a heterocycle production such as pyrazines and methylpyrazines, and dimethylethyloxazoles. These various compounds present odors of corn-like, pungent, nut, popcorn, roasted hazelnut, toasted, roasted, and ripe fruits (39).

The first evidence that microorganisms were able to synthesize pyrazines were provided by Kosuge et al. (40) who showed that tetramethylpyrazine could be produced by *Bacillus subtilis.* 2,5-Dimethylpyrazine (2,5-DMP) and tetramethylpyrazine (TTMP) were produced using *Bacillus subtilis* grown on soybeans. 2,5-DMP was obtained using soybeans enriched with threonine, giving metabolite after 6 days. TTMP production involved addition of acetoin to soybeans, and was recovered after 14 days. These results demonstrated the suitability of solid-state cultivation for production of high-added-value compounds (41). Optimization studies demonstrated that solid-state cultivation of *Bacillus subtilis* IFO 3013 involving massive enrichment of the medium with L-threonine and acetoin could be used for production of high-added-value compounds (42).

G. Methyl-Branched Aldehydes and Carboxy Acids

Enzymatic degradation of amino acids plays an important role in the development of cheese flavor. In particular, branched chain amino acids (BCAAs) are precursors of cheesy aroma compounds, such as isovalerate (precursor, leucine) and isobutyrate (valine), and aromatic amino acids are precursors of floral or phenolic aroma compounds, such as phenylacetate and phenylacetaldehyde (phenylalanine),

indole (tryptophane) and phenol (tyrosine) (43). Branched chain amino acid degradation seems to follow chain reaction that commences by transamination producing a keto acid, subsequent non-oxidative decarboxylation into aldehydes which is then oxidized or reduced to acids or alcohols. Amino acid catabolism of valine, leucine, isoleucine, phenylalanine and methionine may also lead to the corresponding aldehydes and acids (44).

Staphylococcus carnosus and *S. xylosus* are important starter cultures for production of essential flavor compounds, such as aldehydes, alcohols, esters, and carboxy acids in dried fermented sausages. Many of these compounds are derived from degradation of amino acids and provide the product with its unique taste and aroma. Catabolism of the methyl-branched amino acids, leucine, isoleucine, and valine, leads to production of methyl-branched aldehydes, 3-methylbutanal, 2-methylbutanal and 2-methylpropanal, respectively. Leucine catabolism is of particular interest, since key sausage aroma compounds like 3-methylbutanal and 3-methylbutanoic acid are derived from catabolism of leucine.

The genetic and physiological evidence of the role of the *Iiv*E enzyme in the degradation of BCAAs in *S. carnosus* has been studied intensively (45). The first step in the catabolism is most likely a transamination reaction catalyzed by BCAA aminotransferase (*Iiv*E proteins). The *Iiv*E enzyme in *S. carnosus* was reported to be the only enzyme that catalyzed the deamination of leucine, isoleucine, and valine. Aminotransferases catalyze the transfer of an alpha-amino group from ArAAs and BCAAs to an alpha-keto acid receptor using pyridoxal 5'-phosphate as a coenzyme, seem to be responsible for deamination of these amino acids (46). The *Iiv*E gene from *S. carnosus* was characterized. An *Iiv*E deletion mutant by gene replacement was constructed. The mutant strain provides the direct evidence of the critical role of aminotransferases in biosynthesis of methyl-branched aldehydes and carboxy acids.

III. CARBOHYDRATE-DERIVED FLAVORS

A. 4-Hydroxy—2,5-Dimethyl-3(2H)-Furanone (HDMF)

Among flavor compounds exhibiting caramel-like odors, HDMF is of special interest because of its relatively low flavor thresholds (47). The odorant was reported for the first time in pineapples and strawberries (48). 4-Hydroxy—2,5-dimethyl-3(2H)-furanone (HDMF) also called furaneol is a carbohydrate-derived natural flavor. HDMF has also been detected in several heat-processed foods, e.g. beef broth (49). HDMF has also been isolated from shoyu (shoyu is the Japanese name for soy sauce) (50).

An aldolase catalyzed reaction was involved in the formation of 4-Hydroxy—2,5-dimethyl-3(2H)-furanone (51). The formation of a homolog of HDMF, HEMF and concluded that D-sedoheptulose 7-phosphate is the precursor of HEMF.A. This study demonstrates that HDMF is secondary metabolite of *Zygosaccharomyces rouxii* that is produced when the medium is supplemented with six-carbon ketoses. Aerobic conditions are more favorable to its production than anaerobic conditions. Two of the tested compounds, 6-deoxyketose and fructose 1,6-bisphosphate, can act as precursors or inducers of the biosynthesis. These findings demonstrate that HDMF is produced by *Z. rouxii* grown aerobically with D-fructose 1,6-bisphosphate (10%) as precursor (52).

Biosynthesis route of HEMF was claimed to be through the pentose-phosphate cycle by *Z. rouxii* (53). Several biotechnological routes have been proposed for the production of natural furaneol. One approach uses the aldolase reaction to form dihydroxyacetone that reacts with lactaldehyde in the presence of aldolase to 6-deoxyfructose-1-phosphate. The equilibrium can be shifted in favor of the product by the addition of triosephosphate isomerase (EC 5.3.1.1). Acid hydrolysis yields 6-deoxyfructose and during heating with base furaneol is formed. The second approach was 6-deoxy-L-sorbose, an isomer of 6-deoxyfructose for the production of furaneol. In this case the deoxysugar is generated by the action of transketolase (EC 2.2.1.1) for 4-deoxy-L-threose and hydroxypyruvate. Hydroxypyruvate is formed from L-serine by serine glyoxylate aminotransferase (serine glyoxylate transaminase, EC 2.6.1.45). Hydroxypyruvate is also the starting material for 4-deoxy-L-erythrulose catalyzed by transketolase (EC 2.2.1.1). The 4-deoxy-L-threose is generated by a microbial isomerization from 4-deoxy-L-erythrulose.

B. Diacetyl

Diacetyl is considered to be one of the most important compounds contributing to the final flavor and aroma in a range of fresh fermented dairy products, such as butter, buttermilk, culture cream, and quark. Diacetyl is formed during the fermentation of milk by the gram-positive microaerophilic bacterium *Lactococcus lactis* subsp. *lactis biovar diacetylactis* and *Leuconoccus* spp. Based on its aroma value, efficient diacetyl (or its precursor alpha-acetolactate) production from lactose rather than from citrate by *Lactococcus lactis* has been one of the targets of various metabolic engineering strategies. *Lactococcus lactis* has been developed as a cell factory for high-level diacetyl production (54).

Metabolic engineering strategies that involve inactivation of undesired genes and/or over-expression of existing or novel ones have been used to create rerouting of the metabolic fluxes by changing the energy metabolism or the concentrations of metabolic intermediates or of existing or completely new end-products (55).

Diacetyl is a by-product of fermentation by many microorganisms. It is produced by oxidative decarboxylation of the metabolic intermediate alpha-acetolactate. One molecule of alpha-acetolactate is produced from two molecules of pyruvate by the condensing enzyme, alpha-acetolactate synthase (EC 2.2.1.6) (56). Specific *Lactococcus lactis* strains isolated from dairy cultures that produce large amounts of alpha-acetolactate from citric acid were shown to lack the alpha-acetolactate decarboxylase enzyme (57). New selection methods and deletion of alpha-acetolactate decarboxylase encoding *ald*B gene by genetic engineering have made these mutants more ready available.

Recent studies of pyruvate and citrate metabolism in *Lactococcus lactis* and *Leuconoccus* spp demonstrate that diacetyl is formed by an oxidative decarboxylation of alpha-acetolactate. A possible method for improving the diacetyl level would be to redirect and adjust the metabolic activities involved in the formation of alpha-acetolactate (58). An innovative approach is to increase the amount of enzyme involved in conversion of pyruvate to alpha-acetolactate. Two enzymes are known in *Lactococcus lactis* that catalyze this reaction: alpha-acetolactate synthase (EC 2.2.1.6, ALS-encoded by the *als* gene) and alpha-acetohydroxy acid synthase (IL VBN-encoded by the *ilv*BN gene). A 100-fold increase in ALS enzyme level was achieved by cloning the *als* gene on a multi-copy plasmid, resulting in a 40% rerouting efficiency of the pyruvate pool towards acetoin under aerobic conditions. This is due to the endogenous alpha-acetolactate decarboxylase (EC 4.1.1.5, ALDB-encoded by the *ald*B gene) activity that efficiently converts alpha-acetolactate to acetoin was inactivated. An elegant approach to obtain ALDB deficient natural *Lactococcus lactis* variants has recently been developed (59). A strain in which all three mutations are combined (LDH- and ALDB-deficiency and ALS or IL VBN overproduction) could be an effective diacetyl producer. The introduction of an NADH oxidase encoding gene in an alpha-acetolactate decarboxylase deficient strain (*aldB* mutant) led to the efficient re-routing of the pyruvate metabolism towards alpha-acetolactate and diacetyl (60). Carroll et al. (61) suggested that manipulation of the enzyme alpha-acetolactate synthase from *Leuconostoc lactis* would also yield strains with increased diacetyl production.

IV. LIPID-DERIVED FLAVORS

A. Hexenals

Leave aldehyde (E)-2-hexenal and (Z)-3-hexenal are responsible for the green flavors and aromas of fruits and vegetables. The natural compounds derived from plant tissue that have been disrupted in some fashion are tried to replace the chemically synthetic compounds. In general, the unsaturated fatty acids linoleic and linolenic acids are degraded via a lipoxygenase (EC 1.13.11.13)-catalyzed formation of hydroperoxides and a subsequent cleavage by a lyase to form aliphatic C6-compound such as (Z)-3-hexenal, which may further isomerized to (E)-2-hexenal. Much research has already been conducted on lipoxygenases especially those from soybean. They catalyze the addition of molecular oxygen to the molecule at carbon 13 (62). Lipoxygenases are essential components of the oxylipin pathway, converting unsaturated fatty acids into (Z)-3-hexenol and (E)-2-hexenal. Lipoxygenases have also been detected in microorganism and plant lipoxygenases have been expressed in host organism. They are available for the biotechnological production of the 13-hydroperoxide. The other decisive enzyme is the hydroperoxide-lyase. Recently, the construction of recombinant yeast cells containing the hydroperoxide lyase gene from banana fruit (*Musa* sp.) has been published (63). Researchers from Givaudan succeeded in the isolation and transfer of the lyase gene from banana to yeasts. The yeast produces hexenals from fatty acids.

B. Lactones

The naturally occurring, organoleptically important lactones generally have gamma or delta-lactone structure, and are straight-chained. Lactone flavor substances play an important role in the overall aroma presentation of many foods and beverages. Lactones are important flavor substances for pineapple, apricots, strawberry, raspberry, mango, papaya, passion fruit, peach and plum. At present, lactones are made fairly expensively via chemical synthesis from keto acids. On the other hand, microbially produced lactones have the advantage of being optically pure and natural. Application focuses mainly on the production of added-value products such as gamma and delta-lactone (from US$6000/kg to US$1200/kg) (64). The gamma-and delta-lactone of less 12 carbons constitutes a group of compounds of great interest to the flavor industry. Gamma-lactone is one of the most produced lactones. Its production through biotechnology results in a natural lactone. The annual market for gamma-lactone has been growing in recent years and was estimated in 1997 at about 10 t (65).

Usually, the precursor used for the production of a lactone is a hydroxy fatty acid. Depending upon the position of the hydroxy group on the aliphatic chain, this acid could lead to the formation of a gamma or delta-lactone. Lactones can be formed either by de novo synthesis, by beta-oxidation from ricin-oleic acid, free fatty acids or hydroxy acids. The 9-10-epoxyoctadecanoic acid formed by epoxidation from oleic acid was proposed as the precursor for dodecano-4-lactone in strawberry fruits. Subsequent beta-oxidation and cyclization leads to the formation of the lactone. Gamma-lactone is generally obtained by biotransformation of a long-chain hydroxy fatty acid precursor by yeast cells. Ricin-oleic acid is a convenient substrate since this hydroxy acid represents almost 90% of

hydrolyzed castor oil (66). 4-Decanolide is an important component in a number of fruits and can be obtained from coriolic acid, which is the major fatty acid present in the seed oil of *Coriana nepalensis* and in rice lipids. Delta-octalactone can be produced by *Saccharomyces cerevisiae* from 3,11-dihydroxymyristic acid, which is present in Jalap resin. After a bioprocess was established, the price for natural 4-decanolide decreased from US$20000/kg to $1200/kg (67).

The general strategy used for the production of lactone by microorganisms involving the bioconversion of a hydroxy fatty acid. The main pathway by which a microorganism catabolizes a fatty acid is the beta-oxidation system. Free fatty acids are converted to coenzyme A (CoA) esters before being catabolized. Beta-oxidation is a four-reaction sequence resulting in a two-carbon chain-shortening catalyzed in peroxisomes by the following activities: acyl-CoA oxidase (EC 1.3.3.6), 2-enoyl-CoA hydratase (EC 4.2.1.17), 3-Hydroxyacyl-CoA dehydrogenase (EC 1.1.1.35) and 3-ketoacyl-CoA thiolase (EC 2.3.1.16). The commonly accepted pathway from ricin-oleyl-CoA to gama-decalactone was proposed to follow the four beta-oxidation cycles, yielding 4-hydroxy-decanoly-CoA, which is then cyclised to gamma-decalactone (68).

Yarrowia lipolytica is one of the yeast species that are able to produce gamma-decalactone from ricin-oleic acid or its methyl ester. *Y. lipolytica* was also reported in patents dealing with the production of some other lactone aroma compounds: gamma-dodecalactone, gamma-nonalactone, unsaturated lactones and delta-lactones (69). Because there are few natural sources of cheap fatty acid precursors other than castor oil, processes have been developed for the biotechnological production of hydroxy fatty acids, such as the microbial production of 10-hydroxystearic acid by *Nocardia cholesterolicum* for the synthesis of gamma-dodecalactone (70). Recently, solid-state fermentation with economical and practical advantages had been used as a model for the production of volatile flavor compounds. These include high productivity, low capital investment, reduced energy requirement, low wastewater output, improved product recovery and elimination of foam products. The production of 6-pentyl-alpha-pyrone, a compound with a strong coconut-like aroma, by *Trichoderma harzianum* in solid state cultivation was developed (71).

C. Esters

The distinctive flavor of wine, brandy, and other grape-derived alcoholic beverages is affected by many compounds, including esters produced during alcoholic fermentation. The characteristic fruity odors of the fermentation bouquet are primarily due to a mixture of hexyl acetate, ethyl caproate (apple-like aroma), iso-amyl acetate (banana-like aroma), ethyl caprylate (apple-like aroma), and 2-phenylethyl acetate (fruity, flowery flavor with a honey note) (72).

1. Acetate Esters

The synthesis of acetate esters by the wine yeast *Saccharomyces cerevisiae* during fermentation is ascribed to at least three acetyltransferase activities, namely, alcohol acetyltransferase (AAT, EC 2.3.1.84), ethanol acetyltransferase (EC 2.3.1.84), and iso-amyl acetyltransferase (AAT) (EC 2.3.1.84) (73).

Esters are produced by fermenting yeast cells in an enzyme-catalyzed intracellular reaction. In the volatile ester production by *S. cerevisiae* alcohol acetyltransferases, the respective genes Atf1p, Atf2p and Lg-Atf1p were either deleted or over-expressed in a laboratory strain and a commercial brewing strain. Analysis of the fermentation products confirmed that the expression levels of *ATF1* and *ATF2* greatly affect the production of ethyl acetate and isoamyl acetate. Atf1p and Atf2p are also responsible for the formation of a broad range of less volatile esters, such as propyl acetate, isobutyl acetate, pentyl acetate, hexyl acetate, heptyl acetate, octyl acetate, and phenyl ethyl acetate. Atf1p and Atf2p are responsible for the total cellular isoamyl alcohol acetyltransferase activity.

Interestingly, over-expression of different alleles of *ATF1* and *ATF2* led to different ester production rates, indicating that differences in the aroma profiles of yeast strains may be partially due to mutations in their *ATF* genes. The over-expression of acetyltransferase genes such as *ATF1* could profoundly affect the flavor profiles of wines and distillates deficient in aroma, thereby paving the way for the production of products maintaining a fruitier character for longer periods after bottling (74). The *ATF1* gene, located on chromosome XV, was cloned from a widely used commercial wine yeast strain of *S. cerevisiae*, and placed under the control of the constitutive yeast phosphoglycerate kinase gene (*PGK1*) promotor and terminator. The level of ethyl acetate, iso-amyl acetate, and 2-phenylethyl acetate increased 3- to 10-fold, 3.8- to 12-fold, and 2- to 10-fold, respectively, depending on the fermentation temperature, cultivar, and yeast strain used (75). The drastic increases in the levels of ethyl acetate and iso-amyl acetate had a pronounced effect on the aroma of the fermented and distilled products. Some of other esters whose concentrations were also increased as a result of the over-expression of *ATF1* include hexyl acetate, ethyl caproate, and 2-phenylethyl acetate, presenting a flowery and fruity aroma. Oda et al. (76) developed a system based on the double coupling of glucose metabolism for the production of acetyl-CoA and microbial esterification of alcohol by using a nutrient agar plate as hydrophilic carrier and decane as a hydrophobic organic solvent. This system can be used to produce acetate ester of alcohol without adding any acetyl donors.

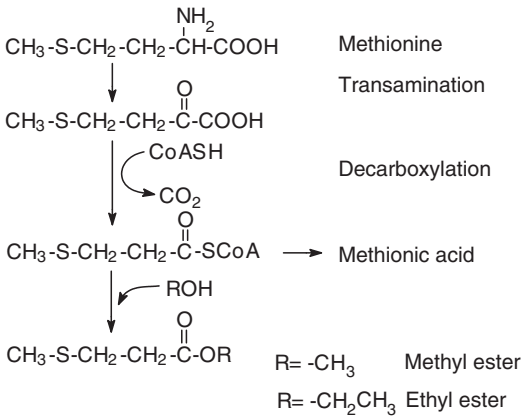

FIGURE 87.1 Proposed biosynthesis pathway for methyl and ethyl esters.

2. Methyl and Ethyl Esters

Methyl and ethyl esters and interesting thioesters, methylmethylthiopropanoate, and ethyl 3-methylthiopropanoate could be synthesized following a pathway shown in Figure 87.1. Amino acid may undergo a transamination to form a keto acid, subsequent decarboxylation leads to the formation of a CoA ester. The release of the CoA moiety results in the generation of an acid following the similar pathway proposed by Dirinck et al. (77). Incorporation of methanol and ethanol to the CoA ester may form methyl and ethyl esters, respectively.

The fate of amino acids in relation to aroma biogenesis has been studied in strawberries using the in vitro growth approach. Incubations of strawberries with L-isoleucine gave rise to an increase of fourteen compounds in this fruit aroma, either not detected previously or constituents of strawberry aroma. Strawberry feeding with L-isoleucine resulted in a 7-fold increase in the sum of 2-methylbutanoate esters, and a double production of 2-methylbutyl esters compared to those of control fruits. Around 94% of the ester increase corresponded to 2-methylbutanoates, with ethyl 2-methylbutanoate being the most representative compound (92%). On the other hand, among the 2-methylbutyl esters, comprising around 6% of total aroma volatiles increase, 2-methylbutyl acetate was the major compound (95%) arising from L-isoleucine strawberry feeding. The role of enzymatic activities within the amino acid metabolic pathway in strawberry fruits is discussed (78).

In *Lactococcus lactis*, which is widely used as a starter in the cheese industry, the first step of aromatic and branched-chain amino acid degradation is a transamination that is catalyzed by two major aminotransferases. In lactococci, transamination is the first step of the enzymatic conversion of aromatic and branched-chain amino acids to aroma compounds. The major aromatic aminotransferase (AraT) of a *Lactococcus lactis* subsp. *cremoris* strain has been purified and biochemically characterized. The corresponding gene was characterized , and evaluated for the role of AraT in the biosynthesis of amino acids and in the conversion of amino acids to aroma compounds. It is also highly involved in methionine and leucine conversion (79).

Pseudomonas fragi strain CRDA 037 produced a fruity aroma when grown in skim milk-, whey and whey permeate-based culture media. Addition of C(3)-C(7) fatty acids to the culture stimulated the production of the corresponding fatty acid esters from 12 to 1570 times compared to unsupplemented media. Lipase is responsible for the biosynthesis of these fatty esters. Lipases are generally defined as glycerol ester hydrolases (e.g., triacylglycerol lipase EC 3.1.1.4) hydrolyzing tri-, di- and mono-glycerides present at an oil-water interface. They can also synthesize and transfer esters. As water is a product of ester synthesis reactions, organic solvents with a very low water activity are generally used and the water formed during the reaction must be extracted (80). Synthesis of esters had been observed in the presence of the lipase from *Candida parapsilosis* (81). The enzyme was inactive in anhydrous systems, however its activity increased with increasing water concentration in the liquid phase or water activity of the system. In the case of very high Aw values, the enzyme preparation contained a large amount of free water, and diffusion of hydrophobic substrates was limited, causing a decrease of the reaction rate (82).

CONTENTS

I. INTRODUCTION

Flavor not only is a major quality attribute to foods, but it also plays a critical role in consumer acceptability. There are many ways to classify flavors. An easier and more realistic way for flavor classification is based on its mode of formation, either biosynthesized naturally from known raw materials or formed artificially by processing imposed on natural or artificial starting materials. Therefore, the terms "natural flavors" and "synthetic flavors" are used. According to the Code of Federal Regulations, the Title 21, Section 101.22 (a)(3) [1] published by the U.S. Government, the term "natural flavor" or "natural flavoring" is defined as:

> *the essential oil, oleoresin, essence or extractive, protein hydrolysate, distillate, or any product of roasting, heating or enzymolysis, which contains the flavoring constituents derived from a spice, fruit or fruit juice, vegetable or vegetable juice, edible yeast, herb, bark, bud, root, leaf or similar plant material, meat, seafood, poultry, eggs, dairy products, or fermentation products thereof, whose significant function in food is flavoring rather than nutritional. Natural flavors include the natural essence or extractives obtained from plants listed in Secs. 182.10, 182.20, 182.40, and 182.50 and part 184 of this chapter, and the substances listed in Sec. 172.510 of this chapter…*

Thus, on one hand, "natural flavors" include those volatile compounds derived from nuts, meats, and seafood that possess natural, mild or weak aromas unless further processed thermally; on the other hand, the term also comprises chemical components produced by enzymatic and/or fermentation processes. The latter could be savory flavors or flavor modifiers such as cheese and soy sauce. Since the processed "natural flavors" will be discussed in other chapters, this chapter will focus on those derived from selected natural fruits, vegetables, herbs and spices based on the preference of the authors, to illustrate the chemical basis of key flavors responsible for the natural materials. Detailed discussion on a single character-impact compound for a specific raw material will not always be attempted since many flavor profiles from the natural source are attributed to a mixture of aromatic compounds rather than a single compound though it might play an important role in flavor contribution in certain cases. Besides, it is not the objective of this chapter to cover many biosynthetic pathways of the natural flavors in depth. However, examples will be given, where appropriate and when the information is available, to illustrate the mechanisms, characteristics and biofunctions of some of the important flavors. The aim of this chapter is to present an outline of the most important aspects of the current knowledge and the recent progress in natural flavors, rather than to present an in-depth review on one subject. Nevertheless, interested readers can find more detailed information for the topics in excellent references, reviews and books [2,3,4,5,6,7] listed at the end of this chapter.

II. FRUIT FLAVORS

Fruits are widely accepted by consumers because of their floral, pleasant, and elegant aromas, as well as their association with the firm idea of benefits to health [8]. Natural flavors in ripened fruits usually exist in complicated and delicate ratios of hundreds of volatile compounds composed of short chain alcohols, aldehydes, ketones, esters, acids, lactones, terpenic compounds, etc. The flavors are formed gradually during ripening and usually reach their richest profiles when fruits become mature [9]. At that time, the fullest aromas in fruits are often correlated well with the sugar content, acidity, and colors [9]. When fruits become overripe, their colors turn unappealing, their sugars grow syrupy, and their flavors might lose the attractive freshness. Nevertheless, successful commercial blending of various fresh fruit juices together to make desirable beverages, such as the fruit-flavored teas, lemonades, and yogurts, have created many well-known products being the myth of many companies. As a result, enthusiasm to better understand the components in fruit flavors increases. Although many characteristic aromas in fruits have been identified so far, many more aromas in exotic fruits are still a mystery due to their low concentrations in the fruits.

This section will focus on some character-impact and quantitatively important flavor components in selected fruits to provide a basis to those determined readers who are interested in formulating fruity-flavored products and in performing quality control during fruit processing and storage of the fruits.

A. APPLE

Apples are the fruits of the plant *Malcus sylvestris* Mill., and one of the most common edible fruits accepted by consumers all over the world. In most varieties, apples are spherical in shape and in different sizes, with skin colors from green to red. Apples are generally either freshly consumed or made into apple juice, or cider after fermentation. The volatile flavor constituents of apples have been studied over half a century and have been reviewed by Dimick and Hoskin [10]. Common flavor components in apples

TABLE 88.1
Important Flavor Compounds Found in Apples

Ethyl acetate	Hexyl acetate	6-methyl-5-hepten-2-one
Propyl acetate	Acetylaldehyde	Ethanol
2-Methylpropyl acetate	Propanal	1-Propanol
Ethyl butyrate	Butanal	1-Butanol
Propyl propionate	2-Methylbutanal	2-Methyl-l-butanol
Ethyl 2-methylbutanoate	Hexanal	β-damascenone
Butyl acetate	Trans-2-hexenal	γ-octalactone
2-Methylbutyl acetate	Octanal	4-methoxylallybenzene
Ethyl pentanoate	Acetone	
Butyl proprionate	1-Phenyl ethanone	

Source: From Refs. 4, 7, 11, and 12.

are short-chain esters, alcohols, lactones and aldehydes (Table 88.1). For example, 6-methyl-5-hepten-2-one and γ-octalactone were often detected. Other compounds claimed to be important contributors to the aroma of apples include: ethyl 2-methylbutanoate, n-hexanal, *t*-2-hexenal, 4-methoxyallylbenzene, etc. Though β-damascenone in apples is in very low concentration, it is likely the most potent aroma compound due to its low threshold value of 2 ppt in water [13]. For instance, β-damascenone has been measured to contribute 32% of the total aroma potency in thermally processed apple juice [14]. However, similar to many other fruits, apple aroma does not simply rely on the presence of a limited number of character-impact components but a more complex mixture of the aforementioned chemicals in a delicate ratio.

B. Banana

Banana is a collective term for the fruits of several *Musa* species which are grown throughout the tropics. Commercially, it is picked at its green, unripened stage and consumed at its yellow, ripened stage for easy digestion and absorption of its rich nutrients [15]. Banana is easily subject to physical damages during transportation and distribution, also it is very sensitive to storage conditions and readily turns brown after enzymatic reactions. Nevertheless, banana is one of the most favorite fruits by many consumers all over the world because of its soft, smooth texture and distinctive, mild but delectable aromas released during consumption. Though majority of the banana is freshly consumed as a table fruit, some others are consumed as a snack food, e.g. banana chips.

Analysis of the aroma compounds in banana has been carried out for the past 40 years. With the aid of modern sensitive, high resolution state-of-the-art instruments such as gas chromatography coupled with mass spectrometry (GC-MS) and nuclear magnetic resonance (NMR), many flavor components in bananas have been identified, which were discussed by several researchers [7,15,16,17,18], and summarized and published by TNO-CIVO [4]. Major compounds of banana fruits are acetates, butanoates, and/or 3-methylbutyl esters. Other principle or characteristic flavor components isolated from bananas include pentan-2-one, 3-methyl-1-butanol, 2-methyl-1-butanol, and esters of pentan-2-ol, hexan-2-ol, hept-4(*Z*)-en-2-ol, oct-4(*Z*)-en-2-ol, etc. Shiota [17] also reported some uncommon esters in bananas, such as alkenyl esters and alkan-2-yl esters. They possessed green, sweet, fruity, banana-like or pineapple-like flavors which might also be important contributors to the overall banana aroma. Interested readers may consult the article [17] that listed more than 150 aromas and provided some odor descriptions to the flavor-impact esters.

C. Citrus Fruits

The citrus family contains many popular table fruits with significant commercial values [19]. It has been extensively studied not only for its nutritional benefits but for its distinguished aromatic fruity flavor sensation. Traditionally, citrus flavorings, either in the form of oil phase (essential oils) or of water phase (concentrated fruit juices), are used to extend, enhance or substitute for fresh fruit juices in beverages or other finished food products [19]. With the continued demand and growth of natural flavorings, research in the citrus fruits has been receiving more attention. However, when taking into account of the enormous economic importance of citrus fruits, the published information on its flavorings is still sparse, let alone the confidential restrictions imposed by the beverage companies. Therefore, it might be helpful to summarize some of the previous works found in the literature on citrus flavorings in order to facilitate the readers to get an access to some of the data available. The natural flavors in the orange, tangerine, grapefruit, lemon and lime are discussed in the subsequent sections.

1. Orange

Among the essential oils from the commercially important citrus species, orange oil has been analyzed the most extensively. Shaw and Coleman in 1974 [20] determined 17 components in the cold-pressed orange oil, in which *d*-limonene was found to be the most predominant chemical accounting for an amount of more than 94% in the oil. Beside limonene, other identified chemicals were pinene, myrcene, linalool, citronellal, decanal, neral, geranial, perillaldehyde, dodecanal, β-elemene, β-caryophyllene, β-copaene, β-farnesene, valencene, β-sinensal, and α-sinensal. Subsequent investigations on the chemical composition of the orange oil were reviewed by Shaw [21], who summarized and reported that there were 109 volatile constituents that had been identified. Since the peel oil is inevitably dropped in the fruit juice during the expressing, it is not surprising that many orange oil components have also been found in the fruit essence though there is a remarkable difference in flavor profiles between the

essential oil and the essence [22]. Other than the major chemical classes (Table 88.2) such as terpenes and terpenoids, alcohols, esters, lactones, and carbonyls, trace amounts of *N*-containing compounds were also identified in the oil [24,25]. Among them, alkyl and phenylpyridines were among the most potent flavor constituents. For example, 3-hexylpyridine found in the oil was described as having a fatty, citrus, orange note and has a threshold value of 0.28 ppb [24]. Therefore, these naturally occurring pyridines are also considered as the major aroma contributors. Recent development in the search of novel chemicals in the citrus essential oils has resulted in the identification of some oxygen-containing heterocyclic compounds [26] and vanillin [27]. However, their roles in the oil are still uncertain.

2. Grapefruit, Lemon, Lime, and Tangerine

Grapefruit oils have been studied by utilizing many of the same analytical methods used for orange essential oils. Many of the same aromas in orange oils were also found in grapefruit oils (Table 88.2). In the grapefruit oil, both nootkatone [28] and 1-*p*-methene-8-thiol [29] were considered to be the major flavor contributors providing synergistic grapefruit odor. Interestingly, the magic facet of nootkatone is not only limited to its aromatic character, but to its wide-spectrum efficacy against insects, such as the *Formosan* subterranean termites, cockroaches, fire ants, and ticks [30]. For 1-*p*-methene-8-thiol, it is one of a few *S*-containing compounds that play important roles in the citrus flavors.

Lemon oil usually has a higher market value per unit than orange and grapefruit oils, and is nearly as equally valuable as lime oil [21]. However, the demand for lemon juice, although significant and popular for its fresh, acidic taste commonly used in soft drinks, is not as high as for orange juice. Similar to the chemical composition of orange oils, lemon oil contains a large quantity of terpene hydrocarbons and oxygenated terpenic compounds [21, 31] that include limonene, β-pinene, γ-terpinene, α-pinene, myrcene, sabinene, citral, linalool, citronellal, neral, geranial, α-terpineol, etc. In addition, esters, short chain acids, ketones and aldehydes have also been found. Like lemon juice, lime juice is very acidic but has a pleasant flavor and cooling taste, which makes it suitable for the production of a refreshing beverage. Lime oils are commercially produced in much higher quantity by distillation method than cold-pressed method since the former product possesses a stronger harsh, lime-type flavor. Tangerine, or mandarin essence was analyzed by Moshonas and Shaw [32] who identified 34 volatile compounds that were categorized into alcohols, aldehydes, ester, ethers, ketones and limonene. Like orange and grapefruit oils, tangerine oils contain a higher percentage of limonene. Other investigations have led to the identification of additional volatile flavor components in the tangerine. These compounds in the tangerine oils and in other citrus oils are collectively shown in Table 88.2.

D. Mango

Mango (*Mangifera indica* L.), one of the earliest cultivated fruits grown in India with a history of more than 5000 years, is one of the most popular tropic fruits in southeast Asia [33]. Mangoes vary considerably in size, shape, and flavor, as well as color from green to yellow. The fruit is usually picked at its unripened stage when it is still raw and firm. Within a week of storage at room temperature, it gradually ripens and is ready for consumption. But the ripening process slows down if the fruit is refrigerated. The reason that mango is so welcomed by consumers is particularly attributed to its strong and desirable

aromas. Though different mango varieties are distinguished by the amount and type of volatile compounds present, similar chemical groups such as esters, lactones, furanones and certain terpenes are commonly found in them. The flavor components of mangoes have been investigated by various researchers [34,35,36,37] and the following constituents were reported: terpenic compounds including Δ-3-carene, α- and β-pinene, β-myrcene, limonene, *cis*- and *trans*-ocimene, terpinene, α-copaene, β-caryophyllene, α-guaiene, α-humulene, *alto*-aromadendrene, gurujunene, δ-cadinene, β-selinene, β-phellandrene, α-terpinolene, β-cubebene, linalool, α-terpineol, etc.; esters with isobutyl acetate, ethyl butanoate, ethyl hexanoate, ethyl heptanoate, ethyl octanoate, hexyl butanoate, etc.; and alcohols, aldehydes ketones and other miscellaneous compounds such as acetophenone, benzaldehyde, dimethylstyrene, benzothiazole, ionone, as well as 2(3H)-furanones. The presence of furaneol (see I.2.F Pineapple), a characteristic pineapple-like aroma that imparts a herbal, sweet, fruity aroma and is commonly found in pineapples and several other fruits, might be responsible for the major flavor attribute in mangoes that contain pineapple-like aroma [35].

E. Peach

Peaches (*Prunus persica* L.), one of the most popular fruits due to their various textures and flavors, are associated with many selectable commercial varieties in the fruit market. Peaches are usually consumed fresh or processed into canned food because they are easily subject to physical wounding and enzymatic browning that will significantly deteriorate the quality of products (i.e., texture and flavor) and shorten their shelf-life for sale. Since peach flavor is a critical factor influencing the product value, many investigations [38,39,40,41] have been conducted on the topic and have resulted in the identification of about 70 volatile compounds. Lactones are considered as a group of important flavor contributors in peach aroma. Generally, C-5 to C-12 γ-lactones have low threshold values and bear the characteristic peach aroma. Among them, γ-decalactone is an important flavor compound. In nature, it exists as two enantiomers (R and S) at a ratio of 9 to 1. As a result, γ-decalactone has been used as an index to detect adulteration in food products since the synthetic one is in racemic form [42]. The status of δ-lactones is uncertain due to their low concentrations in peaches. Other major compounds identified in peaches comprise hexanal, (E)-2-hexenal, benzaldehyde, linalool, esters and other aldehydes [41,43,44].

F. Pineapple

Pineapple (*Ananas cosomus* (L.) *Merr.*) is a herbaceous, perennial plant of the bromeliad family with large, pointed leaves. It might be one of the most beautiful fruits in the world with many hexagonal sections arranged spirally and embedded in the juicy pulp. It is cultivated in the tropical regions of the world, with plantation centers in Hawaii, Florida, and Puerto Rico in the United States. Though pineapple is frequently consumed as a dessert fruit together with other fresh fruits, a large quantity of them are processed into canned or juiced products, and both are excellent food flavoring ingredients used in the preparation of marinated and baked goods.

The taste and flavor profiles of pineapples change markedly with seasons from sweeter in summer to more aromatic in winter. With the aid of instrumental analysis such as GC-MS, Takeoka et al. [45,46] separated and identified in pineapples more than 180 compounds, among which the following constituents were considered as the important flavor contributors: 2,5-dimethyl-4-hydroxy-3(2H)-furanone (furaneol), methyl-2-methylbutanoate, ethyl-2-methylbutanoate, ethyl acetate, ethyl hexanoate, ethyl butanoate, ethyl-2-methylpropanoate, methyl hexanoate, and methyl butanoate. Some compounds have a very high odor unit value (an odor intensity value) indicative of their importance in contributing to the overall flavor of pineapples. For instance, furaneol [47] has an odor threshold value of 0.03 ppb, its odor unit value in pineapple has been measured as high as approximately 2.5×10^5. Besides, many esters listed above largely possess pineapple or apple aromas. Ethyl 2-methylbutanoate, a character-impact flavor found in apples, was measured at a threshold value of 0.006 ppb that made it the second largest odor contributor (after furaneol) to pineapple aroma in the pineapple essence [46]. Other than those flavor compounds discussed, terpenes and terpenoids were also detected in pineapples, though their odor contributions were less significant. Meanwhile, it is worth noting that the enantiomeric ratio of numerous chiral components, such as 3-and 5-hydroxy esters, 3-, 4-, and 5-acetoxy esters, γ- and δ-lactones, were found to remain nearly unchanged during the ripening process in pineapples [42,48]. Such stability in the ratios of chiral constituents at different physiological stages is therefore very useful for the investigation of the intended adulterations in fruit products.

III. VEGETABLE FLAVORS

Vegetable flavors continue to be of interest commercially and scientifically for a variety of reasons that rely heavily on health concerns [49,50]. Contemporary dietary recommendations encourage consumption of more fresh vegetables not only to satisfy the gustatory feelings, but to be good for the health. Whether the marketed vegetables can be successfully acceptable to consumers is largely influenced by their inherent flavor sensation delivered after processing and storage. Therefore, characterization of the important vegetable flavor components and illustration of their formation mechanisms are important and will provide

a solid foundation for their quality and desirability evaluation. This is possible by taking advantage of the current modern analytical techniques.

A. *Allium* Species

Interest in the flavor components of plants in the genus *Allium*, e.g. onion and garlic, has led to the isolation and identification of the strong, penetrating, and lachrymatory sulfur-containing chemicals. Today the general features of the biosynthesis of the flavor constituents, the enzymatic conversion to primary products, the rearrangements, decomposition and interaction to produce the secondary products responsible for those irritating aromas have been generally understood and agreed. Not only did the *S*-containing compounds in the *Allium* species contain strong lachrymatory sensation, but they were suggested to have many positive health claims [51,52,53,54]. However, a discussion on the health benefits of these plants is beyond the scope of this section. The subsequent sections will be confined to illustrate the flavor biogenesis and flavor profiles in the genus.

1. Onion

Onion (*Allium cepa* L.) flavors usually do not "break out" unless the tissue is damaged releasing the embedded enzyme alliinase which reacts with the precursor compounds. The enzyme alliinase is a pyridoxal 5'-phosphate dependent α, β-eliminating lyase that hydrolyzes the flavor precursor S-(1-propenyl)-L-cysteine sulfoxide to a hypothetical sulfenic acid intermediate along with ammonia and pyruvate [29,55]. The sulfenic acid is very unstable and readily undergoes further rearrangements to produce the thiopropanl S-oxide, which releases spicy, lachrymatory odor, a typical flavor of cut onions. Besides, part of the unstable sulfenic acid decomposes to form a wide range of *S*-containing compounds. Investigations in the chemical composition of fresh onions and onion oils [56,57,58,59] have identified the following chemical classes: thiosulfinates, thiosulfonates, monosulfides, disulfides, trisulfides, tetrasulfides, thiophene derivatives, thiols, ketones, aldehydes, and other miscellaneous compounds (Table 88.3). The abundant disulfides and other polysulfides were suggested to be formed by disproportionation of the unstable thiosulfinates. Sensory evaluation and threshold determinations (Table 88.4) of the aforementioned chemicals revealed that thiosulfonates with four or more carbon atoms displayed powerful and distinct odor of freshly cut and/or cooked onions, while the propyl- and propenyl-containing di- and trisulfides possessed the flavor of cooked onions. Also, dimethylthiophenes were shown to have distinctive fried or fresh onion flavors. 3-Mercapto-2-methylpentan-1-ol was recently identified [63] as another powerful onion aroma with an odor threshold value at 0.15 ppb in 5% saltwater.

TABLE 88.3
Important *S*-containing Aromas in Onion and Garlic

Dimethyl sulfide	Hydrogen sulfide	2,5-Dimethylthiophene
Allyl propyl sulfide	Methyl propenyl sulfide	3,4-Dimethylthiophene
Dipropenyl sulfide	Methyl propenyl trisulfide	Allylthiol
Tetrasulfide	Isopropyl propyl trisulfide	Propanethiol
Propenyl propyl sulfide	Methyl propyl trisulfide	Propyl methanethiosulfonate
Allyl methyl disulfide	Allyl methyl trisulfide	Propyl propanethiosulfonate
Isopropyl propyl disulfide	Diisopropyl trisulfide	Methyl methanethiosulfonate
Methyl propyl disulfide	Propenyl propyl trisulfide	Allyl isothiocyanate
Propenyl propyl disulfide	Allyl propyl trisulfide	
Diallyl disulfide	Diallyl trisulfide	
Allyl propenyl disulfide	Dipropyl trisulfide	
Dipropyl disulfide	Dimethyl trisulfide	
Dipropenyl disulfide	Dimethyl tetrasulfide	
Allyl propyl disulfide	3,4-Dimethyl-2, 5-dihydrothiophen-2-one	
Methyl propenyl disulfide	Methanethiol	

Source: From Refs. 4, 56, 60, 61 and 66.

TABLE 88.4
Threshold Values of Some *S*-Containing Compounds in *Allium* Species

Compounds	ppb in Water	Description
3,4-Dimethylthiophene	1.3	Fresh onion
2-Methanethiophene	3	Heated onion, sulfury
Dipropyl disulfide	3.2	Cocked onion
Methyl propenyl disulfide	6.3	Cocked onion
Propenyl propyl disulfide	2.2	Cocked onion
Propyl methanethiosulfonate	1.7	Fresh onion
Methanethiol	2.0	Sulfurous
Dimethyl disulfide	3.0–12	Onion, Cabbage
Dimethyl trisulfide	10	Alliaceous, Meaty
Allyl isothiocyanate	375	Strong, Pungent

Source: From Refs. 56, 60, 61 and 62.

2. Garlic

Unlike the flavor precursor in onion, the primary precursor in garlic (*Allium sativum* L.) is S-(2-propenyl)-L-cysteine sulfoxide. One of its products is the volatile chemical diallyl thiosulfinate (allicin) which has a characteristic garlic flavor [64]. With further degradation, additional important components such as methyl allyl and

diallyl disulfide, thiosulfonate, and trace quantities of allyl trisulfide are formed as part of the overall garlic flavor profile (Table 88.3) [65,66,67]. In recent years, garlic with its inherent bioactive components has attracted much attention for its nutritional and clinical values [54,68]. Like other medicinal herbs and spices such as tea, ginger, ginseng, ginkgo, etc., garlic has been recognized as a major functional food or "nutraceutical" that helps to reduce the occurrence of cardiovascular disease and cancer [54,68].

B. Tomato

Tomatoes (*Lycopersicon esculentum* Mill.) are no doubt one of the most popular and favorite vegetables because of its colors, flavors and many claimed healthy benefits. The study of the chemical composition of tomatoes, particularly its characteristic flavors, has been the subject of much research over many years [69,70,71,72,73,74]. Many different and important aspects of tomatoes have been reviewed by Petro-Turza [75]. In particular, the author reported more than 300 volatile compounds in tomatoes. The volatile components which contribute to the flavor of tomatoes are (*Z*)-3-hexenal, 3-methylbutanal, β-ionone, 1-penten-3-one, hexanal, (*Z*)-3-hexenol, (*E*)-2-hexenal, 2- and 3-methylbutanol, 2-(2-methylpropyl)-thiazole, eugenol, 6-methyl-5-hepten-2-one, geranylacetone, 2-phenylethanol, dimethyl sulfide, β-damascenone, methional, 1-nitro-2-phenylethane and 3-methylbutyric acid [69,70,76]. Amino acids, fatty acids and carotenoids serve as their major precursors [72,77]. Furaneol, a character-impact flavor in pineapple, was also suggested to be an important flavor contributor to tomato in subsequent investigations [73,76]. Some investigators believed the tomato flavors were significantly influenced by its rich sugar and acid contents [7,78]. Besides, investigation in flavor precursors in tomatoes, particularly the glycosides, has received considerable attention like that in other fruits [79,80]. 2-Phenylethanol and benzyl alcohol were found to be the major components bound as glycosides in tomatoes, and other glycosidically bound chemicals existing in small quantities include monoterpene alcohols and C13 norisoprenoids [78].

IV. HERBS, SPICES, AND ESSENTIAL OILS

In the olden days, herbs, spices and silk were once objects of relentless exploration by various countries and a symbol of wealth. Currently, as defined in the Title 21, Section 101.22 (a)(2) in the Code of Federal Regulations published by the U.S. Government, the term "spices" is given the meaning of

> *any aromatic vegetable substance in the whole, broken, or ground form, except for those substances which have been traditionally regarded as foods, such as onions, garlic and celery; whose significant function in food is seasoning rather than nutritional; that is true to name; and from which no portion of any volatile oil or other flavoring principle has been removed. Spices include the spices listed in Sec. 182.10 and part 184 of this chapter, such as the following: Allspice, Anise, Basil, Bay leaves, Caraway seed, Cardamon, Celery seed, Chervil, Cinnamon, Cloves, Coriander, Cumin seed, Dill seed, Fennel seed, Fenugreek, Ginger, Horseradish, Mace, Marjoram, Mustard flour, Nutmeg, Oregano, Paprika, Parsley, Pepper, black; Pepper, white; Pepper, red; Rosemary, Saffron, Sage, Savory, Star aniseed, Tarragon, Thyme, Turmeric, Paprika, turmeric, and saffron or other spices…*

while "herbs" are traditionally defined for those botanical materials with aromatic leaves, flowers, stems, and in many cases roots, which have been used in history as medicines or considered to be with health benefits, though some of them have not been specifically defined or approved by the US FDA [81]. In close connection with herbs and spices, essential oils extracted from spices and herbs have found ready use in the food and pharmaceutical industries for their various properties [6,27]. Essential oils are generally obtained by either steam/water distillation, expression extraction, or solvent extraction. Modern extraction of essential oils utilizes supercritical fluid (especially the liquid carbon dioxide) extraction (SFE) method by taking advantage of both its environmental-friendly property and extraordinary extraction ability [82].

A. Tea

Plant tea (*Camellia sinensis* L.) has a long history in China with more than 5000 years. According to legend, it was discovered in the year 2737 BC by a Chinese emperor when some tea leaves accidentally blew into a pot of boiling water. In 800 A.D., Lu Yu wrote the first definitive book on tea, *The Bible of Tea*, that significantly promoted the plantation and consumption of tea. Since then tea culture has spread throughout the Chinese history, as coffee has in the Western countries, reaching into every aspect of the society. Tea was imported to the continental Europe from China in the early 1600s by Dutch traders. In the late 1700s, tea shared a part of historical events when a demonstration against taxation by the English known as the "Boston Tea Party" occurred. This event was one of the fuses for the revolution and founding of the United States of America. Today, tea has become one of the most widely consumed beverages in the world. Its popularity depends largely upon its fragrant, pleasant aromas combined with its medicinal effects that revive, refresh and relax the human bodies and minds before and after their daily work [83]. Depending on the processing procedures, tea leaves are classified into black tea, oolong tea, and green tea after full, semi and without fermentation, respectively. Fermentation by natural enzymes in tea leaves causes many changes in the taste, flavor profile and color

of the end tea products. The chemical constituents of teas have been investigated by many researchers [84,85,86, 87,88,89,90,91], and more than 600 volatile compounds have been identified [91,92,93,94]. Although some character-impact flavors and flavor precursors were identified, there is no uniform flavor profile for various types of teas [86,92] or even with the same type of tea. For example, by using GC-O with the aid of AEDA method, Kumazawa and Masuda [87] found the following most potent flavors in the Japanese green tea: 4-methoxy-2-methyl-2-butanethiol (meaty), (*Z*)-1,5-octadien-3-one (metallic), 4-mercapto-4-methyl-2-pentanone (meaty), (*E,E*)-2,4-decadienal (fatty), β-damascone (fruity), (*Z*)-methyl jasmonate (floral), and indole (animal-like), while Guth and Grosch [94] reported (*Z*)-1,5-octadien-3-one, 3-hydroxy-4,5-dimethyl-2(5H)-furanone, and 3-methylnonone-2,4-dione were the most important odorants in the Chinese green tea. Such variation in the potency of compounds in green teas reflected the difference in chemical compositions that might be caused by the differences in raw materials and in processing methods. In contrast, investigation by Kumazawa and Masuda [88] on black teas showed that 3-methylbutanal, methional (potato-like), β-damascenone (sweet), dimethyl trisulfide (putrid), and 2-methoxy-4-vinylphenol (clove-like) had the highest flavor dilution (FD) values, and aliphatic alcohols and terpenic alcohols were found to be the main aromas of black and oolong teas.

B. Licorice

Native to both Asia and the Mediterranean region, licorice (or liquorice) (*Glycyrrhiza glabra* L.) belongs to the family Leguminosae and is a well-known plant in China called "Gancao," which literally means "sweet grass." Licorice root is one of the oldest and most frequently used folk medicine in China for its diverse therapeutic functions. In the first Chinese medicinal book "Shen Nong Ben Cao Jing," licorice was claimed to possess some special healthy benefits such as "prevention from diseases" that have been confirmed by the modern medical studies due to the presence of some inherent bioactive chemicals, such as the chemical classes of alkaloids, polysaccharides, polyphenols, flavonoids, terpenoids, etc. These compounds have been demonstrated to possess either cancer chemopreventive or detoxification capabilities [95]. Licorice extract is currently widely used in the food and pharmaceutical industries as a flavoring and sweetening agent because of its distinguished flavors. In particularly, it contains glycyrrhizin, a sweetener, that is about 50 times as sweet as sucrose [96]. Licorice extract is typically used in tobaccos, chewing gums, candies, toothpastes, and beverages. Despite its well-known intrinsic sweetness, there is limited information of the volatile flavor components of licorice. Frattini et al. [97] reported that the most abundant components in heated licorice essential oil were acetol, propionic acid, 2-acetylpyrrole, 2-acetylfuran and furfuryl alcohol, whereas the furan derivatives was the largest chemical class due to the pyrolysis and condensation reactions among sugars. Further investigation by Fenwick et al. [98] revealed the following volatiles might be additional important flavor contributors: estragole, eugenol, indole, cumic aldehyde and nonalactone.

C. Angelica

Angelica with the scientific name of *Angelica archangelica* (L.), also known as *Archangelica officinaiis* Hoffm., is unique amongst the family of Umbelliferae for its pervading, strongly aromatic odor in musky, earthy flavors extracted from its root or seed. Its bitter-sweet, warmly pungent but pleasant flavor profile makes it different from others of the same family members like anise, caraway, fennel, and parsley. The major components in angelica root oil (seed oil has similar profile) were identified by Taskinen and Nykanen [99] with the following quantities: α-pinene (24.0%), limonene (13.2%), Δ-3-carene (10.1%), β-phellandrene (10.1%), para-cymene (9.8%), α-phellandrene and myrcene (7.6%), trans-ocimene (2.68%), α-copaene (1.91%), camphene (1.3%), α-muurolene (1.2%) and cis-ocimene (1.2%). Other terpenic compounds are less than 1% each.

D. Anise

Anise is native to Egypt and the Mediterranean countries, then its cultivation extends to the central Europe, Russia, India, China, etc. This dainty, white-flowered Umbelliferous annual plant yields 1.5–6% of colorless to pale yellowish aniseed oil. This syrupy oil is characterized by its main component, *cis/trans*-anethole, which is in approximately 90 percent of the whole oil that is readily solidified due to the crystallization of anethole when cooled down below 19°C. The other major components of aniseed oil, reported by Lawrence [100,101], include methyl chavicol (1.02%), *trans*-ocimene + acetoanisole (0.94%), anisaldehyde (0.91%), and safrole (0.58%). Other terpenes and terpenoids are in trace amounts.

E. Basil

Sweet basil (*Ocimum basilicum* L.) oil is extracted from the dried, broken leaves and floral parts of the labiate, herbaceous plant which belongs to the Family *Labiatae*. Typical India sweet basil leaves give off a strong aromatic scent very much like that from cloves. In France, sweet basil is also a common culinary flavoring ingredient. There are more than one hundred varieties of basil from which the essential oils are extracted. Their differences in flavor profiles have been discussed by Lawrence [102] and Reineccius [6]. The following components were commonly found in and considered as major constituents among

different sweet basils, though their quantities might vary significantly. These compounds are: 1,8-cineole, ocimene, camphor, linalool, methyl chavicol, geraniol, methyl eugenol, methyl-cinnammate, and eugenol.

F. Caraway

Caraway (*Carum Carvi* L.) is a biennial Umbelliferous plant that is mainly distributed throughout the northern and central European regions. The caraway oil is commonly used as a food flavoring in cookery, confectionery and liqueurs. The major constituents of its oils summarized by Lawrence [103] are listed below: limonene (49.8%), carvone (47.1%), *trans*-dihydrocarvone (0.6%), *cis*-dihydrocarvone (0.2%), *trans*-carveol (0.4%), *cis*-carveol (0.2%), and other terpenic compounds in less than 0.1% or in trace amounts.

G. Cinnamon

Cinnamon trees are typically grown in the hot tropical rain forests. Two of the most important species [104] used to prepare commercial cinnamon oils are: Ceylon cinnamon (*Cinnamomum zeylanicum* Nees.) and Cassia-cinnamon (*C. cassia* L.). The former is indigenous to and mainly cultivated in Sri Lanka and China, while the latter is grown in southern China, Burma, and Vietnam. Commercial cinnamon oils are extracted by steam-distillation from scabrous bark of the plant after drying. Though oils from both sources give slightly different sensory characters, both of them are characterized by sweetly aromatic, warmly pungent flavors and burning effect. The main components in Ceylon cinnamon oil [105] include cinnamic aldehyde, eugenol, linalool, 1,8-cineole, α-terpineol, caryophyllene, α-pinene, α-humulene, etc., whereas the China cassia-cinnamon oil has cinnamic aldehyde, cinnamyl acetate, cinnamic acid, benzaldehyde, salicylaldehyde, courmarin, etc. Comparison between the constituents of the two cinnamon oils is listed in Table 88.5.

TABLE 88.5
Comparison of the Major Chemical Constituents between the Ceylon Cinnamon Oil and the China Cassia-Cinnamon Oil

Celylon-Cinnamon	China Cassia-Cinnamon
Cinnamic aldehyde	Cinnamic aldehyde
Cinnamylacetate	Methoxy cinnamaldehyde
Eugenol	Cinnamylacetate
Caryophyllene	Benzaldehyde
Linalool	Ethyl cinnamate
1,8-Cineole	Salicylaldehyde
α-Terpineol	Coumarin
Terpinen-4-ol	

Source: From Refs. 6, 23, and 105.

H. Clove

Clove (*Eugenia caryophyllata* Thumb.) oils are commercially classified into oils of clove bud, clove leaf and clove stem. They are an important source of the chemical eugenol which is usually used as a quality index for the product. Generally, clove bud oil gives out more fruity and pleasant flavors than its counterparts, leaf oil and stem oil. The chemical profile of the clove bud oil as investigated by Deyama and Horiguchi [106] was found to contain: eugenol (80.9%), eugenyl acetate (7.3%), caryophyllene (9.12%), α- and β-humulene (1.7%), and α-ylangene (0.4%).

I. Coriander

Coriander, an annual Umbelliferous plant (*Coriandrum sativum* L.) originated from the East, is now cultivated in many temperate countries. Coriander fruit contains about 1% of pale yellowish to colorless volatile oil, and its odor could be fruity or warmly spicy. In British Pharmacopoeia, it is described as a functional agent to disguise unpleasant medicines. Taskinen and Nykanen [107] identified the following major components in the Coriander oil: linalool (65.0%), γ-terpinene (10.1%), camphor (5.0%), α-pinene (6.5%), *p*-cymene (3.7%), geranyl acetate (2.6%), limonene (1.7%), geraniol (1.7%) and other chemicals in minor or trace amounts. Since the chemical linalool is dominant in quantity in the oil, it is usually recommended as a flavoring quality index for the recovered essential oil.

J. Fennel

Fennel is a perennial Umbelliferous herb (*Foeniculum vulgare* Mill.) that grows wild in most temperate European countries, but is generally considered indigenous to the Mediterranean regions. Fennel is well known for its succulent, edible shoots and aromatic leaves which are an excellent flavoring ingredient for culinary use. Fennel oils are generally pleasant in flavor, though they differ in some degrees with varieties and sources. There are two principle varieties of fennel: bitter and sweet. Bitter fennel is a synonym for the most common variety. Its principle constituents are anethole (approx. 50%) and fenchone (>10%). Anethole is also a major component in anise oil (see section 1.4.4 Anise). Fenchone is a colorless

TABLE 88.6
Important Flavors in Fennel

α-Thujene	α-Terpinene	p-Cymene	Δ-3-Carene
β-Fenchene	Limonene	Camphor	Myrcene
α-Pinene	l,8-Cineole	Terpinen-4-ol	α-Phellandrene
α-Fenchene	cis-β-ocimene	Methyl chavicol	Terpinolene
Camphene	β-Phellandrene	Linalool	Anisaldehyde
β-Pinene	γ-Terpinene	Fenchone	cis-Anethole
Sabinene	trans-β-Ocimene	α-Terpineol	trans-Anethole

TABLE 88.7
Major Components in Ginger Oil

Hydrocarbons		Oxygenated Compounds	
α-Thujene	*trans*-β-Farnesene	*trans*-2-Hexenal	Elemol
α-Pinene	Selina-4, 11-diene	Nonanal	*cis*-sesquisabinene hydrate
Camphene	Selina-3, Il-diene	Decanal	Nerolidol
β-Pinene	δ-Amorphene	Undecanal	β-Bisabolol
Sabinene	Zonarene	Citronellal	Zingiberenol
δ-3-Carene	α-Cadinene	Myrtenal	10-α-cadinol
Myrcene	γ-Cadinene	Phellandral	α-Eudesmol
α-Phellandrene	δ-Cadinene	Neral	β-Eudesmol
α-Terpinene	γ-Bisabolene	Geranial	*trans*-β-sesquiphellandrol
Limonene	β-Bisabolene	α-Terpineol	Cubebol
β-Phellandrene	Zingiberene	Citronellol	2-Heptyl acetate
γ-Terpinene	β-Sesquiphellandrene	Geraniol	α-Fenchyl acetate
cis-Ocimene	Germacrene B	1,4-Cineole	Bornyl acetate
Copaene	β-Curcumene	1,8-Cineole	Citronellyl acetate
Sesquithujene	ar-Curcwnene	Linalool	α-Terpinyl acetate
β-Ylangene	Calamenene	Isopulegol	Methyl heptenone
β-Elemene		Caryophyllene oxide	2-Hexanone
γ-Elemene		Terpinolene epoxide	2-Heptanone
trans-α-Bergamotene			2-Nonanone
Caryophyllene			2-Heptanol

Source: From Refs. 6, 23, 111, 112, and 113.

liquid possessing a pungent, camphoraceous flavor, and accounts for the undesirable bitterness of the oil. Sweet fennel is also known as French or Roman fennel that is derived from *Foeniculum vulgare* var. *dulce* Mill. Since it has much less anethole and no fenchone, its oil possesses a milder and sweeter taste. The constituents of fennel oils are shown in Table 88.6 [108,109].

K. Ginger

Commercially traded ginger (*Zingiber officinale* Rosc.) is a herbaceous perennial monocotyledon plant that belongs to the *Zingiberaceae* family. The *Zingiber* genus is estimated to consist of about 80–90 species. Ginger is native to southeast Asia and has been cultivated in countries such as India and China for over 3,000 years. Today, it is widely cultivated in almost all tropical and subtropical countries for its end use either as a fresh root vegetable or as a dry culinary spicy ingredient. In some Asiatic countries, ginger also serves as a folk medicine to cure diarrhea and to prevent catching cold [90,110]. The dry rhizome of ginger yields about 1 to 4% of a light yellowish essential oil which is characterized by its distinctive and strong pungent smell. However, considerable differences exist in sensory properties of ginger oils extracted from different sources [111]. Representative chemical composition of the ginger oil prepared by the steam distillation includes the following major components: α-pinene, camphene, β-pinene, sabinene, Δ-3-carene, myrcene, β-phellandrene, limonene, tricyclene, zingiberene, 1,8-cineole, borneol, zingiberol, methyl heptanone, citral, n-decylaldehyde, linalool, geraniol, farnesene, curcumene, and bisabolene. More comprehensive information on ginger oil constituents (Table 88.7) has been contributed by various research teams [112,113] and summarized in a review by Lawrence [111] who reported that the ginger oil was mainly composed of about 83.0% hydrocarbons, 10% oxygenated compounds and other unidentified compounds determined by using a combination of techniques, e.g., distillation, column chromatography, GC, NMR, IR, and MS. Among the aforementioned volatile chemicals, Bednarczyk and Kramer [114] used statistical chemometrics to correlate the following compounds in ginger oil to the overall faintly lemon-like, earthy, woody characters of the ginger aroma. These compounds are α-terpineol, neral, geraniol, β-sesquiphellandrene, ar-curcumene, nerolidol, and β-sesquiphellandrol. Nevertheless, the pungency of ginger is attributed to some nonvolatile analogues which include gingerols, shogaols, paradols and zingerone (Figure 88.1) [110,115]. Connell noted that some of the ginger homologues would undergo a retro-aldol reaction into zingerone and aliphatic aldehydes if heated, and some of them would be dehydrated to shogaol under alkaline conditions. These degradations and changes would increase the pungency in the products.

L. Mustard

In general, mustard is a herbaceous perennial plant that can be found wildly throughout Europe, India, North African

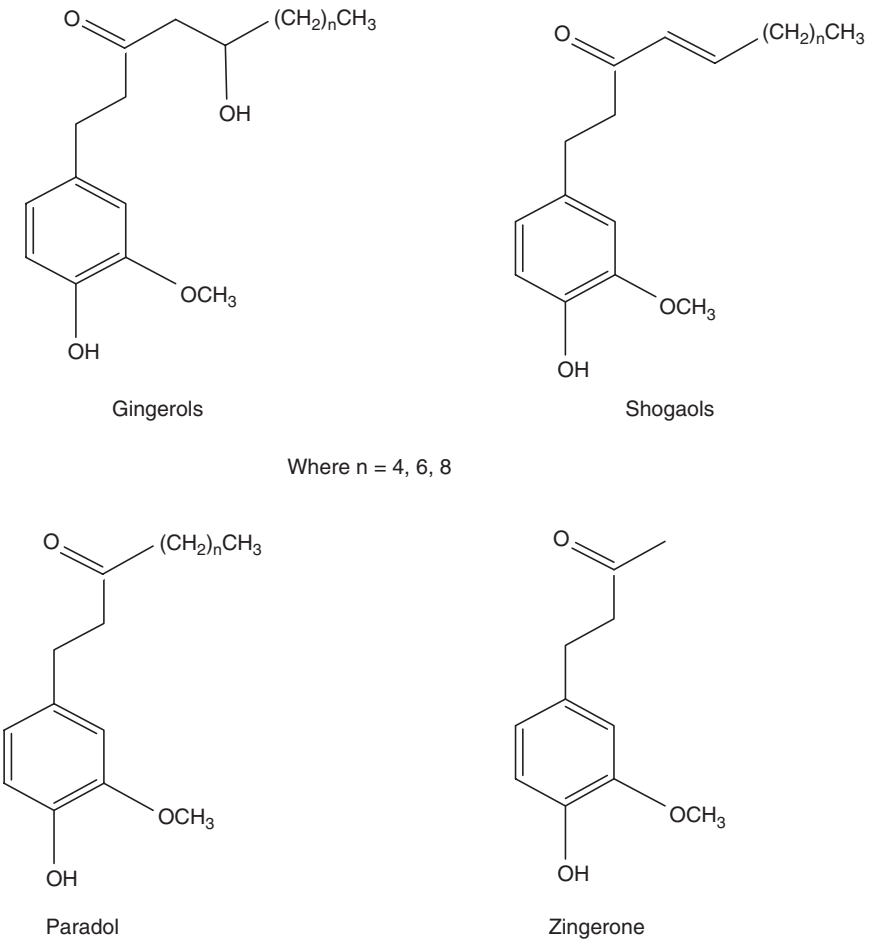

FIGURE 88.1 Key components responsible for ginger pungent aroma.

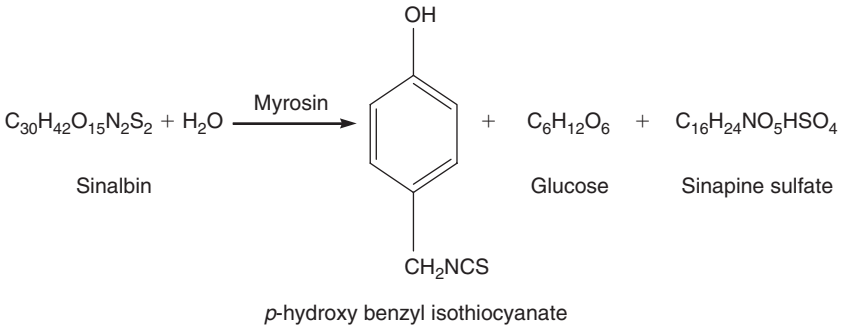

FIGURE 88.2 Proposed enzymatic scheme for the formation of *p*-hydroxy benzyl isothiocyanate in mustard.

and American continent. Under the family Cruciferae, the White mustard (*Brassica alba* Boiss. or *Sinapis alba* L.) and the Black mustard (*Barssica nigra* L.) are known to be associated with other common vegetables such as cabbage, cauliflower, turnip, radish, horseradish, watercress, etc. due to their pungent aromas attributed to the presence of some sulfur-containing compounds. The compound responsible for the characteristic pungent flavor in white mustard is *p*-hydroxyl benzyl iso-thiocyanate which is a decomposed product of the glycoside precursor, sinalbin. The reaction takes place in the presence of both the enzyme myrosin and water (Figure 88.2). By contrast, the pungency of black mustard is caused by the presence of allyl isothiocyanate which is formed from another glycoside sinigrin under the same enzymatic reaction as in white mustard. Generally, mustard oil is extracted by boiling alcohols instead of the steam distillation method. Since mustard oil is dominated in quantity by isothiocyanate that

may cause intensive irritating sensation and lachrymatory effects, considerable precautions should be taken before handling the material.

M. Parsley

Fresh green parsley (*Petroselinum ctispum* Mill.) is popular and welcomed for its pleasant aroma. It is often used in culinary preparations as a flavouring material to spice up sauces, soups, stuffings, and even vegetables or salads. The composition of parsley leaf oil was studied by several researchers [116,117,118], and is summarized and presented in Table 88.8. Among the flavors listed in the table, MacLeod et al. [118] noted that β-phellandrene, terpinolene, α-*p*-dimethyl styrene, *p*-mentha-1,3,8-triene, myristicin and apiole were the character-impact components in parsley leaf.

N. Pepper

The black and white peppers are derived from the same plant (*Piper nigrum* L.) of family Piperaceae, but prepared under different procedures. The plant is now widely cultivated in the tropical regions, especially in the southern Asian countries such as India, Malaysia, Indonesia, Cambodia, Sri Lanka, and China. Since pepper powders are one of the most popular food flavorings in our everyday life, intensive research has been carried out over the years to characterize their chemical profiles [119,120]. Early studies revealed that the volatile compounds contributed to the pepper flavor, and the nonvolatile components, mostly piperine, resulted in the pungent taste. Delicate balance between these two chemical groups determines the quality of peppers and distinguishes peppers that come from different sources. For example, Indian peppers are generally

more aromatic, whereas the counterparts from Malaysia and Indonesia are more pungent. Further investigation [121] in the essential oil of pepper has led to the identification of more characteristic flavors which are listed in Table 88.9. Along with the characterization of the oil, the principle pungency of pepper was found to be attributed, in most part, to the alkaloid piperine, which was less pungent than capsaicin, but stronger than gingerol [122].

O. Peppermint and Spearmint

Peppermint (*Mentha piperita* L.) and spearmint (*M. viridis* L.) are two major species of mint in the family Labiatae. Both of them can thrive best in an environment with a fairly warm climate, favorable humidity and nutritious soil. Peppermint might be one of the world's most popular flavoring materials. Peppermint is used in a wide range of applications in candies, chewing gums, and medicinal supplements, whereas spearmint, in many ways resembling peppermint, is mainly used for culinary products. Their essential oils with special flavors are so important that a lot of research [123,124,125] has been conducted in an attempt to better understand their chemical profiles, which are presented in Table 88.10. As noted in the table, menthol and menthone in the peppermint oil are the two major quantitative components that account for approximately 70% of the amount in the oil. In particular, menthol provides the cooling sensation. Other quantitatively important volatiles include menthyl acetate, 1,8-cineole, menthofuran, limonene, iso-menthone, pulegone, octan-3-ol, oct-1-en-3-ol, and mint lactone. Since the pulegone is suspected to be toxic, peppermint oil is used with provisional limits for pulegone levels ranging from 25 ppm in food to 350 ppm in mint confectionery [23]. In spearmint oil, carvone is the predominant volatile compound that presents a sweet, spearmint odor, followed by other terpenic compounds and esters, such as limonene, myrcene, 1,8-cineole, carvyl acetate, dihydrocarvyl acetate, dihydrocarveol, *cis*-jasmone, etc. (Table 88.10).

TABLE 88.10
Important Flavors in Peppermint and Spearmint Oils

Peppermint	Spearmint
Menthol	Carvone
Menthone	Limonene
Menthyl acetate	Myrcene
1,8-Cineole	1,8-Cineole
Menthofuran	Carvyl acetate
Terpinolene	Dihydrocarvyl acetate
Limonene	Dihydrocarveol
Iso-menthone	3-Octanol
3-Octanol	*cis*-Jasmone
Oct-1-en-3-ol	
Mint lactone

P. Rosemary

Rosemary (*Rosmarinus officinalis* L.) (family Laminaceae) is a small evergreen shrub with small needle-like leaves. It is cultivated in nearly all countries around the Mediterranean Sea, as well as England and the US. Rosemary leaves contain about 1–2% of the essential oil, which is colorless to pale yellowish and gives off sweetly aromatic flavors typical of camphoraceous, herbaceous and bitter odor. No doubt rosemary is one of the most popular spices in many Western countries, especially Italy and France where rosemary is often used as a flavoring ingredient in their cookery. In Italian cuisine, mutton is hardly ever cooked without rosemary, and broiled poultry wrapped in rosemary twigs is also very popular. Rosemary is also well known for its presence of natural antioxidants, which contribute to the retention of a good red color in processed meats [126]. Rosemary oil is typically composed of the following major components: α-pinene, 1,8-cineole, camphor, camphene, β-pinene, borneol, myrcene, bornyl acetate, and α-terpineol.

Q. Tea Tree

The essential oil of *Melaleuca alternifolia*, commonly known as Australia tea tree oil, is obtained by steam distillation of a small perennial shrub species which is cultivated in the northern New South Wales, Australia. With recent recognition of its strong and wide-spectrum antibacterial and antifungal properties [127,128], tea tree oil has gained widespread acceptance and has been used in a wide range of consumer products from pharmaceuticals to cosmetics. The essential oil has a characteristic strong greenish aroma and its principle component is terpinen-4-ol [129], which is now known to possess some bioactive functions mentioned above. Other major constituents of this oil include monoterpenes or monoterpenoids, such as γ-terpinene, α-terpinene, 1,8-cineole, and α-terpineol. Using the simultaneous steam distillation and solvent extraction (SDE) method, more volatile chemicals have been identified [130]. These chemicals are presented in Table 88.11 and its chromatographic profile is shown in Figure 88.3.

R. Vetiver

Vetiver grass (*Vetiveria zizanoides*, L.), a fast growing perennial plant originated from India, belongs to the same

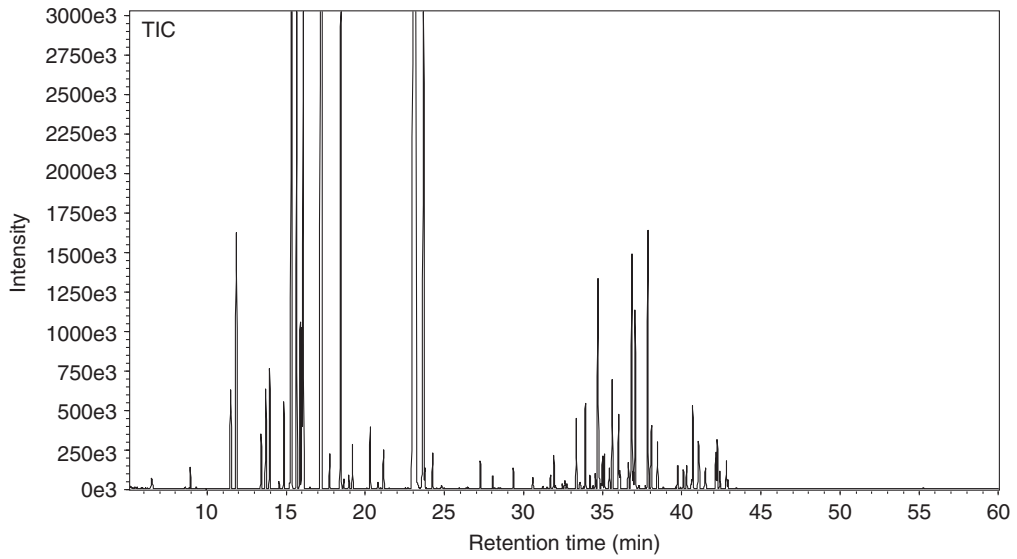

FIGURE 88.3 Total ion chromatogram of tea tree oil (TTO) using Shimadzu GC-17A/QP5000 GC-MS system with DB-5 column (60 m × 0.25 mm × 0.25 μm). The oven temperature was programmed from 60°C to 240°C at 3°C/min and held at 240°C for 10 min.

grass family as maize, sorghum, sugarcane, and lemongrass. So far twelve known species of vetiver grass and many hundreds of different cultivars have been found in the tropical and the semi-tropical countries such as southern Africa countries, India, Thailand, Malaysia, Indonesia, China, Central and South America, the Caribbean, and the United States. The driving force for the popularity in cultivating this plant is attributed to the commercial profits gained by the essential oil industries from vetiver oil, which contains a strong, penetrating, fragrant odor with versatile applications, not limited to be used as food flavoring or medicinal additive but also used a as cosmetic. Another recent principle application of the vetiver oil is its use as a strong repellent and toxic efficacy against the *Formosan* subterranean termite (*Coptotermes formosanus*) discovered by Henderson and co-workers [30].

Vetiver oil is extracted by distillation from vetiver roots in yield of 1–1.5%. The perfumery industry describes it as "heavy, woody, earthy" in sensory character. Investigation of the chemical composition of the vetiver oil, which was thought to possess one of the most complex flavor profiles in essential oils, has been conducted by several research groups during the last four decades [131,132,133,134,135]. Though vetiver oils from different sources do not have a uniform flavor profile, the following chemicals are generally found and considered as the major components of the oils: zizanol, khusimol, bicycle-vetivenol, β-vetivone, α-vetivone (syn. isonootkatone), zizanal, khusimon, β-vetivenene, α- and β-bisabolol, nootkatone, and β-eudesmol, which are shown in Table 88.12. More detail on the composition of the vetiver oil can be found in the literature as noted.

TABLE 88.12
Major Components in Vetiver Oil

V. SUMMARY

A comprehensive review to cover all natural flavors is not possible facing more exotic aromas identified and more biosynthetic pathways illustrated. What has been possible to achieve is to select some materials typically bearing characteristic flavor profiles to enable the readers to gain an overview and other more important aspects of the natural flavors. This chapter has therefore examined some fruits, vegetables, herbs, and spices, as well as their extracts, which are excellent sources of natural flavors that have been extensively used in food industries and in our lives. Finally, this chapter has outlined the main forms of aromatic flavors in plants, and hopefully can provide food chemists, flavorists, and culinary artists who are involved with natural flavors the basic information to approach to the complexity of the natural flavor in a more systematic way.

CONTENTS

I. INTRODUCTION

A. Use of Spices in History and Various Cultures

Spices and herbs have been used in various cultures for centuries in food preparation for better flavor, appearance, and consumer acceptance and, to a lesser extent, for therapeutic purposes. They were and still are important in commerce among different countries, and also led to the discovery of the New World. With the current cultural exchange activities among countries nowadays, spices, herbs, and seasonings such as Indian curry, used by one ethnic group, are common in many countries, and have been adapted into their cultures with modifications, such as in Thailand and Japan. In the U.S., spices, herbs, and seasonings not common in the past have emerged as important flavoring agents in the food industry. Flavoring of food products by ethnic grouping such as Italian, Mexican, or Chinese in the past has expanded into Mediterranean, Latin American, Carribean, and Asian. Many technical books and review articles on spices, herbs, and seasonings have been published in the past several decades. This chapter attempts to present to readers, especially in the food science and technology area, a concise summary on spices, herbs, and seasonings. Readers are encouraged to consult books published in this area such as those listed in references at the end of this chapter (1–17).

B. Definitions by Various Agencies and Groups (6–21)

There is no clear distinction between spices and herbs and their definitions. Even in the same country, such as the U.S., various definitions are available, even within the federal government. In addition, each country has its own definition(s). However, for international trade, commonly used names and scientific names are used to distinguish the identity of a spice, and international standards are available such as the ISO (International Organization for Standardization) (http://www.iso.ch). Generally speaking, spices are derived from a variety of plant parts, e.g., the bark (cinnamon), buds (cloves), flowers (saffron), fruit (allspice, chilies), roots, (ginger, licorice), or seeds (caraway, mustard). They are obtained from plants that normally flourish in semitropical and tropical climates where the sun's heat is said to influence the strength and pungency of the spice. Spices are highly aromatic due to their high content of essential oils.

In contrast, herbs are the leaves and stems of soft-stemmed plants of which the main stem dies down to the ground at the end of the growing season. Herbaceous plants usually grow in temperate climates and may be annuals, biennials, or perennials. However, herbaceous plants are not the exclusive source of the substances we consider culinary herbs. For example, woody- or semiwoody-stemmed plants give rise to rosemary, sage, and thyme; and a large, woody-trunk evergreen tree, the laurel, is the source of bay leaves. An additional point of interest is that some herbaceous plants such as coriander and fennel are sources of herbs (the leaves), spices (the seeds), and vegetables (the bulb of fennel). Herbs are further distinguished from spices by their low content of essential oils, and are used to produce delicate or subtle flavors in contrast to the aromatic flavors imparted by spices.

The American Spice Trade Association (ASTA) defines spices in very broad terms dried plant products used primarily to season food. This definition encompasses all types of products found on the supermarket spice shelf, such as the spices considered "true spices" (e.g., pepper, cinnamon, nutmeg), as well as herbs (e.g., basil, marjoram), aromatic seeds (e.g., sesame, poppy, cardamom), blends (e.g., pumpkin pie spice), and dehydrated vegetable seasonings (onions, garlic, celery, sweet pepper).

Similarly, the U.S. Food and Drug Administration (FDA) has a broad definition for spices — with one important exception: it excludes dehydrated vegetables such as onions, garlic powder, and celery powder from the spice list. According to their definition, a spice is "any aromatic vegetable substance in the whole, broken, or ground form that is used primarily to season food rather than to contribute nutrients." This definition also requires spices to be true to the name and unmodified so that no volatile oil or other flavoring principle has been removed. FDA regulations state that spices may be labeled as "spices;" however, color-contributing spices — paprika, turmeric, and saffron — must be declared as "spice and coloring" or by their common names. Essential oils, oleoresins, and other natural plant extractives containing flavor constituents may be declared as "natural flavor." Dehydrated vegetables must be declared by their usual or common names.

The USDA defines the term spice as any aromatic vegetable substance in the whole, broken, or ground form, with the exception of onions, garlic, and celery, whose primary function in food is seasoning rather than nutritional and from which no portion of any volatile oil or other flavoring principle has been removed.

Spices and herbs are the basis of several spice blends such as chili powder, curry powder, poultry seasoning, Chinese five spices, and pumpkin pie spice. These blends, which are considered seasonings by consumers, are different from the industrial product called seasonings. Industrial seasonings contain one or more spices or spice extractives in addition to a number of other dissimilar ingredients such as acidulants, salts, sugars, monoglutamate, and ribonucleotides. Prepared by a specialized process called compounding, seasonings are used to enhance the flavor of food and improve its acceptance to consumers. They are added during the processing or manufacture of food and so are distinguished from condiments (e.g., mustard, catsup) which are also spice- or spice extractive-containing compounds but are added to the food after it is served. Industrial seasonings are widely used in meat products (e.g., bologna, frankfurthers, sausage), soups (e.g., French onion soup seasoning and mix), dry gravy mixes, instant sauces, and salad dressings.

II. THE VARIOUS SPICES AND HERBS AND THEIR BASIC INFORMATION

It is important to have some basic understanding about spices, as different names may be used for one particular spice in the same or different countries. It is not the intention of this chapter to list all the names for one spice. Interested readers should consult the references listed in the earlier section. (1 to 15).

Common and scientific names, plant family, botanical classification, and parts used in selected spices are presented in Table 89.1. Place of origin and current major sources of some common spices are presented in Table 89.2. The product forms and appearances of some common spices are presented in Table 89.3.

III. USES OF COMMON SPICES AND HERBS

As mentioned earlier, spices and herbs are used for various purposes. Table 89.4 summaries some of the basic

TABLE 89.1
Scientific Name, Plant Family, Botanical Classification, and Parts Used in Some Common Spices

Spice	Scientific Name	Plant Family	Growth Characteristics	Plant Part
Allspice	*Pimenta doica*	Myrtle	Evergreen	Berries
Anise seed	*Pimpineela anisum*	Parsley	Annual	Seeds
Basil	*Ochimum basilicum*	Mint	Annual	Leaves
Bay leaf	*Laurus nobilis*	Laurel	Evergreen	Leaves
Cassia	*Cinnamonum cassia*	Laurel	Evergreen	Inner bark
Caraway seed	*Carum carvi*	Parsley	Annual or biannual	Seeds
Cardamon	*Elettraia cardamomum*	Ginger	Perennial	Seeds
Celery seed	*Apium graveolens*	Parsley	Biannial or annual	Fruits
Chervil	*Anthriscus cerefolium*	Parsley	Annual	Leaves
Chives	*Appium schoenoprasum*	Onion	Perennial	Leaves
Cinnamon	*Cinnamomum zelancium*	Laurel	Evergreen	Inner bark
Clove	*Syzgium aromaticum*	Myrtle	Evergreen	Unopened flower buds
Coriander	*Coriandrum sativum*	Parsley	Annual	Fruits
Cumin seed	*Cumium cyminum*	Parsley	Annual	Ripe fruits
Dill seed	*Anethum graveciens*	Parsley	Annual	Seeds
Dill weed	*Anethum graveciens*	Parsley	Annual	Leaves
Fennel seed	*Foeniculum vulgare*	Parsley	Perennial	Seeds
Fenugreek	*Trigonella foenum-gracecum*	Bean	Annual	Fruit
Garlic, dehydrated	*Allium sativum*	Onion	Perennial	Bulbs
Ginger, dehydrated	*Zingiber officinale,* Roscoe	Ginger	Perennial	Rhizomes
Lemongrass	*Cymbopogon citratus*	Grass	Perennial	Stem and leaves
Lovage	*Laristicum efficuale*	Parsley	Annual	Stem and leaves
Mace	*Myristica fragans*	Nutmeg	Evergreen	Aril of seed
Marjoram, sweet	*Origanum majorana*	Mint	Perennial	Leaves
Mint, Peppermint (Black mint)	*Mentha piperita* variety *vulgaris*	Mint	Perennial	Leaves
Mint, Spearmint	*Mentha spicata*	Mint	Perennial	Leaves
Mustard seed, black	*Brassica hira* or *B. alba*	Cabbage	Annual	Seeds
Mustard seed, brown	*Brassica juncea*	Cabbage	Annual	Seeds
Mustard, white	*Brassica nigra*	Cabbage	Annual	Seeds
Nutmeg	*Myristica fragans*	Nutmeg	Evergreen	Seeds
Onion, dehydrated	*Allium cepa*	Onion	Biannial	Bulbs
Oregano	*Origanum spp.*	Mint	Perennial	Leaves
Paprika (pepper red)	*Capsicum annum*	Nightshade	Annual or perennial	Fruit pericarp
Parsley	*Petrosalinum crispum*	Parsley	Biannial	Leaves
Pepper, black	*Piper nigum*	Pepper	Perennial	Unripe berries or peppercorns
Pepper, chili	*Capsicum minimum*	Pepper	Annual or Perennial	Fruit
Pepper, red (Capsicum)	*Capsicum fructescens*	Nightshade	Perennial	Fruit pods
Pepper, white	*Piper nigum*	Pepper	Perennial	Skinless, ripe berries
Poppy seed	*Papaver somniferum*	Poppy	Annual, biannial, or perennial	Seeds
Rosemary	*Rosemarinus officinalis*	Mint	Perennial	Leaves
Saffron	*Crocus sativus*	Iris	Perennial	Stigma
Sage	*Salvia officinalis*	Mint	Perennial	Leaves
Savory, (sweet summer)	*Satureja indicum*	Mint	Annual	Leaves
Sesame seed	*Sesamum indicum*	Unicorn	Annual	Seeds
Star anise, Chinese	*Illicum vercum*	Illiciaceae	Perenial	Fruit
Tarragon	*Artemisia dracunculus*	Sunflower	Perennial	Flowering tops and leaves
Thyme	*Thymus vulgaricus*	Mint	Perennial	Leaves and flowering tops
Turmeric	*Curcuma longa*	Ginger	Perennial	Rhizomes
Vanilla	*Vanilla fragrans, V. planilfolia, or V. tahitensis*	Orchid	Perennial	Fruits

TABLE 89.2
Places of Origin and Current Major Sources of Some Common Spices

Spice	Places of Origin	Current Major Sources
Allspice	Western hemisphere	Carribean and Central America
Anise seed	Middle East	Turkey, Egypt, Syria, Spain, China, Mexico
Basil	Middle East	Egypt, U.S., France, Hungary, Bulgaria, India
Bay leaf	Mediterrian countries	Greece, Turkey
Caraway seed	Europe and Western Asia	Canada, The Netherlands, Egypt, Poland, Denmark
Cardamom	Southern India and Sri Lanka (Ceylon) Guatemala	Guatemala, India, Sri Lanka
Celery seed	Eurasia	India, China, France
Chervil	South Europe or Caucasus region	France, U.S.
Chives	Unknown, maybe Central Asia	Freshly grown
Cinnamon	China	China, Indonesia, Vietnam
Clove	Madagascar, Zanzibar, Pemba	Madagascar, Indonesia, Brazil, Zanzibar, Sri Lanka
Coriander	S. Europe, Asia Minor, S.W. Russia	Canada, Mexico, Morroco, Roumania, Argentina
Cumin seed	Egypt and Mediterrian region	Middle Eastern countries, India, Pakistan, Switzerland
Dill, seed	Mediterrain region	Canada, India, Indonesia
Dill weed	Mediterrain region	Canada, India, Indonesia
Fennel seed	Europe	Egypt, India, Turkey, Lebanon, China
Fenugreek (Foenugreek)	Southern Europe and parts of Asia	Southern Europe and parts of Asia
Garlic	Central Asia	U.S., China
Ginger dehydrated	China	India, Jamaica, Nigeria, China
Lemon grass	India	Tropical Asia
Lovage	Central Asia	South Europe
Mace	Moluccas Islands and East Indian Archipelago	East Indies, Indonesia, West Indies
Marjoram, sweet	Mediterrian region and Western Asia	Egypt, France
Mint, Peppermint	Central or Southern Europe	Egypt, Bulgaria, Yugoslavia
Mint, Spearmint	Central or Southern Europe	Egypt, Bulgaria, Yugoslavia
Mustard seed	Middle East	Canada, U.S., UK, Denmark
Nutmeg	Moluccas Islands and East Indian Archipelago	East Indies, Indonesia, West Indies
Onion	West or Central Asia	U.S.
Oregano	Mediterrian region	Turkey, Mexico, Greece
Paprika	Western hemisphere	U.S., Spain, Hungary, Morocco
Parsley	Mediterrian region	U.S., Israel, Hungary
Pepper, black	Malabar Coast of Southern India	Indonesia, India, Brazil, Malaysia
Pepper, red	Western hemisphere	Africa, China, India, Pakistan, Mexico
Pepper, white	Malabar Coast of Southern India	Indonesia, India, Brazil, Malaysia
Poppy seed	West Asia	Australia, Netherlands, Turkey, Rumania
Rosemary	Mediterrian region	Yugoslavia, Portugal, Spain, France
Saffron	Mediterrian region	Spain
Sage	Mediterrian region	Albania, Croatia, Germany, Italy, Macedonia, Turkey
Star anise	China	China
Savory, sweet (summer)	Southern Europe and Mediterrian region	Yugoslavia, France
Sesame seed	Tropical Africa	Mexica, Central America
Tarragon	Southern Russia, Asia	U.S., France, Yugoslavia
Thyme	Mediterrian region	Spain, France
Turmeric	Southern and Southeastern Asia	India, Jamaica, Haiti, Peru
Vanilla	Mexico, certain tropical South American countries	Bourbon Islands, Indonesia, Mexico, Tonga, Tahiti, Moorea

Source: References 1–14.

TABLE 89.3
Product Forms and Product Appearance of Some Common Spices

Spice	Product Forms (Dried)	Product Appearance (Dried)
Allspice	Whole and ground	Dark reddish-brown pea-sized fruit
Anise seed	Whole and ground	Greyish brown, oval-shaped and about 3/16 inches long
Basil	Bits of leaves and ground	Green leaves (bits)
Bay leaf	Whole and ground	Deep green leaves up to 3 inches long
Caraway seed	Whole only	Brown, hard seeds of 3/16 inches long
Cardamom	Whole pods (bleached and green), decorticated (seed alone), and ground	Irregularly round pod with seeds about 3/32 inches long
Celery seed	Light brown seeds up to 1/16 inches long	Whole, ground, and ground mixed with table salt (celery salt)
Celery flakes	Flakes, granulated, powdered	Light green dehydrated celery leaves
Chervil	Whole and ground	Small and smooth leaves
Chives	Whole only	Bright green, cross-cut section of leaves (Freeze-dried)
Cinnamon	Whole and ground	Brown bark
Clove	Whole and ground	Brown nail-shaped, 1/2 to 3/4 inches in length
Coriander	Whole and ground	Tan to light brown, globular with verticle ridges up to 3/16 inches in diameter
Cumin seed	Whole and ground	Yellow-brown seeds of 1/8 to 1/4 inches long
Dill, seed	Whole and ground	Light brown, oval shaped, up to 1/16 inches in length
Dill weed	Whole (bits of leaves)	Green leaves
Fennel seed	Whole and ground	Green, oblong-oval, straight or slightly curved, size varies up to 5/16 inches
Fenugreek seeds	Whole	Brownish yellow seeds
Garlic, dehydrated	Large sliced, chopped, minced, ground, granulated, powder; also powder or granulated with table salt (garlic salt)	Off white
Ginger dehydrated	Whole, cracked or ground	Even light biff hands or fingers
Mace	Whole or ground	Yellow-orange aril or skin
Marjoram, sweet	Whole (bits of leaves), and ground	Grey-green leaves
Mint, Peppermint	Flakes (broken dried leaves)	Pale green
Mint, Spearmint	Flakes (broken dried leaves)	Pale green
Mustard seed, black	Whole, mustard flour and ground	Black seeds
Mustard seed, brown	Whole, mustard flour and ground	Brown seeds
Mustard, white	Whole, mustard flour and ground	White seeds
Nutmeg	Whole, ground	Greyish-brown, oval fruit size up to 1 1/4 inches in length
Onion, dehydrated	Sliced, chopped, diced, minced, ground, granulated, powdered, toasted (all sizes), powder or granulated onion with table salt (onion salt)	Off white
Oregano	Whole (bits of leaves) and ground	Light green with size about 1/8 inches long
Paprika	Powder	Bright rich red stemless pods
Parsley	Flakes of dried leaves	Green leaves
Pepper, black	Whole, ground, cracked, decorticated	Black seeds
Pepper, red	Whole and ground	Various sized red-colored pods
Pepper, white	Whole and ground	White seeds
Poppy seed	Whole	Bluish grey to black, kidney-shaped seeds about 3/64 inches long
Rosemary	Whole and ground	Brownish-green needles less than 1 inch in length
Saffron	Whole and ground	Orange-yellow stigma
Sage	Whole, cut, rubbed and ground	Silver-grey leaves
Savory, sweet (summer)	Whole (bits of leaves) and ground	Brown-green leaves less than 3/8 inched in length
Sesame seed	Whole (unhulled and hulled)	White, oval-shaped, shiny seeds about 1/8 inch long
Tarragon	Whole (bits of leaves) and ground	Dark green, narrow with small round tips, about 5 cm long
Thyme	Whole (bits of leaves) and ground	Brownish-green leaves seldom exceed 1/4 inch long
Turmeric	Ground	Dark yellow
Vanilla	Whole beans, powder, extract	Dark brown

TABLE 89.4
Basic Uses of Selected Spices in Food Preparation

Basic Use	Selected Spices
Flavoring	
Sweet	Cardamon, anise, star anise, fennel, allspice, cinnamon
Sour	Tamarind
Bitter	Fenugreek, mace, clove, thyme, bay leaf, oregano, celery
Spicy	Clove, cumin, coriander, ginger
Hot	Chili pepper, mustard, black pepper, white pepper, wasabi
Pungent	Pungent, wasabi, ginger, garlic, onion
Fruity	Fennel, coriander, root, tamarind, star anise
Floral aromatic	Lemongrass, sweet basil, turmeric, ginger, black pepper
Woody	Cassia, cardamom, clove
Piney	Rosemary, thyme, bayleaf
Cooling	Peppermint, basil, anise, fennel
Earthy	Saffron, turmeric, black cumin
Herbaceous	Parsley, rosemary, tarragon, sage, dillweed
Sulfury	Onion, garlic, chives
Nutty	Sesame, poppy seeds, mustard seeds
Texture	Garlic, mustard, onion, sesame seed, shallot
Masking/ Deodoring	Garlic, clove, rosemary, onion, bayleaf, thyme, sage, coriander, caraway, oregano
Colorant	
Water-soluble	Saffron, annatto
Oil-soluble	Paprika, turmeric, parsley, basil

uses of selected spices and herbs in food preparations. Spices and herbs are used mainly for flavoring purposes, and to a less extent in coloring foods and providing texture to the final product. Occasionally, spices are used to mask or deodorize food products as the odor of some spices are fairly strong and definitely can serve these purposes.

Spices and herbs are used for special purposes, and there is not one spice or herb that can be used in all food preparations. Consumers learned long ago that certain spices and herbs are more suitable for some food groups than others. Table 89.5 presents the flavor characteristics of some common spices and their applications. Table 89.6 gives some typical components in some common spice mixtures or blends. It should be noted that the percentage of each spice in a spice mixture or blend is proprietary to the spice producer except in special cases such as the US military standard that specifies some minimum content for each spice. Readers interested in this information should consult the US Military Specification EE-S-631J and Reference 9 for general proportions of some spice mixtures and blends.

Consumers in various cultures learned long time ago that selected spice and/or herb combinations from spices available in their regions provide special flavor characteristics. This consumer preference has developed into typical flavors of various cultures. Table 89.7 gives a comparison of basic sensory characteristics of some common spices

TABLE 89.5
Flavor Characteristics and Commercial Applications of Some Common Spices

Spice	Flavor Characteristics	Commerical Applications
Allspice (Pimento)	Warm, sweet and slightly peppery, reminiscent of clove	In almost all meats, sausages, pickles and sauces
Anise seed	Taste and aroma similar to licorice	In fish, shellfish, baked goods
Basil	Mild, sweet, and slightly pungent	In potato dishes, soups, processed meats, tomato sauce
Bay leaf	Warm, spicy, and somewhat bitter	In pickles, soups, fish and vegetable dishes
Caraway seed	Warm, slightly sweet with a slightly sharp after-tone	In cheese products, confectionery, meat stews and pork dishes
Cardamom	Bitter-sweet, aromatic with slight lemony back note	Primarily in curries, pickles and sauces
Cassia	Sweet spicy and distinctve	In spiced confectionery, curries, tomato sauce and to a limitd extent in meat dishes
Celery seed	Powerfully warm with bitter after-flavor	In clam, potato, or other creamy soups and some cheese dressings
Chervil	Sweet and aromatic	In soups, salad and fish dish
Chives	Similar to onion, but less dominant but more subtle	In soups, vegetable stews, egg- or yogurt- based sauces
Cinnamon	Sweet spicy and distinctive	In spiced confectionery, apple products, wines, pickles, and beef and game casseroles. Can mask other flavors if used in excess
Clove	Very aromatic, warm and astringent	In hams, tongue and pork products, pickled and preserved fruits and vegetables, apple dishes, pudding mixes and cream soup
Coriander	Mild and pleasantly aromatic	In pickles, pea soup, cakes and biscuits, various meat stuffings and apple products
Cumin seed	Salty sweet, similar but coarser than that of caraway, bitter after taste	Basic ingredient of curries, cream cheese, processed meats, pickled cabbage and certain fish products
Dill, fruit and seed	Penetrating sharply aromatic flavor similar to that of carraway but with fresher lemony note	In pickles, sauces, confectonery, soups and chicken dishes
Dill weed	Fresh sweet spicy having a slight anise-like back-note	In pickles and sauces
Fennel seed	Strong and penetrating but fragnant	In sweet pickles, fish dishes, confectionery, and as a sauce to pork dishes

(*Continued*)

TABLE 89.5
(*Continued*)

Spice	Flavor Characteristics	Commerical Applications
Fenugreek	Intensely sweet, spicy and caramel-like	In chutneys, pickles and sauces
Garlic, dehydrated	Strong and characteristic	With care in most types of product
Ginger dehydrated	Aromatic, hot, and biting	In biscuits, spice cakes, preserved fruits, chutneys, most meat and seafod products, pickles, and wines
Lemon grass	Fresh and lemon like	In meat dishes
Lovage	Strong nad characteristic, reminiscent of celery	In meat dishes, soups, and sauces
Mace	Finer than but similar to that of nutmeg	In pickles, fruit cakes, gingerbread, processed meat loaf, sausages, and mincemeat
Marjoram, sweet	Distinctive, delicately sweet and spicy with a slightly bitter back note	In most meat dishes, soups, and stuffings
Mint, Peppermint	Quite characteristic, sweet with a cool aftertaste	In canned and frozen peas, soups, lamb, mutton, and veal products, and mint sauce
Mint, Spearmint	Quite characteristic, sweet with a cool aftertaste	In canned and frozen peas, soups, lamb, mutton, and veal products, and mint sauce
Mushroom, Boletus	Characteristic and slightly meaty	In soups and certain meat dishes
Mustard seed, black	No fragrance, but exhibit a pungent taste after chewing	Pungency destroyed during cooking
Mustard seed, brown	No fragrance, but exhibit a pungent taste after chewing	Pungency destroyed during cooking
Mustard, white	No fragrance, but exhibit a pungent taste after chewing	Used as a paste for its pungency
Nutmeg	Sweet and aromatic, adding a certain richness to spice mixes	In spiced confectionery, biscuits, and many meat products
Onion, dehydrated	Characteristic and penetrating	In many dishes requiring an onion flavor
Oregano	Strong, distinctive with bitter after flavor	In spaghetti products, canned pork dishes, cheese spreads, soups, and sauces
Paprika (red pepper)	Piquant and moderately pungent	In all foods to give added zest
Paprika, Rosen	Characteristic and stronger than normal Paprika with a definite pungency	In many specialty meat products
Parsley	Mild and agreeable	In soups, fish and poultry products, and many meat dishes
Pepper	Penetrating, strong, and characteristic	In almost all dishes a small quantity improves the overall flavor
Pepper, Chile	Intense pungent	Used with discretion in any product requiring heat
Pepper, Red	Hot and pungent	Used with discretion in any product requiring heat
Poppy seed	Nutty and pleasant	In baked products and confectionery
Rosemary	Distinctive, delicate and sweet, with a piney slightly bitter aftertaste	In lamb and certain other meat products, cheese sauces, stuffings, and soups
Saffron	Distinctive flavor	Used mainly to color food golden yellow
Sage, Dalmatian	Strongly aromatic, warm with slightly bitter aftertaste	With care in all pork dishes, fish and poultry stuffings, cream soups, cheese, and sauces
Sage, English	A milder and much pleasanter flavor than that of Dalmatian sage, lacks the objectionable “thujone” note	With care in all pork dishes, fish and poultry stuffings, cream soups, cheese, and sauces
Savory, sweet (summer)	Strongly aromatic	With vegetables, legumes, and in mixtures for sausages, pates, or pickles
Sesame seed	Unroasted seeds have mild flavor, but oil from roasted seeds gives strong distinctive flavor	Can be used in seasoning almost any kind of food
Star anise	Warm, sweet, aromatic	In meat dishes, also as a component for Chinese five spices
Tarragon	Distinctive sweetly aromatic with a bitter undertone	In poultry and fish sauces, pickles, and spiced vinegar, and in small quantities in certain meat products
Thyme	Penetratingly warm and pungent, the aroma is long lasting	In tomato products, stuffings, fish dishes, soups, and many other meat dishes
Turmeric	Warmly aromatic with musky undertones	In pickles, relishes, prepared dressings, and to color a wide range of products, in particular curries
Vanilla	Rich, mellow perfumed, tobacco-like aroma	Chocolate, coffee, pudding, ice cream, in dishes such as those made with veal and lobster

TABLE 89.6
Components in Some Common Spice Mixtures or Blends

Name of Mixture (Blend)	Components
Apple pie spice	Cinnamon, cloves, nutmeg or mace, all spice, ginger
Barbecue spice	Chili, peppers, cumin, garlic, cloves, paprika, salt, sugar
BBQ seasoning in chips	*Main:* Onion, garlic, chili pepper, paprika
	Optional: Celery, cumin, cloves, all spice, cinnamon, black pepper, red pepper
Bologna or weiner seasoning	Pimento, nutmeg, black pepper, clove leaf or stem, capsicum, paprika, coriander, cassia, mustard, onion, garlic
Chicken-flavored gravy	Turmeric, celery seed, black pepper, onion, garlic, other spices
Chili powder	Chili pepper, cumin, seed, oregano, garlic, salt
Five spices, Chinese	Black pepper, star anise or anise, fennel, clove, cinnamon
Cinnamon spice	Cinnamon, sugar
Crab boil or shrimp spice	Peppercorns, bay leaves, red peppers, mustard seed, ginger, and other spices
Curry powder (dry masalas)	*Mandatory*: Coriander, cumin, fenugreek, turmeric (yellow coloring)
	Optional: Cardamom, cinnamon, cloves, nutmeg, onion, garlic, poppy seeds, sesame seeds, basil, bay leaves, dill seeds, hot chilies, saffron, black pepper, kiffer lime
Curry paste (wet masalas)	*Main ingredients*: Same as curry powder
	Additional: Coconut milk, yogurt, clarified butter (ghee), mang, cilantro, and tamarind accents
Ham	Cassia, clove stem or leaf, pimento, capsicum, celery, bay leaf, garlic
Herb seasoning	Milder-flavored herbs such as marjoram, oregano, basil, chevil, etc., salt
Hot and spicy seasoning	Chili pepper, red pepper, black pepper, onion, garlic, paprika, capsicum
Italian sausage seasoning	Anise, fennel, paprika, black pepper, red pepper
Italian seasoning	Oregano, basil, red pepper, rosemary, garlic (optional)
Japanese seven spices	Perilla, basil, sesame, poppy seed, hemp, red pepper, Japanese pepper
Marinara-type tomato sauce	Garlic, onion, oregano, basil, parsley
Mixed pickling spice	Mustard seeds, bay leaves, black and white peppercorns, dill seeds, red peppers, ginger, cinnamon, mace, all spice, coriander seeds, etc.
Pork sausage seasoning	Sage, black pepper, red pepper, nutmeg
Poultry seasoning	Sage, thyme, marjoram, savory, rosemary (optional)
Pumpkin pie spice	Cinnamon, nutmeg, cloves, ginger
Ranch tortilla chips	Onion, garlic, parsley, paprika
Roast beef or corned beef rub	Corriander, onion, garlic, celery, oregano, basil, black pepper, paprika
Seafood seasoning	Similar to crab boil and shrimp seasoning, plus salt
Seasoned or flavored salts	Salts with different dehydrated vegetables and spices, e.g., celery salt (celery and salt), garlic salt (garlic and salt), onion salt (onion and salt)
Smoked sausage seasoning	Garlic powder, black pepper, coriander, pimento

Source: References 2, 6–9, 11, 14–15, 18–21.

with cultural differences. It should be noted that the flavor characteristics described in one culture may not be the same in another culture. Table 89.8 shows some ethnic usage of spices and herbs; and each culture has its own characteristic spice(s). Usually, spices and herbs not available in a region are not used commonly there.

In 1993, Nakamasa (22) in Japan proposed the "patterning theory" to describe the relationship of spices to cooking ingredients and techniques. This "patterning theory" of spice use considers the suitability of a spice and certain raw materials to be the result of a "synthesis" that occurs in the mouth. A preference for a specific spice is determined by individual judgement, and the suitability of any spice and any other ingredients is based on individual preference. Flavor preference is evaluated using the senses of taste and smell. If a spice and an ingredient tasted together are well received, it follows that these two can be combined in cooking. This "patterning theory" can be considered as a scientific description of the relationship of spice combinations and consumer patterns in various cultures. Readers interested in this topic should consult References 18 and 23.

Consumers prefer certain spices because these spices contain certain compounds typical of their flavor characteristics, mainly in their essential oils. Principal constituents in common spices are presented in Table 89.9. It should be noted that spices from the same family usually contain some similar flavor compounds.

In the past 20 years, researchers recognized that people sensitive to sodium should reduce their intake of salt (sodium chloride) in order to reduce the risk of hypertension. However, reduction in the use of common salt in most cases makes food bland. It is suggested that these

TABLE 89.7
Comparison of Basic Sensory Characteristics of Some Common Spices

Spice	Basic Sensory Characteristics	Indian	Chinese
Allspice	Sweet	Not commonly used	Not commonly used
Anise seed	Sweet cooling	Anise	Not commonly used
Basil	Floral aromatic	Not commonly used	Pungent
Bay leaf	Bitter	Bitter	Not commonly used
Cassia	Woody, sweet	Not commonly used	Pungent, sweet
Caraway seed	Warm and slightly sweet	Not commonly used	Slightly pungent
Cardamon	Sweet	Sweet	Not commonly used
Celery seed	Bitter	Not commonly used	Not commonly used
Chervil	Floral aromatic	Not commonly used	Not commonly used
Chives	Sulfury	Not commonly used	Not commonly used
Cinnamon	Woody, sweet	Bitter	Pungent, sweet
Clove	Bitter	Bitter	Pungent
Coriander	Spicy	Sweet	Pungent
Cumin seed	Spicy	Sweet	Pungent
Dill, seed	Herbaceous	Not commonly used	Pungent
Fennel seed	Sweet	Sweet	Pungent
Fenugreek	Bitter	Bitter/stringent	Not commonly used
Garlic, dehydrated	Pungent, spicy	Spicy/pungent	Pungent
Ginger, dehydrated	Spicy	Spicy/pungent	Pungent
Lemongrass	Floral aromatic	Not commonly used	Not commonly used
Licorice	Sweet	Astringent	Sweet
Mace	Bitter	Not commonly used	Not commonly used
Marjoram, sweet	Sweet	Not commonly used	Pungent
Mint, Peppermint (black mint)	Cooling	Not commonly used	Pungent
Mint, Spearmint	*Mentha spicata*	Not commonly used	Pungent, sweet
Mustard seed	Hot, pungent, nutty	Spicy/pungent	Not commonly used
Mustard powder, white	Pungent	Not commonly used	Warm
Nutmeg	Bitter	Not commonly used	Pungent
Onion, dehydrated	Pungent	Spicy/pungent	Not commonly used
Oregano (wild marjoram)	Bitter	Not commonly used	Not commonly used
Paprika (Pepper red)	Hot	Not commonly used	Not commonly used
Parsley	Herbaceous	Not commonly used	Not commonly used
Pepper, black	Hot	Spicy/pungent	Pungent
Pepper, Chili	Hot	Spicy/pungent	Pungent
Pepper, red (Capsicum)	Hot	Not commonly used	Not commonly used
Pepper, White	Hot	Not commonly used	Not commonly used
Poppy seed	Nutty	Not commonly used	Not commonly used
Rosemary	Piney	Not commonly used	Pungent
Saffron	Earthy	Not commonly used	Sweet
Sage	Herbaceous	Not commonly used	Not commonly used
Savory, sweet (summer)	Fruity	Not commonly used	Not commonly used
Sesame seed	Nutty	Not commonly used	Not commonly used
Star anise, Chinese	Fruity	Not commonly used	Pungent, sweet
Tamarind	Sweet–Sour	Sour	Not commonly used
Tarragon	Herbaceous	Not commonly used	Not commonly used
Thyme	Bitter	Not commonly used	Not commonly used
Turmeric	Earthy	Bitter	Not commonly used

Source: References 1–15, 18, 22.

consumers can consider the addition of spice(s) and/or herb(s) in their foods to increase their acceptance. Some spice companies provide free information to consumers about low sodium spice combinations. For example, McCormick/Schilling Company recommends the combination of several spices for a few food groups in their Low Sodium Spice and Herb Chart. Table 89.10 shows examples of three low sodium herb blends.

TABLE 89.8
Some Ethnic Usage of Spices and Herbs

Culture	Commonly Used Spices and Herbs
Chinese	Anise, cinnamon, clove, fennel seed, garlic, onion, red pepper, star anise
French	Black pepper, fine herbs, marjoram, rosemary, shallot, tarragon, thyme
German	Caraway seeds, dill seeds, ginger, nutmeg, onion, paprika, rosemary, white pepper
Greek	Bay leaves, black peppper, cinnamon, fennel seed, garlic, onion, oregano, dill, basil, thyme, fennel seed
Hungarian	Caraway seeds, cinnnamon, dill seeds, garlic, onion, paprika, poppy seeds, white pepper
Indian (Eastern)	Black pepper, coriander, cumin seed, curry, ginger, red pepper, tumeric, cardamom, fenugreek, celery, cinnamon, clove, nutmeg
Indonesian	Caraway seeds, cinnamon, clove, curry, garlic, ginger, nutmeg, red pepper
Italian	Basil, fennel seeds, garlic, marjoram, onion, oregano, red pepper, sage, thyme, anise, rosemary, black pepper
Jamaican	All spice, garlic, red pepper, red pepper, thyme, onion, oregano
Mexican	Chili pepper, cinnamon, coriander, garlic, onion, oregano, sesame seeds, cumin seeds, cilantro, red pepper, bay leaves, all spices, cloves, anise
Morracan	Anise, cinnamon, coriander, cumin seeds, mint, red pepper, saffron
Southwestern U.S.	Garlic, onion, chili pepper, oregano, cilantro, cumin, cinnamon, clove
Spanish	Bay leaves, cumin seeds, garlic, onion, paprika, parsley, saffron, sweet pepper, thyme, basil, hot pepper, innamon, nutmeg
Spanish Carribean (Puerto Rican, Cuban)	Garlic, cumin, oregano, bay leaves, onion, cloves, nutmeg, ginger, thyme, cilantro, cayenne, cinnamon, black pepper, turmeric, paprika
Thai	Curry paste (red and green), coriander, cilantro, coriander root, garlic, ginger, lemon grass, basil, mint, black, white, and red peppers, cinnamon, cloves, cardamom, kiffer lime, garlanga
Vietnamese	Chilies, garlic, lemon grass, cilantro, basil, ginger, turmeric, red, white, and black pepper, curry powder, five spice powder, cloves, star anise, galangal

TABLE 89.9
Principal Constituents in Some Common Spices

Spice	% Essential Oil (Range)	Principal Constituents in Essential Oil	Significant Constituents in Oleoresin
Allspice	3.3 to 4.5	Eugenol (60–75%), eugenol methyl ether, cineole, phellandrene, caryophylene	None
Anise seed	1.5 to 3.5	Anethole (major), anisaldehyde, anisketone, methyl chavicol	None
Basil	0.1 to 1.0	Methyl chavicol (estragole), linalool, cineols	None
Bay leaf	1.5 to 2.5	Cineole	None
Caraway seed	1.5 to 3.5	Carvone (major), limonene, dihydrocarvone, dihydrocarvone, dihydrocarveol, acetaldehyde methyl alcohol, furfural, and diacetyl	None
Cardamom	2 to 10	Cineole, alpha-terpinyl acetate, liminone, linalyl linalool, borneol, alpha-terpineol, alpha-pinene, limonene, myracene	None
Celery seed	1.5 to 3	*d*-Limonene, *beta*-selinene	None
Chervil	0.3 to 0.9	Methylcharviol (estragol), hendecane (undecane)	None
Chives	??	Dipropyl disulfide, methyl pentyl disulfide, penthanethiol, pentyl-hydrodisulfide, *cis/trans*-trans-3,5,-diethyl-1,2,4 trithiolane	None
Cinnamon	1.5 to 3.0	Eugenol (clovelike flavor), cinnamic aldehyde (cinnamonlike flavor)	None
Clove	Up to 20%	Eugenol, eugenol acetate, beta-caryophyllene	None
Coriander	0.1 to 1.5	*d*-Linalool (coriandrol), Pinenes, terpinenes, geranol, vorneal, decylaldehyde	None
Cumin seed	2 to 5	Cumaldehyde (cumic aldehyde), dihydrocumaldehyde, ciminyl alcohol, *dl*-pinene, *p*-cumene, diterpene	None
Dill seed	2 to 5	Carvone, *d*-limonene, phellandrene, eugenol, vanillin	None

(*Continued*)

TABLE 89.9
(*Continued*)

Spice	% Essential Oil (Range)	Principal Constituents in Essential Oil	Significant Constituents in Oleoresin
Dill weed	0.3 to 1.5	Carvone, methyl 2-methylbutanoate, alpha-phyllandrene, dill ether, myristicin	None
Fennel seed	1 to 3	Anethole, *d*-fenchone, *d*-alpha-pinene, *d*-alpha-phlladrene, dipentene, methyl chavicol, feniculun, anisaldehyde, anisic acid	None
Fenugreek	Trace	None	Trigonelline, choline
Ginger	??	Gingerols (pungency)	Zingerone, shogoals
Ginger dehydrated	1.5 to 3.0	(−)-alpha — zingiberene, (−)-*beta*-bisabolene, (+)-ar-curcumene (ginger flavor), farnesene, *beta*-sequiphellandrene (ginger flavor), alpha-terpineol (lemony flavor), citral (lemony flavor)	None
Lemon grass	0.2 to 0.5	Citral, nerol, limonene, β-caryphyllene	None
Mace	15 to 25	*Alpha*-pienene, *Beta*-pinene, sabinene, myristicin (main flavor)	None
Marjoram, sweet	0.7 to 3	Terpen-4-ol, *alpha*-terpineol	None
Mint, Peppermint (dried leaves)	2.5	Menthol, menthone and their methyl esters, pulegone, piperitone, methofurane, jasmone	None
Mint, Spearmint	2.5	Carvone, liminene, dihydrocarvone, methone, pulegone, 1,8-cineol, β-pinene	None
Mustard seed, black	0.6 (av.)	Allyisothiocyanate	None
Mustard seed, yellow	None	None	Sinabin mustard oil (pungent)
Nutmeg	6 to 15	*Alpha*-pienene, *Beta*-pinene, sabinene, myristicin (main flavor)	None
Onion, dehydrated	Trace	Ethyl and propyl disulfides, vinyl sulfide	None
Oregano (wild marjarom)	ca. 2	Thymol, carvacol	None
Paprika	None	None	Capsanthin, carotene, capsorubin (pigments)
Parsley	0.05	Myristian, limonene, 1,3,8-*p*-methatriene	None
Pepper, black	0.6 to 2.6	*alpha*-pinene, *beta*-pinene, 1-*alpha*-pellandrene, *beta*-caryophyllene, limonene, sabine-delta-3-carene pungency: piperine, piperettine, peperyline, piperolein A and B, piperanine	None
Pepper, red		Capsaicin, Dihydrocapsaicin	None
Pepper, white	1.0 to 3.0	*alpha*-pinene, *beta*-pinene, 1-*alpha*-pellandrene, *beta*-caryophyllene, limonene, sabine-delta-3-carene pungency: piperine, piperettine, peperyline, piperolein A and B, piperanine	None
Poppy seed	N/A	2-pentylfuran	None
Rosemary	0.5 to 2.0	*Alpha*-pinene, *d*-pinene, camphene	None
Saffron	<1	None	Crocin (coloring agent) picrocrocin (bitter flavor)
Sage	1.5 to 2.5	Thujone, borneol, cineole	None
Savory, sweet (summer)	<1	Carvacrol, thymol, *p*-cymene	None
Sesame seed	N/A	Pyrazines (in toasted seeds)	Sesamin, sesamolin
Star anise	5 to 8	Anethol	None
Tarragon	0.2 to 1.5	Methyl chavicol (estragole), anethole (anise or licorcelike tone), ocimene, phellandrene, *p*-methoxy-cinnamaldhyde	None
Thyme	0.8 to 2.0	Thymol, *p*-cymene, *d*-linalool	None
Turmeric	1.5 to 6	Turmerone, *ar*-turmerone (dehydroturmerone)	Curcumin, desmethoxy-curcumin, bis-desmethoxy-curcumin (pigments)
Vanilla	2 to 2.5	Vanillin	None

TABLE 89.10
Examples of Low Sodium Herb Blends

Blend	Usage	Spices Used	Quantity Ratio
A	For salads or salt shakers	Thyme leaves	2 teaspoons
		Basil leaves	2 teaspoons
		Ground savory	2 teaspoons
		Marjoram leaves	1 tablespoon
		Rubbed sage	2 teaspoons
B	For soups, stews, poultry, or pot roast	Thyme leaves	1 tablespoon
		Rubbed sage	1 teaspoon
		Majoram leaves	2 tablespoons
		Rosemary leaves	1 tablespoon
C	For beef, cooked vegetables and added seasoning at table	Celery seed	1 teaspoon
		Majoram leaves	1 tablespoon
		Thyme leaves	1 tablespoon
		Basil leaves	1 tablespoon

IV. SPICE QUALITY STANDARDS AND SPECIFICATIONS

It is generally accepted that spice quality differs year to year, and from country to country. In addition, spices are produced in various countries in the world and then exported to spice-consuming countries. Also, the same spice may be produced in different countries (24–26). It is therefore deemed necessary to have unified spice standards or specifications for exporting and importing countries in order to make international trade easier. However, there are no unified standards or specifications worldwide for spices. Each country has its own importing or domestic spice standards or specifications to meet its own needs. The quality standards most used are those of the ASTA and the U.S. federal specifications: spices, ground and whole, and spice blends. U.S.-FDA also has an import procedure for spices. Readers interested in this topic should visit FDA's website (http://www.*fda.gov/ora/import/oasis/home*) for details. ISO also has its own established standards. However, exporting nations usually have their own exporting spice standards or specifications to guarantee that their products meet certain quality standards, which in turn usually follow the quality standards or specifications of the importing countries. Although differences from country to country may exist, most spice standards or specifications of importing nations emphasize the following:

- Cleanliness of the spice products (placing limits on the extraneous matters, see section below on US-FA Defective Action Limits)
- Microbial content
- Extraneous matters (such as rodent hair, insect fragments, and mammalian excreta)
- Specific chemical components or sensory potency for selected spices
- Chemical residues (such as pesticides, sterilant gas residues, heavy metal residues, solvent residues, and mycotoxins)
- Moisture content
- Volatile oil content

A. Extraneous Matters

Many spices are produced in Third World countries where production and handling practices differ from those that are used in developed or important countries. These differences resulted in the presence of extraneous matters that are undesirable but sometimes unavoidable. Even spices produced in developed countries may have unavoidable problems. The ASTA published its own "Cleanliness Specifications for Spice, Seeds, and Herbs, Revised Edition, 1999" which can be purchased for reference. U.S.-FDA has established its own standards for cleanliness of spices (such as limits on rodent hair, insect fragments, mammalian excreta, and mold) that are included in its document on "Defective Action Levels (DALs)." Table 89.11 is a summary of DALs for spices.

Spice processors also remove extraneous matters such as metallic pieces, stones, mud balls, other plant materials and foreign matter through their processing lines which may include magnets, sifters, air tables, destoners, sir separators, indent separators, and spiral separators. This extraneous matter should be excluded in the final spice products through processing.

Presence of undesirable bacteria and live insects in spices has been a problem in the spice trade for many decades. Various procedures such as gas fumigation, irradiation, steam treatment, and carbon dioxide/nitrogen treatment are available to overcome the presence of undesirable bacteria and insects. Table 89.12 presents a comparison of various procedures available in reducing bacteria in spices, and their advantages and disadvantages. It should be noted that individual countries have their own regulations on which procedure can be used. For example, irradiation can be used in the U.S., but is not permitted in Japan and many European countries. Live insects can easily be eliminated by carbon dioxide or fumigation treatment. However, care and proper storage precautions must be taken to avoid re-infestation of processed products and growth and development of mold and yeast.

B. Specific Tests for Quality Comparison of Selected Spices

Spices are complex biological materials, and their compositions vary according to production environment. Comparison of quality of spices still relies mainly on sensory evaluation and their volatile content. Even though

TABLE 89.11
Defective Action Levels of Spices

Spice	Defective Action Level (Average)	Direct Source	Significance
Allspice, ground	Insect filth: 30 or more insect fragments per 10 gm	Insect fragment: Pre/post harvest and processing insect infestation	Aesthetic
	Rodent filth: 1 or more rodent hairs per 10 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Allspice, whole	Mold: 5% or more berries by weight are moldy	Mold: Preharvest and/or post harvest infection	Potential health hazard — mold may contain mycotoxin producing fungi
Bay (Laurel) leaves	Mold: 5% or more pieces by weight are moldy	Mold: preharvest infection	Aesthetic
	Insect filth: 5% or more pieces by weight are insect-infested	Insect infestation: preharvest and/or post harvest and/or processing insect infestation	
	Mammalian excreta: 1 mg or more of mammalian excreta per lb after processing	Mammalian excreta: post harvest and/or processing animal contamination	
Capsicum pods	Insect filth and/or mold: more than 3% of pods weight are insect-infested and/or moldy	Insect infestation: preharvested and/or post harvest insect infestation	Aesthetic
	Mammalian excreta: more than 1 mg of mammalian excreta per lb	Mold — preharvest and/or post harvest infection	Potential health hazard — mold may contain mycotoxin producing fungi
		Mammalian excreta: post harvest and/or processing animal contamination	
Capsicum, ground (excluding paprika)	Mold: mold count is more than 20%	Mold: preharvest and/or post harvest mold infection	Aesthetic
	Insect filth: more than 50 insect fragments per 25 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Potential health hazard — mold may contain mycotoxin producing fungi
	Rodent filth: more than 6 rodent hairs per 25 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Cassia (or) cinnamon bark, whole	Mold: 5% or more pieces by weight are moldy	Mold: preharvest infection	Aesthetic
	Insect filth: 5% or more pieces by weight are insect-infested	Insect infestation: preharvest and/or post harvest and/or processing insect infestation	
	Mammalian excreta: 1 mg or more of mammalian excreta per lb	Mammalian excreta: post harvest and/or processing animal contamination	
Cinnamon, ground	Insect filth: 400 or more insect fragments per 50 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: 11 or more rodent hairs per 50 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Cloves	Stem: 5% or more stems by weight	Stem: Harvest	Aesthetic, economic adulteration
Condimental seeds other than fennel seeds and sesame seeds	Mammalian excreta: 3 mg or more of mammalian excreta per lb	Mammalian excreta: post harvest and/or processing animal contamination	Aesthetic
Cumin seed	Sand and grit: 9.5% or more ash and/or 1.5% or more acid insoluble ash	Sand and grit: harvest contamination	Aesthetic

(*Continued*)

TABLE 89.11
(*Continued*)

Spice	Defective Action Level (Average)	Direct Source	Significance
Curry powder	Insect filth: 100 or more insect fragments per 25 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: 4 or more rodent hairs per 25 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Fennel seed	Insects: 20% or more subsamples containing insects	Insects: pre-harvest and/or post harvest insect infestation	Aesthetic
	Mammalian excreta: 3 mg or more of mammalian excreta per lb	Mammalian excreta: post harvest and/or processing animal contamination	
Ginger, whole	Insect filth and/or mold: 3% or more by weight are insect-infested and/or moldy	Insect infestation: preharvest and/or post harvest and/or processing	Aesthetic
		Mold: post harvest and/or processing infection	Potential health hazard — mold may contain mycotoxin producing fungi
	Mammalian excreta: 3 mg or more of mammalian excreta per lb	Mammalian excreta: post harvest and/or processing animal contamination	
Mace	Insect filth and/or mold: 3% or more by weight are insect-infested and/or moldy	Insect infestation: preharvest and/or post harvest and/or processing	Aesthetic
	Mammalian excreta: 3 mg or more of mammalian excreta per lb	Mold: post harvest and/or processing infection	
		Mammalian excreta: post harvest and/or processing animal contamination	
	Foreign matter: 1.5% or more of foreign matter through a 20-mesh sieve	Foreign matter: post harvest contamination	
Marjorum, whole plant, unprocessed	Insect filth and/or mold: 3% or more by weight are insect-infested and/or moldy	Insect infestation: preharvest and/or post harvest and/or processing	Aesthetic
	Mammalian excreta: 1 mg or more of mammalian excreta per lb	Mold: post harvest and/or processing infection	
		Mammalian excreta: post harvest and/or processing animal contamination	
Marjoram, ground	Insect filth: 1175 or more insect fragments per 10 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: 8 or more rodent hairs per 10 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Marjoram, unground	Insect filth: 250 or more insect fragments per 10 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: 2 or more rodent hairs per 10 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Nutmeg, whole	Insect filth and/or mold: 10% or more by weight are insect-infested and/or moldy	Insect infestation: preharvest and/or post harvest and/or processing	Aesthetic
		Mold: preharvest and/or post harvest infection	Potential health hazard — mold may contain mycotoxin producing fungi
Nutmeg, ground	Insect filth: 100 or more insect fragments per 10 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: 1 or more rodent hairs per 10 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	

Oregano, whole plant, unprocessed	Insect filth and/or mold weight: 5% or more insect infested and/or moldy pieces by weight	Insect infestation: preharvest and/or post harvest and/or processing Mold: post harvest and/or processing infection	Aesthetic
	Mammalian excreta: 1 mg or more of mammalian excreta per lb	Mammalian excreta: post harvest and/or processing animal contamination	
Oregano, ground	Insect filth: 1250 or more insect fragments per 10 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: 5 or more rodent hairs per 10 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Oregano, crushed	Insect filth: 300 or more insect fragments per 10 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: 2 or more rodent hairs per 10 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Paprika, ground	Mold: mold count is more than 20% Insect filth: more than 75 insect fragments per 25 gm	Mold: preharvest and/or post harvest infection Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: more than 11 rodent hairs per 25 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Pepper, whole (black or white)	Insect filth and/or insect-mold: 1% or more pieces by weight are infested and/or moldy	Insect infestation: preharvest and/or post harvest and/or processing Mold: preharvest and/or post harvest infection	Aesthetic Potential health hazard — mammalian encreta contain Salmonella
	Mammalian excreta: 1 mg or more of mammalian excreta per lb	Mammalian excreta: post harvest and/or processing animal contamination	
	Foreign matter: 1% or more of pickings and siftings by weight	Foreign matter: post harvest contamination	
Pepper, ground	Insect filth: more than 475 insect fragments per 50 gm	Insect fragments: pre-harvest and/or post harvest and/or processing insect infestation	Aesthetic
	Rodent filth: 2 or more rodent hairs per 50 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Sage, whole plant, unprocessed	Insect filth: 5% or more pieces by weight are infested	Insect infestation: preharvest and/or post harvest and/or processing	Aesthetic
	Mammalian excreta: 1 mg or more of mammalian excreta per lb	Mammalian excreta: post harvest and/or processing animal contamination	
Sage, ground	Insect filth: 200 or more insect fragments per 10 gm	Insect infestation: preharvest and/or post harvest and/or processing	Aesthetic
	Rodent filth: 9 or more rodent hairs per 10 gm	Rodent hair: Post harvest and/or processing contamination with animal hair or excreta	
Sesame seeds	Insect filth: 5% or more seeds by weight are insect-infested or damaged Mold: 5% or more seeds by weight are decomposed	Insect infested: preharvest and/or post harvest and/or processing infestaion Mold: preharvest infection	Aesthetic

TABLE 89.12
Methods to Reduce Bacteria in Spices

Method	Procedure	Advantages/Disadvantages
Ethylene oxide	Product introduced to chamber Replacement of air by pulling vacuum Heating of chamber contents to 110–120 F Introduction of moisture Introduction of ethylene oxide Holding of spice under ethylene oxide for specific period of time relative to bulk density and bacterial reduction level desired (12–18 hr) Expellation of ethylene oxide and flushing air prior to returning to ambient pressure Removal of product to quarantine area to ensure residual ethyl oxide gas level	Proven method for whole spices and seeds Safety of using ethylene oxide is a concern Long treatment time Banned in some countries
Irradiation	Product loaded to carrier and travels on conveyor through a series of doors and locked into cell area containing cobalt 60 Product exposed to high and low levels of gamma radiation for specific time (5 to 15 hr) in the cells to reduce bacterial load relative to initial bacterial load and bacterial reduction level desired Product returned to its place of origin through a series of doors and locks	Cost effective Overall effectiveness Can process packed products Consumer concerns on irradiated products Not universally accepted
Dry steam	Product dropped into chamber containing shaking bed through airlock Product exposed to dry steam between 108 to 125°C briefly Products cooled immediately with continuous filtered airflow Product is dropped through airlock into a second closed chamber to continue the cooling process with ambient air without development of condensation, dust is filtered during the entire process	Highly effective More expensive than irradiation process, but less expensive than etheylene oxide and wet steam process Absence of residual fumigant
Wet steam	Product dropped into chamber containing shaking bed through airlock Exposure of saturated steam as required to inactivate microbes Termination of steam treatment followed by drying process to adjust the moisture content back to original	Absence of residual fumigant Loss of volatile oils Loss of color in some spices Development of unaccepted flavor

Source: References 6–11, 14, 18.

proximate compositions of common spices are available (25), the other measurable chemical components are usually not used in the comparison of quality except for a few spices that have been agreed upon (Table 89.13). It should be noted that the heat level of red pepper (Scoville test) is basically a sensory test even though chemical procedures are used in the preparation of the samples. Even though ASTA has recommended the use of the HPLC (High Performance Liquid Chromatography) method, there is doubt in the U. S. spice industry on its application to replace the Scoville test.

C. Chemical Residues

A few chemicals may be used in the disinfestation of insects and elimination of bacteria, yeast and/or fungi associated with spices. It is unavoidable that these spices have to be examined for these chemical residues. Application of these chemical treatments in one nation may not be permitted in another country. In addition, agricultural chemicals used in the production of spices have to be monitored especially when these chemicals are acceptable in one country but may not be acceptable in another country. Chemical treatment of spices and the use agricultural chemicals have caused complications in international spice trade. The presence of heavy metals in spices is mostly related to production environment, and heavy metals in spices have to be monitored as importing countries usually have defined limits. Readers interested in this topic should consult Reference 8 for further information.

D. Moisture Content

Moisture content in spices not only affects the weights of the spices, but also is related to the water activity. Water activity is one of the primary controlling factors on the growth and development of microorganisms. Microorganisms can grow during the handling, transportation, and storage if the moisture content is not properly controlled. Spice processors usually control the moisture content of their products carefully so that microorganisms and even insects will not grow. Readers should consult references listed in the earlier sections of this chapter for further information.

E. Volatile Oil

Volatile oils are essential in most of spices. Percentage of volatile oil differs from spice to spice (Table 89.9), and is used as one specification for spices. Volatile oils are also

TABLE 89.13
Specific Tests on Quality Comparison for Selected Spices

Spice	Test Conducted	Methodology
Allspice	Total acid	Titration
	Acid-soluble ash	Ashing, extraction, and gravimetry
	Water-soluble ash	Ashing, extraction, and gravimetry
Capsicum	Scoville heat units	Sensory, High Performance Liquid Chromatography
Capsium oleoresin	Capsaicin	High Performance Liquid Chromatography
Nutmeg, mace	Phenol	High Performance Liquid Chromatography
Paprika	Carotenoids	Spectrophotometry
Paprika, defatted	Sample structure	Microscopy, solvent extraction
Parsley	Green color (Chlorophylls)	Sensory
Pepper (black)	Piperine	Spectrophotometry
Saffron	Crocin	Hydrolysis and spectrophotometry
Turmeric oleoresin	Curcumin	Spectrophotometry
Residual solvent tolerance	Various solvents	Gas chromatography

Source: References 6–11, 14, 18.

used as one of the basic components in the manufacture of soluble spices (see below). The equivalencies of some common spices are listed in Table 89.14.

V. PRINCIPLE FORMS OF PROCESSED SPICES

Spices come in a variety of forms for adding the "bite," "pungency," or "character" so desired in food. They are available whole, ground, or as extractives — e.g., essential oils and oleoresins, and their derivatives. Essential oils are the aromatic, volatile compounds present in most spices, and provide the characteristic flavor and aroma of the spice. They are recovered from plant materials primarily by steam distillation, although some are cold expressed, dry distilled, or vacuum distilled. Oleoresins consists of essential oils, organically soluble resins, and other non-volatile principles — such as heat components, fixatives, natural antioxidants, and pigments. Solvents typically used for oleoresin extraction include ethyl acetate, ethanol, and ethylene chloride. Supercritical extraction using carbon dioxide also is used by some companies. Figure 89.1 shows a schematic diagram on the preparation of spice essential oils and oleoresins (16–17).

Spice extractives are further formulated to produce secondary products such as essences, emulsions, liquid-soluble spices, dry-soluble spices, encapsulated spices, heat-resistant spices, and fat-based spices.

TABLE 89.14
Some Common Essential Oils Available, and Their Equivalencies (Per 100 lb of Spice/Herb)

Spice	Oil Produced From	Equivalency
Allspice	Berries	2.5 lb
Basil	Flowering tops	0.8 lb
Bay (Laurel) leaf	Leaves	1 lb
Caraway seed	Seeds	2.5 lb
Cardamom	Seeds	3 lb
Clove	Flowering buds	15 lb
Coriander	Seeds	0.75 lb
Cumin seed	Seeds	3 lb
Fennel seed	Seeds	3 lb
Nutmeg	Seeds	5 to 15 lb
Oregano	Flowering plant	13 oz
Pimenta leaf	Leaves	0.5 to 1 lb
Rosemary	Flowering tops	11 oz
Sage or Salmatian	Leaves	1.25 lb
Thyme	Flowering plant	2 lb

Source: References 6–9, 11, 14, 16, 20.

- Essences are extractives prepared by macerating the ground spice with 70% ethanol. "Top notes" may be provided by the addition of essential oils or oleoresins (Figure 89.2).
- A spice emulsion is liquid seasoning prepared by emulsification of essential oils and/or oleoresin with gum arabic or other emulsifiers.
- A heat-resistant spice made from oleoresins and/or essential oils is encapsulated with a water-insoluble coating, which extends the product's shelf life and renders it suitable for baking applications.
- A fat-based spice is made from essential oils and/or oleoresins blended with a liquid edible oil or hydrogenated fat, and sold either in bulk or as a spray-cooled, fat-encapsulated spice. Examples of applications include high fat products such as mayonnaise and cream soups. Each spice form is prepared by a different method, and has unique properties that make it more suitable for one particular application over another.
- Water-soluble (dry-soluble) spice is made by dispersion of a blend of volatile oil and oleoresin in sugar, salt, corn syrup solids, gums or modified corn starch.

All these spice extractives have the advantages of constant quality, stability them, and easy handling. They can also be formulated to have certain equivalencies to make user-friendly. Figure 89.2 shows a schematic diagram of the preparation of some of these spice extractives (6–9, 16–17). Tables 89.14 and 89.15 shows the product appearance and spice equivalent (replacement strength) of some common spice volatile oils and oleoresins, respectively. Products

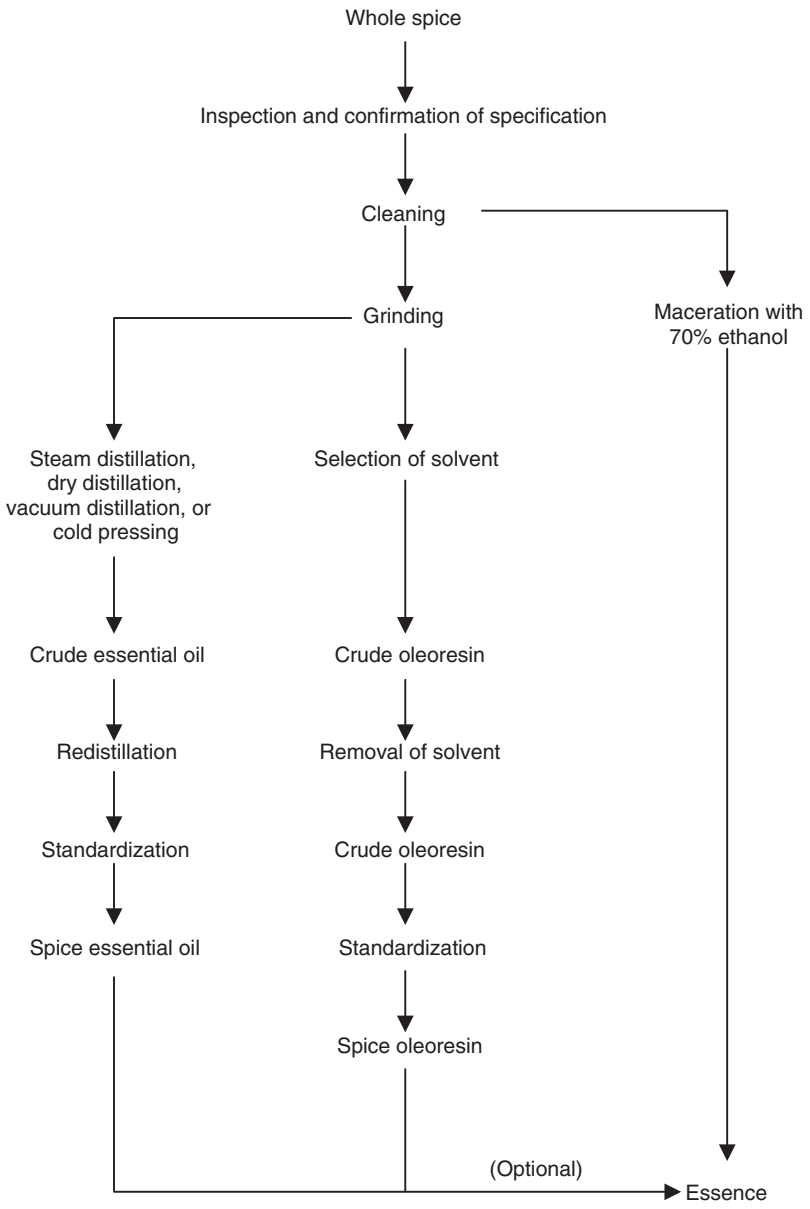

FIGURE 89.1 Schematic processing steps in the production of spice essential oils and oleoresin.

from various spice processors are not the same and have their own spice equivalents due to methods used for oleoresin extraction, and source of raw materials. Table 89.16 compares the advantages and disadvantages of different forms of spices and their derivatives.

VI. BIOACTIVITY IN SPICES AND HERBS

A. Natural Occurring Toxicants in Selected Spices

It has been known for at least several decades that some spices are toxic even when consumed in small quantities. Some spices are now proven to be either estrogenic, carcinogenic, hallucinogenic, goitrogenic, antithyroidic, lacinmatic, and/or mutagenic to humans, test animals or on Ames test (27–36). Table 89.17 presents examples of these toxicities of some common spices. However, readers should not be scared away from using small amount of spices in their food preparations. No reported case of harmful or unhealthy effects exists from consuming spices in quantities commonly applied in food preparation. Anything consumed in excessive amounts is bound to have undesirable effects.

B. Antioxidative Effects of Spices

In recent years, interest in antioxidants has increased because of their possible beneficial health effects. Many common food items have been observed for their

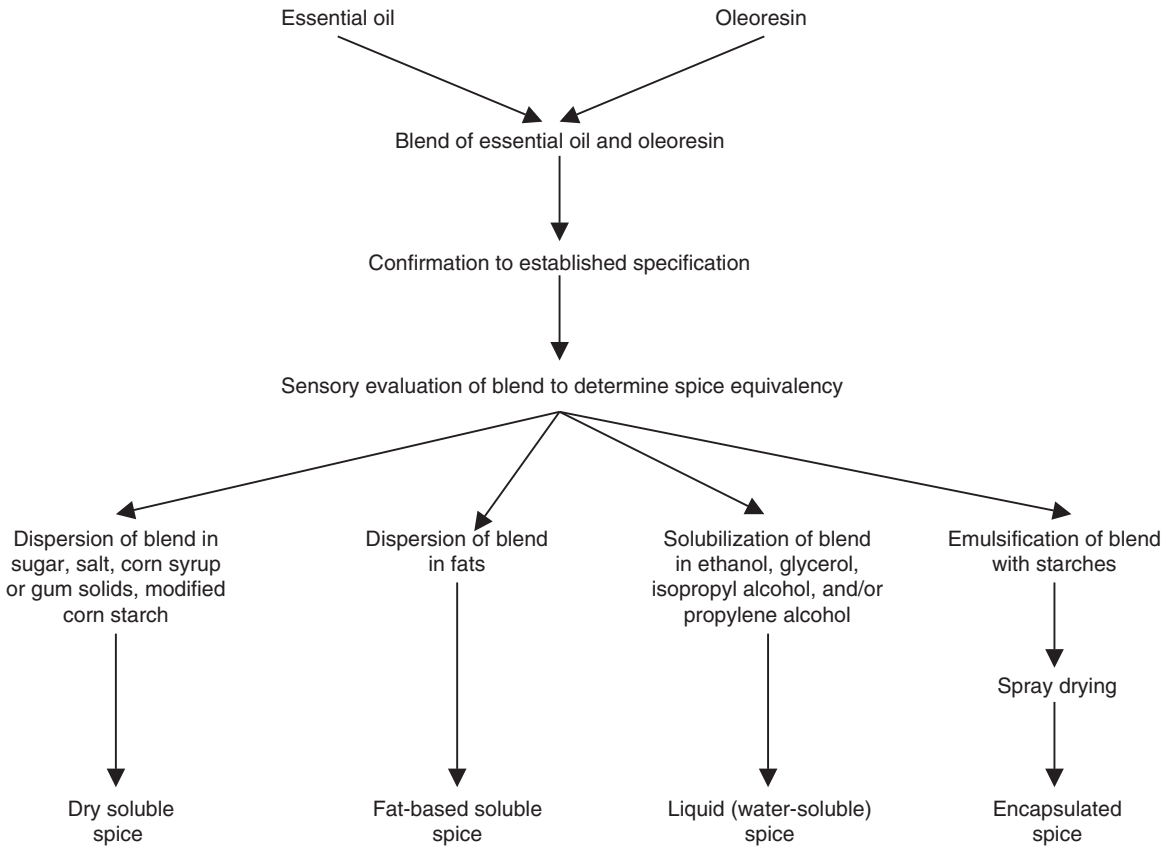

FIGURE 89.2 Schematic diagram on production of various soluble spices.

TABLE 89.15
Product Appearance and Spice Equivalent (Replacement Strength) of Common Spice Oleoresins

Spice	Product Appearance	Spice Equivalent or Replacement Strength
Allspice	Reddish brown to green liquid	1 lb to 28–30 lb
Basil	Dark green semi-solid	1 lb to 0.5–1 lb
Bay leaf	Dark green semi-solid	1 to 5 lb
Caraway seed	Greenish yellow to light green liquid	1 lb to 5 lb
Cardamom	Green to dark green liquid	1 lb to 4 lb
Celery seed	Green to light green liquid	1 lb to 3–7 lb
Cinnamon	Reddish or dark brown liquid or Yellowish green liquid	1 lb to 40 lb
Clove	Reddish brown or yellowish green liquid	1 to 20 lb
Coriander	Greenish brown or brownish yellow liquid	1 to 15 lb
Cumin seed	Brownish to yellowish-green liquid	1 to 5 lb
Dill seed	Green or light amber liquid	1 to 4–6 lb
Fennel seed	Brownish green liquid	1 to 5–6 lb
Garlic, dehydrated	Brownish-tan or brownish viscous liquid	1 to 2 lb (fresh) 1 to 8 lb (dehydrated)
Ginger, dehydrated	Brown to dark brown liquid or semi-solid	1 to 28 lb
Mace	Amber or brownish- or reddish-orange liquid	1 to 10–20 lb
Marjoram, sweet	Dark green viscous liquid	1 to 7–9 lb
Nutmeg	Yellow-orange or pale yellow viscous liquid	1 to 6–10 lb
Onion, dehydrated	Brown to brownish-tan liquid	1 to 0.5 lb (fresh) 1 to 1 lb (dehydrated)

(*Continued*)

TABLE 89.15
(*Continued*)

Spice	Product Appearance	Spice Equivalent or Replacement Strength
Oreganum	Dark-brown to brownish green viscous liquid	1 to 3–5 lb
Paprika	Dark red liquid	1 to 15 lb
Parsley	Deep green semi-viscous liquid	1 to 1/3 lb (fresh) 1 to 3 lb (dry)
Pepper, black	Thick liquid	1 lb to 20–25 lb
Pepper, red	Oily orange, reddish or brown liquid	1 lb to 5–7 lb
Rosemary	Thick green to greenish brown semi-solid	1 to 4–7 lb
Sage	Brownish green heavy liquid	1 to 6–9 lb
Thyme	Dark green to brown viscous semi-solid	1 to 4 lb
Turmeric	Reddish brown to dark brown liquid	1 to 15–20 lb
Vanilla	Dark brown viscous semi-solid	1 to 10 lb

Source: References 6–9, 11, 14, 16–17.

TABLE 89.16
Comparison of Various Forms of Spices

Forms	Advantages	Disadvantages
Whole/ground spice	Slow release of flavor at high temperature processing	Inconsistent aroma, taste, and color
	Easy to weigh and handle	Greater volume and space during storage
	No labeling problem	Presence of foreign matter and undesirable organisms
		Possibility of contamination during storage
Essential oil		
Liquid	Uniform and standardized flavor	Incomplete flavoring agents
	Undiluted essential oil highly concentrated	Lack of natural antioxidants in spice
	Sterile and free of extraneous matter	Undiluted essential oils difficult to handle
	Space saving	
	Stable under good storage condition	
	Emulsifiable with other liquid solutions	
Encapsulated oil	Uniform and standardized flavor	Incomplete flavoring agents
	Sterile and free of extraneous matter	Loss of volatiles during encapsulation
	Space saving	Very expensive
	Ease of handling and dispersing in food system	Not suitable for liquid
	Stable under good storage condition	
	Can be formulated to be water-soluble	
Oleoresin		
Undiluted	Uniform and standardized flavor	Very viscous and hard to handle
	Highly concentrated	Possible presence of undesirable flavor components
	Hygienic and free of extraneous matter and organisms	Possible presence of undesirable organic solvent
	Presence of natural antioxidants	
	More complete flavor than essential oil	
	Long shelf life	
	Space saving	
Encapsulated oleoresins	Same as encapsulated oil	Same as encapsulated oil
Essential oil + oleoresin	Uniform and standardized flavor	Very expensive
	Benefits of combined flavor from essential oil and oleoresin	Loss of volatiles during encapsulation
		Not suitable for liquid
	Hygienic and free of extraneous matter and organisms	Possible presence of undesirable flavor components
	Ease of handling and dispersing in food system	Possible presence of undesirable organic solvent
	Stable under good storage condition	
	Can be formulated to be water-soluble	

(*Continued*)

TABLE 89.16
(*Continued*)

Forms	Advantages	Disadvantages
	Space saving	
	Can be formulated to be water-soluble	
Dry soluble spice	Uniform and standardized flavor	
	Hygienic and free of extraneous matter and organisms	Carrier such as salt and sugar must be considered in formulation of food products
	Ease of handling and dispersing in food system	
	Stable under good storage condition	Not as stable as encapsulated products
	Can be formulated to be water-soluble	Possible presence of undesirable flavor components
	Space saving	Possible presence of undesirable organic solvent
	Price more stable than raw spice	
Liquid spice	Uniform and standardized flavor	Expensive
	Sterile and free of extraneous matter	Possible presence of undesirable flavor components
	Space saving	Possible presence of undesirable organic solvent
	Stable under good storage condition	Nature of carrier must be considered
	Emulsifiable with other liquid solutions

TABLE 89.17
Natural Occurring Toxicants in Selected Spices

Spice	Toxicant or Toxic Activity
Anise volatile oil	Anethole (estrogenic activity)
Basil oil	Estragole (carcinogenic activity)
Black pepper	Safrole (carcinogenic activity)
	Piperine (carcinogenic activity)
Black pepper + nitrate	*n*-Nitrosopiperidine (carcinogenic activity)
Fennel volatile oil	Anethole (estrogenic activity)
Mustard, brown	Sinalbin then allylisothiocyante (lacinmater, mutagenic in Ames test,carcinogenic in rats)
Mustard, white	Glucosinolates (goitrogenic and antithyroid activities)
	Sinalbin then allylisothiocyante (lacinmater, mutagenic in Ames test, carcinogenic in rats)
Parsley	Evidence of estrogenic activity
Paprika + nitrate	*N*-Nitrosopyrrolidine (carcinogenic activity)
Nutmeg	Myristicin (hallucinogen)
Sage	Evidence of estrogenic activity
Tarragon oil	Estragole (carcinogenic activity)
Turmeric	Evidence of carcinogenic activity

Source: References 6, 7, 9, 14, 27–33.

TABLE 89.18
Antioxidative Effect of Spices

Medium	Antioxidative Effectiveness	Spice
Lard	Remarkably effective	Rosemary, sage
	Effective	Oregano, thyme, nutmeg, mace, turmeric
Oil-in-water emulsion	Strongest	Clove
	Strong	Turmeric, allspice, rosemary, ginger, cassia, cinnamon, oregano, savory, sage
	Some	Aniseed, basil, cardamom, marjoram, black pepper, white pepper

Source: References 6, 9, 14, 23, 34–37.

antioxidative effect(s), and spices are no exception. In fact, spices have been looked at for their antioxidative effect at least two decades ago for possible applications in food processing. A notable example is rosemary. This discovery was first patented and now is available as a food antioxidant (9, 6, 14, 18, 34–37). Table 89.18 shows examples of antioxidative activity of some common spices in lipid and oil-in-water emulsions.

C. Some Common Foodborne Bacterial Pathogens Inhibited by Selected Spices

Synthetic food preservatives have not enjoyed a good reputation over the years. With the trend of using more natural ingredients in formulations targeted for special groups of consumers, spices have been looked at as possible alternatives, and there are some successful reports. About 150 scientific reports have been published in this area between 1970 to 2000, and it is not the intention of this chapter to go into the details. Instead, a summary of inhibitory effect of spices [either in the form of the spice itself, its extractive or its effective compound(s)] on some common foodborne pathogens is presented in Table 89.19. (38–94). Garlic and cloves proved to be most effective in inhibiting these foodborne pathogens. It is not surprising that garlic is one of the most effective spices, as garlic has long been suspected of providing beneficial health effects. Even the slaves building the great pyramids used garlic and reported health benefits. With this better understanding of the inhibitory effects of various spices, it is possible that combinations may be developed to serve this purpose in certain food preparations. In fact, attempts are being made to achieve this goal (Daniel Y.C. Fung, personal communication, 2003). Research works on inhibitory effects on yeast and fungi are also available (95–106).

TABLE 89.20
Prospective Beneficial Medical Effects of Some Common Spices

Spice	Scientific Name	Prospective Beneficial Medical Effects
Allspice	*Pimenta dioica*	High blood pressure, infection, rheumatism
Anise seed	*Pimpineela anisum*	Not known
Basil	*Ochimum basilicum*	Not known
Bay leaf	*Laurus nobilis*	Cancer, infection
Cassia	*Cinnamonum cassia*	Cancer, cold/flu, dyspepsia
Caraway seed	*Carum carvi*	Cancer, cold/flu, hepatosis
Cardamom	*Elettraia cardamomum*	Cold/flu, hepatosis
Celery seed	*Apium graveolens*	High blood pressure, rheumatism
Chervil	*Anthriscus cerefolium*	Not known
Chives	*Appium schoenoprasum*	Not known
Cinnamon	*Cinnamomum zelancium*	Dyspepsia, infection
Clove	*Syzgium aromaticum*	Bronchosis, toothache
Coriander	*Coriandrum sativum*	Not known
Cumin seed	*Cumium cyminum*	Not known
Dill seed	*Anethum graveciens*	Not known
Dill weed	*Anethum graveciens*	Not known
Fennel seed	*Foeniculum vulgare*	Not known
Fenugreek	*Trigonella foenumgraecum*	Dermatosis, diabetes, high cholesterol
Garlic, dehydrated	*Allium sativum*	Cardiopathy, infection
Ginger, dehydrated	*Zingiber officinale, Roscoe*	Cold/flu, dyspepsia
Lemongrass	*Cymbogon citratus*	Cold/flu, pain
Mace	*Myristica fragans*	Cancer, infection
Marjoram, sweet	*Origanum majorana*	Not known
Mint, Peppermint (black mint)	*Mentha piperita* variety *vulgaris*	Not known
Mint, Spearmint	*Mentha spicata*	Not known
Mustard seed, black	*Brassica hira* or *B. alba*	Not known
Mustard seed, brown	*Brassica juncea*	Not known
Mustard, white	*Brassica nigra*	Not known
Nutmeg	*Myristica fragans*	Cancer, infection
Onion, dehydrated	*Allium cepa*	Colds, diabetes
Oregano	*Origanum spp.*	Not known
Paprika	*Capsicum annum*	Cardiopathy, cold/flu, rheumatism
Parsley	*Petrosalinum crispum*	Not known
Pepper, black	*Piper nigum*	Dermatosis, high cholesterol
Pepper, red (Capsicum)	*Capsicum fructescens*	Cardiopathy, cold/flu, rheumatism
Pepper, white	*Piper nigum*	Dermatosis, high cholesterol
Poppy seed	*Papaver somniferum*	Not known
Rosemary	*Rosemarinus officinalis*	Not known
Saffron	*Crocus sativus*	Cancer, infection
Sage	*Salvia officinalis*	Not known
Savory, sweet (summer)	*Satureja indicum*	Not known
Sesame seed	*Sesamum indicum*	Cancer, dermatosis
Star anise, Chinese	*Illicum verum*	Bronchitis, dyspepsia, fungus
Tarragon	*Artemisia dracunculus*	Not known
Thyme	*Thymus vulgaricus*	Not known
Turmeric	*Curcuma longa*	Cancer, dyspepsia, infection, antiinflamatory
Vanilla	*Vanilla fragrans, V. planilfolia,* or *V. tahitensis*	Cancer, cramp, infection

D. Prospective Beneficial Medical Effects of Some Common Spices

It was common practice in ancient cultures such as Greek, Egyptian, Indian, and Chinese to use spices and herbs to treat patients with various problems. It should be understood that in these cultures, the lists of spices and herbs are much more extensive than what is presented in this chapter. However, this method of treating patients is still practiced to some extent in China and India. With the modern

TABLE 89.21
Use of Spices as Food Cures in Traditional Chinese Medicine (TCM)

Spice	Food Cures According to Traditional Chinese Medicine (TMC)
Caraway seeed	Stomach ache, abdominal pain, hernia, lumbago
Cinnamon bark	Cold limbs, abdominal pain, diarrhea, hot sensations in the upper region with cold sensations in the lower region
Cinnamon twig (stick)	Pain in the back and shoulder, chest pain, menopause
Clove	Vomiting, hiccuping, upset stomach, diarrhea, abdomnal pain, hernia
Coriander (Chinese parsley)	Indigestion, measles prior to rash
Dill seed	Abdominal pain, poor appetite, shortage of milk secretion after childbirth
Fennel seed	Hernia, cold pain in lower abdomen, lumbago, stomachache, vomiting, dry and wet beriberi
Garlic	Common cold, abdominal pain, edema, diarrhea, dysentery, whooping cough
Ginger, dried	Commn cold, abdominal pain, vomiting, and diarrhea, cold limbs, rheumatism
Ginger, fresh	Common cold, vomiting, cough, asthma, diarrhea
Licorice	Abdominal pain, poor appetite, fatigue, fever, cough, palpitation, convulsions, sore throat, digestive ulcers, drug poisoning, food poisoning
Marjoram	Common colds, fever, vomiting, diarrhea, jaundice, malnutrition in children, skin rash
Nutmeg	Abdominal swelling and pain, diarrhea, vomiting, indigestion
Pepper, black and white	Common cold, adbominal pain, upset stomach, vomiting of clear water diarrhea, food poisoning
Pepper, red	Abdominal pain, vomiting diarrhea
Peppermint	Common cold, headache, sore throat, indigestion, cores, toothache, skin eruptions
Rosemary	Headache
Saffron	Congested chest, vomiting of blood, suppression of menstruation, abdominal pain after childbirth due to blood coagulation, injuries from falls
Spearmint	Common cold, cough, headache, abdominal pain, menstrual pain
Star anise, Chinese	Hernia, abdominal pain, lumbago, beriberi, vomiting
Sweet basil	Headache in common cold, diarrhea, indigestion, stomachache, irregular menstruation
Thyme	Whopping cough, acute bronchitis, laryngitis

Source: Reference 22.

methodology in studying therapeutic effects of chemicals or natural products, there are indications that some spices do have certain therapeutic effects. Table 89.20 lists some examples, and Table 89.21 lists some claims in Traditional Chinese Medicine (TMC) on therapeutic effects of some common spices and herbs. Readers interested in this area should consult the references cited for these two tables and also References 22, 107–112 listed at the end of this chapter. With the increasing interest of Complimentary and Alternative Medicine (CAM), it is expected that research reports and books in this area will be more abundant in the immediate future. However, consumers must be very careful in the use of dietary supplements that include spices and herbs in ground or concentrated forms to treat ailments, as responses differ among people. Consumers are advised to consult physicians or professionals who have had training in this area before taking these products to treat ailments.

ACKNOWLEDGMENT

We would like to thank Dr. Daniel Y. C. Fung, Department of Animal Sciences and Industry, Kansas State University, Manhattan, Kansas for his generosity in sharing his database on spices.

90 Eggs as Nutritional and Functional Food Ingredients

Yoshinori Mine and Jennifer Kovacs-Nolan
Department of Food Science, University of Guelph

CONTENTS

I. INTRODUCTION

Eggs have long been recognized as an important source of nutrients, providing all of the proteins, lipids, vitamins, minerals, and growth factors for the developing embryo, as well as defense factors against bacterial and viral invasion.

More recently, however, eggs have been recognized as a source of biologically active substances, with significant therapeutic potential. Some pharmacologically significant egg components, for example, have been shown to possess antibacterial, antiviral, and anticancer action, suggesting potential medical, nutraceutical, and food-fortification applications.

Some of these egg components have been the subject of intense study and are currently produced and used on an industrial scale, including egg white lysozyme and avidin. As well, a thorough understanding of the egg and its components has allowed for the manipulation of egg contents, to further enhance their nutritional and therapeutic potential. Examples include the feeding of hens special diets to produce eggs with increased levels of ω-3 polyunsaturated fatty acids, which have demonstrated numerous health benefits, and the immunization of hens to produce specific egg yolk immunoglobulins, capable of preventing and treating bacterial and viral infections.

Here we describe in detail the biological activities of egg components, and review their numerous applications in the food and pharmaceutical industries.

II. STRUCTURE AND CHEMICAL COMPOSITION OF HEN EGGS

A. Structure of Hen Eggs

The hen egg is composed of three main parts: the shell and its membrane, the albumen (egg white), and the yolk (1, 2).

The egg shell is an inflexible, mineralized structure which gives the egg its shape (1). It is covered with fine pores, each approximately 10 to 30 μm in diameter, which allow for the exchange of atmospheric gases and water vapor (1, 2). These pores are in turn covered by a cuticle layer, which permits the exchange of gases, and protects the egg from moisture and invasion of microorganisms (2). On the inside of the shell is an inner and outer membrane, with a mesh-like structure for obstructing invading microorganisms (2, 3).

The egg albumen consists of thin and thick albumen, and a chalaziferous layer. The thick albumen is sandwiched between an inner and outer layer of thin albumen (2). The thick albumen, with increased viscosity due to a higher concentration of ovomucin, covers the inner thin albumen and chalaziferous layer, keeping the egg yolk in the center of the egg (2). The chalaziferous layer is a fibrous layer which covers the yolk, and is twisted at both ends of the yolk membrane, stretching into the thick albumen and suspending the yolk in the center of the egg (2).

The egg yolk, surrounded by the vitelline membrane, is composed of yellow yolk, and at the center, white yolk, which originates from the white follicle which matures in the ovary. The yellow yolk contains layers of alternate light and deep yellow yolk, and it is here that the embryo develops (1, 2).

B. Biosynthesis of Egg Components

The formation of an egg involves the conversion of nutrients in the feed into egg constituents through several intricate and highly coordinated steps (4).

The reproductive system of the hen consists of the ovary and oviduct (4). The ovary is the site of assembly of the yolk, each yolk beginning as a cell formed in the embryo. As the hen matures, the yolk cells are transformed into oocytes. A mature ovary contains many oocytes, and at least 600–700 of them will become mature yolk. Each oocyte becomes a follicle after being covered with a granular layer. The follicles in the ovary are surrounded by the hen's veins (4). Yolk constituents are synthesized in the liver in response to hormonal stimulation, some as protein precursors which are later enzymatically modified, and are transported to the follicular walls in the blood. The follicle undergoes several changes, including a separation of the cells of the granular layer, in order to facilitate the transfer of material to the yolk, which occurs via receptor-mediated endocytosis, producing yolk granules (5). The follicle undergoes a rapid development during which most of the yolk is deposited 6–10 days prior to ovulation.

When sufficient yolk has accumulated, the follicle then enters the oviduct. As it travels through the oviduct the vitelline membrane of the yolk and chalazal layer of the albumen are added, followed by the secretion of the albumen (2, 6). The proteins of the albumen are synthesized in the oviduct, also in response to hormonal stimulation, with ovalbumin and the other major proteins being synthesized by the tubular gland cells, and avidin being synthesized in the goblet cells (6). Following albumen deposition, the shell membranes are immediately added.

The egg is then held in the uterus, where several glands secrete fluid with a high concentration of calcium ion, which is transported from the blood, onto the inner surface of the uterus. The mechanism by which the calcium reaches the shell is unclear, but the eggshell structure is formed by assembling a crystalline-like calcium structure on the newly formed shell membranes (2, 4).

C. Chemical Composition of Eggs

1. General Composition

In general, an egg is composed of 9–11% eggshell (shell and shell membrane), 60–63% egg white, and 28–29% egg

yolk. The main components are 12% lipids, 12% proteins, and around 75% water, carbohydrates and minerals (1, 7).

Proteins are distributed throughout the egg, but most of them are present in the egg yolk (44%) and egg white (50%), the remaining 6% in the eggshell and eggshell membrane (7). Very small amounts of free amino acids have also been reported, presumably for immediate use by the developing embryo (1).

Egg lipids are found almost exclusively in the egg yolk, mainly in the form of lipoproteins, and include phosphorus, nitrogen, and sugar-containing lipids. A very small amount of lipid has also been reported in the egg shell (1, 7).

Carbohydrates are a minor component of eggs, with 40% of the carbohydrate content being present in the egg yolk, and they are present as free and conjugated forms which are attached to proteins and lipids. Glucose is found in the egg white, and mannose and galactose are present as complex carbohydrates attached to proteins (7).

Numerous minerals have also been found in eggs, most of them in the egg shell (7).

2. Egg Shell and Membrane

The egg shell is made up of a matrix consisting of interwoven protein fibers and spherical masses, and interstitial calcite or calcium carbonate crystals (8). Approximately 95% of the egg shell is minerals, around 98% of this being calcium, along with 0.9% magnesium, and 0.9% phosphorus (7, 8).

The egg shell is covered with a cuticle layer which is composed of about 90% protein, with a high content of glycine, glutamic acid, lysine, cystine, and tyrosine, a small amount of carbohydrate, including galactosamine, glucosamine, galactose, fucose, glucose, and sialic acids, as well as a very small amount of lipid (7, 8).

The egg shell membranes are made up of protein fibers, with a high content of arginine, glutamic acid, methionine, histidine, cystine, and proline; they are considered keratins, due to a lack of hydroxyproline and presence of high concentrations of sulfur-containing amino acids (8).

3. Egg White

The egg white, or albumen, makes up about 60% of the total egg weight (7). Water and protein are the major constituents of albumen, accounting for about 88% and 11%, respectively (7, 8). The albumen proteins include ovalbumin, which is the major protein, followed by ovotransferrin and ovomucoid. Other egg white proteins include ovomucin, which is responsible for the viscosity of the albumen, lysozyme, avidin, cystatin, and ovoinhibitor (7).

Carbohydrates, minerals, and lipids are minor albumen components. The carbohydrates exist both in free form and bound as glycoprotein. Most of the free form carbohydrate is glucose; however, small amounts of fructose, mannose, arabinose, xylose, and ribose have also been detected (7). The major inorganic compounds found in the albumen are sulfur, potassium, sodium, and chlorine, as well as phosphorus, calcium, magnesium, and traces of iron. Lipid is found in only trace amounts (7).

4. Egg Yolk

Egg yolk is a homogeneously emulsified fluid. The major constituents of the solid matter of yolk are proteins and lipids, present mainly in the form of lipoproteins, which can be separated by high speed centrifugation into a sedimented fraction called the granules, and a clear fluid supernatant called plasma (7).

The granules are composed of 70% α- and β-lipovitellins (the high density lipoprotein fraction), 16% phosvitin, and 12% low-density lipoproteins (9). The plasma is divided into the low-density lipoprotein fraction (87%) and the water soluble fraction (WSF) (13%), which contains the livetins, which are lipid-free globular proteins, including γ-livetin, also referred to as immunoglobulin Y (8).

The egg yolk lipids include triglycerides, phospholipids, cholesterol, cerebrosides or glycolipids, and some other minor lipids (7).

Egg yolk also contains minerals, of which phosphorous is the most abundant. More than half of the phosphorus is contained in phospholipids. The content of carbohydrates in the yolk is approximately 1%, most of it as oligosaccharides bound to protein; that which is free is in the form of glucose. Finally, egg yolk contains pigments, primarily carotenes and riboflavin, which are the source of the colour of the yolk (7).

III. BIOLOGICAL ACTIVITIES OF EGG COMPONENTS

A. Egg Shell

1. Egg Shell Calcium and Matrix Proteins

Chicken eggshell is a highly specialized mineralized structure which consists of approximately 95% calcium carbonate by weight, and of the remaining material, 3.5% is an organic matrix consisting mainly of glycoprotein and proteoglycans (10, 11). Currently, eggshells are disposed of in many ways, and are generally considered a waste product. Only recently has significant research been conducted into the possibility of the value-added utilization of eggshells as a food ingredient (12, 13). Eggshell calcium has been proposed for pharmaceutical applications for calcium deficiency therapies in humans, and in animals for bone mineralization and growth (14). Eggshell powder was shown to have antirachitic effects in rats (15). *In vitro*, eggshell powder stimulated the growth of chick embryo

cartilage cells (16), and in humans the use of the eggshell powder resulted in decreased pain and increased bone mineral density (17). In piglets, the apparent absorbability of calcium from eggshell powder was found to be at least as good as that from purified $CaCO_3$ (17). However, the factors resulting in increased bone mineral density have not been discovered.

The eggshell consists of various organic matrix components. Numerous proteins which are present in various mineralized tissues and thought to be involved in the mineralization process possess calcium binding properties (18). Some eggshell matrix proteins also possess calcium-binding properties (19). Cortivo et al (20) separated a low molecular weight acidic protein with calcium affinity; this property was associated with a high content of aspartic and glutamic acid and a high content of sulphate groups. Similarly, ovotransferrin (78 000 Da), ovalbumin (45 000 Da) and others (36 000 Da) express calcium affinity (19, 21). A recent study demonstrated that a 21 000 Da protein present in soluble eggshell matrix proteins plays an important role in increasing calcium transport across intestinal epithelial cells *in vitro*, using Caco-2 cell monolayers (22). Eggshell calcium is proposed as an excellent calcium supplement to increase bone mineral density in individuals with osteoporosis (23).

2. Egg Shell Membrane

Eggshell membrane is composed of collagen-like proteins (collagen type I and V) (24), in a ratio of 100 of type I to 1 of type V. Coarse fibers (2.5 μm in diameter) contain more type I collagen, while type V collagen predominates in the fine fibers (0.6 μm in diameter), which are largely located in the inner membrane (25).

Eggshell membrane protein hydrolysate has been prepared by alkaline treatment, and the peptides derived from the membrane were shown to stimulate human skin fibroblasts *in vitro* (13). The membrane proteins (peptides) are currently utilized as a cosmetic ingredient for their emollient properties (26). Eggshell membranes also contain antimicrobial substances. Lysozyme activity was reported in the outer and inner membranes (27) and an anti-bacterial enzyme, β-N-acetylglucosaminidase, was found in the outer membrane (28).

B. Egg White

Various biological activities are associated with the egg white, and are summarized in Table 90.1.

1. Ovomucin

Hens' egg white ovomucin is a macromolecular and heavily glycosylated glycoprotein, consisting of a peptide-rich α-subunit and a carbohydrate-rich β-subunit (29). Ovomucin serves physical functions such as maintaining the structure and viscosity of the egg white albumen (30), thus serving to prevent the spread of microorganisms (31), and possessing good foaming and emulsifying properties (32). However it has also demonstrated several biological applications.

Ovomucin has been shown to possess virus hemagglutination inhibition activity, attributed primarily to its carbohydrate-rich β-subunit (33). Antiviral activity against newcastle disease virus, bovine rotavirus, and human influenza virus has been demonstrated *in vitro* (30, 33–36). It has also been demonstrated that ovomucin fragments, produced by treatment with pronase, showed increased solubility, as compared to its native form, while still retaining virus-binding activity (30, 36).

Pronase-prepared glycopeptides of ovomucin have also demonstrated anti-tumor effects in a double grafted tumor system in mice (37), suggested to be related to the anti-angiogenic activity of ovomucin, inhibiting tumor growth (38).

Ovomucin peptides may also act as immunomodulators, showing macrophage-stimulating activity *in vitro* (39). Finally, ovomucin was found to inhibit cholesterol uptake *in vitro* by Caco-2 cells, and reduce serum cholesterol in rats, displaying hypocholesterolemic action (40).

2. Ovotransferrin

Belonging to the transferrin family, a group of iron-binding proteins which are widely distributed in various biological fluids, ovotransferrin is a monomeric glycoprotein consisting of a single polypeptide chain of 686 amino acids, which has the capacity to reversibly bind two iron ions per molecule (41). Its suggested function is as an iron scavenger, preventing availability of iron to microorganisms, and as an iron delivery agent (42).

Ovotransferrin has been suggested as a natural food antimicrobial, and its antibacterial activity has been shown against a wide spectrum of bacteria, including *Pseudomonas* spp., *Escherichia coli*, *Streptococcus mutans* (43), *Staphylococcus aureus*, *Bacillus cereus* (42) and *Salmonella enteritidis* (44). Similar results have been obtained with immobilized ovotransferrin (43, 45) and iron-saturated ovotransferrin (46), indicating that its antibacterial activity may not be due to its iron binding alone, but also due to interaction between the protein and the bacterial cells. A 92-amino acid ovotransferrin antimicrobial peptide, OTAP-92, was found to be capable of killing Gram-negative bacteria by crossing the bacterial outer membrane by self-promoted uptake, and damaging the cytoplasmic membrane (47). The OTAP-92 peptide shares sequence similarity with a group of peptides referred to as defensins, which kill bacteria by forming a pore or ion channel in the cytoplasmic membrane (47). It has also been shown that ovotransferrin possesses both antiviral activity, against Marek's disease virus in chicken embryo fibroblasts (48), as well as antifungal activity, against species of *Candida* (46).

TABLE 90.1
Biological Properties of Egg white Proteins

Protein	Properties	Reference
Ovomucin	Antiviral activity	30, 33–35
	Antiviral activity of ovomucin-derived fragments	36
	Anti-tumor activity	37, 38
	Immunomodulating activity	39
	Hypocholesterolemic activity	40
Ovotransferrin	Antibacterial activity	41, 43–45
	Antimicrobial activity of ovotransferrin-derived peptide, OTAP-92	47
	Antiviral activity	48
	Antifungal activity	46
	Immunomodulating activity	49–51
	Enhancement of activity of certain antibiotics	52
Ovalbumin	Anti-mutagenic and anti-carcinogenic activity	55
	Immunomodulating activity	56–58
	Antioxidant activity	59, 60
	Anti-hypertensive activity of ovalbumin-derived peptides ovokinin and ovokinin (2-7)	61-63
	Angiotensin 1 converting enzyme (ACE) inhibitory activity of ovalbumin-derived peptides	64
	Immunomodulating activity of ovalbumin-derived peptides	65–68
Ovomucoid	Serine proteinase inhibitor	69, 71, 72, 76
	Drug delivery to small intestine	73, 75
	Biospecific ligand to lectins in gastrointestinal tract	74
	Immunomodulating activity	77
Lysozyme	Antibacterial activity	81, 83–85, 88, 89
	Enhanced antimicrobial activity when coupled to hydrophobic carrier or phenolic aldehyde	90, 91
	Antimicrobial action of lysozyme-derived peptides	92-95
	Application as a food preservative	81, 83, 84, 96–99
	Protection against periodontis-causing bacteria when added to oral health care products	100, 101
	Antiviral activity	81, 100, 102
	Anti-inflammatory activity	100
	Immunomodulating and immune-stimulating activity	100, 102, 103
	Anti-tumor activity	104–107
Avidin	Antimicrobial activity	111, 112
	Pre-targeting and drug delivery of anti-cancer drugs	114–118
	Application in adoptive immunotherapy	119
	Drug delivery to brain	120
Cystatin	Cysteine proteinase inhibitor	8
	Antibacterial activity	125, 129, 130
	Inhibition of growth of *P. gingivalis* by cystatin-derived peptides	131
	Immunomodulating activity	134–137
	Inhibition of tumor invasion	140
Ovomacroglobulin	Serine, cysteine, thiol, and metallo proteinase inhibitor	142, 143, 149–152
	Antibacterial activity	143–146,
	Enhancement of wound healing	147, 148
Ovoinhibitor	Serine proteinase inhibitor	155–157
	Antiviral activity	158
	Potential anti-inflammatory and anti-mutagenic activity	159
	Protein purification applications	161, 162

Ovotransferrin has been described as an acute phase protein in chickens, with serum levels increasing during inflammation and infections. It has been suggested that acute phase proteins may facilitate the biological activities of phagocytic cells and help produce factors that lead to the restoration of homeostasis (49). Xie et al. (49) demonstrated that ovotransferrin can act as an immunomodulator by modulating macrophage and heterophil functions in chickens. Further immunomodulating effects of ovotransferrin have also been shown, including the

inhibition of proliferation of mouse spleen lymphocytes (50) and the enhanced phagocytic response of peripheral blood mononuclear cells and polymorphonuclear cells in dogs (51).

Finally, when administered with Syn 2190, an inhibitor of AmpC lactamases, lactoferrin increased the activity of various antibiotics against beta-lactamase-producing bacteria (52).

3. Ovalbumin

Ovalbumin constitutes over half of the total egg white proteins (31). It is a monomeric phosphoglycoprotein, with a molecular weight of 45 000 Da, and has been used extensively as a model for studying the structure-function relationships of proteins (31, 53). Functionally, ovalbumin is important for the gelling, foaming, and emulsifying properties of egg white (54); however, its biological role in the egg remains unknown. It has been suggested that ovalbumin may serve as a source of amino acids for the developing embryo (31). Although ovalbumin shows no proteinase inhibitory activity, it shows structural homology with a family of serine proteinase inhibitors, called serpins (31).

The anti-mutagenicity of ovalbumin toward N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), a well known and highly reactive model nitrosamine, has been examined (55). Vis et al. (55) found that ovalbumin, especially when heat-denatured, was strongly anti-mutagenic against MNNG, suggesting a role for ovalbumin as an anti-mutagen and anti-carcinogen.

Ovalbumin may also possess some immunomodulatory activity, as it was found to induce the release of tumor necrosis factor (TNF) alpha in a dose-dependant manner *in vitro*, when modified with dicarbonyl methylglyoxyl (MGO) (56), and immunogenic ovalbumin peptides have been used to enhance immune responses for cancer immunotherapy (57, 58).

Ovalbumin was found to possess a strong antioxidant activity against linolenic acid and docosahexaenoic acid (DHA) (59). Three antioxidant peptides with sequence of Ala-His-Lys, Val-His-His and Val-His-His-Ala-Asn-Glu-Asn derived from ovalbumin hydrolysis were identified and it has been suggested that metal chelation plays a major role in the antioxidant activity (60).

A vasorelaxing peptide (ovokinin; OA 358–365) was isolated from the peptic digestion of ovalbumin (61), and was found to be a weak bradykinin B1 agonist peptide. Ovokinin(2–7), a peptide produced by the chymotryptic digestion of ovalbumin, corresponding to OA 359–364, was also found to possess vasorelaxing effects (62). Following oral administration of ovokinin(2–7) at a dose of 10 mg/kg, the systolic blood pressure in a spontaneously hypertensive rat was significantly lowered (62). The anti-hypertensive activity of ovokinin(2–7) was enhanced by replacement of the C-terminal Phe residue with Trp (63). Two angiotensin I converting enzyme (ACE)-inhibitory peptides were also identified in ovalbumin by peptic (OA 183–184) and tryptic (OA 200–218) digestions (64). Furthermore, phagocytic activity of macrophages was increased by the addition of OA 77–84 and OA 126–134 peptides, derived by peptic and chymotryptic digestions of ovalbumin, respectively (65).

Immunoactive peptides produced by *Saccharomyces cerevisiae* fermentation of egg white were prepared and the administration of these peptides enhanced non-specific resistance in mice (66) and calves (67) infected with *Escherichia coli*. These peptides also exhibited high phagocytic activity in rainbow trout (68). However, their active components have not yet been identified.

4. Ovomucoid

Ovomucoid is a glycoprotein, with a molecular weight of 28 000 Da, comprised of 186 amino acids arranged into three domains, which are cross-linked by intradomain disulfide bonds (69). It is relatively resistant to treatment with heat or digestive enzymes, and it is this stability that has led to its being one of the dominant egg white allergens (70). Ovomucoid is also one of several egg white proteinase inhibitors, belonging to the group of serine proteinase inhibitors, namely inhibiting trypsin (69, 71). The inhibitory activity of ovomucoid toward trypsin and chymotrypsin was recently shown to be enhanced by site-directed mutagenesis, replacing amino acids around the reactive site of ovomucoid domain 3 (72).

The incorporation of ovomucoid into polymeric microparticles, to overcome the degradation of protein drugs by proteolytic enzymes, has been examined. Agarwal et al. (73) found that when ovomucoid was included, the stability of insulin in polymethacrylate based microparticulates was increased significantly. Inclusion of ovomucoid also resulted in targeting of drugs to the blood, by acting as a biospecific ligand to lectins on the walls of the gastrointestinal tract (74). The presence of ovomucoid was found to enhance insulin flux across rat jejunum (75), suggesting the use of ovomucoid to enhance the oral delivery of insulin. Using a rat model of experimental pancreatitis, intravenous ovomucoid was found to decrease the trypsin-like activity to the level of intact rats, and reduce the primary pancreas destruction (76).

Synthetic ovomucoid peptides have also demonstrated immunomodulating activity, inducing T-cell secretion of cytokines interleukin-(IL) 4, IL-10, IL-13, interferon-(IFN) gamma, and IL-6 (77).

Because of its allergenic nature, ovomucoid has limited biological and medical applications. It has however been used as a ligand in HPLC columns for the affinity and chiral separation of compounds of pharmaceutical importance such as trypsin, pentazocine and bupropion hydrochloride enantiomers (78, 79).

5. Lysozyme

Lysozyme is a ubiquitous enzyme, present in almost all secreted body fluids and tissues of humans, as well as plants, which plays an important role in the natural defense mechanism (80). The most plentiful source, however, is hens' egg white, containing around 0.3–0.4 g of lysozyme per egg (81).

Lysozyme acts as a mucopeptide N-acetylmuramyl hydrolase, exerting bacteriolytic activity by hydrolyzing the β(1–4) linkage between N-acetylmuraminic acid and N-acetylglucosamine of peptidoglycan, which is the structural component of bacterial cell walls (82). Gram-positive bacteria are more susceptible to lysozyme, as the cell wall contains around 90% peptidoglycan. Gram-negative bacteria, on the other hand, contain only 5–10% peptidoglycan, and this peptidoglycan lies beneath the outer membrane of the cell envelope (81). The lipopolysaccharide layer of the outer membrane acts as a barrier against macromolecules and hydrophobic compounds, making it more resistant to the action of lysozyme (81).

Lysozyme is ideal as a natural food preservative, as it is endogenous to many foods, specific to bacterial cell walls, and harmless to humans (81). It has been found to be most effective against *Bacillus stearothermophilus*, *Clostridium tyrobutyricum*, *Clostridium thermosaccharolyticum*, *Clostridium sporogenes* and *Bacillus* spp. (81). However, this spectrum can be broadened by the use of lysozyme in conjunction with other compounds, such as nisin and EDTA, to include *Enterococcus faecalis*, *Weissella viridescens* (83), *Brochothrix thermosphacta*, *Lactobaccilus sakei*, *Leuconostoc mesenteroides*, *Listeria monocytogenes* (84), and *Carnobacterium* sp. (85).

The physical treatment of lysozyme, including heat denaturation (86, 87) has been found to increase its antimicrobial activities against Gram-negative bacteria, as does high pressure treatment (88, 89). Other strategies have also been adopted to increase its activity against Gram-negative bacteria, including equipping the enzyme with a hydrophobic carrier to enable it to penetrate and disrupt the bacterial membrane (90, 91), and coupling it with a safe phenolic aldehyde with lethal activity toward the bacterial membrane (91). Enzymatic treatment, to expose amino acids 98–112 of lysozyme, which have been found to exert antimicrobial action (92, 93), as well as synthetic peptides corresponding to the C-terminal of lysozyme (94), have also been examined. Recently, Pellegrini et al. (95) demonstrated that polypeptides derived from lysozyme were capable not only of damaging the outer membrane of *Escherichia coli*, but could also inhibit DNA and RNA synthesis.

The use of lysozyme has been proposed for numerous antimicrobial applications in food, including inhibiting *C. tyrobutyricum* and *L. monocytogenes* in cheese and dairy products (81), controlling lactic acid bacteria in beer and wine (96–98), preventing *Edwardsiella tarda* infection in fish (99), inhibiting spoilage bacteria in meats (83–85), and for the bacterial decontamination of vegetables (81). Lysozyme has also been added to oral health care products, such as toothpaste, mouthwash and chewing gum to protect against periodontis-causing bacteria and to prevent infections in the oral mucosa (100, 101).

Lysozyme has been shown to exert antiviral activity, reportedly associated with its charge, rather than its lytic ability (81). Oral and topical applications of lysozyme were found to be effective in preventing and controlling several viral skin infections, including herpes simplex and chicken pox (100), as well as acting as exerting anti-inflammatory action (100). It has also been shown, when combined with immunotherapy, to be effective in improving chronic sinusitis (102), and to normalize humoral and cellular responses in patients with chronic bronchitis (100).

Finally, lysozyme has also been shown to act as an immune-modulating and immune-stimulating agent, enhancing immunoglobulin production, and regulating and restoring the immune responses in immune-depressed patients undergoing anti-cancer treatments (100, 103), and as an anticancer agent, the inhibitory action of lysozyme being demonstrated in a number of experimental tumors (104–107).

6. Avidin

Chicken avidin is a tetrameric glycoprotein, with an extremely high affinity for the water soluble vitamin biotin (108). The unique feature of this binding is the strength and specificity of the formation of the avidin-biotin complex, formed when avidin binds four molecules of biotin, the resulting affinity constant being the highest known for a protein and an organic ligand (109).

Due to the lack of interaction between the carboxy-containing side chain of biotin with avidin, biotin lends itself to chemical modification and conjugation to a wide variety of biologically active molecules, without altering its binding to avidin (109). This has led to numerous biochemical and diagnostic applications, including affinity chromatography, enzyme immunoassays, microscopy, and biosensors (110).

It has been suggested that avidin possesses antimicrobial properties, and it has been found to inhibit the growth of biotin-requiring bacteria and yeasts (108, 111). The antibacterial activity of avidin has also been attributed to its ability to bind to various Gram-negative and Gram-positive bacteria, including *Escherichia coli* K-12, *Klebsiella pneumoniae*, *Serratia marcescens*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, and *Staphylococcus epidermis*, in a dose-dependent manner, and independent of the saturation of the biotin-binding sites of the bacteria (112).

The strong binding between avidin and biotin was recently used as a model system in mice to examine the

use of proteins with high affinity binding sites to establish an absorptive barrier in the gastrointestinal tract to prevent the uptake of low molecular weight chemicals (113).

Avidin has also been found to be useful in medical applications, to localize and image cancer cells and to pre-target drugs to tumors. Because of its tight biotin binding and signal amplification due to the tetrameric structure of avidin, it leads to the accumulation of higher effective doses and increased persistence of biotinylated anti-cancer drugs, as compared to other immunotherapeutic procedures (114). Tumor pre-targeting with avidin has also been found to be effective in increasing the uptake of tumor necrosis factor (TNF) alpha conjugated to biotin *in vitro*, improving the anti-tumor activity of TNF (115–117). Yao et al. (118) found that radiolabelled avidin also bound to lectins expressed on the surface of tumor cells, and localized highly and rapidly in various types of tumors in mice, reducing radioactivity accumulation in other organs. These results suggest that avidin may be a promising vehicle for the delivery of radioisotopes, drugs, toxins or therapeutic genes to tumors (118).

Avidin was also found to be essential for the activity of adoptively transferred T-cells at tumor sites (119), and the utilization of avidin in drug delivery through the blood-brain barrier has also been demonstrated, allowing delivery of therapeutics to the brain (120).

Several chemically modified forms of avidin have also been developed to improve their pharmacokinetics and biodistribution, while reducing immunogenicity (121–123).

7. Cystatin

A member of a "superfamily" of cystatins, egg white cystatin belongs to the Type 2 cystatins, which have about 115 amino acids and two disulphide bonds, but no carbohydrate (124). Egg cystatin inhibits most cysteine proteinases, including ficin, papain, and cathepsins B, C, H and L, and is found in the egg white at levels of around 60–80 μg/mL (8). Low contents of cystatins in natural resources may limit their applications (125). However, genetic modification and expression of cystatin has been carried out, not only providing a source for increased quantities of cystatin, but also resulting in the production of recombinant cystatin with enhanced proteinase inhibitory activity (126), and increased stability to heat (127) and freezing (128).

Egg white cystatin has been shown to possess antibacterial activity, preventing the growth of group A streptococcus (129), *Salmonella typhimurium* (125), and the periodontis-causing *Porphyromonas gingivalis* (130). Blankenvoorde et al. (131) found that cystatin-derived peptides were also capable of inhibiting the growth of *P. gingivalis*.

It has been suggested that cystatins may not only have a general function of protecting cells against uncontrolled activities of their own proteinases, but may also protect against viral proteinases responsible for viral infection (8). Similar cysteine protease inhibitors have shown antiviral activity against herpes simplex virus, poliovirus (129, 132), and human rotavirus (133).

Cystatins may also have medical applications, resulting in less intensive side effects than other synthetic protease inhibitors currently used in medical treatments (125). A relationship between cystatins, cytokines, and the immune response has been suggested. It has been observed that cystatin induced the synthesis of various cytokines (134), resulting in an up regulation of nitric oxide release *in vitro* using mouse peritoneal macrophages (135, 136), as well as *in vivo*, greatly reducing parasite numbers in a mouse model of visceral leishmaniasis (137).

Increased levels of cysteine proteases, and the concomitant decrease of cystatin, has been observed in various cancers (138, 139), and cystatin has been shown to inhibit tumor invasion in ras-transformed breast epithelial cells (140), suggesting a role for chicken cytstatin in cancer therapy.

The use of chicken cystatin has also been recently suggested for food preservation applications, including its use to inhibit autolysis or gel softening in seafood (141).

8. Ovomacroglobulin (Ovostatin)

Ovomacroglobulin, also referred to as ovostatin, is a glycoprotein composed of four subunits, each with a molecular weight of 175 000 Da, joined in pairs by disulfide bonds (142). It has demonstrated broad-spectrum inhibitory activity against various types of proteases, including serine proteases, cysteine proteases, thiol proteases, and metalloproteases (142, 143).

The antimicrobial effects of ovomacroglobulin against *Serratia marcescens* and *Pseudomonas aeruginosa*, due to its proteinase inhibitory action, have been studied extensively both *in vitro* (143–146). *In vivo*, it was found to reduce corneal destruction in an experimental keratitis model in rabbits, as well as to accelerate wound healing (146, 147). Ovomacroglobulin was also found to enhance periodontal wound healing in rats, by accelerating fibroblast growth, collagen deposition, and capillary formation in tissue (148).

The proteinase inhibitory effects of ovomacroglobulin have also demonstrated a number of other biological effects, including the suppression of septicemia by *P. aeruginosa* and *Vibrio vulnificus* due to the inhibition of kinin generating proteases (149, 150), the *in vitro* inhibition of the inflammatory proteinase medullasin (151), and the suppression of metalloproteinases and enhanced vascular permeability in skin tissues, which play a role in tumor metastasis (152).

9. Ovoinhibitor

Another proteinase inhibitor in egg white, ovoinhibitor is a glycoprotein composed of a single 447-amino acid

polypeptide (153, 154) with a reported molecular weight between 46 000 and 49 000 Da (153, 155, 156). Like ovomucoid, ovoinhibitor is a serine proteinase inhibitor, inhibiting enzymes such as trypsin, chymotrypsin, and elastase, as well as various bacterial and fungal proteinases (155–157).

Ovoinhibitor has been found to prevent the development of rotavirus induced gastroenteritis in a mouse model of rotavirus infection (158), and to inhibit the formation of active oxygen species by human polymorphonuclear leukocytes, which are associated with inflammatory diseases, mutagenicity and carcinogenicity (159). It has also been used to study models of autoimmune arthritis in mice (160) as well as for biochemical applications such as the removal of contaminating proteinases from protein solutions, and the purification of serine proteinases (161, 162).

Proteinases are involved in the regulation of a number of biological processes, and have been implicated as contributors in several diseases, including viral diseases such as HIV (163), and Alzheimer's disease (164). Proteinase inhibitors, therefore, such as those from egg white, have significant potential for the treatment and prevention of proteinases-mediated diseases.

C. Egg Yolk

Several biological activities are associated with egg yolk components, and are summarized in Table 90.2.

1. Immunoglobulin (Ig) Y

Immunoglobulin (Ig) Y is the functional equivalent of IgG, the major serum antibody in mammals (165). It is transferred to the developing embryo, to give acquired immunity to the chick (166, 167). The yolk then may contain from 5 to 25 mg/mL of IgY (168, 168). Specific IgY can be produced by immunization of chickens with the desired protein, and then conveniently purified from the egg yolk (165, 170). The use of egg yolk antibodies presents many advantages over those produced in mammals, including being less invasive and less stressful on the animal, being more cost-efficient, and resulting in a higher yield of antibody per animal (165, 169). As well, yolk antibodies do not activate the mammalian complement system or interact with mammalian Fc receptors that could mediate inflammatory response in the gastrointestinal tract (165).

While IgY has been applied for numerous immunodiagnostic and immunoaffinity purification purposes,

TABLE 90.2
Biological Properties of Egg Yolk Components

Component	Properties	Reference
Immunoglobulin Y	Antibacterial activity	177–191, 194, 195

considerable research has focused on the use of IgY for immunotherapeutic applications, especially for the oral passive immunization of immunocompromized individuals against various bacteria and viruses. IgY has been produced against several bacteria and viruses, and has been shown to bind to and inhibit the infection and disease symptoms, *in vitro* and *in vivo*, of gastrointestinal pathogens such as human and bovine rotavirus (171–175), bovine coronavirus (176), *Escherichia coli* (177–183), *Salmonella* spp. (184–188), *Yersinia ruckeri* (189), *Edwardsiella tarda* (190), *Helicobacter pylori* (191), porcine epidemic diarrhea virus (192), infectious bursal disease virus (193), *Staphylococcus aureus* (194, 195) and *Pseudomonas aeruginosa* (194).

Egg antibodies against *Streptococcus mutans* have been shown to prevent adhesion of the bacteria *in vitro* and *in vivo*, and reduced dental caries development in an animal model (196–199). Chicken anti-venom IgY has been produced, for treatment of snake and spider bites, and was found to have a higher bioactivity than anti-venom raised in horses (200, 201). IgY also has a lower likelihood of producing significant clinical side effects, such as serum sickness and anaphylactic shock, which can occur upon administration of mammalian serum proteins (200, 202).

The use of IgY has also been examined to replace the anti-inflammatory drugs used to treat Crohn's disease and ulcerative colitis. Worledge et al. (203) reported that anti-TNF antibodies produced in chickens were capable of effectively treating acute and chronic phases of colitis in rats, and were also found to neutralize human TNF *in vitro*, indicating its possible use for the treatment of inflammatory bowel disease in humans.

Finally, IgY has been suggested for use in targeting cancer cells, to act as a carrier for anti-tumor drugs (204).

2. Phosvitin

Phosvitin is a highly phosphorylated protein with a molecular weight of 35 000 Da, containing 10% phosphorus and 6.5% carbohydrates (205). It contains 123 serine residues, which account for 57.5% of the total amino acid residues (206). Ninety-five percent of the iron in eggs is present in the yolk and is bound to phosvitin (207); however, its bioavailability is very low (208). This is due to the strong binding of phosvitin, or its phosphopeptide derivatives, with Fe^{3+}, and the formation of phosvitin-iron complexes which promote the precipitation of iron in the small intestine. Thus, phosvitin is presumed to be responsible for the poor bioavailability of egg yolk iron (209–211). However, Jiang and Mine (212, 213) produced functional phosphopeptides, with a molecular weight of 1000–3000 Da, derived from tryptic hydrolysis following partial alkaline dephosphorylation. These peptides exhibited enhanced calcium-binding capacity and inhibited the formation of insoluble calcium phosphates. These results suggest that novel functional phosvitin phosphopeptides may have potential applications as nutraceuticals.

Phosvitin also demonstrated a capacity to inhibit iron catalysis of phospholipid oxidations (214). Thus, phosvitin could be useful in foods as a natural antioxidant.

3. Lipoproteins (Low Density Lipoproteins, LDL)

The low density lipoproteins (LDL) fraction of yolk plasma is composed of 89% lipid and 11% protein (215). The lipid content of LDL is 70% triacylglycerol, 4% cholesterol, and 26% phospholipids (216).

The proliferative activity of LDL has been demonstrated using human histocytic lymphoma cells (U-937), human monocytic leukemia cells (THP-1) and U-937-derived macrophage-like cells (U-M) (217). LDL was also shown to enhance the production of IgM in human-human hybridomas (218).

LDL is widely used as a cryoprotectant for bull semen and it has shown better efficiency than commercial extenders (219).

4. Sialic Acid

Sialic acid is a general term for derivatives of neuraminic acid which have an acyl group on the amino nitrogen. The most widely distributed sialic acid in nature is N-acetylneuraminic acid (Neu5Ac) (220). Egg yolk has been examined as a source of sialic acid, and was found to be an excellent source for the large scale preparation of Neu5Ac (221, 222).

Sialic acids possess many biological functions, including acting as receptors for microorganisms, toxins, and hormones, and masking receptors and immunological recognition sites of molecules and cells (223).

Sialic acid may act as an anti-inflammatory agent. Cells carrying a carbohydrate ligand called sialyl-Lewis X were found to bind to endothelial leukocyte adhesion molecule-1 (ELAM-1), which mediates the adhesion of circulating leukocytes to the vascular endothelium during inflammation (224, 225). The anti-inflammatory effects of sialyl-Lewis X were also shown *in vivo*, reducing lung injury in rats (226) and reducing tissue injury in rabbit ears, caused by a temporary increase in blood supply (227).

Finally, a sialic acid analogue, zanamivir, has demonstrated potent antiviral effects, and was found to reduce the symptoms of influenza infections in humans, by inhibiting influenza A and B virus neuraminidases, enzymes essential for the release of virus from infected cells (228).

5. Sialyloligosaccharides

Several sialyloligosaccharides in chalaza, egg yolk membrane and delipidated egg yolk have been isolated by acid hydrolysis or protease digestion (229, 230). These

sialyloligosaccharides are likely to be naturally present as glycoproteins or glycopeptides (230). A sialylglycopeptide, Lys-Val-Ala-Asn-Lys-Thr, the Asn of which was modified with the disialylglycan moiety, was isolated from egg yolk (231). Sialylglycoconjugates, sialylgangliosides, sialyloligosaccharides and sialylglycoproteins have been reported to play various important roles in animal and human tissue cells.

The oligosaccharide-enriched fraction of sialyloligosaccharide was found to significantly inhibit rotavirus infection both *in vitro* and *in vivo*, with the sialic acid moiety of the oligosaccharide playing an important role in the inhibition (232). Sialyloligosaccharides also inhibited *Salmonella* infection not by activating macrophages, but by inhibiting the entry of bacteria through the gut (233).

6. Yolk Lipids

Dry egg yolk contains approximately 60% lipids (234), and of this around 65% is triglyceride, 28% is phospholipid, and 5% is cholesterol (8). The fatty acid composition of the lipid fraction of egg yolk varies, and is influenced by the type of fat in the hen's diet (8). Egg yolk lipids have found numerous applications in the food, cosmetic, pharmaceutical and nutraceutical industries.

Egg yolk lipids are natural surfactants, and have been applied in the food industry as emulsifying, wetting, and dispersing agents, releasing agents, sealants and lubricants (234). Food products containing unsaturated fatty acids are often susceptible to oxidation. To prevent this antioxidants are commonly added; however the safety of synthetic antioxidants is often questioned (220, 235). Yolk lipids have been shown to possess antioxidant activity in fish oil, vegetable oil, and animal oil, both alone and in conjunction with primary antioxidants (234–236). Egg yolk lipids have also been used in the cosmetic industry, due to their non-toxic nature, as they replenish lipid deficiency in the skin and closely resemble skin lipids (234).

Rabinowich et al. (237) noted that the administration to elderly individuals of an egg yolk-derived lipid mixture, formulated for *in vivo* rectification of rigidified cell membranes in an attempt to restore proper physiological function, resulted in an increase in lymphocyte responsiveness, and suggested that immune functions may be modulated by the dietary manipulation of lipids.

A well established parenteral fat emulsion derived from egg yolk lipids is often used as a carrier of fat soluble drugs (220).

Cholesterol is an important component in cell membranes and is needed for the growth of infants. As well, it is a precursor of bile acids, sex hormones and cortex hormones (234). The supplementation of infant formulas with egg yolk lipids has been suggested to more closely resemble the mother's milk; it has been found that while providing essential nutrients, the yolk lipids did not result in an increase in plasma cholesterol, indicating that it could safely be included in the infant diet (238). Egg yolk cholesterol has also been suggested for use in the treatment of Smith-Lemli-Opitz syndrome, a condition in which the activity of 7-dehydrocholesterol delta(7)-reductase, the final enzyme in cholesterol biosynthesis, is reduced resulting in reduced plasma and tissue concentrations and an accumulation of cholesterol precursors. Patients receiving supplemental dietary cholesterol from egg yolk exhibited a significant increase in plasma cholesterol levels, and a decrease in plasma levels of cholesterol precursors which may be toxic (239).

7. Phospholipids

Phospholipids (PLs) are lipids which contain phosphate and have a glycerol-phosphate backbone (234). About 31% of the egg yolk lipids are PLs (234), of which phosphatidylcholine (PC) makes up around 73% of the total PLs, followed by phosphatidylethanolamine (PE 15%), lysophosphatidylcholine (LPC 5.8%), and sphingomyelin (SM 2.5%). The remaining 3.7% is made up of lysophosphatidylethanolamine (LPE 2.1%), plasmalogen (0.9%) and inositol phosholipid (IP) (240).

Phospholipids are amphiphilic molecules, having both polar and non-polar groups, therefore most PLs will spontaneously form a bilayer when exposed to an aqueous environment (234), making them ideal for studying membranes and preparing liposomes (aqueous compartments enclosed by a lipid bilayer), the latter of which the main constituent is PC (220). Phospholipids from soy beans are typically used to prepare liposomes, but egg yolk PLs present several advantages, including high entrapment efficiency, stability, and low cost (241). Egg PC-containing liposomes have been shown to be effective for drug delivery to tumors (242–254), and for drug delivery to the brain (246), reducing the toxicity and side effects, as well as prolonging the concentration compared to the free drug by itself.

Feeding infants with formula containing egg PLs was found to reduce the incidence of necrotizing enterocolitis, suggesting that one or more of the compounds of egg PLs may enhance the immature intestinal functions of infants (247).

Egg yolk PLs were also shown to decrease serum cholesterol levels in rats (248), with PC in particular reducing the intestinal absorption of cholesterol (249). As well, PLs have been found to improve memory retention and increase concentrations of acetylcholine, a neurotransmitter which decreases in concentration in cases of Alzheimer's disease (250, 251). A diet including egg PC was also found to enhance "maze-learning" ability and brain functions in old mice (252).

It has been suggested that egg PLs may exert a degree of antiviral activity by interfering with the viral envelope formation, and by protecting or restoring transmembrane

signaling functions in host cells (253). Furthermore, bacterial or viral infections may also be reduced by an activation of immune cells by egg PLs, as immune cells grown *in vitro* require exogenous fatty acids, which could be provided by egg PLs (253).

The more recent focus has been on the specific PL components namely arachidonic acid (AA), docosahexaenoic acid (DHA), and choline, whose metabolic products may play a role in membrane integrity, modulation of the membrane, and activation of immune cells (253). Egg yolk PC is a significant source of choline, which is an important nutrient in brain development, liver function, and cancer prevention (254). DHA and AA are important in the maintenance of normal neural functions, and have been shown to promote effects that are hypolipidemic, antithrombic, vasodilatory, and anti-inflammatory (255). DHA and AA will be discussed in more detail later.

IV. MODIFICATION OF YOLK LIPIDS FOR HEALTH BENEFITS

It has already been demonstrated that eggs possess a number of compounds beneficial for human health. However, the laying hens' diet can be manipulated to modify the resulting egg yolk lipids, and further enhance the nutritional benefits of the eggs.

Considerable focus has been placed on the enrichment of eggs with long chain omega (ω-3 polyunsaturated fatty acids (PUFAs), the ω referring to the position of the first double bond counted from the terminal methyl carbon of the fatty acid (255). The health benefits of ω-3 fatty acids are significant, suggested for the prevention and treatment of hypertension, arthritis, autoimmune disorders, as well as inhibiting certain cancers, and being essential for fetal brain and visual development (255).

It is widely recognized that the Western diet is deficient in ω-3 PUFAs, which include linolenic acid (LNA), eicosapentaenoic acid (EPA), docosapentaenoic acid (DPA), and docosahexaenoic acid (DHA), and which can generally be obtained through the consumption of fish (256). Consequently, the ratio of ω-6 fatty acids, which include linoleic acid (LA) and arachidonic acid (AA) and come from sources such as vegetable oils, to ω-3 fatty acids is approximately 20–30:1, rather than the desired ratio of 1–2:1 (257).

Researchers have been actively pursuing the design of a commercially viable ω-3 fatty acid-rich egg for several years (258). A number of dietary supplements have been shown to increase the ω-3 PUFA levels in hens' eggs, each producing a different ω-3 fatty acid distribution. These include flax seed, canola seed, fish oils, marine algae, linseed oil, vegetable oils and oil mixtures (256, 259, 260). This research has resulted in the production of so called "designer eggs," capable of supplying around 600 mg of total ω-3 fatty acids, which is approximately equivalent to a 100 g serving of fish (261). The feeding of conjugated linoleic acid (CLA) to hens' has also been suggested as a method to manipulate the fatty acid profile of egg yolk (262, 263).

Because ω-3 PUFAs are highly susceptible to peroxidation, the addition of vitamin E to hens' diets, along with the ω-3 PUFAs, has been examined, to control the production of cytotoxic aldehydic lipid peroxidation products during production and storage of the eggs (264). Cherian et al. (265) also described the addition of palm oil to hens' diet to increase the levels of antioxidants (tocopherol, tocotrienol, carotene, and retinol) in the egg yolk.

Lewis et al. (260) found that feeding individuals four ω-3 PUFA-enriched eggs a day for four weeks did not significantly increase plasma cholesterol and low-density lipoprotein (LDL) levels. Rather, plasma triglycerides and blood platelet aggregation decreased, and it was suggested that the inclusion of ω-3 PUFAs may influence LDL particle size, resulting in a less artherogenic particle.

The health benefits of ω-3 PUFAs have been well documented. Dietary ω-3 PUFAs have been shown to exert antihypertensive effects and decrease blood pressure in hypertensive rats, as well as altering the fatty acid composition of plasma triacylglycerols, cholesterol esters and red blood cell total lipids (266–268). DHA has demonstrated anti-tumor activity against various cancers, inhibiting the growth of and inducing apoptosis in Caco-2 colon cancer cells (269, 270), inhibiting carcinogenesis and reducing tumor size and number in a multi-organ carcinogenesis model in rats (271), as well as increasing the toxicity of anti-tumor drugs in tumor cells. The results indicate that DHA may have the potential to selectively target anti-tumor drugs to the tumor cells while at the same time reducing toxicity towards host cells (272). It has also been suggested that ω-3 PUFAs possess immunomodulatory activity, and their consumption may be useful for the management of inflammatory and autoimmune diseases (273, 274). Finally, ω-3 PUFAs, and DHA in particular, have demonstrated a key role in infant health, increasing visual acuity and cognitive development (275, 276), and improving PUFA profile in infants with cholestasis (277).

Therefore, ω-3 PUFA-enriched eggs may help to increase the intake of ω-3 fatty acids in the general population, leading to a restoration of the ω-6 to ω-3 fatty acid ratio, and resulting in increased health benefits of egg consumption.

V. SUMMARY

Egg is the largest biological cell known which originates from one cell division and is composed of various important chemical substances that form the basis of life. Therefore, the avian egg is considered to be a storehouse of nutrients

such as proteins, lipids, enzymes and various biologically active substances including growth promoting factors as well as defence factors against bacterial and viral invasion. In the last decade, numerous extensive studies characterizing biophysiological functions of egg components and seeking novel biologically active substances in the hen eggs have been conducted. By compiling a review of these studies into a single focussed work, this review provides evidence that hen eggs contain various biologically active substances with specific benefits for human health and would be ideal sources for medical, cosmetic, nutraceutical and food-fortification applications. Our base of knowledge is dynamic and rapidly expanding with new information continually appearing.

91 Enzymes as Functional Ingredients

Conrad O. Perera
Palmerston North, New Zealand

Anne D. Perera
Crop and Food Research Institute of New Zealand

CONTENTS

I. INTRODUCTION

This chapter will attempt to cover the importance of enzymes in the biotransformation of a number of food products. The existence of enzymes has been known for well over a century. In 1835 the Swedish chemist Jon Jakob Berzelius found the catalytic action of enzyme. The first enzyme obtained in pure form was in 1926, by James B. Sumner of Cornell University. Sumner was able to isolate and crystallize the enzyme urease from the jack bean. His work earned him the 1947 Nobel Prize (1).

Although a reaction may have a large negative Free Energy ($-\Delta G$) value, it does not necessarily proceed at a measurable velocity. For example the oxidation of glucose to CO_2 and H_2O has a ΔG value of -163 kJ/mole. Yet, crystalline glucose or a sterile solution of glucose does not spontaneously oxidize in the presence of air. The rate of a reaction depends on the number of molecules that attain a certain minimum "activation energy." The activation energy is a barrier that must be overcome for the reaction to take place spontaneously.

The activation energy for a chemical reaction could be supplied by adding heat to the system to raise the temperature. However, living biological systems can only exist within narrow temperature limits and have no mechanism to specifically add heat to certain reactions and not to others. Enzymes are catalysts that increase the rate of specific chemical reactions in biological systems by lowering the activation energy required. All known enzymes are proteins. They have molecular weights ranging from 10,000 to 2,000,000, but most fall in the range 15,000 to 60,000. Many enzymes require the presence of other compounds called cofactors before their catalytic activity can be exerted. This entire active complex is referred to as the holoenzyme; i.e., apoenzyme (protein portion) plus the cofactor (coenzyme, prosthetic group or metal-ion-activator) is called the holoenzyme (1).

$$\text{Apoenzyme} + \text{Cofactor} = \text{Holoenzyme}$$

The cofactor could be:

1. A coenzyme — a non-protein organic substance which is dialyzable, thermostable and loosely attached to the protein part.
2. A prosthetic group — an organic substance which is dialyzable and thermostable which is firmly attached to the protein or apoenzyme portion.
3. A metal-ion-activator — these include K^+, Fe^{++}, Fe^{+++}, Cu^{++}, Co^{++}, Zn^{++}, Mn^{++}, Mg^{++}, Ca^{++}, and Mo^{+++}.

Specificity of enzymes makes them important as diagnostic and research tools. A few enzymes exhibit absolute specificity. Other enzymes are specific for a particular type of chemical bond or functional group. In general, there are four distinct types of specificity:

- Absolute specificity — the enzyme will catalyze only one reaction.
- Group specificity — the enzyme will act only on molecules that have specific functional groups, such as amino, phosphate and methyl groups.
- Linkage specificity — the enzyme will act on a particular type of chemical bond regardless of the rest of the molecular structure.
- Stereochemical specificity — the enzyme will act on a particular steric or optical isomer.

Though enzymes exhibit great degrees of specificity, cofactors serve many apoenzymes. For example, nicotinamide adenine dinucleotide (NAD) is a coenzyme for a great number of dehydrogenase reactions in which it acts as a hydrogen acceptor, e.g. alcohol dehydrogenase, malate dehydrogenase, and lactate dehydrogenase reactions. Enzymes are used in the food industry as processing aids or to improve or maintain the quality of various food products. Use of enzymes further provide the possibilities for novel product and process developments.

The world market for sale of industrial enzymes has more than doubled in the last six years and is projected to more than triple in 2005 what it was in 1992 (Table 91.1).

II. ENZYME CLASSIFICATION

There are six classes of enzymes and they are denoted by an EC number according to the Enzyme Commission. The

Table 91.1
Industrial Enzymes: Worldwide Market Forecast, 1997–2002 ($Million)

Market Sector	1997	1998	2002	% Average Annual Growth Rate 1997–2002
Food and animal feed	705.0	729.7	833.1	3.5
Detergents/cleaners	475.2	498.0	600.9	4.8
Textiles, leather, and fur	161.0	164.2	182.7	2.0
Pulp and paper	97.6	104.3	136.0	6.9
Chemicals manufacture	59.2	60.8	67.6	2.7
Total	1,498.0	1,557.0	1,820.3	4.0

Source: Business Communications Company, Inc. (May 11, 1998)

first digit is the class (general reaction type — see below). The second digit is the bond involved. The third digit defines the bond more closely and a fourth, the number of enzymes identified to date performing the function (over 90 in the case of alpha-amylases).

Six classes of enzymes published in *Enzyme Nomenclature* 1992 (2) are shown below:

1. Oxidoreductases (EC 1…) — Catalyse oxidation–reduction reactions. Act on a number of groups, each group has a number. For example: CH-OH is 1.1; Aldehyde is 1.2; peroxide is 1.11; superoxide radical is 1.15, etc. Examples: dehydrogenases, oxidases, hydroxylases.
2. Transferase (EC 2…) — Catalyse functional group transfers. Transfer the following groups. For e.g. one carbon is 2.1; aldehydes or ketones 2.2; acyl 2.3; glycosyl 2.4; etc. Examples: kinases, aminotransferases.
3. Hydrolases (EC 3…) — Catalyse hydrolysis reactions. Hydrolyse the following bonds. For e.g. ester 3.1; glycosidic 3.2; ether 3.3; peptide 3.4 etc. Examples: trypsin, carboxypeptidase, amylase, maltase.
4. Lyases (EC 4…) — Catalyse elimination or addition of groups to form double bonds. Lyse the following bonds. For example, C-C 4.1; C-O 4.2; C-N 4.3; C-S 4.4; C-halide 4.5; P-O 4.6; other 4.99. Examples: synthases, decarboxylases, fumarase, aldolase.
5. Isomerases (EC 5...) — Catalyse reactions that alter the structure but not the composition (optical, geometric or structural isomers). Isomerise a given molecule. For example, racemases and epimerases EC 5.1; cis-transe isomersase EC 5.2; intra oxidoreductase EC 5.3; etc. Example: gluose-6-phosphate isomerase.
6. Ligases (EC 6…) — Catalyse coupling of two compounds along with hydrolysis of a phosphoanhydried bond. Act on compounds forming the following bonds. For eg. C-O 6.1; C-S 6.2; C-N 6.3; C-C 6.4; P-ester 6.5. Example: synthetases, DNA Ligase.

III. PRODUCTION OF ENZYMES

Enzymes were originally extracted in very impure forms from animal and plant sources. Today, however, industrial production is usually via a bacterial, fungal, or yeast fermentation. Such fermentations are usually carried out using well tried and tested species — notably the fungi *Aspergillus niger*, *A. oryzae*; bacteria *Bacillus subtilis*, *Streptomyces griseus*; or yeasts *Saccharomyces cerevisiae*, *Kluyveromyces fragilis* (3). These species have the advantage that regulatory authorities worldwide recognize them as safe.

A major problem with many enzymes is that the output from fermentation is not a single pure enzyme of well defined concentration. Much work has been concentrated on achieving reproducible products. There are a number of companies in the western world producing enzymes commercially, of which 10–12 are major players.

A. Applications

Classic enzyme modulated reactions in food processing include:

- Starch hydrolysis using amylases (brewing, ethanol and glucose production, baking)
- Other carbohydrases such as beta-glucanase and pectinase in wine processing, beer, and juice clarification
- Proteinases both have a role in viscosity reduction (endoproteases) and Maillard reaction flavouring (exoproteases)
- Lipases and proteases are critical to the development of cheese flavours — especially enzyme modified cheese

B. Legislation

Enzymes in the EU are almost always treated as processing aids, rather than components of the food matrix. In these circumstances, they do not currently need to be declared on a label.

In recent years, the issue of genetically modified (GM) foods has caused concern to food manufacturers. Without considering the scientific logic of the issue, the current legislative climate in the EU requires that labeling identifies the possibility that GM ingredients are, or may be, present. In this context, it is likely that the processing aid exception may be reviewed and this could have a significant effect in slowing the development of novel and more efficient enzyme systems.

IV. USE OF ENZYMES IN FOODS

A. Use of Enzymes in Juice Manufacture

Plant tissue contains vacuoles, which contain all the water-soluble components and their precursors such as sugars, acids, salts etc. The vacuole is enclosed in a semi-permeable membrane system consisting of lipoproteins that allows transport of only the water molecules.

This is how osmotic pressure is created — presses the membranes against the cytoplasm and cell wall — gives turgor pressure, which keeps the fruits and vegetables firm and fresh.

The cell walls are also permeable. They are rigid structures consisting of pectin, cellulose, and hemicellulose. Pectin is the main constituent of middle lamella, which glues the cells together (Figure 91.1).

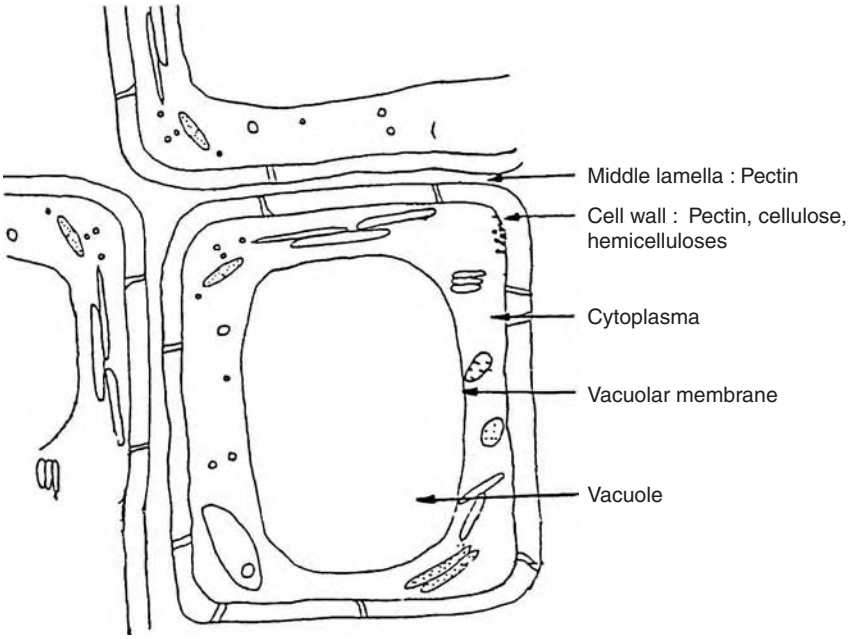

Figure 91.1 Schematic diagram of a parenchymal cell.

Enzymes are located in mitochondria found in the cytoplasm. Juice is really the cell sap, which can only be obtained by destroying the membrane. This can be done by mechanical cell disruption, or exposing the vacuoles when the restraining cell walls are enzymatically removed, or by denaturing the membrane in diffusion processes with hot water or alcohol.

1. Pressing

The traditional way of making fruit juice is by pressing. It is essentially a process of cell disruption with mechanical separation. Different techniques are used for clear and cloudy juices. Cell disruption means the compartmentalization of the tissue is destroyed. As a consequence many chemical, biochemical, and physical changes may occur.

Pectin is important in juicing, because a fraction of the pectin is found in the soluble form in the cell wall. It becomes dissolved in the liquid phase during grinding and pressing. The pectin in the juice can cause the following changes:

1. Increase in viscosity
2. Stabilize the cloud particles
3. Cause gelling of concentrates
4. Cause formation of flocks during storage

Clarification treatments therefore include enzymatic degradation of pectin using commercial fungal enzymes with strong pectolytic activity. A schematic diagram of a pectin molecule and the points of attack of the pectolytic activities (4, 5) are illustrated in Figure 91.2. Pectin is a chain of 1-4 linked galacturonic acids, part of which is esterified with methanol.

Pectin Lyases depolymerise highly esterified pectin by splitting glycosidic linkages next to methylesterified carboxyl groups through a β-elimination process. Another depolymerisation pathway is by the combination of pectin esterase (PE), also known as Pectin methyl esterase (PME) and polygalacturonase (PG).

PE splits off methanol from highly esterified pectin, transforming it into low ester pectin, which is hydrolyzed by PG attacking glycosidic linkages next to a free carboxyl group. PE and PG are also found as endogenous enzymes.

Pectate Lyase (PAL) also attacks glycosidic links next to a free carboxyl group. Thus PE also prepares the substrate for this enzyme.

PAL is a bacterial enzyme and is not found in fruits and vegetables or enzyme extracts from fungal preparations. It has a high pH optimum and is unsuitable for fruit processing.

2. Clarification of Juice

For clarification of juice, only the pectolytic activities are necessary. Raw pressed juice is a viscous liquid with a persistent cloud of cell wall fragments and complexes of such fragments with cytoplasmic protein.

Addition of pectinase lowers the viscosity and causes the cloud particles to aggregate and sediment, and can be easily centrifuged off (see Figure 91.3). This mechanism was first proposed by Yamasaki in 1964 (6) and elucidated in another paper by him and his colleagues in 1967 (7).

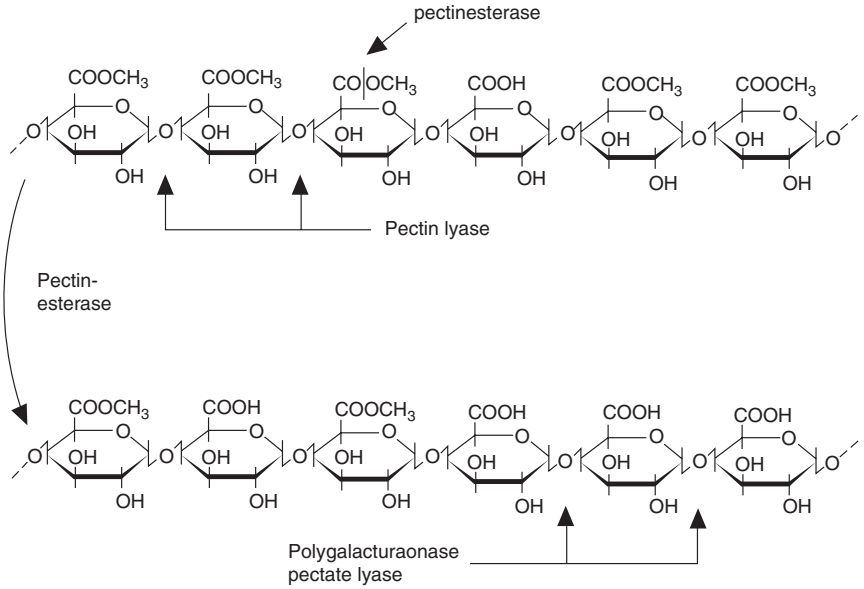

Figure 91.2 Schematic diagram of a pectin molecule and the points of attack of the different pectinase enzymes.

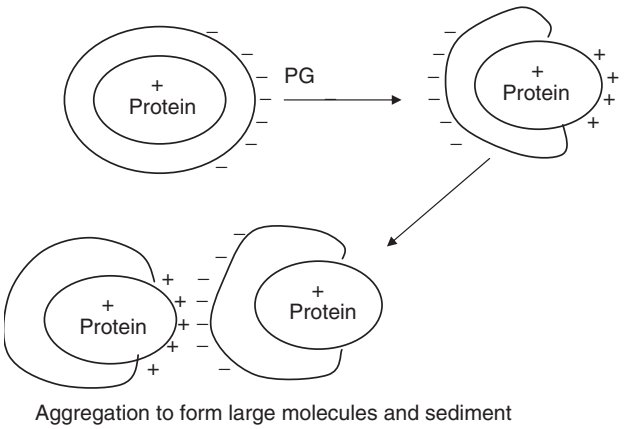

Figure 91.3 Schematic diagram of the principle of juice clarification.

The cloud particles have a protein nucleus with a positive surface charge, coated by negatively charged pectin molecules. Partial degradation of these pectin molecules by PG enzymes results in the aggregation of oppositely charged particles.

The reduction in viscosity of raw juice is also brought about by the action of pectinase enzymes (PG and PE). This same effect is also brought about by pectin lyase (PL), which is found in small amounts in commercial enzyme preparations. Pectin degradation is also important in the manufacture of high Brix concentrates to avoid gelling and the development of haze.

Clarification also includes starch degradation by amylase in cases where starch is present and has had the chance to gelatinize. Haze formation occurs in apple and pear juices that have been sparkling clear, after concentration and storage. Analysis of the haze has shown that most of it due to arabinans with α–(1-5) main chain and α–(1-3) side chain. These can be hydrolyzed by a combination of exo- and endo-arabinases (4).

3. Pulp Enzyming

Certain fruits do not press well after storage or if they are over-ripe. e.g. apples, plums, nectarines, etc. develop a mealy texture — does not give rise to good juice extraction. This is due to large fractions of pectin that have been solubilised, so that the viscous juice adheres to the pulp. Use of pressing aids such as cellulose fiber or rice hulls can improve this situation.

Pectolytic enzymes can also be used to for juicing of soft fruits. Breakdown of pectin releases thin free-flow juice, so that at high pressures a thin juice can be extracted. Prevention of the inactivation of added enzymes by polyphenols is an important aspect of the process.

In the case of apples, endogenous Polyphenol oxidase (PPO) is encouraged to oxidize the phenols by aeration and polymerize. The polymerized phenols are unable to combine with the added enzymes. An alternative is to add PVPP to bind the phenols.

Enzyme preparations that work well with juice clarification are also suitable for enzyme treatment of pulp. In the case of apples, any combination of enzymes that de-polymerize highly esterified pectin can be successfully used (8).

A better release of anthocyanins of fruits into the juice is also achieved by cell wall destruction by pectinase enzymes. This is also a distinct advantage in red-wine making.

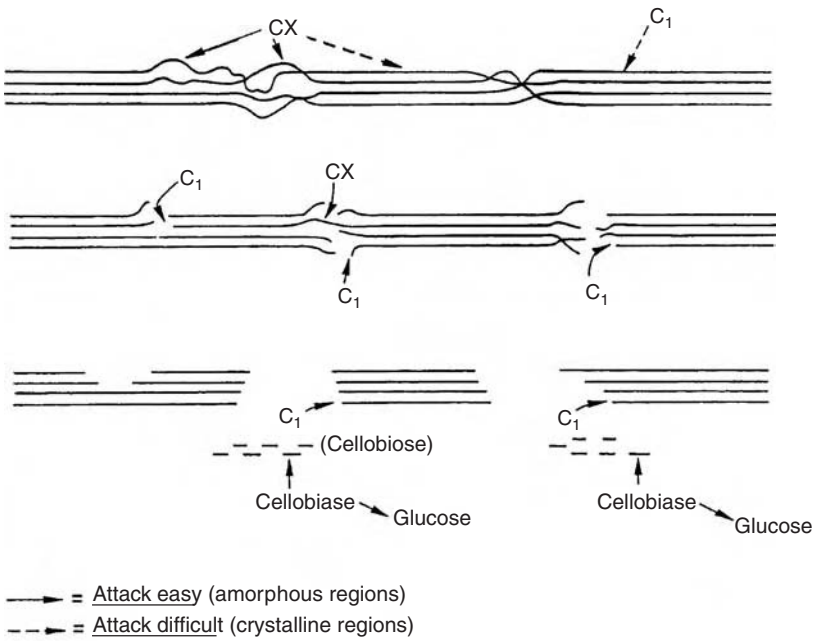

Figure 91.4 Schematic diagram of the points of attack of the endo- and exocellulose enzyme on the cellulose molecule.

4. Liquefaction

Commercial preparations of cellulase obtained from *Trichoderma* species became available in the 1970s. Degradation of crystalline cellulose requires a particular set of enzymes. With respect to hydrolysis, cellulases can be divided into endo- and exo-acting enzymes. The presence of exo-β-glucanase (C1 cellulase or cellibiohydrolase) is typical of cellulase preparations which are able to degrade highly ordered cellulose to form cellobiose (4).

Degradation of crystalline cellulose is believed to occur at the surface of the cellulose fibril by endo-β-glucanase, followed by exo-β-glucanase. Cellibiose, a competitive inhibitor of cellulases, is hydrolyzed by cellobiase to glucose.

A combination of cellulase and pectinase act synergistically, to decrease the viscosity dramatically (9). The low viscosity values reached corresponds to complete liquefaction shown by the disappearance of cell walls under a microscope. Enzyme liquefied papaya and cucumber are almost clear, apples and peaches are cloudy, carrots are pulpy. This depends on the accessibility of the cell compounds to the enzymes.

The exo cellulase (C1 cellulase) works in cooperation with endo-β-glucanase (CX-cellulase) and a β-glucosidase also known as cellobiase (Figure 91.4). Cellobiose, the disaccharide obtained by partial hydrolysis of cellulose, consists of two D-glucopyranoses joined by a 1,4′,-beta-glycoside bond (Figure 91.5). Both maltose and cellobiose are reducing sugars because the anomeric carbons on the right-hand sugar are part of a hemiacetal.

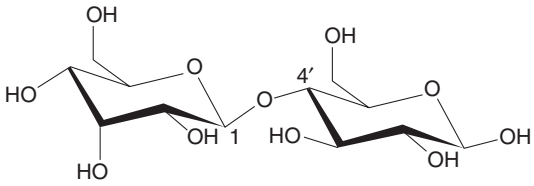

Figure 91.5 Cellobiose, a 1,4′-beta-glycoside [4-O-(beta-D-Glucopyranosyl)-beta-Dglucopyranose].

Liquefaction products can be clarified further by the usual techniques. The action of enzymes in these products can be followed by comparing the amount of galacturonic acid and neutral sugars found in alcohol insoluble solids (AIS) compared to those of the untreated (control) products. It has been found that the pectinase activity alone releases about 75% of the pectic material. Cellulose alone had very little activity on pectin and solubilized only 22% cellulose. No glucose was released from cellulose. Combined pectinase and cellulase released 80% of the polysaccharides. This is the synergistic effect noticed in pulp viscosity experiments. The breakdown products increase the soluble solids content in the juices. Thus high yields of juice and solids are obtained.

Liquefaction enzymes are important in the manufacture of fruit and vegetable juices, which yield no juices on pressing. For example mango, guava, banana, durian, etc. No presses have been developed for extracting juices from such products. Therefore there is good potential for using enzyme liquefaction technique to manufacture juices from such tropical fruits.

One has to be carefully with the choice of selecting commercial enzymes used for enzyme liquefaction. Most commercial enzymes have a number of side activities other than the major activities. Thus some of the fruity esters may be hydrolyzed and the finished product may give rise to bland/reduced flavor intensities (4, 9).

Enzyme liquefied juices may have an increase in titratable acidity and may have an enhanced the acid taste. Free methanol from Pectinesterase is also present from about 60–450 mg/L of the juice. The presence of these high levels of MeOH is of concern to consumers as MeOH is regarded as a poison.

The lethal dose is highly variable, ranging from less than 10 mL to more than 500 mL of MeOH, which is well within the amounts found in highly enzyme treated products.

- Although methanol itself is relatively innocuous, it is metabolized to the toxic byproducts formaldehyde and formic acid, which are responsible for its ocular and CNS toxicity.
- Because of the relatively slow conversion of methanol to its toxic metabolites, there is frequently a delay between the time of ingestion and the development of toxic signs and symptoms. This delay typically ranges from 12–24 hours.
- Toxic signs and symptoms include:
  - Ocular: blurred vision, scintillations, decreased visual acuity, scotomata, unreactive pupils, papilledema, partial or complete blindness. Blindness may be permanent in survivors.
  - CNS: drunkenness, stupor, coma, seizures, meningeal signs, cerebral edema, basal ganglia infarction.
  - GI: nausea, vomiting, epigastric pain, gastritis, GI hemorrhage, pancreatitis.
  - Respiratory: faint odor of methanol or formaldehyde on breath, respiratory failure.
- Severe degrees of poisoning may be associated with profound metabolic acidosis, circulatory shock, and death.

In the modern fruit juice industry, volatiles are stripped off from the juice and are traded separately. Therefore it is possible to control the MeOH content in the finished product. Enzyme treated juices can undergo more rapid browning reactions compared to the traditional juices, due to the presence of reducing sugars.

Enzymatically extracted apple juice is yellowish in color because of the yellow flavanol glucosides (quercitin).

The comparison of volatiles of apple juice obtained by pressing and by liquefaction. One notable fact is the reduction in esters, reduction of aldehydes to alcohols and disproportionately high increase of C6 aldehydes in the enzyme treated juices. The high C6 aldehyde content is explained by the increase in endogenous lipoxygenase activity which results in increase in C6 aldehyde. Hence precautions should be taken to minimize these changes.

5. Cloudy Juices

Cloudy juices are becoming popular in the market place. It is most important to pasteurize the freshly pressed juice immediately to inactivate endogenous enzymes. The pasteurized juice should be passed through screens or centrifuged to remove large particles, which would sediment on standing. Short enzyming of pulp is also described as a factor which would improve the cloudiness and cloud stability (4, 8).

B. Enzyme Applications in Other Products of Plant Origin

1. Vanillin from Vanilla Beans

When the Spanish conquistadores were in Mexico in 1520, one of their officers observed that the emperor Montezuma was drinking a beverage consisting of powdered cocoa bean and ground corn, flavored with ground black vanilla pods and honey. This was the first introduction of vanilla and chocolate to the world.

Today vanilla is one of the most expensive natural flavors in the food, pharmaceutical, and perfumery industry. World production of vanilla beans is in excess of 1800 tons (worth nearly $1.5 billion).

Vanillin (4-hydroxy-3-methoxybenzaldehyde) is a crystalline phenolic aldehyde and is the most abundant aromatic compound in vanilla bean. However, in its natural state it is found as a glucoside, glucovanillin, which is not aromatic. During the drying and curing process the natural beta glucosidase found in the bean slowly converts the glucovanillin to vanillin and the aroma is developed (10, 11). The conversion of glucovanillin to vanillin by Beta-glucosidase is shown in Figure 91.6.

2. Removal of Cyanogens from Cassava and Other Foods

A number of food products are known to contain cyanogenic glucosides which may give rise to cyanide toxicity after ingestion due to enzymatic reactions in the stomach. Table 91.2 lists some of the most prominent cyanogenic glucosides found in common foods. Cassava is a well known example of a staple food containing cyanogenic glucosides. Lactic fermentation is a common processing technique used for cassava in Asia and Africa

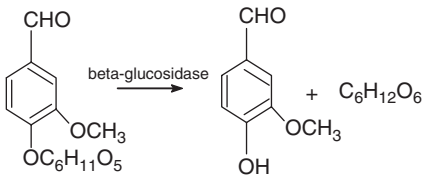

Figure 91.6 Conversion of gluco-vanillin to vanillin.

Table 91.2
Food Sources of Cyanogenic Glycosides and Amount of hydrogen cyanide (HCN) Produced

Plant	mg/100g HCN	Glucoside
Bitter almond	250	Amygdalin
Cassava root	53	Linamarin
Whole sorghum	250	Dhurrin
Lima beans	10–312	Linamarin

to eliminate these toxic factors. Fermentation is carried out on the grated roots by soaking the roots. Knowledge of the mechanisms of cyanogen reduction during lactic fermentation is important to optimize the reaction.

Microorganisms play little or no role in cyanogen reduction during the fermentation of grated cassava. Although a high proportion of the microorganisms present have the ability to hydrolyze linamarin, 90% of the initial linamarin content is hydrolyzed within 3 hours of grating (12). This demonstrates that grating is the key step in cyanogenic glucoside hydrolysis bringing endogenous linamarase into contact with linamarin.

In soaked roots, microbial growth is essential for efficient cyanogen reduction. Although there is some reduction in cyanogens in the absence of microbial growth, efficient cyanogen reduction only occurs when microbial growth takes place and the roots soften. The mechanisms of cyanogen reduction are more complex for fermented roots than for grated roots, but leaching of cyanogens from the softened roots plays a significant role. It has been demonstrated that after root softening, approximately one third of the initial linamarin of the roots was present in the soaking water. The enzymatic reactions involved in the reduction of cyanogens from linamarin is shown in Figure 91.7.

Because of the above reaction involving beta-glucosidase and hydroxynitrile lyase at relatively low temperatures, cyanide can be removed by simple grinding and drying slowly at low temperature. Slow boiling in water in an open pan is also useful in reducing the linamarin content.

3. Amygdalin

Amygdalin is a natural substance found in a variety of plants. Common sources of amygdalin include seeds of apples, pears, black cherry, almond, cherry, plum, peach, and apricot. Amygdalin is a cause of concern, because once ingested

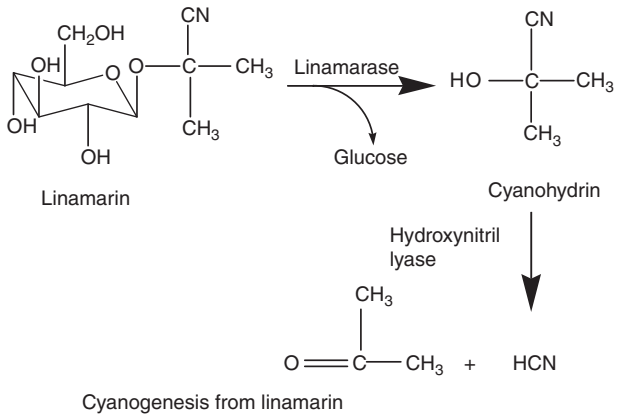

Figure 91.7 Removal of cyanogens from Linamarin in cassava.

it is metabolized to the deadly poison hydrogen cyanide (HCN). Cyanide causes toxic effects by binding to the terminal enzyme in the electron transport chain of the mitochondria, essentially halting ATP generation and oxygen utilization. In small doses, the body can detoxify cyanide. However, if untreated, large doses of cyanide are fatal.

Despite amygdalin's potentially deadly effects, in the 1970s and early 1980s, amygdalin was proposed as an anticancer drug (Laetrile) capable of killing cancerous cells. However, the dangers and ineffectiveness of laetrile were soon uncovered (13). The American Cancer Society has since dubbed Laetrile as a "toxic drug that is not effective as a cancer treatment."

Amygdalin is converted to HCN and benzaldehyde by the reaction shown in Figure 91.8. The above reaction may be used to manufacture the important natural flavour compound benzaldehyde (almond flavour).

4. Removal of Beany Flavour

During soya processing, volatile degradation compounds such as hexanal, pentanal, etc. are produced, which give a "beany" flavour to products, because of the action of lipoxygenase on unsaturated fatty acids such as linoleic and linolenic acids (14). These defects can be overcome by the enzymatic oxidation of the aldehydes to the corresponding carboxalic acids by the use of aldehyde dehydrogenase as follows.

$$\text{n-hexanal} + NAD^+ \xrightarrow{\text{Aldehyde dehydrogenase}} \text{caproic acid} + NADH + H^+ \quad (91.1)$$

5. Removal of Bitter Taste in Grapefruit and Other Citrus Juices

Some citrus juices, especially grapefruit, contain naringin, a dihydro-calcone with a bitter taste. The causes of the bitter taste that leads many shoppers to reject grapefruit juice

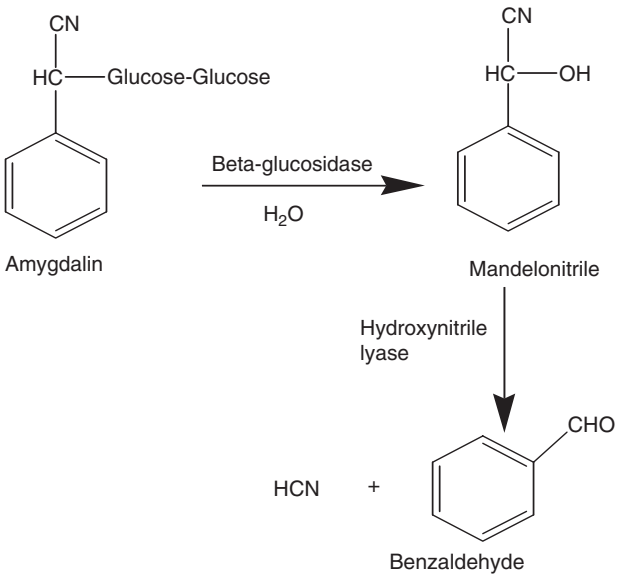

Figure 91.8 Conversion of amygdalin to benzaldehyde.

are two compounds, glycosidic flavanone naringin and triterpenoid lactone limonin (15). Naringin is the bitter component found in most fresh citrus fruit, and therefore, in freshly processed citrus juices. Limonin forms when the fresh fruit juice is pasteurized. Fruit acids give an undesirable bitterness to the packaged juice. Naringin bitterness can be reduced by the application of naringinase (16). Naringinin is non-bitter.

$$\text{Naringin} \longrightarrow \text{naringinin} + \text{rhamnose} + \text{glucose} \qquad (91.2)$$

A thin cellulose–acetate film layer on the inside of the packaging is used in place of the normal polymer lining. This layer of film contains an enzyme naringinase (which contains alpha-rhamnosidase and beta-glucosidase); when the juice comes into contact with the food-safe film, its bitter taste is reduced due to the activity of the enzymes (17).

6. α and β-Amylases

For starch hydrolysis, α and β-amylases are normally used. Bacterial amylases have a high temperature tolerance and hence they are of commercial value. α-amylase added to the wort in the beer manufacture accelerates starch degradation. These enzymes are also used in the baking industry.

7. Starch Saccharification

Acid hydrolysis of starch has had widespread use in the past. It is now largely replaced by enzymatic processes, because the acid hydrolysis requires the use of corrosion resistant materials, gives rise to high colour and ash content (after neutralisation), needs more energy for heating, and is relatively difficult to control.

Of the two components of starch, amylopectin presents the great challenge to hydrolytic enzyme systems. This is due to the residues involved in 1,6-glycosidic branch points which constitute about 4–6% of the glucose present. Most hydrolytic enzymes are specific for 1,4-glucosidic links yet the 1,6-glucosidic links must also be cleaved for complete hydrolysis of amylopectin to glucose (18). Some of the most impressive recent exercises in the development of new enzymes have concerned debranching enzymes.

It is necessary to hydrolyse starch in a wide variety of processes, which may be condensed into two basic classes:

1. Processes in which the starch hydrolysate is to be used by microbes or man.
2. Processes in which it is necessary to eliminate starch.

In the former processes, such as glucose syrup production, starch is usually the major component of reaction mixtures, whereas in the latter processes, such as the processing of sugar cane juice, small amounts of starch, which contaminate non-starchy materials, are removed. Enzymes of various types are used in these processes. Although starches from diverse plants may be utilised, corn is the world's most abundant source and provides most of the substrate used in the preparation of starch hydrolysates.

There are three stages in the conversion of starch (see Figure 91.9):

1. Gelatinisation, involving the dissolution of the starch granules to form a viscous suspension
2. Liquefaction, involving the partial hydrolysis of the starch, with concomitant loss in viscosity
3. Saccharification, involving the production of glucose and maltose by further hydrolysis

Gelatinisation is achieved by heating starch with water, and it occurs necessarily and naturally when starchy foods are cooked. Gelatinised starch is readily liquefied by partial hydrolysis with enzymes or acids and saccharified by further acidic or enzymic hydrolysis.

The starch and glucose syrup industry uses the expression dextrose equivalent, or DE, similar in definition to the DH units of proteolysis, to describe its products, where:

$$DE = 100 \times \left(\frac{\text{Number of glycosidic bonds cleaved}}{\text{Initial number of glycosidic bonds present}} \right) \qquad (91.3)$$

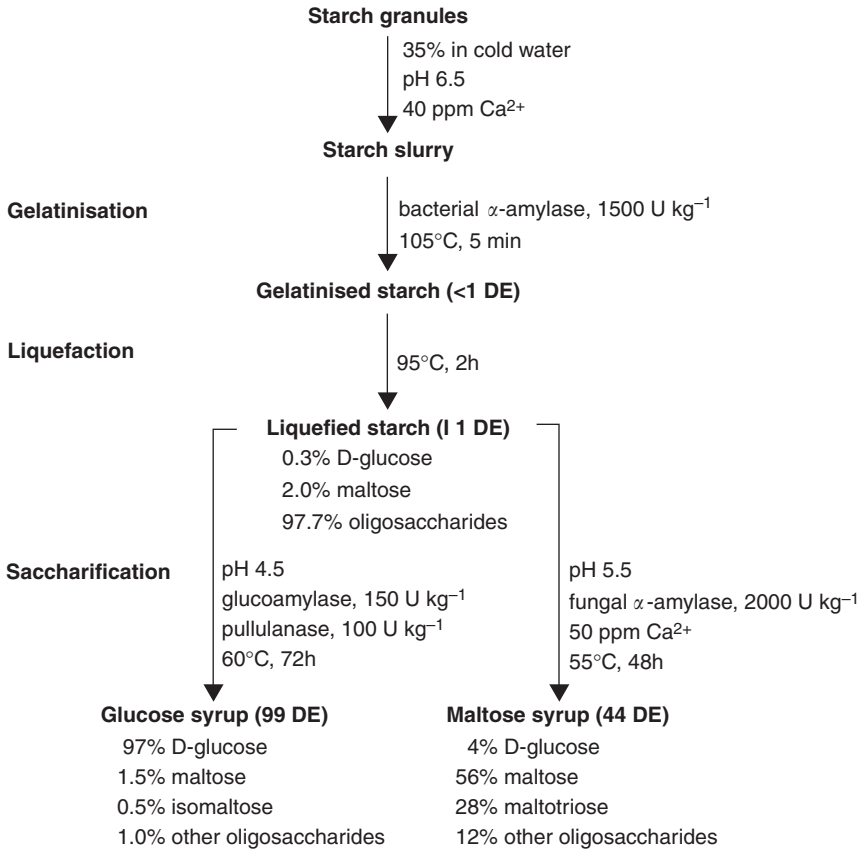

Figure 91.9 Schematic diagram of the use of enzymes in starch saccharification.

In practice, this is usually determined analytically by use of the closely related, but not identical, expression:

$$DE = 100 \times \left(\frac{\text{Reducing sugar, expressed as glucose}}{\text{Total carbohydrate}} \right) \qquad (91.4)$$

Thus, DE represents the percentage hydrolysis of the glycosidic linkages present. Pure glucose has a DE of 100, pure maltose has a DE of about 50 and starch has a DE of effectively zero. During starch hydrolysis, DE indicates the extent to which the starch has been cleaved. Acid hydrolysis of starch has long been used to produce "glucose syrups" and even crystalline glucose (dextrose monohydrate). Very considerable amounts of 42 DE syrups are produced using acid and are used in many applications in confectionery. Further hydrolysis using acid is not satisfactory because of undesirably coloured and flavoured breakdown products. Acid hydrolysis appears to be a totally random process which is not influenced by the presence of α-1,6-glucosidic linkages.

The nomenclature of the enzymes used commercially for starch hydrolysis is somewhat confusing and the EC numbers sometimes lump together enzymes with subtly different activities. For example, α-amylase may be subclassified as liquefying or saccharifying amylases, but even this classification is inadequate to encompass all the enzymes that are used in commercial starch hydrolysis. One reason for the confusion in the nomenclature is the use of the anomeric form of the released reducing group in the product rather than that of the bond being hydrolysed; the products of bacterial and fungal α-amylases are in the α-configuration and the products of β-amylases are in the β-configuration, although all these enzymes cleave between α-1,4-linked glucose residues.

The α-amylases (1,4-α-D-glucan glucanohydrolases) are endohydrolases, which cleave 1,4-α-D-glucosidic bonds and can bypass but cannot hydrolyse 1,6-α-D-glucosidic branch-points (19). Commercial enzymes used for the industrial hydrolysis of starch are produced by *Bacillus amyloliquefaciens* and by *B. licheniformis* (supplied by Novo Enzymes as Termamyl). They differ principally in their tolerance of high temperatures, Termamyl retaining more activity at up to 110°C, in the presence of starch, than the *B. amyloliquefaciens* α-amylase (20). The maximum DE obtainable using bacterial α -amylases is around 40 but prolonged treatment leads to the formation of maltulose (4-α-D-glucopyranosyl-D-fructose), which is resistant to hydrolysis by glucoamylase and

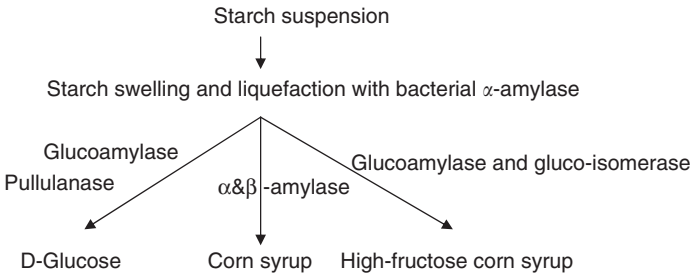

Figure 91.10 Summary of starch conversion to glucose syrup, corn syrup, and high-fructose syrup.

α-amylases. DE values of 8–12 are used in most commercial processes where further saccharification is to occur. The principal requirement for liquefaction to this extent is to reduce the viscosity of the gelatinised starch to ease subsequent processing.

Various manufacturers use different approaches to starch liquefaction using α-amylases, but the principles are the same. Granular starch is slurried at 30–40% (w/w) with cold water, at pH 6.0–6.5, containing 20–80 ppm Ca^{2+} (which stabilises and activates the enzyme) and the enzyme is added (via a metering pump). The α-amylase is usually supplied at high activities so that the enzyme dose is 0.5–0.6 kg tonne^{-1} (about 1500 U kg^{-1} dry matter) of starch. When Termamyl is used, the slurry of starch plus enzyme is pumped continuously through a jet cooker, which is heated to 105°C using live steam. Gelatinisation occurs very rapidly and the enzymic activity, combined with the significant shear forces, begins the hydrolysis. The residence time in the jet cooker is very brief. The partly gelatinised starch is passed into a series of holding tubes maintained at 100–105°C and held for 5 min to complete the gelatinisation process. Hydrolysis to the required DE is completed in holding tanks at 90–100°C for 1 to 2 h. These tanks contain baffles to discourage backmixing. Similar processes may be used with *B. amyloliquefaciens* α-amylase but the maximum temperature of 95°C must not be exceeded. This has the drawback that a final "cooking" stage must be introduced when the required DE has been attained in order to gelatinise the recalcitrant starch grains present in some types of starch which would otherwise cause cloudiness in solutions of the final product.

The liquefied starch is usually saccharified but comparatively small amounts are spray-dried for sale as "maltodextrins" to the food industry mainly for use as bulking agents and in baby food. In this case, residual enzymic activity may be destroyed by lowering the pH towards the end of the heating period.

Fungal α-amylase also finds use in the baking industry. It often needs to be added to bread-making flours to promote adequate gas production and starch modification during fermentation. This has become necessary since the introduction of combine harvesters. They reduce the time between cutting and threshing of the wheat, which previously was sufficient to allow a limited sprouting so increasing the amounts of endogenous enzymes. The fungal enzymes are used rather than those from bacteria as their action is easier to control due to their relative heat lability, denaturing rapidly during baking.

Corn syrup, high-fructose corn syrup, and glucose can be obtained from starch by enzymatic process as shown in Figure 91.10.

8. Interesterification of Fats

There is no opportunity or established need to build up polymers or oligomers using lipases or esterases, yet it is possible and commercially advantageous to use these enzymes as transferases in transesterifications (carboxyl group exchange between esters) (21), acidolyses (carboxyl group exchange between esters and carboxylic acids), and alcoholyses (alcohol exchange between esters and alcohols). Certain triglycerides, cocoa butter being the outstanding example, have high value because of their physical properties and comparative rarity. There is a commercial pull, therefore, to fund routes to the production of high value triglycerides from more plentiful, cheaper raw materials. This may be done using lipases (e.g. from *Rhizopus* or *Mucor Miehei*) acting as transacylases.

This acidolysis reaction may be used for increasing the value of rapeseed oil by exchanging linoleic acid for linolenic acid residues and increasing the value of palm oil and sunflower oil by increasing their content of oleic acid residues.

Cocoa butter fat is a high value product, because TAGs are high in stearates, which give a melting point of 37°C. It is used in confectionery, because of its sharp melting point between room temperature and body temperature; chocolate literally melts in the mouth. This is due to the fairly small variation in the structure of the constituent triglycerides; 80% have palmitic acid or stearic acid in the 1 and 3 positions with oleic acid in the central 2 position. For the production of cocoa butter substitute from palm oil, a process, which increases the value of the product three-fold, the acidolysis utilises stearic acid

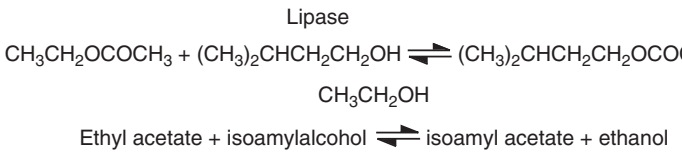

Figure 91.11 Interesterification of ethyl acetate with isoamylalcohol to form isoamyl acetate.

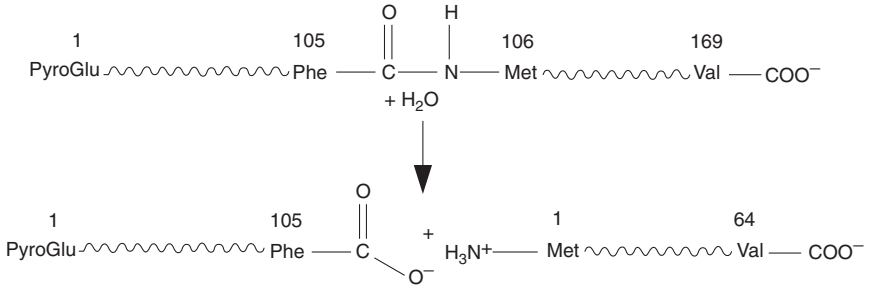

Figure 91.12 Action of chymosin on casein.

(i.e. R_4 is $C_{17}H_{35}$) in hexane containing just sufficient water (~10%) to activate the lipase (22).

Palm oil TAGs are high in palmitate and they give a melting point of 23°C. Therefore, it is an oil at room temperature and is a low value product. Conversion of palm oil into cocoa-butter fat substitute can be achieved by interesterification and is now a commercial process.

The products may be recovered by recrystallisation from aqueous acetone. Such reactions may also be used for the resolution of racemic mixtures of carboxylic acids or alcohols, the lipase generally being specific for only one out of a pair of optical isomers.

The secret of success has been the selection of lipases with the correct specificity and the selection of reaction conditions that favour transacylation rather than hydrolysis. Because the hydrolytic activity of industrial lipases is 10–15 times the transacylation activity, it is advantageous to minimise the water content of the reaction system and use the aqueous/organic biphasic systems described earlier. An example of lipase being used in an alcoholysis reaction is the biphasic production of isoamyl acetate, a natural aroma (Figure 91.11).

C. Use of Proteases and Other Enzymes in the Food Industry

1. Milk

Certain proteases have been used in food processing for centuries and any record of the discovery of their activity has been lost in the mists of time. Rennet (mainly chymosin), obtained from the fourth stomach (abomasum) of unweaned calves has been used traditionally in the production of cheese. Similarly, papain from the leaves and unripe fruit of the pawpaw (Carica papaya) has been used to tenderise meats. These ancient discoveries have led to the development of various food applications for a wide range of available proteases from many sources, usually microbial. Proteases may be used at various pH values, and they may be highly specific in their choice of cleavable peptide links or quite non-specific. Proteolysis generally increases the solubility of proteins at their isoelectric points.

The action of rennet in cheese making is an example of the hydrolysis of a specific peptide linkage, between phenylalanine and methionine residues (-Phe_{105}-Met_{106}-) in the κ-casein protein present in milk (23, 24). The κ-casein acts by stabilising the colloidal nature of the milk, its hydrophobic N-terminal region associating with the lipophilic regions of the otherwise insoluble α- and β-casein molecules, whilst its negatively charged C-terminal region associates with the water and prevents the casein micelles from growing too large. Hydrolysis of the labile peptide linkage between these two domains, resulting in the release of a hydrophilic glycosylated and phosphorylated oligopeptide (caseino macropeptide) and the hydrophobic para-κ-casein, removes this protective effect, allowing coagulation of the milk to form curds, which are then compressed and turned into cheese (Figure 91.12). The coagulation process depends upon the presence of Ca^{2+} and is very temperature dependent ($Q_{10} = 11$) and so can be controlled easily. Calf rennet, consisting of mainly chymosin with a small but variable proportion of pepsin, is a relatively expensive enzyme and various attempts have been made to find cheaper alternatives from microbial sources. These have ultimately proved to be successful and microbial rennets are used for about 70% of US cheese and 33% of cheese production world-wide.

The major problem that had to be overcome in the development of the microbial rennets was temperature lability (25, 26). Chymosin is a relatively unstable enzyme and once it has done its major job, little activity remains. However, the enzyme from *Mucor miehei* retains activity during the maturation stages of cheese-making and produces bitter off-flavours (27). Treatment of the enzyme with oxidising agents (e.g. H_2O_2, peracids), which convert methionine residues to their sulfoxides, reduces its thermostability by about 10°C and renders it more comparable with calf rennet. This is a rare example of enzyme technology being used to destabilise an enzyme. Attempts have been made to clone chymosin into *Escherichia coli* and *Saccharomyces cerevisiae* but, so far, the enzyme has been secreted in an active form only from the latter.

The development of unwanted bitterness in ripening cheese is an example of the role of proteases in flavour production in foodstuffs. It has been found that peptides with terminal acidic amino acid residues give "meaty," appetising flavours akin to that of monosodium glutamate. Non-terminal hydrophobic amino acid residues in medium-sized oligopeptides give bitter flavours, the bitterness being less intense with smaller peptides and disappearing altogether with larger peptides. Application of this knowledge allows the tailoring of the flavour of protein hydrolysates. The presence of proteases during the ripening of cheeses is not totally undesirable and a protease from *Bacillus amyloliquefaciens* may be used to promote flavour production in cheddar cheese. Lipases from *Mucor miehei* or *Aspergillus niger* are sometimes used to give stronger flavours in Italian cheeses by a modest lipolysis, increasing the amount of free butyric acid. They are added to the milk (30 U l^{-1}) before the addition of the rennet.

2. Lactase in Dairy Industry

Lactose is present at concentrations of about 4.7% (w/v) in milk and the whey (supernatant) left after the coagulation stage of cheese-making. Its presence in milk makes it unsuitable for the majority of the world's adult population, particularly in those areas which have traditionally not had a dairy industry. Real lactose tolerance is confined mainly to peoples whose origins lie in Northern Europe or the Indian subcontinent and is due to "lactase persistence;" the young of all mammals clearly are able to digest milk but in most cases this ability reduces after weaning. Of the Thai, Chinese, and Black American populations, 97%, 90%, and 73% respectively, are reported to be lactose intolerant, whereas 84% and 96% of the U.S. White and Swedish populations, respectively, are tolerant. Additionally, and only very rarely, some individuals suffer from inborn metabolic lactose intolerance or lactase deficiency, both of which may be noticed at birth. The need for low-lactose milk is particularly important in food-aid programmes as severe tissue dehydration, diarrhoea, and even death may result from feeding lactose-containing milk to lactose-intolerant children and adults suffering from protein-calorie malnutrition. In all these cases, hydrolysis of the lactose to glucose and galactose would prevent the severe digestive problems.

Another problem presented by lactose is its low solubility resulting in crystal formation at concentrations above 11% (w/v) (4°C). This prevents the use of concentrated whey syrups in many food processes as they have an unpleasant sandy texture and are readily prone to microbiological spoilage. Adding to this problem, the disposal of such waste whey is expensive due to its high biological oxygen demand. These problems may be overcome by hydrolysis of the lactose in whey; the product being about four times as sweet, much more soluble and capable of forming concentrated, microbiologically secure, syrups [70% (w/v)].

Lactose may be hydrolysed by lactase, a β-galactosidase. Commercially, it may be prepared from the dairy yeast *Kluyveromyces fragilis* (*K. marxianus* var. *marxianus*), with a pH optimum (pH 6.5–7.0) suitable for the treatment of milk (28), or from the fungi *Aspergillus oryzae* or *A. niger* (29), with pH optima (pH 4.5–6.0 and 3.0–4.0, respectively) more suited to whey hydrolysis. These enzymes are subject to varying degrees of product inhibition by galactose (30). In addition, at high lactose and galactose concentrations, lactase shows significant transferase ability and produces β-1,6-linked galactosyl oligosaccharides.

Lactases are now used in the production of ice cream and sweetened flavoured and condensed milks. When added to milk or liquid whey (2000 U kg^{-1}) and left for about a day at 5°C about 50% of the lactose is hydrolysed, giving a sweeter product, which will not crystallise if condensed or frozen. This method enables otherwise-wasted whey to replace some or all of the skim milk powder used in traditional ice cream recipes. It also improves the "scoopability" and creaminess of the product. Smaller amounts of lactase may be added to long-life sterilised milk to produce a relatively inexpensive lactose-reduced product (e.g. 20 U kg^{-1}, 20°C, 1 month of storage). Generally, however, lactase usage has not reached its full potential, as present enzymes are relatively expensive and can only be used at low temperatures.

3. Protease in Meat

The action of endogenous proteases in meat after slaughter is complex but "hanging" meat allows flavour to develop, in addition to tenderising it (31). The evidence indicates that the cysteine proteases, in particular the calpains, are responsible for post-mortem proteolysis and tenderization of meat (32).

Meat tenderisation by the endogenous proteases in the muscle after slaughter is a complex process, which varies

with the nutritional, physiological, and even psychological (i.e. frightened or not) state of the animal at the time of slaughter. Meat of older animals remains tough but can be tenderised by injecting inactive papain into the jugular vein of the live animals shortly before slaughter. Injection of the active enzyme would rapidly kill the animal in an unacceptably painful manner, so the inactive oxidised disulfide form of the enzyme is used. On slaughter, the resultant reducing conditions cause free thiols to accumulate in the muscle, activating the papain and so tenderising the meat. This is a very effective process, as only 2–5 ppm of the inactive enzyme needs to be injected. Recently, however, it has found disfavour as it destroys the animal's heart, liver, and kidneys that otherwise could be sold and, being reasonably heat stable, its action is difficult to control and persists into the cooking process.

Proteases are used to recover protein from parts of animals (and fish) would otherwise go to waste after butchering. About 5% of the meat can be removed mechanically from bone. To recover this, bones are mashed incubated at 60°C with neutral or alkaline proteases for up to 4 h. The meat slurry produced is used in canned meats and soups.

When proteases are used to depolymerise proteins, usually non-specifically, the extent of hydrolysis (degree of hydrolysis) is described in DH units where:

$$DH = 100 \times \left(\frac{\text{Number of peptide} - \text{bonds cleaved}}{\text{initial number of peptide bonds present}} \right) \quad (91.5)$$

Commercially, using enzymes such as subtilisin, DH values of up to 30 are produced using protein preparations of 8–12% (w/w). The enzymes are formulated so that the value of the enzyme: substrate ratio used is 2–4% (w/w). At the high pH needed for effective use of subtilisin, protons are released during the proteolysis and must be neutralised:

$$\mathrm{H_2N\text{-}aa\text{-}aa\text{-}aa\text{-}aa\text{-}aa\text{-}COO^-} \xrightarrow{\text{subtilisin (pH 8.5)}} \mathrm{H_2N\text{-}aa\text{-}aa\text{-}aa\text{-}COO^-} + \mathrm{H_2N\text{-}aa\text{-}aa\text{-}COO^-} + \mathrm{H^+} \quad (91.6)$$

where, aa is an amino acid residue.

4. Proteases on Soy Proteins

Correctly applied proteolysis of inexpensive materials such as soya protein can increase the range and value of their usage, as indeed occurs naturally in the production of soy sauce. Partial hydrolysis of soya protein, to around 3.5 DH greatly increases its "whipping expansion," further hydrolysis to around 6 DH improves its emulsifying capacity. If their flavours are correct, soya protein hydrolysates may be added to cured meats. Hydrolysed proteins may develop properties that contribute to the elusive, but valuable, phenomenon of "mouth feel" in soft drinks.

5. Bakery Products

Proteases are also used in the baking industry. Where appropriate, dough may be prepared more quickly if its gluten is partially hydrolysed. A heat-labile fungal protease is used so that it is inactivated early in the subsequent baking. Weak-gluten flour is required for biscuits in order that the dough can be spread thinly and retain decorative impressions. In the past this has been obtained from European domestic wheat but this is being replaced by high-gluten varieties of wheat. The gluten in the flour derived from these must be extensively degraded if such flour is to be used efficiently for making biscuits or for preventing shrinkage of commercial pie pastry away from their aluminium dishes.

D. Glucoseoxidase in Food Industry

Glucose oxidase is a highly specific enzyme for D-glucose, obtained from the fungi *Aspergillus niger* and *Penicillium*, which catalyses the oxidation of β-glucose to glucono-1, 5-lactone, and releasing hydrogen peroxide (Figure 91.13).

It finds uses in the removal of either glucose or oxygen from foodstuffs in order to improve their storage capability. Hydrogen peroxide is an effective bacteriocide and may be removed, after use, by treatment with catalase (derived from the same fungal fermentations as the glucose oxidase) which converts it to water and molecular oxygen:

$$2\mathrm{H_2O_2} \xrightarrow{\text{catalase}} 2\mathrm{H_2O} + \mathrm{O_2} \quad (91.7)$$

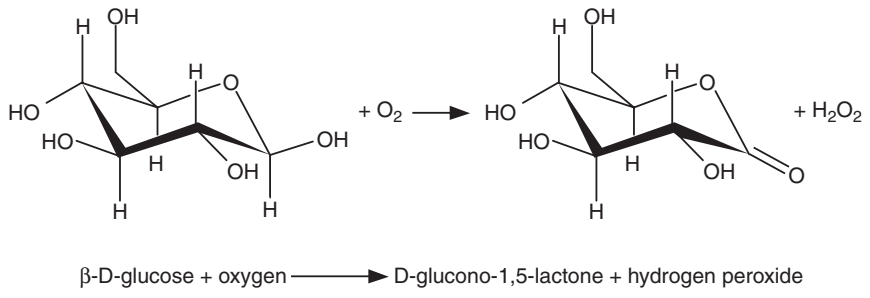

Figure 91.13 Oxidation of glucose to gluconolactone.

For most large-scale applications the two enzymic activities are not separated. Glucose oxidase and catalase may be used together when net hydrogen peroxide production is to be avoided.

A major application of the glucose oxidase/catalase system is in the removal of glucose from egg-white before drying for use in the baking industry. A mixture of the enzymes is used ($165\,U\,kg^{-1}$) together with additional hydrogen peroxide (about 0.1% (w/w) to ensure that sufficient molecular oxygen is available, by catalase action, to oxidise the glucose. Other uses are in the removal of oxygen from the head-space above bottled and canned drinks and reducing non-enzymic browning in wines and mayonnaises.

E. Enzymes in Brewery Industry

In brewing, barley malt supplies the major proportion of the enzyme needed for saccharification prior to fermentation. Often other starch containing material (adjuncts) are used to increase the fermentable sugar and reduce the relative costs of the fermentation. Although malt enzyme may also be used to hydrolyse these adjuncts, for maximum economic return extra enzymes are added to achieve their rapid saccharification. It is not necessary nor desirable to saccharify the starch totally, as non-fermentable dextrins are needed to give the drink "body" and stabilise its foam "head." For this reason the saccharification process is stopped, by boiling the "wort," after about 75% of the starch has been converted into fermentable sugar (33).

The enzymes used in brewing are needed for saccharification of starch (bacterial and fungal α-amylases), breakdown of barley β-1,4- and β-1,3- linked glucan (β-glucanase), and hydrolysis of protein (neutral protease) to increase the fermentation rate later. Cellulases are also occasionally used, particularly where wheat is used as adjunct. Due to the extreme heat stability of the α-amylase from *B. amyloliquefaciens*, where this is used, the wort must be boiled for a much longer period (e.g. 30 min) to inactivate it prior to fermentation. Papain is used in the later post-fermentation stages of beer-making to prevent the occurrence of protein-tannin "chill-haze" otherwise formed on cooling the beer.

Recently, "light" beers, of lower calorific content, have become more popular. These require a higher degree of saccharification at lower starch concentrations to reduce the alcohol and total solids contents of the beer. This may be achieved by the use of glucoamylase and fungal α-amylase during the fermentation.

1. Malting

Malting serves the purpose of converting insoluble starch to soluble starch, reducing complex proteins, generating nutrients for yeast development, and development of enzymes. The three main steps of the malting process are steeping, germination, and kilning (33).

Generally, barley variety (six-row) that has a higher enzyme content, more protein, less starch, and a thicker husk than "two-row" barley is used for malting. Malting barley has higher level of diastatic enzymes (α and β amylases).

Steeping begins by mixing the barley kernels with water to raise the moisture level and activate the metabolic processes of the dormant kernel.

During malting, enzymes break down the cell structure of the endosperm, release nutrients necessary for yeast growth, and make the starch available for enzyme degradation during mashing. Modification of the endosperm correlates with growth of the acrospire. As the acrospire grows, chemical changes are triggered that result in the production of numerous enzymes. Their function is to break down the complex starches and proteins of the grain (33).

2. Biochemical Changes at Mashing

The mashing process is done over a period of time at various temperatures to activate the enzymes responsible for acidulation and reduction in proteins and carbohydrates.

Although there are numerous enzymes present in the mash, only three groups and their respective processes are paramount to biochemical transformations in beer manufacture (33). These enzymes are

1. Phytases (acidifying)
2. Proteolytic enzymes (protein-degrading)
3. Carbohydrase enzymes (starch-degrading)

The acid rest is responsible for reducing the initial mash pH for traditional decoction mashing of lager beers. In recent years, because of the use of well-modified malts, the general trend has been to simplify and shorten the lager mash by eliminating the acid rest in mashing.

The protein rest is responsible for reducing the overall length of high-molecular-weight proteins, which cause foam instability and haze, to low-molecular-weight proteins in the mash. The enzymes proteinase and peptidase are two main enzymes of this group.

By far the most important change brought about in mashing is the conversion of starch molecules into fermentable sugars and unfermentable dextrins. The principal enzymes responsible for starch conversion are alpha and beta-amylase. Alpha-amylase very rapidly reduces insoluble and soluble starch by splitting starch molecules into many shorter chains polysaccharide fractions — dextrins and maltotriose that can be attacked by beta-amylase (33).

Given a long enough "rest," the alpha-amylase can dismantle all the dextrins to maltose, glucose, and small, branched "limit dextrins." However, starch conversion is more effective by the faster-acting beta-amylase.

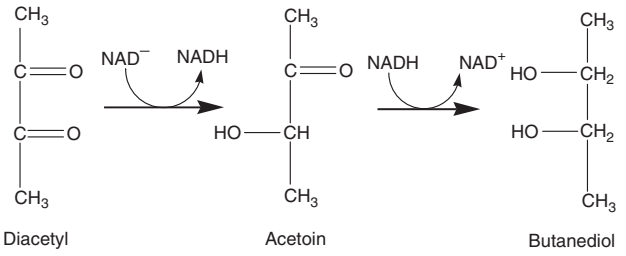

Figure 91.14 Reduction of diacetyl to acetoin and butanediol.

Beta-amylase is more selective than alpha-amylase since it breaks off two sugars at a time from the starch chain.

A number of factors lead to diacetyl formation, but only one reliable method can reduce diacetyl levels: enzymatic reduction by yeast using butanediol dehydrogenase in the presence of NADH (Figure 91.14). Acetoin, the intermediate product, has a rather unpleasant, musty taste, but because it has a flavor threshold of 3.0 mg/L its effect is not nearly as damaging to beer flavors as an equivalent amount of diacetyl. The final product, butanediol, is neutral as far as beer flavor is concerned.

F. Soy Sauce Fermentation

Soy sauce is a very important condiment in most cooking in the Orient as well as in the west. Its great antiquity is illustrated by the fact that it is mentioned in the book of Chau Lai, one of the 13 classics of Confucius, written before 1000 B.C.

The basic process of soy sauce manufacture is a two-stage fermentation process. In the first stage of the fermentation, the soybeans or a mixture of equal parts of beans and wheat are inoculated with *Aspergillus oryzae* (34). The mould grows rapidly on this substrate and after three days the first stage of the fermentation is complete. The mould covered material known as Koji is then broken up and immersed in 18% brine solution. The introduction of pure cultures in soybean fermentations has not only improved process efficiency, but has also improved product quality and consistency. New and better microbial strains introduced into the process include the fungi *A. oryzae* (35) and *A. sojae* for koji production (36).

Because of the activities of the enzymes produced by the moulds, considerable breakdown of proteins and polysaccharides present in the substrate takes place. Thus substantial amounts of fermentable sugars, peptides, and amino acids are released into the brine.

The Koji preparation utilizes principally *Aspergillus oryzae*. This mould releases a variety of enzymes to its surrounding, such as acid, neutral and alkaline proteases, peptidases, amylases, cellulases, lipases, and invertases.

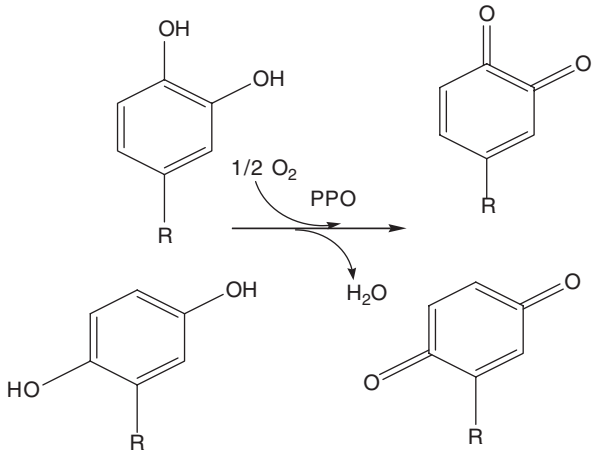

Figure 91.15 The oxidation of phenolic compounds in the presence of PPO in tea fermentation.

G. Tea Fermentation

In the case of tea leaves, fermentation is the process during which the polyphenols in the tea leaf are oxidized in the presence of polyphenoloxidase enzymes and subsequently condensed to form colored compounds contributing to the quality attributes of black tea. Fermentation starts immediately after cell rupture and proceeds through the enzymatic reactions shown in Figure 91.15.

Formation of the black pigments, viz theaflavins, thearubigins etc., during enzymatic fermentation of different components of tea leaves followed their PPO activity (37).

H. Enzymes in Health and Wellbeing

Celiac Sprue (a.k.a. celiac disease, coeliac disease, or gluten intolerance) is a hereditary disorder characterized by a sensitivity to the toxic effects of gluten in the diet, leading to abnormal small-intestinal structure, malabsorption, and intolerance to gluten, a component of nutritionally important proteins found in common dietary food grains such as wheat, rye, and barley (38).

The disease commonly presents in early childhood with severe symptoms including chronic diarrhea, abdominal distension, and failure to thrive. The general condition of these children is severely impaired. In many patients, symptoms may not develop until later in life when the disease presents with fatigue, diarrhea, and weight loss due to malabsorption of nutrients and vitamins, anemia, and neurological symptoms (38).

This is a lifelong disease, and if untreated, patients have a substantially enhanced risk for the development of complications such as infertility, osteoporosis, intestinal cancer, and lymphoma. There is no therapeutic option available to Celiac Sprue patients, the only treatment being a lifelong adherence to a strict gluten-free diet.

Recently it was discovered that a relatively short fragment of the gluten protein is exceptionally toxic to Celiac Sprue patients. This gluten fragment is unusually resistant to breakdown by digestive enzymes in the intestine, where it remains intact to have a destructive effect on the intestinal lining. Using this information, the researchers identified a bacterial enzyme (a peptidase) that can rapidly degrade this peptide and other related toxic fragments from gluten (39). Thus it may be possible to cure certain diseases by the use of enzymes in our diet.

V. CONCLUSION

The enzymes used as functional ingredients in food processing and manufacture of food ingredients are numerous. Because enzymes can lower the activation energy of a particular reaction under different conditions of temperature, pH, and prosthetic groups, they are ideal catalysts for biological systems. In the preceding pages, it was demonstrated how various biotransformations could be effected to produce desirable end-products with the mediation of enzymes. Thus basic knowledge about the structure and composition of various plant and animal tissues and enzyme reaction kinetics would lead to interesting novel developments, such as the enzymatic peeling of citrus products, yams, tubers, removal of skin from animal carcasses, and so on. Such applications would give rise to low wastage of raw materials and lead to production efficiencies and environmentally friendly processes. Fermentation, which utilizes microorganisms and hence enzymes, is used extensively to produce a large number of natural food ingredients and will continue to play a strong part in the future, especially in the biotechnology area.

92 Composition and Structure-Function Relationships in Gums

Stefan Kasapis
Department of Chemistry, National University of Singapore

CONTENTS

I. INTRODUCTION

In the food industry the term "gum" refers to polysaccharides, which are widely distributed in nature and possess a broad range of functional properties. Particularly important examples of their functionality are the capacity to alter the flow characteristics of fluids and to interact in the hydrated state with other dispersed or dissolved molecular species, which they may bind, chelate, complex, emulsify, encapsulate, flocculate, stabilize, or suspend (1). As a result, they perform either by themselves or in association with lipids, proteins, or other molecules vital physicochemical functions, by providing structural support and energy reserve, and by mediating various biological processes such as cellular recognition and growth. This broad range of functional properties, frequently unique in their nature, is increasingly exploited by the food industry and since the 1970s has lead to a flurry of activity in the

published literature (2,3). Normally, a review of the subject provides an outline of gums and discusses within each chapter the properties and uses of individual cases (4). The approach of the present compendium will emphasize the understanding of why gums behave in different ways. Groupings of primary structure and conformational characteristics of the most popular gums should rationalize their functional properties and indicate to the reader the best material for a particular end-use application.

II. THE CHEMISTRY AND CONFORMATION OF MONOSACCHARIDES

The functionality of gums is derived by the chemical characteristics of the individual residues and the conformation of the linkages between them (5). In almost all gums of industrial importance, the repeat unit is based on a six-membered (pyranose) ring structure. Figure 92.1 shows the two stable chair conformations of the pyranose ring ($^4C_1$ and $^1C_4$) in which all bonds are fully staggered (6). In the chair conformations, groups attached by bonds that project vertically from the ring are sterically crowded whereas substituents that point outwards have much more space. The former type of bond is called axial whereas the latter is called equatorial. According to the steric arrangement at C(5), hexose sugars are classified into two categories: the D-series where the bulky hydroxymethyl group is equatorial in the $^4C_1$ ring form and the mirror image L-series where the hydroxymethyl group is equatorial in $^1C_4$. In both series, monosaccharides are named according to the position of hydroxyl-group bonds on carbons 2, 3 and 4 of the pyranose ring. For example, the stable ring form of glucose has all the hydroxyl groups equatorial, whereas in mannose and galactose O(2) and O(4) are respectively axial. Axial linkage on carbon 1 of the monosaccharide ring is denoted as α and equatorial as β.

III. ORDERED CONFORMATIONS OF GUMS WITH LINEAR CHAINS

The linkage between adjacent monosaccharides in carbohydrate chains is known as the glycosidic bond, and involves the hemiacetal OH group at carbon 1 on one residue and one of the alcohol groups of the next residue, with formal elimination of water. There are three significant classes of chain bonding pattern (7):

- Polysaccharides linked di-equatorially at positions 1 and 4 of the pyranose ring adopt **flat ribbon** structures upon gel formation.
- Where linkage is again at carbons 1 and 4, but through axial bonds at each position, the chains adopt a highly **buckled ribbon** structure.
- Finally, where the bonds to and from the ring are no longer parallel (e.g. 1,3 linkages or 1,4 axial-equatorial), this introduces a systematic change in chain direction at each residue, which gives rise to **helical structures** in the ordered state.

Those ordered conformations are the origin of the wide range of structural properties of industrial gums, as it will be demonstrated below.

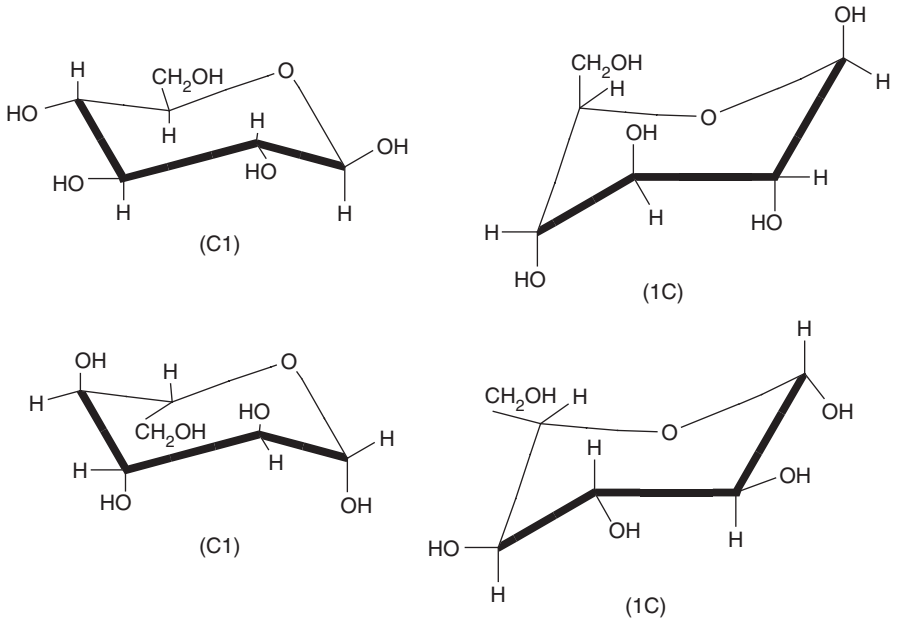

FIGURE 92.1 Pyranose chair conformations illustrated for β- and α-glucose (from reference 6, with permission).

A. Helical Structures

Three different modes of helix formation have been suggested. They are based on the principle that an empty space along the axis of a hollow helix would not be expected to be stable in a natural situation. Depending on the state of extension of helix the three models are (8,9):

i) A least extended helix that uses a molecule of suitable diameter to fill the void along its axis (inclusion complex).
ii) A more extended helix that forms a close-packed structure, by turning round two or three chains, in an embrace that can fill the void of the each other.
iii) An even more extended helix where the chains pack by nesting together without twisting round each other.

Tertiary structures in the form of hollow helix conformation have been characterized in the solid state for starch and a number of marine red algal polysaccharides (10). It is not within the scope of this treatise to discuss the properties and applications of starch and its derivatives but in the context of the hollow helix, there is now evidence that the linear component of starch, amylose forms a double helix in the ordered state. This can be converted by crystallisation to a less extended form (V-amylose) in which the chains include suitable small molecules, such as in the familiar complex with iodine.

Any hollow-helix gum can form these inclusion complexes provided it is hydrophobic because the D-glucopyranose units are adjusted in a way that arranges the axial C-H bonds on carbons 3 and 5 as well as one of the H atoms on each carbon 6 inwards, giving hydrophobic character to the vacant space (11). Therefore the bonding which holds the enclosed molecule serves as a source of helix stability. Stability is enhanced further by hydrogen bonds between oxygen 2 and 3 of successive residues and between oxygen 2 and 6 of glucose units which are separated by several units in the chain and are therefore adjacent on the helix surface.

1. Carrageenans

Among the carbohydrate sequences with more than one type of sugar unit and/or more than one type of linkage, the family of carrageenans is a prime example (12). Carrageenans are extracted from marine red algae (seaweed). In the helix-forming members, the basic repeating unit contains 1,3-linked β-D-galactose-4-sulphate and 1,4-linked 3,6-anhydro-α-D or L-galactose, with various degrees of 2-sulphation of the latter, but no 2-sulphation in kappa carrageenan (Figure 92.2). The anhydride bridge has the effect of holding the sugar ring in the normally unfavoured chair conformation with C(6) axial, which facilitates the

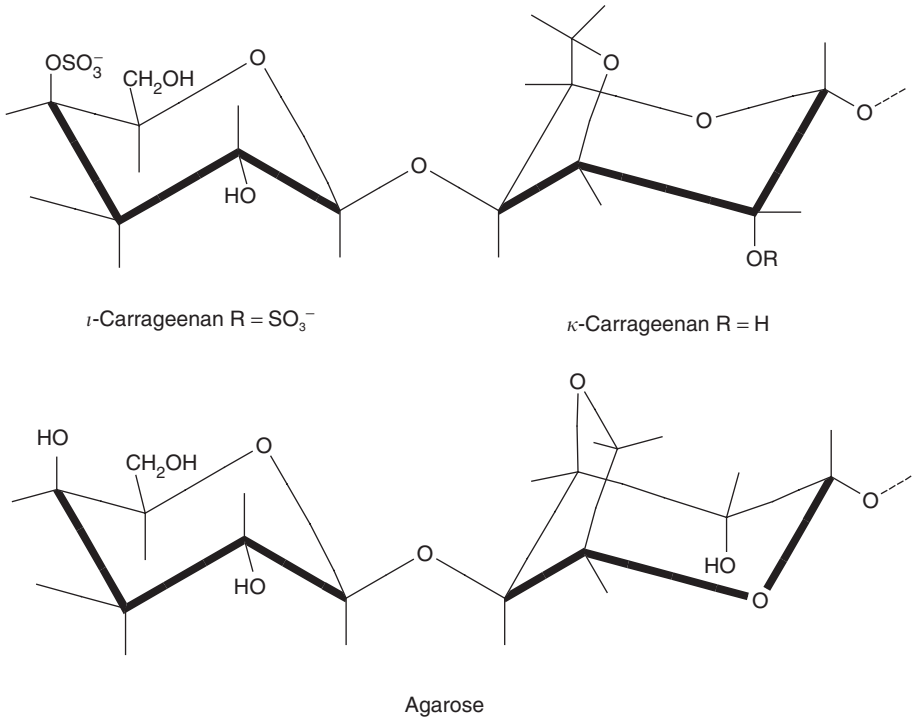

FIGURE 92.2 Idealized disaccharide repeating units of carrageenan and agar polysaccharides (from references 12 and 19, with permission).

formation of a coaxial double helix. However, complete ordering and precipitation is avoided because a proportion of the 1,4-linked residues in natural carrageenans occur as unbridged D-galactose sulphate or disulphate. These residues adopt the normal chair conformation and act as 'kinks,' which limit the extent of helix formation and thus solubilise the network (13).

Sigmoidal changes in optical rotation verified the disorder-to-order transformation of kappa carrageenan chains during cooling. X-ray diffraction studies and model building taking into account the angles of glycosidic bonds, the closeness of adjacent atoms and the space available to the partner chain, argued for the formation of a double helical structure with three disaccharides per turn of helix (14). This is further stabilised with hydrogen bonding, perpendicular to the helix axis, between the OH groups at positions 6 and 2 of the galactose rings of the two strands. Helices come together to form aggregates, which constitute the structural unit of the kappa carrageenan network (15). K^+ are the main stabilizing counterions of the aggregates and according to the "domain model," they form an array between adjacent helices in the gel (Figure 92.3).

Iota carrageenan is the most highly sulphated member of the helix-forming family. Its double helix structure is three-fold, parallel and right-handed with the sulphate groups protruding away from the helix area. As in kappa carrageenan, the double helix is further stabilized by hydrogen bonds between O(2) and O(6) of D-galactose residues on different strands. Because of the high negative charge of iota carrageenan, helix-helix aggregation and thus gelation occurs only in the presence of cations which can suppress electrostatic repulsion between the participating chains. The dependence of the gel strength on cation type follows the series (16):

$$Ca^{2+} > Cs^+ > Rb^+ \sim K^+ \gg Na^+ > Li^+$$

Aggregation stabilizes the ordered conformation to temperatures above those at which it would normally form, giving thermal hysteresis between gel formation and melting. Lambda carrageenan has a high ester sulphate content (three sulphate groups per disaccharide repeat unit) and it does not gel (17).

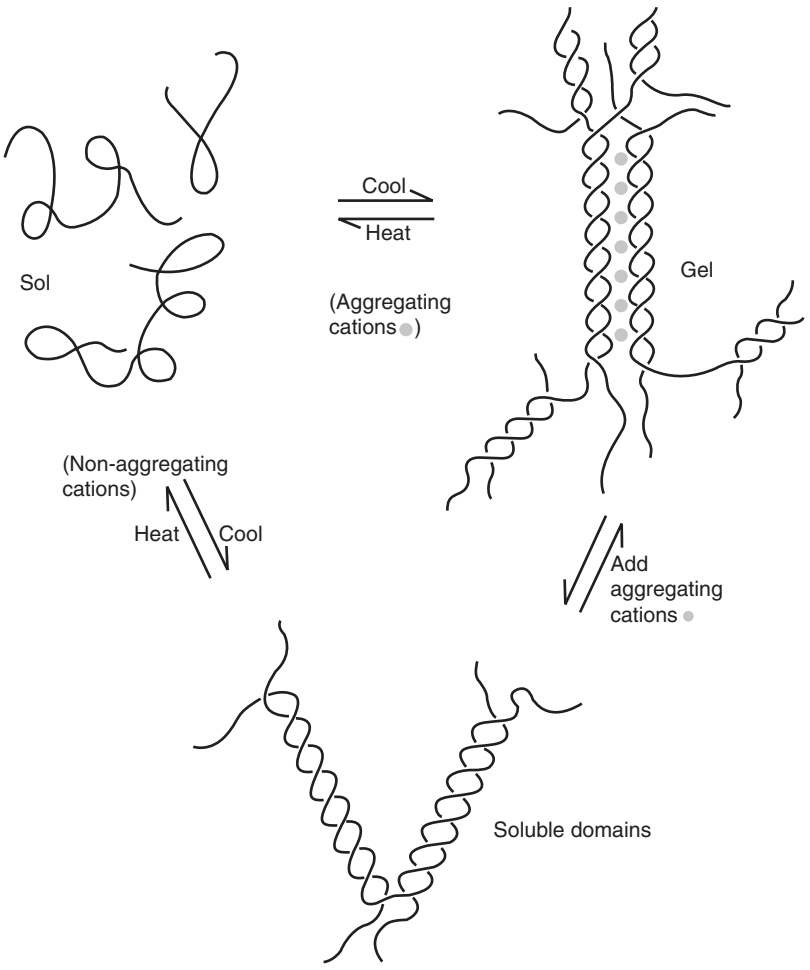

FIGURE 92.3 Domain model of carrageenan gelation (from reference 15, with permission).

Carrageenans have a wide range of food applications functioning as gelling agents, stabilizers or viscosity enhancers (18). Chocolate or evaporated milk is stabilized against sedimentation of cocoa particles or creaming of the fat globules by addition of the gum between 0.02 and 0.05% in the formulation. In gelled water deserts and low sugar preserves carrageenans (0.5 to 1%), often in mixture with galactomannans, form thermally stable gels with gelatin-like textural properties. In meat, fish and bakery products, the polysaccharide (0.2 to 2%) is used to maintain the moisture content in cooked hams and rolls, increase the binding properties of canned products and aspics, and gel or glaze tart or pie fillings.

2. Agarose

Agarose is a structural gum occurring in different species of red seaweed (*Rhodophyceae*). As illustrated in Figure 92.2, its primary structure comprises an alternating repeating sequence of 1,3-linked β-D-galactopyranose and 1,4-linked (3→6)-anhydrogalactopyranose (A and B units, respectively). The 3,6-anhydro units are in the L form which is reflected in left-handed helix geometry. Furthermore, the anhydride bridge may be absent in a proportion of the 4-linked residues, which changes the geometry of the sugar ring to a form that is sterically incompatible with incorporation in the ordered double helix (19). The presence of this "kinking" residue is essential for the development of gel networks, as it terminates the ordered junction zone association and allows each chain to participate in more than one intermolecular junction zones.

At high temperature, agarose exists in solution as disordered, random coils, but upon cooling it undergoes a co-operative conformational transition to a rigid, ordered form (20). It is generally accepted that agarose gels are cross-linked by ordered aggregates of double helices. The double helix appears to have an interior cavity with a diameter of 0.45 nm (measured at the narrowest points between atomic centers). Oxygen atoms, namely O(2) of galactose and O(5) of 3,6-anhydrogalactose which are engaged in hydrogen bonds can be found in the interior of the helix. According to this, it was suggested that the agarose cavity is occupied by water molecules, which participate in a hydrogen bond that contributes to the stability of the double helix (21). This comes in agreement with the proposal that water is the single solvent in which agarose forms gels and that it is necessary part in the aggregation of the helices and the formation of the junction zones (22). The agarose network consists of long, flexible chains connecting junction zones, which are somewhat crystalline, and the other regions are amorphous.

Agarose is insoluble in cold water but soluble in hot. Its solutions are heat-stable with essentially constant viscosity in neutral pH and it gives gels even at concentrations of 0.1% or lower. Agarose gels exhibit thermal hysteresis and the melting temperature is dependent on the concentration used (23). The gel finds a wide range of non-food applications especially as a moulage material capable of reproducing fine details with great accuracy thus being used in dentistry, plastic surgery, criminology, etc. (24). In U.S., it is mostly used in microbiology at liquid media concentrations of 0.007 to 0.08%. Even at such low concentrations, agarose is able to prevent the entry of oxygen into liquid media, making the cultivation of anaerobes feasible in air-exposed broths. Agarose is also used in a wide range of food products to improve texture and stability (yoghurts, cream cheeses), as an antitackiness or antistaling ingredient (cookies, cakes, pie fillings, meringues), and in vegetarian and health food products (cereals, meat/fish substitutes).

B. Flat Ribbons

The monomer units of this group of polysaccharides are diequatorially linked through positions 1 and 4, diagonally opposite each other across the pyranose ring. Cellulose and chitin provide a simple illustration of the way in which intermolecular associations can arise.

1. Cellulose

Cellulose is a 1,4-linked β-D-glucan that occurs in almost all higher plants as extended ribbons of 2-fold chain geometry. The ribbon-like chains lie side by side in sheets, which are laid on top of each other in a way that staggers the ribbons. The chain packing is parallel, i.e. the chain termini at each end of the bundle are all of one type. The chain geometry is stabilized by hydrogen bonding of each successive residue to its nearest neighbours through O(3) and O(5). This compact and tightly bonded structure is characterized by high strength, fibrous character, insolubility and inertness, providing strength and support in plant tissues (25).

Food applications utilize cellulose derivatives like the carboxymethylcellulose (CMC). Modification of the cellulose is achieved by introducing a controlled amount of sodium carboxymethyl groups onto the molecule. This holds the chains apart thus imparting water solubility. Therefore, CMC is able to increase viscosity, prevent syneresis and stabilize suspensions (26). Other cellulose derivatives include methylcellulose (MC) and hydroxypropylmethylcellulose (HPMC). Upon heating, these form gels from a hydrophobically crosslinked network in regions of dense substitution. Despite the presence of hydrophobic character, unsubstituted or sparingly substituted regions of cellulosic structure impart enough hydrophilicity for the molecule to be highly water-soluble at ambient temperatures (27). Thus, MC and HPMC possess unique hydration-dehydration characteristics acting

as emulsifiers and adhesion improvers of the batter or coating in a food product. Finally, microcrystalline cellulose (MCC) is used in dairy and nondairy frozen desserts including ice cream, ice milk and soft-serve to control growth of ice crystals under adverse heat shock conditions, and in novelty products to improve extrusion characteristics and foam control (28).

2. Chitin

Chitin is the structural polysaccharide of insects and crustaceans. The structure of chitin is identical to that of cellulose except that the hydroxyl group on each C(2) is replaced by an acetyl group (-$NHCOCH_3$). Therefore the ordered conformation is closely similar (extended ribbons of two-fold symmetry) and the way in which the chains pack side by side in a strongly hydrogen-bonded crystalline manner is also very similar (29). However, both parallel and anti-parallel sheets can occur in nature. Native chitin, like cellulose, is totally insoluble in water and most other solvents.

Commercial chitin is available at various degrees of acetylation (DA). At high degrees of acetylation, the polymer is only soluble in a few solvents, which limit its applications. Partial deacetylation, however, drops the DA below 50% making the polymer soluble in aqueous acidic conditions. This is known as chitosan, which can be considered as a copolymer containing (1→4) linked 2-acetamido-2-deoxy-β-D-glucopyranose and 2-amino-2-deoxy-β-D-glucopyranose residues (30). Chitosan in aqueous solutions of dilute acids exhibits a polyelectrolyte character owing to the presence of protonated amino groups, which have an intrinsic pK_0 value of 6. Thus, the physicochemical properties of solutions of chitosan are expected to be governed by factors such as pH, ionic strength, degree of acetylation and temperature. It is documented that the charge density along the chitosan macromolecule increases with decreasing degree of acetylation. This means that chain flexibility can be manipulated in response to DA (31).

In addition, the hydrophobicity of the chitosan chain influences the steady shear viscosity and dynamic mechanical properties of solutions and gels. The hydrophobic character can be intensified by chemical modification on the free amino groups or the hydroxyl groups present along the main chain by grafting, for example, alkylated side chains. Numerous food and non-food applications for chitin are foreseen and some are actively being developed (32). Currently, chitosan is used in animal feeds in amounts up to 0.1%. Its chelating/binding properties are explored in structuring of pelleted fish foods, the separation of heavy metals, recovery of proteinaceous materials and in pharmaceuticals. The polysaccharide forms good quality films with potential use in dye, textile, photographic and paper sheet applications.

C. Buckled Ribbons

The 1,4-diaxial linkage arrangement, in which the effective residue is changed from the almost linear form described above to 'Z' shaped, gives rise to buckled ribbon structures. Well-characterised examples of this type of structure occurs in the alginates from brown seaweed and pectin.

1. Alginates

These are 1,4-linked linear polymers of β-D-mannuronate and α-L-guluronate, containing homopolymeric sequences of both types and heteropolymeric regions in which residues occur in various arrangements (33). The latter can range from almost statistically random to almost regularly alternating, depending on the botanical source and state of maturation of the plant. Pure polymannuronic acid, having 1,4-diequatorial linkage geometry, adopts a flat ribbon-like two-fold conformation (as in cellulose and chitin), which converts in the salt form to a similarly extended three-fold ribbon (Figure 92.4). The corresponding x-ray fibre diffraction structure for polyguluronate, by contrast, is a highly buckled two-fold zig-zag, irrespective of charge or counterion (34).

Investigation of molecular models of polyguluronate in the invariant two-fold structure identified by x-ray shows cavities of the size required to accommodate a calcium ion, and with oxygen atoms well placed for cation chelation. It has therefore been proposed that the interchain junctions in alginate gels involve polyguluronate sequences locked in a two-fold conformation, with arrays of site-bound cations sandwiched between them like eggs in an egg box (35). The "egg-box model" rationalizes a well-known property of alginates, which is of major importance for both their biological function and industrial applications. This is the formation of strong, rigid gels with divalent cations, usually Ca^{2+} (Figure 92.5). Gel strength increases with increasing content of polyguluronate and calcium ion activity is solutions of guluronate oligomers shows a sharp decrease above a critical sequence length of about twenty residues. This indicates the onset of co-operative binding behaviour, where the binding of each ion facilitates the binding of the next. Such effects are not seen for the corresponding mannuronate sequences, which remain soluble in the presence of Ca^{2+}, and show only simple polyelectrolyte binding behaviour, indicating that they must act as solubilising interconnecting regions in alginate gels (36).

Commercial applications for alginates in foods/non-foods necessitate the formation of a continuous network rather than a precipitate. Thus it is essential to control the affinity of polyguluronates for Ca^{2+} by ensuring that the ions are introduced in a controlled way that allows intermolecular junctions to form slowly enough. Diffusion setting, internal setting, and a third alternative method when

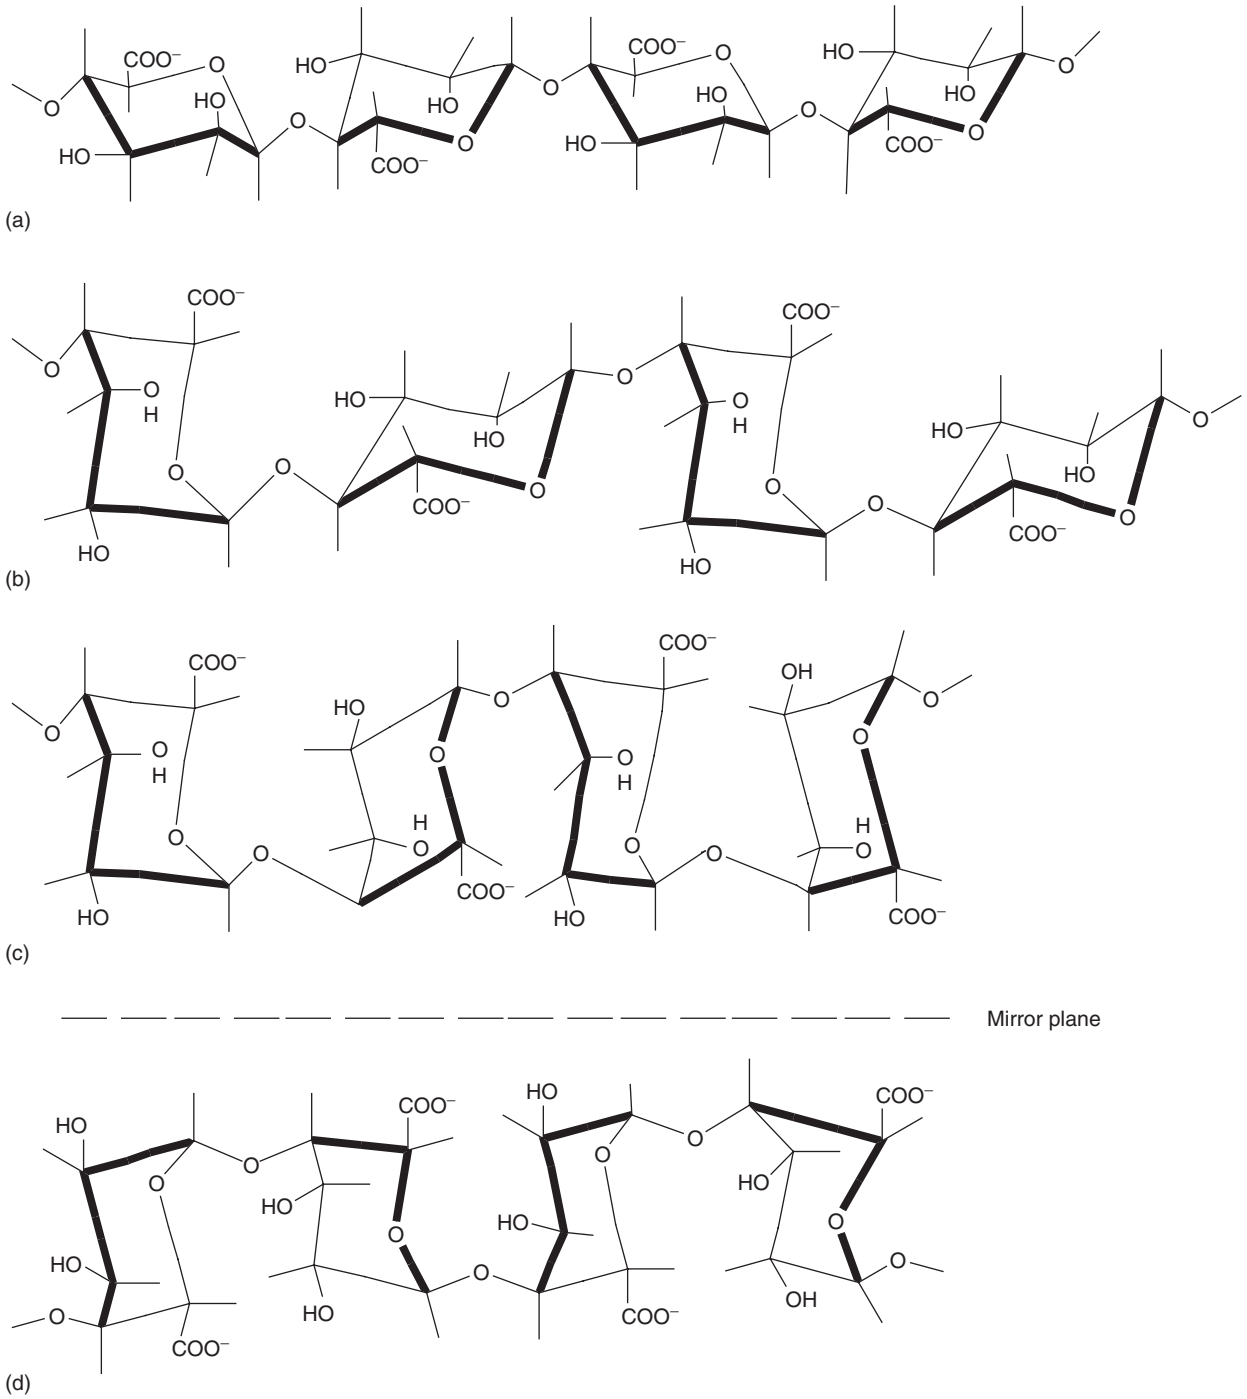

FIGURE 92.4 Comparison of backbone geometry in (a) alginate poly-D-mannuronate sequences, (b) alginate heteropolymeric sequences, (c) alginate poly-L-guluronate sequences and (d) poly-D-galacturonate from pectin (from references 34 and 42, with permission).

setting occurs on cooling in the presence of sequestrants are the recommended recipes to prepare alginate gels (37). Through the years, alginate found its way to a widespread range of products. Alginate setting is used in the production of pimiento strips, onion rings, structured food and fruits, and other thin gelled coating applications. Alginate forms heterotypic interactions with low methoxy pectin due to the mirror-image conformation of the chains of the two gums, which allows applications in low pH jellies, jams and fruit-filled gels (38). Thick pastes, instead of gels, can be

achieved with the sodium or potassium salt and the propylene glycol partial ester of the polysaccharide. These are utilized in salad dressings and fruit drinks containing pulp.

2. Pectin

Pectin is a complex, structural polysaccharide present in all plant tissues and its name comes from the Greek word "πηχτos," which means "to thicken." Commercially accepted pectins are produced from either apple pomace or citrus peel formed as residues from fruit juice, citrus oil and cider industries (39). Other sources of pectins are sugar beet residues (after the extraction of sucrose) and sunflower (from production of edible oil). Commercially, pectin is extracted by treating the raw material with hot dilute mineral acid at ≈ pH 2 and filtering. Apple pectin is treated with carbon to remove colour. The clarified extract is concentrated under vacuum and then mixed with alcohol (isopropanol, methanol) to precipitate the gum in the form of a stringy gelatinous mass. The pure powder is pressed, washed, dried and ground. Since pectin is extracted from a variety of raw materials, production of a consistent product is normally achieved by blending of a number of production batches and diluting them with sugar or dextrose to a standard performance (40).

This process yields pectin with a degree of esterification of approximately 70%, which is called "rapid set" pectin. To produce other types, some of the ester groups must be hydrolysed. This is mainly carried out by the action of acid, either before or during a prolonged extraction, in the concentrated liquid, or in the alcoholic slurry before separation and drying. The procedure results in a range of slower

setting high methoxyl and calcium reactive low methoxyl pectins. Alternatively, alkaline can be used, but since pectin readily degrades at neutral or alkaline pH by a β-elimination reaction, this must be carried out at low temperature. The use of ammonia for alkaline hydrolysis leads to a conversion of some of the ester groups into amide groups, producing amidated pectins, which are usually low methoxyl (41).

Compositional analysis produces the following primary structure: (1) "Smooth" regions made up of a backbone of linear (1→4)-linked α-D-galacturonic acid (pectic acid in Figure 92.4) that may be partially methyl esterified and (2) "hairy" regions in which the galacturonic acid residues are interspersed with (1→2) linked α-L-rhamnopyranosyl residues (42). Attached to the latter are oligosaccharide side chains, containing mainly D-galactopyranose and L-arabinofuranose residues. Sidechains degrade during extraction with acid and, for practical purposes, the pectin molecule may be considered as an unbranched chain of 200 to 1000 galacturonic acid units. According to the degree of esterification (DE), pectin is classified into high methoxy pectin (HM) for DE >50%, low methoxy pectin (LM) with DE <50%, amidated low methoxy pectin and pectic acid for DE <10% (43).

The rate of gelation and the gelation temperature of high methoxy pectin on cooling from the pre-gel solution increase with increasing DE for a given level of sugar (usually above 60% in the formulation). The purpose of reducing pH in preparation of HM gels is to suppress electrostatic repulsion further, by partial conversion of COO^- to COOH. Thus gelation of high methoxy pectins requires a subtle balance of hydrophobic and hydrophilic interactions involving formation of aggregated helices supported by hydrogen bonds and grouping of methyl ester groups within a cage of water molecules (44). In contrast with HM, the gelation in low methoxy pectin takes place by ionic linkages *via* calcium bridges between two carboxyl groups belonging to two different chains in close contact. This mechanism of gelation ("egg-box") is congruent with that of alginates and it has been described in Figure 92.5 (45).

Apple pomace gives a heavier, more viscous gel, commonly used in bakery filings, whereas citrus peel has a lighter colour and consistency, which makes it suitable for confectionery jellies. Thus high methoxy pectin is used as a gelling agent in the formulation of high sugar jams, marmalades, jellies and confectioneries (65 to 85% solids). Low methoxy pectin is suitable for the production of low-sugar jams at levels of solids between 30 and 55% (46). Pectin has a good stability at acidic conditions relevant to food produce even when they are prepared hot and as a result it is popular in the making of fruit sauces or fruit preparations in the form of sheared gel particles for yoghurts (47). The usual concentrations for the above products are between 0.3 and 0.8% pectin but higher amounts of the polysaccharide are needed for bakery glazing and jam fillings (0.7–1.3%), where the requirement is for gel films that maintain their integrity at baking temperatures.

IV. EFFECT OF BRANCHING

There are two distinct groups of branched polysaccharides: plant and bacteria. They differ in the distribution pattern of the branches along the backbone, which is normally irregular for the former group but often regular for the latter. Irregular branching, by interfering with ordered intermolecular association and packing, usually provides a drive to enhance solubility in plant polysaccharides where it occurs. Solubility is further increased if the branches (or other irregularly-distributed substituents) are charged. Regularly-spaced sidechains in bacterial polysaccharides can have a similar solubilising effect. In some cases, however, they can have a quite different role, by modifying or restricting the conformational options of the polymer backbone and participating in the formation of ordered structures with different backbone geometry from that adopted when sidechains are absent (48). Illustrative examples of the effects of both types of branching are given in the following section.

A. The Galactomannans

Galactomannans are energy reserve carbohydrates found in the endosperms of some legume seeds. They consist of a linear backbone of 1,4-linked β-D-mannose units, some of which carry a single α-D-galactopyranosyl sidechain at C(6). Commercially available galactomannans include locust bean (carob), tara and guar gum and their typical mannose/galactose ratios are 3.5, 3.0 and 1.6, respectively (49). Early investigations on the "fine structures" of these galactomannans led to the conclusion that they have a block-like distribution of sidechains. Later work was interpreted as showing that guar gum has a uniform structure, with galactose residues attached to alternate mannose residues, so that in the preferred two-fold conformation of the polymer backbone all the sidechains would be located on one side of the main chain. The same workers also suggested a block structure for carob gum. However, more recent results obtained by intelligent use of rigorously-purified enzymes in combination with computer modeling indicate a more irregular distribution pattern of galactose residues along the mannose backbone (50).

The difference in pattern of substitution of galactomannans reflects on their ease of solubilisation. The overall composition is also an important determinant of hydration. In general, their solubility increases with increasing galactose content. Thus guar gum hydrates rapidly in either hot or cold water, complete dissolution of carob gum required heating to elevated temperatures, and their parent mannan is totally insoluble in water (51). On dissolving, the galactomannans adopt an extended, disordered conformation,

giving solutions of high viscosity at low polymer concentration. In the solid state the backbone adopts an ordered, two-fold conformation with the individual chains packing together into flat sheets.

Galactomannans serve the function of economical and natural thickeners in the food industry (52). Their primary function is to bind water and minimize the growth of ice crystals in confectioneries, pie fillings and chocolate-based frozen desserts. As mentioned earlier, they are combined with gelling carrageenans and agarose to increase the pliability and reduce the syneresis of gels used as gelatin mimetics and with carboxymethylcellulose to stabilise ice creams. A wide range of dips, sauces, salad dressings, mayonnaise, soups and toppings utilize galactomannans to provide desirable viscosity and stability at high temperatures and relatively acidic conditions (53). Locust bean gum, in particular, is used as an efficient binding agent thus contributing to a homogenous texture in sausages made of comminuted meat and canned petfoods with gravy.

B. Xanthan

The bacterial polysaccharide xanthan is an example of a true periodic branched repeating sequence. It is produced during fermentation by the organism *Xanthomonas campestris*. Its primary structure consists of a cellulose backbone, substituted on O(3) of alternate glucose residues by charged trisaccharide sidechains of β-D-Man*p*-1,4-β-D-GlcA*p*-1,2-α-D-Man*p* to give a branched pentasaccharide repeating unit (54). Substantial sample-to-sample variations are observed in the degree of acetylation at O(6) of mannose residues adjacent to the polymer backbone, and in the content of pyruvate ketal 4,6-linked to terminal mannose units. X-ray diffraction studies on oriented xanthan fibres can accommodate equally two trial models. One is an extended five-fold single helix stabilized by hydrogen bonding of sidechains along the polymer backbone and the other is a coaxially packed double helix where the individual chains have the same conformation as the single helix model (55).

It is documented that the disorder-to-order transition of xanthan obeys first order kinetics, with little change in molecular weight until conformational ordering is virtually complete, arguing for an intramolecular single helix rather than an intermolecular double helix. A subsequent approximate doubling of molecular weight observed at lower temperature may then be attributed to lateral association of ordered chain sequences. This proposal offers a likely interpretation of the tenuous gel-like behaviour of xanthan solutions, which is utilized technologically in emulsion stabilization and particle suspension (56). The associations indicated by light scattering provide a mechanism for the development of a network comprising intermolecular associations. The network structure, however, breaks down readily under stress, allowing the solution to flow freely. This unusual combination of properties falls into the category of "weak gels."

The weak-gel properties of xanthan are used widely in the food industry. Salad dressings, mayonnaise and ketchup may contain xanthan up to 0.3% in order to impart a functional texture (57). Thus the foodstuffs are readily pumped in the production line, flow easily from the bottle during use and restructure well "at rest" on a salad, piece of pizza, a toast or a burger. Xanthan's ability to disperse and then dissolve in cold water or to retain its stability and viscosity in acidic formulations finds applications in beverages, sauces and gravies. Its interaction with galactomannans create paste-like heterotypic associations (58), which are used in the stabilization and creaming of processed soft cheeses, and to impart smooth texture and improved organoleptic properties in frozen confectionery (ice cream, milk shakes, etc.).

C. Gellan, Welan and Rhamsan

The structurally-related extracellular polysaccharides gellan, welan and rhamsan share the same four-sugar backbone repeating unit. Gellan is unbranched, whereas welan and rhamsan display comb-like branching. Gellan is biosynthesized by the organism *Sphingomonas elodea* with an L-glyceryl substituent at O(2) of each 3-linked glucose unit of the polymer backbone and an acetyl group at O(6) of the same residue; although the latter substituent may be present in substoichiometric proportion (59). Both groups are often removed by alkaline hydrolysis in preparation of gellan for commercial use. In the case of welan, each 4-linked D-glucose residue carries a 1,3-linked single sugar sidechain of either α-L-rhamnose or α-L-mannose, in the approximate ratio of 2:1. In rhamsan the sidechain is a disaccharide (β-D-Glc*p*-1,6-α-D-Glc*p*-) attached at C(6) of the 1,3-linked glucose residue (the same point of attachment as the acetyl substituents in gellan).

The effect of chain branching on backbone conformation and thus on the physical properties of the polymers, is profound (60). The major industrial use of gellan gum is as a gelling agent with physical properties ranging from weak and elastic in the native polymer to stiff and brittle in the fully deacylated form. The strength and thermal stability of the gels formed by the deacylated polymer is strongly influenced by the type and concentration of cations present (61). For monovalent cations, gel strength increases in the order:

$$Me_4N^+ < Li^+ < Na^+ < K^+ < Cs^+ < H^+$$

whereas for divalent cations, which can form gels at far lower salt concentrations, the order is:

$$Mg^{2+} \sim Ca^{2+} \sim Sr^{2+} \sim Ba^{2+} < Zn^{2+} < Cu^{2+} < Pb^{2+}$$

The ordered structure of gellan involves two left-handed, three fold helical chains organized in a parallel fashion in an intertwined duplex. Gel formation is believed to occur by cation-mediated helix-helix aggregation. The sensitivity of gellan to acyl content and salt composition of the gelation media permits use as a thermosetting, cold-setting, thermo-reversible or thermo-irreversible gelling agent. Additionally, it is highly resistant to enzymic breakdown and can withstand autoclaving, allowing it to be used as a substitute for agarose in microbiology or for plant tissue cultivation. Attempts have been made to find a use for gellan in a wide range of food systems requiring good gelling properties (62). The gum is popular in the making of "halal" table jellies and high sugar confectioneries, which are gelatin and cholesterol free. It may also find use in pie fillings, dairy products and petfoods.

Welan and rhamsan, by contrast, do not gel but give viscous aqueous solutions, which are very stable to temperature, pH and salt, and have characteristic "weak gel" properties similar to those of xanthan (63). Like xanthan, welan was developed initially for commercial application in oil recovery (hence the name). Calorimetric and chiroptical studies showed no evidence of a conformational transition for welan or rhamsan at any accessible temperature. Thus the molecules are either "random coils" which do not order under hydrated conditions, or they are locked in a stable, ordered structure which is very resistant to denaturation. Recent evidence from NMR linewidth, optical rotation, differential scanning calorimetry and response of intrinsic viscosity to changes in ionic strength favours the latter proposal (64). A likely interpretation is that in both of these materials the sidechains pack along the polymer backbone, enhancing the stability of the ordered structure but preventing the helix-helix aggregation required for gel formation.

D. Gum Arabic

Gum arabic is an exudate obtained from the bark of the *Acacia tree* in the form of a very viscous liquid. It is transported all over the world from Sudan, Senegal and other African countries where the main tree species is *Acacia senegal*. Clarified grade is required for food and pharmaceutical applications, which is obtained by filtering, centrifuging, freeze drying and grinding to fine powder (65). Even in this form, the gum is a complex composite of polysaccharide chains covalently linked with proteins. The backbone and side chains of the polysaccharide consist mainly of β-D-galactopyranosyl molecules, which have attached α-L-arabinofuranosyl, α-L-rhamnopyranosyl, β-D-glucuronopyranosyl and 4-O-methyl-β-D-glucuronopyranosyl units. The main appeal of gum arabic in the food industry is its ability to stabilize oil-in-water emulsions, for example, citrus oil emulsion concentrates. In addition, foam and cloud producing ability is utilised extensively in beers and non-alcoholic beverages (66). Another major application of gum arabic is in confectionery products where it prevents sugar crystallization, enhances product homogeneity and provides adhesion for film coatings and nuts (67).

V. PRINCIPLES OF GUM PROPERTIES IN SOLUTIONS AND GELS

The advent of microcomputing in recent years has allowed the rapid development of rheological techniques, with computer driven rheometers becoming commonplace in the laboratory or the research and development department of food companies. These are now established as the most productive line of attack for the development of function-structure-texture relationships in food products (68). The aim of this section is to give a basic introduction to rheological approaches sufficient for the practical examination of gum based sample systems, interpretation of results and to provide enough background information for the accounts of food application types described in this chapter.

A. Dilute Solutions

A particularly convenient and useful experimental parameter in studies of dilute solutions is the intrinsic viscosity [η], a measure of the volume occupied by the individual polymer molecules in isolation, which is directly related to molecular weight (M) [69]. This is widely used in routine characterisation of polymer batches (Mark-Houwink equation):

$$[\eta] = KM^{\alpha} \qquad [92.1]$$

where K and α are constants whose values depend on the shape of the polysaccharide, the solvent used and the temperature of measurement. Typical values of α for flexible coils are 0.5–0.8, and for rigid rods 1.5–1.8 (70).

Intrinsic viscosity is defined by the standard equations:

$$\eta_{rel} = \eta/\eta_s \qquad [92.2]$$

$$\eta_{sp} = (\eta - \eta_s)/\eta_s = \eta_{rel} - 1 \qquad [92.3]$$

$$[\eta] = \lim_{c \to 0} (\eta_{sp}/c) \qquad [92.4]$$

where η and η_s denote the viscosities of the solution and solvent, respectively, and η_{rel} and η_{sp} are, respectively the dimensionless parameters of relative viscosity and specific viscosity. Experimental values of η_{sp} for extrapolation to intrinsic viscosity at infinite dilution (Equation [92.3]) should be in the range 0.2 to 1.0 (71).

Treating now molecules as particles widely separated, the Einstein relationship for laminar flow can be derived (72):

$$\eta = \eta_s(1 + k_1\phi) \qquad [92.5]$$

where ϕ is the phase volume of the disperse phase and k_1 takes the value of 2.5 for spheres. From Equations [92.3] and [92.5], η_{sp} can be expressed as a function of phase volume:

$$\eta_{sp} = k_1\phi \qquad [92.6]$$

Combination of Equations [92.4] and [92.6] for infinite dilution gives the identity:

$$k_1\phi = \eta_{sp} = [\eta]c \qquad [92.7]$$

At higher concentrations, where the increase in viscosity is not directly proportional to the mass of the disperse phase, the Einstein relation is extended by including higher order terms in Equation [92.6]:

$$\eta_{sp} = k_1\phi + k_2\phi^2 + k_3\phi^3 + k_4\phi^4 + \cdots \qquad [92.8]$$

Experimentally, a linear intrinsic viscosity-concentration relationship is observed for specific viscosities up to about 1 and its numerical form is obtained by keeping terms up to quadratic in Equation [92.8] and substituting ϕ from Equation [92.7]:

$$\eta_{sp}/c = [\eta] + k'[\eta]^2c \qquad [92.9]$$

where $k' = k_2/k_1^2$. This is the Huggins equation and the extrapolation to give intrinsic viscosity is obtained from a plot of η_{sp}/c *vs* c. Alternative extrapolations are given by the equation of Kraemer and the single point method (73). In practice, these extrapolations may not be strictly linear, but using all of them, intrinsic viscosities can be well bracketed.

B. Effect of Entanglement

Moving now from the case of very dilute solutions, where the intention was to acquire information about the volume occupied by individual molecules, up to the real range of practical viscosity behaviour ($\eta_{sp} > 1$), the Huggins and the other associated extrapolations become irrelevant because higher order powers such as those in Equation [92.8] start to be significant. With further increase in concentration, viscosity begins to show appreciable dependence on shear rate (74). At low shear rates, viscosity remains constant at a fixed, maximum value (the "zero shear" viscosity, η_0), but at higher values "shear thinning" is observed (Figure 92.6). Taking the maximum "zero shear" value, it has been observed empirically that for a wide range of gums with flexible coils the log of specific viscosity varies approximately linearly with the log of concentration over the viscosity range $1 < \eta_{sp} < 10$, with a slope of about 1.4 (75).

At higher values of η_{sp}, however, the concentration dependence changes dramatically to a slope of about 3.3,

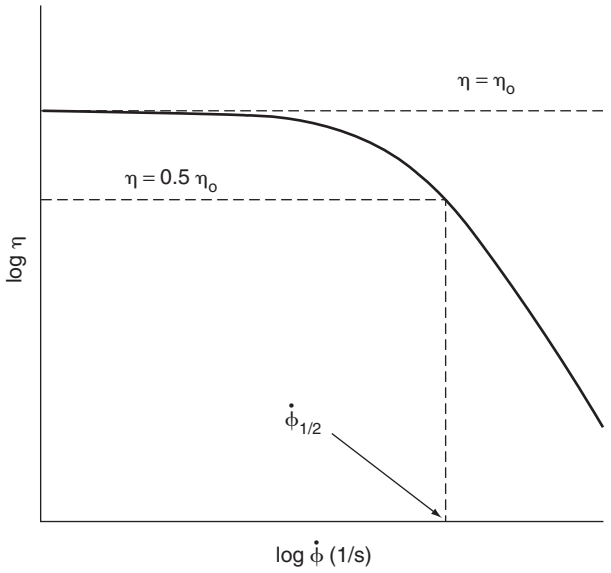

FIGURE 92.6 Shear-rate dependence of viscosity for a typical concentrated gum solution (from reference 75, with permission).

because a point is reached where the individual coils start to entangle ($c = c^*$). The relationship between absolute concentration and the onset of entanglement can be seen from equation [92.7]. According to this equation, increasing concentration leads to a stage where the volume fraction occupied by the coils becomes equal to the total volume ($\phi = 1$). The degree of space-occupancy by the polymer coils is characterized by the right-handside of Equation [92.7] ($c[\eta]$), which is called the "coil overlap parameter" (76). This has been found to have a value of about 4, at the onset of entanglement, regardless of polymer primary structure and molecular weight (Figure 92.7). The zero shear specific viscosity at this critical concentration (c^*) is invariably close to 10 (77).

The spectacular change in concentration-dependence of solution viscosity during the transition from a dilute solution of independently moving coils to an entangled network can be rationalised as follows. At concentrations below the onset of coil overlap and entanglement ($c < c^*$), the main effect of the polysaccharide coils is to perturb the flow of the solvent by tumbling around and setting up "countercurrents," with mutual interference of countercurrents from adjacent chains giving a somewhat more than proportional increase in viscosity with increasing concentration (78). At concentrations above c^*, however, where flow requires chains to move through the entangled network of neighbouring coils, the restriction of mobility increases steeply with increasing network density, giving rise to the higher concentration-dependence of viscosity.

Shear thinning behaviour in polysaccharide solutions can be similarly rationalised in terms of polymer entanglement At concentrations below c^*, shear thinning is minimal (typically less than 30% over several decades of shear rate), and can be attributed to elongation of individual coils in the direction of flow at high enough shear rate. The

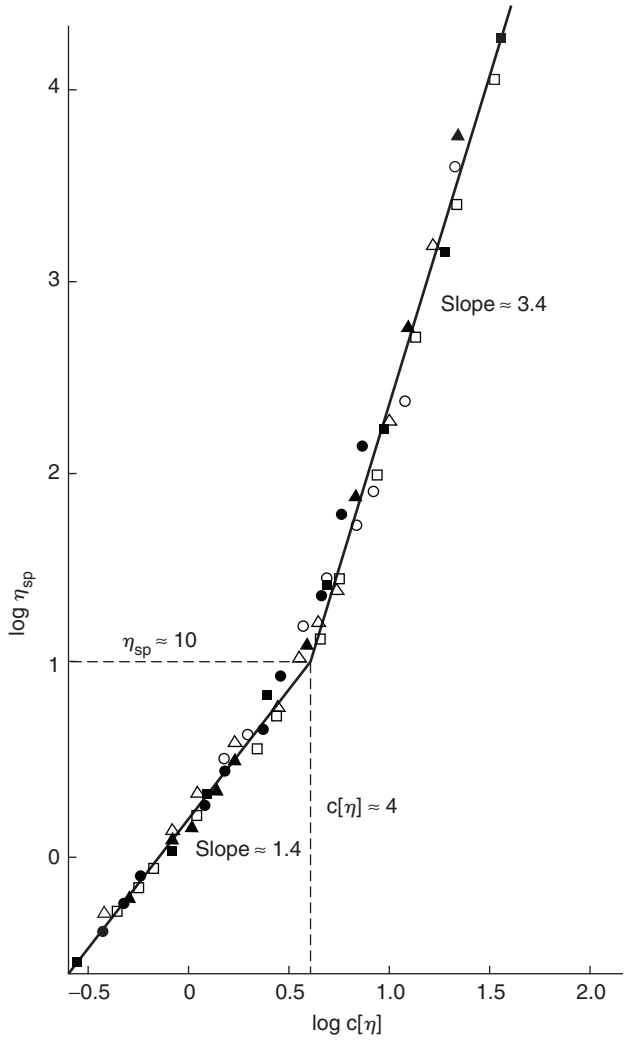

FIGURE 92.7 The variation of "zero-shear" specific viscosity with degree of space-occupancy for linear polysaccharides in solution (from reference 76, with permission).

"Newtonian plateau" observed for entangled coils ($c > c^*$) at low shear rates corresponds to a dynamic equilibrium between forced disentanglement (to allow the solution to flow), and re-entanglement with new partners (79). At higher values of shear rate, where the pace of disentanglement exceeds the pace at which new entanglements can form, the overall crosslink-density of the network is reduced, with consequent reduction in viscosity (often by several orders of magnitude).

C. Viscoelasticity

So far the discussion has been confined to the liquid-like behaviour of gum systems, measured under "large deformation" conditions, i.e. steady shear. Gum networks, including entangled "flexible coils," however, also show a substantial element of solid-like response (80). The degree of solid-like and liquid-like character can be quantified by the technique of mechanical spectroscopy in which the resistance of the sample to a very small oscillatory deformation is resolved into the storage (G') and loss (G'') moduli (68). The oscillatory analogue of shear rate is the frequency of oscillation (ω) and the ratio of the unresolved "complex modulus" ($G^* = (G'^2 + G''^2)^{1/2}$) to the applied frequency gives the "dynamic viscosity," η^* (81).

Polysaccharide systems can give three characteristic types of small deformation response (Figure 92.8). Polymer solutions with concentrations lower than c^* yield the first general type of spectrum (82). There is little variation of dynamic viscosity with frequency and G'' dominates over the G', although with increasing frequency G' approaches G'' due to storage of energy by contortion of the chains into strained conformations. Concentrated gum solutions provide the second type of mechanical behaviour (83). At lower frequencies the principal response is rearrangement of the network to accommodate the strain, and G'' predominates (as in the case of dilute solutions). At high frequencies, where interchain entanglements do not have sufficient time to come apart within the period of one oscillation, $G' > G''$ showing little change with frequency (solid-like response). The dynamic viscosity is independent of frequency initially, but decreases steeply on reaching higher values of ω.

The last general category of spectrum is the permanent network (e.g. true gum gels) that show properties approaching those of elastic solids, hence G' predominates over G'' at all frequencies with neither showing any appreciable frequency-dependence. Dynamic viscosity decreases steeply with increasing frequency, and the slope of log η^* vs log ω approaches the value of -1 expected when G' and G'' are constant (84). An unusual combination of liquid-like and gel-like properties is the case of weak gels, with xanthan the best documented example mentioned above. Xanthan solutions show quite different shear-thinning behaviour from the generalized shear rate dependence observed for flexible polysaccharide coils and, when measured under small deformation conditions, G' is greater than G'' with little frequency-dependence in either modulus, behaviour typical of a gel rather than a normal solution (85). Additionally, the small-deformation dynamic viscosity is greater than the large-deformation steady shear viscosity, in contrast to flexible coil polysaccharides where both types of measurement give the same numerical values. This implies a weak, gel-like structure, which can survive a low amplitude oscillation, but is disrupted by continuous shear (86).

VI. MIXED GELS

Two gelling gums in the same system can create three general types of network structure, as shown in Figure 92.9 (87):

a) Interpenetrating networks
b) Coupled networks and
c) Phase-separated networks

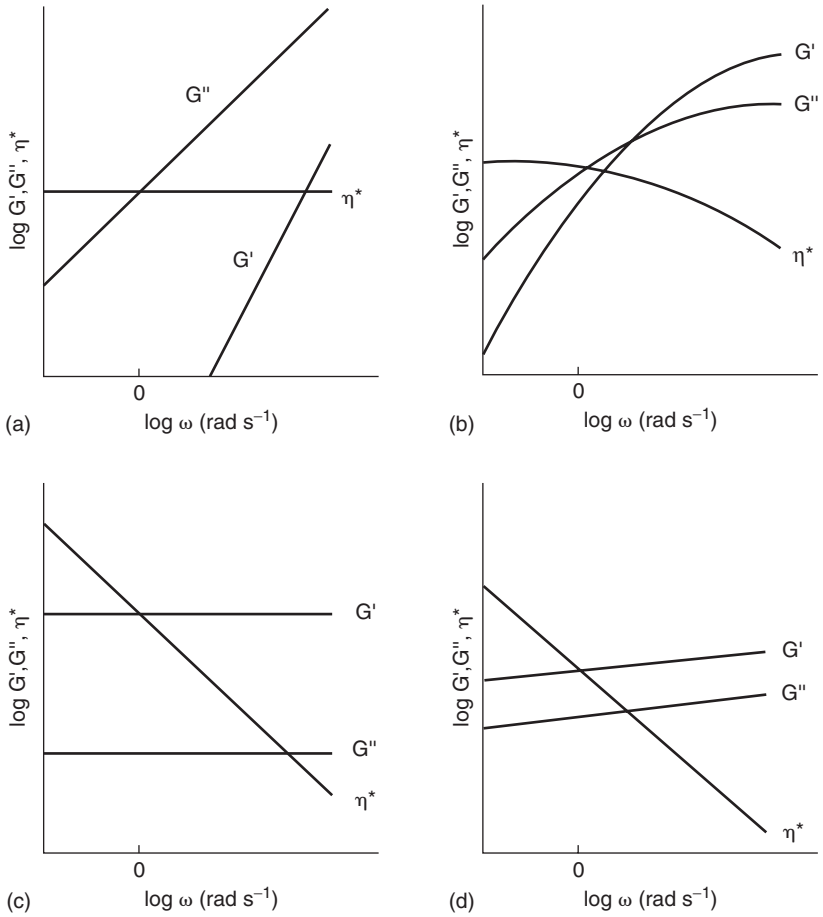

FIGURE 92.8 The four principal categories of mechanical spectra: (a) Dilute solution, (b) entangled solution, (c) strong gel and (d) "weak gel" (from reference 82, with permission).

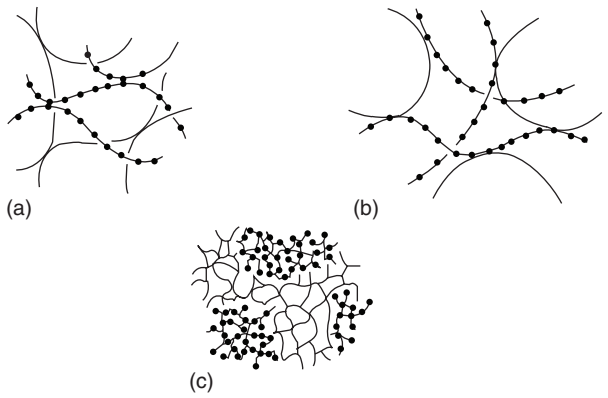

FIGURE 92.9 The three possible network topologies for binary gelling systems: a) interpenetrating, b) coupled and c) phase-separated networks (from reference 87, with permission).

A. Interpenetrating Networks

These represent the simplest situation, rarely encountered in mixed gum gels, where the two components gel separately forming two independent network structures. Both networks span the entire system, interpenetrating one another, but interaction is solely topological (88). One way of ensuring bicontinuity is to introduce a second polymer into the pores of a pre-existing network, and then to alter conditions in such a way that this second species forms its own network without disruption of the original gel. The problem of slow diffusion of a polymer solution into a gel can be tackled by using small globular proteins as the diffusing species. An alternative would be to prepare a xerogel of a gum and then swell this gel in the protein solution. A final requirement is the thermal irreversibility of the pre-existing gum network in order to allow for the heat-set process of the protein.

B. Coupled Networks

This kind of interaction involves a direct association between two different polymers to form a single network. Three different types of intermolecular binding may then arise:

i) Covalent linkages
ii) Ionic interactions
iii) Co-operative junctions

Chemical cross-linking between different chains offers a direct way of forming a gel network. The main characteristic of a system held by covalent bonds is its thermostability. One reasonably well-understood interaction of this type involves the formation of amide bonds between the propylene glycol esters of alginate and uncharged amino groups of gelatin (89). Direct interactions can also occur between biopolymers of opposite net charge, by formation of an insoluble coacervate. Complex coacervation between, for example, gum arabic and gelatin has extensive practical use in microencapsulation. Ionic attraction may also be involved in the highly specific interaction of κ-carrageenan with κ-casein, to give a weak gel network of practical importance in, for example, preventing sedimentation of cocoa particles in chocolate milk desserts (90).

Finally, it has been suggested that in some systems the interactions of unlike polysaccharides may involve formation of specific co-operative junction zones analogous to those in single-component gel systems, such as carrageenans, but with the participating chains being heterotypic rather than homotypic. The mixed gels formed between alginate and pectin under acid conditions are believed to involve junctions of this type (91). As mentioned earlier, another example of co-operative synergism is between certain galactomannans (notably carob and tara gum) and certain helix-forming polysaccharides (agarose, xanthan, κ-carrageenan). In general, the phenomenon is believed to involve unsubstituted regions of the mannan backbone associating with the ordered conformation of the second polymer to create mixed-junction zones.

C. Phase-Separated Networks

When favourable interactions (such as those in polyanion-polycation systems) are absent, thermodynamic incompatibility between chains of dissimilar polysaccharides tends to cause each to exclude the other from its polymer domain, so that the effective concentration of both is raised. This is true even when the energies of interaction between the chains involved are small (disordered chain segments) in comparison with the much stronger interactions of ordered sequences in gum gels (92).

At low concentrations, thermodynamic incompatibility can promote conformational ordering within a single phase, which, for gelling systems can increase the rate of network formation (93). At higher concentrations, the system may separate into two discrete liquid phases. Generally, phase separation in protein-polysaccharide-water systems occurs only when the total concentration of the macromolecular components exceeds 4%, although there are variations from system to system (94). In the case of carboxyl-containing or sulphated polysaccharides, ionic strength and pH play an important role. For example, proteins and carboxyl-containing polysaccharides phase separate at pH values above the isoelectric point (at any ionic strength) or when the pH is equal to or less than the protein isoelectric point but the ionic strength is greater than ≈ 0.25 (95). Phase separation phenomena are manipulated in the food industry to develop novel textures, a notable example of which is low fat spreads, processed soft cheeses, low protein yoghurts and chocolate mousses. In these products, starch and its hydrolysates, pectin, alginates, gelatin and sodium caseinate play an important role (96).

VII. GUMS IN A HIGH SUGAR ENVIRONMENT

As described earlier, gums comprise an important class of confectionery products. These are based on a mixture of sucrose and glucose syrups and typically contain 10–25% moisture in the final product. A hydrocolloid is incorporated to control texture. Gummy sweets are made by preparing first the 'liquor,' which is a mixture with all the ingredients at 30% moisture content (97). Liquors are deposited hot (e.g. 70°C) into dry-powdered starch moulds and the excess moisture is extracted by stoving the sweets in these moulds for the required period of time at about 50°C.

Gelatin which for almost a century has been produced on an industrial scale is the most frequently used structuring agent in confectionery products, but is increasingly falling 'out of fashion' with consumers and producers alike (98). Reasons for the change in attitudes include the need to circumvent diet and health problems or perceptions such as the BSE scare, vegetarianism and religious dietary laws (e.g. Muslim and Hindu). Furthermore, high sugar/gelatin confectioneries tend to become sticky during handling, or when stored in warehouses at high ambient temperatures resulting in partial structural collapse, welding and crystallization (caking) of the product. For these reasons, there is an incentive to understand the behavior of polysaccharides in high sugar environments since this class of biopolymers may provide an alternative to gelatin.

Recent studies have mapped out the structural properties of gums in the presence of increasing levels of sugar (99). Small deformation dynamic oscillation described in the 'Viscoelasticity Section' of this chapter was used to identify the structural characteristics of the gums from the rubbery plateau (elastic consistency) through the transition region to the glassy state (brittle texture). In contrast to the collapse of the firmness of polysaccharide gels (agarose, gellan gum, κ-carrageenan) at intermediate levels of co-solute, gelatin forms reinforced networks between 40 and 70% sugar in the mixture (Figure 92.10). The drop in polysaccharide network strength is accompanied by a decline in the enthalpy of the coil-to-helix transition, whereas the transition enthalpy is more pronounced in gelatin gels in accordance with their strengthening (100). Tangible evidence of the molecular transformations was obtained using electron microscopy, with polysaccharides

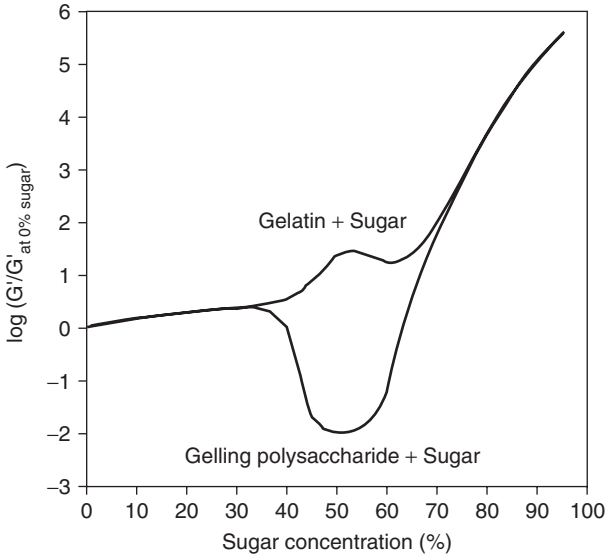

FIGURE 92.10 Variation of normalized shear modulus ($G'/G'_{at\ 0\%\ sugar}$) as a function of sugar concentration for polysaccharide/sugar and gelatin/sugar mixtures (from reference 100, with permission).

disaggregating and dissolving in the saturated sugar environment. Gelatin, on the other hand, is visualized in an aggregated form thus producing a phase-separated topology with sugar. It is speculated that this behaviour may have implications and lie behind the difficulties encountered in the commercial replacement of gelatin with small additions of gelling gums in high sugar confectionery products (101).

93 Heat Induced Aggregation, Gelation and Phase Separation of the Globular Protein β-Lactoglobulin

Dominique Durand and Taco Nicolai
Université du Maine, Le Mans Cedex

CONTENTS

I. INTRODUCTION

Generally, heat induced denaturation of globular proteins leads to aggregation of the proteins and above a characteristic concentration (C_g) eventually a gel is formed [1–3]. The aggregation process, the structure and the visual aspect of the gels depend on external conditions such as the pH, the ionic strength (C_s), the protein concentration (C) and the temperature (T). At a pH far from the isoelectric point (pI) and at low ionic strength the gels are generally transparent and electron microscopy shows that linear aggregates are formed. At high ionic strength or close to pI the gels are turbid and more densely branched aggregates are observed.

Among the most common globular proteins such as serum albumin (BSA), ovalbumin (OA) and lysozyme, β-lactoglobulin (β-lg) is the most intensively studied. β-lg is the major component of whey and has molar mass 18.4 Kg/mol and radius 2 nm [4–6]. At pH2 β-lg has a purely positively charge of +21, while at pH7 it has a net negative charge of −7, but contains both positively and negatively charged groups. The isoelectric point pI equals 5.2.

Apart from being a good model, β-lg is widely used in food industry and it is important to understand the heat induced aggregation process either because one wants to avoid it, e.g. in sterilization of milk, or because one wants to exploit it for building new textures for specific applications.

The purpose of this chapter is to present some of the major features of heat induced aggregation and gelation of β-lg based mainly on the research carried out in our laboratory over the last decade [7–22]. Experimental and technical details of the results shown in this chapter can be found in the original papers where the reader can also find references to the relevant literature. One aspect that has received relatively little attention until recently, is the influence of phase separation on the gel structure. We will address that issue here through a study of mixed systems of β-lg and κ-carragheenan (κ-car) [18–21]. The latter is a polysaccharide issued from blue algae and is fully

compatible with native β-lg under the conditions of our investigation. However, κ-car and β-lg aggregates are, under some specific conditions, incompatible, which leads to (micro) phase separation with important consequences for the gel structure. We will argue that the effect of micro phase separation may play an important role in the elaboration of new textures with new properties.

II. NATIVE PROTEIN CONSUMPTION

β-lg aggregates are stable to cooling and dilution and can be characterized in dilute solutions at room temperature [7, 14]. Figure 93.1 shows an example of the size distribution of β-lg after different heating times obtained by size exclusion chromatography (SEC). The chromatographs show a clear separation between a narrow peak corresponding to residual native proteins and a broad peak that corresponds to the aggregates. This observation implies that the minimum size of the aggregates contains already many monomers and that no or very few stable oligomers are formed. This separation is also observed in-situ in dynamic light scattering experiments both at pH7 and pH2 [7, 12].

With increasing heating time the aggregates grow in size and the size distribution broadens, while the fraction (F) of native proteins decreases. Unfortunately, the resolution of SEC is rather limited and already relatively small aggregates are fully excluded and no longer resolved. The evolution of F with heating time of β-lg at pH7 and 0.1 M NaCl salt is shown in Figure 93.2 for three temperatures. The rate with which the protein aggregates is strongly temperature dependent, but the shape of the time dependence is the same at each temperature. This is illustrated in Figure 93.3 where the data are plotted as a function of the heating time normalized by the time needed to aggregate half of the protein (t_h). The aggregation rate has an Arrhenius temperature dependence with a large activation energy

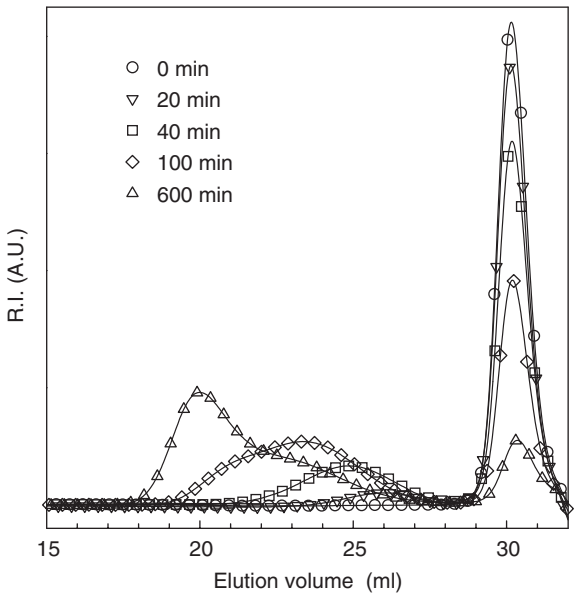

FIGURE 93.1 Chromatograms of β-lg solutions at pH7, 0.1 M salt and C = 18.6 g/L after different heating times at 60°C.

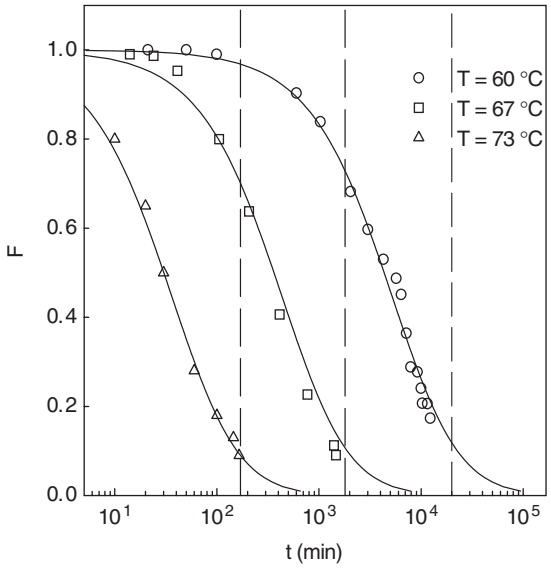

FIGURE 93.2 Heating time dependence of the unaggregated β-lg fraction (F) at pH7, 0.1 M salt and C = 18.6 g/L at different temperatures indicated in the Figure. The dashed lines indicate the gel time defined as the time when we first observed a fraction of non-soluble protein. The continuous lines represent a fit with a reaction order 1.5.

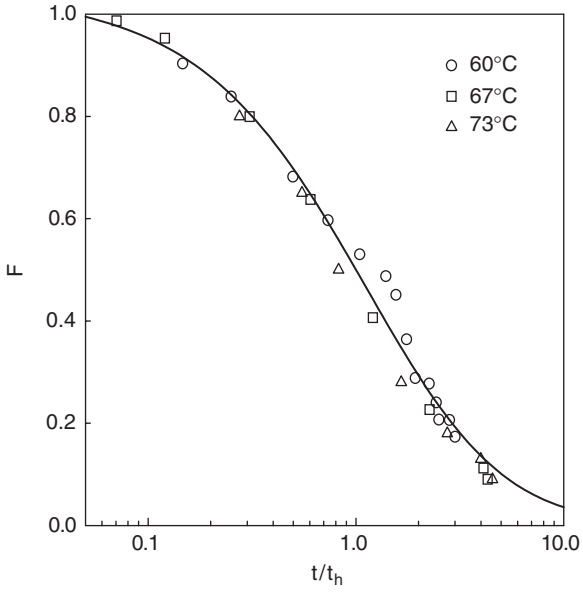

FIGURE 93.3 Same data as in Figure 2 plotted as a function of the heating time normalized by the time needed to consume half of the native proteins t_h. The continuous line represents a fit with a reaction order 1.5.

(250–400 KJ/mol) that depends weakly on the concentration and the ionic strength [13]. The temperature dependence of the aggregation rate is most likely controlled by the temperature dependence of the protein denaturation, which has a large activation energy because it is a co-operative process. For most of the situations that we have investigated the temperature has only an effect on the rate of aggregation and there is no indication for a critical gelation temperature other than the constraint that the gelation will take too long at lower temperatures [13].

The influence of the protein concentration on the aggregation process is more complicated. In general the rate of native protein consumption decreases with decreasing concentration [13, 23]. It has been investigated in detail for β-lg at pH7 and at 0.1 M NaCl ionic strength, for which it is shown that the aggregation rate can be characterized by an apparent order of 1.5 [13]. But, unexpectedly, at low protein concentrations not all proteins aggregate and the fraction of unaggregated β-lg (F) decays to a plateau value, F_p. Figure 93.4 shows examples of the dependence of F on heating time at 80°C for two ionic strengths at pH7. We do not claim that protein depletion stops entirely at F_p, but clearly it decreases relatively rapidly to a given value after which the decrease becomes logarithmically slow. For all ionic strengths, F_p increases with decreasing protein concentration. A systematic study of the concentration dependence of F_p over a range of ionic strengths shows that the proteins only aggregate above a critical association concentration, CAC, which decreases with increasing ionic strength, see Figure 93.5.

At pH2, as at pH7, the rate at which the protein is involved in the formation of aggregates increases with the temperature and the initial protein concentration. The ionic strength has also a strong influence on the decrease of the fraction of unaggregated β-lg (F) as shown in Figure 93.6. After long heating time, the fraction of unaggregated

protein stabilizes at a value that increases with decreasing ionic strength as was found at pH7.

III. AGGREGATE GROWTH AND GELATION KINETICS

Static light scattering (SLS) has proven to be a powerful technique to characterize the growth of the aggregates [11]. Figure 93.7 shows the scattering wave vector (q) dependence of the intensity scattered by the aggregates formed after different heating times at pH7 and 0.1 M NaCl salt. The solutions were highly diluted so that interaction may be neglected. The scattering intensity (I_r) is normalized by that of β-lg monomers at the same concentration, so that the value of I_r extrapolated to q = 0 corresponds to the weight average aggregation number (m_w), according to the relation $I_{rel}(q) = m_w.S(q)$ where S(q) is the structure factor of the aggregates [24, 25]. In Figure 93.7, clearly m_w increases with increasing heating time, while the q-dependence becomes more important because the average size of the aggregates increases The z-average radius of gyration of the aggregates (R_{gz}) can be obtained from the initial q-dependence of S(q) through the relation $S(q) = (1 + q^2R_{gz}^2/3)^{-1}$ for $qR_{gz} \ll 1$. At larger heating times this initial q-dependence can no longer be reached in the q-range accessible in the experiment. Very large aggregates show a power law q-dependence, $I_{rel}(q) \propto q^{-df}$, which means that the aggregates have a self similar structure with fractal dimension d_f [11, 24]. After dividing $I_r(q)$ by m_w and plotting the result, the so called structure factor S(q) [24, 25], as a function of $q \cdot R_{gz}$, we obtain a master curve, see Figure 93.8, which confirms that aggregates are self similar [11, 24]. We will discuss the structure of the aggregates in more detail in the section IV.

In the following part, we will examine the influence of the temperature, concentration and ionic strength on the kinetics of aggregation and gelation.

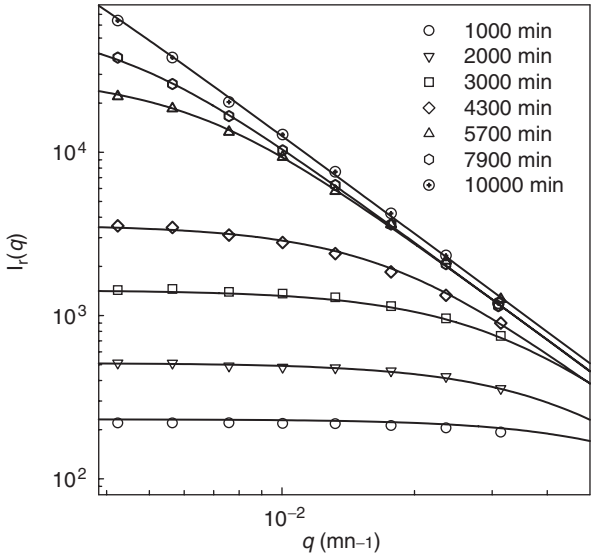

FIGURE 93.7 Scattering wave vector (q) dependence of the relative excess intensity of light scattered (I_r) by dilute solutions of β-lg aggregates formed after different heating times at 60°C, pH7, 0.1 M salt and C = 18.6 g/L. The heating times in minutes are indicated in the Figure. The solid lines represent fits to the equation $I_{rel}(q) = m_w (1 + q^2R_{gz}^2/3)^{-1}$. The straight line through the data at t = 10000 min. has slope −2.

A. Temperature Dependence

Figures 93.9 and 93.10 show, respectively, the effect of heating temperature on the aggregate growth and on the evolution of G″ and G′ at 0.1 Hz at pH7 and 0.1 M salt. It is clear that the gelation rate increases strongly with increasing temperature. However, there is not a significant effect of the temperature on the shapes of $m_w(t)$, G′(t) and G″(t). This is shown in Figures 93.11 and 93.12 where we have superimposed the data by time shifts. Master curves of two other protein concentrations are also shown in Figure 93.12.

In Figure 93.11 we have compared the evolution of m_w, with that of the loss (G″) and the storage (G′) shear moduli. The shear modulus was measured at 0.1 Hz in the linear regime (10% deformation) using a couette geometry [16]. We have defined here the gel time (t_g) as the time when we first observe an insoluble gel fraction after dilution indicated by the dashed line in Figure 93.11. Alternatively, one can define t_g as the time when m_w diverges or when G′ and G″ follow the same power law frequency dependence in the law frequency domain [26].

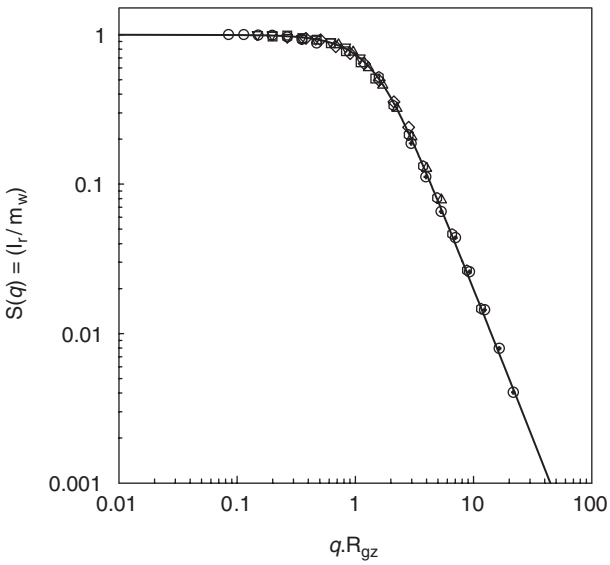

FIGURE 93.8 Same data as in Figure 7 with I_r normalized by the weight average aggregation number (S(q)) and q by the z-average radius of gyration R_{gz}. The solid line represents the theoretical structure factor $S(q) = (1 + q^2R_{gz}^2/3)^{-1}$.

These definitions give similar values for t_g, but they are less convenient for systematic investigation. Taking the observation of an insoluble gel fraction as t_g leads to an overestimation of t_g by at most 20%.

The temperature dependence of the gel time (t_g) is characterized by the same activation energy as that of the protein denaturation. This means that the temperature dependence of the gelation rate is controlled by the process of protein denaturation [13]. Above the gel time G′ increases rapidly at first and later continues to increase slowly over the whole duration of the measurement.

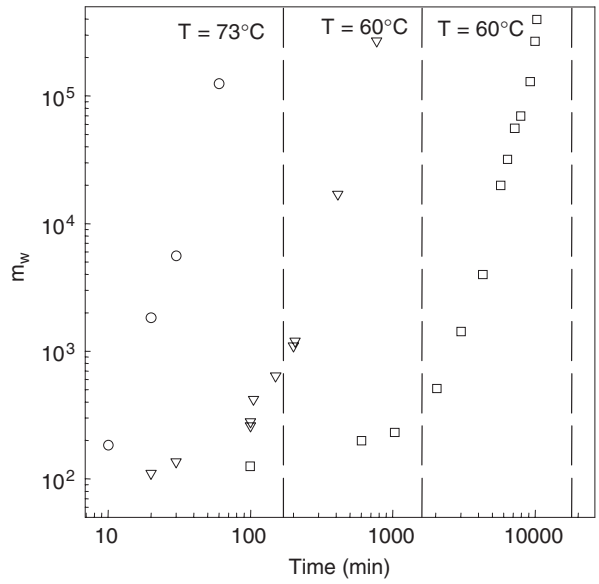

FIGURE 93.9 Time dependence of the weight average aggregation number (m_w) at different temperatures. Symbols are the same as in Figure 2. The dashed lines indicate the time (t_g) when we first observed a fraction of non-soluble protein.

B. Concentration Dependence

In order to form a gel the aggregates have to grow sufficiently large to fill up the whole space. If aggregates have

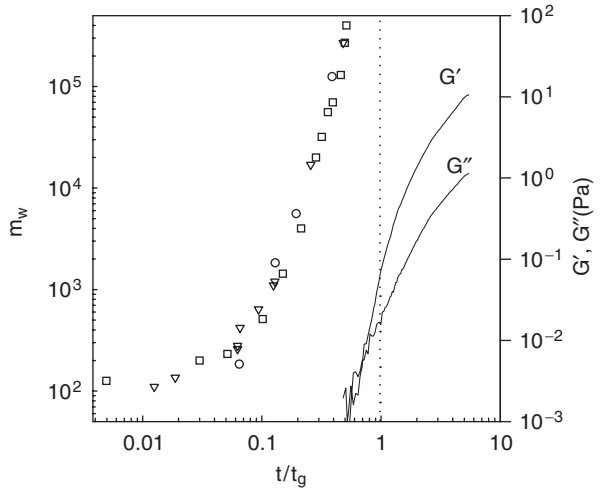

FIGURE 93.11 Same data as in Figure 9 normalized by the gel time and time evolution of the loss (G″) and storage (G′) shear modulus at 70°C (pH7, 0.1 M NaCl salt and C = 18.6 g/L). The dotted line indicates the time (t_g) when we first observed a fraction of non-soluble protein.

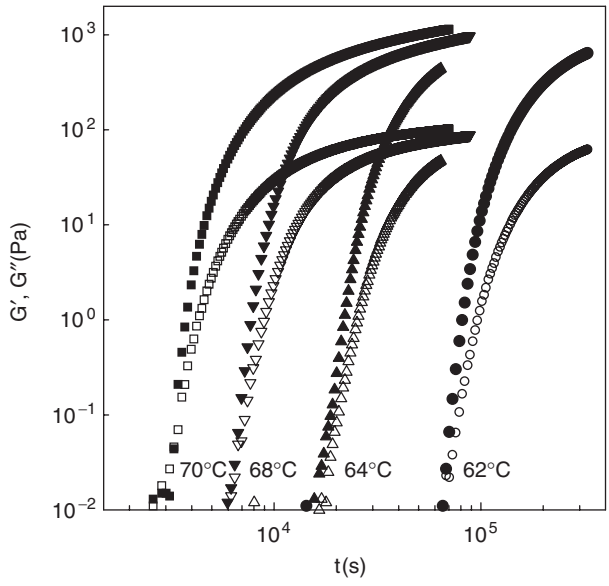

FIGURE 93.10 Evolution of the loss (open symbols) and storage (closed symbols) modulus at 0.1 Hz as a function of heating time for β-lg solutions (C = 5.0 g/L, 0.1 M NaCl, pH7) at different temperatures indicated in the Figure.

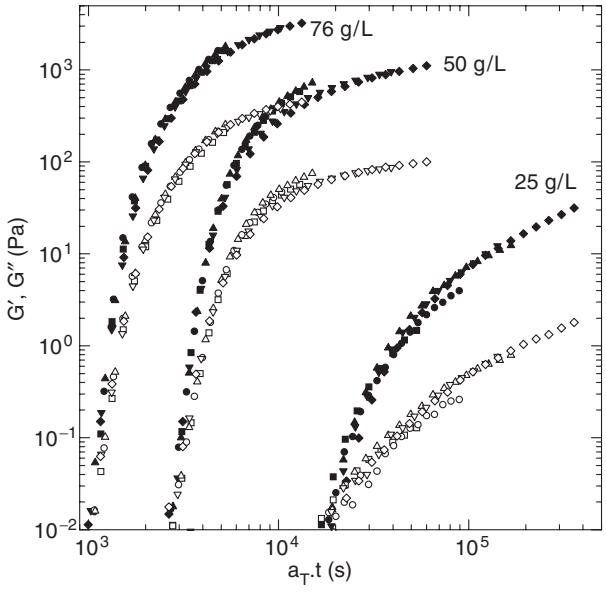

FIGURE 93.12 Master curves of the evolution of G′ and G′′ at reference temperature 70°C constructed by superposition of data obtained at different heating between 61 and 72°C for different β-lg concentrations indicated in the Figure.

a fractal structure there is no lower concentration limit for space filling and gelation to occur, as has been demonstrated by computer simulations [27]. Of course, as the concentration decreases the gel becomes less dense and weaker so that in practice there is always a lower concentration limit below which the gel modulus is no longer measurable. For globular proteins, however, a lower concentration limit for gelation (C_g) is observed for a different reason. This is illustrated in Figure 93.13, where we plotted the growth of the aggregates with heating time at different concentrations for β-lg at pH7 and 0.1 M CH_3COONH_4. Above a critical concentration $C_g = 7$ g/L we observe a clear divergence of the weight average aggregation number m_w after which a gel is formed. Below this concentration $C < C_g$, the growth of the aggregates stagnates when most native proteins have aggregated [13, 17]. The size of the aggregates, at which their growth stagnates, increases with the protein concentration. C_g depends strongly on the ionic strength, but also on the type of salt, see below.

In Figure 93.14 we show the evolution of G′ at 80°C for a range of concentrations at pH7 and 0.1 M NaCl. The gel time increases with decreasing concentration and diverges as $C \to C_g$. As expected, at a given temperature both the rate of gelation and the value of the modulus at the measured longest time increase with increasing concentration.

C. Ionic Strength Dependence

Figure 93.15 shows how m_w varies with the protein concentration at different ionic strengths between $3 \cdot 10^{-3}$ M and 0.4 M. The data were obtained for β-lg solutions at pH7 that were heated for 24 h at 80°C. After this prolonged heat treatment the growth of the aggregates has stagnated. For ionic strength up to $2 \cdot 10^{-2}$ M we observe a plateau at low concentrations. At these concentrations, only small so-called primary aggregates are formed. There appears to be a small increase of the mass of the primary aggregates with increasing ionic strength. The association of the primary aggregates into larger self-similar aggregates leads to an increase of m_w with increasing concentration and a divergence at C_g. The increase occurs at higher concentrations with decreasing ionic strength. For $C > C_g$ we observe the formation of a homogeneous gel if $C_s < 0.2$ M.

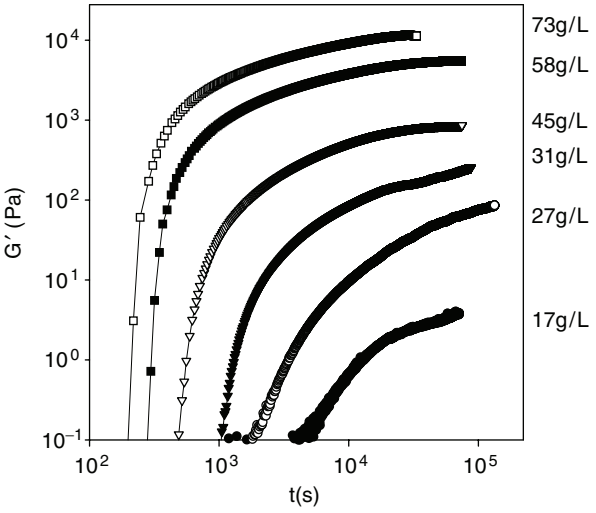

FIGURE 93.14 Evolution of the storage shear modulus at 0.1 Hz with heating time at 80°C for β-lg solutions at different concentrations indicated in the Figure (pH7 and 0.1 M NaCl).

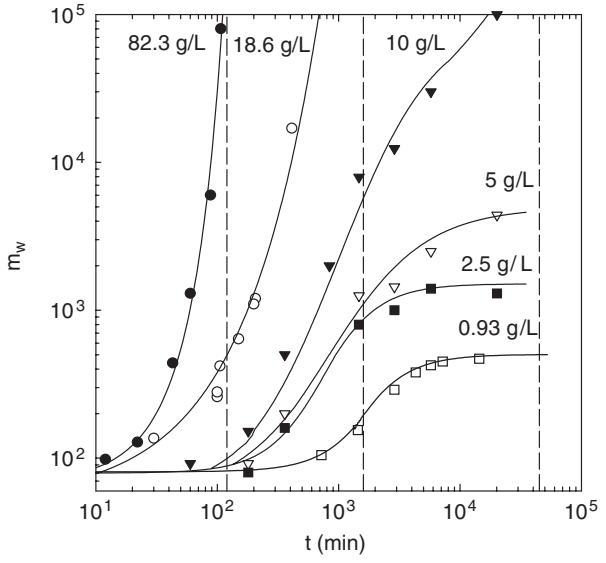

FIGURE 93.13 Growth of the weight average aggregation number (m_w) of β-lg aggregates formed after heating at 67°C for different concentrations indicated in the Figure (pH7, 0.1 M CH_3COONH_4). The vertical line indicates the gel point.

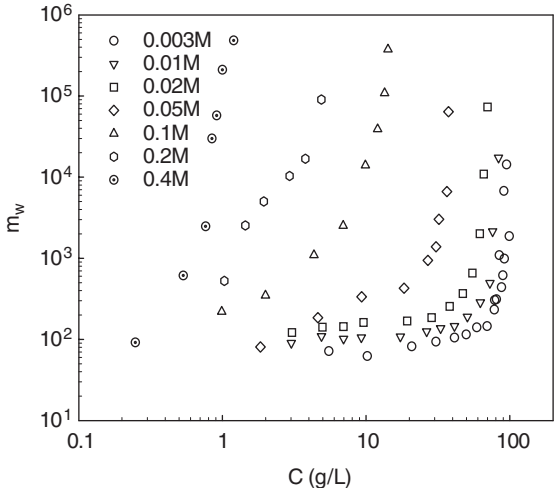

FIGURE 93.15 Concentration dependence of the weight average aggregation number (m_w) of β-lg aggregates formed at pH7 after heating 24 h. at 80°C at different ionic strengths indicated in the Figure.

However, at higher ionic strengths we observe a precipitation of protein flocs between C_g and about 10 g/L. We interpret this precipitation as the formation of a gel that is not sufficiently strong to resist gravity. Figure 93.16 shows the dependence of C_g on the ionic strength. C_g increases strongly with decreasing ionic strength, but the relative variation weakens below 0.02 M. We speculate that the latter effect is caused by the contribution of counterions that becomes important at very low ionic strength where C_g is large. C_g also depends on the type of added salt since at 0.1 M CH_3COONH_4 we observed $C_g = 7$ g/L while at 0.1 M NaCl we found $C_g = 15$ g/L. We note that in the presence of even a small amount of $CaCl_2$ (10^{-3} M) C_g is less that 1 g/L. C_g increases as well if the pH is further from the isoelectric point [28].

At pH2, as at pH7, the growth of m_w is faster when the temperature and the concentration are higher. A remarkable feature is that although the rate of protein depletion is low at low ionic strength, some long fibrilar aggregates are observed even if a vast majority of the proteins is unaggregated, see section IV.

IV. STRUCTURES OF β-lg AGGREGATES AND MECHANISMS OF AGGREGATION

We will discuss now the structure of aggregates formed at pH2 and pH7 and for each pH at low and high ionic strength. These 4 different conditions lead to 4 different situations that are in our opinion typical for a wide range of situations encountered in heat induced aggregation of globular proteins.

At pH7 and 0.1 M salt, as seen in Figure 93.8, the static structure factor S(q) obtained from scattering techniques presents for $q \cdot R_{gz} \gg 1$ a power law behavior $S(q) \propto q^{-df}$ which means that aggregates are self similar with a fractal dimension $d_f = 2$. Independent information about the structure of the aggregates can be obtained from Figure 93.17 where m_w is plotted versus R_{gz}. For fractal objects $m_w = aR_{gz}^{df}$, where the prefactor a depends on the local structure of the aggregates and their size distribution [11, 24]. The value of d_f is consistent with the measured static structure factors and confirms independently $d_f = 2$. The lower limits of R_{gz} and m_w are given by that of the primary aggregates.

At low ionic strength 3×10^{-3} M and low concentrations (see Figure 93.15), the growth leads only to the formation of primary aggregates which have a weight average aggregation number of about 100 and a hydrodynamic radius of about 15 nm. Figure 93.18 shows the structure factors of the aggregates at pH7 at low and high ionic strength by a combination of SLS and Small Angle Neutron Scattering (SANS). SANS measurements were done in D_2O in which the primary aggregates are a bit smaller. The large scale structure of the aggregates formed at 0.1 M is again characterized by a fractal dimension $d_f = 2$. The internal cut-off for the fractal regime corresponds to a weight average aggregation number of about 100, which confirms that the larger aggregates are formed by random association of the primary aggregates. Figure 93.19 shows the combination of Small Angle Light Scattering (SALS), SLS and SANS data for dilute solutions of very large aggregates at pH7 0.1 M. $I_r(q)$ has a power law dependence on q in the range $2 \times 10^{-4} < q < 2 \times 10^{-1}$ nm^{-1} which implies that the aggregates have a fractal structure

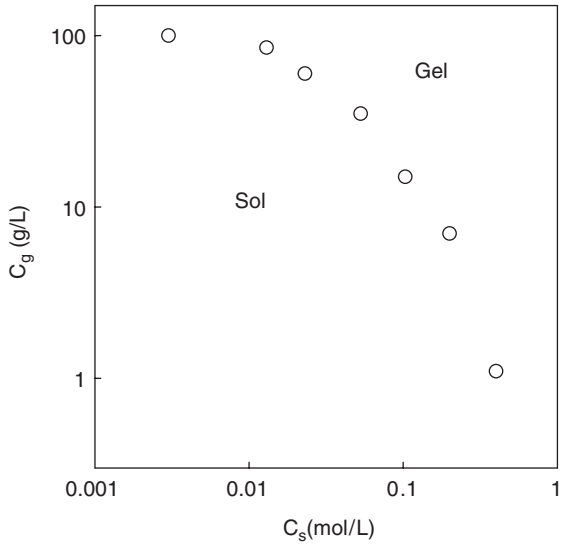

FIGURE 93.16 Ionic strength dependence of the critical gelation concentration for β-lg solutions at pH7 heated 24 h at 80°C.

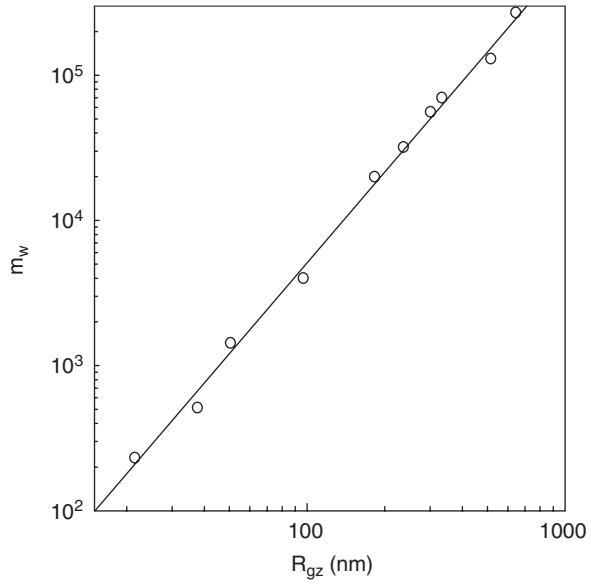

FIGURE 93.17 Weight average aggregation number (m_w) of β-lg aggregates formed after different heating times at 60°C, pH7, 0.1 M salt and C = 18.6 g/L as a function their z-average radius of gyration.

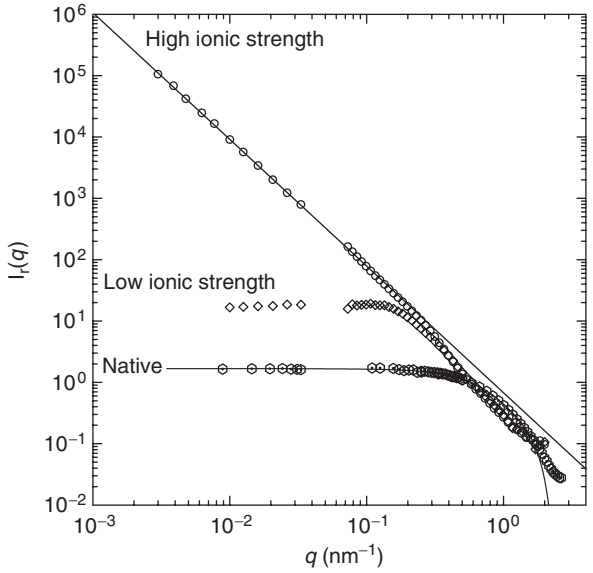

FIGURE 93.18 Scattering wave vector (q) dependence of the relative excess intensity of light (I_r) scattered by dilute solutions of β-lg aggregates formed after heating 24 h at 80°C, pH7 and two ionic strengths 0.1 M (o) and 0.003 M (◇). The straight line through the data at 0.1 M (o) has slope −2. For comparison we also show the results for native protein.

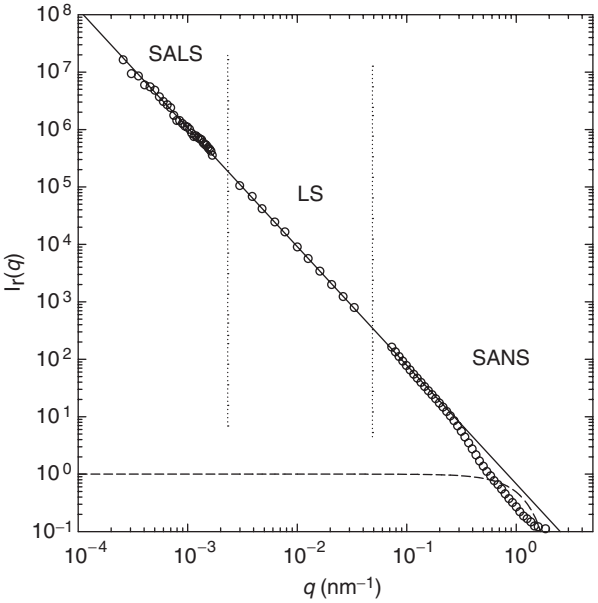

FIGURE 93.19 Scattering wave vector (q) dependence of the relative intensity (I_r) scattered by dilute solutions of native β-lg (dotted line) and very large β-lg aggregates formed pH7, 0.1 M (o). The straight line through the data has slope −2.

over at least three orders of magnitude up to several micrometers. The weight average aggregation number is much bigger than 10^7 protein monomers.

The structure of the aggregates may also be investigated at larger scales using microscopy techniques. Figure 93.20 shows micrographs of β-lg aggregates obtained using Cryo-Transmission Electron Microscopy (Cryo-TEM). At pH 7 small elongated aggregates are formed at low ionic strength (3×10^{-3} M), while at high ionic strength (0.1 M) we observe larger aggregates that appear to be formed by random association of the small aggregates. At low ionic strength the primary aggregates are inhibited from further association, probably due to electrostatic repulsion. However, at high protein concentrations we do observe further association partially caused by the presence of protein counterions that increases the ionic strength. The structure of the aggregates does not depend on the heating temperature nor on the protein concentration although higher concentrations are needed to form large aggregates at lower ionic strength, see Figure 93.16.

The large scale fractal structure is little influenced by the ionic strength, but the local structure varies with the ionic strength [17]. The aggregates become significantly denser for ionic strengths higher than 0.05 M. The origin of this local densification is probably the stronger branching of the aggregates at higher ionic strength. From Cryo-TEM and X-ray scattering experiments it appears that at low ionic strength the primary aggregates associate mainly head to tail, while at high ionic strength side ways association leading to branching becomes more common [29].

The aggregation at pH 2 is different. At pH2 thin linear aggregates are formed which are very rigid at low ionic strength (10^{-2} M) and flexible at high ionic strength (0.2 M), see Figure 93.20. In Figure 93.21 we compare the structure factor of large aggregates formed at pH 2 at different ionic strengths. The amount of residual non-aggregated proteins is negligible for these samples. Over some q-range $I_r \propto q^{-1}$, which is characteristic for a rigid rod-like structure. The q-range over which $I_r \propto q^{-1}$ decreases with increasing ionic strength and is no longer visible at 0.2 M. The fit of the data with the structure factor of large worm-like chains leads to estimate the persistence lengths as 38, 300 and 600 nm at ionic strengths 0.1 M, 0.03 M and 0.013 M, respectively. The value at 0.013 M should be considered as a minimum value, as the deviation from $I_r \propto q^{-1}$ is small. Notice that at high ionic strength the values of d_f happen to be the same for the aggregates formed at pH2 and pH7 even though it is obvious from Figure 93.22 that their local structure is very different. The elementary unit of the fractal structure at pH7 is the primary aggregate while at pH2 it is the persistence length of the strands.

The hydrodynamic radius (R_h) and the degree of flexibility of the aggregates can be probed by dynamic light scattering (DLS). The q-dependence of the apparent diffusion coefficient (D) was measured for highly diluted aggregates formed at pH7 for different ionic strengths. For rigid spherical particles D does not depend on q even for $qR_h > 1$. For rigid fractal aggregates D increases somewhat with increasing q due to the influence of rotational diffusion. Finally, for flexible particles one expects $D \propto q$

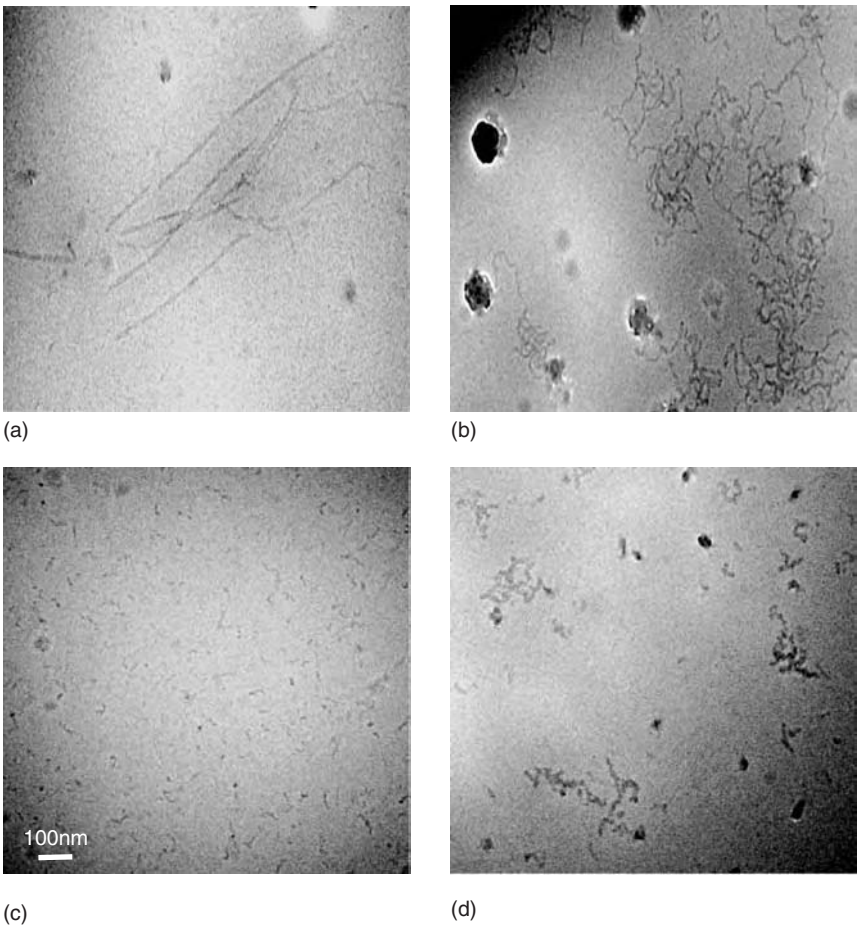

FIGURE 93.20 Cryo-TEM micrographs of β-lg aggregates formed upon heating 24 h at 80°C at pH2, 0.01 M (a); pH2, 0.2 M (b); pH7, 0.003 M (c); pH7, 0.1 M (d).

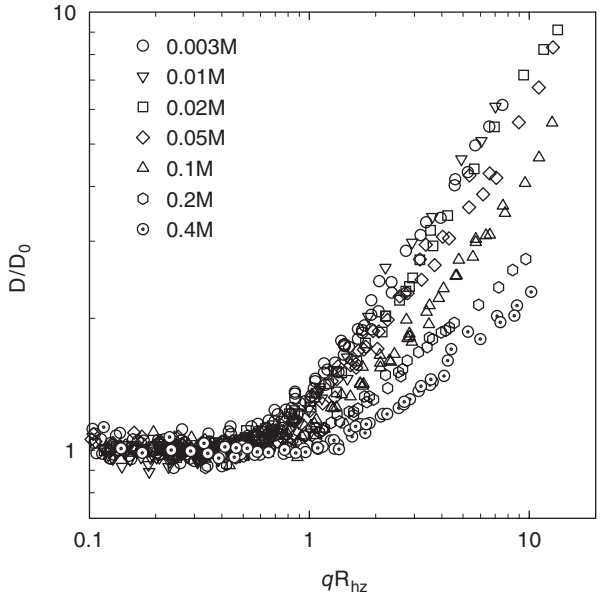

FIGURE 93.23 Dependence of D/D_0 on $q.R_{hz}$ for highly diluted β-lg aggregates formed at ph7 for different ionic strengths. The master curves were constructed by superposition of the data obtained from aggregates that were formed by heating protein solutions for 24 h at 80°C at different protein concentrations.

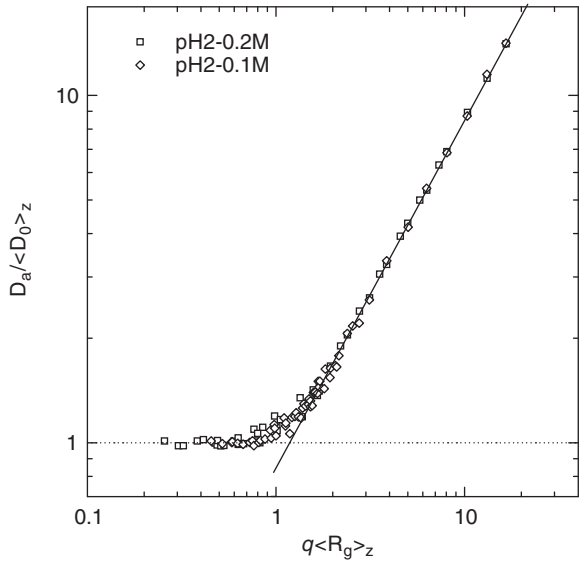

FIGURE 93.24 Dependence of D/D_0 on $q \cdot R_{hz}$ for highly diluted β-lg aggregates formed at pH2 0.1 M and 0.2 M. The master curves were constructed by superposition of the data obtained from aggregates that were formed by heating protein solutions at 80°C during various times.

for $qR_h \gg 1$. If D_0 denotes the extrapolated value of D at $q \to 0$, master curves can be obtained by plotting the values of D/D_0 obtained at different protein concentrations as a function of qR_{hz} [7, 14]. Figure 93.23 shows master curves obtained at different ionic strengths. In all cases D increases with increasing q for $qR_{hz} > 1$, but the increase is more important at lower ionic strength implying that the aggregates formed at lower ionic strength are more flexible. The lower flexibility at higher ionic strength is probably caused by the increasing degree of branching of the aggregates. The full flexibility which leads to $D \propto q$ is only reached at large length scales, i.e. for $qR_{hz} > 10$ [14, 17].

Figure 93.24 shows the dynamic structure factor of diluted aggregates formed after different heating times at 80°C at pH2 at 0.1 M and 0.2 M salt. For $qR_{gz} \gg 1$, the linear q dependence of the apparent diffusion coefficient shows that the aggregates formed at high ionic strength are fully flexible. At lower ionic strength a weaker q-dependence of D was observed because the aggregates are more rigid.

The aggregation of β-lg occurs in first instance by a unidirectional growth. This first step of the aggregation leads to particles of a small and rather well defined size at pH7, but at pH2 it leads to large linear aggregates. One may speculate that the aggregation is initially a process of nucleation and growth. This is especially clear at pH2 and low ionic strength, where immediately very large rod-like aggregates are formed even if only a tiny fraction of the native proteins has been consumed. But also at all other conditions investigated we never observed the formation of oligomers. At present we do not know why the initial aggregation of β-lg stops at a relatively small size at pH7. The formation of well defined primary aggregates was not observed for ovalbumin at similar conditions [30].

The second step of the aggregation, which is clearly distinguished at pH7, involves the entirely different process of random association of the primary aggregates. It is difficult to judge from the micrographs shown in Figure 93.20 to what extent this further association also takes place at pH2. Some further association at pH2 seems implied by the fact that gels are also formed at pH2. With the increase of the ionic strength, the aggregates are more flexible and some branching appears. Figures 93.25 and 93.26 show schematic drawings of the aggregation processes at pH7 and pH2 respectively.

V. STRUCTURE AND RHEOLOGICAL PROPERTIES OF THE GELS

The structure of globular protein gels is traditionally described in terms of finely stranded and particulate gels, but mixed structure are also observed [31]. β-lg at pH2 leads to finely stranded gels, while β-lg at pH7 and high ionic strength leads to particulate gels. Clearly, the fine strands seen in the gels at pH2 are simply more or less associated linear aggregates. On the other hand micrographs of so-called particulate protein gels typically show dense domains with a characteristic size that varies with the ionic strength [32], the pH [23] and the heating conditions [33].

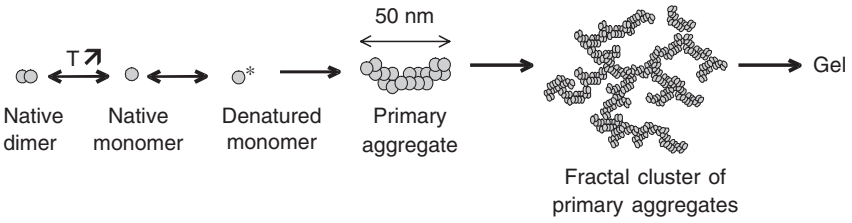

FIGURE 93.25 Schematic representation of the gel formation of heated β-lg at pH7 and 0.1 M salt.

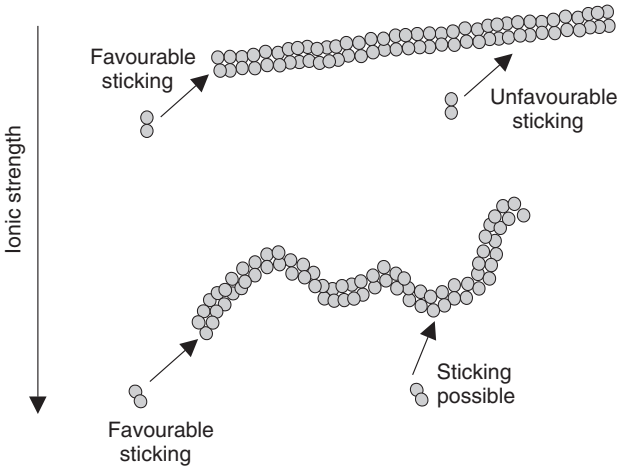

FIGURE 93.26 Schematic representation of the gel formation of heated β-lg at pH2 at low and high ionic strengths.

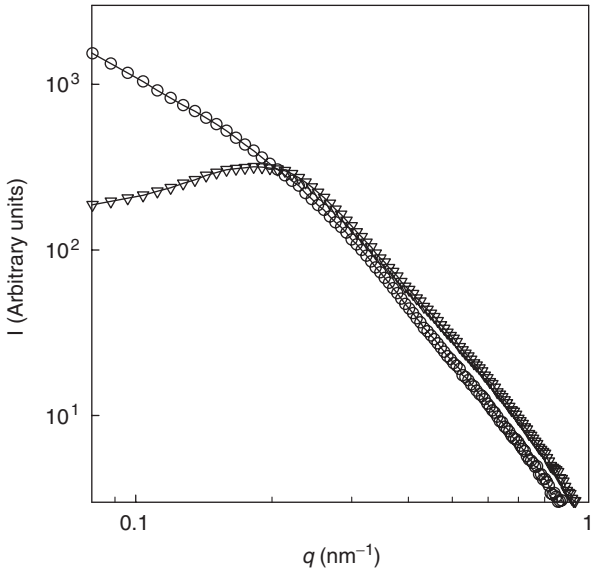

FIGURE 93.27 X-ray scattering wave vector (q) dependence of the intensity scattered by β-lg gels formed after heating 20 h at 80°C β-lg solutions at 60 g/L, pH7 and two ionic strengths 0.1 M (squares) and 0.01 M NaCl (triangles).

The dense domains result from micro phase separation, which is observed very clearly in mixed systems.

The structure factor of heat-set protein gels at small length scales has been studied using neutron and X-ray scattering [29, 34, 35]. They show for transparent gels a maximum caused by electrostatic interactions. Transparent gels are homogeneous at length scales larger than a few tens of nanometers and thus show no q-dependence over the q-range covered by light scattering. When the ionic strength is increased the interaction peak disappears and instead an increase of the scattering intensity is observed at low scattering wave vectors (q), see Figure 93.27. So far structure factors of turbid gels could not be studied at the smaller q-values covered by light scattering because multiple scattering influences the results. However, it has recently been shown that the structure factor of turbid globular protein gels can be determined using cross-correlation dynamic light scattering [16, 36].

This new experimental technique has been used to study the relationship between the rheological properties of globular protein gels and their structure in the specific case of β-lg at pH7 and 0.1 M salt.

A. Gel Structure

As we have already mentioned, the structure of heated globular protein solutions and gels is determined by the interplay between the growth of the aggregates and the electrostatic interaction between the aggregates. This interplay leads to a maximum turbidity and heterogeneity at some protein concentration. Figure 93.28 shows the turbidity of a series of β-lg solutions at pH7 and 0.1 M NaCl that were heated at 80°C during 24 h. The turbidity increases due to the increase of the concentration and the aggregate size up to $C_{max} \approx 30$ g/L, then decreases at higher concentrations because repulsive electrostatic interactions start to dominate. The repulsive electrostatic interactions are screened by added salt. Therefore they increase with decreasing ionic strength. As a consequence the turbidity at a given concentration decreases with decreasing ionic strength, see Figure 93.28. There is no direct correlation between C_{max} and the critical gelation concentration C_g. The weaker is the electrostatic interaction the smaller is C_g compared to C_{max}.

Figure 93.29 shows the q-dependence of I_r of a series of β-lg solutions at pH7 0.1 M salt that were heated at 80°C during 24 h (the fraction of unaggregated protein is about 5% over the whole range of concentrations

investigated). By analogy with the highly diluted system, we define an apparent aggregation number (m_a) which is the value of I_r extrapolated to $q = 0$ and an apparent radius R_a. After dividing $I_r(q)$ by m_a and plotting the result as a function of $q \cdot R_a$, we obtain the structure factor of the samples, see Figure 93.30. The solid line through the data represents the structure factor of the diluted aggregates (replacing R_{gz} by R_a). These two structure factors

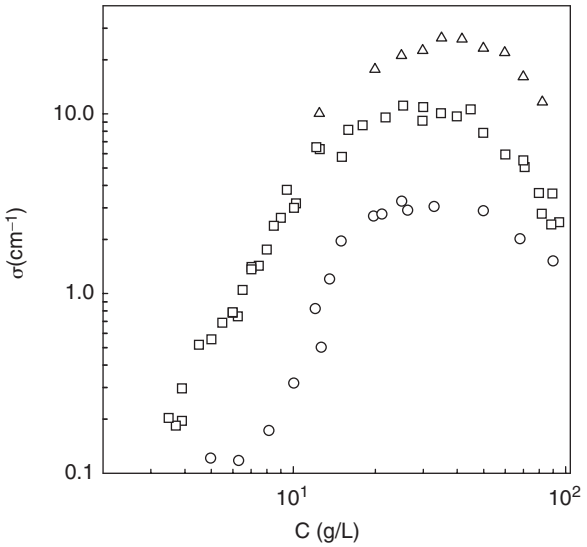

FIGURE 93.28 Concentration dependence of the measured turbidity of β-lg solutions at pH7 after heating 24 h at 80°C for three ionic strengths 0.1 M (circles), 0.15 M (squares) and 0.2 M (triangles).

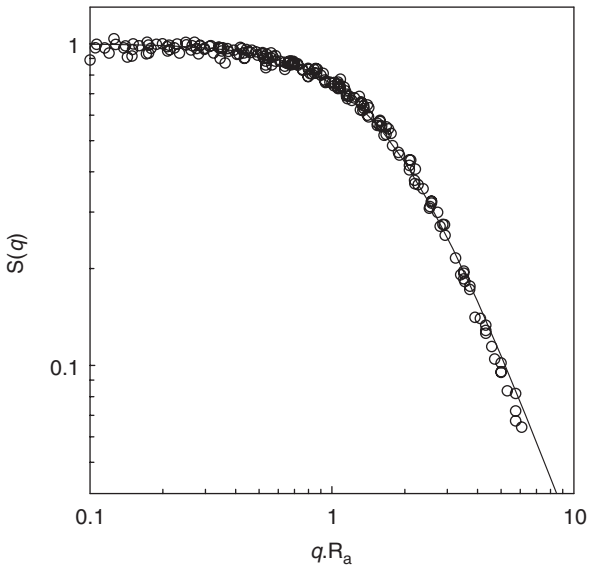

FIGURE 93.30 Structure factor of β-lg solutions at different concentrations after heating 24 h at 80°C (pH7 and 0.1 M NaCl). The solid line represents $S(q) = (1 + q^2R_a^2/3)^{-1}$.

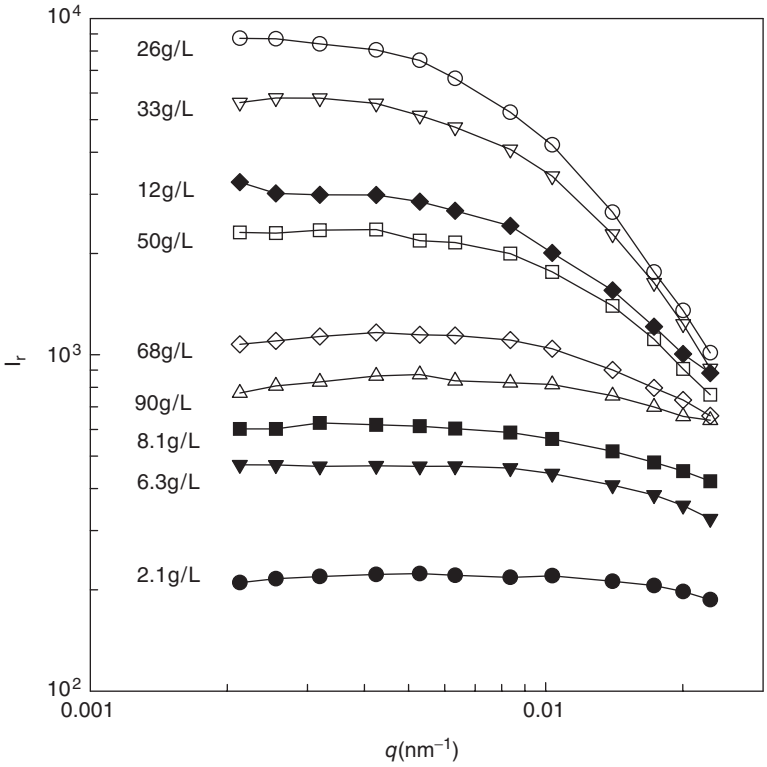

FIGURE 93.29 Wave vector dependence of I_r for β-lg solutions at different concentrations indicated in the Figure after heating 24 h at 80°C (pH7, 0.1 M NaCl). Filled symbols represent data for $C < C_g$ and open symbols represent data for $C > C_g$.

are almost the same. This is consistent with the Figure 93.31 that compares the dependence of m_a on R_a with the dependence of m_w on R_{gz} for the diluted aggregates. The solid line in Figure 93.32 has slope 2 implying that $d_f = 2$.

The concentration dependence of R_a and R_{gz} is shown in Figure 93.32. For very dilute solutions interactions between the aggregates are small and $R_a \approx R_{gz}$. With increasing concentration the aggregates become bigger and R_{gz} diverges at C_g. However, R_a remains finite due to excluded volume interaction that increases with increasing concentration. Above $C \approx 20$ g/L interaction dominates and R_a decreases approximately linearly with C: $R_a \propto C^{-1.1}$ [16]. The system may be described as a collection of randomly close packed blobs with radius R_a and apparent aggregation number m_a if $R_a \propto C^{1/(d_f - 3)}$ and $m_a \propto R_a^{d_f}$. These relations are consistent with the experimental results for $C > 20$ g/L with $d_f = 2.0 \pm 0.1$.

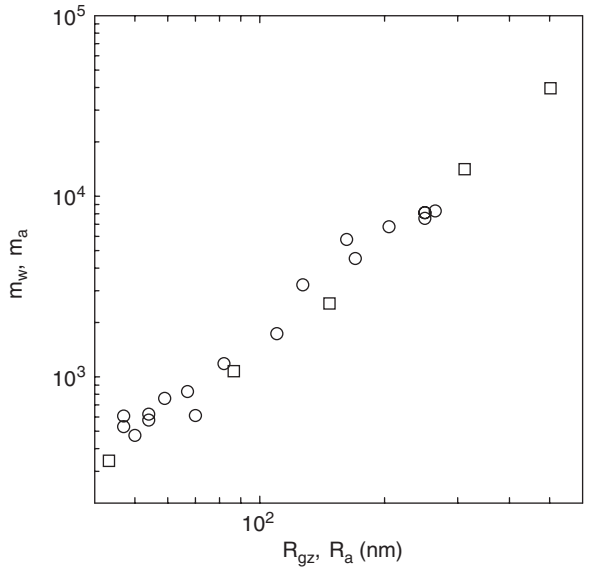

FIGURE 93.31 Comparison of the dependence of m_a on R_a (circles) with that of m_w on R_{gz} (squares). The solid line represents $m_a = 3 \times 10^3 R_a^2$.

B. Shear Modulus

Figure 93.14 shows the evolution of the storage shear modulus (G′) at 0.1 Hz for different concentrations at pH7 and 0.1 M NaCl during heating at 80°C. Above the gel time G′ increases rapidly at first and later continues to increase slowly over the whole duration of the measurement. The gel time increases with decreasing concentration and diverges as $C \to C_g$. As G′ is almost independent of the frequency in the range 0.01–10 Hz and $G' \gg G''$ we consider G′ at 0.1 Hz as the elastic modulus G_0. The concentration dependence of G′ after 24 h heating is shown in Figure 93.33. After 24 h heating at 80°C almost all the native proteins have aggregated, so that the sol fraction is negligible except close to C_g. For $C > 20$ g/L the concentration dependence can be approximated by a power law dependence: $G' \propto C^{4.5}$. At lower concentrations, G′ decreases strongly and the sol-gel transition occurs approximately at $C_g = 15$ g/L. Renard et al. [34] measured the concentration dependence of G′ for β-lg after heating at 80°C for 1 h under the same conditions and observed a stronger concentration dependence ($G' \propto C^{6.1}$) in their tested concentration range 25–60 g/L. Verheul and Roefs [37] found

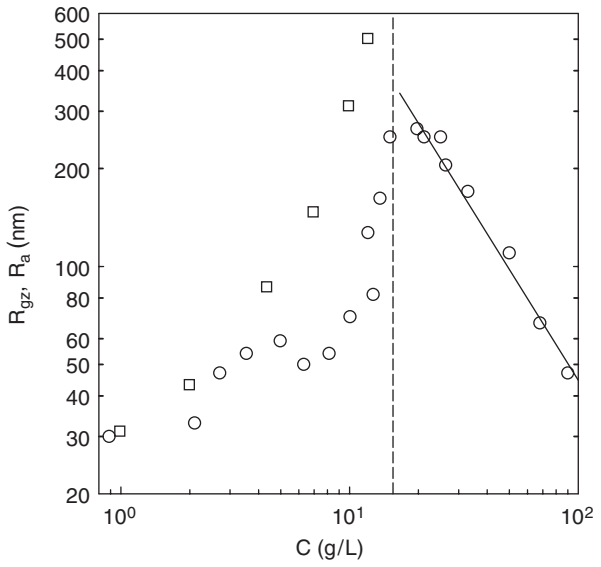

FIGURE 93.32 Comparison of the concentration dependence of R_a (circles) and R_{gz} (squares). The dashed line indicates the gel concentration, C_g, and the solid line has slope −1.1.

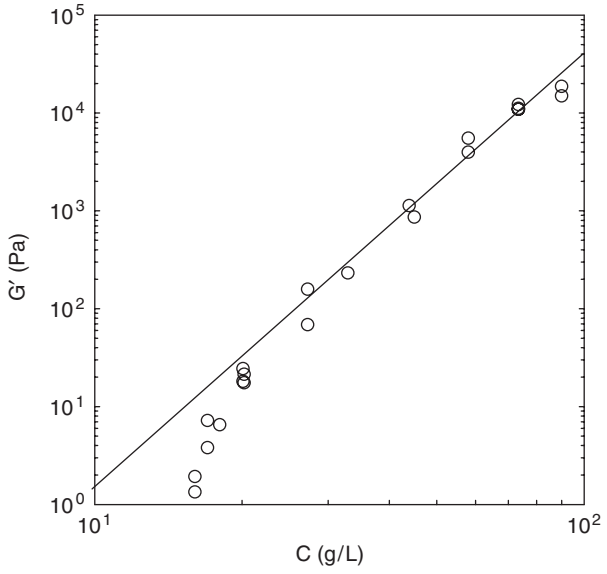

FIGURE 93.33 Concentration dependence of the storage shear modulus at 0.1 Hz of β-lg solutions after heating 24 h at 80°C (pH7, 0.1 M NaCl). The solid line has slope 4.5.

$G' \propto C^{4.5}$ in the range 35–80 g/L for a whey protein isolate with 70% β-lg after heating at 68.5°C for 20 h. Obviously, the concentration dependence of G′ depends on the heating time (and temperature), because G′ evolves differently at different concentrations especially close to C_g. E.g. we also found a stronger concentration dependence of G′ after heating for 1 h at 80°C. Therefore one should be cautious when comparing data obtained with different heat treatments.

Light scattering shows that at C_g the aggregates are already strongly interpenetrated. The sol-gel transition may therefore be described as a bond percolation process of close packed blobs. Whereas light scattering is sensitive to the structure of the whole system, the elastic modulus is determined by the structure of the gel fraction. Percolation of blobs would explain the initial rapid increase of the modulus above t_g for a given concentration (see Figure 93.10) and above C_g after prolonged heating. For $C > 20$ g/L, where C has a power law dependence, all the blobs can be considered as connected and the structural unit of the gel may be identified with R_a.

According to the model of fractal gels [38], $G_0 \propto C^n$ with $n = (3 + d_b)/(3 - d_f)$ where d_b is the fractal dimension of the elastic backbone that is necessarily between unity and d_f. The experimental values $n = 4.5$ and $d_f = 2$ leads to $d_b \approx 1.5$. After cooling to 20°C the gel modulus increases by a factor 2–3, but the concentration dependence is the same as already reported by Renard et al. [34]. After 20°C the elastic modulus is larger. The temperature dependence of the elastic modulus is probably caused by a temperature dependence of the bending constant of the individual bonds.

The frequency dependence of the shear modulus was determined by performing frequency sweeps of G′ and G″ during the gelation process [22]. The values of G′ and G″ at equal times were obtained by interpolation. The values of G′ at all heating times can be superimposed by vertical and horizontal shifts which implies that the system is self-similar at different stages of the gelation process. Master curves obtained in this way are shown in Figure 93.34 for 4 concentrations. These master curves show that the frequency dependence of the shear modulus of fractal globular protein gels is self-similar at different concentrations and heating times. G′ has a close to linear frequency dependence at high frequencies which crosses over to a very weak frequency dependence at low frequencies. The high frequency dependence can be understood in terms of internal relaxation of the fractal blobs that form the gel. The low frequency decay indicates that the relaxation on the larger length scales is not fully elastic.

We conclude that the particular heat-set protein gels that we studied here (pH7, 0.1 M) can be successfully described as ensembles of close packed fractal blobs with an elastic energy dominated by their bending energy [16]. However, this description is only valid if the concentration and heating times are sufficiently high so that the sol fraction

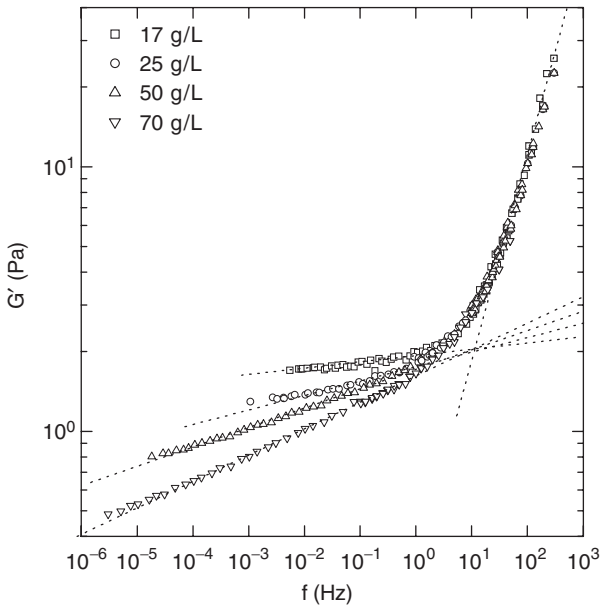

FIGURE 93.34 Master curves of the frequency dependence of G′ obtained from superposition of the data obtained at different heating times for different β-lg concentrations (0.1 M NaCl, pH7).

can be ignored and if the interaction between the protein are short range and repulsive. Long range electrostatic interaction decreases R_a as was observed at lower ionic strengths and can even lead to a peak in the static structure factor. In addition, if electrostatic interactions are important generally linear aggregates are formed that are only weakly branched. On the other hand close to the isoelectric point or at very high ionic strength attractive interactions may lead to the formation of heterogeneous gels containing dense micro-domains. Therefore the fractal gel model is valid for heat-set protein gels only over a limited range of concentrations, pH and ionic strength.

VI. AGGREGATION INDUCED PHASE SEPARATION

As we have already mentioned, aggregation can induce a phase separation if the ionic strength is high enough. Another way to induce phase separation is to add a polysaccharide. We have investigated the aggregation and gelation of β-lg at pH7 in the presence of κ-car [18–21]. At the conditions used in our investigation the two biopolymers are both negatively charged and are compatible. Figure 93.35 compares micrographs of gels with and without κ-car. Clearly the presence of κ-car leads to much more heterogeneous gels containing domains rich in β-lg with the polysaccharide situated between these domains. Under certain conditions of high κ-car concentrations and slow aggregation, we observe a macroscopic phase

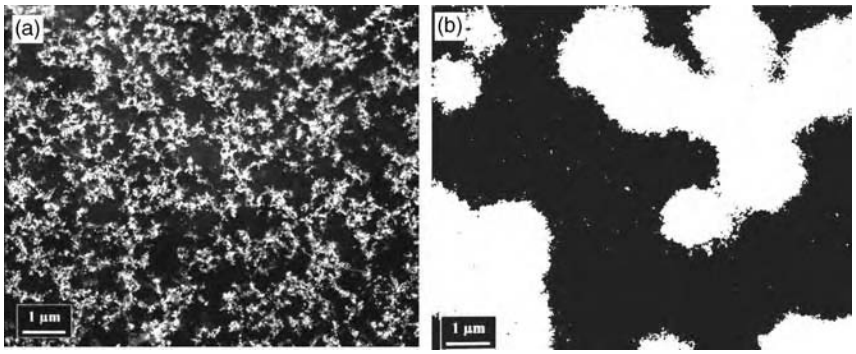

FIGURE 93.35 TEM micrographs of β-lg gels formed after 2 hours at 78°C pH7, 0.1 M NaCl, with 60 g/L β-lg (a) and 60 g/L β-lg + 4 g/L κ-Car (b). Protein domains are white.

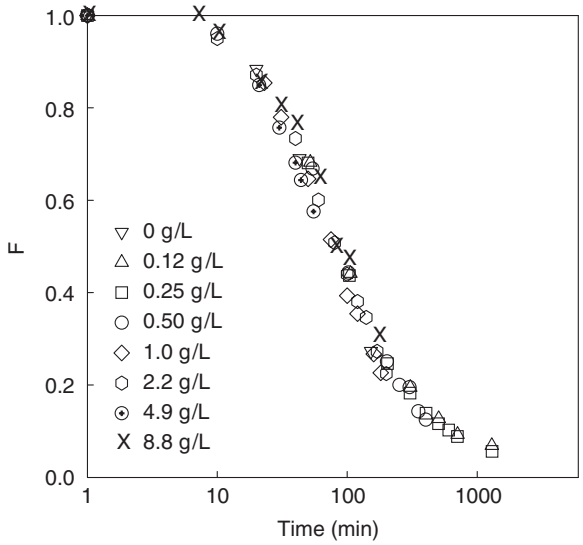

FIGURE 93.36 Fraction of unaggregated β-lg as a function of heating time at 70°C in a solution of 20 g/L β-lg, pH7, 0.1 M NaCl, and various concentrations of κ-car indicated in the figure.

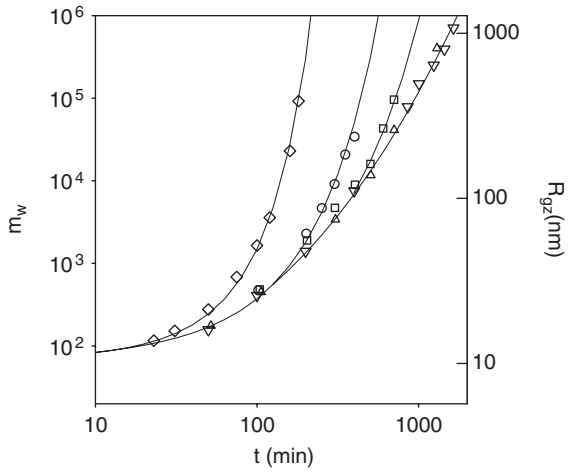

FIGURE 93.37 Time dependence of m_w and R_{gz} for β-lg aggregates formed in a solution of 20 g/L β-lg, pH7, 0.1 M NaCl, and various concentrations of κ-car heated at 70°C. Symbols are as in Figure 93.36.

separation with a gel-like sediment containing most of the protein and a clear supernatant, which contains most of the polysaccharide.

Figure 93.36 shows the fraction of unaggregated proteins as a function of heating time at 70°C for a solution containing 20 g/L β-lg and varying amounts of κ-car between 0 and 8 g/L. Within the experimental error there is no influence of κ-car on the rate of protein consumption, i.e. on the rate of the first aggregation step [21]. It was also shown that the structure of the aggregates is not modified by the presence of κ-car [21].

However, κ-car accelerates the second step of the aggregation process, i.e. the growth of the aggregates, as is shown in Figure 93.37. Comparing the growth at different κ-car concentrations, we find that initially the growth is the same as in the absence of κ-car. But once the β-lg aggregates have reached a certain size the growth rate increases and a gel is formed rapidly. The influence of κ-car becomes significant for $C > 0.2$ g/L, which is somewhat smaller than the overlap concentration of κ-car (0.5 g/L). The size of the β-lg aggregates where κ-car influences the growth rate decreases rapidly with increasing κ-car concentration between 0.25 and 1.0 g/L, although the correlation length of κ-car varies little in this range (16–26 nm) [39].

If we use higher κ-car concentrations we observe very rapid formation of large particles together with small aggregates and the residual fraction of native proteins. These systems either develop into a gel or segregate into a turbid bottom phase and a transparent top phase. Whether these systems gel or segregate, depends not only on the concentrations of β-lg and κ-car but also on the temperature [21].

We have investigated the structure of the gels on a larger scale using confocal microscopy. Within the resolution of the confocal microscope, the β-lg gels formed in the presence of no, or a small amount of κ-car, appear homogeneous. However, in the presence of more κ-car

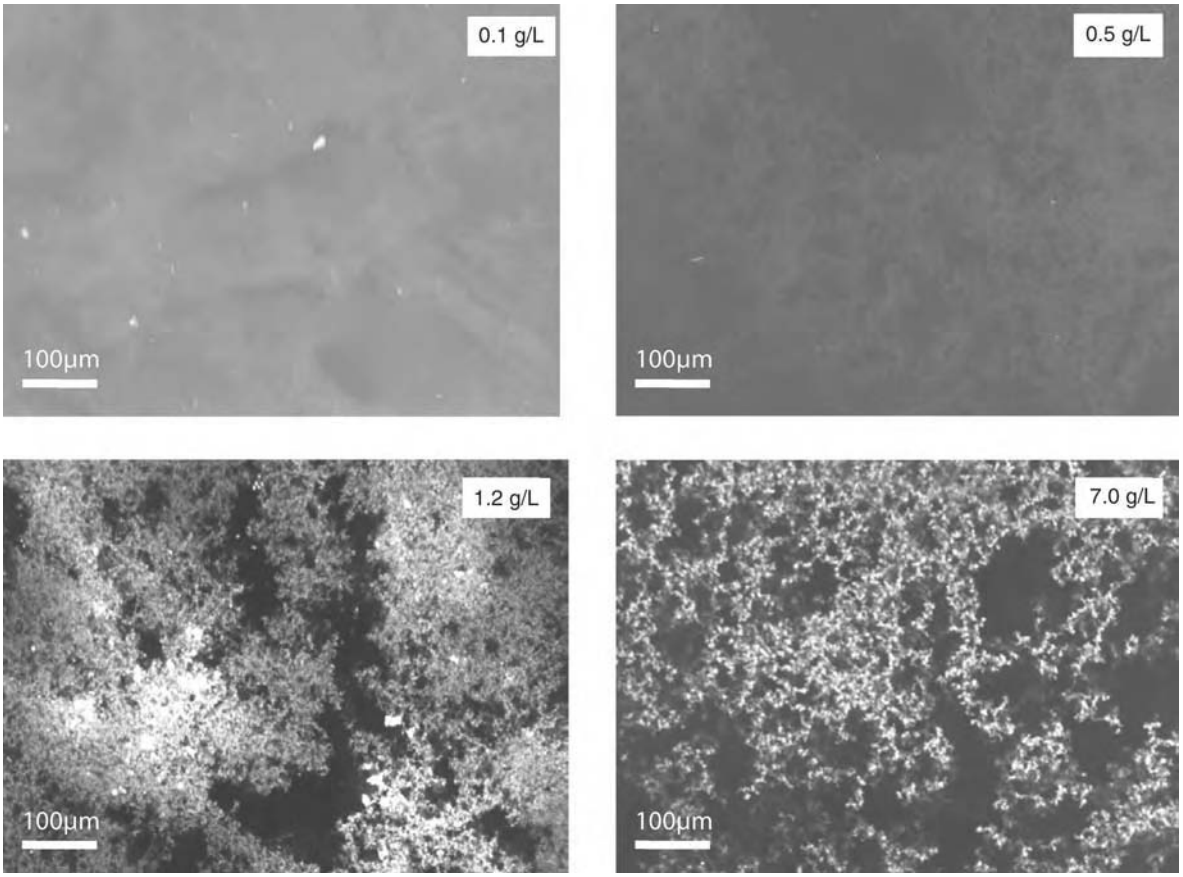

FIGURE 93.38 Micrographs obtained from confocal laser scanning microscopy of solutions of 20 g/l β-lg, pH7, 0.1 M NaCl, and various concentrations of κ-car indicated in the figure after heating 25 h at 70°C. Protein domains are white.

one observes a micro phase separation leading to the formation of β-lg rich domains that appear to cluster [21], see Figure 93.38.

As shown in Figure 93.39, the presence of κ-car has a profound influence on the mechanical properties of the gels [18]. Though the gels form more quickly with increasing κ-car concentration, the coarsening of the gel structure caused by the microphase separation weakens the gel. The gel modulus as a function of κ-car concentration goes through a maximum, and, as mentioned above, in some cases we do not even observe gel formation, but rather macroscopic segregation.

In order to understand better the competition between aggregation and phase separation, we have mixed β-lg aggregates and κ-car at room temperature [20]. After mixing, one observes by optical microscopy the formation of spherical micro-domains rich in protein aggregates, see Figure 93.40. The micro-domains slowly precipitate and form a viscous sediment. The micro-domains contain the larger aggregates while the residual native proteins and smaller aggregates remain in solution together with the polysaccharide. As can be seen in Figure 93.40 the

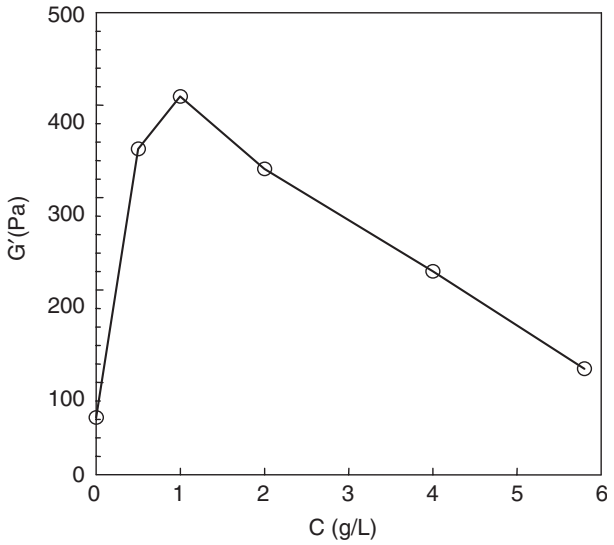

FIGURE 93.39 Dependence of the storage shear modulus G′ at 1 Hz on the κ-car concentrations after heating a solution of 50 g/L β-lg, pH7, 0.1 M for 2 h at 75°C.

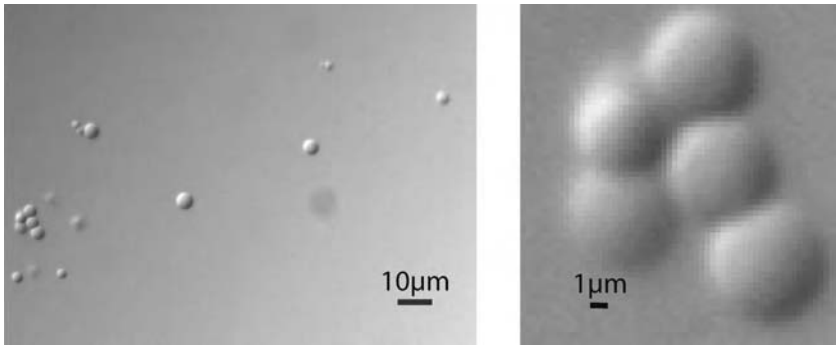

FIGURE 93.40 Micrographs of protein rich micro-domains obtained with optical microscopy for a mixture of 5.7 g/L β-lg aggregates with R_{gz} = 20 nm and 9.2 g/L κ-car.

micro-domains have a tendency to stick together, but the sediment can be easily redispersed in the form of small clusters of micro-domains. If we increase the κ-car concentration, smaller and smaller aggregates will phase separate and become part of the micro-domains.

The formation of the micro-domains is due to decomposition into two liquid phases. If the system is diluted soon after the micro-domains are formed, we recover the initial distribution of aggregates. However, the longer we wait the slower becomes dissolution of the micro-domains after dilution. If we wait for more than a few days the micro-domains can no longer be dissolved by dilution. The reason for the progressive stabilization of the micro-domains is very slow association of the aggregates that are concentrated in the micro-domains. We have observed such slow association at room temperature in more concentrated solutions of β-lg aggregates even without phase separation.

The size of the micro-domains depends somewhat on the concentration of κ-car and β-lg, but is close to that of the dense domains seen in the gels of the heated mixed systems, (compare Figures 93.35 and 93.40). We propose that the dense protein domains in the mixed gel are due to micro phase separation of the growing aggregates. The micro-domains formed in the heated mixtures cannot precipitate because they are trapped in the gel. The structure of the gels formed by the heated mixtures is controlled by the balance between aggregation and phase separation. As long as the aggregates are small enough to be compatible with κ-car, the growth and the structure of the aggregates are not influenced by the presence of the polysaccharide. However, as soon as they become larger they will start to phase separate. The extent of the phase separation and thus the heterogeneity of the gels depend on the rate of phase separation compared to the rate of aggregation. The latter is strongly temperature dependent and can be slowed down by using a lower heating temperature. If the aggregation rate is sufficiently slow the micro-domains can precipitate and we observe a macroscopic phase separation.

The influence of micro-phase separation is particularly clear for the mixed system discussed here. However, as we have said, gel structures very similar to that of the mixed system are observed in pure β-lg gels at high ionic strength or at pH close to the isoelectric point. In these situations the gel structure is also influenced by micro-phase separation.

VII. CONCLUSION

Heat-induced denaturation of β-lactoglobulin leads either to the formation of large linear aggregates or to small primary aggregates. In a second step the primary aggregates may associate further to form self-similar clusters. At low concentrations the growth of the aggregates stagnates, while above a given concentration C_g the aggregates fill up the whole space and form a gel. Under conditions of high ionic strength, pH close to the isoelectric point or added polysaccharide very large aggregates will phase separate, which leads to the presence of protein rich micro domains. In such situations the morphology of the protein gels is determined by the competition between phase separation on the one hand and aggregation and gelation on the other.

The knowledge of these structures is essential for understanding the rheological properties of protein gels as we have seen in the specific case of the system at pH7 and 0.1 M salt where the elasticity of the gels can be explained by the so-called fractal gel model. However, further work is needed in order to elucidate the rheological properties of globular protein gels over the whole range of pH and ionic strength. This work is a necessary step for the development of new routes for texturing globular proteins with new properties.

94 Emulsions and Emulsifiers

Jan Sajbidor
Faculty of Chemical and Food Technology, Slovak University of Technology

CONTENTS

An emulsion is a colloidal dispersion of liquid droplets in another liquid phase. Often this colloidal dispersion is complex because the dispersed phase is partially solidified or because the continuous phase contains crystalline material. All emulsions have in common that they are (thermodynamically) unstable.

Emulsifiers are substances that lower interfacial tension between two non-miscible liquids with different polarity. Emulsifier molecules consist of lipophilic and hydrophilic parts [8]. When an emulsifier is added to a mixture of water and oil, the emulsifier is arranged on the interface, anchoring its hydrophilic part into water and its lipophilic part into oil. On the interface surface of water and air and of oil and air, the hydrophilic part and the lipophilic part are adsorbed and arranged around the interface [11]. The hydrophilicity and lipophilicity are different among emulsifiers, and the balance between the two is called the hydrophilic-lipophilic balance — HLB value [9]. The HLB number is a parameter that has been assigned to each surfactant molecule, and has a range of 0 to 20. A higher number represents a more hydrophilic molecule. Emulsifiers can form two types of emulsions. Emulsifiers with prevalent hydrophilic part form emulsion type oil in water (O/W) and emulsifiers with prevalent hydrophobic component form an emulsion (W/O)[19]. Characteristic behaviours of emulsifiers depending on HLB are summarized in Table 94.1.

Because the molecule of emulsifier has hydrophilic and lipophilic part, its solution does not become a simple aqueous solution but a colloidal one, of which properties vary greatly depending on their concentration. In an extremely-diluted solution, there is no special change, but the emulsifier gathers on the interface and the surface tension is reduced as an increase of its concentration. As further increase of the concentration, a uniform monomolecular layer, is made on the surface and the surface tension drops to the minimum. A further increase of the concentration causes micelle formation. Micelles formation occurs when the excess molecules, in which the lipophilic groups are positioned face to face gather and there is no change in the surface tension. The concentration to start micelle formation is called critical micelle concentration (CMC) and the properties of the solution change greatly with a change of this concentration [20]. Similar changes are developed on the interface of oil and water, when the interfacial tension reaches the CMC point. When the concentration exceeds CMC, spherical micelles appear at first and disperse into water [6].

Emulsions are thermodynamic unstable systems, and their tendency is to reach equilibrium state by linking the dispersed share. This effect is called coalescence [17]. Substances that increase emulsion stability are stabilizers or subsidiary emulsifier agents. Among the principle food

TABLE 94.1
Characteristic Behaviour of Emulsifiers Depending on HLB

Characteristic Behaviours Related to Water	HLB	Ratio Hydrophilic Part	Ratio Lipophilic Part	Functions

stabilisers belong alginates, cellulose derivate, gelatine, agar, pectin, starch and other jelly-forming substances.

It is obvious that temperature is an important factor in relation to the emulsion-forming characteristics of a surface-active agent. An emulsifier that tends to be preferentially soluble in water at relatively low temperatures may become preferentially soluble in oil at higher temperatures at which hydrophobic interactions become stronger. Determination of the temperature at which this inversion occurs provides a useful basis for emulsifier selection. A strong positive correlation has been observed between the phase-inversion temperature (PIT) of emulsifiers and emulsion stability [5].

I. FOOD EMULSIFIERS

Food emulsifiers can be divided into two main groups that include natural and synthetic ones. The first group represents a not very large number of substances present in natural plant or animal sources where it is possible to separate them. Synthetic emulsifiers use natural substances (fats, sucrose) or their components (glycerol, fatty acids) treated with chemicals. To set up synthetic emulsifiers we can use the substances that are not present in natural sources (1,2-propylenglycol, polyglycerol, succinic acid). At present, food industry makes intense use of about one-tenth of available synthetic emulsifiers, with an emphasis on emulsifiers based on monoacylglycerols and their derivatives.

II. MONOACYLGLYCEROL EMULSIFIERS

Fats and oils are an excellent source for many amphiphilic molecules since they are inexpensive, easy to extract and handle [16]. Chemical reactions and/or enzymatic processes are often carried out on certain fats and/or oils, to obtain molecules with hydrophobic and hydrophylic groups attached to each other. One of the most common emulsifiers for water-in-oil emulsions is monoacylglycerol of fatty acids. Hydrogenated oils or natural fats give mixtures of mono and diesters of fatty acids when they are transesterified with glycerol. Mechanism of transesterification is illustrated in Fig. 94.1.

The reaction by itself can be realized most often at temperatures 200–240°C in the presence of 0.1% alkaline catalyst (CaO, KOH and others) under intensive stirring. Transesterification is finished at 230°C in one hour. The reaction mixture contains mainly mono a diacylglycerols. Acyl in monoacylglycerol can occupy border (alpha) or central glycerol position (beta form). This conventional process, even with widespread use, presents two main disadvantages. One is the difficulty in obtaining pure compounds and secondly the use of high temperatures which leads to flavour and colour impurities. When the molecule of interest is

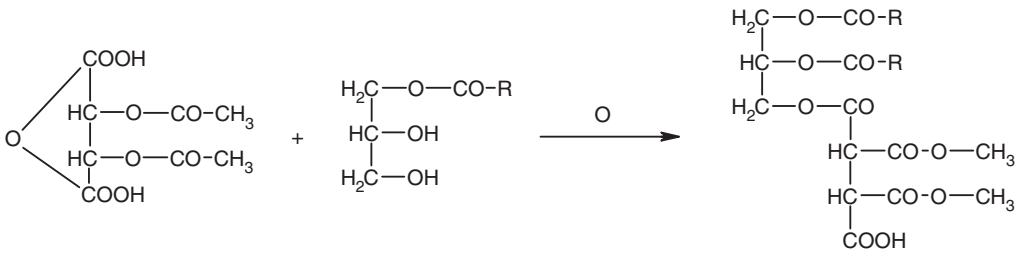

FIGURE 94.2 Reaction of monoacylglycerol ester with diacetyltartaric anhydride.

monoavylglycerol and when high purity is needed, a very interesting alternative route is the use of lipase-catalyzed esterification, taking advantage of the high specificity of the catalyst and of the mild conditions used [4].

From the mixture of acylglycerols a relatively pure >92% alpha monoacylglycerol ester can be prepared. Distillation takes place in a evaporator at 200–210°C and pressure 0.8–4 Pa. Melting point of these distillates moves about 65°C and therefore they are very hard. Because of good handling and application, they are pulverized by spraying molten material in a cold air stream into crystallization vats.

The phase behaviour of monoacylglycerol-water systems is critical for optimum functionality of monoacylglycerols in aqueous systems. With pure monoacylglycerols, the lamellar-type liquid crystal dominates for esters of the 12:0 and 16:0 fatty acids, hexagonal II or cubic type liquid crystals are usually produced from fatty acid esters with longer chains. When the water content is low, unsaturated monoacylglycerols yield lamellar-type liquid crystals at room temperature. By increasing the water content to approximately 20%, a viscous isotropic phase forms that transforms into a hexagonal II phase at temperatures above 70°C. If the water content is increased above 40% the viscous isotropic phase will separate as gelatinous lumps, making uniform distribution very difficult [7].

Distilled monoacylglycerols are widely used, especially in the baking industry because they improve the quality of pastries.

III. DERIVATIVES OF MONOACYLGLYCEROLS

The hydrophilic nature of a monoester can be increased by increasing the number of free hydroxyl groups in the alcoholic moeity of the molecule. Polyglycerol esters with a wide range of HLB values are thus produced by esterification of fatty acids with polyglycerols. Polyglycerol chains containing up to 30 glycerol units can be prepared by polymerisation of glycerol. On the other hand the hydrophobic character of monoacylglycerols can be enhanced by the addition of various organic acid radicals yielding esters of monoacylglycerols with hydroxycarboxylic acids.

IV. ESTERS OF MONOACYLGLYCEROLS WITH DIACETYLTARTARIC ACID (DATEM)

The diacetyltartaric and fatty acid esters of glycerol consist of glycerol esters of mono- and diacetyltartaric acid and fatty acids of food fats. It can be manufactured either by the interaction of diacetyl-tartaric anhydride and monoacylglycerols of fatty acids in the presence of acetic acid, or by the interaction of acetic anhydride and monoacylglycerol of fatty acids in the presence of tartaric acid [15] (Fig. 94.2). Because of inter- and intramolecular exchange of acyl groups, the two methods of production result in essentially the same components. The distribution depends on the relative proportions of the basic raw materials, on temperature and on reaction time. Diacetyltartaric and fatty acid esters of glycerol may contain small amounts of free glycerol, free fatty acids and free tartaric and acetic acids. They may be further evaluated according to the acid value, total tartaric acid content, free acetic acid content, saponification value, iodine value, free fatty acid content and the solidification point of the free fatty acids.

Esters of monoacylglycerols and diacetyltartaric acid form stable O/W emulsion. They interact with flour proteins and raise its quality [14]. Biochemical studies suggest that diacetyltartaric and fatty acid esters of glycerol are hydrolysed in the gastrointestinal tract to yield monoglycerols and acetylated tartaric acid. As monoglycerols are natural dietary constituents, they would be subjected to natural digestion and absorption processes. Diacetyltartaric acid is not a natural constituent of the diet, and there is evidence that it may be further hydrolysed to yield acetic and tartaric acids. The studies reviewed previously indicated little toxicity after administration of a single oral dose of diacetyltartaric and fatty acid esters of glycerol [21].

V. ESTERS OF MONOACYLGLYCEROLS WITH SUCCINIC ACID

They are produced in reaction of distilled monoacylglycerols with succinic acid anhydride in molar proportion 1:1. The product is mixture of partial and total ester.

The diacetyl tartaric acid esters, as well as the succinic acid esters, form lamellar liquid crystals that have

limited swelling capacity in water. However, as is true of distilled monoacylglycerols, their capacity to imbibe water can be increased drastically by the addition of NaOH. Malic acid esters form cubic mesomorphic phases with water contents of up to 20% and hexagonal II phases at higher temperatures and water concentrations. Succinic acid esters do not form mesomorphic phases with water, but they do exhibit mesomorphism [18].

These esters are used in baking industry as an emulsifier to improve rheological properties of dough, enlarging its volume, giving light and uniform porosity and elongating its freshness.

VI. ESTERS OF MONOACYLGLYCEROLS WITH CITRIC ACID

The esters may be produced by the esterification of glycerol with citric acid and edible fatty acids or by reaction of a mixture of monoglycerols of edible fatty acids with citric acid.

Reaction is carried out at 105–150°C during 1.5 hour. The product (Fig. 94.3) is a white to ivory-coloured, oily to waxy material of a consistency determined by the fatty acids. Esters are typically dispersible in hot water, insoluble in cold water and soluble in edible oils and fats.

This product is widely used within the food industry, e.g. as an emulsifier, stabiliser, anti-spattering agent, flour improver, protein-binding agent and as a synergist for antioxidants [2].

VII. ESTERS OF MONOACYLGLYCEROLS WITH LACTIC ACID

These esters, also called lactoglycerols are prepared by esterification of monoacylglycerols with lactic acid in molar proportion about 1:1 at temperatures above 100°C and by lowered press (Fig. 94.4). A less used way of production consists in straight esterification of about equal volumes of higher fatty acid, lactic acid and glycerol.

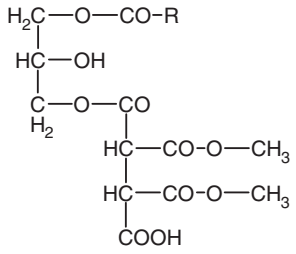

FIGURE 94.3 Ester of monoacylglycerol with citric acid.

The product is a light yellow to amber-coloured, oily to waxy material with a consistency determined by the fatty acids and the proportion of lactic acid. Lactoglycerols are dispersible in hot water, indispersible in cold water and soluble in edible oils and fats. Lactoglycerols are good emulsifiers for emulsion W/O and they crystallize in *alpha* form and moreover in this form they stabilize monoacylglycerols. They are used alone or in combination with 2-stearoyllactates for ice cream and cream-cakes preparation. Lactic acid esters of monoglycerols are used to improve aeration and foam stability as well as texture and volume. Applications include topping powders, non-dairy creams, fine bakery wares, shortening or chocolate compounds.

VIII. ESTERS OF MONOACYLGLYCEROLS WITH ACETIC ACID

They are prepared by esterification of distilled monoacylglycerols with acetic acid anhydride with cooling at 110 to 140°C for about 1 hour. After the reaction has finished, the mixture is thoroughly rinsed with water to remove free acetic acid. The product is a colourless to ivory, oily to waxy material with a consistency determined by the fatty acids and the proportion of acetic acid. Esters of monoacylglycerols with acetic acid are typically insoluble in cold and hot water and dispersible to soluble in edible oils and fats. These compounds have excellent aerating and foam stabilising properties. They are also used as lubricants and release agents.

Acetic esters prepared from total hydrogenated fat give products transparency and are characterized by elasticity and flexibility. These products can be used as an edible coat for some food [1] or in topping powders, chewing gum base or cakes. Emulsifier ability of acetoglycerols is insignificant. Acetic acid esters of monoglycerols of fatty acids have been evaluated by the Joint FAO/WHO Expert Committee.

IX. PROPYLENGLYCOL ESTERS

The product is produced either by the direct esterification of 1,2 propylene glycol with fatty acids or by transesterification

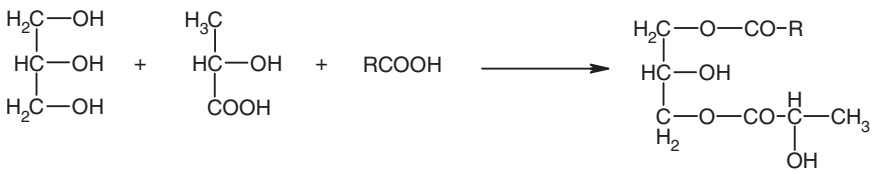

FIGURE 94.4 Synthesis of lactoglycerols.

of 1,2 propylene glycol with fats and oils. The process may be followed by molecular distillation or other separation techniques to separate the monoesters. Propylenglycol ester is white to yellowish-white. The consistency is determined by the fatty acids. The product is dispersible in hot water, indispersible in cold water and soluble in edible oils and fats. Ester imparts excellent aerating and foam stabilising properties. Propane-1,2-diol esters of fatty acids are permitted in fine bakery wares, fat emulsions for baking purposes, milk and cream analogues, beverage whiteners, edible ices, sugar confectionery, desserts, whipped dessert toppings other than cream, dietetic foods intended for special medical purposes or dietetic formulae for weight control [10].

X. POLYGLYCEROL ESTERS

This type of emulsifiers is produced by condensation of glycerol and by partial esterification of polyglycerol with higher fatty acids. Glycerol condensation gives rise to a mixture of linear and cyclic polyglycerols with various molecular weights and their composition depends on condensation temperature and duration. In the group of polyglycerol emulsifiers belong partial glycerol esters (n = 3−10). Higher polyglycerol monoesters are water-soluble or dispersible substances [12] (Fig. 94.5).

Polyglycerol esters are widely used in foods as aerating agents, crystal modifiers, starch-complexing agents, dough conditioners, humectants, defoaming agents and anti-spattering agents. These esters are permitted in fine bakery wares, emulsified liqueurs, egg products, beverage whiteners, chewing gum, milk and cream analogues or dietary food supplements. Polyglycerol esters are often used in mixture with sorbitan esters or their polyoxyethylen-derivates to improve the quality of bakery products.

XI. SORBITAN ESTERS

Sorbitan fatty acids esters (Fig. 94.6) are usually mixed esters of fatty acids with sorbitol anhydride or sorbitan. Sorbitol is dehydrated first to form hexitans and hexides, which are then esterified with fatty acids. The resulting products are known commercially as "Spans."

These agents tend to promote W/O emulsions. Compounds that are more hydrophilic can be produced by reacting sorbitan esters with ethylene oxide. Polyoxyethylene chains add to the hydroxyl groups through ether linkages. The resulting polyoxyethylene sorbitan fatty acid esters are commercially known as "Tweens." In general, these compounds form hexagonal I liquid crystals in water and they can solubilise small quantities of triacylglycerols. With larger amounts of triacylglycerols, transformation to a lamellar-type liquid crystal takes place. The ability of an emulsifier to solubilise nonpolar lipids is important to the formation of phase equilibrium at the emulsion interface [13].

Within the EU sorbitan monopalmitate is permitted in fine bakery wares, toppings and coatings for fine bakery wares, milk and cream analogues, or liquid tea concentrates and liquid fruit and herbal infusion concentrates or edible ices.

XII. SACCHAROSE ESTERS

The products may be prepared from sucrose and the methyl and ethyl esters of food fatty acids or by extraction from sucroglycerols [3]. Depending on the food legislation applicable the following organic solvents are used in their production: dimethylsulphoxide, dimethylformamide, ethyl acetate, propane-2-ol, 2-methyl-1-propanol, propylene glycol, methyl ethyl ketone or isobutanol.

The structural formula of saccharose ester is shown in Fig. 94.7.

Products based on saturated fatty acids are white to slightly greyish powders. Derivatives based on unsaturated fatty acids are yellowish, pasty to waxy substances. The products are sparingly soluble in water and soluble in ethanol. They are insoluble in vegetable oils. The more fatty acids are linked to saccharose, the higher the fat solubility and the lower the swelling ability in water. Sucrose esters of fatty acids are used, for instance, as aerating and starch-complexing agents. They are also used to improve fat dispersion and stability.

95 Phytates

Shridhar K. Sathe and Mahesh Venkatachalam
Department of Nutrition, Food and Exercise Sciences, Florida State University

CONTENTS

I. INTRODUCTION

Phytate discovery is believed to have its beginnings in 1855–1856 when Hartwig first isolated small particles, nonstarch grains, from several plant seeds. He suggested that these small particles to be a source of reserve nutrients for seed germination and plant growth (1). Subsequent studies [1872–1896] on the chemical composition of the particles by Pfeffer, Palladin, Schulze, and Winterstein established the "inosite-phosphoric acid" nature of the particles. Extensive studies that ensued over the next two decades resulted in several suggestions for the structure of the molecule. Anderson (2) finally determined the precise structure of phytic acid [Figure 95.1]. The currently accepted name of phytic acid is *myo*-inositol 1, 2, 3, 4, 5, 6 hexakis dihydrogen phosphate or *myo*-inositol hexakisphosphate. Salts of phytic acid are referred to as "phytate(s)." In seeds, K^+, Na^+, Ca^{++}, Zn^{++}, Fe^{+++}, Cu^+ and Mg^+ are the most frequently encountered cations in naturally occurring seed phytates. In this chapter we will use the term phytate to describe both acid and salt forms. A detailed account of the historical background of phytic acid and deduction of its chemical structure has been described earlier (3–5). Although much of the early work centered around naturally occurring seed and grain phytic acid and phytates, presence of phytic acid in avian erythrocytes (6), several vertebrates (7), domestic fowl (8), as well as soil (9, 10) has been reported. For a more detailed account of occurrence of phytates, please refer to Reddy (5).

A continued and explosive growth in phytate literature over the last twenty years alone is an excellent indication of not only the complexity of reactivity of the molecule but also the diversity of chemical/biochemical reactions it may participate. During the period of 1920–1950 much of the scientific efforts were directed in developing methods to analyze the phytate content of various foods and food products and understanding the chemical behavior of the molecule under a variety of environmental conditions of pH, buffers, temperatures, and presence of other chemical compounds, notably proteins, tannins, and minerals. It is through these early studies that it became apparent that phytate has a strong affinity towards certain minerals (such as Zn^{2+}, Cu^{2+}, Mg^{2+}, and Fe^{2+}) that leads to formation of metals chelates (both soluble and insoluble). In certain instances, formation of such mineral chelates may lead to reduced bioavailability. It was therefore not surprising that during this period early studies on the role of phytate in human nutrition also began to appear (11–14). As methodologies in biochemistry, analytical chemistry, and nutrition continued to make significant progress, sophisticated research tools became available to a larger number of scientists around the world and significant advances in

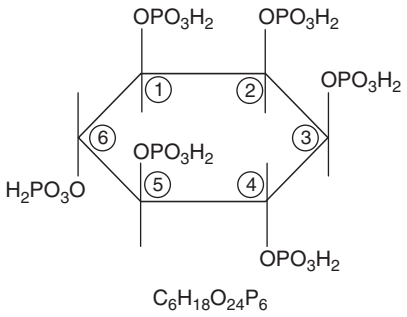

FIGURE 95.1 Phytic acid structure as proposed by Anderson [1914] (2).

molecular understanding of phytate followed over the next several decades (1950–1980). In particular, the structural complexity of the molecule as well as the chemical ramifications of the structural diversity became increasingly evident. During these years, significant progress was also made in unraveling the biochemical synthesis of the molecule in plant seeds (15). From a nutritional point of view, elaborate and extensive studies on role of phytate on nutrient bioavailability also began to appear at regular and increasing frequency during the last few decades (notably 1970–1990). These studies have significantly improved our understanding of phytate in human and animal nutrition, especially with respect to influence of phytate on mineral absorption and utilization. During these decades it also became apparent that phytate interaction with food components is much more complex than originally anticipated.

More recently, phytate is receiving increased attention for its possible importance in human health. With the realization that inositol 3 phosphate (IP3) acting as a second messenger molecule *in vivo* (16) scientific interest in understanding the role of phytate degradation products (IP6-IP1) has increased considerably. In addition, several initial *in vitro* studies also suggest that phytate (and phytate related compounds) may have chemical and biological properties that may be relevant to human health.

Since extensive and very large body of phytate literature is available to readers through various resources (particularly the electronic resources and electronic library databases) as well as some of the recent books on the subject matter, the primary focus of this chapter will not be on providing exhaustive data compilation. Instead, an attempt will be made to summarize important new developments in selected areas and outline a few suggestions for future research.

II. CHEMICAL AND BIOLOGICAL PROPERTIES

A. Chemical Properties

A topic of scientific contention over half a century, modern analytical chemistry techniques (x-ray crystallography and ^{31}P nuclear magnetic resonance in particular) finally solved the problem of determining the chemical structure of phytic acid (Figure 95.1) originally proposed by Anderson in 1914 (2). The accepted name for the molecule is *Myo*-Inositol 1,2,3,4,5,6 hexakis dihydrogen phosphate or *Myo*-Inositol hexakisphosphate. Phytic acid salts are generally referred to as "phytate(s)." Details of recommended name and pertinent references for the IUPAC/IUB nomenclature can be found at the IUPAC website (17). Phytic acid is a small molecule ($C_6H_{18}O_{24}P_6$; MW = 660.08) with six phosphate groups. With the exception of the only one phosphate group on carbon 2 (which is axial to the plane of the inositol ring), the remaining five phosphate groups are in equatorial position with respect to the inositol ring. It is important to mention here that presence of diphosphorylated inositol phosphates is well documented in the literature (18, 19) however presence of triphosphates at a single carbon (or multiple carbons) is not yet demonstrated.

Phytate is synthesized from D-glucose 1-P. The first committed step in this synthetic pathway is the conversion of D-Glucose 1-P to 1L-*myo*-inositol 1-P [also known as Ins(3)P_1 or 1D-*myo*-inositol 3-P] by 1L-*myo*-inositol-1-P-synthase. Ins(3)P_1 synthase (E.C. 5.5.1.4) catalyses the conversion of hexose 6-P to Ins(3)P_1. A magnesium-dependent monophosphatase (E.C. 3.1.3.25) effects the removal of phosphate to release free *myo*-inositol. Free *myo*-inositol (a ubiquitous sugar alcohol), is an important intermediate in a host of biochemical pathways (and therefore its regulation is of interest to many), also serves as the building block for phytic acid synthesis. A detailed account of phytate synthesis can be found in the chapter by Loewus (15).

The phytate molecule has 12 dissociable protons. Of these twelve, six are strongly dissociated with a p*K* value of about 1.8, two are weakly dissociated [p*K* of about 6.3] and the remaining four are very feebly acidic [p*K* value of about 9.7] (20). More recent studies on phytic acid interactions with rare-earth ions [Ce^{3+}, Pr^{3+}, Sm^{3+}, Gd^{3+}, Tb^{3+}, Dy^{3+}] further indicate that eight protons in phytic acid are highly acidic, two weakly acidic, and two very weakly acidic [titrable in the pH range of 1.2–4.9, 5.0–8.15, and 8.3–11.0, respectively] (21). Consequently, the molecule is chemically very reactive. It can participate in reactions that are electrostatic in nature. The degree of reactivity and the affinity towards the molecule reacting with phytate is dependent on several factors that include:

1. The p*K* of the reactive phytate proton(s).
2. The reaction environmental factors such as pH, ionic strength, temperature, viscosity of the medium, presence or absence of ionic polymers, etc.
3. Stability and reactivity of molecules interacting with phytate.
4. Duration of reaction.
5. Solubility of products resulting from interaction of phytate(s) with component(s) of interest.
6. Whether or not phytate is being degraded during the interaction(s). For example, if phytate is being degraded to lower phosphates, each of the lower phosphates in turn may influence the reactivity of the intact phytate molecule by potentially competing with phytate and also through independent binding with the reactive molecule (the one that is interacting with phytate).

In food, minerals (di- and tri-valent metal ions), proteins, and certain carbohydrates are the likely components

that may react with phytate. The strength of the interaction will obviously depend on a host of parameters. When phytate interacts with such food component(s) the resulting complex(s) may be soluble or insoluble. Depending on the type of complex and its solubility properties, bioavailability of the interacting component(s) may be adversely influenced. If the interacting food component is an essential nutrient, such as an essential mineral, influence of phytate on the bioavailability of that nutrient may be of nutritional concern. Mineral phytate interactions are also of interest for a variety of other reasons that include potential use of phytate as:

1. An antioxidant in foods [such as meats] (22).
2. As an inhibitor of plaque formation in tooth paste (23).
3. Intermediate in production of special unleaded fuel (24).
4. Antirust agent on metal surfaces (25).

Because phytate can form complexes with several minerals, notably the divalent minerals such as Fe^{2+}, Ca^{2+}, Cu^{2+}, Mg^{2+}, Mn^{2+}, Sn^{2+}, Co^{2+}, Ni^{2+}, and several others, any chemical, biochemical, or organic reactions that depend on such minerals can therefore be potentially influenced. Depending on the stability and solubility of mineral phytate complexes under a variety of pH, temperature, as well as other environmental factors, several possibilities may be explored. For example, divalent metal ions are involved in catalysis of numerous oxidation and reduction reactions [chemical and biochemical]. Polyphenol oxidases [PPOs] are a group of oxidative enzymes that naturally occur in many fruits and vegetables. PPOs cause enzymatic browning that may be desirable [e.g. in black tea and chocolate manufacture] or undesirable [as in case of cut apples or bananas]. The PPOs partly depend on Cu^{2+} for catalysis. It may be useful to find out whether one can apply acceptable levels of phytate to fruits/vegetables to prevent such undesirable browning. Another example is that of loss of chlorophyll Mg^{2+} during fruits/vegetables processing that results in development of undesirable off-color [dull green pheophorbide formation]. Using phytate to stabilize the chlorophyll Mg^{2+} may be useful in stabilizing green color of several fruits/vegetables. Use of phytate in controlling such reactions remains largely unexplored. Similarly, several non-food uses of phytates also need to be explored to utilize this naturally occurring, abundant compound. It should be mentioned here that the number of studies examining the phytate-mineral complexes are rather limited. Most studies on phytate-mineral complexation are typically restricted to specific experimental conditions such as selected pH, temperature, reactant ratio(s), buffer conditions, and type of resultant salts. Such studies are often limited in scope partly due to number of minerals that can interact with phytate, nature of complexes formed, analytical tools available, environmental influences on the complexation can change significantly depending on the mineral involved in complex formation, and time/resource limitations. It is however important to recognize that targeted, detailed studies are needed to improve our basic understanding of these complex interactions. With the exception of very few studies (26), even less is known about the mineral interactions with lower inositol phosphates [such as inositol penta-, tetra-, tri-, di-, and mono- phosphates]. With the increasing realization and understanding of possible biological role(s) of lower inositol phosphates, notably the triphosphate, it is important to investigate the mineral interactions with lower inositol phosphates as improved understanding of such interactions may help us define the biological role(s) of inositol phosphates more precisely.

B. Biological Properties

The recognition of ubiquitous presence of phytic acid in animal kingdom launched a search for physiological function(s) of phytate in earnest. Of particular interest was the possible involvement of phytate in various cellular regulatory processes with particular reference to health and disease. With the publication of possible role of IP3 in cellular calcium signaling by Berridge and Irvine (16), it became increasingly apparent that inositol phosphates, other than inositol hexakis phosphate, may have important cellular functions *in vivo*. A recent review (18) provides an in-depth overview of role of inositol hexakisphosphate [and some of the lower phosphates] in cellular regulation. Reported functions of phytate [and lower phosphates] are summarized in Table 95.1. Some of the difficulties in interpreting published literature on biological role(s) of phytate [and lower phosphates] include:

1. *In vivo* and *in vitro* studies do not always correlate. For this reason it is important to evaluate the results of *in vitro* investigations with caution.
2. *In vivo* studies from one animal species cannot be directly applied to another species or humans.
3. Purity and chemical structure(s) of inositol phosphate(s) and/or intermediates used in studies.
4. Rigor of controls and experimental variables in a study. For example, were experiments done under conditions relevant to physiological conditions? Was placebo effect accounted for in *in vivo* experiments? Was the placebo relevant and proper? Were the cell line(s) used relevant? What criteria were used to select specific cell line(s) for a particular experiment? Was physiologically appropriate ionic strength employed and was it relevant?
5. Were any attempts made to separate the effect(s) of individual, specific phosphates or were the results representing collective effect?

6. In metal binding experiments, were the concentrations of minerals [mineral salts] used in the experiments physiologically relevant? Were there any attempts to separate the mineral-mineral interactions? How does the presence of specific, relevant protein(s) influence such interactions?

Obviously, not all of the above listed concerns are applicable to all the experiments. However, these and other such concerns, when applicable, need to be addressed in relevant experimental designs.

Despite the inherent difficulties and limitations to accurately define the *in vivo* role of inositol phosphates in cellular regulation, based on the available data, it is apparent that inositol phosphates do have important roles in cellular signaling processes, notably in calcium regulation. Since calcium is a mediator of several important biological processes, it is evident that increased number of investigations designed to understand the role of inositol phosphates in cellular regulation will continue. Indeed the explosive growth of number of papers published in just last ten years supports this notion.

TABLE 95.1
Reported Biological Functions of Phytate (and Lower Phosphates)

Reported Function	Mechanism/Specific Role	Phytates	References
ANIMAL CELLS			
Cellular			
Calcium mobilization	Second messenger in signalling	IP3, IP(s)	27
Receptor regulation	Agonist-induced receptor desensitization	IP5, IP6	28
Vesicle trafficking	Binding to vesicle adaptor proteins AP-2, AP-180, arrestins, synaptotagmin	IP4-IP6	29, 30, 31
Activation of protein kinase C (PKC)	Calcium-dependent enzymes	IP(s)	32
Inhibition of protein phosphatase activities	Serine/threonine protein phosphatases	IP6	33
Nuclear			
DNA repair	Activation of enzymes (DNA dependant protein kinase)	IP3-IP6	34, 35
mRNA export	Regulate conformation of nuclear pore complex, faciliate removal of an export inhibitor	IP6	36, 37
Neural			
Related neuropathological disorders			
Down's syndrome, hypernatremia, stroke	Volume regulation (physiologically important osmolyte)	Inositol	38
Bipolar disorder, neural tube defects, diabetic peripheral neuropathy, ataxia talengiectasia, Alzheimer's disease	—	Inositol	38
Neurotransmitter release	Blocks synaptic transmission by preventing vesicular fusion, vesicle trafficking	IP4-IP6	39, 40
Renal			
Renal lithiasis, kidney stone prevention	Prevent crystallization of cacium salts (oxalate and phosphate)	IP6	41
Immune			
Natural Killer cells	Colon carcinogenesis	IP6	42
Neutrophils	Priming action on stimulated respiratory burst in human neutrophils	IP6	43, 44
Iron/Antioxidant	Chelation of iron, iron transport, prevent formation of free radicals, protection from vitamin E and selenium deficiency, cardiovascular effects, carcinogenesis	IP3-IP6	45, 46, 47
Antidiabetic			
Hypoglycemic effects	Inhibition of starch digestion/absorption, colon carcinogenesis	IP6	48
Hypolipidemic effect	Decrease sucrose induced increases in total hepatic lipids, serum triacylglycerols and phospholipids	IP6	49
Cardiovascular			
Hypercholesterolemic	Alteration of Zinc/Copper ratio	IP6	50
Protection from ischemic and reperfusion injury	Iron chelation, reduce free radical formation and lipid peroxidative damage	IP6	51
Prevent aortic calcification/hypertension	Calcium chelation	IP6	52
Anticancer	Various mechanisms described in this table	IP6, IP(s)	53
PLANT CELLS			
Stomatal pore closing	Mobilization of endomembrane calcium store	IP6	54

III. RESEARCH NEEDS

The ability of inositol hexakis phosphate [and lower salts] to interact with minerals, proteins, fiber, and other positively charged entities are at the heart of their chemical and biological reactivity. The inherent negative charge on the molecule at neutral pH is the driving force behind such interactions. Although sporadic attempts have been made to thermodynamically define and characterize phytate-mineral interactions, there is a clear inadequacy of in-depth understanding of chemical reactivity of inositol phosphates and minerals and other positively charged species. Sound understanding of chemical reactivity of the molecule before embarking on defining the biological implications of reaction(s) is not only desirable but also imperative for several reasons. Perhaps the most compelling reason to precisely define and understand the thermodynamics of such reactions is that such information should enable the researchers to eliminate numerous reactions that may be feasible to occur in an *in vitro* experiment but not feasible in an *in vivo* situation simply based on unfavorable energy of reaction, thus narrowing down the number of experiments to test a hypothesis. In order to derive such data base, ground state(s) of phytate [and lower phosphates] must be defined with respect to free energy associated with such molecules under defined environmental conditions such as the temperature, pH, ionic strength, etc. Since many divalent minerals such as Ca^{2+}, Mg^{2+}, Fe^{2+}, Cu^{2+}, Mn^{2+}, Sn^{2+}, Co^{2+}, Zn^{2+}, and others are important in *in vivo* catalytic interactions, improved and thorough investigations of interactions between these minerals and phytate would be of importance.

Phytate interactions with trivalent minerals such as Al^{3+}, Fe^{3+}, Cr^{3+}, and others are much less understood when compared to the interactions of the divalent metal ions. Since many of the trivalent [and higher valency] minerals are important in metallurgical operations, material developments, and material applications, improved understanding of reactions between trivalent (and higher) minerals and phytate is needed.

Any experiments designed to evaluate physiological function(s) of phytate or its lower salts must be done under conditions relevant to *applicable* physiology. Often many studies report findings of experiments done under conditions not physiologically relevant thus severely limiting the utility of the resulting data.

96 Sorbates

Peter Šimko
Institute of Food Science and Biotechnology, Brno University of Technology

CONTENTS

I. INTRODUCTION

Preservatives are chemical compounds that prevent or inhibit the activity and growth of microorganisms after adding to foods. The main aim is to prolong the shelf life of foods, by protecting them against food deterioration caused by microorganisms. Various kinds of microorganisms bring about food spoilage and these microorganisms are able to vegetate at different conditions of pH, temperature, water activity, relative humidity, presence or absence of special growth factors. One of the most effective chemical preservatives is sorbic acid (SA) and its sodium, potassium, and calcium salts which are collectively known as "sorbates."

II. DEFINITION

SA is an organic, straight-chain, *trans-trans* unsaturated monocarboxylic fatty acid that is metabolized in the same way as other food fatty acids such as corn oil's linoleic and margarine's oleic acid (1). The carboxyl group of SA is highly reactive and can form various salts and esters. The conjugated double bonds are also reactive and can be influential in its antimicrobial activity and the quality and safety of food products (2). Physicochemical properties as well as other relevant data relating to sorbates are shown in Table 96.1.

TABLE 96.1
Physico-Chemical Properties of Sorbates

Properties	Sorbic Acid	Potassium Sorbate	Sodium Sorbate	Calcium Sorbate
Synonyms	Acetic acid (2-butenylidene); Acetic acid crotylidene; Hexadienic acid; Hexadienoic acid; E,E-2,4-Hexadienoic acid; (E,E)-2,4-Hexadienoic acid; Hexa-2,4-dienoic acid; 2,4-Hexadienoic acid; 2,4-Hexadienoic acid, (E,E)-; 2,4-(E,E)-Sorbic acid; *trans-trans*-2,4-Hexadienoic acid; 1,3-pentadiene-l-carboxylic acid; 2-Propenylacrylic acid; 2-Propenyl-acrylic acid; *alpha-trans-gamma-trans-Sorbic* acid; *trans, trans-Sorbic* acid; Sorbistat; Unistat; Tristat;	BB powder; 2,4-Hexadienoic acid potassium salt; 2,4-Hexadienoic acid, potassium salt (9CI); 2,4-Hexadienoic acid, (E,E)-, potassium salt; 2,4-Hexadienoic acid, (E,E′)-, potassium salt; 2,4-Hexadienoic acid, potassium salt; Potassium 2,4-hexadienoate; Potassium (E,E)-sorbate; Sorbic acid potassium salt; Sorbic acid, potassium salt; Sorbistat; Sorbistat-K; Sorbistat-potassium; Unistat K;	2,4-Hexadienoic acid, sodium salt; 2,4-Hexadienoic acid, sodium salt, (E,E); Sodium (E,E)-hexa-2,4-dienoate; Sorbic acid, sodium salt	2,4-Hexadienoic acid calcium salt; Calcium dihexa-2,4-dienoate; (E,E)-Calcium 2,4-hexadienoate; Calcium sorbate; 2,4-Hexadienoic acid, calcium salt, (E,E)- (9CI); Sorbic acid, calcium salt
Summary formula	$C_6H_8O_2$	$C_6H_7O_2K$	$C_6H_7O_2Na$	$C_{12}H_{14}O_4Ca$
Molecular formula	CH_3-CH=CH-CH=CH-COOH	CH_3-CH=CH-CH=CH-COOK	CH_3-CH=CH-CH=CH-COONa	(CH_3-CH=CH-CH=CH-COO)$_2$Ca
State of matter	solid	solid	solid	solid
Colour	Colourless needles or white powder	White crystals, white powder	White fluffy powder	White fine crystalline powder
Molecular weight [g.mol^{-1}]	112.14	150.23	134.12	
Melting point [°C]	134.5	270 (decomposes, emits toxic fumes of K_2O)	(decomposes, emits toxic fumes of Na_2O)	decomposes, emits acrid smoke and irritating fumes at about 400°C
Boiling point [°C]	228 (decomposes to acridic smoke, irritating fumes)			
pK_a	4.75			
Flash point [°F]	260			
Solubility at 25°C (g/L)	1.6 (water) 0.7 (10% saline) 130 (ethanol) 5–10 (edible oil)	582 (water) 65 (alcohol)	320 (water)	
Density		1.363		
LD_{50} in rate, oral [mg.kg^{-1}]	7 360	4 920	7 160	
ADI [mg.kg^{-1}]	0–2.5	0–2.5	0–2.5	0–2.5

From ref. 4, 190–192.

III. HISTORY

SA as naturally occurring compound was isolated for the first time by A. W. van Hoffman, a German chemist in 1859 in London, who analyzed oil to be obtained from unripe rowanberries (1), where it occurs as the lactone, parasorbic acid (190). The compound was named after the Latin name of mountain ash (*Sorbus aucupartia L.*), which is the parent tree of the rowanberries. The structure of SA was elucidated during 1870–1890, and synthesized for the first time by O. Doebner in 1900 (2,3). In 1945, a U.S. patent was awarded to C. M. Gooding, who found out that unsaturated fatty acids with a double bond in the α-position (crotonic acid and its homologues) behaved as fungistatic agents in foods, or on food wrappers, respectively (4). In 1953, sorbates were approved as food preservatives.

IV. SYNTHESIS AND MANUFACTURE

SA was synthesized in 1900 by Doebner by condensation of crotonaldehyde and malonic acid

$$CH_3\text{-}CH{=}CH\text{-}CH{=}O + HOOC\text{-}CH_2\text{-}COOH \longrightarrow CH_3\text{-}CH{=}CH\text{-}CH{=}CH\text{-}COOH + CO_2 + H_2O$$

Commercial synthesis of SA involves the reaction of ketene $CH_2{=}CH{=}O$ with crotonaldehyde $CH_3\text{-}CH{=}CH\text{-}CH{=}O$. Ketene is produced from acetic acid or acetone by thermal decomposition in a tubular furnace. Crotonaldehyde is formed as a secondary product from acetaldehyde condensation. Methods of industrial production use a catalyst reaction to produce a polyester of molecular weight 1,000–5,000 of the form by reacting the ketene and crotonaldehyde in an excess of aliphatic, alicyclic, aromatic hydrocarbons, or their derivatives as solvents. The polyester is decomposed in either an acid media or by thermal decomposition. The more stable *trans, trans* structure can be obtained in preference to *cis* isomers by solubility or with the use of catalysts. Further purification using recrystallization and carbon treatment is carried out to meet food-grade specifications. The SA is sold as dried powder. The water-soluble potassium, sodium or calcium salts are produced by neutralizing the SA with potassium, sodium or calcium hydroxide, respectively, and by drying the pelletized product or by directly spray granulating the potassium/sodium/calcium sorbate solution. Various modifications and improvements to this process are being practiced at the industrial scale by Hoechst in Germany, Daicel, Ueno, Chisso, and Nippon Gohsei in Japan, Cheminova in Denmark, and Tennessee Eastman in the USA (1).

V. MODES OF ACTION

Sorbates can inhibit yeasts, molds, Gram-positive and Gram-negative and catalase-negative, aerobic and anaerobic, and mesophilic and psychrotropic microorganisms as well as spoilage and pathogenic bacteria. However, come bacterial strains are not inhibited, some may even metabolize the sorbates. Usually, sorbates in foods under the level of 0.3% inhibit microbial activity, at higher level may cause the death. Sorbate inhibits cell growth and multiplication as well as germination and out growth of spore-forming bacteria (2). Several studies have indicated that sorbates inhibit bacterial spore germination (5–9). Inhibition has involved various species of bacteria in laboratory culture media and in foods and has been influenced by species, strains, pH, and sorbate concentration (2). Sorbates can act as a competitive and reversible inhibitor of amino acid-induced germination (6). But, it was also reported that sorbates inhibited spores triggered to germinate or after germinant binding (9). As also postulated, sorbates probably inhibit a postgerminant binding step in the process of germination, and it was thus concluded that it inhibits spore commitment to germination, not triggering. Inhibition of the not well-defined connecting reactions of spore germination may be taking place through inhibition of sporeolytic enzymes involved in germination or through the interaction of sorbates with spore membranes and increase in their fluidity (8,9). Several mechanisms of inhibition of metabolic function by sorbate have been proposed, and it may be possible that several of them may be functional under various conditions, including types and species of microorganisms, type of substrate, environmental conditions, and type of food processing. Under certain conditions sorbates have changed the morphology and appearance of microbial cells (10,11). Such changes have been observed in yeast cells as dense phosphoprotein granules, irregular nuclei, increased numbers and variable sizes of mitochondria, and vacuoles. Cells of *C. botulinum* were long, with bulbous formation and defective division (7,12,13). *C. sporogenes* cells treated by sorbates were usually filamentous and nonseptate, but with distorted shapes characterized by numerous bends and bulges. Septation, when present, resulted in minicells, and the inner cell wall appeared to be thickened; the outer cell wall was absent in many areas (11). Treatment of *C. putrefaciens* with sorbate at pH 7.0 increased cell hydrophobicity and cell wall lysis upon exposure to lysozyme, which could be overcome to some extent by addition of magnesium ions. There was also evidence of other membrane damage in sorbates treated cells (10). Although the significance of such alterations is unknown, they may be due to incorporation of sorbate into specific cell structures and alteration of biosynthetic processes in the cell (14). Other proposed mechanisms of inhibition of microbial growth by sorbates include alterations in the morphology, integrity, and function of cell membranes and inhibition of transport functions and metabolic activity (2). Death of microorganisms exposed to high concentrations of preservatives, such as sorbates, has been attributed to generation of holes in the

cell membrane. Sorbates have decreased the assimilation of carbon from several substrates, including glucose, acetate, succinate, pyruvate, lactate, oxaloacetate, α-ketoglutarate, ethanol, and acetaldehyde (2,15). Inhibition of cell metabolism by sorbates in these studies may have been due to inhibition of enzymes, nutrient uptake, or various transport systems. Sorbates inhibit the activity of several enzyme systems, which may lead to disruption of vital processes involved in transport functions, cell metabolism, growth, and replication. Enzymes inhibited by sorbates include alcohol dehydrogenase, fumarase, enolase, aspartase, catalase, malate dehydrogenase, α-ketoglutarate dehydrogenase, ficin and succinic dehydrogenase. However, some reports have also indicated no inhibition of enzymatic activity by sorbates (56), when aldolase, enolase and pyruvate decarboxylase of *S. cerevisiae* were not inhibited by SA. Therefore it was assumed that SA affected the yeast cell mainly by influencing its cell membrane and its permeability in its undissociated form after the adsorption on surface cells. Inhibition of sulfhydryl enzymes by sorbates has been attributed to binding with sulfhydryl groups and decreasing the number of such active sites on the enzyme. Inhibition of yeast alcohol dehydrogenase has been attributed to formation of a covalent bond with the sulfydryl or ZnOH group of the enzyme and the α- and/or β-carbon of sorbates. It was also proposed that sorbates inhibit the sulfhydryl enzymes through the formation of a thiohexenoic acid derivative. Inhibition of catalase by sorbates was attributed to the formation of sorbyl peroxides through the autoxidation of SA. These peroxides then would inactivate catalase (2). Another postulation has indicated that sorbate may act competitively with acetate at the site of acetyl coenzyme A formation (15). Binding and inhibition of coenzyme A should result in inhibition of oxygen uptake and microbial growth. Lipophilic acid food preservatives, such as sorbates, may interfere with substrate and electron transport mechanisms. Inhibition of substrate transport into the cell by uncoupling it from the electron transport system results in cell starvation (16,17). SA has inhibited the uptake of glucose (18) and amino acids 19), as well as the electron transport system (2). Inhibition of nutrient uptake may be due to neutralization of the proton-motive force needed for substrate uptake, inhibition of the electron transport system, inhibition of synthesis or depletion of ATP, inhibition of transport enzymes, and inhibition of metabolic energy utilization by the amino acid transport systems (2). Since inhibition of microbial growth by sorbates has been associated with decreased levels of ATP (15), a proposed mechanism of ATP depletion includes hydrolysis of ATP by the primary sodium/hydrogen pump in an attempt to maintain ion balance in the cell (20). A proposed mechanism of inhibition of microbial growth by sorbates is based on the theory that lipophilic, weak acid preservatives starve the cells of compounds that are transported actively only by the proton-motive force (PMF) that exists across the cell membranes (21–24). According to this theory, the weak acids, such as SA, reduce the intracellular pH and neutralize the transport-driving PMF. In general, however, more than one mechanism may be involved in inhibition of various microorganisms under different conditions.

VI. EFFECT TO MICROORGANISMS

Microbial inhibition is variable and depends on species, strains composition of substrate, pH, water activity, additives present, processing treatment, temperature of storage, composition of atmosphere, type of packaging and concentration of sorbates. Variations or resistance to inhibition by sorbates may lead to failures in preservation and defective food products (2). In general, various species and strains of microorganisms exhibit different sensitivities to inhibition by sorbates. Early studies indicated that sorbates could be used as a selective agent for catalase-negative lactic acid-producing bacteria and clostridia because exhibited highly inhibition against catalase-positive organisms. Overall, however, the inhibitory action against lactic bacteria by sorbate is less than that against yeasts. Bacterium that appears to be more resistant to inhibition by sorbate than other spore formers is *Sporolactobacillus* (25). Growth of *Gluconobacter oxydans* in the presence of sublethal concentrations of SA before determination of the minimal inhibitory concentration (MIC) resulted in a substantial increase in the MIC within 1 h (26). Varying sensitivities of bacterial species and strains to sorbates may lead to shifts in the microbial population during storage of foods (9,27,28,29,30,31,32,33). Under certain conditions some species and strains of yeasts and molds are also resistant to inhibition by sorbates. Yeast strains resistant to sorbates belong to the genera *Zygosaccharomyces*, *Saccharomyces*, *Torulopsis*, *Brettanomyces*, *Candida*, and *Triganopsis* (34–41). Resistance of yeasts to sorbates depends on species and strains, sorbate concentration/content, pH, inoculum level, storage temperature, and previous exposure of the organism to low levels of sorbate. When the yeast cells have been previously adapted to sorbate in media containing glucose or sucrose, subsequent exposure of the cells shows little effect of solute type on sorbate resistance (42). Resistance of osmotolerant yeasts to inhibition by sorbate was acquired by reconditioning the yeast to sorbate (40). One proposed mechanism of resistance of osmotolerant yeasts has involved an inducible, energy-quiring system that transports the preservative out of the cell (34). Other proposed mechanisms of yeast resistance to sorbates at reduced water activities have been related to yeast cell shrinkage and decreases in membrane are size, retarding the flow of sorbates into the cell (38), or protection of enzyme systems from inhibition by sorbates through production of compatible solutes, such as polyols (40).

VII. METABOLIC DEGRADATION

At normal conditions of alimentation, sorbates are completely metabolized and fully oxidized to carbon dioxide and water like other fatty acids. It means that sorbates yields 6.6 kcal/g, of which 50% is biologically utilizable. Mechanism of degradation in metabolic pathways of organisms has been studied extensively. Sorbates can be metabolized as fatty acids through β-oxidation by animals and certain microorganisms. When sorbate levels are high, there is also evidence of ω-oxidation (44). At special conditions, some mold strains can grow and metabolize sorbates. The decomposition of sorbates by molds has been detected in cheeses and fruit products. Mold strains of the genus *Penicillium* isolated from cheeses treated with sorbates were able to grow and metabolize high (0.18–1.20%) sorbate levels (44, 45). It should be noted that 0.1% sorbates are usually sufficient to inhibit sensitive molds (46). It seems that selection may occur in sorbate-treated cheeses for certain molds tolerant to the compound (47). One of products of sorbate metabolism by molds include 1,3-pentadiene, which is volatile and has an odor like kerosene, plastic paint, or hydrocarbon and is formed through a decarboxylation reaction (48, 49). Other strains of molds that may degrade sorbates belong to the genera *Aspergillus, Fusarium, Mucor,* and *Geotrichum* (2). It appears, however, that there is no apparent relationship between sorbates resistance and the toxigenic properties of molds (50). In general, although many molds are sensitive to inhibition by sorbates, certain strains are resistant and can utilize them, as a carbon source. Degradation of sorbates by molds depends on species and strains, prior exposure to subinhibitory levels of sorbate, level of inoculum, amount of sorbate present, and type of substrate. Some bacterial strains may also degrade sorbates under appropriate conditions. This metabolism is mostly associated with lactic acid-producing bacterial strains present as high inocula in sublethal concentrations of sorbates (46, 51, 52). Degradation of sorbates by lactic acid bacteria has been associated with geranium-type off-odors in wines and fermented vegetables, caused by ethyl sorbate, 4-hexenoic acid, l-ethoxyhexa-2,4-diene, and 2-ethoxyhexa-3,5-diene (53, 54). In general, a geranium-like odor is usually associated with wines treated with sorbates and contaminated with high microbial loads. Yeasts *Zygosaccharomyces rouxii* and *Debaryomyces hansenii* are able to decarboxylate SA to produce 1,3-pentadiene as major compound of petroleum off-odor (72).

VIII. PHYSICOCHEMICAL DEGRADATION

Autoxidation of aqueous SA solutions increased in the presence of citric acid and further increased in the presence of Fe^{3+} ions and lowered in the presence of Cu^{2+} salts unless ascorbic acid was also added. In the absence of metal ions, ascorbic acid had no effect on autoxidation of SA (57). Solutions of SA are also unstable in the presence of SO_2 and light. At pH 2.1 in the presence of excess SO_2, SA was totally degraded in 8 days. SA is also unstable in solutions of dilute H_2SO_4. Two volatile products from the degradation in SO_2 solution and in dilute H_2SO_4 were identified as β-angelica lactone and 2-methyl-5-acetylfuran (58). SA degraded in aqueous glycerol solutions at pH 4.0 over the water activity range 0.71–1.00 and the temperature range 40–60°C by first-order reaction kinetics and to conformed to the Arrhenius equation. Activation energy values obtained were 5.8 kcal mol^{-1} and 7.8 kcal mol^{-1} for systems at a_w 0.80 with and without added Co^{2+} ions, respectively. The rate of SA degradation increased with decreasing a_w i.e. increasing glycerol concentration. The presence of added Co^{2+} decreased the rate of SA breakdown at any particular a_w or temperature. Browning of sorbate solutions during storage was markedly inhibited by Co^{2+} ions (59). Acetaldehyde and β-carboxylacrolein were identified as the major degradation products of SA in the presence of glycine and $CuSO_4$. Crotonaldehyde and acetone were also detected, but in very small amounts. Studies of the role of carbonyl compounds in SA-mediated browning revealed that, in the presence of amino acids, β-carboxylacrolein polymerizes rapidly to brown pigments. In the presence of Cu^{2+} brown pigments were not formed (60). SA degraded in model systems composed of sugar solutions at pH 3.5 and 4.5 and its destruction was described by first-order kinetics. Nonenzymic browning reactions, which occurred in systems containing lysine, greatly influenced the kinetics of SA destruction (61). Aspartame reduced sorbate destruction in aqueous system without sugars as well as in systems containing glucose, but in the presence of sucrose, it enhanced degradation (96). Loss of SA in stored peaches preserved by combined factors followed first order reaction kinetics, when rate constants and activation energy were almost identical to previously reported data (62). NaCl showed a pronounced stabilizing effect on degradation of SA in aqueous solutions to which glycerol and citric acid had been added to adjust a_w to 0.91 and pH between 5 to 6 (63). SA in aqueous solutions underwent to autoxidation, forming malonaldehyde and other carbonyls. Oxidative degradation followed first-order reaction kinetics, and the rate of reaction decreased with a rise in pH. Amino acids except histidine and arginine increased while NaCl, KCl, sucrose, and metal ions (Cu^{2+}; Fe^{2+}; Mn^{2+}) decreased the rate of degradation. In an other study, NaCl enhanced SA degradation when the destruction seemed to be related to the NaCl and concentration rate of SA degradation increased significantly with increasing temperature (68). Acetic acid, glycerol, and the majority of other salts enhanced the rate of degradation (64). In liquid model systems containing water-glycerol-glucose, water-glycerol-sucrose, sucrose and 30 sucrose

glucose mixtures, SA degraded during storage forming brown pigments. Addition of amino acids (glycine or lysine) increased rate of browning development while Cu^{2+} reduced SA degradation and browning development. In all systems, addition of amino acids decreased SA degradation but increased browning development. Rate of SA-induced browning was considerably higher than that caused by sugar-amino acid interactions (65). In an other study it confirmed the accelerate role of SA in the glucose-glycine browning reaction (66). The kinetics of brown pigment formation in a water-glycerol-sorbate-glycine model system at pH 4 was studied as a function of a_w (0.55–0.90) in the interval of 40–60°C. The rate of browning was found to follow zero-order kinetics and to increased with decreasing a_w. Activation energy values ranged from 15.5 to 22.2 kcal/mol, and were higher at the lower a_w levels. Glycerol was found to participate actively in the formation of brown pigments by reaction with sorbates or glycine; the rates also followed zero-order kinetics obeying the Arrhenius equation (67). Important is effects of additives (propyl gallate, sodium nitrite, sucrose, ascorbic acid, glycerol, glycine and polyphosphates) on stability of sorbates in aqueous model systems of a_w 0.91 and pH 5.0. Rate constants of SA destruction could be described by 1st order kinetics and non-enzymatic browning reactions exhibited zero order kinetics. Both were greatly influenced by SA destruction, when the correlation between the natural logarithm of sorbates retention and the increase in absorbance at 420 nm was found in all systems. Addition of glycine increased sorbate destruction and browning development. To the opposite, SA catalysed Maillard reaction between glycine and glucose heated to 100°C, while no loss of the SA was observed during the experiment (83). Polyphosphates and propyl gallate showed an important protective effect against SA degradation and also against non-enzymatic browning. Ascorbic acid showed a dual effect: in the absence of sodium nitrite, it exhibited a pro-oxidant effect; in the presence of nitrite, a protective effect was apparent. Sucrose did not influence the rate of SA degradation but enhanced non-enzymatic browning. The effect of sodium nitrite on sorbate destruction was diverse: it accelerated destruction in systems containing NaCl, glycerol and glycine, diminished the destruction rate when polyphosphates were also present, and had no effect in the presence of sucrose and/or sucrose and polyphosphates. Conversely, in the presence of ascorbic acid, sodium nitrite exerted a protective effect (69). EDTA enhanced sorbate degradation as a result of Fe scavenging from the glass and polypropylene packaging materials through EDTA complexation. It was proposed that SA autoxidation is catalyzed by EDTA-Fe^{2+} complexes, accompanying with production of carbonyls followingly involved in non-enzymatic browning (70). To lower sorbate destruction, the use of glass instead of PET containers, and a mixture of citric and acetic acids, ascorbic acid and EDTA was proposed (97). SA was highly susceptible to radiolytic degradation in aqueous systems exposed to gamma-irradiation. Rate of degradation decreased with rise in pH. Sugars, hydrocolloids except pectin, citric acid, lactic acid, malic acid, arginine and threonine, catalyzed degradation while oxalic acid, maleic acid, Cu^{2+}, nitrite, nitrate and phthalate had protective effects. SA was more stable in alcohols and vegetable oils than in aqueous solutions. In wheat flour radiolytic degradation of SA was less at lower moisture. SA was more stable in chapattis than in dough. Gelatinization and addition of oil into dough reduced degradation of SA (71).

IX. INTERACTION AND FORMATION OF ADDUCTS

SA and methyl ester of SA react with sodium nitrite to form ethylnitrolic acid (ENA) after heating at 90°C for 1 h (73,74). As found, ENA could also be formed at lower temperature of 60°C and pH 3.5–4.2 after 30 min when the formation of an other mutagenic compound 1,4-dinitro-2-methylpyrrole (DNMP) was observed. Formation of both mutagenic compounds was inhibited by ascorbic acid and cysteine (75, 79), and the loss of mutagenicity could be reached by reduction of the C-nitro group to the C-amino group in DNMP (76) by conversion to 1-nitro-2-methyl-4-aminopyrrole (77). Nitrite reacted optimally with SA at pH 3.5, but the reaction did not take place at pH 6. Most mutagenic products formed were C-nitro and C-nitroso compounds, and the conjugated dienoic structure for mutagen formation was essential (78). Thiols (mercaptoethanol, cysteine or an alkylthiol) reacted slowly with SA during heating for several days at 80°C and pH 3.7–7.8 in a bimolecular reaction via nucleophilic attack by thiolate anion at position 5 of the SA molecule, in the case of amines, cyclization to form substituted dihydropyridones may follow (80, 85). The nucleophilic attack by alkylthiols led to formation of diadducts, while reaction with mercaptoethanol, esters of 2-mercaptoacetic acid and cysteine ethyl ester gave the 2,5-addition product. Products of monoaddition of thiols to SA had a double bond in position 3 (81). Cysteine added to the conjugated diene in position 5 formed the substituted 3-hexenoic acid (87). Reaction between SA and thiols could be accelerated by some cationic surfactants i.e. dodecyltrimethylammonium bromide as well as nonionic surfactants also behaved as catalysts (82). Even thought, bovine serum albumin could also behave as catalyst (84). The formation of the reaction intermediate in bovine serum albumin-SA-mercaptoethanol mixtures involved the binding of equimolar amounts of the reactants at up to some 90 sites on the BSA molecule. 3-hexenoic acid reduced the rate-enhancing effect of BSA due to competitive binding between 3-hexenoic acid and SA

to the reaction intermediate (88). SA-thiol irreversible adducts were formed in a dough made from cereal flours (89). Reaction of SA with sulfite species (S^{4+}) was affected in a presence of O_2, and involved a pH-dependent oxidative mechanism leaded to loss of S^{4+}. In the absence of O_2, a much slower nucleophilic addition of sulphite ions to undissociated SA took place (86). SA and ethyl sorbate reacted with various amines (methylamine, ethylamine, butylamine and benzylamine) in model systems. At ambient temperature, the reaction of sorbates with amines resulted in formation of linear mono adducts, while cyclic adducts were formed from double addition in temperature interval of 50–80°C mainly in the presence of O_2 which significantly accelerated adduct formation reaction (90,91). Potasium sorbate reacted with methylamine and butylamine and adducts were identified as cyclic dihydropyridone esters, formed by a double addition reaction (92). Under conditions typical of food processing (50–80°C), the cyclic derivatives resulting from a double addition reaction between SA and various amines (including methylamine, ethylamine, propylamine, butylamine and benzylamine) were formed and analysed. Major formed compounds were N-methyl-6-methyl-3,6-dihydro-2-pyridone, N-ethyl-6-methyl-3,6-dihydro-2-pyridone, N-propyl-6-methyl-3,6-dihydro-2-pyridone, N-butyl-6-methyl-3,6-dihydro-2-pyridone, N-benzyl-6-methyl-5,6-dihydro-2-pyridone and minor compounds were N-methyl-6-methyl-5,6-dihydro-2-pyridone, N-ethyl-6-methyl-5,6-dihydro-2-pyridone, N-propyl-6-methyl-5,6-dihydro-2-pyridone, N-butyl-6-methyl-5,6-dihydro-2-pyridone, N-benzyl-6-methyl-5,6-dihydro-2-pyridone. Mutagenesis studies involving the Ames test using *S. typhimurium* (strains TA98 and TA100), and genotoxicity studies with HeLa cells and plasmid DNA, showed that none of the compounds studied presented either mutagenic or genotoxic activities (93,94). Mutagenicity and DNA damage by products formed during oxidation of sorbates by H_2O_2, produced by reaction of ascorbate with Fe-EDTA, ferric citrate, ferrous gluconate, ferric pyrophosphate or ferrous sulphate, were assessed *in vitro* using the Ames test and a rec-assay, respectively. Products from a reaction carried out in the absence of O_2 did not exhibit mutagenicity, which confirmed that the mutagenic effects resulted from an oxidation reaction (95).

X. TOXICOLOGY

Sorbates are considered for the least harmful antimicrobial preservatives, even at levels exceeding those normally used in foods. The LD_{50} for sorbates in rats ranges from 7.4 to 10.5 g/kg body weight. Rats fed SA at 10% in feed for 40 days had no ill effects. When the feeding period was increased to 120 days, the growth rate and liver weight increased. SA at 5% in the diet of rats did not affect health after 1 000 days (except for two tumors in 100 rats). When rats were given SA (10 mg/100 mL) or potassium sorbate (0.3%) in drinking water or 0.1% levels in the diet, no tumors were observed after 100 weeks. The growth of tumors was not seen when mice were fed 40 mg SA per kilogram body weight. Repeated subcutaneous administration of SA in peanut oil or water in rats produced sarcomas at the site of injection. Sarcomas produced locally in this manner were not considered a valid index of carcinogenicity. Weak mutagenic activity was detected in the ether extract of bacon-curing brines containing potassium sorbate. Retesting the sample indicated that the mutagenic activity was due to a compound in the ether to be used as the extraction solvent. (136). Also other studies did not reveal carcinogenic effects of sorbates (99,100). When SA is used for cosmetic and pharmaceutical products, it may irritate the mucous membranes, and in highly sensitive individuals it may cause skin irritation (98). An allergic-type response has been reported for SA in a study, when panelists tasted bacon treated with sorbate-nitrite mixture (101).

XI. REGULATORY STATUS

The application of sorbates is limited by national legislation of individual countries to prevent to the use them in excessive amounts due to their possible toxicity. In most countries of the world, food legislation has given procedures for application of sorbates in various food products. This legislation identifies approved sorbates, establishes permitted concentrations, and includes labeling requirements. From an international point of view, the Joint Expert Committee for Food Additives (JECFA) deals periodically with evaluation of a real situation and adopts maximum limits for food additives including sorbates (see Table 96.2) on the basis of all available scientific data. Such information provided by JEFCA is used by the Joint FAO/WHO organ — Codex Alimentarius Commission in implementing Joint FAO/WHO Standards Programme, which has been established to elaborate international standards for foods to protect the health of consumers, ensure fair practices in food trade, and facilitate international trade. To identify individual food additives, so called "General Standard for Food Additives" embraces the list of preservatives permitted for application in food industry together with their International Numbering System (INS) numbers (102). Similarly, European Union has adopted the same numbering system of permitted food additives, the only difference is replacing "INS" by "E" letter on labels (103). In the United States, sorbates are generally recognized as safe (GRAS), and this status has been reaffirmed again April 1st 2001 by a select committee of the U.S. Food and Drug Administration, which regulates all antimicrobials used in or on processed food under FFDCA §409, as food additives. According to the Code of Federal Regulations, when a food preservative is used in a food product, its common name should be listed on

TABLE 96.2
Maximum Limits of Sorbates for Food Products Adopted by Codex Alimentarius Commission

Food Cat. No.	Food Category	Max. Level [mg/kg]	Food Cat. No.	Food Category	Max. Level [mg/kg]
01.1.1	Milk and buttermilk	1 000	01.1.2	Dairy-based drinks, flavored and/or fermented (e.g., chocolate milk, cocoa, eggnog, drinking yoghurt, whey-based drinks)	300
01.2.1	Fermented milks (plain)	300	01.2.2	Renneted milk	1 000
01.3.2	Beverage whiteners	200	01.6	Cheese	3 000
01.7	Dairy-based desserts (e.g., ice cream, ice milk, pudding, fruit or flavoured yoghurt)	1 000	02.1.1	Butter oil, anhydrous milkfat, ghee	1 000
02.2.1	Emulsions containing at least 80% fat	1 000	02.2.2	Emulsions containing less than 80% fat (e.g., minarine)	2 000
02.3	Fat emulsions other than food category 02.2, including mixed and/or flavoured products based on fat emulsions	1 000	02.4	Fat-based desserts excluding dairy-based dessert products of food category 01.7	1 000
03.0	Edible ices, including sherbet and sorbet	1 000	04.1.1	Fresh fruit	1 000
04.1.2.1	Frozen fruit	1 000	04.1.2.2	Dried fruit	2 000
04.1.2.3	Fruit in vinegar, oil, or brine	2 000	04.1.2.4	Canned or bottled (pasteurized) fruit	1 000
04.1.2.5	Jams, jellies and marmelades	1 500	04.1.2.6	Fruit-based spreads (e.g., chutney) excluding products of food category 04.1.2.5	1 000
04.1.2.7	Candied fruit	1 000	04.1.2.8	Fruit preparations, including pulp, purees, fruit toppings and coconut milk	1 500
04.1.2.9	Fruit-based desserts, including fruit-flavoured water-based desserts	1 000	04.1.2.10	Fermented fruit products	1 000
04.1.2.11	Fruit fillings for pastries	1 000	04.1.2.12	Cooked or fried fruit	1 200
04.2.2.3	Vegetables and seaweeds in vinegar, oil, brine, or soy sauce	2 000	04.2.2.4	Canned or bottled (pasteurized) or retort pouch vegetables	1 000
04.2.2.5	Vegetable, and nut and seed purees and spreads (e.g., peanut butter)	2 000	04.2.2.6	Vegetable, and nut and seed pulps and preparations (e.g., vegetable desserts and sauces, candied vegetables, soybean curd) other than food category 04.2.2.5	2 000
04.2.2.7	Fermented vegetable products	1 000	04.2.2.8	Cooked or fried vegetables and seaweeds	2 000
05.1.1	Cocoa mixes (powders and syrups)	1 500	05.1.2	Cocoa-based spreads, including fillings	1 500
05.1.3	Cocoa and chocolate products (e.g., milk chocolate bar, chocolate flakes, white chocolate) other than food categories 05.1.1, 05.1.2 and 05.1.4	1 000	05.1.4	Imitation chocolate, chocolate substitue products	1 500
05.2	Confectionery including hard and soft candy, nougat, etc. other than food categories 05.1, 05.3 and 05.4	2 000	05.3	Chewing gum	1 500
05.4	Decorations (e.g., for fine bakery wares), toppings (non-fruit) and sweet sauces	1 500	06.2	Flours and starches	1 000
06.4.2	Pre-cooked or dried pastas and noodles and like products	2 000	06.5	Cereal and starch based desserts (e.g., rice pudding, tapioca pudding)	1 000
06.6	Batters (e.g., for fish or poultry breading)	2 000	07.0	Bakery wares	2 000
08.2	Processed meat, poultry, and game products in whole pieces or cuts	2 000	08.3	Processed comminuted meat, poultry, and game products	2 000
08.4	Edible casings (e.g., sausage casings)	GMP*	09.2.1	Frozen fish, fish fillets, and fish products, including mollusks, crustaceans, and echinoderms	2 000
09.2.2	Frozen battered fish, fish fillets, and fish products, including mollusks, crustaceans, and echinoderms	2 000	09.2.3	Frozen minced and creamed fish products, including mollusks, crustaceans, and echinoderms	2 000
09.2.4.1	Cooked fish and fish products	2 000	09.2.4.2	Cooked mollusks, crustaceans, and echinoderms	2 000
09.2.5	Smoked, dried, fermented, and/or salted fish and fish products, including mollusks, crustaceans, and echinoderms	2 000	09.3	Semi-preserved fish and fish products, including mollusks, crustaceans, and echinoderms	2 000
10.2.1	Liquid egg products	5 000	10.2.2	Frozen egg products	1 000

(*Continued*)

TABLE 96.2
(*Continued*)

Food Cat. No.	Food Category	Max. Level [mg/kg]	Food Cat. No.	Food Category	Max. Level [mg/kg]
10.2.3	Dried and/or heat coagulated egg products	1 000	10.4	Egg-based desserts (e.g., custard)	1 000
11.1	White and semi-white sugar (sucrose or saccharose), fructose, glucose (dextrose), xylose; sugar solutions and syrups, also (partially) inverted sugars, incl. molasses, treacle, and sugar toppings	1 000	11.2	Other sugars and syrups (e.g., brown sugar, maple syrup)	1 000
11.4	Table-top sweeteners, including those containing high-intensity sweeteners	1 000	12.2	Herbs, spices, seasonings (including salt substitutes), and condiments (e.g., seasoning for instant noodles)	1 000
12.3	Vinegars	1 000	12.4	Mustards	1 500
12.5	Soups and broths	1 000	12.6	Sauces and like products	2 000
12.7	Salads (e.g., macaroni salad, potato salad) and sandwich spreads excluding cocoa- and nut based-spreads of food categories 04.2.2.5 and 05.1.2	1 500	13.3	Dietetic foods intended for special medical purposes, including those for infants and young children	1 500
13.4	Dietetic formulae for slimming purposes and weight reduction	1 500	13.5	Dietetic foods (e.g., supplementary foods for dietary use) excluding products of food categories 13.1–13.4	2 000
13.6	Food supplements	2 000	14.1.1.2	Table waters and soda waters	200
14.1.2.1	Canned or bottled (pasteurized) fruit juice	2 100	14.1.2.2	Canned or bottled (pasteurized) vegetable juice	1 000
14.1.2.3	Concentrate (liquid or solid) for fruit juice	1 000	14.1.2.4	Concentrate (liquid or solid) for vegetable juice	1 000
14.1.3.1	Canned or bottled (pasteurized) fruit nectar	2 000	14.1.3.2	Canned or bottled (pasteurized) vegetable nectar	1 000
14.1.3.3	Concentrate (liquid or solid) for fruit nectar	1 000	14.1.3.4	Concentrate (liquid or solid) for vegetable nectar	1 000
14.1.4.1	Carbonated drinks	1 000	14.1.4.2	Non-carbonated, including punches and ades	1 000
14.1.4.3	Concentrates (liquid or solid) for drinks	1 500	14.1.5	Coffee, coffee substitutes, tea, herbal infusions, and other hot cereal and grain beverages, excluding cocoa	1 000
14.2.1	Beer and malt beverages	500	14.2.2	Cider and perry	1 000
14.2.3	Wines	2 000	14.2.4	Fruit wine	1 000
14.2.5	Mead	1 000	14.2.6	Spirituous beverages	600
15.1	Snacks — potato, cereal, flour or starch based (from roots and tubers, pulses and legumes)	1 000	15.2	Processed nuts, including covered nuts and nut mixtures (with e.g., dried fruit)	1 000
16.0	Composite foods (e.g., casseroles, meat pies, mincemeat) — foods that could not be placed in categories 01–15				1 000

GMP* — good manufacturing practice.

the product label and its function should be indicated by an explanatory description (e.g., "to maintain freshness," "to extend shelf life," or "as a preservative"). The use of sorbates may be requested for any food product that allows preservatives (2).

XII. ANTIMICROBIAL ACTIVITY

Sorbates have broad spectrum activity against yeast and molds, but are less active against bacteria. Food-related yeasts inhibited by sorbates include species of *Brettanomyces, Byssochlamys, Candida, Cryptococcus, Debaryomyces, Endomycopsis, Hansenula, Oospora, Pichia, Rhodotorula, Saccharomyces, Sporobolomyces, Torulaspora, Candida,* and *Zygosaccharomyces*. Food-related mold species inhibited by sorbates belong to the genera *Alternaria, Ascochyto, Aspergillus, Botrytis, Cephalosporium, Fusanum, Geotrichum, Gliocladium, Helminthosporium, Humicola, Mucor, Penicillium, Phoma, Pullularia (Auerobasidium), Sporotrichum,* and *Trichoierma* (2). Bacteria sensitive to sorbate embraces genera *Salmonella, Clostridium, Yersinia, Staphylococcus, Bacillus, Lactobacillus, Escherichia, Proteus, Streptococcus* (98). Optimum effectiveness of sorbates extends from lower values to pH ≈ 6.5 (4), but and the antimicrobial activity of SA is greatest when the compound is in the undissociated state. Because of pKa value, the antimicrobial activity is greatest as the pH is rather lower and below the value 6.0 (98). The effect of pH on inhibition activity of SA was determined for *B. subtilis*, *B. cereus*, *E. coli*, *P. aeruginosa*, *S. aureus* and *C. albicans*. As observed, the inhibitory action of undissociated acid was 10–600x

greater than that of dissociated acid (22). The inhibitory effect of sorbates may be lethal as well as static. Conidia of *A. parasiticus* lost viability in the presence of sorbate (20). Differential effect on growth and patulin production by strains of *P. patulum* and *P. roqueforti* isolated from cheese was observed, when potassium sorbate delayed initiation of growth, prevented spore germination, and decreased the rate of growth of *P. patulum* in potato dextrose broth, while *P. roqueforti* was affected less (104). Similar results were observed with *A. parasiticus* and *A. flavus* in yeast extract sucrose broth (105). Potassium sorbate reduced or prevented the production of the patulin by *P. patulum* and aflatoxin B_1 by *A. parasiticus* and *A. flavus* (104,105). Potassium sorbate has been found to inhibit markedly the growth and patulin production of *P. expansum* and *B. nivea* in grape and apple juice (106,107,108,109). On the other hand, sorbate delayed only mold growth, but did not inhibit biosynthesis of aflatoxin by *A. parasiticus*. The ability to synthesize aflatoxin was greater in the early stages of growth and then decreased as mold growth progressed (110). Potassium sorbate at the concentration of 0.2% (pH 5.5) or 0.05% (pH 4.5) completely inhibited *A. parasiticus* growth and toxin production for 3 days in a glucose-yeast extract salts medium. However, growth and toxin production were nearly normal by day 7 of incubation (111). *A. flavus* grown on yeast extract-sucrose medium produced higher amounts of aflatoxin B_1 in the presence of 0.025% SA than without it. Addition of 0.05–0.0125% SA stimulated T-2 toxin production of *F. acuminatum* cultures grown on maize meal and highest amounts of the mycotoxin were detected in 14-day-old cultures containing 0.025% SA. It was assumed that certain amounts of SA near the minimum inhibitory concentration reduced the activity of the tricarboxylic acid cycle. This may leaded to an accumulation of acetyl coenzyme A, which is an essential intermediate in the biosynthesis of aflatoxin B_1 and T-2 toxin (152). Potassium sorbate was more effective against injured spores of *A. parasiticus* and an intensity of inhibition depended on the concentration of sorbate and pH (112). Sorbate has been found to inhibit the growth of *Salmonella, C. botulinum,* and *S. aureus* in cooked, uncured sausage (113), of *S. aureus* in bacon (114), of *P. fluorescens* and *P. putrefaciens* in trypticase soy broth (115,116), of *V. parahemolyticus* in crab meat and flounder homogenates (117), of *S. aureus* (118), microbiological growth in cooked turkey products (119), *C. botulinum* toxin production in commercially prepared bacon (120). Sorbates also inhibited *S. typhimurium* in skim and evaporated milk (121). Potassium sorbate at 0.5% inhibited growth and histamine production by *P. morgani* and *K. pneumoniae* strains in a trypticase soy broth fortified with histidine (122). Potassium sorbate inhibited anaerobic growth of *S. aureus* more than growth under aerobic conditions in a model sausage system and inhibition was strengthened after lactic acid addition (123). While combinations of sorbate and NaCl were more effective in inhibition of *S. typhimurium* than sorbate alone at pH 6.3 (124), NaCl did not appear to enhance effectiveness of sorbate on growth of *S. aureus* MF-31 in tryptic soy broth at same pH (125). Microorganisms isolated from seafood showed differential sensitivity to sorbate (126). Potassium sorbate inhibition of *B. cereus* T spore germination induced by L-alanine and L-α-NH_2-n-butyric acid was shown to be competitive in nature. It was also a competitive inhibitor of L-alanine- and L-cysteine-induced germination of *C. botulinum* 62A spores (127). Reports in the 1950s concluded that sorbates had either stimulatory or no effect on clostridia, but later studies concluded that sorbates have acted as an anticlostridial agent in cured meat products (5,14,29). The contradictory results of the studies were most likely due to the fact that in the 1950s, media with pH values approaching 7.0 were used. This was optimal for growth of clostridia but not optimal for the activity of sorbates, since only about 0.6% of SA is in the undissociated form at pH 7.0 (98). Potassium sorbate, sufficient to give an undissociated SA concentration of 250 mg/liter in culture medium at pH 5.5–7.0, retarded the growth of proteolytic strains of *C. botulinum* from spores and vegetative cells (29,30). Sorbate has been shown to prevent spores of *C. botulinum* from germinating and forming toxin in poultry frankfurters, ham, emulsions as well as beef, pork, and soy protein frankfurter emulsions, bacon, and canned comminuted pork (120,128, 129,130,131). *C. botulinum* toxin production was significantly decreased in a model cured meat system adding 3.5% NaCl, 0.26% potassium sorbate at pH less than 6.0, and low storage temperatures (132). A systematic study to determine the concentration of potassium sorbate necessary to inhibit a single *C. botulinum* cell in culture medium showed that 0.1% at pH 5.0 would reduce the probability of growth of *C. botulinum* at 30°C in 14 days to 1 in 10^8. It was also concluded that 0.2% SA alone in meat products at pH 6.5 would not significantly inhibit *C. botulinum* vegetative cells (133). The effect of sorbate on thermal inactivation and recovery of injured microorganisms is variable among species and strains. Low concentrations of sorbic and fumaric acids in the heating medium had little effect on the heat resistance of *E. herbariorum*, an aerophilic mold involved in the spoilage of grape preserves (138). The antimicrobial activity of sorbate is usually enhanced under vacuum or modified gas atmosphere storage conditions, including meat (32,139,140) and fish products (141,142,143). Combinations of carbon dioxide and sorbate have also been reported as effective inhibitors of microbial growth of *S. enteriditis* (144), *S. aureus* on tryptic soy agar (145) as well as on fresh poultry to be dipped into sorbate pollution (146). Synergistic antimicrobial

activity was optimal at pH 5.5 at 1.5% sorbate solution and 100% CO_2 treatment. Although food acids may reduce the water solubility of sorbate, they can enhance its antimicrobial activity by increasing the concentration of undissociated SA. In addition, the specific anion itself may contribute antimicrobial activity (129). Specific effects, however, vary with substrates, microorganisms, and types of acids. Combinations of sorbate with antioxidants, such as butylated hydroxyanisole, butylated hydroxytoluene, tertiary butyl hydroxyquinone, and propyl gallate, had increased antimicrobial activity compared to individual components (147,155). Variations existed, however, with types of microorganisms, antioxidants, and substrates. These combinations offer the advantage of simultaneous inhibition of microbial growth and development of rancidity. A few studies have also indicated increased antimicrobial effects when sorbate was combined with various phosphates (148). Combinations of sorbate with benzoate or propionate may be used to expand the range of microorganisms inhibited with reduced concentrations of each preservative (149). In addition, mixtures of sorbate with various antibiotics have demonstrated increased antimicrobial activity (150,151). Fungicidal activity of SA against *S. cerevisiae* was enhanced 64-fold in combination with half-minimum fungicidal concentration of polygodial, a bicyclic sesquiterpene dialdehyde isolated from the sprout of *P. hydropiper*. This synergistic activity of presumably came from its ability to inhibit the plasma membrane H^+-ATPase (154). Different effect of SA was observed on *P. membranifaciens.* At 25°C, SA completely inhibited yeast growth, but at temperature greater than 43 degree C appeared to protect the yeast from thermal death (156). The antilisterial effects of a sorbate-nisin combination were assessed *in vitro* and on beef at refrigeration temperature. Treatment with the sorbate-nisin combination did not significantly affect pathogenicity of the *L. monocytogenes* cocktail recovered from vacuum- or CO_2-packages after storage, in contrast to the in vitro study, where pathogenicity was clearly attenuated. The reason for this difference was unknown (157).

XIII. RESISTANCE

Potassium sorbate (0.1%) added to scallops (pH 6.3–6.5) resulted in more rapid *C. botulinum* toxin formation than in controls. It was postulated that this might be due to inhibition of microflora competitive to C. *botulinum* (134). Resistance to sorbate was observed at *P. roqueforti*, which was able to decarbolise SA and produce 1,3-pentadiene (135). Lowering the a_w enhanced the resistance of *S. rouxii* to increasing concentrations of sorbate (38.) *S. rouxii* cells, preconditioned in 0.1% sorbate showed an increased resistance to sorbate when inoculated into the growth medium and the chocolate syrup *S. rouxii* cells preconditioned in 60% sucrose/0.1% sorbate were more sensitive to sorbate than cells preconditioned in 0% sucrose/0.1% sorbate (40). Effect of sorbate on growth of *Z. rouxii* was evaluated at reduced a_w, using sucrose, glucose and polyethylene glycol (PEG). Sorbate-adapted and unadapted cells were grown aerobically at pH 5.0 in media adjusted to a_w 0.92 by addition of solutes. Sorbate resistance by unadapted cells increased in the order of glucose less than PEG less than sucrose. Solute type had little effect on sorbate resistance by sorbate-adapted cells in media containing glucose and sucrose (137). Certain strains of microorganisms were not only resistant to inhibition by sorbate, but also increased levels of microbial contamination. Thus, sorbates should be used to preserve foods processed using good manufacturing practices, not as a substitute for sanitation and hygienic practices (2).

XIV. APPLICATION

Sorbates are some of the most widely used food preservatives in the world and they are being applied in human foods of all types, animal feeds, pharmaceuticals, cosmetic products, packaging materials, and technical preparations that come in contact with foods or the human body. As food preservatives, sorbates have found wide application in various foods, especially as yeast and mold inhibitors. Major groups of foods that may be preserved with sorbates include dairy products, bakery items, fruit and vegetable products, edible fat emulsion products, certain meat and fish products, and sugar and confectionery items. Application methods for sorbates include direct addition in the formulation, spraying or immersing the food material in a solution, dusting with a powder, or addition in a coating or packaging material. However, release of sorbates from plastic films is limited, so, the antimicrobial effectiveness is low (194). Selection of the most appropriate method depends on processing procedures, type of food, objectives to be accomplished, equipment available, and convenience (2).

XV. ANALYSIS

Analytical determination and occurrence of sorbates in foods is permanently actual and frequently published/reviewed (159,160,161). There are a lot of procedures and techniques for determination of sorbates in foods. If necessary, sorbates are isolated from the matrix prior to analysis. Two main procedures of isolation methods are generally used as follows:

1. Steam distillation, followed by an extraction of SA from the aqueous distillate with organic solvents

TABLE 96.3
Sample Treatment and HPLC Conditions Used for Determination of Sorbates

Sample, Sample Preparation	Stationary Phase	Mobile Phase	Detector	Ref.
Extraction of margarine, washing with diethyl ether, extraction with NaOH and H_2SO_4	μ-Bonda Pak C_{18}	Phosphate buffer-methanol (20:80) (v/v); phosphate buffer-methanol (40:60) (v/v)	UV at 235 nm	166
Filtration of orange juice	Shodex RP pak DS-(150 × 6 mm) Polystyrene-divinyl benzene resin RP-18 guard column (40 × 3.4 mm)	0.05 M KH_2PO_4 (pH 2.65)-acetonitrile (60:40) (v/v); flow rate 1.0 mL/min	UV 230 nm	160 161 167
Coffee drink steam- distilled, cleanup SPE technique	Nucleosil 5 C_{18} (150 × 3.4 mm), Lichrosorb RP-18 (150 × 4.3 mm); Develpsil ODS 5 μm	Acetonitrile-water-0.2 M phosphate buffer, pH 3.6 (7:12:1) + CTA	UV at 235 nm	168
Fatty samples cleaned on Extrelut column, elution with dichloromethane-diethyl ether (4:1)	LiChrosorb Si 60 (150 × 4.6 mm) μ-BondaPak C_{18} 10 μm (300 × 4.6 mm)	Heptane-diisopropyl ethyl-glacial acetic acid (88:12:0.1), (90:10:0.05), 1.8 mL/min; water-acetonitrile-H_3PO_4 (90:10:0.5), flow rate 0.8 mL/min	UV at 230 nm	160 161 167
Beverages, jams; filtration, Degassing	PhaseSep C_{18}, Spherisorb ODS 1 (250 × 4.6 mm) 5 μm	Methanol-phosphate buffer (8:92) (v/v) pH 6.7 using H_3PO_4 flow rate 1.0 mL/min	UV at 227 nm	169
Fruit juice; filtration	μ-BondaPak CN	2% Acetic acid-methanol (95:5) (v/v)	UV at 254 nm	170
Citrus juices filtration	μ-Bondapak CN	2% Acetic acid-methanol (19:1) (v/v)	UV at 240 nm	171
Citrus juices; filtration	Partisil 10 SAX	0.225 M KH_2PO_4 1.0 mL/min	UV 254 nm	172
Cheese; steam distillation	LiChrosorb RP-18 (250 × 4 mm)	Methanol-0.02 M phosphate buffer (30:70) (v/v) + tetrabutylammonia 1.0 mL/min	UV 235 nm	173
Beverages, tomato sauce; extraction	μ-BondaPak C_{18}	Methanol-acetic acid-water (20:5:75) (v/v/v) (35:5:60) (v/v/v)	UV 254 nm	174
Sweet commercial wines; synthetic wines diluted with 0.01 N H_2SO_4, filtered 0.45 μm	AMINEX HPX 87-H (300 × 7.9 mm); 65°C	0.01 N H_2SO_4:CH_3CN (75:25)	UV 258 nm	175
Fruit juices, sodas, soy sauce, ketchup, peanut butter cream, cheese, other foods liquid samples: dilution acetonitrile/ammonium acetate solid samples: blending with the same solution	reversed phase C_{18} column	Acetonitrile/ammonium acetate	255 nm	176
Wines direct injection	Hydrogen sulfonated divinyl benzene-styrene copolymer	Isocratic elution 0,01 N H_2SO_4:CH_3CN (75:25)	UV 258 nm	177
Quince jams extraction 0,1 M orthophosphoric acid or steam distillation or via Amberlite XAD 2 after mixturing of sample with 0,05 M HCl	C_{18} column	Acetate buffer (pH 4,4) — methanol (65:35)	DAD	178
Fishery products ion-exchange chromatography	Nucleosil 100-5 C_{18}	Gradient elution: A: 0,02 M H_3PO_4/ acetonitrile (93+7, v/v) B: 0,02 M K_2HPO_4 with 5% H_3PO_4, pH 6,7: acetonitrile (80:20, v/v)	DAD,	179

2. Direct extraction using diethyl ether and petroleum ether, chloroform, benzene, acidified methanol or their mixtures as the most suitable organic solvents

XVI. COLOR DETERMINATION

Determination is based on oxidation of SA by $K_2Cr_2O_7$ in acidic medium to form a malonic dialdehyde, which

TABLE 96.4
Sample Treatment and GC Conditions for Determination of Sorbates

Sample, Sample Preparation	Stationary Phase	Carrier Gas	Detector	Ref.
Marmalades, mustard, mayonnaise, Fish products, alcoholic beverages; extraction and derivatization	Packed column, 3% SE-30 on Aeropak(3 m)	Nitrogen, 30 mL/min	FID	180
Cheese; distillation	Packed column with Porapak QS (1 m × 3 mm)	Nitrogen, 40 mL/min	FID	173
Rennet, extraction with diethyl ether	Packed column Chromosorb W AW DMSC,15% EGA (2 m × 2 mm)	Nitrogen, 30 mL/min	FID	181
Mustard, mayonnaise, fish products, juices	Glass capilary column coated with OV-73 (24 m × 0.22 mm)	Nitrogen	FID	182
Soft drinks, skim yogurts, jams, sauces	Fused-silica columns (15 m × 0.53 mm i.d.) packed with 5% diphenyl-95% dimethylsiloxane or 50% diphenyl-50% dimethylsiloxane	Nitrogen	FID	183
Margarine, oil, fresh cheese, mayonnaise	Fused-silica column (30 m × 0.32 mm i.d.) coated with 5% diphenyl-95% dimethylpolysiloxane, HP-5)	Helium	FID	184
Rye bread, extraction with diethyl ether-phosphoric acid	Fused-silica column WCOT (25 m × 0.53 mm i.d.), FFAP-CB coating, 1.0 μm thickness	Nitrogen	FID	185

reacts with thiobarbituric acid to give a red coloration, intensity of which is measured (162).

XVII. TRADITIONAL DETERMINATIONS

The principle of the titration method is based on the iodometric determination by following reactions

$$2KBrO_3 + 3CH_3\text{-}CH{=}CH\text{-}CH{=}CH\text{-}COOH + 10KBr + 6H_2SO_4 \longrightarrow 3CH_3\text{-}(CHBr\text{-}CHBr)_2\text{-}COOH + 6K_2SO_4 + 6H_2O$$

$$KBrO_3 + 6KI + 3H_2SO_4 \longrightarrow KBr + 3K_2SO_4 + 3I_2 + 3H_2O$$

$$I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6$$

A direct spectrofotometric determination of SA in clarified liquid media is based on a linear dependence of absorbance on SA concentration in a liquid media at the maximum absorption wavelength of 262 nm by Lambert-Beer's law (163).

XVIII. THIN-LAYER CHROMATOGRAPHY

SA may be determined directly in alkaline extracts (164). Separation on a silica gel layer is effective with mobile–phase n-hexane–diethylether–formic acid mixture. Samples are usually developed on by ascending or descending techniques in n-butanol–ammonia–water–ethanol, or n-butanol–ethanol–ammonia mixture, respectively. For detection, $K_2Cr_2O_7/H_2SO_4$ mixture is applied first, then sprayed with saturated thiobarbituric acid solution. After further drying, a pink spot on a white background appears (165).

XIX. HIGH-PRESSURE LIQUID CHROMATOGRAPHY

Sample treatment is usually limited only to filtration (removal of solid particles) and sonication (removal of gases, mainly CO_2 from carbonated drinks). The detection limit can be enhanced by measuring the absorption maximum of SA at 259 nm. When solid samples are analyzed, SA is extracted from a matrix by the following procedures:

1. Direct extraction of an acidified sample by organic solvent
2. Solid-phase extraction
3. Extraction as an ion pair
4. Steam distillation

Fatty samples such as margarine are dissolved in non-polar solvent (diethyl ether, hexane, petroleum ether), and extracted twice with NaOH in a separating funnel. The basic aqueous extracts are acidified with H_2SO_4 and diluted to the appropriate volume with methanol. Sample preparation as well as HPLC conditions are summarized in Table 96.3.

XX. GAS CHROMATOGRAPHY

Also, gas chromatography is a simple and reliable method for the determination of SA directly or after derivatisation

TABLE 96.5
Sample Treatment and Determination of Sorbates by Capillary Electrophoresis

Sample	Separation Conditions	Detection Wavelength	Ref.
Fruit juices, cordials, soft drinks, wine, jams, dips, cheese slices	50 mM SDS, 20 mM disodium hydrogen phosphate (pH 9.2)	230 nm	186
Soy sauce, dilution with ethanol-water Plum preserves, sonication and extraction	Running buffer α/β-cyclodextrin in borax-NaOH buffer, fused capillary column 50 μm × 47 cm, electric potential of separation 20 kV	diode array	187
Soft drinks, soy sauces, bean curd	25 mM sodium phosphate (pH 10.0)	248 nm	188

without any interference from coextracts using FID or MS detectors. Sample preparation as well as GC conditions are summarized in Table 96.4.

XXI. CAPILLARY ELECTROPHORESIS

CE is a highly effective analytical technique, applied for sorbates determination over the recent decade. It possesses the advantages of high separation efficiency, excellent resolution and short analysis time. Also, it consumes less solvent and sample than HPLC. Moreover, CE methods employing cyclodextrins as modifiers can satisfactorily separate enantiomers and chiral drugs (193). Some data regarding separation conditions are summarized in Table 96.5.

XXII. ENZYMATIC DETERMINATION

The method is based on spectroscopic measurement of sorbyl coenzyme A (sorbyl CoA) at 300 nm. SA is converted to sorbyl CoA with acyl CoA synthetase in the presence of coenzyme A and ATP. The reaction is made quantitative by the irreversible hydrolysis of pyrophosphate, formed during the acylation reaction, to phosphate in the presence of inorganic pyrophosphatase Absorbance measured at 300 nm is specific for sorbyl CoA and is proportional to the SA concentration in the sample solution (189).

97 Artificial Sweeteners: An Overview

Mia M.E. Eeckhout
Department of Biotechnological Sciences, Hogeschool Gent

CONTENTS

I. INTRODUCTION

Although sweeteners can be grouped in a number of different ways, the grouping "nutritive" and "non-nutritive" acknowledges a difference in the amount of energy provided by sweeteners. (1) Nutritive sweeteners provide a sweet taste and a source of energy; non-nutritive sweeteners are sweet without providing energy. Nutritive sweeteners include sugar sweeteners (e.g., refined sugars, high fructose corn syrup, crystalline fructose, glucose, dextrose, corn sweeteners, honey, lactose, maltose, various syrups, invert sugars, concentrated fruit juice) and reduced-energy polyols or sugar alcohols (e.g., sorbitol, mannitol, xylitol, isomalt, and hydrogenated starch hydrolysates).

The claim that nutritive sweeteners have caused an increase in chronic disease (e.g., obesity, cardiovascular disease, diabetes, dental caries, behavioral disorders) is not substantiated but many consumers want the taste of sweetness without added energy. (2) The food industry has responded to this demand by producing a number of energy-reduced or non-nutritive sweeteners. Although some of the non-nutritive sweeteners are natural (e.g. Thaumatin) consumers refer to them as artificial components resulting from chemical or enzymatic production processes.

Non-nutritive sweeteners (e.g., saccharin, aspartame, acesulfame-K, cyclamate, neohesperidin, etc.) offer no energy, and, as they are to be used in small amounts, can also be referred to as *high-intensity* sweeteners. Both polyols and non-nutritive sweeteners can replace sugar sweeteners and are therefore termed sugar substitutes, sugar replacers or alternative sweeteners. Some of those non-nutritive sweeteners are artificial (e.g., aspartame and acesulfame) others are extracted from natural raw material (e.g. Stevioside, Thaumatin, etc.). (3) With five sweeteners already in use on the European continent, several new sweeteners, including aspartame-acesulfame salt and sucralose are pending approval, and the derivates of aspartame, alitame, and neotame are being reviewed by the U.S. Food and Drug Administration (FDA).

II. SWEETNESS PERCEPTION AND MEASUREMENT

The theory for sweetness perception was developed by Shallenberger and Acree, describing sweet taste as a result of an interaction between a proton donor and a proton acceptor on the sweet molecule, with a distance of approximately 0.3 nm, and a complimentary system located in the membrane of taste receptor cells. (4) This initial step in taste reception takes place at the apical end of the taste receptor cells that are situated in taste buds in the papillae of tongue, palate, and throat. Each bud is composed of 50–100 cells. Sweetness response depends on the accession of the sweetener molecule to a receptor site of the plasma membrane of a receptor cell in the mouth. Chemically a complexation reaction resulting in conformational changes stands at the base of a change in electrical potential of the cell membrane. The sweet taste sensation is caused by the potential change of the membrane, resulting in a release of neurotransmitters. Stereochemical fitting influences the intensity of the sweet taste. (4,5,6)

Extensive studies on three well-known commercial sweeteners (saccharin, acesulfame-K, and sodium cyclamate) resulted in a good understanding of the mechanism responsible for the sweet taste. The sweetness of these molecules has been rationalised on the basis of molecular models of their multiple interactions with the protein receptor in which the hydrophobic attractions are critical for both sweetness and intensity.

Substitution of the crucial bounding positions of the sweetener molecule resulted in a loss of sweet taste. (7,8) Recent studies identified the T1R2–T1R3 receptor responsible for sweet taste (9,10,11).

Artificial sweeteners have low molecular weight in contrast to some sweet tasting proteins (thaumatin) which are large molecules. Temussi (12) proposes that those proteins also do attach to a binding site on the T1R2–T1R3 receptor and probably stabilize the active form of the receptor, resulting in sweet taste. One can expect that future

TABLE 97.1
Sweetness Intensity of Sweetners Compared to Sucrose

Sweetener	Intensity
Sucrose	1
Fructose	1.73
Invert sugar	1.30
Glucose	0.74
Maltose	0.32
Lactose	0.16
Saccharin	550
Aspartame	200
Acesulfame K	200
Cyclamate	35
Neohesperidin dihydrocalcone	330
Thaumatin	3500
Alitame	2500
Neotame	2000
Stevioside	160
Rebaudioside A	250
Sucralose	600

studies will result in a better understanding of molecular mechanisms underlying taste transduction.

Sweetness is commonly measured by comparison to reference solutions of sucrose. Sucrose is the standard to which all sweeteners are compared. Humans can recognize sweetness in about 1 or 2% sucrose solution. Coffee is typically sweetened to about the level of 5% sucrose. A level of 15% sucrose is very sweet and starts to feel syrupy. In between these concentrations, taste panellists usually are trained to quantify sweetness using 2–15% sucrose solutions as references. (13) The evaluation of sweeteners results in intensity factors relatively versus sucrose which is given the intensity factor 1 (Table 97.1) These factors can vary depending on the concentration of the sweetener and the system they are used in. The presence of other substances as salt, starch, and proteins will influence the intensity. Some of the sweeteners have an extremely bitter aftertaste which limits their use in food systems.

III. SUGAR ALCOHOLS: OVERVIEW

Two types of sweeteners, including sugar alcohols and no-calorie or non-nutritive sweeteners, are used to replace sugars in foods.

Sugar alcohols or polyols are bulk sweeteners, also called extensive sweeteners, which provide sweet taste without a bitter aftertaste. They introduce less calories in comparison with sucrose and may be useful to people with diabetes.

They are suitable for a variety of products reduced in calories, sugar, or fat and some of them have been used for almost half a century.

The energetic value of polyols is difficult to measure and varies from product to product. The European Union (EU) has provided a Nutritional Labeling Directive stating that all polyols have a caloric value of 2.4 kcal/g or 10 kJ/g, which is 50% compared to sucrose. The FDA accepts this value and so, as in the U.S. a product qualified as "reduced calorie" should have a reduction in calories of at least 25% and products referred to as "light" must have a one-third reduction, polyols can be used in formulation of "reduced calorie" products.

Another benefit of the use of polyols is that they are non-cariogenic because they are resistant to metabolism by oral bacteria which break down sugars to release organic acids that may lead to cavities or erode tooth enamel. (1)

When sugar alcohols are used, they are slowly absorbed so the increase in blood glucose level and insuline response associated with the ingestion of glucose is significantly reduced.

A. SORBITOL

Sorbitol or glucitol has first been discovered in 1872. It occurs naturally in a wide range of fruits and berries. Today it is commercially produced by the catalytic hydrogenation of glucose at high temperature and pressure, and is available in both liquid and crystalline form.

Sorbitol is used as a humectant in many products for protection against loss of moisture content. The moisture-stabilizing and textural properties of sorbitol are used in the production of confectionery, baked goods, and chocolate, where products tend to become dry or harden. Its moisture-stabilizing action protects these products from drying and maintains their initial freshness during storage.

Sorbitol is very stable and chemically unreactive. It can withstand high temperatures and does not participate in Maillard reactions, which are responsible for the browning of food products containing reducing sugars.

Sorbitol has been affirmed Generally Recognised As Safe (GRAS) by the FDA and is approved for use by the EU and numerous countries around the world, including Australia, Canada, Japan.

The Joint Expert Committee on Food Additives (JEFCA) has established an acceptable daily intake (ADI) for sorbitol of "not specified." In 1985 the Scientific Committee for Food (SCF) of the EU concluded that sorbitol is acceptable for use without limit. When one may expect that daily consumption of a food would result in the ingestion of 50 grams of sorbitol, the label should carry the warning: "*Excess consumption may have a laxative effect*."

B. XYLITOL

Xylitol is a polyol used in foods since the 1960s. It was discovered in 1891. It is a white crystalline powder with a

sweet taste, and is odourless. It occurs naturally in many fruits and vegetables and is even produced by the human body. It is commercially produced from plants such as birch and other hard wood trees and fibrous vegetation. Xylitol can be synthesized by hydrogenation of Xylose. Xylitol can also be produced by microbial transformation reactions, such as from D-glucose by yeast or from D-glucose by yeast and bacteria. For example Xylitol can be produced from D-xylose using the commercial immobilized D-xylose isomerase of *Bacillus coagulans* or immobilized cells of *Mycobacterium smegmatis*.

Xylitol has the same sweetness and bulk of sucrose with one-third fewer calories.

One of the most important advantages of xylitol is his effect in reducing tooth decay rates.

Xylitol is approved for use in foods (chewing gum, hard candy), pharmaceuticals (cough syrup, chewable multivitamins) and oral health products (toothpastes and mouthwashes) in more than 35 countries.

C. Lactitol

Lactitol, discovered in 1920, was first used in foods in the 1980s. Lactitol has a sweet taste that closely resembles the taste profile of sucrose. It has only 40% of sucrose's sweetening power. This mild sweetness makes it an ideal bulk sweetener to partner with low-calorie sweeteners such as acesulfame K, aspartame, and saccharin.

Lactitol is produced by reduction of the glucose part of the disaccharide lactose. Unlike the metabolism of lactose, lactitol is not hydrolysed by lactase. It is neither hydrolysed nor absorbed in the small intestine. Lactitol is metabolised by the bacteria in the large intestine, where it is converted into biomass, organic acids, carbon dioxide, and a small amount of hydrogen. The organic acids are further metabolised, resulting in an energy contribution of 2 kcal or approximately 8.4 kJ per gram.

Internationally it is approved as safe for use in many countries, including the EU, Canada, Japan, Israel, and Switzerland. Due to its GRAS status production, distribution of foods containing lactitol is allowed in the US.

Due to its stability at high temperatures, its solubility similar to glucose, and similar taste to sucrose, lactitol can be used in a variety of low-calorie, low-fat, and/or sugar-free foods such as ice cream, chocolate, candies, baked goods, and chewing gums.

D. Maltitol

Maltitol is made by the hydrogenation of maltose, which is obtained from starch. Like other polyols it does not brown or caramelise as sugars do. Maltitol has a sweet taste similar to sucrose. It is about 90% as sweet as sucrose, with the supplementary advantages of being non-cariogenic and reduced in calories.

Although maltitol is often used to replace sugars in the manufacture of sugar-free foods, it may also be used to replace fat, as it gives creamy texture to food.

IV. NON-NUTRITIVE SWEETENERS

A. Aspartame

Aspartame, currently market leader among artificial sweeteners, was discovered accidently in 1965 by James Schlatter.

Aspartame was approved for use as a tabletop sweetener and in powdered mixes in 1981 by the FDA. Since then, a number of people have questioned the studies that led to this decision. However, repeated studies done on aspartame show that it is harmless to people in the amount that it is normally ingested. In 1996, it was approved for use in all foods and beverages, including products such as syrups, salad dressings, and certain snack foods where prior approval had not yet been obtained. Products that may contain aspartame include low-calorie beverages, sugar-free gelatins, puddings, frozen desserts, and cereals as well as tabletop sweeteners (13).

1. Chemical and Physical Properties

Amino acids are relatively tasteless, nonetheless they contribute to the flavour of foods where they show flavour enhancing properties.

Glycine, for example, has a refreshing sweetish flavour when used as an additive in vinegar, pickles, and mayonnaise. Beyond its attenuation of the sweet taste, it lends some sweetness to the aroma. For same reason, D- and L-Alanine are used in the Far East. For the most part, dipeptides and oligopeptides have a bitter flavour. For this the sweet taste of aspartame was very remarkable (14).

Aspartame (E 951) is a methylester of two amino acids, aspartic acid and phenylalanine. N-L-alpha-Aspartyl-L-phenylalanine 1-methyl ester (Figure 97.1), or aspartame, is 150–200 times sweeter than sucrose. Its molecular weight is 294.31 g/mol and its melting point is 249°C. It is a white crystal solid which has a modest solubility in aqueous solution, but because of its high sweetening capability there is no need to dissolve large amounts (14). It mixes well with other solids.

Aspartame has a sweet taste comparable to saccharose. As aspartame is a dipeptide ester, it can be metabolised and has a nutritive factor of 17 kJ/g. Because of his high sweetening intensity it is only used in small amounts in comparison to bulk sweeteners, so calorie intake is reduced.

It is heat unstable so it can not be added previous to cooking or baking process.

Encapsulation of aspartame is used in chewing gum. Through encapsulation the product can be protected from

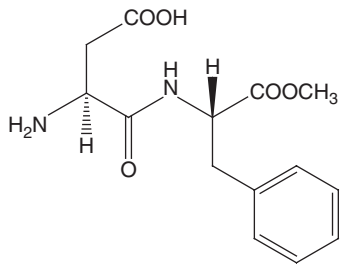

FIGURE 97.1 Aspartame.

moisture, heat, or other extreme conditions, thus enhancing stability and maintaining viability. It also can induce the slow release of flavour (15).

The major degradation product at higher temperatures is dioxopiperazine. The dioxopiperazine is also formed during storage. These two compounds have been satisfactorily assessed in a large number of studies in humans, and an ADI has been established for each of them: 40 mg/kg body weight for aspartame and 7.5 mg/kg body weight for dioxopiperazine.

2. Metabolism

The metabolites of aspartame in humans are compounds generally occurring in food. They are also produced by the endogenous cellular metabolism.

Aspartame is a minor source of phenylalanine, aspartic acid, and methanol compared with the standard dietary intake of these substances. Therefore, one can suppose they cannot be the source of the toxic neurological effects attributed to aspartame. The only problem with aspartame is in the case of phenylketonuric patients, due to inability to metabolise phenylalanine.

3. Synthesis

The synthesis of aspartame can be carried out via enzymatic or chemical methods.

Phenylalanine and aspartic acid are both chiral, which means that they have two isomers. If the incorrect enantiomers are used, the aspartame molecule will not have sweetening capacity due to the fact that it will not fit the binding site of the "sweetness" receptors on the tongue.

In the synthesis of aspartame, the starting materials are a racemic mixture of phenylalanine and aspartic acid. Only the L enantiomer of phenylalanine is used, which is separated from the racemate by reacting it with acetic anhydride and sodium hydroxide. Treatment of L-phenylalanine with methanol and hydrochloric acid esterifies the $-CO_2H$ group, and this ester is then reacted with aspartic acid to give the final product (16).

The chemical synthesis of aspartame requires protection of both the β-carboxyl and the α-amino groups of the L-aspartic acid. Even then, it produces aspartame in low yield and at high cost. If the β-carboxyl group is not protected, a cost saving is achieved but about 30% of the β-isomer is formed and has, subsequently, to be removed. When thermolysin is used to catalyse aspartame production the regio-specificity of the enzyme eliminates the need to protect this β-carboxyl group but the α-amino group must still be protected to prevent the synthesis of poly-L-aspartic acid. More economical racemic amino acids can also be used, as only the desired isomer of aspartame will be formed (17).

4. Applications

Aspartame's most important use is as tabletop sweetener, and it is commercialised under various brands (Canderel™, Equal™, NutraSweet™). Because of its numerous advantages such as low calorie, cost saving, no aftertaste, tooth-friendly, etc., aspartame is used in the manufacture of many sugar-free, energy-reduced, diet or light products, such as beverages (carbonated and still soft drinks, dilutables, fruit-juice drinks, and fruit syrups), dry mixes (hot and cold chocolate and beverage mixes and instant desserts), dairy products, confectionery, and pharmaceuticals (tablets, sugar-free syrups, etc.).

5. Safety and Legislation

Prior to marketing, the safety of the high-intensity sweetener aspartame for its intended uses as a sweetener and flavor enhancer was demonstrated by the results of over 100 scientific studies in animals and humans. In the postmarketing period, the safety of aspartame was further evaluated. The results of the extensive intake evaluation in the United States, which was done over an 8-year period, and the results of studies done in other countries demonstrated intakes which were well below the acceptable daily intakes set by the FDA and regulatory bodies in other countries, as well as the Joint FAO/WHO Expert Committee on Food Additives. Scientific evidence confirms that, even in amounts many times what people typically consume, aspartame is safe for its intended uses as a sweetener and flavour enhancer (18).

B. Saccharin

The first artificial sweetener discovered was Saccharin. It was accidentally found in 1879 by Fahlberg. The name "saccharin" results from the Latin word *saccharum*, which means sugar. Saccharin was used as a sweetener only sporadically until World War I. During and after the war the consumption of saccharin increased, as did the number of products that used saccharin. World War II led to another significant increase in the saccharin use and a proliferation of products that used the sweetener.

When, in 1960, tests began to suggest that saccharin caused bladder cancer in lab rats, the FDA moved to limit

its use. Its use was banned in Canada in 1977. The FDA considered banning it in 1977 based on this animal research. Later, more research on saccharin's safety was carried out. The FDA withdrew the ban in 1991, safety studies carried on. While numerous studies since 1977 have clearly shown that saccharin does not cause cancer in humans in the doses that people take it in, in the U.S. labels on products with saccharin must still carry a statement that says saccharin has caused cancer in laboratory animals. Currently saccharin is used in more than 90 countries, including the EU.

Saccharin is about 300 times sweeter than table sugar. It is used in several brands of tabletop sweeteners and in canned foods and beverages and low-calories soft drinks.

1. Chemical and Physical Properties

Saccharin (E954), discovered in 1879, is the oldest non-nutritive sugar which has been used in foodstuffs since 1884. Saccharin has many desirable properties that make it a valuable food ingredient. It is extremely sweet and counts no calories.

The ionised form of saccharin is about 300–500 times as sweet as sucrose. Its sweetness depends upon concentration and the type of food it is used in.

Saccharin is the chemical compound 1,2-benzisothiazol-3-one-1,1-dioxide (Figure 97.2). Solid saccharin is a white crystalline, odourless powder. It has poor water solubility with a maximum of 40 g/L at 100°C. The most important form is the sodium salt, which has excellent solubility (19). It is heat stable but has an unpleasant metallic, bitter after-taste. Therefore it is combined with cyclamate.

2. Metabolism

Saccharin is not metabolised in the human body.

3. Synthesis

Saccharin is mostly produced by the Remsen-Fahlberg process, a reaction of toluene and chlorosulfonic acid to a mixture of toluene sulfochlorides. After reaction with ammonia, followed by oxidation, saccharin is formed (14).

4. Safety and Legislation

Because of some concerns raised in the late 1970s, saccharin was at the end of 1972 no longer regarded as GRAS. The use of saccharin was only permitted in certain "special dietary foods" as mentioned, soft drinks, dietary products, and candy. The declaration "this product contains … mg saccharin per ounce." Later, a cancer warning label was required in food stores on shelves containing these food products. In January 1997, on advice of the Calorie Control Council, the FDA agreed to disclaim a supplementary warning system for products containing saccharin (20). In 2000, after more than 20 years of scientific studies, saccharin was given green light for application without a warning label.

In June 1995 the SCF of the European Commission set the ADI for saccharin on 5 mg/kg body weight.

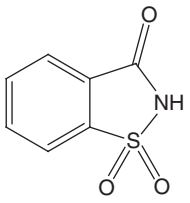

FIGURE 97.2 Saccharin.

5. Benefits and Application

Saccharin provides no calories, can be used in foods for diabetics and has low cost. It is highly stable and shows very good shelf life. Of all sweeteners saccharin has the widest range of applications. It shows some synergetic effect when combined with other sweeteners, resulting in a sweetness which exceeds the sum of both individual additives (21).

It is used in soft drinks, tabletop sweeteners, baked goods, jams, chewing gum, canned fruit, candy, etc. It is also used in cosmetic products, vitamin supplements, and pharmaceuticals.

C. Cyclamate

Cyclamate was developed in 1937 by Abbott Laboratories in the U.S. It has been in broad use in many countries since the 1950s.

Cyclamate is one of the most thoroughly tested food additives. In 1969 cyclamate was banned in the U.K. and U.S. for nearly 30 years. This ban was based on the results of a single study, showing that very high doses of cyclamate caused bladder tumors in rats. These results have not been reproduced in further studies and it was proven that bladder tumors in rats are not relevant for human health.

The FDA concluded in 1984, after reviewing all the scientific evidence available, that there is little data to implicate cyclamate as a carcinogen at any organ or tissue. This was also confirmed by the U.S. Academy of Sciences in 1985. Similar conclusions were reached by the JECFA, the SCF, and the U.K. committee on Toxicity of Chemicals in Foods. (22) As a result, cyclamate was included in the European Directive 94/35/EC (23) on low-calorie sweeteners for use in foodstuffs. In the U.K. it was not permitted until 1 January 1996. It is approved for use in over 55 countries worldwide and has undergone stringent testing 1995 with a review by the European SCF. In July 2002, the SCF reevaluated the sweetener and although the epidemiological data revealed no indications of harmful effects of cyclamates on humans, the committee decided to lower

the ADI for this substance from 11 to 7 mg/kg bodyweight. New scientific evidence has shown the conversion rate of cyclamate in the body to be higher than was previously thought. So the committee proposed reducing the use of cyclamate by banning its use in certain food categories like chewing gums and breath freshening microsweets, and by reducing it in soft drinks (from 400 mg/l to 350 mg/l) to assure that the intake of cyclamates stays below the revised ADI (23,24).

1. Chemical and Physical Properties

The most important cyclamate sweetener is sodium cyclamate. It has been in broad use in many countries since the 1950s.

Cyclamate (E 952) in fact is the name for cyclamic acid or cyclohexylsulphamic acid (Figure 97.3) and its sodium or calcium salts. Its sweetness is approximately 30–50 in comparison with sucrose. Due to its very low sweetening ability and because of the low allowable usage level, it is not possible to use cyclamate on its own to produce an acceptable sweet taste as wished, for example, in soft drinks. So, cyclamate is always used in association with another low calorie sweetener, usually saccharin in a 10:1 mix.

Cyclamate is a white crystalline powder with a melting point of 170°C. It is water soluble up to concentrations of about 150–200 g per litter. It is relatively heat-stable. Cyclamates can add heat stability to formulations with aspartame. It has good shelf life. In high concentrations cyclamate has an unpleasant aftertaste but at low concentrations it has some bitterness-masking ability.

When combined with acesulfame and aspartame it appears to have some synergistic qualities, resulting in a higher sweetness of the sweetener mix than the sum of the individual non-nutritive sweeteners. Cyclamate can serve as an excellent complement to other low-calorie sweeteners which are available and, particularly because of its unique synergistic sweetening properties, makes possible a wider variety of good-tasting low-calorie products.

2. Synthesis

The production of Sodium and Calcium Cyclamate includes the reaction of cyclohexylamine with sulfamic acid, salt determination, isolation, filtration, re-crystallization, drying and selection of particle size desired by the customer.

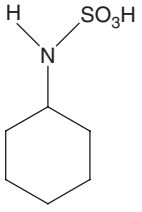

FIGURE 97.3 Cyclamate.

The reaction is carried out under high pressure and elevated temperature (25).

3. Metabolism

Cyclamate is not metabolized in the body, so it is considered as non-nutritive.

The metabolic conversion of cyclamate to cyclohexylamin (CHA) has been extensively studied in over 1000 human subjects. Research showed an extreme individual variability and urinary excretion of cyclohexylamin. The urinary excretion of cyclohexylamin was found to be extremely variable from individual to individual and fluctuated greatly from day to day. Approximately 30% of the test population convert cyclamate to cyclohexylamin, but the majority of these convert less than 0.1% to approximate 8% of the ingested cyclamate. A minor part converted up to 60% of the ingested cyclamate to CHA (26,27,28).

Neither cyclamic acid nor its salts are metabolised in the human body. In humans transcyclohexan-1,2-diol is found as a metabolite of cyclohexylamine which could probably be synthesized from cyclamate due to some *Enterococcus* species in the intestine.

4. Benefits and Applications

Calcium cyclamate is less sweet than sodium cyclamate. The primary use of cyclamate is as a non-caloric sweetener in combination with other sweeteners. Cyclamates can also be used as flavouring agents, such as to mask the taste of unpalatable drugs. Cyclamates have use in a variety of applications: as tabletop sweeteners, in tablet, powder, or liquid form, in beverages, fruit juice drinks, processed fruits, chewing gum and confectionery, salad dressings, gelatin desserts, jellies, jams, and toppings

Due to their good heat stability, cyclamates can be used in baked goods, jams, jellies and candies, and canned fruit. The main application of cyclamates is in blends with saccharin in a 10:1 ratio.

5. Safety and Legislation

Cyclamate is approved for use in over 55 countries worldwide and has undergone stringent testing as recently as 1995 with a review by the European SCF. In the opinion expressed in March 2000, the SCF established a new ADI of 0–7 mg/kg bodyweight for cyclamic acid and its sodium and calcium salts, expressed as cyclamic acid. More recent intake data submitted in Denmark suggest that the intake of cyclamates in children with a body weight of 15 kg (3 years old) could easily exceed the ADI. As a consequence the commission of the European Communities presented in July 2002 a proposal for a directive amending directive 94/35/EC on sweeteners for use in foodstuffs (16). In this proposal the maximum usable dose

of "400 mg/l" is replaced by "350 mg/l" for the category "water-based flavoured drinks, energy reduced or with no added sugar" furthermore, some food categories and maximum usable doses are deleted (confectionery, chewing gum, breath freshening micro-sweets, edible ices). Some commissions within the European Parliament suggest an even lower maximum dose of 250 mg/l and propose that the allowable dose for milk-based drinks should also be reduced.

D. Acesulfame-K

A third artificial sweetener, acesulfame potassium, was discovered in 1967 by Hoechst AG. It was approved for use in the U.S. by the FDA in 1992 for gums and dry foods, and it was finally approved for liquid use in 1998. As soon as it was approved, it was used in a new soft drink (Pepsi One).

1. Chemical and Physical Properties

Acesulfame-K is the potassium salt of 6-methyl-1,2,3-oxathiazin-4-one-2,2-dioxide (Figure 97.4). Its properties are very similar to those of saccharin but it has a better flavour with a much reduced bitter aftertaste. It is about 200 times sweeter than sugar and is often used in soft drinks combined with aspartame. It is soluble in water, resulting in a neutral solution. At 225°C it starts decomposing. In a pH range of 3–7 it is virtually stable. It has a very good stability to baking, UHT, and microwave heating.

Acesulfame-K is not metabolised in the body and is in this way excreted by the kidneys.

2. Benefits and Application

It has a nice sweet taste with only slight aftertaste at high concentrations above normal use levels. It has good shelf life and is very stable to processing. It shows some synergistic effects and has the capacity to enhance and intensify flavours.

Acesulfame-K can be used in all areas where sweeteners can be used to enhance taste or to reduce calories by replacing sugar: beverages, dairy products, jams, and baked goods.

3. Safety and Legislation

Like all other low-calorie sweeteners, acesulfame-K has been tested in numerous studies to determine its safety. It is not metabolised by the body but is excreted unchanged and does not affect the normal functions of the human body.

The World Health Organisation's Joint FAO/WHO Expert Committee on Food Additives have set an ADI for acesulfame-K of 15 mg per kg of body weight per day. In addition at European level, in March 2000, the European Commission's SCF confirmed its ADI of 9 mg/kg.

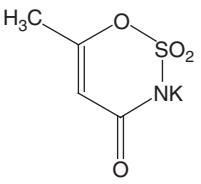

FIGURE 97.4 Acesulfame-K.

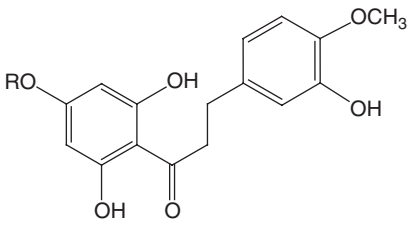

FIGURE 97.5 Neohespiridin DC.

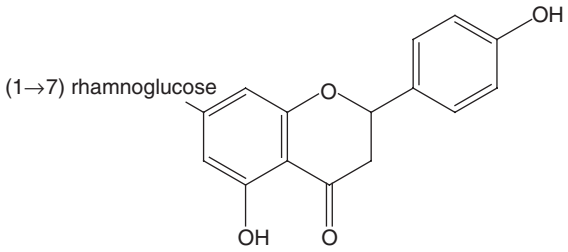

FIGURE 97.6 Hesperidin.

E. Neohesperidin DC

Neohesperidin dicalcone (Figure 97.5) has been known for some time. It is sweet with a specific aftertaste and is always used in combination with other (intensive) sweeteners. It is also used as flavour enhancer. Its produced by hydrogenation of hesperidin (Figure 97.6), a flavonoid occurring in bitter oranges. Neohesperidin is not absorbed by the human body, but it can be metabolised by the intestinal flora.

1. Chemical and Physical Properties

Neohesperidin DC is stable in aqueous solutions and shows a good shelf life at normal storage temperatures and pH 1–7. It is heat stable and can therefore be used in processed food.

Neohesperidin DC is an intensive sweetener and has the capability to intensify the sweetness of intensive and bulk sweeteners when used in combination (31).

Table 97.2 shows the experimental values for maximum synergy of mixtures with Neohesperidin for aqueous systems. This result implicates that the dose of any other sweetener used in combination with Neohesperidin can be lowered. Although Neohesperidin is more expensive, the

TABLE 97.2
Sweetening Synergy of Neohesperidin DC in Combination with Intense Sweeteners and Sugar Alcohols

Sweetener	Sweetening Synergy (%)
Aspartame	64
Acesulfame-K	83
Saccharin	81
Cyclamate	42
Lactitol	60
Xylitol	86
Isomalt	60

use of combinations with other sweeteners saves ingredient cost. As an example, for use in chewing gum a concentration of 3000 ppm of aspartame may be replaced by a mixture of 1500 ppm aspartame in combination with 190 ppm Neohesperidin, resulting in equal sweetness.

Not only is sweetness intensity changed, but there is also an influence on the quality of the taste, resulting, for example, in a less bitter aftertaste when combined with saccharin or acesulfame-K, even at low concentrations. Neohesperidin DC can still improve the overall flavour profile of foods (32).

2. Benefits and Applications

In fruit drinks, carbonated drinks, still drinks, powdered drink concentrates, syrups, sport drinks, dark sweet beer etc. Neohesperidin DC can extend shelf life by masking the off flavour resulting from the decomposition of unstable flavour components. It is used as sweetener or as flavour enhancer, the latter in a much lower concentration level (ex. 5 ppm versus 30 ppm in beverage). Neohesperidin DC enhances creaminess and fruit flavours in yoghurts and other dairy products. Furthermore, it can be used in chewing gum, confectionery, and pharmaceuticals. Neohesperidine DC improves the organoleptic properties and palatability of animal feed and pet foods.

F. SUCRALOSE

The discovery by Hough and Khan of the enhanced sweetness of the chlorodeoxy-derivatives of sucrose raised the problem of the explanation of the enhancement of sweetness after chlorinating (33). Wiet and Miller suggested that chlorine substitution is merely enhancing the intrinsic sensory qualities of sucrose. Other chemical modifications of sugars generally lead to bitter derivatives. Depending on the position of the chloro-substituent and the resulting hydrophilic/hydrophobic balance of the molecule, the derivatives of sucrose may be found to be intensely sweet, sweet, bitter-sweet, or even extremely, bitter (34).

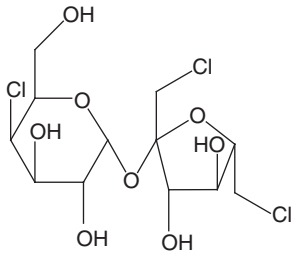

FIGURE 97.7 Sucralose.

1. Chemical and Physical Properties

Sucralose (trichlorogalactosucrose or 1,6-dichloro-1,6-dideoxy-β-D-fructofuranosyl-4-chloro-4-deoxy-β-D-galactopyranoside) (Figure 97.7) is the only non-nutritive sweetener based on sucrose which was selectively chlorinated. It has been developed by Tate and Lyle and McNeil Speciality Products in the United States.

Its sweetness is 400–800 times the sweetness of sucrose, depending upon the concentration of sucrose which is being matched. For water the more the concentration of sucralose increases the lower the response.

Its flavour profile indicates that it is very similar to sugar, with less aftertaste often associated with intense sweeteners. This sweetener is relatively heat stable in cooking and baking. The instability of three intense sweeteners, aspartame, acesulfame-K, and sucralose, has been evaluated. They were added as a single product in lime-lemon flavoured carbonated beverage which was stored for 60 days at 4°, 27°, and 37°C. At the end of 60 days storage the loss of aspartame was maximum (29.5%), acesulfame-K decreased with 6.1%, while the loss of sucralose was minimum (1.9%). Thus sucralose was more stable than the other sweeteners (35).

At high temperature in aqueous solution it is hydrolysed to a limited extent producing 4-chloro-4-deoxy-galactose and 1,6-dichloro-1,6-dideoxy-fructose. It is stable during long term storage. It blends with sugar, which enables the production of products with reduced sugar level. It is very soluble in water.

2. Metabolism

The glycosidic link between the two rings is resistant to hydrolysis by acid or enzymes, so it is not metabolised. Sucralose provides no energy and there are no known derivates. It is not well absorbed and is excreted in the urine essentially.

3. Safety and Legislation

Sucralose was approved in the U.S. in April 1998 as a tabletop sweetener and for use in a number of desserts, confections, and non-alcoholic beverages. FDA concluded from a review of more than 110 studies in human beings and animals that this sweetener did not pose

carcinogenic, reproductive, or neurologic risk to human beings. Towards the end of 2000 Tate and Lyle applied for approval of sucralose on an EU-wide basis. The SCF has assessed the data on the safety of sucralose and issued its opinion in September 2000. This concluded that "sucralose is acceptable as a sweetener for general food use and a full Acceptable Daily Intake (ADI) of max 15 mg/kg body weight can be established" The SCF proposed an amendment to the EC Sweeteners Directive, including the addition of sucralose to the list of approved sweeteners. The ADI set for sucralose by the joint FAO/WHO Expert Committee on Food Additives made the same statement in 1990. In the U.K. the Committee on Toxicity in Food, Consumer Products, and the Environment (COT) which advises the U.K. government on food safety issues relevant to the use of additives has endorsed the SCF opinion on sucralose and concluded no further separate safety assessment was needed.

TABLE 97.3
Maximum Usable Dose Proposed for Sucralose in Some Foodstuff Categories

EC No	Name	Foodstuff	Maximum Usable Dose
955	Sucralose	Non-alcoholic drinks	300 mg/l
		Desserts and similar products	400 mg/l
		Confectionery with no added sugar	1000 mg/l
		Breath-freshening micro-sweets, energy reduced or with no added sugar	2400 mg/l
		Chewing gum with no added sugar	3000 mg/l
		Energy reduced jams, jellies, marmalades	400 mg/l
		Fine bakery products, energy reduced or with no added sugar	700 mg/l

In July 2002 the commission of the European Community proposed a Directive amending Directive 94/35/EC on sweeteners for use in foodstuffs with as major amendment the authorisation of two new sweeteners; sucralose and the salt of aspartame-acesulfame.

Table 97.3 gives some examples of foodstuffs with maximum usable dose as listed in the annex of the directive.

4. Benefits and Applications

Intense sweeteners have benefits for diabetics and for people who wish to reduce their calorie intake by reducing the sugar intake. If a new sweetener is introduced and asks for approval some additional benefits should be available. These benefits result from the taste profile and the stability characteristics of sucralose. Its heat stability will enable the food industry to produce a wider range of calorie reduced products and a commercialised tabletop sweetener can be used in home cooking and baking process.

G. Aspartame-Acesulfame Salt

The salt of aspartame and acesulfame (6-methyl-1,2,3-oxathiazine-4(3h)-one-2,2-dioxide salt of l-phenylalanyl-2-methyl-l-alpha-aspartic acid) is, as the name already indicates, a salt of two already authorized sweeteners (E 950 and E 951). It is manufactured from these two substances by replacing the potassium ion of acesulfame K by aspartame. For the purposes of ingredient listing, the product would be known as "aspartame – acesulfame salt." As the salt is not yet approved for use in the EU it does not have an "E" number. The SCF regarded, after assessment of the safety data, the use of the salt of aspartame and acesulfame acceptable as an additive considering that it is in fact an alternative for two already authorized additives, the potential exposure equals that of an equivalent blend of aspartame and acesulfame K, and no additional safety considerations were made (24). The

TABLE 97.4
Maximum Usable Dose for Aspartame-Acesulfame Salt and its Constituents Equivalent in Some Foodstuff Categories

			Maximum Usable Dose		
EC No	Name	Foodstuff	Salt	Aspartame Eq.	Acesulfame K Eq.
E 962	Aspartame-Acesulfame Salt	Non-alcoholic drinks	796 mg/kg	512	350
		Desserts and similar products	796 mg/kg	512	350
		Confectionery with no added sugar	1137 mg/kg	731	500
		Breath-freshening micro-sweets, energy reduced or with no added sugar	5683 mg/kg	3656	2500
		Chewing gum with no added sugar	4546 mg/kg	2925	2000
		Energy reduced jams, jellies, marmalades	1554 mg/kg	1000	350
		Fine bakery products, energy reduced or with no added sugar	2273 mg/kg	1462	1000

use of the salt is therefore proposed for food categories where both aspartame and acesulfame are used. Aspartame and acesulfame moieties are covered by the ADIs established previously for aspartame (0–40 mg/kg body weight) and acesulfame potassium (0–15 mg/kg body weight). The maximum usable doses for aspartame shall, however, not be exceeded by the use in combination with the salt.

1. Physical Properties

The benefits mentioned by the manufacturer and listed in annex of the Directive are the following.

The potassium in acesulfame K is eliminated when the salt is made, as is the moisture contained in aspartame. Therefore, the salt represents a more concentrated source of sweetness without the functionless presence of potassium and water.

It dissolves in water significantly more rapidly than an equivalent blend of aspartame and acesulfame-K. Instant powder products such as desserts, toppings, and powder beverage mixes perform better during reconstitution by the consumer. Similarly, tabletop sweeteners dissolve faster, especially in cold beverages.

It is more stable in certain applications than aspartame alone. Therefore, it can be used in applications where aspartame has either required encapsulation for protection or has been substituted by sweeteners of inferior taste such as saccharin. The consumer benefits from products of an improved taste and prolonged shelf life.

2. Benefits and Applications

It improves the sweetness of chewing gum and gives the gum a very long-lasting quality without recourse to encapsulation of the sweetener, for example with polymer coatings. The consumer experiences an improved product quality at potentially lower costs.

It disperses easily in previously difficult applications, such as sugar-free hard candy and sugar-free chocolate, where a blend of sweeteners is difficult to employ.

In instant powder products, the salt provides a guaranteed balanced sweetness throughout the dissolution process where a blend of the two individual sweeteners does not, since acesulfame K dissolves faster than aspartame.

It is not hygroscopic and thus much easier to store and requires less stringent packaging. This benefits products that are stored in containers that are repeatedly opened and closed allowing contact with atmospheric moisture.

It has superior powder-flow properties and thus avoids inconsistencies in powdered products in which the consumer may previously have experienced variations in taste quality and/or sweetness level.

H. Neotame

Neotame is a derivative of the dipeptide composed of the amino acids aspartic acid and phenylalanine. It is 7,000–13,000 times as sweet as sucrose and 30–60 times as sweet as aspartame. It produces no aftertaste. It can used alone or in blends with other high intensity sweeteners or bulk sweeteners (36).

The stability of Neotame is dependent on pH, moisture and temperature (37). It is stable under dry conditions and has comparable stability to aspartame in aqueous food systems and is more stable in neutral pH conditions. When stored under conditions relevant to commercial use (25°C and 60% RH) no loss of Neotame occurred.

The major metabolic pathway is hydrolysis of the methyl ester resulting in de-esterified neotame and methanol. The peptide is not further metabolised because of blockage of the peptidase responsible for the break down of the dipeptide. It is fully eliminated by the body through urine and feces and does not accumulate.

Because it is not metabolised, no phenylalanine is formed and no special labelling for individuals with phenylketonuria (see aspartame) is required.

Extended research has been conducted on Neotame to establish its safety as a general sweetener. Neotame has been approved for general use in Australia and New

TABLE 97.5
Maximum Application Dose of Intense Sweetener in Foodstuffs (mg/kg)

Product Category	Acesulfame	Aspartame	Cyclamate	Saccharin	Thaumatin	NHDC

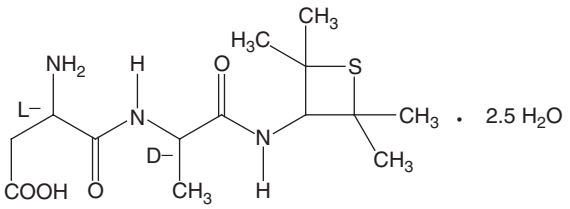

FIGURE 97.8 Alitame.

Zealand. In July 2002 the FDA approved the use of Neotame as a general purpose sweetener. In Europe it is used in Poland, Czech Republic and Roumania (www.neotame.com).

It can be used in foods and beverages and as a table-top sweetener. It can also be used in cooking and baking.

I. Alitame

Alitame (l-a-aspartyl-N-(2,2,4,4-tetramethyl-3-thi-etanyl)-d-alaninamide) is a dipeptide of the complex series l-a-aspartyl-d-alaninamide. It was synthesized in 1979 by Pfizer laboratory researchers and possesses an intense sweet taste, resembling sugar, due to the terminal amide (2,2,4,4-tetramethyl-thietanyl-amine or TTA) (38).

A request of authorization for use was presented to the FDA (U.S.) in 1986 and other countries. It is classified as a non-nutritive sweetener that is approximately 2000 times sweeter than sucrose (39).

The structure of the alitame molecule (Figure 97.8) resembles the well-known artificial sweetener aspartame (N-l-a-aspartyl-l-phenylalanine 1-methyl ester) in the amino acid moiety of aspartic acid. The l-phenylalanine was replaced by d-alanine and the methoxy group of the ester part was replaced by the TTA group in alitame. Alitame owes its increased stability to the terminal amide TTA, forming a second peptide link in the molecule, in comparison with aspartame's methyl ester group (39).

Alitame starts decomposing at 136–137°C. Its solubility is good. Its stability is superior to aspartame at all pH levels.

Alitame is not recognized in the U.S. or Europe. In Australia, New Zealand, Mexico, and China it is used in foods and beverages.

V. NATURAL SWEETENERS

A. Thaumatin

Thaumatin was originally isolated drom fruits of *Thaumatococcus danielli* (Benth), an African plant named in 1839 after Dr. W.F. Daniell. The Talin Food Group markets it under the trade name Talin. It has a sweetness of 1600–2700 times that of a 8–10% solution of surose. The discovery, chemistry, chemical modifications, safety, and practical applications of Thaumatins have been described in several articles (12,40,41,42). Research has been done to reproduce Thaumatin by DNA recombinant technology, but this resulted in a protein with difference in structure and no sweet taste (43).

1. Chemical and Physical Properties

Thaumatin is known as E 957, as a polypeptide with 207 amino acids and a molecular weight for Thaumatin I of 22209 and for Thaumatin II of 22293. The N content is 16%.

Its a creamy coloured powder without smell and with an intense sweet taste. It has a good solubility in aqueous solutions. Energetic value, as for any other protein, is 17 kJ/gram.

Either heat denaturation or cleavage of the disulfide bridges of Thaumatin result in loss of sweetness, implicating that the tertiary structure of the protein is important to sweetness reception.

2. Applications

Applications are few because of a low stability. In the European Community it is used in confectionery, chewing gum, and cacao-based confectionery, ice cream, and tooth paste with a maximum addition of 50 mg/kg. Another important application is the use in animal feed to reduce the bad taste of some raw material used in the formulation.

B. Stevioside and Rebaudioside

Stevia rebaudiana (Bertoni) is one of the 154 members of the genus Stevia. It is a member of the Compositae family with small, white flowers. It is a plant native to the region of Northeastern Paraguay. Stevioside, a diterpene glycoside isolated from the leaves of *Stevia rebaudiana B.*, was first described by Bridel and Laveille in 1993 (44).

The four major glycosides present in the plant tissue are (w/w): stevioside 5–10%; rebaudioside A 2–4% and rebaudioside C 1–2%; and dulcoside A 0.5–1%. During plant breeding studies Brandle noticed high concentrations of rebaudioside C (14.4%) in an *S. rebaudiana* line and a new sweet steviol glycoside F (2.7%) (45,46). They are synthesized in the plant using initially the same pathways as gibberellic acid, a plant hormone. The purpose of the sweet compounds in the plant is not yet determined. Hypothesis exists on their role are as repellent for insects or as a pool for the synthesis of gibberellic acid.

Stevioside is a glycoside with a glycosil and a sophorosyl residue attached to the aglycone steviol. It is a white, crystalline, odourless powder. It ranges in sweetness from 40 to 250 times sweeter than sucrose. Rebaudioside seems to have the best sensory properties.

Good stability has been reported for storage in solution with water at 30°C for 30 days and during long-term storage in carbonated phosphoric acidified beverages (48). Some

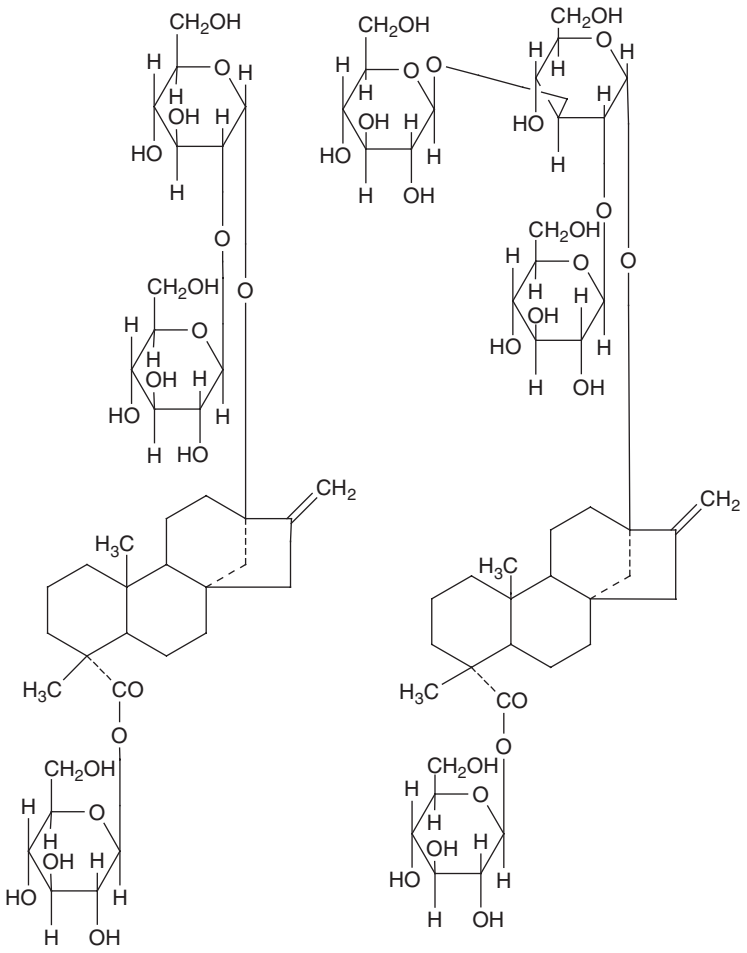

FIGURE 97.9 Stevioside and Rebaudioside.

loss was found for storage at low pH and after heating. Steviol glycosides are heat- and pH-stable, non-fermentable, and do not result in brown colouring effect during the baking process. Therefore they may have a wide range of applications in food products.

Studies carried out mainly in Asian countries have demonstrated no significant toxic activities of stevioside. Stevia sweeteners are in use in Japan, Brazil, and China. In some countries of the European continent (Czech Republic) it is now being used as a food additive. Stevioside is not approved for use in the EU.

VI. METHODS FOR ANALYSIS

The use of sweeteners is, in similarity with all other food additives, regulated and specified by law in most countries. Therefore analytical control of legal limits is essential.

For determination of food additives over the last decades, chromatographic techniques have been applied with large success. HPLC is well suited for the quantitative determination of a wide range of constituents and is well suited for the quantitative determination of complete groups of closely related compounds.

The noncaloric sweeteners do not form a uniform chemical group. Nevertheless simultaneous determination of some sweeteners is possible. In the case of soft drinks the determination is simplified due to the absence of an extraction procedure. For juices, desserts, and other applications an additional extraction step has to be performed. An overview on analysis of noncaloric sweeteners by HPLC is given by Flak and Pilsbacher (52).

Saccharin can be determined with reversed-phase HPLC method and absorbance detection, simultaneous with other sweeteners, namely acesulfame-K, aspartame, etc. (53).

Liquid chromatography with different detection techniques has been evaluated for determination of cyclamate, but the most common method is gas chromatography with flame ionisation detection of the pre-column derivatisation product Cyclohexylamine (18).

An HPLC isocratic method with pre-column derivatization, because of the absence of a chromophore for UV detection, and UV detection for the quantification of

cyclamate and cyclohexylamine in urine samples is described. The method requires very little sample preparation. Free cyclohexylamine is analysed in a first run and subsequently cyclamate is analysed as cyclohexylamine, after the simple process of oxidation of the sample by means of hydrogen peroxide. Cycloheptylamine is used as internal standard. Trinitrobenzenesulfonic acid (TNBS) appears to be a good reagent for the pre-column derivatisation (30)

Acesulfame-K determination with reversed-phase liquid chromatography is reported by Grosspietch and Hachenberg in 1980 and by Veerabhadrarao et al. in 1987 with UV absorption detection respectively at 237 nm and 254 nm (52). Also ion chromatographic methods for the simultaneous determination of saccharin, aspartame, acesulfame-K, and even cyclamate in combination with other food additives were reported (54,55). This method has been successfully applied to the analysis of soft drinks and various food products, and average recoveries varied from 85% to 104%. In 1999 Qu et al. used ion chromatography and amperometric detection to determine aspartame in a mixture of acesulfame and saccharin, without interference of these sweeteners (56).

Vanek et al. described the determination of stevioside in plant material based on water extraction and HPLC isocratic elution (57). Farhadi et al. developed a capillary column gas chromatographic method for the measurement of urinary sucralose used as a probe in an *in vivo* study of intestinal permeability. Concentration levels of 200 ppm were successfully reported (58).

VII. SUGAR REPLACEABILITY

The food industry uses sugar not only for its sweetening function. Sugar also serves some technological purposes and therefore in some way does not seem to be completely replaceable.

Sugar helps to preserve food by lowering the water activity, a parameter which is correlated with the microbiological stability of the product (50).

Sugar increases boiling point and reduces freezing point, acts as a bulking agent, and serves as a flavour-enhancer, important properties in food production and conservation.

Therefore sugar replacement is determined by the technical suitability of a sweetener.

One of the largest applications of intense sweetener addition is the production of soft drinks. In these products sugar can be replaced for the full 100% of its amount. Since sugar can represent up to half of the raw material costs of a regular soft drink and the volume loss is simply compensated by a larger amount of water, significant cost savings can be made. The replacement of sugar by intense sweeteners is estimated to result in a reduction of the input cost up to 50%.

Another advantage is the synergetic effect of a combination of sweeteners. This allows for lower dosage levels and a decrease in the cost of soft drink manufacturing. The first commercial sweetener blend was saccharin and cyclamate. Today blends of aspartame/saccharin, saccharin/sorbitol and others are frequently used in soft drinks, candies, and chewing gum.

The technical substitutability of sugar in food and drink products are estimated to be 100% for soft drinks, ice cream, yoghurt, frozen confectionery, canned fruit, and pickles; 10% for sugar confectionery, and 5% for biscuits, chocolate, and jams.

The sweetening power of each intense low-calorie sweetener varies depending upon the type of product for which it is to be used and the level of its usage.

Therefore each soft drink company decides which low-calorie sweetener to use only after it has considered the type of product and the availability and cost of ingredients in the marketplace at that time.

In addition, owing to technological developments, manufacturers have found that blending different low-calorie sweeteners, sometimes with sugar, can lead to a better product taste profile. For this reason, many producers now use a blend of low-calorie sweeteners rather than one single low-calorie sweetener in their drinks (51).

VIII. ECONOMICS

The European internal market is evolving into one single market without trade barriers. The Sweeteners Directive of the EU is in place and is implemented by the national laws of member states. Low-calorie sweeteners are being used in more products than ever before. The use of intense sweeteners is no longer restricted to the use as a sugar replacer in conventional food products, there are a lot of new products based on the use of sweeteners, such as extra strong breath fresheners. These are products for which there is no high-calorie "normal" version. Cosmetic chewing gum, and newer better tasting food products aimed at the fitness, wellness, and sports markets are showing strong growth. As the sales of diet and light products are growing more slowly than in the past, the use of low-calorie sweeteners in combinations with each other, with nutritive sweeteners, and even as flavour enhancers, is increasing.

The soft drinks sector is the largest consumer of artificial sweeteners and will maintain its position. Because of the cost benefits to food and drink manufacturers, the usage of high intensity sweeteners is continuing to rise (52).

A sugar replacement of about 25% of the total sugar consumption is technically feasible. The International Sugar Organization reported that, with an annual growth high intensity sweeteners could grab 10% of the global sweetener market by 2005 (53). Each year an average amount of 15,000 tonnes of intensive sweeteners are used

worldwide. They replace about 13 million tonnes of white sugar and have contributed to the buildup of annual stocks of around 60 million tonnes of refined sugar (Financial Post, 11/08/2000). In 2001 tabletop sweeteners grew by more than 10%, while diet soft drinks outpaced regular soft drinks with a growth of 0.7% in comparison with 0.5%. Most diet soft drinks are sweetened with aspartame, or a blend of aspartame and saccharin. The global market of artificial sweeteners was estimated in 2000 as €2.5 billion.

Aspartame has the largest share of the market, currently around 90%, and is likely to dominate the market during this decade, with its share expected to fall to only around 70% by 2009. Acesulfame-K and sucralose are expected to share a similar slice of most of the remaining 30% in the years to come.

IX. LEGISLATION REGULATION AND FOOD LABELLING

In the European community all sweeteners, natural or artificial, reduced or low-calorie, have to be approved for use. The European Directive on sweeteners in food 94/35/EC, as amended by directive 96/35/EC, regulates the use of acesulfame K, aspartame, cyclamate, neohesperidine, saccharin, and thaumatin. The amending directive was adopted in 1996 and implemented by 15 member states by June 1998.

In June 2002 an amendment proposes the use of sucralose and aspartame-acesulfame-K salt.

Denmark suggested that cyclamate intake for children can be higher than the ADI. As stated in the directive on food additives 89/107/EC, all additives should be continuously supervised to guarantee their safety and to amend the directive, if necessary, the Comission proposes to reduce the ADI for cyclamate, to reduce the maximum level of use in some food products, and to prohibit the use in some products as chewing gum, ice cream, etc.

The use of sweeteners is prohibited in any foods for infants and young children, and this prohibition now includes foods for infants not in good health. Foods for infants include foods specially prepared for infants (under the age of 12 months) generally known as "baby foods" and young children (under the age of 3 years), healthy or not.

On the label one should find correct information on additives used.

The Directive on Sweeteners defines:

- "*With no added sugar*": without any added mono- or disaccharides or any other foodstuff used for its sweetening properties
- "*Energy reduced*": with an energy value reduced by at least 30% compared with the original foodstuff or a similar hypothetical one with same characteristics but with use of nutritive sweeteners (glucose, fructose, sucrose)

Furthermore, Article 5 of the directive mentions the sales description of tabletop sweeteners must include the term "…-based tabletop sweetener" using the name of the sweetener(s) used in its composition.

When *polyols* or sugar alcohols are used the label should bear the warning "excessive consumption may induce laxative effects." For the purposes of these regulations, polyols are considered to be sorbitol syrup [E420 (i) and (ii)], mannitol (E421), isomalt (E953), maltitol and maltitol syrup [E956 (i) and (ii)], lactitol (E966) and xylitol (E967).

In the case of *aspartame*, the phrase "contains a source of phenylalanine" is to be used.

The directive includes a list with all sweeteners allowed in foodstuffs. Acceptable ADIs are also set for each low-calorie sweetener. These indicate levels for safe consumption of low-calorie sweeteners every day over a lifetime, and have a built-in safety factor of 100 times.

I. INTRODUCTION

China, the most populous country in the world, has a territorial area of 9,600,000 km^2. Situated in the Eastern Hemisphere and also including tropical, subtropical, temperate, and frigid zones, it has complex topography, landscape, and climates. As a result of these, China forms a great biodiversity. For higher seed plants, there are a total of 30,586 species recorded on Earth, which are divided into 343 families and 3155 genera. Of these, about

243 genera containing 527 species are found only in China (1).

Many higher plants in China have found various usages such as staple foods (e.g., rice, wheat, maize, etc.), vegetables (e.g., carrot, cucumber, cabbage, etc.), medicines (e.g., ginseng, liquorice, angelica, etc.), forage (e.g., clover, fescue, timothy, etc.), flavors (e.g., perilla, Japanese mint, basil, etc.), pigments (e.g., gardenia, fish storkbill, garden balsam, etc.) and sweeteners (e.g., sugar cane, sugar beet, etc.). These plants have been domesticated and cultivated by Chinese for thousands of years. In addition, there are many wild plants that have been utilized by Chinese as staple foods, food additives, vegetables, and medicines, which were the main source of foods of ancient people (2). In China, there are more than 1,800 edible seed plant species that are rich in proteins, vitamins, dietary fibre and minerals, and are also tasty (2). At the same time, these plants are more disease- and pest-resistant than cultivated crops. Therefore, wild edible plants are considered important gene pools for crop improvement.

In this chapter, some seed plants utilized by Chinese as staple foods, food additives, vegetables, and medicines are introduced. Edible wild plant species and their types, efficacy, and safety will also be discussed in detail. The map of China is shown in Figure 98.1.

II. TYPES OF EDIBLE PLANTS

According to plant parts (or organs) and components, edible plants can be divided into several groups such as edible flowers, edible fruits, edible young stems and leaves, edible roots and tubes, edible pigments, and edible flavors.

A. Edible Flowers

In Europe and North America, the main edible flower plants are *Brassica oleracea* var. *botrytis* and *Brassica oleracea*

FIGURE 98.1 Map of the People's Republic of China.

var. *italica*. In the Middle East, flowers of pumpkin and orange are used for making jams and syrups. In Asian countries, many plant flowers are eaten directly, because these countries have had a flower-eating culture for centuries. Flowers of plants such as *Dendranthema grandiflorum* in Japan, *Rhododendron* spp. and *Caragana arborescens* in Korea, *Musa errans* var. *botoan*, *Sesbania grandiflora*, *Moringa oleifera*, *Nymphaea pubescens*, *Bombax ceiba*, *Amomum maximum*, *Telosma cordata*, *Curcuma sessilis*, *Syzygium malaccense*, *Syzygium samarangense* and *Psophocarpus tetragonolobus* in Southeast Asia are widely consumed as foods by local people.

Eating flowers also has a long history in China (3, 4). In ancient books called "Shi-Jin," "Shan-Hai-Jin" and "Shen-Nong-Ben-Cao-Jin," the flowers of *Chrysanthemum morifolium*, *Hibiscus syriacus*, *Hemerocallis fulva*, *Lonicera japonica*, *Sophora japonica*, *Prunus mume*, *Carthamus tinctorius* were recorded to be edible (4). These flowers, however, are eaten mainly among national minorities of China. Some of the edible flowers in China are listed in Table 98.1 (2–5).

B. Edible Fruits

China possesses a rich resource of wild edible fruits that are the origins of many cultivated fruit varieties. There are more than 30 fruit species such as apple, pear and orange that are widely cultivated in China. The number of wild edible fruit species in China is more than 300 (4–8). More wild edible fruit species are distributed in Tianshan Mountains of Xinjiang (7) and Xishuangbannan of Yunnan (4) than those in any other regions of the country. There are 84 forma specialis of wild apple (*Malus sieversii*), 44 forma specialis of wild apricot (*Armeniaca valgaris*), 21 forma specialis of wild plum (*Prunus divaricata*), and 14 forma specialis of wild Persia walnut (*Juglans regia*) distributed in the region of Tianshan Mountains of Xinjiang at the northwestern part of China (7). These wild fruit species form natural forests in Xinjiang. They possess strong resistance to diseases and cold and salt stresses, and thus are considered the gene bank for breeding fruit resistance, and are also good stock materials in horticulture.

TABLE 98.1
Plants in China with Edible Flowers

Scientific Name	Family Name	Distribution Area	Collection Time
Alpinia kwangsiensis	Zingiberaceae	Southern China	Mar. to Apr.
Bauhinia variegata var. *candida*	Leguminosae	Yunan, Guangxi, Fujian, Taiwan	Feb. to Apr.
Bombax ceiba	Bombacaceae	Yunan, Guizhou, Guangxi	Jan. to Mar.
Cassia fistula	Leguminosae	Yunnan	Mar. to Jul.
Cassia siamea	Leguminosae	Guangdong, Yunnan, Hainan, Taiwan, Sichuan	Jul. to Sep.
Clerodendrum japonicum	Verbenaceae	Southern China	Apr. to Aug.
Curcuma longa	Zingiberaceae	Southern China	Jul. to Aug.
Dendranthema indicum	Compositae	Whole country	Autumn
Etingera elatior	Zingiberaceae	Tropical and subtropical area	Whole year
Globba racemosa	Zingiberaceae	Southern China	Jun. to Sep.
Hemerocallis nana	Liliaceae	Whole country	Spring, autumn
Hibiscus mutabilis	Malvaceae	Southern China	Aug. to Oct.
Hibiscus sabdariffa	Malvaceae	Fujian, Guangdong	May to Oct.
Hibiscus syriacus	Malvaceae	Yunnan, Guizhou, Guangxi	Jan. to May
Hemerocallis fulva	Liliaceae	Whole country	Aug. to Oct.
Jasminum sambac	Oleaceae	Whole country	Apr. to Dec.
Mayodendron igneum	Bignoniaceae	Yunnan	Feb. to Apr.
Musa acuminata	Musaceae	Southern China	Whole year
Musella lasiocarpa	Musaceae	Southwestern China	Whole year
Nymphaea lotus var. *prbescens*	Nymphaeaceae	Tropical and subtropical area	Whole year
Perotis indica	Gramineae	Whole country	May to Jun.
Plumeria rubra	Apocynaceae	Southeast Asia	May to Jun.
Pseuderanthemum polyanthum	Acanthaceae	Yunnan	Jan. to Apr.
Punica granatum	Punicaceae	Tropical and subtropical area	May to Aug.
Saraca indica	Leguminosae	Yunnan	Feb. to May
Sesbania grandiflora	Leguminosae	Southeast Asia	Whole year
Sophora japonica	Leguminosae	Whole country	Apr. to May
Thunbergia grandiflora	Acanthaceae	Guangdong, Yunnan, Guangxi	Dec. to May
Woodfordia fruticosa	Lythraceae	Yuannan, Guangxi	Jan. to Apr.

Source: Data from Ref. 2–5.

TABLE 98.2
Some Wild Edible Sarcocarp Fruit Species in China

Scientific Name	Family Name	Distribution Area	Products
Actinidia callosa var. *henryi*	Actinidiaceae	Whole country	Jam, syrup, canned food, eaten directly
Actinidia chinensis	Actinidiaceae	Whole country	Jam, syrup, canned food, edible directly
Actinidia kolomikta	Actinidiaceae	Whole country	Jam, syrup, canned food, eaten directly
Akebia quinata	Lardizabalaceae	Southern China	Ratafee
Akebia trifoliate	Lardizabalaceae	Southern China	Ratafee
Amalocalyx yunnanensis	Apocynaceae	Yunnan	Vegetable
Amomum maximum	Zingiberaceae	Guangdong, Guangxi, Yunnan, Tibet	Vegetable
Armeniaca valgaris	Rosaceae	Xinjiang	Syrup, canned food, jam
Broussonetia papyrifera	Moraceae	Southern China	Ratafee
Canarium album	Bursteraceae	Guangdong, Gangxi, Fujian, Taiwan, Hainan, Yunnan	Jam
Cajanus cajan	Leguminosae	Yunnan	Vegetable
Carica papaya	Caricaceae	Tropical area	Vegetable, preserved fruit
Celtis sinensis	Ulmaceae	Southern China	Jam
Choerospondias axillaris	Anacardiaceae	Southern China	Syrup, ratafee, jam
Crataegus cuneata	Rosaceae	Henan, Guangdong, Guangxi, Fujian	Canned food, jam, syrup, preserved fruit
Crataegus hupehensis	Rosaceae	Henan, Jiangxi, Jiangsu	Canned food, jam, syrup, preserved fruit
Cyphomandra betacea	Solanaceae	Tropical area	Vegetable
Dendrobenthamia angustata	Cornaceae	Southern China	Jam, ratafee
Dendrobenthamia capitata	Cornaceae	Southern China	Jam, ratafee
Dendrobenthamia japonica	Cornaceae	Southern China	Jam, ratafee
Diospyros kaki	Ebenaceae	Whole country	Eaten directly, preserved fruit
Diospyros lotus	Ebenaceae	Whole country	Eaten directly, preserved fruit
Diospyros rhombifolia	Ebenaceae	Fujian, Jiangsu, Hunan	Eaten directly, preserved fruit
Dolichandrone stipulata	Bignoniaceae	Southern China	Vegetable
Eriobotrya cavaleriei	Rosaceae	Southern China	Canned food, syrup
Eriobotya japonica	Rosaceae	Gansu, Shaanxi, Henan	Canned food, syrup
Euryale ferox	Nymphaeaceae	Whole country	Jul. to Oct.
Ficus carica	Moraceae	Whole country	Canned food, preserved fruit, drink
Ficus henryi	Moraceae	Southern China	Canned food, preserved fruit, drink
Ficus pumila	Moraceae	Southern China	Canned food, preserved fruit, drink
Ficus samentosa	Moraceae	Southern China	Canned food, preserved fruit, drink
Ficus tikoua	Moraceae	Southern China	Canned food, preserved fruit, drink
Fragaria gracilis	Rosaceae	Tibet, Shaanxi, Gansu	Eaten directly, jam, canned food, syrup, ratafee
Fragaria orientalis	Rosaceae	Northern China	Eaten directly, jam, canned food, syrup, ratafee
Hippophae rhamnoides	Elaeagnaceae	Western China	Syrup, jam
Holboellia coriacea	Lardizabalaceae	Western China	Ratafee
Holboellia grandiflora	Lardizabalaceae	Southern China	Ratafee
Hovenia acerba	Rhamnaceae	Southern China	Ratafee, sugar
Hovenia dulcis	Rhamnaceae	Southern China	Ratafee, sugar
Hovenia trichocarpa	Rhamnaceae	Southern China	Ratafee, sugar

Source: Data from Ref. 4–9.

Apart from their edibility, these wild fruits can be processed into all kinds of food products such as jam, syrup, and ratafee. These wild fruits can be divided into sarcocarp fruits and dry fruits, which are tabulated in Tables 98.2 and 98.3 (4–9), respectively.

C. Edible Young Stems and Leaves

The number of plants with edible young stems and leaves may account for up to 60–70% of the total edible plants in China (4, 5, 9). They are usually collected in their growth stages especially in springtime. These edible young stems and leaves can be divided into two groups, herbaceous and woody, which are shown respectively in Tables 98.4 and 98.5 (4, 5, 9).

D. Edible Roots and Tubers

Many plant roots and tubers can be eaten because they contain mainly starches together with other nutrient

components. The roots of sweet potato (*Ipomoea batatas*), wayaka yambean (*Pachyrhizus erosus*), yam (*Dioscorea* spp.), and kudzuvine (*Pueraria* spp.) are the most common edible plant roots. The tubers of potato (*Solanum tuberosum*) and giantarum (*Amorphophallus* spp.) are usually consumed as either staple food or vegetables. Some of these plants have been domesticated and cultivated, whereas many of the plants with edible roots and tubers are still grown in the wild (2). Some examples of the wild edible roots and tubers are shown in Table 98.6 (2, 4, 5, 9).

E. Edible Plant Pigments

There are two groups of edible pigments: chemically synthesized colorings and natural colorings derived from living organisms. Natural plant colorings are believed to be safer than the synthetic ones. Some synthetic pigments are suspected of causing hyperactivity and learning difficulties in children, and causing other diseases such as cancers. Pigments of plant origins are not only safer, but also more environmentally friendly. Hence, with increasing suspicion that certain synthetic food pigments may be harmful, natural food colorings are increasing in popularity (10).

The plant kingdom possesses an abundant supply of plant pigments of which four main groups are suitable for coloring foods: 1) anthocyanines are intensely colored, water-soluble, orange, red, violet, or blue flavonoid pigments commonly found in flowers, fruits, and vegetables. For stability, they are usually kept in a rather acid medium; 2) betalains are a small group of red or yellow pigments sensitive to pH, heat, and light; the most common one is betanin from *Beta vulgaris* (beetroot); 3) carotenoids are red, orange, or yellow in color, and are sensitive to oxidation, hence their usefulness in the food industry necessitates

Source: Data from Ref. 4, 5, and 9.

limiting their exposure to air; and 4) chlorophyll pigments are green, and are sensitive to acidity and light.

Some Chinese plants containing edible pigments are shown in Table 98.7 (4, 5, 10). Even for pigments with the same color, their chemical structures may be quite different. For example, most red pigments from plants belong to anthocyanin, but the red pigment shikonin from *Lithospermum erythrorhizone* is naphthoquinone. Up to now, the chemical compositions of most plant pigments are still not known.

F. Edible Plant Spices

Some Chinese botanicals have been used as spices. Plant spices are the main source of food additives (5). Some cultivated and wild edible spices-producing plants in

Zanthoxylum piasezkii	Rutaceae	Fruits	Northwestern China
Zanthoxylum schinifolium	Rutaceae	Fruits	Northern China
Zanthoxylun simulans	Rutaceae	Fruits, leaves	Hebei, Henan
Ziziphus jujuba var. *inermis*	Rhamnaceae	Fruits	Northern China

Source: Data from Ref. 4 and 5.

China are listed in Table 98.8 (4, 5). Among them, some originated from Europe, South America, or Southeast Asia. Spices are widely used in the food industry, e.g., meat products, biscuit, beverages, and salad dressing. Plant spices were the most important component in ancient culture communion between Eastern and Western countries. Some plant spices originated from China and other Asian countries, such as cinnamon (*Cinnamomum zeylanicum*), cassia (*Cassia cinnamon*), cardamon (*Elettaria cardamomum*), ginger (*Zingiber officinale*), and turmeric (*Curcuma longa*), were exported and were widely used in European and Arabian countries centuries ago.

III. EFFICACY OF EDIBLE PLANTS

Edible plants with rich nutrient contents and medicinal efficacy have been recognized and utilized by the Chinese for thousands of years. These plants are considered either functional foods or medicines. In addition, some edible plants also have other functions such as serving as industrial materials and forages, and are being used for ecological protection. The nutritional and medicinal functions of some edible plants are described below.

A. Nutritional Functions

1. Definition of Nutrients

Nutrient components of a food may embrace protein, carbohydrate, fat, dietary fiber, cholesterol, carotene, retinal, thiamin, riboflavin, niacin, vitamin C, vitamin E, and a variety of mineral elements such as calcium (Ca), phosphorus (P), potassium (K), sodium (Na), magnesium (Mg), iron (Fe), zinc (Zn), copper (Cu), manganese (Mn), selenium (Se), and other trace elements which are essential to human and animals to grow and develop (11). For example, the element magnesium participates in energy transformation in human cells, promotes myocardium activity, promotes the dissolution of fiber protein, inhibits fibrin ferment formation, and prevents arteriosclerosis, high blood pressure, or heart diseases. Calcium is an important cation for maintaining blood moisture balance, acid-alkali balance, and osmotic pressure. Iron produces protoferriheme to

prevent iron-sufficient anemia. The relationship of zinc with impediment to taste sensation has also attracted great attention. In addition, selenium shows functions to retard oxidation and in the regulation of immunity. Selenium combines with other metals in the body and forms certain kinds of unsteady metal–selenium–protein complexes which are helpful in eliminating toxicants from the body.

2. Main Nutrients in Edible Wild Plants

Wild edible plants often have superior nutritional qualities, whether eaten raw or cooked. They contain rich dietary fiber, vitamins, minerals, and other nutritious components (11) which are beneficial to humans and animals. Many edible wild plants are considered functional foods. The contents of organic compounds in some wild edible plants are shown in Table 98.9 (11), while the contents of mineral components are shown in Table 98.10 (11).

B. Medicinal Functions

In China, many edible plants are also used as herbal medicines, which are a part of traditional Chinese medicines (TCM). Chinese medicines have a long history in Eastern cultures, especially in China, where foods and medicines are considered to be equally important in preventing and curing diseases.

Since foods and Chinese medicines are believed to share a common origin in the Chinese tradition, it is not easy to distinguish the two. Difficulty arises in classifying a product as a functional food or as a medicine. To solve this problem, based on the safety profile of Chinese medicines,

the Ministry of Public Health of the People's Republic of China has formally recognized 97 plant species as both functional foods and Chinese medicines which are shown in Table 98.11 (12–14). The plants listed in Table 98.11 can be consumed either as food or as medicine, and they are almost non-toxic. The plants shown in Table 98.12 (12–14) can be used as functional ingredients to be incorporated into health food. They are also considered safe, provided the amount consumed is not higher than the dosage set in Chinese pharmacopoeia (14).

In the past decades, the consumption of botanicals and nutritional supplements has increased dramatically. The most popular Chinese botanicals in western countries are astragalus (*Astragalus membranaceus*), angelica (*Angelica sinensis*), ginger (*Zingiber officinale*), foti (*Polygonum multiflorum*), jujube (*Ziziphus jujuba*), licorice (*Glycyrrhiza uralensis*), and Asian ginseng (*Panax ginseng*). In recent years, more and more Chinese medicinal herbs and edible plants have been exported to other countries, especially in Europe and North America. Many wild edible plants that have evident pharmacological activities according to modern pharmacology are summarized in Table 98.13 (15–21).

C. Some Medicinal Plants in China

1. Tartary Buckwheat

Buckwheat, which belongs to the family Polygonaceae, has two species, common buckwheat (*Fagopyrum esculentum*) and tartary buckwheat (*F. tataricum*). Common buckwheat is widely cultivated in many countries over the world, while tartary buckwheat has only been cropped and used in the Loess Plateau of northern China and Yungui Plateau of southwestern China.

a. Nutrient contents

Comparison of nutrients between tartary buckwheat and other cereals is shown in Table 98.14 (22). It is clear that tartary buckwheat flour has higher protein and fat contents than those of wheat or rice. It should be noted that tartary buckwheat has rutin (vitamin P) which is absent in crops from the grass family. Besides, the levels of minerals in tartary buckwheat are higher than those in other crops. The contents of protein, fat, vitamin B2, and vitamin P in tartary buckwheat are higher than those in common buckwheat.

b. Medicinal functions

Tartary buckwheat has significant healing effects on hyperlipidemia, hypoglycemia and diabetes mellitus, as well as gastric disease. In China, tartary buckwheat has been developed into various health foods, drinks, and other products such as powder, health-care paste, custard, dried noodle, jelly, biscuit, cake, vinegar, wine, tea, and soft drinks.

2. Walnut

Although walnut (*Juglans* spp.) of the family Juglandaceae is distributed in many countries of the world, the major
