

Textbook of Natural Medicine (2-Volume Set) 2nd edition (September 15, 1999) by Joseph E. Pizzorno (Editor), Michael T. Murray (Editor) By Churchill Livingstone

By OkDoKeY

- **Frontmatter**
 - **Dedication**
 - **Title Page**
 - **Copyright Page**
 - **Contributors**
 - **Preface**
- + **Section One - Philosophy of natural medicine**
- + **Section Two - Supplementary diagnostic procedures**
- + **Section Three - Therapeutic Modalities**
- + **Section Four - Syndromes and special topics**
- + **Section Five - Pharmacology of natural medicines**
- + **Section Six - Specific health problems**
- **Appendix 1: *Candida* questionnaire**
- **Appendix 2: Crohn's disease activity index**
- + **Appendix 3: Fasting – patient guidelines**
- **Appendix 4: Gluten and gliadin content of selected foods**
- + **Appendix 5: Healthy exchange lists**
- **Appendix 6: Hydrochloric acid supplementation – patient instructions**
- + **Appendix 7: Patient instructions for measuring basal body temperature**
- **Appendix 8: Premenstrual syndrome questionnaire**
- + **Appendix 9: Rotation diet master chart, plans I and II**
- **Appendix 10: Sit and reach test**
- + **Appendix 11: Vaginal depletion pack**

– **Section One - Philosophy of natural medicine**

+ 1 - Functional medicine in natural medicine

+ 2 - History of naturopathic medicine

+ 3 - Philosophy of naturopathic medicine

+ 4 - Placebo and healing

+ 5 - Women in the history of medicine

– Section Two - Supplementary diagnostic procedures

- + 6 - Apoptosis assessment
- + 7 - Bacterial overgrowth of the small intestine breath test
- + 8 - Cell signaling analysis
- + 9 - Comprehensive digestive stool analysis
- + 10 - ELISA/ACT test
- + 11 - Erythrocyte sedimentation rate
- + 12 - Fantus test for urine chloride
- + 13 - Fatty acid profiling
- + 14 - Folic acid status assessment
- + 15 - Food allergy testing
- + 16 - Functional assessment of liver phase I and II detoxification
- + 17 - Hair mineral analysis
- + 18 - Heavy metal assessment

/table>

- + 19 - Heidelberg pH capsule gastric analysis
- + 20 - Immune function assessment
- + 21 - Intestinal permeability assessment
- + 22 - Laboratory tests for the determination of vitamin status
- + 23 - Lactose intolerance breath test
- + 24 - Mineral status evaluation
- + 25 - Oral manifestations of nutritional status
- + 26 - Rapid dark adaptation test
- + 27 - Serum bile acids assay
- + 28 - Tryptophan load test
- + 29 - Urinary organic acids profiling for assessment of functional nutrient deficiencies, gut dysbiosis, and toxicity
- + 30 - Urinary porphyrins for the detection of heavy metal and toxic chemical exposure
- + 31 - Urine indican test (Obermeyer test)
- + 32 - Zinc status assessment

– Section Three - Therapeutic Modalities

- + 33 - Acupuncture
- + 34 - Ayurveda: the science of life and mother of the healing arts
- + 35 - Botanical medicine – a modern perspective
- + 36 - Contemporary homeopathy
- + 37 - Environmental medicine
- + 38 - The exercise prescription
- + 39 - Faith: a powerful force for healing
- + 40 - Glandular therapy
- + 41 - Homeopathy
- + 42 - Hydrotherapy
- + 43 - Manipulation
- + 44 - Nutritional medicine
- + 45 - Peat therapeutics and balneotherapy
- + 46 - Soft tissue manipulation: diagnostic and therapeutic potential
- + 47 - Therapeutic fasting

– Section Four - Syndromes and special topics

- + 48 - Chronic candidiasis
- + 49 - Chronic fatigue syndrome
- + 50 - Detoxification
- + 51 - Food allergies
- + 52 - Homocysteine metabolism: nutritional modulation and impact on health and disease
- + 53 - Immune support
- + 54 - Intestinal dysbiosis and dysfunction
- + 55 - Maldigestion
- + 56 - Non-pharmacological control of pain
- + 57 - Role of dietary fiber in health and disease
- + 58 - Rotation diet: a diagnostic and therapeutic tool
- + 59 - Sports nutrition
- + 60 - Stress management

– Section Five - Pharmacology of natural medicines

- + 61 - Alkylglycerols
- + 62 - *Allium cepa* (onion)
- + 63 - *Allium sativum* (garlic)
- + 64 - *Aloe vera* (Cape aloe)
- + 65 - *Angelica* species
- + 66 - *Aspergillus oryzae* enzyme therapy
- + 67 - Beta-carotene and other carotenoids
- + 68 - Boron
- + 69 - Bromelain
- + 70 - *Camellia sinensis* (green tea)
- + 71 - *Capsicum frutescens* (cayenne pepper)
- + 72 - Carnitine
- + 73 - Catechin [(+)-cyanidanol-3]
- + 74 - *Centella asiatica* (gotu kola)
- + 75 - *Cimicifuga racemosa* (black cohosh)
- + 76 - Coenzyme Q₁₀
- + 77 - *Coleus forskohlii*
- + 78 - *Commiphora mukul* (mukul myrrh tree)
- + 79 - *Crataegus oxyacantha* (hawthorn)
- + 80 - *Curcuma longa* (turmeric)
- + 81 - Dehydroepiandrosterone
- + 82 - *Echinacea* species (narrow-leafed purple coneflower)
- + 83 - *Eleutherococcus senticosus* (Siberian ginseng)
- + 84 - *Ephedra* species
- + 85 - Fatty acid metabolism
- + 86 - Fish oils
- + 87 - Flavonoids – quercetin, citrus flavonoids, and HERs (hydroxyethylrutosides)
- + 88 - *Ginkgo biloba* (ginkgo tree)
- + 89 - Glucosamine
- + 90 - *Glycyrrhiza glabra* (licorice)
- + 91 - *Hydrastis canadensis* (goldenseal) and other berberine-containing botanicals

- + [92 - 5-Hydroxytryptophan](#)
- + [93 - *Hypericum perforatum* \(St John's wort\)](#)
- + [94 - Introduction to the clinical use of Chinese prepared medicines](#)
- + [95 - *Lobelia inflata* \(Indian tobacco\)](#)
- + [96 - *Melaleuca alternifolia* \(tea tree\)](#)

I

II

This book is dedicated to Dr John Bastyr and all the natural healers of the past and future who bring the virtues of the “healing powers of nature” to all the people of the world. Dr Bastyr, the namesake for Bastyr University, exemplified the ideal physician/healer/ teacher we endeavour to become in our professional lives. We pass on a few of his words to all who strive to provide the best of health care and healing: “Always touch your patients – let them know you care”, and “Always read at least one research article or learn a new remedy before you retire at night”.

Note

This is a textbook and references for students and practitioners of natural medicine and other professionals interested in learning about this healing art.

For several reasons important reasons, this work should not be viewed as providing a single answer applicable to all individuals.

First, the practice of natural medicine is constantly evolving. New research and on going clinical experience continue to give us a better understanding of the human body, its interaction with the physical environment, its reaction to the stresses of modern life, and its response to various forms of therapy and treatment.

Second, diagnosis and therapy are so personalized and individualized that the same problem for the same person may call for different treatment at different ages or in different settings.

Third, all readers need to be aware of the times at which more invasive interventions are more appropriate.

The Publisher, the Editors, and the Contributors do not assume any responsibility for any injury and/or damage to persons or property arising out of or related to any use of the material contained in this textbook. The reader is advised to check the appropriate literature and the product information currently provided by the manufacturer of each therapeutic substance to verify dosages, the method and duration of administration, or contraindications. It is the responsibility of the treating practitioner, relying on independent experience and knowledge of the patient, to determine dosages and the best treatment for the patient.

There is no substitute for individualized diagnosis and treatment.

This personalized approach is at the heart of naturopathic medicine.

These recommendations are particularly important for new forms of treatment and for rare or serious health problems.

Most of the laboratory procedures presented in Section 2 are on the cutting edge of our understanding of the assessment of the physiological function of metabolically unique individuals. As an emerging field, few experts exist and most are employed by the commercial laboratories providing the procedures. The following is a list of the Textbook authors employed by laboratories providing these tests:

Preface

The scientific support for the philosophical and therapeutic foundation of natural medicine has evolved remarkably over the past 25 years. Concepts that were once considered “quaint” at best, are now recognized as fundamental to good health and the prevention and treatment of disease. This textbook, with its some 10 000 citations to the peer-review research literature, provides well-documented standards of practice for natural medicine. Based on a sound combination of philosophy and clinical studies, this work provides the astute practitioner with a reliable informational resource to provide health care that identifies and controls the underlying causes of disease, is supportive of the body’s own healing processes, and considerate of each patient’s unique biochemistry.

The Textbook is composed of six Sections, each focused on a fundamental aspect of the practice of natural medicine. “Philosophy of natural medicine” covers the history and conceptual basis of natural medicine. “Supplementary diagnostic procedures” provides a primer on diagnostic procedures not commonly taught in conventional medical schools. Diet analysis, food allergy testing, immune function assessment, fatty acid profiling, and hair mineral analysis are examples of these analytical procedures. The next section, “Therapeutic modalities”, provides a descriptive, practical, scientific, and historical review of the common modalities of natural medicine, including botanical medicine, nutritional therapy, therapeutic fasting, exercise therapy, hydrotherapy, counselling, acupuncture, homeopathy, and soft tissue manipulation. “Syndromes and special topics” considers underlying issues relevant to many diseases. “Pharmacology of natural medicines” covers the pharmacognosy, pharmacology and clinical indications for the most commonly prescribed botanical medicines, special nutrients, and other natural agents. Finally, “Specific health problems” provides an in-depth natural medicine approach to over 70 specific diseases and conditions. The comprehensive therapeutic rationales are well documented and based on the pathophysiology and causes of each condition.

PART I: THE PHILOSOPHY OF FUNCTIONAL MEDICINE

INTRODUCTION

This textbook bears witness to the remarkable evolution of naturopathic medicine in the USA since Benedict Lust first opened his American School of Naturopathy at the end of the 19th century. During the intervening century, naturopathic physicians have become recognized as primary health care providers in about one-fourth of all states; naturopathic practice has become part of publicly funded clinics, and accredited training has become available in all regions of the country. In addition, naturopathic philosophy has influenced medical philosophy as a whole, including the functional approach which we have espoused in our own work. Naturopathic recognition of key medical principles, including *tolle causam* (identify and treat the causes), *primum non nocere* (first do no harm) and *docere* (doctor as teacher), has helped us clarify our vision of a functional approach to health which derives from a patient-centered, self-care, outcomes-based model.

Through functional medicine, we have worked to develop an approach to health care which can be incorporated into the everyday practice of all health care practitioners

regardless of training or specialty. Moreover, we have tried to carve out an approach which capitalizes not only upon the foremost accomplishments of basic and applied science, but also upon the strengths of specialty fields and specialized approaches to clinical practice. It is our hope that naturopaths, osteopaths, chiropractors, medical doctors, nutritionists, dietitians, herbalists, homeopaths, acupuncturists, Ayurvedic physicians, and other diversely trained practitioners will be able to find in functional medicine an approach which naturally extends and enhances their current practice. Functional medicine is not an “alternative” approach which requires a change in basic clinical orientation or political allegiance. It requires only a willingness to take

seriously one’s basic medical philosophy, and to engage the science of our time with the spirit of true discovery, open-mindedness, and due diligence. In this chapter, we specifically address the consequences of such an approach for naturopathy and its clinical practice.

THEORETICAL ASPECTS

The philosophy of function in a medical context

Most dictionary definitions of “function” indicate that the word is derived from the Greek term *ergon*, which means “the kind of action or activity proper to a person or thing; the purpose for which something is designed or exists”.^[1] This definition tells us the concept of function must be viewed in the same category as the concepts of “purpose” and “design”. It tells us we cannot understand the function of a person or thing without also understanding the purpose for which that person or thing is designed.

In early Greek philosophy, the term *ergon* was frequently contrasted with the term *pathemata*– things that happened to a person or thing.^[2] This comparison focused on the difference between things with the capacity to act (*poiein*) and things that were, in contrast, “passive activations” (*pathe*).^[2] *En-ergia* – being in activity, or functioning – was considered to be the *telos* (end purpose) of being alive. Today, when we refer to disease as “pathology-based”, we are actually linking disease, etymologically, to this realm of *pathemata* and *pathe*. We are defining disease as something that “happens to” a person, something that is not a part of that person’s purposeful activity. Etymologically, the term “functional medicine” moves us away from this pathological model and aligns us with a medicine that views disease as part of something that is purposeful and is proceeding actively in accordance with some design.

The history of philosophy – at least as far back as the writings of Aristotle in the third century BC – has witnessed an ongoing debate between “vitalistic” and “mechanistic” approaches to life and health. Naturopathic medicine has consistently aligned itself with the vitalistic side of this argument. Naturopathy recognizes a vital force – *vis medicatrix naturae*, or healing power of nature – that is present in all living things, including the human body. For naturopaths, it is this vital force which is ultimately responsible for

healing.

The functional medicine emphasis on purpose and design is closely related to this recognition of vital force in naturopathy. When functional practitioners recognize purpose and design in physiological events (including “disease of unknown origin”), they are acknowledging that body function is guided by a universal, supra-individual set of principles. They are acknowledging that physiological function originates from an infinite, complex, patterned matrix of occurrences which both precede and transcend individual human experience. The purpose and design of functional medicine therefore echo the spirit of vitalism.

This spirit of vitalism does not mean, however, that the healing force is totally mysterious or unapproach-able. While the universal, patterned matrix of events is infinite and cannot be fully understood, it is nevertheless a complex pattern which can be observed and analyzed within the limits of a human perspective. Pursuit of this possibility is essential to a functional approach. The more that can be learned about the patterned matrix of universal events, the better able is the practitioner to support healing.

The terms “form” and “function” are probably most familiar to us from the field of architecture. At the turn of the 20th century, US architect Louis Sullivan coined the phrase “form follows function”, recognizing that purpose precedes the blueprint. But in our philosophy of the body’s architecture, how do these terms apply? In the case of several body systems – the musculoskeletal system or the circulatory system, for example – shape and form give an initial hint about function, design, and purpose. It is difficult to observe the body’s skeleton without concluding that it has been designed for structural support. With other physiological systems, these connections are not nearly so obvious.

Phrenology, described by English historian J. C. Flugel a century after its origin as “psychology’s greatest *faux pas*”, argued that the quality of a person’s mental faculties was determined by the size of the brain area upon which those faculties depended, and this quality could be judged by the contours of the skull adjacent to the area.^[3] This literal equating of brain function with brain form, proposed in 1810 in Paris by Francois Joseph Gall and his student J. C. Spurzheim, met with some immediate difficulty in application. After discovering that the skull of French philosopher René Descartes was particularly small in the anterior and superior regions of the forehead, understood to be the seat of a person’s rational faculties, Spurzheim reportedly commented:^[3] “Descartes was not so great a thinker as he was held to be.”

The inability of phrenologists to make sense of function by reference to form alone is one example of a difficulty that continues to permeate 20th century medicine. Naturopathy has made great strides in linking form with function, by accommodating into its practice long-standing medical traditions which treat function by working with form. Naturopathy’s embrace of physical medicine – from craniosacral therapy and osseous manipulation to hydrotherapy and physiotherapy – has made the connection between form and function more accessible.

naturopathic medicine involves the very idea of a “medical *philosophy*”. The need for practical solutions in everyday medical practice is great (so great that most practitioners will not see themselves as having the time – or inclination – to “philosophize”). Yet from a functional and naturopathic perspective, it is impossible to approach health without paying continual attention to one’s *philosophy* of medicine. In the remainder of this section, we look at several examples of philosophical thinking that we believe continue to represent stumbling blocks for an integrated 21st century medicine. Each of these examples thinks “dualistically” about medical concepts and in so doing, we believe, loses sight of function.

Function as a mediator for opposition thinking in the sciences

Part/whole

The traditional philosophical dualism of “part/whole” has been directly addressed in the field of holistic health. Two national organizations – the American Holistic Health Association (AHHA), with headquarters in Anaheim, California, and the American Holistic Medical Association (AHMA), located in Raleigh, North Carolina – have each referred to this dualism in defining their field of study.

According to the American Holistic Health Association:^[4]

Rather than focusing on illness or specific parts of the body, holistic health considers the *whole person* and how it interacts with its environment. It emphasizes the connection of body, mind, and spirit. Holistic Health is based on the law of nature that *a whole is made up of interdependent parts*. The earth is made up of systems, such as air, land, water, plants, and animals. If life is to be sustained, they cannot be separated, for what is happening to one is also felt by all of the other systems. In the same way, an individual is a whole made up of interdependent parts, which are the physical, mental, emotional, and spiritual. When one part is not working at its best, it will impact all the other parts of that person. Further, this whole person, including all of the parts, is constantly interacting with everything in the surrounding environment.

And according to the American Holistic Medical Association:^[5]

Wellness is defined as a state of well-being in which an individual’s body, mind, emotions, and spirit are in harmony with and guided by an awareness of society, nature, and the universe. ... [It] encompasses all safe modalities

of diagnosis and treatment, including the use of medications and surgery, emphasizing the necessity of looking at the whole person.

On its Internet website, the AHMA states:^[6] “Optimal health is much more than the absence of sickness. It is the conscious pursuit of the highest qualities of the spiritual, mental, emotional, physical, environmental, and social aspects of the human experience.”

With respect to their characterization of “part” and “whole”, these definitions of holistic medicine are largely compatible with a functional approach. Because the concept of function asks us to consider why a thing is here, i.e., what it is “doing” in the universe, it asks us to be holistic and take into account the *holon* – which in early Greek philosophy meant both “universe” and “organism”. Wholeness becomes a necessary concept for understanding function, and holistic medicine has done medical philosophy an important service by renewing its focus on the whole.

At the same time, we invite supporters of holistic medicine to consider an extension of their philosophy in two ways. First, we invite consideration of a multi-level understanding of wholeness that does not predetermine a frame of reference or specific context in which wholeness is to be evaluated. For example, if we do not presently know whether planetary indices of geomagnetic disturbance – such as sunspot relative number, area, and geomagnetic activity – are as valuable a “whole” or “universe” against which to evaluate and treat cardiovascular disease as homocysteine imbalances (the “whole” or “universe” of the cell) or “heartlessness” and “disheartenment” (a psychological or sociocultural “whole” or “context”), we might expect to benefit by keeping a radical open-mindedness about frames of reference, levels of wholeness, and their ultimate interrelationship in a holistic model. Instead of trying to simplify with three or four frames of reference based on early 20th century psychology (i.e., wholeness as the sum of physical, emotional, mental, and spiritual frames of reference) or a few contexts based on specialty (physical body, immediate external environment, global environment), we might simply postpone such conclusions until we learn more about levels of wholeness and their relationship. From a functional perspective, we suspect this relationship will closely resemble the one described by US engineer, designer, and architect, Buckminster Fuller, in his discussion of “functions” in his 1975 opus, *Synergetics*:^[7] “Functions occur only as inherently cooperative and accommodatively varying subspects of synergistically transforming wholes.”

The relationship of part to whole is a second area in which a holistic perspective could be logically extended. We believe the concept of function necessitates a view of “part” and “whole” that is quite different from the image of a disassembled jigsaw puzzle or a shattered china teacup, which can be reassembled or glued back together to re-establish the “whole” from which it came. In both of these examples, the parts have a visible connection to the whole, but in and of themselves are a diverse array of pieces in all shapes and sizes, bearing no individual resemblance to the whole from which they came. From a functional perspective, we believe this image of part and whole should be changed. Instead of

a shattered teacup or a disassembled puzzle, we propose a shattered *hologram*. When a hologram breaks, it does not shatter into discrete pieces with different sizes and shapes that individually bear no resemblance to the original hologram. It splits into separate pieces, each of which visibly contains the complete and original hologram.

From a medical perspective, this change means that we would stop assigning partial functions to anatomically distinct body parts or systems and begin treating all parts as visibly containing the original hologram, i.e., whole-body capability. For example, we have traditionally viewed the gastrointestinal (GI) tract, brain, and immune system as separate, identifiable parts unable to carry out each other's basic functions. In the case of the GI tract, these functions have traditionally been limited to digestion, absorption, secretion, and motility. We now know the GI tract has its own immune system (GALT) and its own brain (memory T-cells disseminated to the intestinal epithelium and lamina propria providing the functional basis for oral tolerance),^[8] and that it can carry on functions traditionally reserved for other systems of the body. Similarly, we now recognize that the eye does not simply "see". We know it helps set the body's circadian rhythms through the production of melatonin,^[9] and that it may therefore coordinate reproductive signaling as well.^[10] These findings encourage recognition of the whole inside each part. Equally encouraging have been the many "reflexologies" that have dotted the landscape of alternative medicine, and which have been given open-minded consideration in naturopathy – foot reflexology, iridology, intestinal reflexology in colonics, contact reflex analysis – each pointing toward a "shattered hologram" model in which the unbroken whole is visible in its seemingly separate parts.

Inside/outside

The classic debate over nature vs. nurture, heredity/environment, and genetics/experience has had troublesome consequences for a patient-centered approach to well-being. We have seen what can happen when the "insides", in their purest form, are equated with the chromosomal material inside the nucleus of the cell. What can happen is a philosophy of development that treats the three billion base pairs in the human genome as a largely unalterable blueprint working from the inside to define a person's potential with respect to the "great taskmaster outside", i.e., the environment. This extremist view of inside/outside, equating inside – the true "inner sanctum" – with the gene, has given us a national eugenics movement based on misinterpretation of ethnic differences in IQ, a national backlash against elementary school "mainstreaming" based on misinterpretation of learning disorders, and a popular anthropology of racial difference based on misinterpretation of the anthropological facts.

Two examples from the history of biology can help place the dualism of "inside/outside" in a more functional context. The first example involves a chapter of a book written by Swiss zoologist Adolph Portmann in 1967. In his chapter, titled "The Outside and the Inside", Portmann writes:^[11]

Biologists ... have worked from the outside inwards, from what is visible and

tangible to what is more and more deeply hidden. ... But such probing makes us strangers to the appearance of the living creatures around us. ... With a knowledge of the developmental conditions under which, for instance, a feather primordium develops and its pigment is formed, it is only the problem of shape that has been solved. But it still remains to be shown what brings about that special distribution of color in the pattern on the feather germ which is specifically directed towards the whole form in its final condition.

In his book, Portmann argues that outsides of animals are in fact expressions of their inwardness, i.e., their developmentally unfolding uniqueness and individuality. He also concludes that the ultimate purpose of this “insides-becoming-outsides” is to help living creatures find each other and “break the ban of isolation”.^[11]

What we hear in Portmann’s writing is a desire to blur (or even erase) the line between inside and outside. What is innermost “feels a desire” to become outermost, and for the purpose of connecting up with the innermost sanctum of another.

As health care practitioners, we are all familiar with the notion of a *milieu interieur* – an interior, homeostatic, calm harbor maintained in the wake of outside, stormy seas. Pasteur’s contemporary, Claude Bernard, first wrote about this concept in 1865 in his classic text *An Introduction to the Study of Experimental Medicine*,^[12] and it still serves as a cornerstone of our understanding of cellular events. But what we are not familiar with, in this second example, is the extent to which Bernard was forced to dismiss the relevance of purpose and design in positing the *milieu interieur*:^[12]

Neither physiologists nor physicians need imagine it their task to seek the cause of life or the essence of disease. That would be entirely wasting one’s time in pursuing a phantom. The words life, death, health, disease have no objective reality.

Sickness and death are merely a dislocation or disturbance of the mechanism which regulates the contact of vital stimulants with organic units.

It is, of course, the interior milieu that regulates this contact. But by making such an absolute division between inside and outside, Bernard ends up placing all responsibility and focus on this “mechanism” that connects “in” with “out”, and turning his back on the purpose and essence of life/death and health/disease.

Both of these examples caution us against drawing

absolute lines between inside and outside. So does the concept of function itself. When we recognize that function requires purpose – some goal or end-point toward which activity is directed – we are also recognizing that function requires *potential*, a goal or

end-point that is capable of being reached but has not yet been attained in actuality. Without potentiality, there is no function.

In functional medicine, no question is more critical than the question of this potentiality and its “location”. To what extent is potential “inside” of us, inside of our cells, our thought, our genes? How are “outside” events related to this potential? In immunology, at least since the end of World War II, we’ve developed a self/non-self model that is forcing us to relabel long lists of diseases as diseases of autoimmunity, diseases in which the distinction between self and non-self has become confused. But from a functional perspective, an absolute division between self and non-self is a too-literal separation of inside from out. Autoimmune diseases cannot be a set of inside, interior dynamics in which “self” mistakes “self” for “non-self” and self-destructs. If this were the case, we wouldn’t be discovering all the risk factors for autoimmune disorders on the outside, removed from the self. Yet that is exactly where we are finding them. The 17-amino acid sequence in bovine serum albumin that travels from cow’s milk formulas to pancreatic beta- cell surface proteins (protein 69) and increases risk for the autoimmune disease we call juvenile-onset diabetes,^[13] the links between xenobiotic exposure and systemic lupus erythematosus,^[14] and the newly designated “autoimmune polyendocrine syndromes” and their responsiveness to dietary modification are all examples that point to dangers *outside* the self and their key role in the development of autoimmune disease.

But it is not only negative potential that gets locked outside the self when we draw a line too absolutely between inside and out; it is positive potential as well. Function requires purpose. Purpose requires potential. To be “pluri-functioning” organisms, we must also be “pluri-potential”. And because the unbroken whole is visible in the parts, this pluripotential must reside in the parts as well, even in that innermost part we call the human genome, locked away inside the nucleus of the cell.

Molecular medicine is teaching us that there is no untouchable inside. Our outside experience – including our dietary intake – continually modifies the expression of our genes. Control of gene expression is highly encrypted, i.e., genes have inducer binding sites and promoter sequences that modify their expression. Numerous nutritional components have been shown to modify that expression, including linoleic and alpha-linolenic acid, isoflavones, quercetin, ellagic acid, vitamin A, and vitamin B₆.^[15] The potentiality is ever-present, even when IQ suggests otherwise. At our innermost, genetic selves, we are always also outside of ourselves, linked to wholes through our potential.

Cause/effect

In the fourth century BC, in a treatise entitled *Physica*, the Greek philosopher Aristotle described a doctrine of four causes: formal cause (*eidōs*), producing in a thing its constitutive essence; material cause (*hylē*), providing a thing with its matter and embodiment; efficient cause (*kinoun*), initiating change in a thing; and final cause (*telos*), providing an ultimate purpose for the change. Since the word “cause” has several meanings, Aristotle wrote: “It follows that there are several causes of the same thing (not merely in virtue of a concomitant attribute), e.g., both the art of the sculptor and the

bronze are causes of the statue.”^[16]

What appears treatable or preventable to us as practitioners depends entirely on our philosophy of medicine. Whether dysfunction is treatable or preventable depends on what caused the dysfunction in the first place, i.e., on our concept of causality. Keith Block, MD, medical director of the Cancer Institute at Edgewater Medical Center in Chicago, Illinois, has recently argued that the labeling of any cancer as “terminal” is both scientifically and spiritually unjustifiable.^[17] His argument is based on a view of cancer causality that includes an active role for the self in deciphering and acting upon the cosmic event that cancer represents.

But the views of Aristotle and Block, welcoming a complex view of causality into our understanding of health, are far from our classic heritage in the sciences. As French Nobel Prize winner Jacques Monod wrote, in his classic 1970 work *Chance and Necessity*:

The cornerstone of the scientific method is ... *systematic* denial that “true” knowledge can be got at by interpreting phenomena in terms of final causes – that is to say of “purpose”.^[18]

Against this notion, this powerful feeling of destiny, we must be constantly on guard.^[18]

Monod’s philosophy is our reigning medical philosophy – a philosophy steeped in the Darwinian legacy of a universe with minimal original essence, minimal momentary stability, and an indefinite horizon of possibilities.^[19] It is a philosophy that tells us we must be careful when reading purpose into dysfunction, and that we should accept whole categories of disability and death as purposeless, chance events that are essentially not preventable.

Naturopathy, with its focus on prevention, has helped to transform this perspective. Most naturopaths would readily subscribe to the mission statement of the Foundation for Preventive Medicine, based in New York City, when it describes its mission as “enhancing the public’s awareness of recent information indicating that most

causes of death in our society ... are now regarded as potentially preventable”. Preventive, functional, and naturopathic medicine all seem to agree that lack of well-being, lack of vitality, depression, and deficiency in energy are also associated with largely preventable conditions,^[20] and that each time we transfer a health condition from the category of “not preventable” to “preventable”, we are honoring our medical philosophy.

Energy/matter

As scientists, most of us subscribe to an energy-based view of human function. We believe that healthy function rests on the shoulders of gated ion channels, electrolyte balance, membrane potential, redox, electrochemical gradients, and high-energy phosphate bonds. In our view, the release of heat energy from cells is what makes biological order actually possible in the first place.^[21] Yet in spite of its acceptance at a biological and biochemical level, this energy-based paradigm has yet to become fully integrated into our *medicine*. While electrocardiographic, magnetic resonance, and single photon emission imaging have become standard parts of our diagnostic repertoire, electroacupuncture biofeedback devices, despite their research record and use in many countries,^[22] remain unapproved for clinical use in the USA.

Once again, naturopathic medicine has provided leadership in this area. Energy-based medicine has been given open-minded consideration in naturopathy, and whole traditions based on principles of energy, including acupuncture and Oriental medicine, have been treated as essential areas for understanding and research. Similarly, acceptance of homeopathy, an energy-based medicine used by a quarter of a million practitioners worldwide,^[23] has been nurtured in the USA by the supportive position adopted by naturopaths and naturopathic institutions.

From a functional perspective, the rightful place of “energy medicine” in health care approaches is woven into the term “function” itself, which derives from the Greek *en-ergia*, literally “functioning” or “being in activity”. But clearly, as practitioners, we are just starting to explore this energy–matter relationship in our medical philosophy. In nutrition, for example, we are just beginning to shed our 19th century steam engine model, which perceives the body as a large furnace combusting matter (food) for the sake of extracting caloric energy. In this model, energy is not useful unless extracted out of matter, and matter, once depleted of its energy, is of little use as well. This food-as-fuel model has left us with an under-appreciation of food’s matter and its energy. As raw material for caloric extraction, food becomes most important for its gross, undifferentiated macronutrient content – its 20 g of fat or 100 g of carbohydrate. Subtler distinctions involving omega 3:omega 6 or oligosaccharide:polysaccharide ratio have been slow to evolve. Likewise, food energetics – including the issues of raw food, live food, food enzymes, and active cultures – have been negligibly addressed. Interestingly, we are finding the role of light – in the form of food pigments, including the hemes, chlorophylls, carotenoids, and flavonoids – is slowly revolutionizing our approach to food in the same way that light (and the frame of reference it represented) revolutionized our approach to mass and energy in physics.

Body systems from a functional medicine perspective

Historical and philosophical perspective

Students of science and medicine in the USA and other Western countries learn anatomy and physiology from a systems approach. They learn to view organ systems, individual organs, tissues, cells, and subcellular spaces as separate entities that interact

with one another to create form and function. The better one understands any one system or entity, by this model, the more skilled one will be at treating dysfunction of that entity. This model served well in developing a rational method of inquiry into the etiology of many diseases. Indeed, the advancement of medical science has long been measured by progress made in understanding the mechanisms of disease related to dysfunction in the body's distinct compartments.

Fundamental to the systems model has been the assumption that the more we know about individual organs or systems, the better our medicine will be. Until very recently, this assumption had been widely validated throughout medical history by remarkable progress in diagnosis and treatment of disease, surgical practice, and the development of medications for symptom reduction related to specific diseases.

The progress that resulted from this compartmentalizing approach can be compared to advances in biology that followed Linnaeus's development of a system of taxonomic classification of living organisms in the 18th century. The formalized system of learning allowed for significant advancement in the field of biology. By the 1970s, however, many biologists had become aware of the limitations of description and classification as an epistemology. Their science had outgrown the model. Through advancements in the disciplines of ecology and environmental science, they knew they could classify all the plants and animals in an ecosystem and yet understand nothing about the functioning of the ecosystem as an integrated whole. The need had arisen to address the larger issues of how compartments within the ecosystem interacted to give rise to its function and survival.

From the perspective of these advancements in biology, one could view medicine as a specialized discipline within the broader field of human ecology. To understand health and disease, one would be required to examine the functional interaction of organ systems with the human environment. Furthermore, one would have to observe the functional interaction between the total human environment and the energy processing and control systems within it.

Examining any discipline from a new point of view makes it possible to ask new questions and gain new insights. Looking at human health and medicine from the point of view of interactive function raises questions about the homeodynamic interplay between the external and internal environments of the individual. The functional viewpoint is the longer, larger view; it moves away from the narrow focus on pathology of various parts of the body. It removes the principal focus from diagnosis of pathology and places it on evaluation of genetic pluripotential and its translation into homeodynamic function. It views disease not as an enemy with which to grapple, but as a manifestation of the breakdown of mechanisms that establish control and resilience. To restore these processes, functional medicine uses a broader range of methods than the cut-and-paste tools of compartmentalized medicine. Among others, it employs nutrition, environmental adaptation, lifestyle changes, activity or stress pattern adjustment, or molecular pharmacology, and its selection of tools is based on the

unique needs of the individual.

The traditional anatomy/physiology model of Western medicine still has great value in diagnosis and treatment, and it has wide application in responding to many specific disease states. This traditional model breaks down, however, when it is applied to chronic conditions that transcend individual organs or organ systems. Among these chronic health problems are inflammation, fatigue, pain, immune dysfunction, and problems of digestion. All of these conditions are characterized, not by end-stage pathologies, but by altered physiological function, and they require a more integrative model to design a therapeutic approach that can improve long-term outcome. This more integrative model is built upon the understanding that dysfunction is not compartment- or organ-specific, but is an alteration in integrated homeodynamic processes.

The functional medicine approach incorporates evaluation of antecedents to a health problem, its triggering factors, mediators of altered physiological function, and the relationship to signs and symptoms, to develop an integrated view of the patient's health status. It focuses less on defining the disease and more on understanding the functions that give rise to the expression of symptoms.

A woman may approach her physician complaining of chronic intestinal pain and symptoms of irritable bowel syndrome, for example. A medical history and initial evaluation might uncover other symptoms, including joint pain, headache, low energy, sleep disturbances, and eczema. Rather than coming up with a primary and secondary diagnosis and prescribing symptom-relieving medications, a functional medicine practitioner would delve further in evaluating the source of the inflammation. The practitioner might assess gastrointestinal function, hepatic detoxification ability, and immunological status, and assess their relationship to oxidative stress mediators. Based on this "second tier" of assessments, the practitioner would develop an integrated approach to modify triggers and mediators using specific biological response modifiers and lifestyle alterations of the individual.

Systems integration and functional medicine

The emerging science of today has blurred distinctions among organs, and separation of function into distinct compartments is less useful as a concept. We now know, for example, that identical signalling molecules are released and received by all organ systems, and each influences the function of the others. The view of the body as a collection of separate, interconnected parts is being replaced by an image of the body as a hologram. The endocrine system synthesizes a neurotransmitter that is released by the nervous system and has a receptor site on the white blood cell. A blood cell synthesizes cytokines that are released by the immune system and have receptor sites on the glial cell in the brain. The liver synthesizes steroid hormones that are released by the endocrine system and have immune and nervous system receptors, and vice versa. In other words, all the organs and organ systems of the body are constantly engaging in "cross-communication", which makes distinctions among them a matter of definition rather than function.

In the past 10 years, medicine has witnessed a revolution in molecular biology. We now

know, for example, that modifiers of gene expression are produced not only by different organs but also by exposure to various agents in the diet and environment, including chemicals and electromagnetic radiation. We have learned that the processes that give rise to an individual's health or disease are not controlled by genes alone. Instead, modification of function comes about through alteration in gene expression, transmitting new physiological messages about individual regulation and control.

This new view of health focuses on maintaining metabolic and homeodynamic freedom based on interconnectedness, pluripotential, diversity, and redundancy of function. Loss or decline in any of these parameters can be seen as an altered state of health. Altered physiological diversity, for example, translates to a loss of metabolic freedom and a subsequent state of lower

health reserve. Assessing health, therefore, depends on measuring this reserve rather than evaluating pathology. Functional challenge tests, an integral part of the practice of functional medicine, make it possible to measure specific reserves under conditions of stress. Examples of functional tests include the exercise treadmill test for cardiac function, oral glucose tolerance testing for blood sugar management, and food provocation challenges for food sensitivity.

Functional medicine practitioners use the patient as his or her own "universe", or point of reference in which his or her unique set of interconnections, potentials, diversities, and redundancies is realized. Whether changing conditions involving time, temperature, electro-magnetic energy gradients, infective organisms, or trauma will lower degrees of metabolic freedom is a question that can be answered only in the context of the individual and his or her ability to maintain reserve and avoid reduced stability that comes from lost potential.

Functional medicine focuses on maintenance of stability and pluripotential across organ domains. From this perspective, all organ-specific symptoms the patient possesses at any one moment reflect homeodynamic alterations at a broad, "weblike" level and result in new metastable physiological states characterized by lowered stability and reduced degrees of metabolic freedom and efficiency. The more freedom is lost at this "weblike" level, the more symptoms will become manifest, and the more closely they will resemble classical pathology. It is the integrative, homeodynamic, regulatory role of the web that is being altered, however, not a circumscribed set of functions within a specific organ domain. As a diagnostician, a practitioner might look through a focused lens such as an X-ray, blood chemistry, or CAT scan at an isolated, compartmentalized organ system. As a functional medicine practitioner, however, he or she will view alteration in this seemingly distinct compartment as a reflection of change in the web, the whole of which is the individual and his or her unique life experience in the world.

PART II: THE CLINICAL APPLICATION OF FUNCTIONAL MEDICINE

BASIC CONCEPTS IN FUNCTIONAL MEDICINE PRACTICE

The practice of functional medicine is guided by three basic concepts: biochemical individuality, health as positive vitality, and life processes as homeodynamic.

Biochemical individuality

Each individual is unique. This uniqueness encompasses voluntary activities, such as decision-making, personality development, and emotional response, and involuntary activities like metabolism of nutrients, cellular processing of information, and communications among the body's organ systems. The concept of biochemical individuality is central to every aspect of the practice of functional medicine, from clinical assessment and diagnosis to the broad spectrum of treatment modalities.

As traditionally practiced, medicine and nutrition have given only token consideration to the concept of individuality. In conditions such as phenylketonuria (PKU) or maple sugar urine disease (MSUD), for example, although medicine has long recognized that specific metabolic aberrations alter the afflicted individual's nutrition and health needs, it has taken the view that these defects are so rare as to be inconsequential. A functional medicine practitioner, on the other hand, considers that all individuals have unique metabolic patterns that affect their nutrition and health needs. In comparing two individuals whose blood levels of B vitamins are nearly identical, for example, one might have five times as high a level of B vitamins in his or her cells as the other. Individuals also respond uniquely to environmental toxins, food additives, and prescription medications.

Health as a positive vitality

Functional medicine views health as more than the absence of disease. Health, in the functional medicine model, is the state of positive vitality unique to each individual within his or her life context. Functional medicine employs new assessment tools to help quantify individual well-being and evaluate his or her physiological, cognitive/emotional, and physical function.

Functional medicine practitioners cannot narrowly focus on a patient's symptoms, complaints, or history of illness. They must also evaluate the patient's history of wellness by asking when in life the individual has felt best and what circumstances would be necessary to make that patient feel truly well again. Although relief of symptoms might be one goal of the application of functional medicine, the broader goal would be to support vitality in the patient's life experience.

Life processes as homeodynamic

Homeodynamics as a principle of functional medicine contrasts with the concept of “homeostasis” in conventional medicine. Homeostasis describes the balance of interconnected components that keep a physical or chemical parameter of the body relatively constant. Homeodynamics posits a similar control system functioning to maintain biochemical individuality.

Applied to the body, the term “homeodynamic” describes

11

a range of continuously occurring metabolic and physiologic activities that enable an individual to adapt to changing circumstances, stresses, and experiences. The homeodynamics of one’s health are constantly at work to enable a person to function as a unique individual. Supporting health at a homeodynamic level may require one to focus attention on cellular processes or organ function at sites that seem to be far removed from the patient’s area of discomfort, and at levels that may be unusual from a conventional point of view.

ASSESSMENT AND TREATMENT FROM A FUNCTIONAL PERSPECTIVE

Healing practices in any society evolve within a cultural context and draw upon the belief systems and resources of the healers within that culture. In traditional societies, the background and support of healing derive from the natural world. In industrialized societies, evolving in a framework erected by Newton and Descartes, medicine formed a different understanding of the body and its function.

The term “diagnosis” derives from the Greek word *diagnosis*, which means, literally, “through gnosis, through the knowledge gained through a perspective”. In conventional Western medicine, diagnosis is defined as “the art of distinguishing one disease from another” or “the determination of the nature of a case of a disease”. *Clinical diagnosis* is “diagnosis based on symptoms, irrespective of the morbid changes producing them”. *Differential diagnosis* is “determining which of two or more diseases or conditions a patient suffers from, by systematically comparing and contrasting their symptoms”.

Key concepts in these definitions are “disease”, “symptoms”, and “suffers from”, and analysis of these concepts yields clues to the philosophical perspective underlying the Western medical approach to managing health. This underlying perspective is the key factor that differentiates one healing system from another. It is the basis by which we examine patients and develop our plan of action or treatment. A physician whose perspective is oriented toward pharmacology views patients in terms of what drugs are needed. A nutritionist might look for specific nutrients or dietary changes that would benefit patients. A psychotherapist might ask which form of counseling or behavioral intervention is warranted. In each case, the course of action is dictated by the

practitioner's underlying perspective.

The underlying perspective of functional medicine is based on process, dynamics, and purpose. Functional medicine focuses on dynamic processes that underlie and precede the pathological state. Acknowledging the existence and necessity to understand pathology, functional medicine focuses on underlying processes and seeks solutions that address these processes.

The practice of functional medicine does not focus on diagnosis that compartmentalizes diseases into known entities. Such a system, although it might be useful, is apt to presume that if we can name a disorder we can understand how it came about. Functional medicine practitioners recognize diagnosis categories, but they also investigate underlying dietary, nutritional, lifestyle, environmental, and psychosocial factors that might alter the patient's state of health and investigate the "purpose" behind the expression of illness.

Illness as information

From the traditional medical viewpoint, illness "happens" to a human being; an outside force upsets a system of the body. The clinician then seeks to discover precisely what it was that caused the illness. Although this method remains a useful view in diagnosis (since a number of factors, including food, chemicals, and microorganisms, affect our homeodynamics), it places constraints on both patient and clinician. On the other hand, if we take the view that the human body is an energy-driven, energy-sensitive system that interacts constantly with its surroundings, we can begin to view illness as a form of communication from one level to a level of conscious awareness. Conscious awareness enables the individual to begin to understand the factors that collectively led to the illness.

Because it has a purpose, illness can be seen as a functional condition. It may function as an agent for change. It may itself be an epiphenomenon that requires treatment, but paying heed to the "message" that is being communicated by the illness may be what finally enables healing to take place. Both scientific and popular literature often describe cases of recovery from serious illness that occurred as a result of the individual's paying attention to the message contained in the symptoms.

In clinical practice, illness communicates its messages in many ways, including symptoms arising from exposure to chemicals, rashes or breathing difficulties from consuming food allergens, neck pain from repetitive workplace activity, and stress-induced chest pains. Patients who present with these complaints are all getting messages about their bodies' interactions with their surroundings. In neurology, occurrences of hysterical blindness or hemiplegia are examples of illness as information. In both conditions, physical symptoms arising from deep psychological problems mimic severe organic disease.^[24]

In making a diagnosis, the functional medicine practitioner must be aware of the message being sent and approach the patient's illness not as an adversary to be

overcome but as information that must be understood and acted upon.

Treatment decisions

The experienced practitioner of functional medicine knows that illness typically arises from multiple influences, and his or her assessment and treatment take this array of influences into account. In dealing with a problem like migraine headaches, for example, this approach contrasts with the traditional approach of Western medicine. The latter would identify the symptom pattern, rule out vascular and intracranial pathology, and test for the presence of hypertension or renal disease. Treatment would be with drugs like sumatriptan, propranolol, or ergotamine. Biofeedback might be employed as an adjunctive therapy. The functional medicine practitioner, in contrast, would ask the migraine sufferer about dietary, nutritional, genetic, environmental, lifestyle, psychosocial, or spiritual factors that might be interacting in his or her life. The practitioner would inquire into functional changes that might underlie the expression of migraine symptoms. The goal would be to develop a range of potential patient-centered solutions to migraine headache. Remediation of migraine, for example, has been reported with oral magnesium therapy (M. A. Schmidt, unpublished data), essential fatty acid supplementation (S. Baker, personal communication, 1996), removal of food, chemical, and inhalant triggers,^[25] sublingual neutralization therapy,^[26] spinal manipulation (P. Bolin, personal communication, 1996), acupuncture, homeopathy, and the botanical feverfew (*Tanacetum parthenium*).^[27] The functional medicine practitioner might employ any one or a combination of these therapies, realizing that no single approach is effective with all migraine sufferers. Rea^[25] found that the headache symptoms of 100% of a group of 30 migraine sufferers were triggered by chemicals under controlled challenge, but these were patients who reported chemical sensitivity. A patient-centered approach that recognizes statistical tendencies and diagnostic categories, but is not constrained by them, is desirable.

Another example of the value of the functional medicine approach is in assessing microbe-associated illness. The traditional approach to infectious disease regards the organism as an external threat that must be eradicated by intervention that targets that organism specifically. The microbe is the enemy, and drug therapy is the typical weapon. A broader, functional medicine approach would view the microbe as just one (albeit important) factor contributing to poor health. The functional medicine practitioner would consider the state of the host's defenses and evaluate factors that influence host defenses by examining nutritional, metabolic, environmental, lifestyle, and psychosocial factors that influence immune vigilance.

The philosophical basis of functional medicine leads to treatment decisions that are quite different from those typically encountered in an infectious disease model. For example, a patient with Down's syndrome who suffers from recurrent infection with *S. pneumoniae* or *H. influenzae* may experience an increase in IgG₂ and IgG₄ production and a reduction in infection susceptibility with selenium supplementation.^[28] A child with

otitis media with effusion might be treated not with antimicrobials, but with elimination of allergenic foods.^[29] An endurance runner who suffers from upper respiratory tract infection associated with heavy training might be given antioxidants.^[30]

Concept of total load

Total load refers to the sum of influences affecting an individual's life. Initially advanced by environmental medicine practitioners, the concept is now widely adopted. Included in the total load are chemicals, food, microbes, psychological stressors, and other factors, each of which alone might not give rise to the symptoms of illness. Together, however, the factors that comprise the total load may overwhelm the patient's metabolic management system. According to Rea^[25], more than 20,000 patients at his Environmental Health Center in Dallas, Texas, experienced relief of symptoms of a range of clinical disorders through reduction of total load.

A person's biochemical individuality affects his or her susceptibility to toxins, and intervention aimed at improving function can help reduce susceptibility or sensitivity. A defective sulfur metabolism pathway, for example, might cause an individual who reacts to sulfur-rich foods to react to other substances in ways that lead to metabolic disturbance. Nutrient modulation might lessen his or her sensitivity to these environmental substances. Efforts to reduce total load should be balanced by efforts to restore function, with the long-term goal being reduced susceptibility.

Depth of action

The functional perspective requires the practitioner to examine the processes that give rise to symptoms. Arriving at a diagnosis does not guarantee that we understand what is happening or what the patient needs. For example, we might arrive at a diagnosis of "mood disorder" in a depressed patient and assume that he or she would benefit from a drug like fluoxetine. If the depression arose from a spiritual or relationship crisis, however, the drug therapy might actually interfere with the problem-solving processes that would lead to true healing. Mood and quality of life might appear to improve with drugs, but the patient's long-term healing would not have been facilitated.

A group of epileptic children who were videotaped as they interacted with their families illustrates the

point. Emotionally fraught family encounters were, in many cases, followed by seizures. When the epileptic patients were later shown films of these episodes, and they saw the relationship between emotional events and seizures, they were able, in many instances, to become almost seizure-free.^[31] Granted, drug therapy might have helped these patients to control seizures, but if drugs were the only means of intervention employed, the epileptic children would not have had the opportunity to experience healing at a deeper level.

Mechanism and outcome

Understanding biochemical mechanisms enables functional medicine practitioners to apply them in diagnosis and treatment. Understanding the mechanism of homocysteine accumulation, for example, allows them to recommend nutritional strategies like folic acid and vitamin B₁₂ therapy. By understanding fatty acid synthesis and the arachidonic acid cascade, they can develop nutritional therapies that modify inflammation. Knowing that copper accumulation leads to Wilson's disease allows them to utilize zinc therapy.

Some treatment modalities bring positive outcomes for which the mechanism is not yet well understood. Spinal manipulation in asthmatics admitted to the emergency room, for example, can lessen anxiety and ease breathing. This treatment typically brings about a 25–70% improvement in measurement of peak blood flow.^[32] Using pre- and post-manipulation tympanographs, Fallon showed that spinal manipulation in children with otitis media led to normalization of abnormal tympanograms (J. Fallon, personal communication, 1995). Similarly, Fryman (personal communication, 1996) has shown that cranial manipulation normalizes tympanographic measurements in some children.

The knowledge that viscerosomatic and somatovisceral reflexes influence the flow of information within the human body suggests the possible mechanism by which manipulation affects visceral function, although the mechanism is not yet clearly understood. Improved function, patient outcome, and quality of life are central to the success of any healing system, however, whether or not we understand the mechanisms of action.

Homeopathic medicine is a discipline that is not bound by mechanism, but is rooted in careful analysis and pattern recognition. Reilly^[33] demonstrated that asthmatic patients who took homeopathic preparations showed significant improvement in only 1 week compared with those taking placebo. These dramatic results led him to conclude that either homeopathic medicine worked beyond a shadow of a doubt, or the double-blind, placebo-controlled trial, the gold standard of proof upon which modern pharmacology is built, was essentially invalid.

Throughout the range of healing arts and sciences, there are numerous examples of positive treatment outcomes that occur even though the mechanism cannot be explained. In functional medicine, the value of understanding mechanisms is in improving human function and patient outcome.

Prevention, early detection, and functional medicine

“Prevention” has become a welcome and popular concept in recent years in the practice of medicine. A distinction must be made, however, between true prevention and “early detection”. Although periodic mammography has been heralded as a form of preventive medicine, for example, it is clearly in the realm of early detection. Prevention assumes an understanding of factors that give rise to breast cancer and

recommendation/adoption of habits or patterns that prevent disease occurrence.

Both prevention and early detection are included in the practice of functional medicine, but the patient's individuality remains paramount. Functional medicine practitioners work to prevent a specific disorder by managing risk factors, but they also strive to raise the individual's functional capacity within his or her unique life circumstances.

Approach to the patient

Functional medicine is always patient-centered, but it is not the only discipline that fits this description. Naturopathic medicine has helped to pioneer a patient-centered medical approach, not only by making the whole person the center of its practice, but also by incorporating highly patient-centered traditions into its repertoire, including traditional Chinese medicine, Ayur-vedic medicine, homeopathy, chiropractic, and physical therapy, including manipulation and massage. The focus on the patient is important, however, because as methods of data management become more sophisticated, the tendency is to think in terms of probability instead of thinking in terms of the individual patient. Probability is useful in understanding the broad context of health and disease, but clinical practice is filled with so many exceptions that relying on statistics is difficult.

Laboratory and instrumental diagnosis from a functional perspective

In assessing a patient's health, the functional medicine practitioner uses tools that help in understanding how the patient functioned before developing the pathology. These tools also help the practitioner to understand function in the existence of pathology and to assist in predicting preventive measures.

Serum glucose measurement is a traditional assessment

of a fixed analyte at a fixed point in time. Although this measurement yields useful information, it does not reveal how serum glucose will respond under varying dietary conditions. The glucose challenge test, on the other hand, is a functional test that assesses glucose status over time. Similarly, although a resting ECG provides useful information, it does not indicate how the heart would respond to a physical challenge. The stress ECG shows how the heart responds upon exertion.

Assessment of magnesium is a third example. Magnesium is an intracellular element, which means that most of the body's magnesium stores are contained within cells, and only a small amount circulates in blood. A measurement of serum magnesium levels, therefore, does not reflect total body magnesium or the functional status of magnesium. Red cell magnesium is a better indicator of status, although it is a measurement of a fixed analyte at a fixed point in time and has limitations as well. Magnesium loading and subsequently assessing retention by measuring urinary excretion provide a means to

assess the functional magnesium status and the unique needs of a particular patient.

For functional medicine practitioners, tools that view the body under challenge conditions give a more accurate assessment of body function. This is especially true when one wishes to examine the body's response to exogenous substances. Some individuals will experience an adverse reaction to any given drug, and these reactions are regarded as atypical and unavoidable. From a different perspective, however, the reactions are not atypical and unavoidable; they are typical and avoidable for that person, and he or she would typically be expected to have an adverse reaction on ingestion of this drug.

This understanding comes from developments in understanding the body's detoxification mechanisms. When a drug or medication is ingested, it is metabolized by the body and prepared for excretion. The process of detoxification and preparation for excretion takes place in two distinct biochemical phases, known as phase I and phase II. In the biotransformation of a drug or chemical, the agent is progressively converted to a more water-soluble, excretable substance. In phase I, which generally occurs first, a family of isozymes known as cytochrome P450 (cP450) converts the drug or substance into a reactive intermediate, which, although it may be excreted in its present form, typically is further acted upon by phase II processes.

In phase II, conjugating substances are attached to the phase I product to facilitate its excretion. Phase II reactions typically take place through glucuronidation, amino acid conjugation, glutathione conjugation, acetylation, and methylation.^[34] The phase II process, which depends strongly on adequacy of specific nutrients, must be capable of transforming all of the phase I-generated reactive molecules into excretable compounds. If this process is incomplete, toxic intermediates can build up.

Acetaminophen is a typical drug that undergoes conversion for excretion through these two pathways. A common OTC and prescription pain-relieving drug, acetaminophen is a useful model because more than 70,000 incidents of acetaminophen overdose were reported to US poison control centers in 1994.^[35] Acetaminophen normally undergoes phase II transformation through the sulfation and glucuronidation pathways, with a small amount being metabolized through glutathione conjugation after conversion in phase I.^[36] When the drug is not efficiently converted for excretion, the metabolites that build up can have negative metabolic consequences. Accumulations of one extremely toxic metabolite, NAPQI, may cause liver and nervous system damage. An individual with an adequately functioning detoxification ability that facilitates efficient phase II conversion of acetaminophen is much less likely to have a negative experience than one whose ineffective conversion pathways allow toxic intermediates to accumulate.

If one ingests acetaminophen on a regular basis, the sulfur-bearing nutrients glutathione, methionine, and cysteine can be rapidly depleted, with accompanying liver cell damage.^[37]

Adverse acetaminophen reactions may therefore result from alterations in detoxification pathways. The acetaminophen challenge test effectively assesses the function of these pathways. After the individual has consumed a challenge substance, measurements of

acetaminophen metabolites in urine can determine the efficiency of the various conversion processes and provide information about the individual's unique susceptibility.

It may be that alterations in the detoxification pathways of many individuals who have "atypical" drug reactions are making them predictably susceptible to certain kinds of substances. If we can gather this information about them, we may be able to predict their response to drugs, as well as chemicals, foods, and plants. We may be able to understand the functional derangement that underlies the pathology that can result from interaction with the environment; and we may be able to use diet and nutrition to help these individuals restore function in these pathways.

Pattern recognition

The next step in the evolution of functional assessment will be to consider human physiology as a dynamic process, involving the interrelationship of multiple systems. Functional assessment of only one pathway or one series of pathways may yield useful information, but it still provides a very limited view. Functional testing will no doubt soon evolve to assess multiple analytes and utilize sophisticated pattern recognition methods.

15

Pattern recognition is not new. For centuries, in fact, traditional Chinese medicine has dealt with "patterns of disharmony". The clinician trained in this discipline learns to recognize the pattern and assign it to a specific diagnostic category. In homeopathic medicine, it was pattern recognition that led to the extensive *materia medica*. In psychotherapy, an evaluation of the patient's life events and stories is conducted in an effort to understand the patterns that produce disharmony. In all of these examples, the mechanisms are unimportant; the pattern leads to treatment decisions.

SUMMARY

Pattern recognition, depth of action, total load, energetics, information, and patient-centered decisions all describe the early stages of development of the evolving functional approach to assessment and treatment. They also characterize a functional approach with a strong focus on the integrative use of treatment modalities based on recognition of underlying purpose in the transformations viewed by practitioners as they work with individual patients. This is also the integrative paradigm which unites naturopathy with functional medicine.

Chapter 2 - History of naturopathic medicine

George Cody JD

INTRODUCTION

“Naturopathy”, as a generally used term, began with the teachings and concepts of Benedict Lust. Naturopathy, or “nature cure”, is both a way of life, and a concept of healing employing various natural means of treating human infirmities and disease states. The earliest mechanisms of healing associated with the term, as utilized by Lust, involved a combination of hygienics and hydropathy (hydrotherapy). The term itself was coined in 1895 by Dr John Scheel of New York City, to describe his method of health care. But earlier forerunners of these concepts had already existed in the history of natural healing, both in America and in the Austro-Germanic European core.

Lust came to this country from Germany in 1892 as a disciple of Father Kneipp and as a missionary dispatched by Kneipp to bring hydrotherapy to America. Lust purchased the term “naturopathy” from Scheel in 1902 to describe the eclectic compilation of doctrines of natural healing that he envisioned to be the future of natural medicine. In January of 1902, Lust, who had been publishing the *Kneipp Water Cure Monthly* and its German language counterpart in New York since 1896, changed the name of the journal to *The Naturopathic and Herald of Health* and evoked the dawn of a new health care era with the following editorial:

Naturopathy is a hybrid word. It is purposely so. No single tongue could distinguish a system whose origin, scope and purpose is universal – broad as the world, deep as love, high as heaven. Naturopathy was not born of a sudden or a happen-so. Its progenitors have for eons been projecting thoughts and ideas and ideals whose culminations are crystallized in the new Therapy. Connaro, doling out his few fixed ounces of food and drink each day in his determined exemplification of Dietotherapy; Priessnitz, agonizing, despised and dejected through the long years of Hydropathy’s travail; the Woerishofen priest, laboring lovingly in his little parish home for the thousands who journeyed Germany over for the Kneipp cure; Kuhne, living vicariously and dying a martyr for the sake of Serotherapy; A.T. Still,

in Osteopathy; Bernarr Macfadden, fired by the will to make Physical Culture popular; Helen Willmans, threading the mazes of Mental Science, and finally emerging triumphant; Orrison Sweet Maraden, throbbing in sympathy with human faults and failures, and longing to realize Success to all mankind – these and hosts of others have brought into being single systems whose focal features are perpetuated in Naturopathy.

Jesus Christ – I say it reverently – knew the possibility of physical immortality. He believed in bodily beauty; He founded Mental Healing; He perfected Spirit-power. And Naturopathy will include ultimately the supreme forces that made the Man of Galilee omnipotent.

The scope of Naturopathy is from the first kiss of the new-found lovers to the burying of the centenarian whose birth was the symbol of their perfected one-ness. It includes ideally every life-phase of the id, the embryo, the foetus, the birth, the babe, the child, the youth, the man, the lover, the husband, the father, the patriarch, the soul.

We believe in strong, pure, beautiful bodies thrilling perpetually with the glorious power of radiating health. We want every man, woman and child in this great land to know and embody and feel the truths of right living that mean conscious mastery. We plead for the renouncing of poisons from the coffee, white flour, glucose, lard, and like venom of the American table to patent medicines, tobacco, liquor and the other inevitable recourse of perverted appetite. We long for the time when an eight-hour day may enable every worker to stop existing long enough to live; when the spirit of universal brotherhood shall animate business and society and the church; when every American may have a little cottage of his own, and a bit of ground where he may combine Aerotherapy, Heliotherapy, Geotherapy, Aristophagy and nature's other forces with home and peace and happiness and things forbidden to flat-dwellers; when people may stop doing and thinking and being for others and be for themselves; when true love and divine marriage and pre-natal culture and controlled parenthood may fill this world with germ-gods instead of humanized animals.

In a word, Naturopathy stands for the reconciling, harmonizing and unifying of nature, humanity and God.

Fundamentally therapeutic because men need healing; elementally educational because men need teaching; ultimately inspirational because men need empowering, it encompasses the realm of human progress and destiny.

Perhaps a word of appreciation is due Mr. John H. Scheel, who first used the term "Naturopathic" in connection with his Sanitarium "Badekur," and who has courteously allowed us to share the name. It was chosen out of some 150 submitted, as most comprehensive and enduring. All our present plans are looking forward some five or ten or fifty years when Naturopathy shall be the greatest system in the world.

Actually the present development of Naturopathy is pitifully inadequate, and we shall from time to time present plans and ask suggestions for the surpassing achievement of our world-wide purpose. Dietetics, Physical Culture and Hydropathy are the measures upon which Naturopathy is to build; mental culture is the means, and soul-selfhood is the motive.

If the infinite immensity of plan, plea and purpose of this particular magazine and movement were told you, you would simply smile in your condescendingly superior way and straightway forget. Not having learned as yet what a brain and imagination and a will can do, you consider Naturopathy an ordinarily innocuous affair, with a lukewarm purpose back of it, and an ebbing future ahead of it. Such is the character of the average wishy-washy health movement and tumultuous wave of reform.

Your incredulous smile would not discomfit us – we do not importune your belief, or your help, or your money. Wherein we differ from the orthodox self-labeled reformer, who cries for sympathy and cringes for shekels.

We need money most persistently – a million dollars could be used to advantage in a single branch of the work already definitely planned and awaiting materialization; and we need co-operation in a hundred different ways. But these are not the things we expect or deem best.

Criticism, fair, full and unsparing is the one thing of value you can give this paper. Let me explain. Change is the keynote of this January issue – in form, title, make-up. If it please you, your subscription and a word to your still-benighted friends is ample appreciation. But if you don't like it, say so. Tell us wherein the paper is inefficient or redundant or ill-advised, how it will more nearly fit into your personal needs, what we can do to make it the broadest, deepest, truest, most inspiring of the mighty host of printed powers. The most salient letter of less than 300 words will be printed in full, and we shall ask to present the writer with a subscription-receipt for life.

By to-morrow you will probably have forgotten this request; by the day after you will have dropped back into your old ways of criminal eating and foolish drinking and sagged standing and congested sitting and narrow thinking and deadly fearing – until the next progress paper of New Thought or Mental Science or Dietetics or Physical Culture prods you into momentary activity.

Between now and December we shall tell you just how to preserve the right

attitude, physical and mental, without a single external aid; and how, every moment of every day, to tingle and pulsate and leap with the boundless ecstasy of manhood consciously nearing perfection.

A BRIEF HISTORY OF EARLY AMERICAN MEDICINE WITH AN EMPHASIS ON NATURAL HEALING

To understand the evolutionary history of naturopathic medicine in this country, it is necessary to view the internal development of the profession against the historical, social, and cultural backdrop of American social history.

Medicine in America: 1800–1875

In the America of 1800, although a professional medical class existed, medicine was primarily domestically oriented. When an individual fell ill, he was commonly nursed by a friend or family member who relied upon William Buchan's *Domestic Medicine* (1769), John Wesley's *Primitive Physic* (1747), or John Gunn's *Domestic Medicine* (1830).^[1]

Professional medicine

Professional medicine transferred from England and Scotland to America in pre-revolutionary days. However, 18th- and early 19th-century America considered the

concept of creating a small, elite, learned profession in violation of the political and institutional concepts of early American democracy.^[1]

The first medical school in the American colonies was opened in 1765 at what was then the College of Philadelphia (later the University of Pennsylvania) and the school came to be dominated by revolutionary leader and physician Benjamin Rush, a signatory to the Declaration of Independence. The proliferation of medical schools to train the new professional medical class began seriously after the war of 1812. Between 1810 and 1820, new schools were established in Baltimore, Lexington and Cincinnati, and even in rural communities in Vermont and Western New York. Between 1820 and 1850, a substantial number of schools were established in the western rural states. By 1850, there were 42 medical schools recognized in the United States, while there were only three in all of France.

Generally, these schools were started by a group of five to seven local physicians approaching a local college with the idea of establishing a medical school in conjunction with the college's educational facilities. The schools were largely apprenticeship-based, and the professors received their remuneration directly from fees paid by the students.

The requirements for an MD degree in late 18th- and early 19th-century America were

roughly the following:

- knowledge of Latin, natural and experimental philosophy
- 3 years of serving an apprenticeship under practicing physicians
- attending of two terms of lectures and passing of attendant examinations
- a thesis.

Graduating students had to be at least 21 years of age.^[1]

The rise of any professional class is gradual and marked by difficulties, and varying concepts existed as to what was the demarcation of a “professional” physician. There were the graduates of medical school versus non-graduates, medical society members versus non-members, and licensed physicians versus unlicensed “doctors”. Licensing statutes came into existence between 1830 and 1850, but were soon repealed, as they were considered “undemocratic” during the apex of Jacksonian democracy.^[1]

Thomsonianism

In 1822, the rise in popularity of Samuel Thomson and his publication of *New Guide to Health* helped to frustrate the creation of a professional medical class. Thomson’s work was a compilation of his personal view of medical theory and American Indian herbal and medical botanical lore. Thomson espoused the belief that disease had one general cause – “cold” influences on the human body – and that disease had therefore one general remedy – “heat”. Unlike the followers of Benjamin Rush and the American “heroic” medical tradition who advocated blood-letting, leeching, and the substantial use of mineral-based purgatives such as antimony and mercury, Thomson believed that minerals were sources of “cold” because they come from the ground and that vegetation, which grew toward the sun, represented “heat”.^[1]

As noted in Griggs’ *Green Pharmacy* (the best history of herbal medicine to date), Thomson’s theory developed as follows:^[2]

Instead, he elaborated a theory of his own, of the utmost simplicity: “All diseases ... are brought about by a decrease or derangement of the vital fluids by taking cold or the loss of animal warmth ... the name of the complaint depends upon what part of the body has become so weak as to be affected. If the lungs, it is consumption, or the pleura, pleurisy; if the limbs, it is rheumatism, or the bowels, colic or cholera morbus ... all these different diseases may be removed by a restoration of the vital energy, and removing the obstructions which the disease has generated ...

Thus the great object of his treatment was always to raise and restore the body’s vital heat: “All ... that medicine can do in the expulsion of disorder, is to kindle up the decaying spark, and restore its energy till it glows in all its wonted vigor.

Thomson’s view was that individuals could be self-treating if they had a sincere

understanding of his “new guide to health” philosophy *and* a copy of his book, *New Guide to Health*. The right to sell “family franchises” for utilization of the Thomsonian method of healing was the basis of a profound lay movement between 1822 and Thomson’s death in 1843. Thomson adamantly believed that no professional medical class should exist and that democratic medicine was best practiced by lay persons within a Thomsonian “family” unit.

By 1839, Thomson claimed to have sold some 100,000 of these family franchises called “friendly botanic societies”. While he professed to have solely the interests of the individual at heart, his system was sold at a profit under the protection of a patent he had obtained in 1813.

The eclectic school of medicine

Some of the botanics (professional Thomsonian doctors) wanted to separate themselves from the lay movement by creating requirements and standards for the practice of Thomsonian medicine. Thomson, however, was adamantly against a medical school founded on his views. Thus, it was not until the decade after Thomson’s death that independent Thomsonians founded a medical college (in Cincinnati) and began to dominate the Thomsonian movement. These Thomsonian doctors, or “botanics”, were later absorbed into the medical sectarian movement known as the “eclectic school”, which originated with the New Yorker, Wooster Beach.

Wooster Beach was another of medical history’s fascinating characters. From a well-established New England family, he started his medical studies at an early age, apprenticing under an old German herbal doctor, Jacob Tidd, until Tidd died. Beach then enrolled in the Barclay Street Medical University in New York. As noted by Griggs (p. 180):^[2]

Beach’s burning ambition was to reform medical practice generally – not to alienate the entire profession by savage attacks from without – and he was convinced that he would be in a stronger position to do so if he were himself a diplomated doctor. The faculty occasionally listened to criticism from within their own number: against onslaughts of “illiterate quacks” like Samuel Thomson, they simply closed ranks in complacent hostility.

After opening his own practice in New York, Beach set out to win over fellow members of the New York Medical Society (into which he had been warmly introduced by the screening committee) to his point of view that heroic medicine was inherently dangerous to mankind and should be reduced to the gentler theories of herbal medicine. He was summarily ostracized from the medical society.

To Beach this was a bitter blow, but he soon founded his own school in New York, calling the clinic and educational facility “The United States Infirmary”. However, due to

continued pressure from the medical society, he was unable to obtain charter authority to issue legitimate diplomas. He then located a financially ailing, but legally chartered, school, Worthington College, in Worthington, Ohio. He opened there a full-scale medical college; out of its classrooms was launched what became known as the eclectic school of medical theory. As Griggs relates (p. 183):^[2]

Beach had a new name for his practice: while explaining to a friend his notions of combining what was useful in the old practice with what was best in the new, the friend exclaimed, "You are an eclectic!" to which, according to legend, Beach replied, "You have given me the term which I have wanted: I am an eclectic!"

Cincinnati subsequently became the focal point of the eclectic movement and the medical school remained until 1938 (the last eclectic school to exist in America).^[1] The philosophies of the sect helped to form the theoretical underpinnings of Benedict Lust's naturopathic school of medicine.

Despite his criticism of the early allopathic medical movement (although the followers of Benjamin Rush were not as yet known by this term, reputed to have been coined by Samuel Hahnemann) for their "heroic" tendencies, Thomson's medical theories were "heroic" in their own fashion. While he did not advocate blood-letting, heavy metal poisoning and leeching, botanic purgatives – particularly *Lobelia inflata* (Indian tobacco) – were a substantial part of the therapy.

The hygienic school of thought

One other forerunner of American naturopathy, also originating as a lay movement, grew into existence at this time. This was the "hygienic" school, which had its genesis in the popular teachings of Sylvester Graham and William Alcott.

Sylvester Graham began preaching the doctrines of temperance and hygiene in 1830, and published, in 1839, *Lectures on the Science of Human Life*, two hefty volumes that prescribed healthy dietary habits. He emphasized a moderate lifestyle, recommending an anti-flesh diet and bran bread as an alternative to bolted or white bread.

William Alcott dominated the scene in Boston during this same period, and together with Graham, saw that the American hygienic movement – at least as a lay doctrine – was well-established.^[3]

Homeopathy

By 1840, the profession of homeopathy had also been transplanted to America from Germany. Homeopathy, the creation of an early German physician, Samuel Hahnemann (1755–1843), had three central doctrines:

- the "law of similars" (that like cures like)
- that the effect of a medication could be heightened by its administration in minute

- doses (the more diluted the dose, the greater the “dynamic” effect)
- that nearly all diseases were the result of a suppressed itch, or “psora”.

The view was that a patient’s natural symptom-producing disease would be displaced after homeopathic medication by a similar, but much weaker, artificial disease that the body’s immune system could easily overcome.

Originally, most homeopaths in this country were converted orthodox medical men, or “allopaths”. The high rate of conversion made this particular medical sect the arch-enemy of the rising orthodox medical profession. (For a more detailed discussion of homeopathy, see [Ch. 41.](#))

The first homeopathic medical school was founded in 1850 in Cleveland; the last purely homeopathic medical school, based in Philadelphia, survived into the early 1930s.^[4]

The rise and fall of the sects

Although these two non-allopathic sects were popular, they never comprised more than one-fifth of the professional medical class in America. Homeopathy at its highest point reached roughly 15%, and the eclectic school roughly 5%. However, their very existence for many years kept the exclusive recognition desired by

the orthodox profession from coming within its grasp. Homeopathy was distasteful to the more conventional medical men not only because it resulted in the conversion of a substantial number of their peers, but also because homeopaths generally also made a better income. The rejection of the eclectic school was more fundamental: it had its roots in a lay movement that challenged the validity of a privileged professional medical class.

The existence of three professional medical groups – the orthodox school, the homeopaths, and the eclectics – combined with the Jacksonian view of democracy that prevailed in mid-19th century America, resulted in the repeal of virtually all medical licensing statutes existing prior to 1850. But by the 1870s and 1880s, all three medical groups had begun to voice support for the restoration of medical licensing.

There are differing views as to what caused the homeopathic and eclectic schools to disappear from the medical scene in the 50 years following 1875. One view defines a sect as follows:^[4]

A sect consists of a number of physicians, together with their professional institutions, who utilize a distinctive set of medically invalid therapies which are rejected by other sects ...

By this definition, the orthodox or allopathic school was just as sectarian as the homeopathic and eclectic schools. Rothstein's view is that these two 19th century sects disappeared because, beginning in the 1870s, the orthodox school grasped the European idea of "scientific medicine". Based on the research of such men as Pasteur and Koch, and the "germ theory", this approach supposedly proved to be the medically proper view of valid therapy and gained public recognition because of its truth.

Another view is that the convergence of the needs of the three sects for professional medical recognition (which began in the 1870s and continued into the early 1900s), and the "progressive era", led to a political alliance in which the majority orthodox school ultimately came to be dominant by sheer weight of numbers and internal political authority. As Starr^[1] notes (p. 107):

Both the homeopaths and eclectic schools wanted to share in the legal privileges of the profession. Only afterward did they lose their popularity. When homeopathic and eclectic doctors were shunned and denounced by the regular profession, they thrived, but the more they gained an access to the privileges of regular physicians, the more their numbers declined. The turn of the century was both the point of acceptance and the moment of incipient disintegration ...

In any event, this development was an integral part of the drive toward professional authority and autonomy established during the progressive era (1900–1917). It was acceptable to the homeopaths and the eclectic schools because they controlled medical schools that continued to teach and maintain their own professional authority and autonomy. However, it was after these professional goals were attained that the lesser schools of medical thought went into rapid decline.^[1]

The American influence

From 1850 through 1900, the medical counterculture continued to establish itself in America. From its lay roots in the teachings of the hygienic movement, there grew professional medical recognition, albeit a small minority and "irregular" view, that hygiene and hydropathy were the basis of sound medical thought (much like the Thomsonian transition to botanic and eclectic medicine).

Trall

The earliest physician who came to have a significant impact on the later growth of naturopathy as a philosophical movement was Russell Trall MD. As noted in Whorton's *Crusaders for Fitness*,^[3] he "passed like a meteor through the American hydropathic and hygienic movement" (pp. 138–139):

The exemplar of the physical educator-hydropath was Russell Thatcher Trall. Still another physician who had lost his faith in regular therapy, Trall opened the second water cure establishment in America, in New York City in

1844. Immediately he combined the full Preissnitzian armamentarium of baths with regulation of diet, air, exercise and sleep. He would eventually open and or direct any number of other hydropathic institutions around the country, as well as edit the *Water-Cure Journal*, the *Hydropathic Review*, and a temperance journal. He authored several books, including popular sex manuals which perpetuated Graham-like concepts into the 1890's, sold Graham crackers and physiology texts at his New York office, was a charter member (and officer) of the American Vegetarian Society, presided over a short-lived World Health Association, and so on. His crowning accomplishment was the Hygeian Home, a "model Health Institution [which] is beautifully situated on the Delaware River between Trenton and Philadelphia." A drawing presents it as a palatial establishment with expansive grounds for walking and riding, facilities for rowing, sailing, and swimming, and even a grove for open-air "dancing gymnastics." It was the grandest of water cures, and lived beyond the Civil War period, which saw the demise of most hydropathic hospitals. True, Trall had to struggle to keep his head above water during the 1860's, but by the 1870's he had a firm financial footing (being stabilized by tuition fees from the attached Hygeio-therapeutic College). With Trall's death in 1877, however, the hydropathic phase of health reform passed.

As will be seen later in this chapter, this plethora of activity is very similar to that engaged in by Benedict Lust between 1896 and his death in 1945, when he worked to establish naturopathic medicine. The Hygeian Home and later "Yungborn" establishments at Butler, New Jersey, and Tangerine, Florida, were very similar to European nature cure sanitariums, such as the original

Yungborn founded by Adolph Just and the spa/ sanitarium facilities of Preissnitz, Kneipp and Just.

Trall gave a famous address to the Smithsonian Institution in Washington, DC, in 1862, under the sponsorship of the Washington Lecture Association. "The true healing art: or hygienic vs drug medication", a 2.5 hour lecture purported to have received rapt attention, was devoted to Trall's belief in the hygienic system and in hydropathy as the true healing art. The address was reprinted by Fowler and Wells (New York, 1880) with an introduction written by Trall, prior to his death in 1877.

Trall also founded the first school of natural healing arts in this country to have a 4-year curriculum and the authorization to confer the degree of MD. It was founded in 1852 as a "hydropathic and physiological school" and was chartered by the New York State Legislature in 1857 under the name "New York Hygio-Therapeutic College", with the legislature's authorization to confer the MD degree.

In 1862, Trall went to Europe to attend the International Temperance Convention. At this

meeting of reformers, he took prominent part, specifically relating to the use of alcohol as a beverage and as a medicine. He eventually published more than 25 books on the subjects of physiology, hydropathy, hygiene, vegetarianism, and temperance, among many others.

The most valuable and enduring of these was his *Hydropathic Encyclopedia*, a volume of nearly 1,000 pages that covered the theory and practice of hydropathy and the philosophy and treatment of diseases advanced by older schools of medicine. At the time of his death, according to the December 1877 *Phrenological Journal* cover article featuring a lengthy obituary of Trall, this encyclopedia had sold more than 40,000 copies since its original publication in 1851.

For more than 15 years, Trall was editor of the *Water-Cure Journal* (also published by Fowler and Wells). During this period, the journal went through several name changes including the *Hygienic Teacher* and *The Herald of Health*. When Dr Lust originally opened the American School of Naturopathy, an English-language version of *Kneipp's Water-cure* (or in German *Meine Wasser-kurr*) being unavailable, he used only the works and writings of Russell Trall as his texts.

By 1871, Trall had moved from New York to the Hygeian Home on the Delaware River. His water-cure establishment in New York became The New Hygienic Institute. One of the co-proprietors there was Martin Luther Holbrook, who later replaced Trall as the editor of *The Herald of Health*. As noted by Professor Whorton (pp. 139–140):^[3]

But Holbrook's greatest service to the cause was as an editor. In 1866 he replaced Trall at the head of *The Herald of Health*, which had descended from the *Water-Cure Journal* and *Herald of Reforms* (1845–1861) by the way of the *Hygienic Teacher* and *Water-Cure Journal* (1862). Under Holbrook's direction the periodical would pass through two more name changes (*Journal of Hygiene Herald of Health*, 1893–1897, and *Omega*, 1898–1900) before merging with *Physical Culture*.

Trall and Holbrook both advanced the idea that physicians should teach the maintenance of health rather than simply provide a last resort in times of health crisis. Besides providing a strong editorial voice espousing vegetarianism, the evils of tobacco and drugs, and the value of bathing and exercise, dietetics and nutrition along with personal hygiene were strongly advanced by Holbrook and others of the hygienic movement during this era. As described, again by Whorton (pp. 143–144):^[3]

The orthodox hygienists of the progressive years were equally enthused by the recent progress of nutrition, of course, and exploited it for their own ends, but their utilization of science hardly stopped with dietetics. Medical bacteriology was another area of remarkable discovery, bacteriologists having provided, in the short space of the last quarter of the 19th century, an understanding, at long last, of the nature of infection. This new science's implications for hygienic ideology were profound – when Holbrook locked horns with female fashion, for example, he did not attack the bulky, ground-length skirts still in style with the crude Grahamite objection that the

skirt was too heavy. Rather he forced a gasp from his readers with an account of watching a smartly dressed lady unwittingly drag her skirt “over some virulent, revolting looking sputum, which some unfortunate consumptive had expectorated.”

Holbrook expanded on the work of Graham, Alcott and Trall and, working with an awareness of the European concepts developed by Preissnitz and Kneipp, laid further groundwork for the concepts later advanced by Lust, Lindlahr and others:^[3]

For disease to result, the latter had to provide a suitable culture medium, had to be susceptible. As yet, most physicians were still so excited at having discovered the causative agents of infection that they were paying less than adequate notice to the host. Radical hygienists, however, were bent just as far in the other direction. They were inclined to see bacteria as merely impotent organisms that throve only in individuals whose hygienic carelessness had made their body compost heaps. Tuberculosis is contagious, Holbrook acknowledged, but “the degree of vital resistance is the real element of protection. When there is no preparation of the soil by heredity, predisposition or lowered health standard, the individual is amply guarded against the attack.” A theory favored by many others was that germs were the effect of disease rather than its cause; tissues corrupted by poor hygiene offered microbes, all harmless, an environment in which they could thrive. (p. 144)

In addition to introducing the works of Father Kneipp and his teachings to the American hygienic health care movement, Holbrook was a leader of the fight against vivisection and vaccination:^[3]

Vivisection and vaccination were but two of the practices of medicine criticized in the late 19th century. Therapy also continued to be an object of protest. Although the heroism of

standard treatment had declined markedly since mid-century, a prescription was still the reward of any visit to the doctor, and drugless alternatives to healing were appearing in protest. Holbrook published frequent favorable commentaries on the revised water cure system of Germany’s Father Kneipp. A combination of baths, herbal teas, and hardening exercises, the system had some vogue in the 1890’s before flowering into naturopathy. Holbrook’s journal also gave positive notices to osteopathy and “chiroprathy” [chiropractic] commending them for not going to the “drugstore or ransack[ing] creation for remedies nor load[ing] the blood with poison.” But though bathing and musculoskeletal manipulation were natural and nonpoisonous, Holbrook preferred to give the body complete responsibility for healing itself. Rest and proper diet were the medicines of this doctor who billed himself as a “hygienic physician” and censured ordinary physicians for

being engrossed with disease rather than health. (pp. 146–147)

The beginnings of “scientific medicine”

While the hygienic movement was making its impact, the orthodox medical profession, in alliance with the homeopaths and eclectics, was making significant advances. The orthodox profession, through the political efforts of the AMA, had first tried to remove sectarian and irregular practitioners by segregating them from the medical profession altogether. It did so by formulating and publishing its first national medical code of ethics in 1847. (In 1846, the orthodox profession formed the American Medical Association to represent their professional views.) The code condemned proprietary patents (even carrying over into a physician’s development of surgical or other medical implements, which led to its greatest criticism); encouraged the adoption of uniform rules for payment in geographical areas; condemned the practice of contract work, prohibited advertising and fee-sharing even among specialists and general practitioners; eliminated blacks and women; and, most significantly, prohibited any consultation or contact with irregulars or sectarian practitioners. As the code stated:^[5]

... no one can be considered as a regular practitioner, or a fit associate in consultation, whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry. (pp. 234–279)

In the late 1870s and into the 1880s, the major sects – the orthodox, or allopathic school, the homeopaths and the eclectics – began to find more reason to cooperate to obtain common professional goals. These included the enactment of new licensing laws and the creation of a “respectable” medical educational system. Also at this time, the concept of “scientific medicine” was brought to America. (Although Starr differs with Rothstein about the cause of the death of the homeopathic and eclectic sectarian schools, he notes that Rothstein clearly documents the transition, during the 19th century, of medicine to a recognized professional class composed of both the minority sects and the orthodox school.)

This transition from conflict between the major sects resulted in the erosion of the implementation of the code of ethics, the cooperation among the sects to revive medical licensing standards, the admission of sectarian physicians to regular medical societies and, ultimately, a structural reorganization of the American Medical Association, which took place between 1875 and 1903.^{[1] [4]}

Once the cooperation between the three medical views had begun, the medical class as dominated by the regular school came fully into power. And the homeopathic and eclectic schools of thought met their demise, which was finally brought about by two significant events: the rapid creation of new medical educational standards between 1900 and 1910, culminating in the publication of the famous “Flexner Report” (1910); and the effective infusion of millions of dollars into selected allopathic medical schools by the newly created capitalistic philanthropic foundations, principally the Carnegie and

Rockefeller foundations.

The foundations

The impact of the monies from the Carnegie and Rockefeller foundations has been clearly documented^[6] and is described in detail, albeit for the advancement of a particular political point of view, in Brown's *Rockefeller Medicine Men*. The impact of the monies from these foundations, as contributed to medical schools that met the AMA's view of medical education and philosophy, cannot be underestimated.

This process has been well documented. ^[1] ^[6] ^[7] ^[8] As discussed by Burrows,^[8] this educational reform allowed the AMA to form a new alliance with legislators, and push quickly for medical licensing designed to reward the educational and medical expertise of the new orthodox "scientific medicine", and the exclusion of all others.^[8]

Medical education in transition

Based upon the rising example of scientific medicine and its necessary connection to research, the educational laboratory, and a more thorough scientific education as a preamble to medical practice, Harvard University (under the presidency of Charles Elliott) created a 4-year medical educational program in 1871. The primal modern medical educational curriculum was devised and set in motion over 20 years later at Johns Hopkins University under the leadership of William Osler and William Welch, using the resources from the original endowment of the hospital and university from the estate of Johns Hopkins.^[1]

Other schools followed suit. By the time the American Medical Association set up its Council on Medical

Education in 1904, it was made up of five members from the faculties of schools modeled on the Johns Hopkins prototype. This committee set out to visit and rate each of the (160) medical schools then in operation in the country. The ratings used were class "A" (acceptable), class "B" (doubtful), and class "C" (unacceptable).

Eighty-two schools received a class "A" rating, led by Harvard, Rush (Chicago), Western Reserve, the University of California and, notably, Johns Hopkins. Forty-six received a class "B" rating, and thirty-two a class "C" rating. The class "C" schools were mostly in rural areas and many of them proprietary in nature.

Flexner report

Subsequently to the AMA ratings, the Council on Medical Education applied to the Carnegie Foundation to commission an independent report to verify its work. Abraham

Flexner, a young, energetic and noted educator was chosen for this task by the Carnegie Foundation and accompanied by the secretary (Nathan Colwell MD) of the Council on Medical Education, who had participated in all of the committee site visits.

Flexner visited each of the 162 United States medical schools then operating. The publication of the “Flexner Report”, which was widely publicized, put the nails in the coffins of all schools with class “C” ratings and many with class “B” ratings. Significantly, the educational programs of all but one eclectic school (in Cincinnati) and one homeopathic school (in Philadelphia) were eliminated by 1918.

The eclectic medical schools, in particular, were severely affected by the report. According to Griggs (p. 251):^[2]

Of the eight Eclectic schools, the Report declared that none had “anything remotely resembling the laboratory equipment which is claimed in their catalogs.” Three of them were under-equipped; the rest “are without exception filthy and almost bare. They have at best grimy little laboratories ... a few microscopes, some bottles containing discolored and unlabeled pathological material, in an incubator out of commission, and a horrid dissecting room.” The Report found them more culpable than a regular school for these inadequacies: “... the Eclectics are drug-mad; yet, with the exception of the Cincinnati and New York schools, they are not equipped to teach the drugs or drug therapy which constitutes their sole reason for existence.”

The other regular schools that had conducted homeopathic or eclectic programs had by that time phased them out in the name of “scientific medicine”.

Pharmaceutical industry

During this same period of time, the American Medical Association, through several of its efforts, began a significant alliance with the organized pharmaceutical industry of the United States, shaping that industry in a manner acceptable to the allopathic profession.^{[1] [7] [9]}

The new “sects”

The period from 1890 through 1905 saw the rise of three new medical sects and several other smaller “irregular” schools which replaced those soon to pass away. In Missouri, Andrew Taylor Still, originally trained as an orthodox practitioner, founded the school of medical thought known as “osteopathy”, and in 1892 opened the American School of Osteopathy in Kirksville, Missouri. In 1895, Daniel David Palmer, originally a magnetic healer from Davenport, Iowa, performed the first spinal manipulation, which gave rise to the school he termed “chiropractic”. He formally published his findings in 1910, after having founded a chiropractic school in Davenport, Iowa. And, in 1902, Benedict Lust founded the American School of Naturopathy in New York.

Although some of the following discussion will be devoted to the schools of healing called osteopathy and chiropractic, only that portion of their histories related to the history of naturopathy will be mentioned.^[10] (A full study of osteopathic medicine in America may be found in *The D.O.'s* by Gevitz^[11], and a reasonable sketch of chiropractic medicine may be found in Ronald Lee Kapling's chapter in Salmon.^[10])

As noted by Starr,^[1] these new sects, including Christian Science, formulated by Mary Baker Eddy (see Silberger^[12] for further discussion), either rose or fell on their own without ever completely allying with orthodox medicine. Starr theorized that these sects arose late enough that the orthodox profession and its political action arm, the AMA, had no need to ally with them and would rather battle with them publicly. This made these sectarian views separate and distinct from the homeopathic and eclectic schools.

THE FOUNDING OF NATUROPATHIC MEDICINE

Benedict Lust

Benedict Lust came to the United States in 1892 at the age of 23. He had suffered from a debilitating condition in his late teens while growing up in Michelbach, Baden, Germany, and had been sent by his father to undergo the Kneipp cure at Woerishofen. He stayed there from mid-1890 to early 1892; not only was he “cured” of his condition, but he also became a protégé of Father Kneipp. Dispatched by Kneipp to bring the principles of the Kneipp water cure to America, he emigrated to New York City.

By making contact in New York with other German Americans who were also becoming aware of the Kneipp principles, Lust participated in the founding of the first “Kneipp Society”, which was organized in Jersey City, New Jersey, on 3 October 1896.

Lust was also present at the first organizational

meeting (in the middle of October 1896) of the Kneipp Society of Brooklyn, and subsequently, through Lust's organization and contacts, Kneipp Societies were founded in Boston, Chicago, Cleveland, Denver, Cincinnati, Philadelphia, Columbus, Buffalo, Rochester, New Haven, San Francisco, the state of New Mexico, and Mineola on Long Island.

The members of these organizations were provided with copies of the *Kneipp Blatter*, and a companion English publication Lust began to put out called *The Kneipp Water-Cure Monthly*.

The first “sanatorium” using Kneipp's principles was organized in this country shortly before Lust's arrival. Charles Lauterwasser, an earlier student of Kneipp's who called

himself a hydrophic physician and natural scientist, opened the Kneipp and Nature Cure Sanatorium in Newark, New Jersey, in 1891.

In 1895, the Brooklyn Light and Water-Cure Institute was established in Brooklyn, New York, by L. Staden and his wife Carola, both graduates of Lindlahr's Hygienic College in Dresden, Germany. According to their advertising, they specialized in natural healing, Kneipp water treatment, Kuhne's and Preissnitz's principles (including diet cure and electric light baths – both white and blue – electric vibration massage, Swedish massage and movements, and Thure-brandt massage).

In 1895, Lust opened the Kneipp Water-Cure Institute in New York City, listing himself as the owner and a Dr William Steffens as the residing physician. At the same address (on 59th Street) in October of that year, Lust opened the first "Kneipp store". In the originating November 1896 edition of *The Kneipp Water-Cure Monthly and Kneipp Blatter*, he advertised his store and sanitarium as personally authorized by Father Kneipp.

Father Kneipp died in Germany, at Woerishofen, on 17 June 1897. With his passing, Lust was no longer bound strictly to the principles of the Kneipp water cure. He had begun to associate earlier with other German American physicians, principally Dr Hugo R. Wendel (a German-trained *Naturarzt*) who began, in 1897, to practice in New York and New Jersey, as a licensed osteopathic physician. In 1896, Lust entered the Universal Osteopathic College of New York, graduated in 1898, and became licensed as an osteopathic physician. In 1897, Lust became an American citizen.

Once he was licensed to practice as a health care physician in his own right, Lust began the transition toward the concept of "naturopathy". Between 1898 and 1902, when he adopted the term "naturopath", Lust acquired a chiropractic education and changed the name of his Kneipp store to "health food store" (the original facility to utilize that name and concept in this country), specializing in providing organic foods and the materials necessary for drugless cures. He also began the New York School of Massage (listed as established in 1896) and the American School of Chiropractic, all within the same facility – Lust's Kneipp Institute.

Photographs of this facility taken between 1902 and 1907, when the facility moved to another location, show a five-story building listing "Benedict Lust – Naturopath, Publisher, Importer".

In the first part of 1896, just prior to his organizing of various Kneipp Societies around the New York area, Lust returned to Woerishofen to study further with Father Kneipp. He returned again in 1907 to visit with Dr Baumgarten, Kneipp's medical successor at the Woerishofen facility, which was then run, in cooperation with Baumgarten, by the Reverend Prior Reily, the former secretary to Father Kneipp and his lay successor at Woerishofen. As directed by Kneipp, Reily had completed, after Kneipp's death, Kneipp's master work *Das grosse Kneipp – Buch*. Lust was to maintain contact with the partnership of Reily and Baumgarten throughout the early part of the 20th century.

In 1902, when he purchased and began using the term naturopathy and calling himself

a “naturopath”, Lust, in addition to his New York School of Massage and American School of Chiropractic, his various publications and his operation of the Health Food Store, began to operate the American School of Naturopathy, all at the same 59th Street address.

By 1907, Lust’s enterprises had grown sufficiently large that he moved them to a 55 room building. It housed the Naturopathic Institute, Clinic and Hospital; the American Schools of Naturopathy and Chiropractic; the now entitled “Original Health Food Store”; Lust’s publishing enterprises; and New York School of Massage. The operation remained in this four-story building, roughly twice the size of the original facility, from 1907 to 1915.

In the period of 1912 through 1914, Lust took a “sabbatical” from his operations to further his education. By this time he had founded his large estate-like sanitarium at Butler, New Jersey, known as “Yungborn” after the German sanitarium operation of Adolph Just.

In 1912, he attended the Homeopathic Medical College in New York, which, in 1913, granted him a degree in homeopathic medicine and, in 1914, a degree in eclectic medicine. In early 1914, Lust traveled to Florida and obtained an MD’s license on the basis of his graduation from the Homeopathic Medical College.

Thereafter, he founded another “Yungborn” sanitarium facility in Tangerine, Florida, and for the rest of his life, while continuing his publications, engaged in active lecturing. He also continued to maintain a practice in New York City, and operated the sanitariums at Tangerine, Florida, and Butler, New Jersey. His schools were operated by Hugo R. Wendel.

From 1902, when he began to utilize the term naturopathy, until 1918, Lust replaced the Kneipp Societies

with the Naturopathic Society of America. Then, in December 1919, the Naturopathic Society of America was formally dissolved due to its insolvency and Lust founded the “American Naturopathic Association”. Thereafter, the association was incorporated in some additional 18 states.

In 1918, as part of his effort to replace the Naturopathic Society of America (an operation into which he invested a great deal of his funds and resources in an attempt to organize a naturopathic profession) and replace it with the American Naturopathic Association, Lust published the first *Universal Naturopathic Directory and Buyer’s Guide* (a “yearbook of drugless therapy”).

Although a completely new version was never actually published, in spite of Lust’s announced intention to make this volume an annual publication, annual supplements

were published in either *The Naturopath and Herald of Health* or its companion publication, with which *The Naturopath* at one time merged, *Nature's Path* (which commenced publication in 1925). The *Naturopath and Herald of Health*, sometimes printed with the two phrases reversed, was published from 1902 through 1927, and from 1934 until after Lust's death in 1945.

This volume documents the merging of the German and American influences which influenced Lust in his development of the practice of naturopathy. The voluminous tome, which ran to 1,416 pages, is dedicated to:

... the memory of all those noble pioneers and discoverers who have died in the faith of Naturopathy, and to their courageous successors in the art of drugless healing, all of whom have suffered persecution for saving human lives that medical autocracy could not save, this work is respectfully dedicated by its editor Benedict Lust, N.D., M.D., "The Yungborn", Butler, New Jersey, U.S.A., April 1, 1918.

Lust's introduction is reprinted here in its entirety to show the purpose of the directory and the status of the profession in the early 1900s:

Introduction

To the Naturopathic Profession, the Professors of Natural Healing in all its branches, the Professors of Scientific Diet, Hydrotherapy, Heliotherapy, Electrotherapy, Neuropathy, Osteopathy, Chiropractic, Naprapathy, Magnetopathy, Phytotherapy, Exercise, Swedish Movements, Curative Gymnastics, Physical and Mental Culture, Balneopathy, and all forms of Drugless Healing, the Faculties of all Drugless Colleges, Institutions, Schools, and all Professors of Hygiene and Sanitation; Manufacturers of Naturopathic Supplies; Publishers of Health Literature, and Natural Healing Societies, GREETINGS:

I have the honor to present to your consideration and goodwill, this Volume, No. 1, Year 1918–1919, of the Universal Naturopathic Directory, Year Book of Drugless Healing, and Buyers' Guide.

For twenty-two years past, the need of a directory for Drugless Therapy has been felt. The medical world is in a condition of intense evolution at the present time. It is evolving from the Drugging School of Therapy to the Drugless School. People by the million have lost confidence in the virtues of Allopathy and are turning with joyful confidence to the Professions of Natural Healing until it has been estimated that there are at least forty thousand practitioners of Naturopathic healing in the United States.

The motto that IN UNITY THERE IS STRENGTH is the foundation of the present enterprise.

Hitherto, the drugless profession has lacked that prestige in the eyes of the public, which comes from the continuous existence of a big institution, duly organized and wielding the immense authority which is derived no less from organization and history than from the virtues of the principles that are held and practiced by such institutions. The public at large instantaneously respects an institution that is thoroughly organized and has its root earthed in history.

The time has fully arrived when the drugless profession should no longer exist in the form of isolated units, not knowing one another and caring but little for such knowledge. Our profession has been, as it were, as sheep without a shepherd, but the various individuals that constitute this movement so pregnant with benefits to humanity, are now collected for the first time into a Directory and Year-Book of Drugless Healing, which alone will give immense weight and dignity to the standing of the individuals mentioned therein.

Not only will the book add to the prestige of the practitioner in the eyes of his patients, but when the scattered members of our profession in every State desire to obtain legislative action on behalf of their profession and themselves, the appeal of such a work as our directory will, in the eyes of legislators, gain for them a much more respectful hearing than could otherwise be obtained.

Now, for the first time, the drugless practitioner finds himself one of a vast army of professional men and women who are employing the most healthful forces of nature to rejuvenate and regenerate the world. But the book itself throws a powerful light upon every phase of drugless healing and annihilates time and distance in investigating WHO IS WHO in the realm of Drugless Therapy.

A most sincere effort has been made to obtain the name and address of every adherent of the Rational School of Medicine who practices his profession within the United States, Canada and the British Isles. It is impossible at this stage of Naturopathic history, which is still largely in the making, to obtain the name and address of every such practitioner. There were some who, even when appealed to, refused to respond to our invitation, not understanding the object of our work. Many of even the most intelligent members have refused to advertise their professional cards in our pages. But we can only attribute these drawbacks to the fact that every new institution that has suddenly dawned upon human intelligence will find that a certain proportion of people who do not understand the nature of the enterprise because the brain cells that would appreciate the benefits that are sought to be conferred upon them, are undeveloped, but a goodly proportion of our Naturopaths have gladly responded to the invitation to advertise their specialty in our columns. These, of course, constitute the brightest and most successful of our practitioners and their examples in this respect should be

followed by every practitioner whose card does not appear in this book.

We take it for granted that every one of the forty thousand practitioners of Naturopathy is in favor of the enterprise represented by this Directory. This work is a tool of his trade and not to possess this book is a serious handicap in the race for success.

Here will be found an Index of by far the larger number of Naturopaths in the country arranged in Alphabetic, Geographic and Naturopathic sections. Besides this, there is a classified Buyers' Guide that gives immediate information regarding where you can find special supplies, or a certain apparatus, or a certain book or magazine, its name, and where it is published. The list of Institutions with the curriculum of each will be found exceedingly useful.

Natural healing, that has drifted so long, and, by reason of a lack of organization, has been made for so many years the football of official medicine, to be kicked by any one who thought fit to do so, has now arrived at such a pitch of power that it has shaken the old system of bureaucratic medicine to its foundations. The professors of the irrational theories of life, health and disease, that are looking for victims to be inoculated with dangerous drugs and animalized vaccines and serums, have begun to fear the growth of this young giant of medical healing that demands medical freedom, social justice and equal rights for the new healing system that exists alone for the betterment and uplifting of humanity.

I want every Professor of Drugless Therapy to become my friend and co-worker in the great cause to which we are committed, and those whose names are not recorded in this book should send them to me without delay. It will be of far greater interest and value to themselves to have their professional card included amongst those who advertise with us than the few dollars that such advertisement costs.

It will be noted that there are quite a number of Drugless Healers belonging to foreign countries (particularly those of the Western Hemisphere) represented in this Directory. The profession of medicine is not confined to any race, country, clime or religion. It is a universal profession and demands universal recognition. It will be a great honor to the Directory, as well as to the Naturopathic profession at large to have every Naturopathic practitioner, from the Arctic Circle to the furthest limits of Patagonia, represented in the pages of this immense and most helpful work.

I expect that the Directory for the year 1920 will be larger and even more important than the present Directory and that it will contain the names of

thousands of practitioners that are not included in the present work.

The publication of this Directory will aid in abolishing whatever evils of sectarianism, narrow-mindedness and lack of loyalty to the cause to which we are devoted, that may exist. That it will promote a fraternal spirit among all exponents of natural healing, and create an increase of their prestige and power to resist the encroachments of official medicine on their constitutional rights of liberty and the pursuit of happiness, by favorably influencing Legislators, Law courts, City Councils and Boards of Health everywhere, is the sincere belief of the editor and publisher.

Having introduced the volume, Lust leads off with his article entitled "The principles, aim and program of the nature cure system". Again, this relatively brief article is reproduced here in its entirety, so that one can see the merging of influences:

The principles, aim and program of the nature cure system

Since the earliest ages, Medical Science has been of all sciences the most unscientific. Its professors, with few exceptions, have sought to cure disease by the magic of pills and potions and poisons that attacked the ailment with the idea of suppressing the symptoms instead of attacking the real cause of the ailment.

Medical science has always believed in the superstition that the use of chemical substances which are harmful and destructive to human life will prove an efficient substitute for the violation of laws, and in this way encourages the belief that a man may go the limit in self indulgences that weaken and destroy his physical system, and then hope to be absolved from his physical ailments by swallowing a few pills, or submitting to an injection of a serum or vaccine, that are supposed to act as vicarious redeemers of the physical organism and counteract life-long practices that are poisonous and wholly destructive to the patient's well-being.

From the earliest ages to the present time, the priests of medicine have discovered that it is ten times easier to obtain ten dollars from a man by acting upon his superstition, than it is to extract one dollar from him, by appealing to reason and common sense. Having this key to a gold mine within their grasp, we find official medicine indulging at all times in the most blatant, outrageous, freakish and unscientific methods of curing disease, because the methods were in harmony with the medical prestige of the physician.

Away back in pre-historic times, disease was regarded as a demon to be exorcized from its victim, and the medicine man of his tribe belabored the body of his patient with a bag in which rattled bones and feathers, and no doubt in extreme cases the tremendous faith in this process of cure that was engendered in the mind of the patient really cured some ailments for which mental science and not the bag of bones and feathers should be given

credit.

Coming down to the middle ages, the Witches' Broth – one ingredient of which was the blood of a child murderer drawn in the dark of the moon – was sworn to, by official medicine, as a remedy for every disease.

In a later period, the “docteur a la mode”, between his taking pinches of snuff from a gold snuff box, would order the patient bled as a remedy for what he denominated spirits, vapors, megrims, or miasms.

Following this pseudo-scientific diagnosis and method of cure, came the drugging phase in which symptoms of disease were unmercifully attacked by all kinds of drugs, alkalis, acids and poisons which were supposed, that by suffocating the symptoms of disease, by smothering their destructive energy, to thus enhance the vitality of the individual. All these cures have had their inception, their period of extensive application, and their certain desuetude. The contemporary fashion of healing disease is that of serums, inoculations and vaccines, which, instead of being an improvement on the fake medicines of former ages are of no value in the cure of disease, but on the contrary introduce lesions into the human body of the most distressing and deadly import.

The policy of expediency is at the basis of medical drug healing. It is along the lines of self-indulgence, indifference, ignorance and lack of self-control that drug medicine lives, moves and has its being. The sleeping swineries of mankind are wholly exploited by a system of medical treatment, founded on poisonous and revolting products, whose chemical composition and whose mode of attacking disease, are equally unknown to their originators, and this is called “Scientific medicine.”

Like the alchemist of old who circulated the false belief that he could transmute the baser metals into gold, in like manner the vivisector claims that he can coin the agony of animals into cures for human disease. He insists on cursing animals that he may bless mankind with such curses.

To understand how revolting these products are, let us just refer to the vaccine matter which is supposed to be an efficient preventive of smallpox. Who would be fool enough

to swallow the putrid pus and corruption scraped from the foulest sores of smallpox that has been implanted in the body of a calf? Even if any one would be fool enough to drink so atrocious a substance, its danger might be neutralized by the digestive juices of the intestinal tract. But it is a far greater danger to the organism when inoculated into the blood and tissues direct,

where no digestive substances can possibly neutralize its poison.

The natural system for curing disease is based on a return to nature in regulating the diet, breathing, exercising, bathing and the employment of various forces to eliminate the poisonous products in the system, and so raise the vitality of the patient to a proper standard of health.

Official medicine has in all ages simply attacked the symptoms of disease without paying any attention to the causes thereof, but natural healing is concerned far more with removing the causes of disease, than merely curing its symptoms. This is the glory of this new school of medicine that it cures by removing the causes of the ailment, and is the only rational method of practicing medicine. It begins its cures by avoiding the uses of drugs and hence is styled the system of drugless healing. It came first into vogue in Germany and its most famous exponents in that country were Priessnitz, Schroth, Kuhne, Kneipp, Rickli, Lahmann, Just, Ehret, Engelhardt, and others.

In Sweden, Ling and others developed various systems of mechano-therapy and curative gymnastics.

In America, Palmer invented Chiropractic; McCormick, Ophthalmology. Still originated Osteopathy; Weltmer, suggestive Therapeutics. Lindlahr combined the essentials of various natural methods, while Kellogg, Tilden, Schultz, Trall, Lust, Lahn, Arnold, Struch, Havard, Davis, Jackson, Walters, Deininger, Tyrell, Collins and others, have each of them spent a lifetime in studying and putting into practice the best ideas of drugless healing and have greatly enlarged and enriched the new school of medicine.

Life Maltreated by Allopathy

The prime object of natural healing is to give the principle of life the line of least resistance, that it may enable man to possess the most abundant health.

What is life?

The finite mind of man fails to comprehend the nature of this mysterious principle. The philosopher says "Life is the sum of the forces that resist death," but that definition only increases its obscurity. Life is a most precious endowment of protoplasm, of the various combinations of oxygen, hydrogen, carbon and nitrogen, and other purely mineral substances in forming organic tissues. As Othello says, referring to Desdemona's life, which he compares to the light of a candle –

"If I quench thee thou flaming minister,

I can thy former light restore

Should I repent me; but once put out THY light,

I know not whence is that Promethean heat

That can thy light relume.”

The spark of life flickers in the sockets of millions and is about to go out. What system of medicine will most surely restore that flickering spark to a steady, burning flame?

Will [it be] the system that employs poisonous vaccines, serums and inoculations, whose medical value has to be supported by the most mendacious statements, and whose practitioners are far more intent on their emoluments and fame, than they are in the practice of humanity?

The Allopathic system, which includes nine-tenths of all medical practitioners, is known by its fruits, but it is an appalling fact that infant mortality, insanity, heart disease, arteriosclerosis, cancer, debility, impoverished constitutions, degeneracy, idiocy and inefficiency have enormously increased, particularly during the last twenty-five years, that is, during the regime of inoculations, serums and vaccines.

Naturopathy, on the other hand, so far as it has been developed, and so far as official medicine will allow it to act, leaves no such trail of disease, disaster and death behind it. Natural healing is emancipation from medical superstition, ignorance and tyranny. It is the true Elixir of Life.

The Allopaths have endeavored to cure sick humanity on the basis of the highly erroneous idea that man can change the laws of nature that govern our being, and cure the cause of disease by simply ignoring it. To cure disease by poisoning its symptoms is medical manslaughter.

Dr. Schwenninger of Germany says: “We are suffering under the curse of the past mistakes of our profession. For thousands of years medical doctors have been educating the public into the false belief that poisonous drugs can give health. This belief has become in the public mind such a deep-seated superstition, that those of us who know better and who would like to adopt more sensible, natural methods of cure, can do so only at the peril of losing practice and reputation.

“The average medical man is at his best but a devoted bigot to this vain school-craft, which we call the Medical Art and which alone in this age of science has made no perceptible progress since the days of its earliest teachers. They call it recognized science! Recognized ignorance! The

science of to-day is the ignorance of to-morrow. Every year some bold guess lights up as truth to which but the year before the schoolmen of science were as blind as moles.”

And Dr. O.W. Holmes, Professor of Anatomy in Harvard University, states: “The disgrace of medicine has been that colossal system of self-deception, in obedience to which mines have been emptied of their cankering minerals, entrails of animals taxed for their impurities, the poison bags of reptiles drained of their venom, and all the inconceivable abominations thus obtained thrust down the throats of human beings, suffering from some fault of organization, nourishment, or vital stimulation.”

And these misguided drug doctors are not only not ashamed of their work, but they have induced subservient legislators to pass laws that perpetuate the age-long scandal of allopathic importance, and the degenerative influence of the poisons, and to actually make it a crime on the part of nature doctors to cure a man of his ailment. The brazen effrontery of these medical despots has no limits. They boast of making the State legislators their catspaw in arresting, fining and imprisoning the professors of natural healing for saving human life.

Legislators have no right to sit in judgment over the claims of rival schools of healing. They see tens of thousands of sick people go down to their graves by being denied the cures that the employers of nature's forces alone can give them. It is their business to provide for the various schools of medicine a fair field and no favor.

A citizen has an inalienable right to liberty in the pursuit of happiness. Yet the real saviors of mankind are persecuted by the medical oligarchy which is responsible for compulsory vaccination, compulsory medical inspection of public school children, and the demands for State and Federal departments of health, all for the ostensible good of the people, but in reality for the gain of the Medical Trust.

The Naturopaths

The Naturopaths are desirous of freedom for all schools of medicine. They are responsible practitioners who are willing to be examined by an impartial council, appointed by and acting for the State, who will testify to the life and character of every drugless physician before he is entitled to practice medicine. Not one invidious discrimination should be made between the different schools of medicine. The state should see to it that each school should have a full opportunity to do its best for the up-lifting of its citizens.

The Program of Naturopathic Cure

1. **ELIMINATION OF EVIL HABITS**, or the weeds of life, such as over-eating, alcoholic drinks, drugs, the use of tea, coffee and cocoa that contain poisons, meat eating, improper hours of living, waste of vital forces, lowered vitality, sexual and social aberrations, worry, etc.
2. **CORRECTIVE HABITS**. Correct breathing, correct exercise, right mental attitude. Moderation in the pursuit of health and wealth.
3. **NEW PRINCIPLES OF LIVING**. Proper fasting, selection of food, hydrotherapy, light and air baths, mud baths, osteopathy, chiropractic and other forms of mechano-therapy, mineral salts obtained in organic form, electropathy, heliopathy, steam or Turkish baths, sitz baths, etc.

Natural healing is the most desirable factor in the regeneration of the race. It is a return to nature in methods of living and treatment. It makes use of the elementary forces of nature, of chemical selection of foods that will constitute a correct medical dietary. The diet of civilized man is devitalized, is poor in essential organic salts. The fact that foods are cooked in so many ways and are salted, spiced, sweetened and otherwise made attractive to the palate, induces people to over-eat, and over eating does more harm than under feeding. High protein food and lazy habits are the cause of cancer, Bright's disease, rheumatism and the poisons of auto-intoxication.

There is really but one healing force in existence and that is Nature herself, which means the inherent restorative power of the organism to overcome disease. Now the question is, can this power be appropriated and guided more readily by extrinsic or intrinsic methods? That is to say, is it more amenable to combat disease by irritating drugs, vaccines and serums employed by superstitious moderns, or by the bland intrinsic congenial forces of Natural Therapeutics, that are employed by this new school of medicine, that is Naturopathy, which is the only orthodox school of medicine? Are not these natural forces much more orthodox than the artificial resources of the druggist? The practical application of these natural agencies, duly suited to the individual case, are true signs that the art of healing has been elaborated by the aid of absolutely harmless, congenial treatments, under whose ministrations the death rate is but five per cent of persons treated as compared with fifty per cent under the present allopathic methods.

The Germanic influence

The philosophical origins of naturopathy were clearly Germanic. The most significant influences, except those of Russell Trall and the Osteopathic concepts of A. T. Still (at this time strictly the correction of spinal lesions by adjustment), and the chiropractic

principles of D. D. Palmer, were all Germanic. (This is well documented in the January 1902 editorial of *Water Cure Monthly*.)

The specific influences drawn upon by Lust for his work, in order of their chronological contributions to the system of naturopathy, are the following:

1. Vincent Preissnitz (1799–1851)
2. Johann Schroth (1798–1856)
3. Father Sebastian Kneipp (1821–1897)
4. Arnold Rickli (1823–1926)
5. Louis Kuhne (c. 1823–1907)
6. Henry Lahman (no dates known)
7. F. E. Bilz (1823–1903)
8. Adolph Just (?–1939).

Also of note were Theodor Hahn and Meltzer, who, in the 1860s, were well-known for their work in the movement called, in German, *Naturatz* or “naturism”.

In photographs accompanying his article “The principles, aim and program of the nature cure system”, Lust described each of these thinkers as follows:

1. VINCENT PREISSNITZ, of Graefenberg, Silesia. Founder of Hydropathy. Born October 4, 1799. A pioneer Naturopath, prosecuted by the medical authorities of his day, and convicted of using witchcraft, because he cured his patients by the use of water, air, diet and exercise. He took his patients back to Nature – to the woods, the streams, the open fields – treated them with Nature’s own forces and fed them on natural foods. His fame spread over the whole of Europe, and even to America. His cured patients were numbered by the thousands. The Preissnitz compress or bandage is in the medical literature. Preissnitz is no more, but his spirit lives in every true Naturopath.

2. JOHANN SCHROTH, a layman, not described in Lust’s directory, but often talked of in later works and prominently mentioned for his curative theories in Bilz’s master work *The Natural Method of Healing*. Schroth smashed his right knee in an accident with a horse and it remained stiff in spite of repeated medical treatment. At last, a priest told Schroth that Preissnitz’s methods might help, and Schroth decided to give them a try. In order to avoid frequent changing of the packs that were directed by Preissnitz, he placed several packs on top of one another, wrapping the whole portion with a woolen cloth. He left this pack on the injured knee for several hours and produced a moist heat which he theorized to cause the poisonous toxins to dissolve and be swept away. These packs are still used as part of the “Schroth cure” and have reportedly become famous for their blood-cleansing effect. (From an article in the March 1937 *Naturopath and Herald of Health* by Dr. T.M. Schippel.) As noted by Bilz, the Schroth cure, called by Bilz “the regenerative treatment,” was developed for treatment of chronic diseases through the use of an extreme diet following total fasting by

withdrawing of all food and drink and then the use of totally dry grain products and the eventual reintroduction of fluids.

3. FATHER SEBASTIAN KNEIPP, of course, is much described and the photos include one of Kneipp lecturing to the multitudes at Wandelhale at Woerishofen, attending Pope Leo XIII in 1893, noting this is the only consultation on health care matters that Kneipp ever consented to outside of Woerishofen, though many famous and aristocratic individuals desired his counsel, and a picture of Kneipp with

30

the Archdukes Joseph and Francis Ferdinand of Austria walking barefoot in new-fallen snow for purposes of hardening the constitution. It was noted that the older Archduke was cured by Father Kneipp of Bright's disease in 1892, and it noted that the Archduke Joseph, in appreciation of this cure, donated a public park in the town of Woerishofen at a cost of \$150,000 florens. The Archduke Francis Ferdinand, the son of Archduke Joseph, was the individual whose murder precipitated World War I. There is a further picture of Father Kneipp surrounded by "Doctors" from different parts of the world while he gave consultation to numerous patients.

4. ARNOLD RICKLI, founder of the light and light and air cures (atmospheric cure). Dr. Rickli was one of the foremost exponents of natural living and healing. In 1848, he established at Veldes, Krain, Austria, the first institution of light and air cure or as it was called in Europe the "atmospheric cure". In a limited way (rather very late) his ideas have been adopted by the medical profession in America for the cure of consumption. He was an ardent disciple of the vegetarian diet and exemplified the principles of natural living in his own life. The enclosed photo shows him at the age of 97, when he was still active and healthy. He has since passed on, but his work still lives as a testimonial of his untiring efforts. He was the founder and for over 50 years the President of the National Austrian Vegetarian Association.

5. LOUIS KUHNE wrote, in 1891, *The New Science of Healing*, the greatest work of basic principles in natural healing. In the tradition of Natural Healing and prevention, Kuhne has been described as one who "... advocated sun, steam baths, a vegetarian diet, and whole-wheat bread ..." in these relatively early days". His renowned work constitutes the only true scientific philosophy for the application of all Drugless Methods. He was the first to give to the world the comprehensible idea of pathology and the first to proclaim the doctrine of the "unity of cure." His book *Facial Expression* gives the means of diagnosing a patient's pathological condition and determining the amount and location of the systemic encumbrance. He is the founder and first Master of Naturopathy.

6. DR. H. LAHMAN. When the University of Leipzig expelled H. Lahman for

his spreading medical sedition among the students, it added a staunch advocate to natural healing. Dr. Lahman finished his medical education in Switzerland and returned to Germany to refute in practice the false ideas of medical science. He later founded the largest Nature Cure institution in the world at Weisser Hirsch, near Dresden, Saxony. He was a strong believer in the "Light and Air" cure and constructed the first appliances for the administration of electric light treatment and baths. He was the author of several books on Diet, Nature Cure and Heliotherapy. As noted in *Other Healers, Other Cures*: "Heinrich Lahmann came along to stress no salt on foods and no water with meals ...". His works on diet are authoritative and his "nutritive salts theory" forms the basis of rational dietetic treatment. This work has but recently come to light in America, and progressive dietitians are forsaking their old, worn-out, high protein, chemical and caloric theories for the "organic salts theory." Carque, Lindlahr, McCann, and other wide awake food scientists have adopted it as a basis for their work. Dr. Lahman was a medical nihilist. He denounced medicine as unscientific and entirely experimental in its practice and lived to prove the saneness of his ideas as evidenced by his thousands of cured patients.

7. PROFESSOR F.E. BILZ. That real physicians are born, not made, is well illustrated in the case of Dr. Bilz, who achieved his first success in healing as a lay practitioner. As a mark of gratitude, a wealthy patient presented him with land and a castle in which to found a Nature Cure sanitarium... The Bilz institution at Dresden-Rdebeul, Germany, became world renowned and was long considered the center of the Nature Cure movement. Professor Bilz is the author of the first Naturopathic encyclopedia, *The Natural Method of Healing*, which has been translated into a dozen languages, and in German alone has run into 150 editions. He has written many works on Nature Cure and Natural Life, among them being *The Future State*, in which he predicted the present World War, and advocated a federation of nations as the only logical solution of international problems.

8. ADOLPH JUST, famous author of *Return to Nature* and founder of original 'Yungborn' in Germany.

Both Adolph Just's *Return to Nature* and Louis Kuhne's *The Natural Science of Healing* were translated into English by Lust and released through his publication house.

The convergence with American influences

The Universal Naturopathic Directory was truly eclectic in its compilation and composition. Besides the Lust article noted previously, the volume included: "How I became acquainted with nature cure" by Henry Lindlahr MD ND (which has been reproduced in large part in the introduction to volume 1 of Lindlahr^[13]); "The nature cure" by Carl Strueh MD ND; "Naturopathy" by Harry E. Brook ND; "The present position of naturopathy and allied therapeutic measures in the British Isles" by J. Allen Pattreiuex ND; "Why all drugless methods?" by Per Nelson; and "Efficiency in drugless healing" by Edward Earle Purinton (a reprint of the 1917 publication, referred to earlier,

which was composed of a series of articles published in *The Herald of Health and Naturopath* between August 14 and February 1916).

The volume also contained Louis Kuhne's "Neonaturopathy (the new science of healing)" in the first publication of the translation by Lust, and articles on electrotherapy, neuropathy, dietology, chiropractic, mechanotherapy, osteopathy, phytotherapy, apyrtropher, physical culture, optometry, hydrotherapy, orthopedics, pathology, natural healing and living, astroscopy, phrenology, and physiology – all of which were specially commissioned for the directory from practitioners and authors considered expert in these subjects.

The volume also included the directory of drugless physicians in alphabetical order, geographically arranged, and itemized by profession; biographical notes on American contributors of note; the naturopathic book catalog; a guide to natural healing and natural life books and periodicals; a classified list of medical works, a series of book reviews; a buyer's guide for naturopathic supplies; and, in addition to extensive indexes, a "parting word" by Lust.

* See Kruger.^[16]

In addition, the volume contained numerous advertisements for naturopathic schools, sanitariums and individual practices, and closed with the following note:

This, then, completes Volume 1 of the Naturopathic Directory, Drugless Yearbook and Buyer's Guide for the years 1918 and 1919.

Into it, has been placed the conscientious labor of many willing hearts, hands and minds. It is their contribution to the noble cause of natural healing. It will stand as a monument to their endeavors, as well as a memorial to the great souls, the fathers of natural healing, who have passed on.

Let this, then, herald a new era – the era wherein man shall recognize the omniscience of Nature, and shall profit through conforming to her laws.

In the biographical section, it becomes apparent that Lust owed a great deal of the feeling of camaraderie in the nature cure movement to some varied American practitioners. The most prominent of these have had their biographical sections as contained in the 1918 directory. Two of them deserve specific note and attention: Palmer and Still.

Lust met A. T. Still in 1915 in Kirksville, Missouri, shortly before Still's death. From their meetings, Lust noted later in the *Naturopath and Herald of Health* (June 1937) that Still believed that osteopathy by "... compromising with medicine ... is doomed as the school that could have incorporated all the natural and biological healing arts ...". Lust wanted

naturopathy to fill this void.

Lust also had lengthy acquaintance with B. J. Palmer (the son of D. D. Palmer, the founder of chiropractic), who, following in his father's footsteps, put Davenport, Iowa, and the Palmer Chiropractic College on the map.

Lust also became connected with Henry Lindlahr MD ND of Chicago, Illinois (as noted in the autobiographical sketch contained in the directory^[14] and reprinted in the volume 1 of Lindlahr^[13]). Lindlahr was a rising businessman in Chicago with all the bad habits of the "gay nineties" era. Only in his 30s, he had begun to be chronically ill. He had gone to the orthodox practitioners of his day and received no relief.

Then he was exposed to Schroth's works, and in following them began to feel somewhat better. Subsequently, he liquidated all his assets and went to Germany to stay in a German sanitarium to be cured and to learn nature cure. He then came back to Chicago and enrolled in the Homeopathic/Eclectic College of Illinois. In 1903, he opened a sanitarium, which included a residential sanitarium, located in Elmhurst, Illinois, a "transient" clinic (office) on State Street in Chicago, and "Lindlahr's Health Food Store".

Shortly thereafter he founded the Lindlahr College of Natural Therapeutics, which included hospital internships at the sanitarium. The institution became one of the leading naturopathic colleges of the day. In 1908, he began to publish *Nature Cure Magazine* and began publishing his series of *Philosophy of Natural Therapeutics*, with volume 1 ("Philosophy") in 1918. This was followed by volume 2 ("Practice") in 1919, volume 3 ("Dietetics"; republished with revisions as it had originally been published in 1914), and, in 1923, volume 6 ("Iridiagnosis"). The intended volumes 4 and 5 were in production at the time of Lindlahr's death in 1927. As described in *Other Healers, Other Cures*:

Henry Lindlahr, another American, is remembered for his conviction that disease did not represent an invasion of molecules, but the body's way of healing something. In other words, he viewed symptoms as a positive physiological response-proof that the body is fighting whatever's wrong. Accordingly, a fever is a "healthy" sign and one should be let alone, unless it is dangerously high, of course.

The impact of all of these gentlemen on the development of naturopathy in America, under Lust's guidance, was profound.

From these beginnings, the naturopathic movement gathered strength and continued to grow through the 1920s and 1930s, having a major impact on natural healing and natural lifestyle in the United States.

Along the way, Lust was greatly influenced by the writings of *John H. Tilden MD* (largely published between 1915 and 1925). Tilden was originally a practicing physician in Denver, Colorado, who became disenchanted with orthodox medicine and began to rely heavily on dietetics and nutrition, formulating his theories of "auto-intoxication" (the

effect of fecal matter remaining too long in the digestive process) and “toxemia”.

Lust was also greatly influenced by *Elmer Lee MD*, who became a practicing naturopath in about 1910, and whose movement was called the “hygienic system”, following the earlier works of Russell Trall. Lee published *Health Culture* for many years.

In addition to John Tilden MD and Elmer Lee MD, another medical doctor, *John Harvey Kellogg MD*, who turned to more nutritionally based natural healing concepts, was greatly respected by Lust. Kellogg was renowned through his connection with the Battle Creek Sanitarium. The sanitarium itself was originally founded in the 1860s as a Seventh Day Adventist institution designed to perpetuate the Grahamite philosophies of Sylvester Graham and William Alcott. The sanitarium was on the verge of being closed, however, due to economic failure, when in 1876 Kellogg, a new and more dynamic physician-in-chief, was appointed.

Kellogg, born in 1852, was a “sickly child” who, at the age of 14, ran across the works of Graham and converted to vegetarianism. At the age of 20 he studied for a term at Trall’s Hygio-Therapeutic College and then earned a medical degree at New York’s Bellevue Medical School. He maintained an affiliation with the regular schools of medicine during his lifetime, due more to his practice of surgery, than his beliefs in the area of health care.^[3]

Kellogg designated his concepts, which were basically the hygienic system of healthful living, “biologic living”. Principally, Kellogg defended vegetarianism, attacked sexual misconduct and the evils of alcohol, and was a prolific writer through the late 19th century and early 20th century. He produced a popular periodical, *Good Health*, which continued in existence until 1955. When Kellogg died in 1943 at the age of 91, he had had more than 300,000 patients through the Battle Creek Sanitarium (which he had renamed from Western Health Reform Institute shortly after his appointment in 1876), including many celebrities, and the “San” became nationally well known.

Kellogg, along with Tilden and Elie Metchnikoff (director of the prestigious Pasteur Institute and winner of the 1908 Nobel Prize for a contribution to immunology), wrote prolifically on the theory of “auto-intoxication”. Kellogg, in particular, felt that humans, in the process of digesting meat, produced a variety of intestinal self-poisons that contributed to “auto-intoxication”.

As a result, Kellogg became a near fanatic on the subject of helping humans to return to a more healthy natural state by returning to the naturally designed usage of the colon. He felt that the average modern colon was devitalized by the combination of sedentary living, the custom of sitting rather than squatting to defecate, and the modern civilized habit of ignoring “nature’s call” out of an undue concern for politeness. Further, Kellogg concentrated on the fact that the modern diet had insufficient bulk and roughage to

stimulate the bowels to proper action.

Kellogg was also extremely interested in hydrotherapy. In the 1890s, he established a laboratory at the San to study the clinical applications of hydrotherapy. This led, in 1902, to his writing *Rational Hydrotherapy*. The preface espoused a philosophy of drugless healing that came to be one of the bases of the hydrotherapy school of medical thought in America.

Tilden, as mentioned, was of a similar mind. Indeed, he had to have been to have provided natural health care literature with his 200-plus page dissertation entitled “constipation”, with a whole chapter devoted to the evils of not responding when nature called.

This belief in the “evils” drawing away from the natural condition of the colon was extremely important to Kellogg’s work.^[3] Because of Lust’s interest, Kellogg’s *The New Dietetics* (1921) became one of the bibles of naturopathic literature.^[15]

Lust was also influenced by the works of *Sidney Weltmer*, the father of “suggestive therapeutics”. The theory behind Professor Weltmer’s work was that whether it was the mind or the body that first lost its grip on health, the two were inseparably related. When the problem originated in the body, the mind nonetheless lost its ability and desire to overcome the disease because the patient “felt sick”, and consequently slid further into the diseased state. Alternatively, if the mind first lost its ability and desire to “be healthy” and some physical infirmity followed, the patient was susceptible to being overcome by disease.

Weltmer’s work dealt specifically with the psychological process of desiring to be healthy. Lust enthusiastically backed Weltmer’s work and had him on the program at various of the annual conventions of the American Naturopathic Association (which commenced after its founding in 1919).

Lust was also personal friends with and a deep admirer of *Bernarr MacFadden*. MacFadden was the founder of the “physical culture” school of health and healing, also known as “physcultopathy”. This school of healing gave birth across the country to gymnasiums at which exercise programs, designed to allow the individual man or woman to maintain the most perfect state of health and human condition possible, were developed and taught.^[3] As described in *Other Healers, Other Cures* (p. 182):^[16]

The next Naturopathic star, after Kellogg, was Bernarr MacFadden, the physical culturist who built a magazine-publishing empire (his first magazine was *Physical Culture* founded in 1898.) MacFadden proselytizes for exercise and fresh vegetables, hardly eccentric notions. But his flamboyant efforts to publicize them and his occasional crack-pot ideas (like freezing the unemployed, then thawing them out when the Depression was over) alienated many people. Still, he was his own best advertisement. He fathered nine children by four wives and was parachuting from planes in his 80s. One of MacFadden’s admirers was that arch-foe of the medical profession, George Bernard Shaw, the longevous eccentric in his own right

...

Lust was also very interested in, and helped to publicize “zone therapy”, originated by *Joe Shelby Riley* DC, a chiropractor based in Washington, DC, and one of the early practitioners of “broad chiropractic”. Zone therapy was an early forerunner of acupressure as it related “... pressures and manipulations of the fingers and tongue, and percussion on the spinal column, according to the relation of the fingers to certain zones of the body ...”^[14]

Several other American drugless healers contributed to a broad range of “-opathies” that Lust merged into his growing view of naturopathy as the eclectic compilation of methods of natural healing. The *Universal Directory* also contained a complete list of osteopaths and chiropractors as drugless healers within the realm of Lust’s view of naturopathic theory. His other significant compatriots at the time of the publication of the directory were Carl Stueh, described by Lust as “... one of the first medical men in this country who gave up medicine and operation for natural healing”, F. W. Collings MD DO DC, an early graduate of the American School of Naturopathy (1907) who went on to graduate from the

New Jersey College of Osteopathy (1909) and the Palmer School of Chiropractic (1912), another “broad chiropractor”, Anthony Matijaca MD ND DO, the naturopathic resident expert in electrotherapy and an associate editor of the *Herald and Health Naturopath* (the inverted name of the Lust journal at the time of the directory), and Carl Schultz ND DO MD, president and general manager of the Naturopathic Institute and Sanitorium of California, essentially the second school in the country to pursue the education of physicians under the name of “naturopathy.”

EARLY 20th-CENTURY MEDICINE

The metamorphosis of orthodox medicine

In many ways, the progressive health era of 1900–1917 not only marked the formative years of naturopathy, but were also its halcyon days. In many jurisdictions, modern licensing laws, crafted during this time, were not yet in effect, so varied views of health care could be openly practiced. By 1920, however, the American world of medicine had undergone a sharp transition, culminating four decades of change.

A look at the structure of early medical care in the United States, even as practiced and dominated by the orthodox school, is instructive, when one notes the changes occurring between 1875 and 1920.

In 1875 the following was generally true of American medical practice:

- The practice, even in urban areas, sent the doctor to the patient; the “house call” was the norm.
- There was little modern licensing regulation.
- Hospitals were charitable institutions where persons too poor to otherwise receive health care were usually sent when ill.
- The AMA, although formed in 1846, and generally representative of the professional goals of the regular or orthodox school of medicine, had scarcely begun to make any political inroads at all.
- Medical schools required little or no college education for entrance, and were largely apprenticeship-based and proprietary in nature, having changed little throughout the century.
- Although some doctors had begun to specialize, to do so was far from the norm. The major recognized specialties were surgery, obstetrics and gynecology.
- There were many different types of doctors and society’s recognition of the profession neither recognized specific expertise nor necessarily rewarded professionals in medical practice well.
- Although the orthodox school made up roughly 80% of the professional medical practitioners, the homeopaths and the eclectics were visible and respected in their own communities for their abilities and expertise, and much of the public relied on other “irregular” practitioners.

By comparison, in 1920, total metamorphosis of medicine as a profession had occurred:

- By 1920, practices had become office- and clinic-oriented.
- Modern licensing principles had become fully developed, and physicians and surgeons were licensed in all jurisdictions. Most other health care providers had some licensing restrictions placed upon them if they were recognized at all.
- Due largely to the introduction into surgery of the practice of antiseptic techniques and aseptic procedures, and a correspondent decline in operative mortality, institutional care in the hospital became increasingly accepted. Also, clinical pathology and diagnostic laboratory procedures had become well developed, the hospital had become a major training and clinical research facility, and generally more acceptable to the patient.
- The AMA was approaching the peak of its political power, having exercised, through its Council on Medical Education and its Council of Pharmacy and Chemistry, major effects on medical schools and the pharmaceutical industry.
- The transition to research and education-based medical schools, instead of practitioner apprenticeships and proprietary education, had become complete. All recognized medical schools had a 4-year curriculum, with an undergraduate degree or substantial undergraduate study required as a prerequisite. In addition, most schools, in conjunction with most licensing statutes, required a year’s internship.
- Specialization was becoming well developed, and the number of specialty groups had increased considerably. This would continue through the 1930s and into the early 1940s.
- Professional authority and autonomy had undergone a substantial transition; and the allopathic physician was now recognized as the medical expert.
- By 1922, the last eclectic school was on the verge of closure, and in the early 1930s the last of the homeopathic schools in the United States was also on the verge of

closure. The influence of these sects on orthodox medicine had dwindled to almost nothing. Naturopaths and other alternative health care practitioners had adopted the areas of expertise previously considered the territory of homeopaths and eclectics.

The halcyon years of naturopathy

In 1924, Morris Fishbein succeeded George Simmons as editor of the *Journal of the American Medical Association (JAMA)*. Fishbein had joined the editorial staff of *JAMA* under Simmons immediately following his graduation

from Chicago's Rush Medical School in 1913. As Campion points out:^[7]

Over the years Fishbein not only established himself as the gifted editor of the most widely read medical journal in the United States; he also learned how to extend his editorial position, how to project his opinions nationwide. He became, as the saying went in those years, a "personality." *TIME* referred to him as "the nation's most ubiquitous, the most widely maligned, and perhaps most influential medico."

In addition to his development of *JAMA* as an editorial and personal voice, Fishbein also continually railed against "quackery". Lust, among others, including MacFadden, became Fishbein's epitome of quackery. When MacFadden became a wealthy man, after his publishing company included popular magazines like *True Confessions* and *True Detective*, he began campaigning for the 1936 Republican presidential nomination. In response, a physician submitted, under the initials "K.G.", a tongue-in-cheek listing of the cabinet that would exist under MacFadden, including the newly created "Secretary of Aviation" for Benedict Lust. Lust was a popular figure by this time who conducted such a busy lecture schedule and practice, alternating between the "Yungborns" in Butler, New Jersey, and Tangerine, Florida, that he had become almost as well known as an airline traveler. Lust devoted a complete editorial in *Nature's Path* to a response.

If Fishbein had *JAMA* as a personal editorial outlet, Lust had his own publications. Commencing with the *Naturopath and Herald of Health* in 1902 (which changed its name to *Herald of Health and Naturopath* in 1918), Lust continually published this and other monthly journals. In 1919, it became the official journal of the American Naturopathic Association, mailed to all members. Each edition contained the editorial column "Dr Lust speaking".

In the early 1920s, the "health fad" movement was reaching its peak in terms of public awareness and interest. As described, somewhat wistfully, in his June 1937 column, Lust announced the approach of the 41st Congress of Natural Healing under his guidance:

The progress of our movement could be observed in our wonderful

congresses, in 1914 Butler, N.J., 1915 Atlantic City, 1916 in Chicago, 1917 Cleveland, 1918 New York, 1919 Philadelphia, 1920 and 1921 again New York, and 1922 in Washington, D.C., where we had the full support and backing of the Congress of the United States. President Harding received the president and the delegates of our convention and we were the guests of the City of Washington. Through the strenuous efforts of Dr. T.M. Schippel, Hon. Congresswoman Catherine Langley of Kentucky, and eight years of hard work financed and sustained by Dr. Schippel and her powerful friends in Congress, Naturopathy was fully legalized as a healing art in the District of Columbia and the definition was placed on record and the law affirmed and amended by another act which has been fully published over and over again in the official journal of the A.N.A., *Naturopath*.

In 1923 in Chicago, with the help and financing of the great and never-to-be forgotten Dr. Henry Lindlahr, we had a great convention. Not only were all the Naturopaths there but even to an extent our congress was recognized and acknowledged as official and of great importance by the medical people, particularly by the Health Commissioner of Chicago. We held a banquet, and there were discussions covering all platforms of the healing art. It was the first congress in the United States where medicine and Naturopathy in all its branches such as the general old-time Nature Cure, Hydrotherapy and Diet, Osteopathy, Naprapathy, Chiropractic, Neuropathy and Physiotherapy were represented on the same platform. The speakers represented every modern school of healing and the movement at that time was in the direction of an entirely recognized and independent school of healing. There were two camps, official medicine and official Naturopathy, the medical camp having all that is good and bad in medicine and surgery and all the other schools of healing that had sold their birthright and trusted to the allurements of organized medicine, such as Homeopaths, Eclectics, Physio-medics, and the Osteopaths to a large extent. The Osteopaths were always in the wrong camp when they went on mixed boards and Dr. Andrew Taylor Still, the father of Osteopathy, told me in 1915 that by compromising with medicine Osteopathy is doomed as the school that could have incorporated all of the natural and biological healing arts.

The year following we had the great congress in Los Angeles which has never been duplicated. We had to meet in two hotels because the crowds ran over 10,000. The glorious banquet will never be forgotten and the congress celebrated and demonstrated that the initial and first intent of the A.N.A. to teach the public Natural Living and Nature Cure was realized. We will never forget the glorious week in Los Angeles where the authorities and the whole city joined us. The success of that congress was largely due to the talent of Dr. Fred Hirsch, the successor to Prof. Arnold Ehret and the noble and generous Naturopaths of the A.N.A. of Cal. There was never a second congress like that.

Then we had the great congresses of New York in 1925, Indianapolis 1926, Philadelphia 1927, Minneapolis 1928, Portland, Oregon 1929, New York 1930, Milwaukee 1931, Washington, D.C., 1932, Chicago 1933, Denver

1934, San Diego 1935, and Omaha 1936.

In 1925, Lust began to try to reach more of the general populace through the lay publication *Nature's Path*. *The Naturopath* and *Nature's Path* were later merged because the self-supporting advertising and subscription monies were more available by publication to the general populace than to the members of the association (*The Naturopath*, 1902–1927; *Nature's Path*, 1925–1927; merged 1927–1933; separated 1934–1938; *Nature's Path*, 1939–?).

In January of 1934, Lust commenced republication under the title *Naturopath and Herald of Health* in addition to *Nature's Path*. Each of the volumes opened with his column, which was different for each publication. Both publications were issued continuing through 1938, when the *Nature's Path* again became the sole publication until Lust's death in 1945.

Although, after the *Universal Directory*, Lust continued to write volumes on naturopathic principles, he was more of a synthesizer, organizer, lecturer, and essayist than a lasting scientific author of naturopathic articles.

His most enduring contributions remain his early translations of Kuhne's and Just's works.

During the 1920s and up until 1937, Lust's brand of "quackery", as labeled by Fishbein, was in its most popular phase. Although the institutional markings of the orthodox school had gained ascendancy, prior to 1937 it had no real solutions to the problems of human disease.

Instructive in this regard is Louis Thomas' interesting work *The Youngest Science*. Thomas compares his education and internship as a physician to his father's life as a physician. His father believed that bedside manner was more important than any actual medication offered by the physician. Indeed, his father went into general surgery so that he could offer some service to his patients that actually made some change in their condition. Thomas points out that the major growth of "scientific medicine" up until 1937 advanced diagnosis rather than offering any hope of cure.

During this period of time, Lust's naturopathic medicine, and both chiropractic and osteopathic medicine, continued to be on the outside looking in. Practitioners of all three groups were continually prosecuted for practicing medicine without a license, although they often won their cases by establishing before juries that their practices were, even according to the testimony of medical men, not the same at all. Additionally, because the orthodox practitioners could offer little or no actual hope of cure for many diseases, the "health food and natural health" movement was generally popular.

During the 1920s, *Gaylord Hauser*, later to become the health food guru of the

Hollywood set, came to Lust as a seriously ill young man. Lust, through application of the nature cure, removed Hauser's afflictions and was rewarded by Hauser's lifelong devotion. His regular columns in *Nature's Path* became widely read among the Hollywood set.

As noted in *Other Healers, Other Cures* (p. 183):^[16]

The last big name in Naturopathy was Gaylord Hauser, a Viennese-Born food scientist (as one of his early books identified him) turned to Naturopathy in his later years. He is best remembered for advising the eating of living foods, not dead foods, and for escorting Greta Garbo around. In addition to fresh fruits and vegetables, Hauser's "Wonder Foods" were skinned milk, brewers yeast, wheat germ, yogurt, and black strap molasses.

In 1937, however, all this began to change. The change came, as both Thomas and Campion note in their works, with the era of "miracle medicine". Lust recognized this and his editorializing became, if anything, even more strident. From the introduction of sulfa drugs in 1937 to the Salk vaccine's release in 1955, the American public became used to annual developments of miracle vaccines and antibiotics.

Benedict Lust died in September of 1945 in residence at the Yungborn facility in Butler, New Jersey, preparing to attend the 49th Annual Congress of his American Naturopathic Association. On 30 August 1945, for the official program of that congress which was held in October 1945 just after his death, he dictated the following remarks:

What is the present condition of Naturopathy? What is its future? I can give my opinion in a very few words. For fifty years I have been in the thick of the fight to bring to the American people the Nature Cure. During that period I have had an opportunity to judge what Naturopathy has done, and can accomplish and the type of men and women, past and present, who make up the Naturopathic ranks.

Let us take the present situation first. What is Naturopathy accomplishing? The answer to that is: "Everything." Naturopathy holds the key for the prevention, alleviation and cure of every ailment, to man and beast alike. It has never failed in the hands of a competent Naturopath. Whatever the body can "catch" – that same body, with proper handling, can eliminate. And that takes in cancer, tumors, arthritis, cataract and the whole gamut of "incurable medical" disease and ailments. During my years of practice I, personally, have seen every type of human ailment and so-called serious "disease" give way to the simple, proven Naturopathic methods. I make no exception to that statement.

Now let us see the type of men and women who are the Naturopaths of today. Many of them are fine, upstanding individuals, believing fully in the effectiveness of their chosen profession – willing to give their all for the sake of alleviating human suffering and ready to fight for their rights to the last ditch. More power to them! But there are others who claim to be Naturopaths

who are woeful misfits. Yes, and there are outright fakers and cheats masking as Naturopaths. That is the fate of any science – any profession – which the unjust laws have placed beyond the pale. Where there is no official recognition and regulation, you will find the plotters, the thieves, the charlatans operating on the same basis as the conscientious practitioners. And these riff-raff opportunists bring the whole art into disrepute. Frankly such conditions cannot be remedied until suitable safeguards are erected by law, or by the profession itself, around the practice of Naturopathy. That will come in time.

Now let us look at the future. What do we see? The gradual recognition of this true healing art – not only because of the efforts of the present conscientious practitioners but because of the bungling, asinine mistakes of orthodox medicine – Naturopathy's greatest enemy. The fiasco of the sulpha drugs as emphasized disastrously in our armed forces is just one straw in the wind. The murderous Schick test – that deadly "prevention" of diphtheria – is another. All these medical crimes are steadily piling up. They are slowly, but inevitably, creating a public distrust in all things medical. This increasing lack of confidence in the infallibility of Modern Medicine will eventually make itself felt to such an extent that the man on the street will turn upon these self-constituted oppressors and not only demand but force a change. I may not be here to witness this revolution but I believe with all my soul that it is coming. Yes, the future of Naturopathy is indeed bright. It merely requires that each and every true Naturopath carry on – carry on – to the best of his and her abilities. May God bless you all.

The naturopathic journals of the 1920s and 1930s are instructive. Much of the dietary advice focused on poor eating habits, including the lack of fiber in the diet and

an overreliance upon red meat as a protein source. Over half a century later in the 1980s, the pronouncements of the orthodox profession, the National Institute of Health and the National Cancer Institute finally became aware of the validity of the early assertions of the naturopaths that such dietary habits would lead to degenerative diseases, including cancers associated with the digestive tract and the colon.

The December 1928 volume of *Nature's Path* was the first American publication of the works of Herman J. DeWolff, a Dutch epidemiologist who was one of the first individuals to assert, based on studies of the incidence of cancer in the Netherlands, that there was a correlation between exposure to petrochemicals and various types of cancerous conditions. He saw a connection between chemical fertilizers and their usage in some soils (principally clay) that led to their remaining in vegetables after they had arrived at the market and were purchased for consumption. Again, it was 50 years later before orthodox medicine began to see the wisdom of such assertions.

The emerging dominance of AMA medicine

The introduction of “miracle medicine”, the impact of World War II on health care, and the death of Benedict Lust in 1945, all combined to cause the decline of naturopathic medicine and natural healing in the United States. (During the war, the necessity for crisis surgical intervention techniques for battlefield wounds encouraged use of morphine and sulfa drugs, and penicillin for diseases not previously encountered by American citizens. This resulted in rapid development of high-technology approaches to medicine and highly visible successes.)

The effects of these events on osteopathy and chiropractic, however, were completely different. In the early days of osteopathy, there was a significant split between the strict drugless systems advocated by A. T. Still, and the beliefs of many MDs who were converted to osteopathy because of its therapeutic value. The latter group did not want to abandon all of the techniques they had previously learned and all of the drugs they had previously used when those therapy techniques were sometimes effective. Ultimately, most schools of osteopathy, commencing with the school based in Los Angeles, California, converted to more of an imitation of modern orthodox medicine. These developments led to more of an accommodation between the California osteopaths and the members of the California Medical Association. (This developing cooperation between the California Osteopathic and Medical Association was one of the major issues leading to the downfall, in 1949, of Fishbein’s editorial voice in *JAMA*.) Thus, osteopathy found a place in professional medicine, at the cost of its drugless healing roots and therapies.^[7]

The effect on chiropractic of the post-war years was somewhat different. Because of educational recognition under the G.I. Bill, the number of chiropractors in the country grew substantially, and their impact on the populace grew accordingly. The sect eventually grew powerful enough in terms of numbers and economic clout that it could pose a legal challenge to the orthodox monopoly of the AMA. However, in the immediate post-war years, the American Medical Association gained tremendous political clout. Combined with the American Legion and the National Board of Realtors,^[17] these three groups posed a powerful political triumvirate before the United States Congress.

These years, called the years of the “great fear” in Caute’s book by that name,^[18] were the years during which to be unorthodox was to be “un-American”.

Across the country, courts began to take the view that naturopaths were not truly doctors, as they espoused doctrines from “the dark ages of medicine” (something American medicine had apparently come out of in 1937) and that drugless healers were intended by law to operate without “drugs” (which became defined as anything a person would ingest or apply externally for any remedial medical purpose). In this regard, the Washington State Supreme Court case of *Kelly vs. Carroll* (the defendant being Otis G. Carroll of Spokane, Washington, a long-time follower, with his brother Robert V. Carroll, Sr, of Lust), and the Arizona State Supreme Court case of *Kuts-Cheraux vs. Wilson* document how significant limitations were placed on naturopaths under the guise of

calling them “drugless healers”.

In the state of Tennessee, as a reaction to the 1939 publication of the book *Back to Eden* by herbalist Jethro Kloss, court action initiated by the Tennessee State Medical Association led first to the publishers being forbidden to advertise the book for any therapeutic purpose. They were allowed only to acknowledge that it was in stock. The Tennessee State Legislature then declared that the practice of naturopathy in the state of Tennessee would be considered a gross misdemeanor, punishable by up to 1 year in jail.

Although it was under considerable public pressure in those years, the American Naturopathic Association undertook some of its most scholarly work, coordinating all the systems of naturopathy under commission. This resulted in the publication of a basic textbook on naturopathy (*Basic Naturopathy* published in 1948 by the ANA^[19]) and a significant work compiling all the known theories of botanical medicine (as commissioned by the ANA’s successor after its 1950 name change to the American Naturopathic Physicians and Surgeons Association), the *Naturae Medicina* published in 1953.^[20] Naturopathic medicine began splintering when Lust’s ANA was succeeded by six different organizations in the mid 1950s.

The primary organizations among these were the successor to the ANA, which underwent a name change in 1950 to the American Naturopathic Physician and Surgeon’s Association, and subsequently changed to the American Association of Naturopathic Physicians in 1956, and the International Society of Naturopathic Physicians formed under the leadership of M. T. Campenella of Florida shortly after Lust’s death, with its American offshoot, the National Association of Naturopathic Physicians.

By 1955, the AANP, as it ultimately became known, had recognized only two schools of naturopathic medicine, the Central States College of Physiatics in Eaton, Ohio, under the leadership of H. Riley Spitler, and Western States College of Chiropractic and Naturopathy located outside Portland, Oregon, under the leadership of R. A. Budden. Budden was a Lindlahr graduate and among the group which took over control of the Lindlahr College after Lindlahr’s death in the 1920s. He moved west after World War II when the north-west States, including Oregon, became the last bastion of naturopathic medicine in this country.

THE MODERN REJUVENATION

After the counter-culture years of the late 1960s and America’s disenchantment with organized institutional medicine, which began after the miracle era faded and it became apparent that orthodox medicine had its limitations, alternative medicine began to gain new respect. Naturopathic medicine underwent an era of rejuvenation.

As succinctly described in Cassedy's *Medicine in America: A Short History*,^[21] this phenomenon, which is not limited to naturopathic medicine, is consistent with the modern, and continuing, "search for health beyond orthodox medicine" (pp. 147–148):

It should not have been surprising to anyone that certain organized therapeutic sects continue to exist in mid-twentieth century America as successful and conspicuous alternatives to regular medicine. This is not to say that they offer the same threats to the medical establishment or play the same roles as their nineteenth-century counterparts had, as complete therapeutic systems. But they do continue to hold a strong collective appeal for individuals who mistrust or are somehow disenchanting with main line medicine. They have appealed also to anti-authoritarian sentiments that flourish throughout society. Moreover, as earlier, they satisfy a variety of needs that regular medicine continues to neglect or ignore.

The same author, in describing the post-World War II decades and the changing fortunes of such healing theories as naturopathic medicine, observed as follows:

The period also brought about the renewal or updating of certain previously widely used therapies and considerable experimentation with others, some of them exotic. To an extent this trend represented the rediscovery by trained physicians, nurses, and other regular health professionals of certain values and older styles of therapy. The participation of such professionals proved to be an essential ingredient in the rebirth of several such therapies. However, the major reason for the new successes was the wide-spread active interest and involvement of America's literate lay people in the search for more personal or humane forms of treatment.

As another author, John Duffy, has observed in *From Humors to Medical Science* (p. 350):^[22]

Since health is too closely related to cultural, social, and economic factors to be left exclusively to doctors, American lay people have always engaged in do-it-yourself medicine, resorted to "irregulars and quacks", and supported health movements. As a result of the current fad for physical fitness, our streets are beset by sweat-suited individuals of all ages doggedly jogging their way to health and long life. In addition, stores selling "natural" foods are flourishing, physical fitness salons have become a major business, and anti-smoking and weight-loss clinics and workshops are attracting thousands of individuals bent on leading cleaner and leaner lives. And those for whom physical activity in itself is not enough are seeking physical and mental well-being through faith healing, yoga, and a host of major and minor gurus.

When neither mental effort nor physical exercise can solve medical problems, the sceptics of modern medicine can always turn to the irregulars. A recent estimate places a number of Americans who have relied on an irregular practitioner at some time in their lives at 60 million, and, aided by

the high cost of orthodox medicine, irregular medical practice appears to be on the rise ...

At the beginning of this period of rejuvenation, the profession's educational institutions had dwindled to one, the National College of Naturopathic Medicine (which had branches in Seattle, Washington, and Portland, Oregon) which was created after the death of R. A. Budden and the conversion of Western States College to a straight school of chiropractic. As described in *Other Healers, Other Cures*, c. 1970 (p. 183).^[16]

Today, Naturopaths in seventeen states are licensed to diagnose, treat, and prescribe for any human disease through the use of air, light, heat, herbs, nutrition, electrotherapy, physiotherapy, manipulations, and minor surgery. At present, one can earn a D.N. [a misnomer, actually – N.D.] degree at the National College of Naturopathic Medicine in Seattle and Emporia, Kansas, [where, by contract, the first two years of the four year medical education were then taught], or the new North American Naturopathic Institute in North Arlington New Jersey [there is also a school in Montreal]. The four-year curriculum covers many standard medical courses – anatomy, bacteriology, urology, pathology, physiology, X-ray reading etc. – but also includes botanical medicine, hydrotherapy, electrotherapy, and manipulative technique ...

The public, by the late 1970s, was particularly ripe for another rejuvenation of naturopathy's brand of "alternative" health care. As described in Murphy's *Enter The Physician: The Transformation of Domestic Medicine, 1760–1860*, when discussing this cyclical rejuvenation in the mid-20th century (pp. 226–227).^[23]

Contemporary crusaders still stress prevention as the lay

person's primary duty, but a growing chorus is calling for every person to assume the newly proactive role in his or her own health care. This is essential, say the analysts, because both lay people and doctors have placed far too much faith in the power of medicine and technology to work miracles. For a host of different reasons and from a variety of different perspectives, health advocates are calling on each person to "accept a certain measure of responsibility for his or her own recovery from disease or disability."

What would this entail? There are probably as many answers to this question as there are respondents, but it is striking to note how many of the solutions would have been familiar to our ancestors who lived between 1760 and 1860. One recurring idea, for instance, is that each person knows his or her own constitution history the best, and therefore has a duty to communicate that knowledge to medical personnel. Another is a refurbished concept of *vis, medicatrix, naturae*, the belief that many diseases are

self-limiting and therefore do not require much medical intervention – and certainly not the amount or the sort to which contemporary Americans are accustomed. Most significantly, today’s analysts are calling on professionals and non professionals to build and nurture a health-care partnership very much like that envisioned by nineteenth-century health publicists: a partnership based on mutual respect, clear understanding and faithful execution. In that scenario, both as it originally evolved and in its updated version, it is the doctor who directs treatment, but crucial to a successful outcome are the informed and responsible actions of the patients, other care givers, and the patient’s family and friends.

In 1978, the John Bastyr College of Naturopathic Medicine was formed in Seattle, Washington, by Joseph E. Pizzorno, Jr, ND (founding president), Lester E. Griffith ND, and William Mitchell ND (all graduates of the National College of Naturopathic Medicine), who felt that it was necessary to have more institutions devoted to naturopathic care and the teaching of naturopathic therapeutics. During the late 1970s, other naturopathic doctors also recognized this need and naturopathic colleges were established in Arizona (the Arizona College of Naturopathic Medicine), Oregon (the American College of Naturopathic Medicine) and California (the Pacific College of Naturopathic Medicine). Unfortunately, none of these three survived. However, the current status of naturopathic medicine, as represented by Bastyr University and National College of Naturopathic Medicine, and now joined by the Southwest College of Naturopathic Medicine and Health Sciences in Arizona and a program in naturopathic medicine at the University of Bridgeport in Connecticut, is that of growth and presumably a solid future. There are currently favorable commentaries on the state of naturopathic medicine, and its continuing efforts to reinvest various diverse theories of “natural healing” with modern vigor.

In *Other Healers, Unorthodox Medicine In America* (edited by Norman Gevitz, the author of *The D.O.’s*), ^[24] a volume which was written to provide “a scholarly perspective on unorthodox movements and practices that have arisen in the United States” (from the editor’s preface), part of this effort is described by Author Martin Kauffman, (from the Department of History at Westfield State College,) a modern expert on homeopathy (pp. 116–117):

In addition to the revival of classical homeopathy, a major development in recent times has been the teaching of homeopathy at naturopathic colleges on the West coast. In Seattle, John Bastyr, a Naturopath and Homeopath who had been practicing for fifty years, readied the move in 1956 to establish the national college of Naturopathic Medicine, which was later moved to Portland, Oregon. The College’s four-year curriculum includes a required third-year course in homeopathy, with homeopathic electives being available to third and fourth year students.

In 1978, three naturopathic practitioners in Seattle founded the John Bastyr College of Naturopathic Medicine. During the sixth quarter all students at that school are required to take 44 hours of course work in homeopathy, after which they may elect another 66 hours and up to 238 hours of clinical

homeopathic instruction. The significance of the naturopathic schools to the resurgence of homeopathy is demonstrated by the fact that “about one third of the graduating class specialized in homeopathic practice, a total of about 50 each year in all” (citing the *American Homeopath* in italics).

And, as described in the *Encyclopedia of Alternative Health Care* by Olsen (pp. 209–210):^[25]

Today in Germany, the nature care movement in herbal remedies tradition has matured into a well-established health care practice, with about 5,000 professionals throughout the country. ...

One Kneipp practitioner, Benedict Lust, emigrated to America to begin teaching and practicing naturopathy here. By 1902, he had founded the American School of Naturopathy in New York City.

The practice quickly spread across the United States (California was the first State to pass a law regulating natural medicine, in 1919.)

Numerous schools offering a variety of training cropped up and disappeared. The movement peaked in America around 1950 and nearly died out by the early 1960's. The legal climate for naturopathy turned cold in many States, in the face of the powerful modern medical establishment. While naturopathy medicine is now legal (in several states) many naturopaths practicing in other states are old-timers, practicing under their original “drugless therapy” licenses, issued before laws prohibiting new naturopathic practices went into effect. Today, there are only two schools in naturopathic medicine in the United States: the National College in Portland Oregon, and John Bastyr College in Seattle, Washington. The American Association of Naturopathic Physicians is beginning to organize and unify the profession, with its own definition and philosophy of modern naturopathic medicine.

Alaska, Arizona, Connecticut, Oregon, Washington, and Hawaii recognize naturopathy as a primary medicine with specific licensing laws, as do the Canadian provinces of British Columbia, Manitoba, Ontario, and Saskatchewan. In other states, efforts are under way to gain licensure for naturopaths (this description was circa in 1989).

And the movement continues to grow. And so, the impact of natural healing has come full circle. In an era where the statistical number of persons born who are expected to contract cancer, now recognized as a

degenerative disease, has increased rather than declined, and the incidence of other degenerative diseases (arthritis, arteriosclerosis, atherosclerosis, etc.) has increased in

direct relation to the lengthening of life expectancies produced by improved sanitation and nutrition (although speciously claimed by AMA medicine to be the result of their therapies), the early teachings of Lust, Lindlahr, et al appear to have more validity than ever.

Chapter 3 - Philosophy of naturopathic medicine

Randall S. Bradley ND DHANP

INTRODUCTION

This chapter examines the philosophical foundation of naturopathic medicine and its modern applications. Unlike most other health care systems, naturopathy is not identified by any particular therapy or modalities. In fact, there is a wide variety of therapeutic styles and modalities found within the naturopathic community (see [Table 3.1](#)). For example, there are still practitioners who adhere to the strict “nature cure” tradition and focus only on diet, “detoxification”, lifestyle modification, and hydrotherapy. There are also those who specialize in homeopathy, acupuncture or natural childbirth. At the other end of the spectrum are found naturopathic physicians who extensively use natural medicinal substances to manipulate the body’s biochemistry and physiology. Finally, there is the majority who practice an eclectic naturopathic practice that includes a little of everything.

From its inception 100 years ago, naturopathic medicine has been an eclectic system of health care. This has allowed it to adopt many of this century’s more effective elements of natural and alternative medicine, as well as to adopt conventional medicine’s basic and clinical sciences and diagnostics (see [Ch. 2](#) for further discussion). Through all of this eclecticism, it has always identified the Latin expression *vis medicatrix naturae* (the healing power of nature) as its philosophical linchpin.

TABLE 3-1 -- Naturopathic modalities

Naturopathic physicians are trained to use a number of diagnostic and treatment techniques. These modalities include:

- *Diagnosis* – all of the conventional clinical laboratory, physical diagnosis, and imaging (i.e. X-ray, etc.) techniques, as well as holistic evaluation techniques
 - *Counseling* – lifestyle, nutritional and psychological
 - *Natural medicines*– nutritional supplements (i.e. all food constituents), botanical medicine, and homeopathy
-

- *Physical medicine*– hydrotherapy, naturopathic manipulative therapy, physiotherapy modalities, exercise therapy and acupuncture

- *Family practice* – natural childbirth, minor surgery, natural hormones, biologicals, and natural antibiotics

However, the expression *vis medicatrix naturae*, by itself, does not provide a clear picture of naturopathic medical philosophy, or an understanding of the practice of naturopathic medicine in all of its varied forms. With the profession's history of eclecticism, no two practitioners will treat any individual patient exactly alike. While this has its advantages (i.e. individualization of each patient's care, more therapeutic options, etc.), it also makes it difficult to perceive the profession's philosophic cohesiveness. Another major disadvantage of this eclecticism is the difficulty in developing consistent practice standards.

To attempt to solve this problem, the modern profession has articulated a general statement of naturopathic principles expanding on *vis medicatrix naturae* (see [Table 3.2](#)). However, this statement of principles is probably still not adequate to address the issues that concern modern students of naturopathic medicine or other professionals. Therefore, in order to gain a more in-depth understanding of naturopathic medicine, it is necessary to discuss medical philosophy in general.

MEDICAL PHILOSOPHY

The issues fundamental to medical philosophy have changed little since naturopathy first appeared as a distinct profession at the end of the 19th century. What has changed is the level of understanding of the biological process and the language of science. Most people who study the early writers on naturopathic medical philosophy quickly get lost in the archaic language and arguments used to justify the theories. This chapter translates these concepts and issues into modern terms.

Vitalism vs. mechanism

Historically, there have been two main medical philosophies, those of *vitalism* and *mechanism*. Their origins can be traced to the Hippocratic writings of ancient Greece. Throughout history, the line separating these two schools of thought has not always been clear, but their philosophical perspectives have generally been in opposition. The conflicting goals and philosophical foundations of these two concepts remain relevant as the modern practices of conventional and alternative physicians come into conflict. As will be seen, the foundations of naturopathic medical philosophy are found in vitalism. However, naturopathy also recognizes the practical value of the mechanistic approach to health care.

Mechanism

Up to the early part of the 20th century, there was considerable debate over the issue of vitalism vs. mechanism in the field of biology. The mechanists, or materialists, maintained that the phenomenon of life could be explained exclusively as the product of a complex series of chemical and physical reactions. They denied the possibility that the animate had any special quality that distinguished it from the inanimate. It was their contention that the only difference between life and non-life is the degree of complexity of the system.

Mechanism has several other distinctive characteristics. Its most obvious is that it is reductionistic. In fact, “reductionism” is often used as a synonym of mechanism. Mechanistic science is also characterized by an emphasis

TABLE 3-2 -- The principles of naturopathic medicine

• **The healing power of nature: *vis medicatrix naturae***

Nature acts powerfully through healing mechanisms in the body and mind to maintain and restore health. Naturopathic physicians work to restore and support these inherent healing systems when they have broken down, by using methods, medicines, and techniques that are in harmony with natural processes.

• **First do no harm: *primum non nocere***

Naturopathic physicians prefer non-invasive treatments that minimize the risks of harmful side-effects. They are trained to know which patients they can treat safely, and which ones they need to refer to other health care practitioners.

• **Find the cause: *tolle causam***

Every illness has an underlying cause, often in aspects of the lifestyle, diet or habits of the individual. A naturopathic physician is trained to find and remove the underlying cause of a disease.

• **Doctor as teacher: *docere***

A principal objective of naturopathic medicine is to educate the patient and emphasize self-responsibility for health. Naturopathic physicians also recognize and employ the therapeutic potential of the doctor–patient relationship.

• **Treat the whole person**

Health or disease comes from a complex interaction of physical, emotional, dietary, genetic, environmental, lifestyle, and other factors. Naturopathic physicians treat the whole person, taking these factors into account.

• **Preventive medicine**

The naturopathic approach to health care can prevent minor illnesses from developing into more serious or chronic degenerative diseases. Patients are taught the principles with which to live a healthy life; by following these principles they can prevent major illnesses.

on linear causality. Without its emphasis on reductionism and linear causality, Western science and medicine would probably have not been so successful. As the 20th century advanced, each new discovery in biological and medical science reinforced the arguments for mechanism, until by the middle of the 20th century, the biology community had almost exclusively embraced the philosophy of mechanism.

Mechanism is the philosophical foundation of biomedical science and conventional medicine. Mechanistic medicine identifies disease and its accompanying signs and symptoms as simply the result of a disruption of normal chemical reactions and physical activities. Such disruptions are caused by the direct interference in these reactions and activities of a “pathogenic agent”. (For the purposes of this discussion, the general expression “patho-genic agent” refers to any known or unknown etiological agent or condition. Examples include microbial agents, autotoxins, genetic defects, environmental toxins, non-end-product metabolites, and physical and emotional stress and trauma.) A living organism, then, is simply a very complex machine which, due to external agents and “wear and tear”, breaks down. Because the signs and symptoms of disease are thought to be due only to these mechanical disruptions and interference with reactions, they are considered to be completely destructive phenomena and are therefore to be eliminated. Disappearance of the signs and symptoms indicates that the pathogenic agent and its resulting disease have been eradicated, or at least controlled. The goals of mechanistic medicine tend to be the quick removal of the signs, symptoms, and the pathogenic agent.

Mechanistic medicine is being practiced in cases where the intention of the therapy is to intervene in the perceived mechanism of the disease and/or relieve the symptoms. Examples would be the use of antihistamines to relieve rhinitis, vitamin B₆ to help PMS, surgery and emergency care for traumatic injuries, coronary bypass surgery, anti-inflammatory agents in systemic lupus erythematosus (SLE), or insulin in juvenile onset diabetes. Mechanism is also being used when an identified pathogenic agent is directly attacked or eliminated. Instances of this would be the use of antibiotics or the isolation of a patient from a particular allergen. Clearly, mechanistic medicine can be very effective in achieving its goals. In the face of modern medical technology, it is easy to see how this philosophy came to dominate biology, medicine, and the attention of the public.

However, the unsolved problems of mechanistic medicine – particularly those of chronic degenerative disease, authoritarianism which alienates patients from responsibility for their own health, and the increasing cost of health care – suggest that there are limits to the mechanistic perspective and explain why vitalism has not disappeared and is, in

fact, in resurgence.

Vitalism

The philosophy of vitalism is based on the concept that life is too well organized to be explained simply as a complex assemblage of chemical and physical reactions (i.e. a living system is more than just the sum of its parts). This is in contrast to the mechanist's contention that "the only difference between life and non-life is the degree of complexity". Throughout the 19th century, the debate between vitalism and mechanism was mostly carried on by biologists whose interests were mainly in the study of the organism's specific cellular activities, such as morphological development. These activities were argued to be "vital" and, therefore, not explainable by mechanistic science. The tendency was to infer a metaphysical quality to this concept. As can be imagined, these earlier debates lurched from one specific argument to the next as modern biology unraveled the secrets of cellular metabolism. Fortunately, the debate has now shifted back to the relevant and holistic general concepts.

While modern vitalism is inherently holistic in its view and has an emphasis on circularity as its causality (i.e. feedback loops), there is no conflict with the findings of biomedical science. Eventually, all of the individual chemical and physical reactions that are found in the processes of life will probably be identified. What is significant is not the individual reaction, but the fact that they are all coordinated to such a degree as to produce the special activities of a living organism. An organism's unique complexity – as demonstrated by its ability to grow and develop, respond to stimuli, reproduce, and repair itself – requires a level of organization and coordination that suggests a distinct quality that is not readily explained by mechanism. This organization and coordination has been identified as "homeostasis" by physiology. All organisms, up to the point of death, are attempting to return to this ideal state when injured or ill. As there is no inanimate counterpart to this level of complexity and organization, this is the most dramatic general argument in favor of vitalism.

A less dramatic argument used to support the vitalistic perspective is the "problem of entropy". Entropy is the tendency of any closed system to find equilibrium, i.e. the state of least organization. In other words, systems tend to run down and become less complex over time. In defiance of this universal rule, life, up until the point of death, consistently creates more complex systems out of simple ones. To do this, life actively pursues external matter and energy to incorporate into itself, while at the same time selectively eliminating by-products from its utilization of this matter and energy.

When the problem of entropy is examined on the molecular level, the same individual chemical processes and elements may be found in both animate and inanimate systems. In the inanimate system, however, there is a

constant move toward a state of chemical equilibrium. This type of system cannot

maintain an unstable chemical state and always seeks stabilization. Even after the addition of external exciting energy, the system will return to the simplest, least reactive state possible. The animate system is virtually the opposite. It is continuously in a state of dynamic chemical instability, actively seeking energy to maintain this instability, and consistently moving to more complex and organized states (and back again). It is only at the onset of death that an animate system begins to move towards equilibrium.

The third general argument in favor of a vitalistic view of life is evolution. For evolution to exist as a force in nature, generations of living organisms have to survive long enough to grow, reproduce and then evolve. In order for this survival to take place, the organisms' homeostatic and repair processes must be consistently directed towards maintaining a state of balance with the external environment (i.e. health). Any organisms that did not behave biochemically and physiologically in this manner would have died and not evolved. Thus the phenomenon of evolution, as the action of countless living organisms over eons, multiplies life's anti-entropic quality and is incompatible with a mechanistic view of living systems.

These easily observable examples of life's "special quality" suggest an "organizing force" that goes beyond what is possible from mere chemistry. This quality that makes life unique should not be mistaken as a metaphysical concept, although is not intended to argue here for or against such concepts. The point is only that vitalism is a medical philosophy based on observable scientific phenomena. Unfortunately, a definitive definition of this quality (in the old literature called the "vital force", defense mechanism, or simply "Nature") will have to wait for more research.

At this point in the discussion, not many mechanistic practitioners would have reason to be uncomfortable, as the ideas proposed are relatively non-controversial and just follow generally accepted physiological principles. Interestingly, many of these practitioners probably have personal belief systems that are quite compatible with this stage of the vitalistic argument. However, the conflict becomes evident upon examination of the premises upon which the practice of vitalistic medicine is based. What truly separates vitalism from mechanism, and makes it useful as a medical philosophy, is its perspective on disease and the associated symptoms.

Meaning of disease

Vitalism maintains that the pathogenic agent does not directly cause the symptoms accompanying disease; rather, they are the result of the organism's intrinsic response or reaction to the agent and the organism's attempt to defend and heal itself. Symptoms, then, are part of a constructive phenomenon that is the best "choice" the organism can make, given the circumstances at any particular point in time.

These symptoms can be further described as arising from two situations. The first and most common situation is when they are from a "healing reaction", which is the organism's concerted and organized attempt to defend and heal itself. These healing reactions produce what can be called "benign symptoms". Examples include fever and inflammation in infections, almost any reaction of the immune system, and many of the

symptoms of chronic disease.

This interpretation of symptoms is generally ignored by mechanism. Instead, it views them as the result of a destructive process and focuses on intervening by relieving the symptom or manipulating the pathological mechanism. Mechanistic medicine is therefore most often working contrary to homeostasis and the organism's healing attempt (in fact, this is usually its intent). When this therapeutic approach is effective, vitalists call the result a "suppression" (see [Table 3.3](#)). This approach to health care is so pervasive that most people, lay and professional alike, today routinely suppress mild fevers with antipyretics.

In contrast, vitalism considers these symptoms to be the product of a constructive phenomenon and therapeutically stimulates and encourages this directed healing process. Rather than simply trying to eliminate a pathogenic agent, as mechanistic therapy might, vitalism focuses more on augmenting the organism's resistance to that agent. That is not to say that vitalists object to removing the agent, only that it should be done in the context of simultaneously increasing resistance (in other words, decreasing susceptibility). The importance of this approach becomes evident when one recognizes that disease is only possible when both a pathogenic agent and a susceptibility to that agent are present.

Healing reactions can take several forms, as shown in [Table 3.4](#). In the first type, an organism's response to a

TABLE 3-3 -- Cure, suppression and palliation

When symptoms improve following treatment (regardless of the therapeutic system), it is for one of three reasons:

- *Cure*. The symptoms go away and the patient's overall health improves. In this case the treatment can be discontinued and the patient continues to do well.
 - *Suppression*. The symptoms go away but overall the patient becomes less healthy. The treatment can be discontinued and the symptoms will stay away, but the patient feels worse generally (i.e. decreased sense of well-being, energy or moods), or new, often more limiting, symptoms eventually develop (e.g. suppressed eczema leading to asthma).
 - *Palliation*. The symptoms are improved but only as long as the treatment is continued. At best, palliation is something that is done while a curative treatment is given time to work. In and of itself, palliation will never lead to a cure, but unfortunately, continued palliation may eventually lead to suppression.
-

TABLE 3-4 -- The four types of healing reactions

| Reaction | Description |
|-----------------------------|--|
| Acute, asymptomatic | Organism easily defends itself |
| “Healing crisis” | Relative strength of pathogenic agent and organism similar; symptoms of body defending itself apparent |
| Vigorous but unsuccessful | Pathogenic agent stronger than organism; death if no intervention |
| Chronic, mildly symptomatic | Healing reaction feeble, but adequate to maintain life; progressive degeneration |

pathogenic agent does not produce symptoms. When it is capable of easily defending itself from the agent, no symptoms will be perceivable. This is a common homeostatic process and is demonstrated when a potential pathogen, such as beta-hemolytic streptococcus, is cultured from a healthy person’s throat. However, when the organism is more susceptible or the relative strength of the pathogenic agent is greater, a threshold is reached and symptoms become perceivable. Successful healing reactions of this type would include vigorous acute diseases that quickly resolve. The early naturopaths would have called these acute reactions “healing crises”. As the susceptibility of the organism increases relative to the strength of the pathogenic agent, there is a greater likelihood that the healing attempt will not be successful. When such a reaction is unsuccessful but vigorous, death may result, unless there is timely application of vitalistic or mechanistic therapy. Examples of this situation might be acute bacterial meningitis or cholera.

When the healing attempt is feeble and therefore ineffective, it usually goes into the “chronic disease” stage of the reaction. Vitalists observe that suppression seems to increase the likelihood that the reaction will be forced to go into such a chronic stage. In this situation the reaction is “smoldering”, and most often the organism cannot overcome the pathogenic agent unassisted. It just “holds its own”, and if the organism’s general health decreases over the years, the reaction gradually degenerates, producing symptoms that become less benign as it moves to an end-stage pathology. If the organism can be therapeutically stimulated to produce a more vigorous healing reaction, it can often successfully complete the original healing attempt. This augmented reaction is another example of a naturopathic healing crisis and would also be called an “aggravation” by the vitalists who practice homeopathic medicine.

Intervening in the mechanism of disease by relieving symptoms does little to stimulate or encourage the healing response; in fact it usually actually inhibits the healing response. In contrast, vitalistic therapies can be very effective in helping these healing reactions, because their goals are precisely the same as those of the organism. Thus, it is thought that vitalistic medicine works because, by honoring this process and thereby strengthening the whole organism, it encourages a more effective healing effort. Ideally, the organism is then able to accelerate and complete its reaction against the pathogenic agent, leading to the permanent disappearance of the symptoms as it returns to a state of health.

It would be naive to say that every stage of the healing reaction is positive and in the

best interest of the organism, or that no symptoms should be palliated. The modern vitalist acknowledges that intervention is sometimes necessary. On the other hand, it is important to note that routine intervention can encourage its own worst-case scenarios. When mechanistic therapies successfully suppress an organism's chosen healing reaction, a less effective and less desirable response is often produced. Therefore, when suppression occurs, it can lead to a more complicated medical situation. Consequently, the very practice of mechanistic medicine tends to reinforce its practitioner's conviction that intervention is usually necessary. It should be noted, however, that not all intervention leads to suppression. It happens less often when the pathogenic agent can be readily eliminated, such as in non-recurring acute bacterial infections, or when relatively non-invasive therapies are used, such as natural medicines.

The second type of symptom-producing situation occurs when the organism produces symptoms in response to an organic lesion that arises from the direct pathological influence of a pathogenic agent. These can be called "morbid symptoms" and examples would include symptoms from the mass of an invasive tumor, shortness of breath from emphysema, and pain of an injury or MI. It should be mentioned that even these symptoms are the result of the organism's overall effort to maintain homeostasis; benign symptoms are also often present. In addition, a morbid symptom is not necessarily produced for a negative reason. For instance, pain is valuable as an indication of tissue damage. As can be seen, many, if not most, of these situations involve "end-stage" pathology. Here mechanistic therapies can be very positive when the goals of the therapy do not conflict with those of the organism.

There are instances when invasive intervention will probably be required to save "life and limb". These include such conditions as birth and genetic defects, serious traumatic injuries, crisis situations, overwhelming infections, and many malignancies. Unfortunately, conventional intervention does not guarantee a successful outcome either. Even in these situations, however, the effectiveness of vitalistic and natural therapy should not be underestimated, and their concurrent use will certainly augment any mechanistic intervention.

Although the concept of benign and morbid symptoms can be a useful tool to help understand the healing and disease process, in many situations it may not be possible

to categorize the type of symptoms produced. A rough rule of thumb, however, would be that virtually all symptoms accompanying "reversible" or functional pathology are benign. On the other hand, many of the symptoms associated with traumatic injury and end-stage pathology would be morbid symptoms.

Changing society

After this discussion of vitalism's perspective on disease, the question that comes to

mind is: "If most health problems are likely to respond to vitalistic medicine, then why is mechanism dominant?" The best answer is probably found in examination of the general attitudes held by society during the Industrial Age just ending. Mechanism came into dominance during this period because it neatly fit into the Industrial Age's world-view. This is the "man conquers nature" view that holds humanity as above and separate from the world in which it lives. It follows that nature is simply a resource that technology will eventually subdue or subjugate and put into order. Although this perspective is still very strong in Western society, there has been a dramatic change within the last 30 years.

Attitudes are now shifting in favor of the ecological integration of humanity into the environment. This "new" world-view holds that humanity is part of an orderly nature and that to ignore this creates situations that eventually become problems. Most ecological disasters are excellent examples of the results of the old view. In addition, the new view contends that if an effort is made to understand how nature functions and an attempt is made to work within that understanding, humanity's needs can be more efficiently met.

Mechanistic medicine, as part of the "old" world-view, generally sees disease as something to conquer and put into order. Vitalistic medicine, on the other hand, looks at the order that is already present and attempts to integrate its therapy into that orderly process. As a result, vitalism is becoming increasingly popular as society shifts from the old to the new world-view.

The belief systems of many mechanistic practitioners recognize this order. However, due to education and peer pressure, these personal beliefs are rarely translated into clinical practice. The mechanistic view is still relatively pervasive in society, and because mechanism is convenient (e.g. taking aspirin for a headache), vitalistic practitioners can generally shift their perspective and successfully use mechanistic therapy (although their therapeutic goals may be different). On the other hand, since mechanists dispute the premises upon which vitalistic medicine is based, they generally have great difficulty when attempting to practice or research a vitalistic therapy and frequently cannot demonstrate its efficacy.

Scientific medicine

While mechanism and vitalism represent opposing perspectives, the systems of medicine that represent these philosophies can be successfully tested and examined with the scientific method. That is not to say that the philosophy of vitalism has been unquestionably proven – only that the validity of vitalistic interventions can be scientifically demonstrated. If a therapy can be proven effective, then that implies the accuracy of the philosophy upon which it is based. Unfortunately, very few of the vast resources of the 20th century biomedical community have been directed toward investigating vitalistic medicine.

Conventional medicine, as the dominant health care system and a representative of mechanism, has claimed for itself the title of "scientific medicine". However, it is inherently no more or less scientific than vitalistic medicine. A system is scientific only when it has met the criteria of the scientific method. This method requires the collection

of data through observation and experimentation, and the formulation and testing of hypotheses. Non-prejudicial science can effectively study any system, but the researcher must understand the system's particular paradigm. Experiments on a vitalistic therapy based on a reductionistic and mechanistic model are going to be less than satisfactory.

The criteria of the scientific method can be met by vitalistic medicine, but only when the researchers recognize that it cannot be studied as though it is reductionistic or based on a simplistic model of linear causality. When the experimental model acknowledges the complexity of a living system in a social context (i.e. holism and circularity), vitalistic medicine proves to be both verifiable and reproducible, and thus scientific.

Unfortunately, due to conventional medicine's current political and economic dominance, it is in the position to dictate (through economic and publication control) that research, and therefore the scientific method, will primarily be applied to itself. The result is that most conventional practitioners dismiss vitalistic medicine, along with all alternatives, as unscientific.

This is unfortunate because most vitalistic physicians also have extensive training in mechanistic and/or conventional medicine. Generally, they are capable of practicing mechanistically, and do so to greater or lesser

* A thorough review of all health care modalities in use today reveals a category that could be called "esoterica". While this category is not historically relevant to this discussion of medical philosophy, and its brief mention is not intended as an argument for or against "legitimacy", esoterica would include such things as prayer, faith healing, psychic healing, Healing Touch, Touch for Health and medical dowsing. Generally speaking, the actual operator of the therapy must call on God or have some special endogenous skill or "power" that goes beyond intellectual knowledge. These modalities are all "operator-dependent" and cannot be examined separate from the practitioner – thus greatly increasing the difficulty of their scientific verification.

degrees. The conflict between the practitioners of these different systems is very often due to a lack of constructive dialog. This can be attributed to two general causes: the first is simply that each system defines the world of "correct" medicine in terms of its own principles; the second is the issue of who controls the economic and political power.

NATUROPATHIC PHILOSOPHY

Historically, naturopathy is a vitalistic system of medicine. However, over the last 100 years it has also incorporated a number of therapies that can function mechanistically. What makes them acceptable, given naturopathic medicine's vitalistic foundation, is that they are natural therapies. Natural medicines and therapies, when properly used, generally have low invasiveness and there is little evidence that they cause suppression or side-effects. When used mechanistically, they allow some intervention while still allowing the organism's healing abilities the opportunity to continue unopposed,

especially when used to support the body's own healing processes.

Vis medicatrix naturae

Naturopathic physicians assert that all true healing is a result of *vis medicatrix naturae* (the healing power of nature). Unfortunately, some people in the field of alternative medicine (including some naturopathic physicians and students) have mistakenly translocated this concept to the therapy. These practitioners tend to operate as though this "healing power" is an intrinsic property of the natural therapy or medicinal substance itself. In contrast, vitalism and naturopathic medicine have always understood that the "healing power of nature" is an inherent property of the living organism. *Vis medicatrix naturae* is the living organism's "desire" and ability to heal itself.

The application of this principle in practice is, of course, dependent upon the patient's needs. Ideally, it involves only the use of therapies that support the organism and encourage its intrinsic healing process to work more effectively. It also avoids the use of medicines and procedures that interfere with natural functions or have harmful side-effects. Natural medicines and therapies are therefore preferred, since, when used properly and in appropriate circumstances, they are the least harmful, least invasive, and best able to work in harmony with the natural healing process.

Since the total organism is involved in the healing attempt, the most effective approach to diagnosis and treatment is to consider the whole person. In addition to physical and laboratory findings, important consideration is given to the patient's attitude, psychological and spiritual state, social circumstances, lifestyle, diet, heredity, and environment. Careful attention to each person's unique individuality and susceptibility to disease is critical to the proper evaluation and treatment of any health problem.

Naturopathic physicians contend that most disease is the direct result of the ignorance and violation of what would be traditionally called "natural living laws". These general lifestyle (including diet) rules are based on the concept that there is an environment (both internal and external) that optimizes the health of an organism. Analysis of the lifestyles of Paleolithic and healthy primitive and modern cultures gave naturopathic physicians and their progenitors many clues as to what a healthy lifestyle should include.

Throughout most of modern history, biomedical science has focused primarily on researching the sick. Recently it has finally begun to evaluate what makes for a healthy lifestyle. To no-one's surprise, this lifestyle looks like the same one advocated by naturopaths for the last 100 years. A healthy lifestyle could be generalized to include: the consumption of natural unrefined foods; getting adequate amounts of exercise and rest; living a moderately paced lifestyle; having constructive and creative attitudes; avoiding toxins and polluted environments; and the maintaining of proper elimination. During illness, it is also important to control these areas in order to remove as many unnecessary stresses as possible and to optimize the chances that the organism's healing attempt will be successful. Therefore, patient education and responsibility, lifestyle modification and preventive medicine are fundamental to naturopathic practice.

While the practice of naturopathic medicine is grounded in *vis medicatrix naturae*, it also recognizes that intervention in the disease process is sometimes efficacious and, at times, absolutely necessary. Naturopathic physicians treat patients using a wide variety of therapeutic modalities. Some of these are vitalistic and some mechanistic. It is the goal of the therapy that ultimately determines which approach is utilized. Naturopathic physicians have a long-standing tradition of integrating the best aspects of traditional, alternative, and conventional medicine in the interest of the patient. As appropriate, patients are referred to other health care practitioners. Whenever possible, every effort is made to use all treatment techniques in a manner that is harmonious with the naturopathic philosophy.

Natural medicines and therapies

The medicines administered and prescribed by naturopathic physicians are primarily natural and relatively unprocessed. Although it is recognized that some situations may require the use of synthesized medicines, their use is considered less desirable. Some of the arguments in favor of natural medicinal substances have already been discussed. In addition to the reasons noted above,

natural agents are preferred because their constituents have been encountered in nature for millions of years. This long period of exposure has enabled the body to develop metabolic pathways capable of effectively utilizing, processing, and detoxifying these medicines.

Four categories of natural medicines can be defined. The first includes substances found in nature that have been only minimally processed. Examples would include, but are not limited to, foods, clean air and water, and whole herbs. The early “nature cure” practitioners used this category primarily. The second category includes agents extracted or made from naturally occurring products. Although these have undergone pharmacological processing, the constituents of the medicines are still in the form found in the original natural substance. These first two types of natural medicinal substances have synergistic constituents that allow their use at lower doses with a resultant broader and safer therapeutic index. Examples of this category include tinctures and other botanical extracts, homeopathic medicines, glandulars and other substances of animal origin.

The third type of natural medicines are those highly processed medicinal substances that are derived from a natural source. These often have everything removed but the identified active ingredient and no longer have any synergistic constituents. Examples include many new phytotherapeutic agents, constituents of biochemical pathways, enzymes, amino acids, minerals, vitamins, and other food extracts.

The fourth category that may be considered “natural” are those manufactured medicines

which are presumed to be identical to naturally occurring substances. These have the advantage of being less expensive and are typically available in higher concentrations. However, their use is less desirable due to:

- the difficulty of determining whether they are indeed the equivalent of the natural product
- their lack of natural synergistic components
- the inclusion of contaminants from the manufacturing process. These contaminants are often chemically and structurally similar to the desired medicine, but generally interfere with the normal pathways rather than enhance them.

Examples of these manufactured “natural” medicines include hormones, synthetic vitamins and analogs of plant and animal constituents.

Increasingly, medicines of the types identified in categories three and four are being grown “synthetically” by microorganisms specially engineered to produce the desired medicinal substance. It is difficult to say which of these categories best describes this situation. There are also potential problems with this kind of manufacturing process as evidenced by the tryptophan disaster of several years ago.

Naturopathic physicians also use many natural therapies. What makes a therapy “natural” is that it is derived from a phenomenon of nature and is used to stimulate the body to heal itself. Examples of these phenomena are air, light, heat, electricity, sound and mechanical force. Some of these natural therapies include mechanical and manual manipulation of the bony and soft tissues (naturopathic manipulative therapy), physiotherapy modalities (e.g. electrotherapy and ultrasound), hydrotherapy, and exercise therapy. Naturopathic physicians also use lifestyle modification, counseling and suggestive therapeutics. These therapies are all discussed in more detail in other chapters.

Family and specialty practice

Naturopathic physicians, like other types of primary care providers, develop practices that meet their personal interests and skills. While most are engaged in general and family practice, many have also specialized in particular therapeutic modalities and/or types of health problems. However, in all situations the emphasis is still on treating the whole person. The practice of family medicine requires the use of some techniques and devices that are not, in the strict sense of the word, natural therapies, but belong among the comprehensive family practice services offered by the naturopathic profession.

Included in family practice are such services as the prescription and fitting of birth control devices, first aid, and minor surgery. Minor surgery includes the repair of minor wounds and lesions and the removal of growths and foreign bodies from superficial tissues. When necessary, it includes the use of local anesthetics and appropriate first aid procedures. First aid includes the treatment of ambulatory acute injuries and conditions that are routinely seen and handled in general practice.

Many naturopaths have also developed advanced expertise in different natural therapeutic modalities. These practitioners have usually invested in postgraduate training, such as that available through residencies. Three therapeutic specialties that merit mention are natural childbirth, acupuncture, and homeopathy.

THE PHILOSOPHICAL CONTINUUM

When the various healing systems are examined and placed on a philosophical continuum, mechanism and vitalism are on different ends of the same health care spectrum. Both ends of this health care continuum have their strengths and weaknesses. Mechanistic medicine is effective for trauma, crisis care, end-stage pathology and many acute diseases. It is essentially a failure with chronic disease. In fact, conventional medicine considers most chronic diseases incurable. Vitalistic medicine, on the other hand, has its most dramatic successes with

chronic disease and is effective with many kinds of acute disease. It is not very effective with trauma and crisis care and end-stage pathology, although it can be a very useful complement to conventional medicine. As can be seen, both ends of the health care spectrum are necessary if every patient's health care needs are going to be met.

Although aspects of naturopathic (e.g. constitutional hydrotherapy) and conventional medicine (e.g. chemotherapy) represent the archetypes of vitalism and mechanism, the area between the ends of this spectrum is a gray area within which both naturopathic and conventional physicians operate on a continual basis. While naturopathic physicians integrate vitalistic therapies with some mechanistic therapies, it is not possible for everyone to be experts in everything. The vast majority of naturopathic or conventional physicians are not going to be able to learn and competently practice all types of health care. Consequently, to effectively meet society's health care needs, it is necessary to create an integrated health care system. Such an integrated system would have both vitalistic and mechanistic practitioners working together in the same clinical settings.

The trends of popular culture and a biomedical science that is finally beginning to study alternative medicine suggest that the creation of an integrated health care system is now underway. However, it takes no great skill for a mechanistic medical doctor to switch from giving a synthetic drug for a disease to giving a natural medicinal substance. If naturopathic medicine becomes just another mechanistic system using natural medical substances to treat disease (instead of a system identified with treating the whole person vitalistically), it will lose its unique niche in an integrated health care system. For naturopathic medicine to survive and thrive in this new environment, it will need to keep its vitalistic roots. With a thorough grounding in *vis medicatrix naturae*, modern naturopathic medicine will flourish and achieve a leadership position as the

dominant health care paradigm shifts to the integrated medicine of the future.

CONCLUSION

The practice of naturopathic medicine can be summarized most simply as helping the body/mind heal itself in the least invasive, most fundamentally curative manner possible. This approach is not tied to any particular therapy or modality, but rather is oriented to a rational blend of vitalistic and mechanistic principles working with the whole person, and educating the patient in the ways of health.

As naturopathic knowledge of health and disease grows, new therapies and approaches to health care will be added as they satisfy the principle of *vis medicatrix naturae*. As the larger health care system becomes more integrated, naturopathic medicine's place is assured as the profession that truly understands each unique human being's power to heal.

Chapter 4 - Placebo and healing

Peter Bennett ND

INTRODUCTION

The thoughts of a patient's mind and the physician's therapeutic intention on the patient have a profound effect on the health of the patient. The ability of the patient's mind to affect the process of virtually every disease has been well documented,^{[1] [2]} and the internal mechanisms and pathways by which the mind can positively or negatively affect the immune and healing processes has been investigated in the scientific literature of psychoneuroimmunology.^{[3] [4]} As the body of knowledge documenting the critical importance of the patient's psyche on the therapeutic environment has grown, it has become increasingly important for all schools of medicine to teach the healing potential of the human mind.

The potential of the mind to influence human healing has been explored to the greatest depth in medical literature discussing the placebo effect. The "power of placebo" draws upon the innate ability of the body to spontaneously heal itself, a fundamental principle of naturopathic medicine. This point separates the care delivered by naturopathic physicians from the pharmaceutical and surgical approaches of current medical "standard of care" procedures. If common medical texts on internal medicine or ambulatory care are examined, the word "healing" is not found in the index. Except for the diagnostic evaluation of "self-limiting diseases" and "spontaneous regression", the ability of the human organism to self-right and repair from a state of acute or chronic disease does not get explored in modern medicine except under the designation of "placebo response". The placebo response therefore represents all the "unknown" variables which conspire to heal a patient, in spite of pharmaceutical and surgical intervention.

Placebo response

Placebo response is the power of the mind through intention, to effect:

- a change in oneself

- a change in those around us
- a change in the environment we live in.

Intention has been seen to affect machines^[5] and remote biological systems.^[6] Distantly influenced systems include another person's electrodermal activity, blood pressure, and muscular activity; the spatial orientation of fish; the locomotor activity of small mammals and the rate of hemolysis of human red blood cells. Prayer, an example of intention, has been extensively studied as a therapeutic healing modality.^[7] One study showed a dramatic result in cardiac ICU recovery when patients were prayed for by someone at a distant location.^[8] Patients in this study were five times less likely to require antibiotics, three times less likely to develop pulmonary edema, 12 times less likely to require endotracheal intubation and less likely to suffer cardiac mortality.

Our biological systems must conform to the laws of physics. Modern physics has investigated the effect of an observer on the system observed. It has been shown that an electron will acquire a definite axis of measurement in the process of measurement. Bell's theorem supports the idea that our universe consists of particles unified instantly as an indivisible whole; our biological homeostatic systems cannot be analyzed in terms of independent parts. The interconnected nature of our biological systems has been known for thousands of years; the ancient Buddhist concept of "interdependent phenomena" accurately describes this paradigm.

Our current medical system has not shifted with the developments in modern physics. These modern ideas of biological systems are diametrically opposed to Cartesian paradigms that our internal and external environments consist of separate parts joined by local connections. Medicine must take a "quantum leap" to catch up with the knowledge we possess about our environment through quantum physics. We can see clearly that it is impossible for a doctor to observe a patient and not have that observation affect the health of the patient.

Pierre Teilhard de Chardin postulated, and Rupert Sheldrake proved, that the possibility of a "morphogenetic field" for the subliminal communication to all members of our species is possible.^[9] The effect of human thought on other members of society has been described in human society since the beginning of our earliest cultures.

Naturopathic physicians believe that the body has a powerful ability to maintain health and repair to a healthy state after disease by virtue of its inherent power of vitality. This homeostatic healing mechanism has been selected by Nature in the same way that other organs which we consider to be vital to our survival have been selected. Healing occurs unaided by simply maintaining an environment that does not obstruct the path of cure.

Because placebo literature documents the philosophical foundations of the naturopathic health care model, it is important to review the full scope of this subject. Integrating

known placebo initiators in clinical practice is essential for good patient care.

Why study the placebo effect?

For hundreds of years, physicians have watched their patients respond to therapies with a wide range of results. Some patients recover fully, while others, with apparently identical diseases and therapies, wither and die. Today, a skilled physician can correctly diagnose the condition of a patient by applying the sophisticated techniques of modern medicine. Then, an appropriate therapy, the efficacy of which has been thoroughly proven in research and clinical trials, can be prescribed. Through this process the patient will have received the best care available through current medical technology. But if the diagnosis, therapy, and therapeutic interaction do not stimulate the hope, faith, and belief of the patient, the chances of success are measurably diminished. It has been repeatedly demonstrated in the literature on the placebo effect,^[10] psychoneuroimmunology,^[3] and psychosomatic,^[11] behavioral,^{[12] [13]} and psychiatric^[14] medicine that the beliefs of both the patient and the doctor, and their trust in each other and the process, generate a significant portion of the therapeutic results.^[15]

The placebo and its effect are not separate from any aspect of the therapeutic interaction, nor are they “nuisance variables” muddying a clear clinical picture. Rather, they send the physician a strong message: it is a patient’s own belief systems that mobilize the inherent healing powers of the mind. By studying the placebo effect, a physician is better able to fully harness this power to trigger internal healing mechanisms. Yet, despite the amount of documentation, the placebo effect remains one of the most misunderstood areas in modern medicine.

The physician should always strive to stimulate self-healing, or the placebo effect, as fully as possible to maximize its potential for healing. Someday the physician will be able to explore the deepest recesses of the unconscious to directly access therapies that assist the body in the restoration of internal homeostasis. The optimal model for health care is the marriage of appropriate medical technology with the factors that have been shown to generate the placebo effect. This exciting scenario shines on the horizon as the health care of the future.

Since the doctor/patient relationship is such fertile ground for stimulating the healing response,^{[16] [17] [18]} it serves a physician well to comprehend the nature of the placebo phenomena in order to fully realize this potential for healing.

HISTORY OF PLACEBO

The modern physician and the primitive medicine men and shamans of the past have both used ineffective therapies

to stimulate healing in their patients. As Shapiro notes: "... the true importance of placebo emerges with a review of the history of medical treatment".^[19] It has been noted that the historic therapies of the medical profession and traditional healers, "... purging, puking, poisoning, puncturing, cutting, cupping, blistering, bleeding, leeching, heating, freezing, sweating, and shocking",^[20] worked because of the placebo effect. Although in retrospect these practices might seem ludicrous, all of these therapies were once considered effective. As an embarrassing epilogue, placebo literature has shown that ineffective procedures are just as pervasive in modern medicine as in the jungle hut of the shaman. We must therefore ask ourselves the following question: how can unfounded medical therapies survive peer review literature and centuries of cultural acceptance?

The power of the patient's belief in the potential for cure has been consistently observed throughout history. Both Galen and Hippocrates recognized the strong effect of the mind on disease and recommended that faith, treatment ritual, and a sound doctor/patient relationship could provide important therapeutic results.^[21] Recognition of the power of positive expectation was recorded frequently in the medical literature of the 17th and 18th centuries. It was in the 18th century that placebo was first defined as a "... commonplace method of medicine".^[22] As the importance of drug therapy grew in the 19th century, the term placebo became identified with medicines involving substances that resembled drugs. But in the 1940s, because of the increase in double-blind research, it became associated with inert substances that were used to replace active medication.

Origin of the term placebo

The original Latin meaning of placebo is "I shall please".^[23] Although the term had a purely medical application in the first half of the 20th century, its meaning has been subject to various interpretations throughout the last several hundred years.

Before the 1940s, placebos were pharmacologically inactive substances, such as saline or lactose pills, used to satisfy patients that something was being done for them, i.e. the doctor was "pleasing" the patient. In the 1940s and 1950s, there was an explosion of the use of double-blind experimental procedures to evaluate the growing number of new drugs and medical procedures. Suspicion arose that all medical therapies contained an element of placebo phenomena.^[24] This new understanding pressed the scientific community to offer new, far broader definitions.

Shapiro offered the classic definition of a placebo:^[25]

Any therapeutic procedure (or that component of any therapeutic procedure) which is given deliberately to have an effect, or unknowingly has an effect on a patient, symptom, syndrome, or disease, but which is objectively without specific activity for the condition being treated. The therapeutic procedure may be given with or without the conscious knowledge that the procedure is a placebo, may be an active (non-inert) or inactive (inert) procedure, and includes, therefore, all medical procedures no matter how specific – oral and parenteral medications, topical preparations, inhalants, and mechanical,

surgical, and psycho-therapeutic procedures. The placebo must be differentiated from the placebo effect which may or may not occur and which may be favorable or unfavorable. The placebo effect is defined as the changes produced by placebos. The placebo is also used to describe an adequate control in research.

A more accurate definition of placebo would be:

Placebo effect is the process of a physician working with the self-healing processes of a patient. Placebo response means healing that results from the patient's own natural survival and homeostatic defense mechanisms.

Modern placebo definitions extend to its nature, properties, and effects. Placebo can be known or unknown, active or inactive, and positive or negative in results (placebo effect vs. nocebo effect), and can extend to all forms of diagnostic or therapeutic modalities, which are further defined in [Table 4.1](#) .

CLINICAL OBSERVATIONS OF “KNOWN” PLACEBO THERAPY

One of the more dramatic examples of the placebo effect reported in the medical literature involved a patient with advanced lymphosarcoma, which Klopfer^[27] reported was

TABLE 4-1 -- Types of placebo

| Placebo type | Definition |
|---------------------|---|
| Known placebo | Placebo used in a single-blind experiment. The doctor knows it is a placebo but the patient does not |
| Unknown placebo | Double-blind placebo use. Neither the doctor nor the patient knows that the medication is a placebo |
| Active placebo | Any substance that has an intrinsic physiological effect that is irrelevant to the ensuing placebo effect. The vasodilating effect of niacin would make it a good active placebo |
| Inactive placebo | Any substance that is used with medicinal intent but which has no inherent physiological effect. Except for the glucose effect in a sugar pill (or, to complicate things, an allergic reaction to some component of the supposedly inert substance), it has no physiological effect |
| Placebo effect | Any changes that occur in a patient as the result of placebo therapy |
| Nocebo effect | Any changes that occur as a result of placebo therapy that are perceived as negative or counterproductive to the path of cure |

highly susceptible to the patient's faith in an experimental drug called Krebozion. When the patient was placed on the drug, his enthusiasm was so intense that "the tumor masses had melted like snowballs on a hot stove, and in only a few days, they were half their original size!".

The injections were continued until the patient was discharged from the hospital and had regained a full and normal life, a complete reversal of his disease and its grim prognosis. Within 2 months of this recovery, reports that the drug Krebozion was ineffectual were leaked to the press.

Learning of this, the patient quickly began to revert to his former condition. Suspicious of the patient's relapse, his doctors decided to take advantage of the opportunity to test the dramatic regenerative capabilities of the mind; a single-blind study was done on the patient using pure placebo. He was told that a new version of Krebozion had been developed which overcame the difficulties described in the press, and some was promised to him as soon as it could be procured:^[27]

With much pomp and ceremony saline water placebo was injected, increasing the patient's expectations to a fevered pitch.

Recovery from his second near terminal state was even more dramatic than the first. Tumor masses melted, chest fluid vanished, he became ambulatory, and even went back to flying again. At this time he was certainly the picture of health. The water injections were continued, since they worked such wonders. He then remained symptom-free for over two months. At this time the final AMA announcement appeared in the press – "nationwide tests show Krebiozen to be a worthless drug in the treatment of cancer".

Within a few days of this report, Mr. Wright was readmitted to the hospital in extremis. His faith now gone, his last hope vanished, and he succumbed in less than 2 days.

Other famous placebo case studies include one reported by Cannon on belief causing "voodoo death",^[28] and one reported by Kirkpatrick,^[29] who documented the spontaneous regression of lupus erythematosus resulting, in part, from the patient's belief in the removal of a curse.

Other clinical observations

Belief sickens, belief kills, belief heals^[30]

Evans^[31] and Beecher^[32] reviewed, between them, 26 double-blind studies on the efficacy of active analgesic drugs in the treatment of pain. Independently, they

concluded that 35% of patients suffering from pain experienced a 50% reduction in their symptoms following placebo medication. These are particularly remarkable results when viewed in the context of Evans' observation that with a standard dose of morphine only 75% of the patients will get a 50% reduction in pain. In calculating the efficiency index of placebo analgesia, a method often used to determine the relative efficiency of drugs, placebo efficacy compared with a standard dose of morphine was 0.56 as effective. This prompted Evans to remark: "Thus, on

TABLE 4-2 -- Symptoms and side-effects of placebo response

average, placebo is not a third as effective as a standard injection of morphine in reducing severe clinical pain of various kinds but is in fact 56% as effective."^[31]

As discussed above, placebo has been evaluated in a wide variety of clinical settings besides pain management (see [Table 4.2](#)). When a phenomenon such as placebo has been observed to be active in diverse clinical situations, such as surgery, drug therapy, psychotherapy, and biofeedback, and over a range of physical and mental symptoms, the conclusion that it must be a factor in all aspects of medicine is inescapable.

In addition to the variety of positive effects that placebo produces are the nocebo effects, perceived as counterproductive to the therapeutic goals. These side-effects frequently are consistent with the medication that patients think they are getting. For example, the studies that measure the effects of a supposed aspirin usually show nocebo effects of ulcer-like pain.^[40]

In homeopathy, aggravations and ameliorations are commonly seen when a placebo is given to fend off a patient's need to take a medication while the homeopathic physician is waiting to see if a high-potency remedy will effect a cure. Homeopathic doctors report that placebos can cause anxiety and loneliness, as well as calmness and immediate relief from insomnia.^[41]

PLACEBO MYTHS

Investigation of the understanding of placebo found in the current medical literature reveals the misconceptions that prevail about the nature of placebo therapy and its effectiveness.^[42] A study undertaken to examine doctors' and nurses' attitudes about placebo efficacy and use revealed that both groups underestimated the number of patients who could be helped by placebo.^[42] Physicians showed a consistent pattern of placebo use:

- Placebos were used to prove the patient wrong by diagnosing psychogenic symptoms in patients who were thought to be exaggerating, imagining, or faking their symptoms.
-

55

- Placebos were used in the treatment of alcoholic, psychotic, and demanding patients who were disliked by the staff of the hospital.
- In situations where standard treatments had failed or the patient was getting worse, placebos were used as treatment.

These misconceptions regarding the nature of the placebo have accounted for its widespread misuse for patients who are perceived as uncooperative or who are suspected of malingering.

Myths about placebos continue to hinder a full understanding about the power inherent in this aspect of health care. The most common are discussed below.^[43]

Myth 1

Since placebos tend to be physiologically inert, it is not possible for them to have an effect on physiological homeostasis.

Fact. Research shows that placebos have a wide range of effects (see [Table 4.3](#)) that are found throughout all aspects of human physiology.

Myth 2

Placebos are only useful with symptoms that are associated with psychological or

psychosomatic complaints. Patients who need a placebo are hypochondriacs with vivid imaginations and need to be palliated with something “to please them”.

Fact. Placebos have been shown to be effective in the care of all types of patients, with a consistent level of positive results for a wide variety of accurately diagnosed diseases.

Beecher was one of the first to compile a listing of the therapeutic effectiveness of placebo, thereby uncovering the wide range of therapeutic applications that were previously thought to be limited to only pain control.^[15] He concluded:

... there is too little scientific as well as clinical appreciation of how important unawareness of these placebo effects can be and how devastating to experimental studies as well as to sound clinical judgement lack of attention to them can be.

The large and ever-growing number of studies on placebo and double-blind research (see [Table 4.4](#)) supports the assertion made by Beecher 30 years ago:^[15]

Many “effective” drugs have power only a little greater than that of placebo. To separate out even fairly great true effects above those of placebo is manifestly difficult to impossible on the basis of clinical impression. Many a drug has been extolled on the basis of clinical impression when the only power it had was that of a placebo.

Myth 3

The placebo effect is only found in substances that are inert.

Fact. Placebo phenomena have been observed across a wide spectrum of medical disciplines, including surgery,^[103] drug therapy,^[104] and biofeedback.^[93]

Myth 4

The patient who responds to placebo can be characterized as someone who is of a typical neurotic disposition.^[42]

Fact. Although many studies have tried to infer a

personality type, disposition,^[105] ^[106] or certain epidemiological class of patient,^[107] this has yet to be well demonstrated since, given the right circumstances, any person can become a placebo reactor.^[108] ^[109]

After reviewing the bulk of the research on this subject, Bush^[110] and Wolf & Pinsky^[34] concluded that the attempts to pigeonhole personalities into a clinical profile ignored the complexity of the human mind. Gliedman et al^[99] similarly reported that age, sex, marital status, social class, and intelligence are unimportant factors in determining a patient's response to placebo. Wolf summarized that attempts to identify placebo reactors need to:^[104]

... identify the nature of the symptom being treated, the motivation of the patient and physician, the nature of the test agent, its mode of administration and the life situation of the subject at the time he is tested. The significant point here is not the apparently conflicting findings of investigators with respect to placebo reactors, but rather that in any given situation, responses to a placebo may vary as compared to any other situation and the significance of situations to human subjects cannot be precisely duplicated.

PHARMACODYNAMICS

The physiological response of the “inert and inactive” placebo extends into the realm of drug pharmacodynamics. Dose–response time curves, cumulative effects (increasing therapeutic efficacy with repeated doses),^[111] variable strengths of analgesia based on a patient’s drug expectation,^[63] drug interactions,^[34] ^[112] and carry-over effects^[37] ^[106] have all been demonstrated. The effects of placebo are so pronounced that some observers have suggested that they can exceed those attributable to potent pharmacological agents.^[34]

Packaging and delivery

Several studies have found that the effectiveness of a placebo therapy is dependent on the mode of delivery.^[47] For example, one study found that green tablets improved anxiety and yellow tablets improved depression,^[113] while another study found that blue capsules were more sedative and pink capsules were more stimulating.^[48] Placebo injections appear to be more effective than oral administration after oral placebo has failed to relieve the symptoms.^[40]

Placebo interactions

Benson^[114] writes that the patient’s belief is also a powerful force in determining the degree of relief afforded by the placebo. An increase in patient expectation enhances the physician’s ability to elicit a placebo response. Even if patients know that they are receiving placebos, the expectation and relief brought about by the therapeutic interaction provides positive results.^[115] The importance of expectation is further demonstrated by the observation that the greater the stress level of the patient and the greater his or her need for assistance, the greater the effectiveness of placebo.^[36] This is even seen in patient response to psychotropic drugs: LSD-25 can have no effect if the patient is told that the drug is a placebo.^[105] ^[116]

Patients, such as war heroes, who have severe injuries but do not have great mental suffering attached to their pain need less pain medication than similar injuries in persons who have pain that engenders anxiety and connotes disaster.^[117]

PLACEBO HEALING MECHANISMS

Where animals or humans can react to their own deviations from homeostasis and where these deviations set off restorative processes, therapeutic intervention, including placebo, has an already existing substrate of recovery for exploitation.^[12]

A human being has an intrinsic ability to “self-right” – *vis medicatrix naturae*. This is the keystone of a philosophy that has been held for thousands of years by naturally oriented physicians (see [Ch. 3](#)). The concept of a homeostatic, self-regulating mechanism is central to the understanding of basic concepts of physiology: negative feedback loops

control virtually all systems of the body. According to Guyton:^[118]

... the body is actually a social order of about 75 trillion cells organized into different functional structures ... each cell benefits from homeostasis and in turn each cell contributes its share towards the maintenance of homeostasis.

The body can maintain health and re-establish a healthy state after disease by virtue of its inherent vitality. This is part of the definition of a homeostatic mechanism; it has been selected by nature in the same way that organs vital to our survival have been selected. The surviving species are those most fitted and best able to cope with dysfunction. Those organisms that can tolerate the greatest stresses and still maintain a normal physiology are the hardiest survivors and ensure the species' ability to increase the limits of its adaptation. Therefore, given that an organism is self-maintaining when in an environment that it has been selected for, healing happens unaided by simply maintaining an environment that does not obstruct the path of cure. As Norman Cousins observed:^[119]

... without any help, the human body is able to prescribe for itself. It does so because of a healing system that is no less real than the circulatory system, the digestive system, the nervous system, or any of the other systems that define human beings and enable them to function.

The role of emotions

Reviews of studies that explore how specific emotions can increase cancer susceptibility,^[120] ^[121] examine the effect

of emotions and recovery from cancer, ^[122] examine the increased incidence of sudden and rapid death during psychological stress,^[123] and monitor the changes in immune function during emotional stress^[124] ^[125] all confirm that emotions play a powerful role in the prognosis of a patient. Cannon and Tregear document dramatic case histories of pioneering anthropologists who witnessed the power of taboos and curses to kill strong healthy men and women in Third World cultures throughout Africa, South America, and the South Pacific: "I have seen a strong young man die the same day he was tauped; the victims die under it as though their strength ran out as water."^[126]

The *vis medicatrix naturae*

The healing process described as *vis medicatrix naturae* demonstrates the significant power and potential of the self-generated healing capacity. For a physician, there is no more powerful stimulator of this healing mechanism, the placebo effect, than a strong doctor/patient interaction. Just by walking through the door of the physician's office, a patient's internal homeostatic mechanisms are nudged into seeking higher levels of health, healing, and adaptation. The placebo effect is a result or effect of the patient

seeking the assistance of the doctor's ability to heal and cure. As Benson noted:^[114]

When we dissected the placebo effect a number of years ago, we found three basic components: one, the belief and expectation of the patient; two, the belief and expectation of the physician; and three, the interaction between the physician and the patient. When these are in concert, the placebo effect is operative. ... Perhaps nothing is being transmitted from the healer to the patient, but rather it's the belief the patient has in the healer that's helpful.

Conscious control over homeostasis

The body has two internal forces to maintain homeostasis: a lower and a higher drive. The lower drive is the inherent internal healing mechanism, the vital force, or primitive life support and repair mechanism that can operate even in a person who is asleep, unconscious, or comatose. The higher drive is the power of the mind and emotions to intervene and affect the course of health and disease by depressing or stimulating the internal healing capacities. This can be seen in the clinical observation of patients who move toward spontaneous remission of a life-threatening disease through positive emotional support^[10] ^[122] or in patients who fail to express emotions compatible with the body's attempts to survive.^[122]

In any disease process, the consciousness of the patient decides the effectiveness of any therapy. Experiments in remote intention generated healing and prayer show that the intention of others is a factor in the homeostatic capabilities of the mind and body. The fact that the homeostatic mechanism can sense and respond to these remote intentions is a reflection of the power of the human mind. Some authors feel that there is a physiological basis for the unlimited possibility of human voluntary control.^[127]

The ultimate control of psyche over soma demonstrates the priority of the conscious mind over physiologic processes such as immunity and pain control.^[128] This puts an enormous responsibility on the physician. He or she must take full account of a patient's mental and emotional states when treating chronic or life-threatening disease.

Physiological mechanisms

Identification of a biochemical mechanism for placebo analgesia has done more to change the image of placebo than any amount of arguing about the importance of beliefs and the mind.^[129]

The mechanisms of placebo response have been suggested to be a mixture of psychological interactions mediating physiological responses.^[14] Psychological components of the patient's placebo effect have been shown to include the decreased anxiety and the increased relaxation,^[63] conditioning,^[13] expectation,^[18] and well-being generated by the establishment of a sound doctor/patient relationship.^[130] ^[131]

The physiologic mechanisms of the placebo effect have been suggested to include

chemicals, catalysts, and enzymes. It is believed that steroids, catecholamines, ^[10] the autonomic nervous system, ^[14] ^[132] neuropeptides, and endorphins^[133] are also involved. These physiologic mechanisms interrelate synergistically and are presently being researched under the rapidly developing field of psychoneuroimmunology,^[4] through which the links between depression, affective disorders, emotions, and the immune and central nervous systems are being explored. Susceptibility to depression and sensitivity to pain have now been found to be mediated through neurotransmitters such as catecholamines, serotonin, and dopamine.

The current model for explaining the mechanism by which emotions, mood, and psychological stress suppress immune function involves cerebral-hypothalamic and pituitary interaction which translates stress and anxiety into an autonomic-endocrine response. This response adversely affects the immune function, particularly after chronic stimulation. Stressful stimulation is received in the sensory cortex of the brain and is then referred to the limbic system and the hypothalamus. This interface of the higher brain functions and homeostatic regulating centers provides the communication link between the psyche and soma. According to Rossi: "The hypothalamus is thus the major output pathway of the limbic system. It integrates the sensory-perceptual, emotional, and cognitive function of the mind with the biology of the body."^[14]

In the hypothalamus are the nerve centers which

control both branches of the autonomic nervous system, parasympathetic and sympathetic, nerve cells that secrete endocrine-releasing factors, and neural pathways that release hormones directly into the posterior pituitary. The corticosteroids and catecholamines from sympathetic stimulation are key factors in altering disease susceptibility in response to stress. Corticosteroids inhibit the function of both macrophages and lymphocytes, as well as lymphocyte proliferation.^[134] Corticosteroids also cause the thymic and lymphoid atrophy noted by Hans Selye in his experiments on stress-induced immune dysfunction.

The autonomic release of catecholamines stimulates receptors on the surface of lymphocytes, thereby increasing their maturation rate. When in a mature state, the lymphocytes' ability to kill bacteria and cancer cells and produce interferon seems to become paralyzed.^[135] Thus a population of mature lymphocytes develops, ready to defend the body from infection and inflammation yet remaining paralyzed until the "red alert" signal of sympathetic fight or flight is turned off, signaling the appropriate time to rest and repair.

A number of other peptides, E-type prostaglandins, somatotropin, histamine, insulin, endorphins, ADH, and PTH, all have receptor sites on lymphocytes and can stimulate the same cAMP-mediated response resulting in lymphocyte maturation and inhibition.^[134] A study of the effect of catecholamines on the human immune system showed that when a physiologic dose of epinephrine is injected into a healthy volunteer

there is an increase in the number of circulating T-suppressor lymphocytes and a decrease in the number of circulating T-helper lymphocytes (changes similar to those found in AIDS).^[134]

Placebo and stress physiology

Stress “let-down” of a patient in the therapeutic environment is one of the mechanisms producing the placebo effect. This results from the patient’s perception that a transition from a stressful situation to a non-stressful situation has occurred. Mowrer^[135] observed that with a decrease in anxiety there is a concomitant increase in hope, signifying that the period of suffering is over. Certain familiar images and signals, such as white coats, syringes, behavioral procedures, and clinical protocol, create a conditioned response – relief, now that help has arrived. Evans similarly observed that “... the reduction of fear through the shared expectations that the doctor’s medicine will work – even if unknown to the patient it is placebo – mediates powerful therapeutic effects”.^[63]

The placebo effect in the clinical environment transforms the emotional and mental stress of the patient. These effects, also observed and described by Franz Alexander,^[11] Hans Selye,^[136] George Solomon,^[137] and Walter Cannon,^[138] allow the patient to escape the “fight and flight” response that can cause, and maintain, the state of illness.

Physiologic and psychologic stress

Selye^[139] demonstrated that physiologic stress can have a dramatic effect on the immune and endocrine systems of the body. Laudenslager^[140] went on to show that it is not just stress that creates these physiologic changes, but also the perception that stress is “inescapable” that is critical to the response. More recently, studies on the effects of psychological stress have demonstrated significant changes in immune capability. Maladjustment to “life-change stress” correlates with reduced activity of natural killer cells,^[141] decreased T- and B-cell responsivity,^[124] and decreased lymphocyte cytotoxicity.^[142] For example, Riley^[143] observed increased tumor activity in a controlled stress environment and concluded:

Emotional, psychosocial, or anxiety-stimulated stress produces increased plasma concentrations of adrenaline, corticosteroids and other hormones through well-known neuroendocrine pathways. A direct consequence of these increased corticoid concentrations is the injury to elements of the immunological apparatus, which may leave the subject vulnerable to the action of the latent oncogenic viruses, newly transformed cancer cells, or other incipient pathological processes that are normally held in check by an intact immune system.

Current reviews of the literature relating psychological stress and immune dysfunction support the hypothesis that the homeostatic immune mechanisms, both humoral and cellular, are significantly impaired by both natural and experimental stress.^[2] ^[134] ^[115] ^[144] Hypertension,^[145] common colds,^[146] coronary artery disease,^[147] and myocardial ischemia^[148] have been linked to adverse stress physiology. Stress even has the ability to increase permeability of the blood–brain barrier.^[149] The implication of stress altering

the blood–brain barrier exposes important insights into enigmatic diseases like chronic fatigue syndrome and stress-induced neurological disorders.

Endorphins, hormones and neuropeptides

... one rapidly activated psychoneuroendocrine mechanism through which a placebo stimulus may reduce both depression and pain is produced by stimulating the endorphin system.^[13]

Research on endorphins is a relatively new area of study in the field of psychoneuroimmunology. Original research by Levine et al^[97] suggested that the pain relief noted in placebo studies could be explained by the simple mechanism of endorphin-mediated actions. The original emphasis on endorphins and enkephalins was plausible considering their known modulation of pain and mood functions. This position was further supported by later observations that depression increases chronic clinical pain^[150] and that decreased activity in endogenous opioids may be part of the pathophysiology of depression.^[151] With the information that placebo can stimulate endorphins,

Levine et al felt that an explanation for the action of placebos had finally been found. However, this hypothesis failed to account for the broad spectrum of placebo effects, nor did it account for the fact that the analgesia associated with hypnosis is not affected by an opioid antagonist.^[152] ^[153] It is important to note that recent literature suggests that Levine et al were not entirely wrong in implicating the role of endorphins with the placebo mechanism. Rather, they were right for the wrong reason.

Endorphins are mainly derived from three precursor proteins (by separate biochemical processes).^[154] These opioid peptides are released from central and peripheral areas in response to pain, stress, and emotions and perform many physiological functions, of which analgesia is but one.^[155] However, it is becoming evident that the boundaries between the central nervous system and the immune system are not as clear as once thought. The several known effects of endorphins on immune system function are listed in [Table 4.5](#).^[156]

When the functions of neurotransmitters such as endorphins are found to have such an intimate relationship with immune integrity, the paradigm of a body with functions performed independently by its parts – a Newtonian type of thinking – begins to lose credibility. To further blur the already hazy distinction between the central nervous system and the immune system, research has demonstrated that endorphins and peptide hormones such as ACTH, TSH, HCG, and LH are produced by lymphocytes.^[156]

It is clear that the demarcation between the central nervous system and the immune system is impossible to distinguish. Both the brain and the immune system are the only tissues in the body which have a memory, and the level of communication between the

two argues a taxonomy which identifies them as one. Evidence of the innervation of the thymus gland, bone marrow, spleen, and lymph nodes supports the finding that the immune system is subject to efferent CNS information.^[156] In addition, studies demonstrating the atrophy of the thymus and lymphatic tissues in the absence of growth hormone,^[157] corticotropin (ACTH), and increased steroid production by adrenal cells after interferon stimulation indicate that "... in the future it will be difficult to distinguish the receptors and signals that are used within and between the neuroendocrine and immune system".^[156]

CLINICAL APPLICATION

A physician with an interest in the psychopharmacologic treatment which also can be expensive, elaborate, detailed, time-consuming, esoteric, and dangerous will usually generate a strong placebo response. He or she will be interested in the symptoms of the patient, the differential response to various drugs and will be careful to observe side-effects which may be dangerous. The physician may encourage the patient to call at any time if side-effects develop.^[21]

The application of placebo phenomena in clinical practice should not be a vague attempt to replace the skill of the medically trained physician with obscure "hand waving", incantations, and inert lactose pills. In primary care and specialty clinical practice, the physician's intent should be to optimize patient care through engaging restorative defense mechanisms. To effectively apply current placebo research, several principles (listed in [Table 4.6](#) and discussed below) must be understood.

***Prima non nocerum*: prioritize a treatment program and establish a hierarchy of care**

Prima non nocerum is the Hippocratic injunction dictating that a physician care for the patient so that self-healing mechanisms can engage. This ancient phrase means, "don't disturb the organism's ability to heal itself". The body must be given the full range of possibilities in allowing the power of homeostasis, *vis medicatrix naturae*, to have its

optimum capability. Doing no harm means that a patient is supplied with the level of medical intervention that is appropriate to their ability to maintain life support. The job of the physician is to determine when homeostasis or defense mechanism has lost the ability to respond to disease.

Acute traumatic swelling and inflammation and shock are examples of the human defense mechanism responding in a way that threatens the health of the organism. It is most interesting that the organism would make choices, as in shock and inflammation, that could end up killing itself. To practice the principle of *prima non nocerum* a physician must learn when to act and when to let the body heal itself. This is the highest art of medicine; each case and situation will be different and it is up to the physician to interpret the needs of the moment.

TABLE 4-6 -- Six principles of optimizing placebo response in clinical practice

-
- *Prima non nocerum* – prioritize a hierarchy of therapeutic intervention
-
- *Tollum causum* – remove the obstacles
-
- Support the therapeutic relationship
-
- Enhance positive emotional states
-
- Implement therapeutic conditioning or learning
-
- Utilize altered states of consciousness
-

By implication, the physician who seeks to apply this principle understands the principles of physiology upon which human life depends for homeostasis.

Doing no harm means that a patient is supplied with the level of intervention that is appropriate to his or her own ability to maintain life support. *Prima non nocerum* does not necessarily mean that a physician withholds invasive therapy: it is the physician's responsibility to determine when the body is unable to re-establish homeostasis and therapy is indicated. If an arm must be severed to save the patient's life, there is no violation of *prima non nocerum*.

However, to enhance the principle of *prima non nocerum*, a physician sometimes must withhold therapies and be content to leave the patient to self-heal. Hippocrates understood the wisdom of letting the body heal on its own, implicit in the "do no harm" injunction. The treatment of Charles II is a case in point:^[158]

A pint of blood was extracted from his right arm and a half pint from his left shoulder, followed by an emetic, two physics, and an enema comprised of fifteen substances; the royal head was shaved and a blister raised; then sneezing powder, more emetics, and bleeding, soothing potions, a plaster of pitch and pigeon dung on his feet, poisons containing ten different

substances, chiefly herbs, finally forty drops of extract of human skull and an application of bezoar stone; after which his majesty died.

When this treatment is compared with modern procedures such as mammary artery ligation for the relief of angina – a procedure which has no benefit when compared with sham artery ligation – it appears that throughout the centuries physicians have continued to rely on the placebo effect for the care and cure of their patients. Since it plays such an important role in health care, simple, non-invasive, and effective treatments should be the goal of all therapeutic approaches. Robert Burton wrote in 1628: "... an empiric oftentimes, and a silly chirurgeon, doth more strange cures than a rational physician ... because the patient puts confidence in him."^[159]

The rational physician will also recognize that healing and curing are not necessarily the same. If a patient is helped in any way by the doctor, with or without the use of placebo, the path of cure has been assisted, although the specific pathology may not have responded. Not all patients can be cured but most patients can be helped.

***Tollum causum*: remove the cause of disease**

Tollum causum is the principle that seeks to remove the obstacles to cure. The forces "inhibiting the floodgates of health from opening" must be removed for the full force of the patient's beliefs to effect the path of cure. This concept is fundamental to the philosophy of naturopathic medicine with its strong emphasis on diet, detoxification, and a pattern of living that is consistent and compatible with the context in which humans evolved. Obstacles to cure are defined as blocks to the self-healing capacity of the organism. Contamination with heavy metals and xenobiotics (see [Ch. 37](#)), focal infections, electromagnetic pollution, scar tissue, genetic metabolic abnormalities, and parenchymal organ damage defeat the best therapeutic intentions and must be addressed.

The patient's habitat is an important aspect of the therapeutic protocol, not only in the diagnosis and care of internal mental and physiological dysfunction, but also in determining which environmental factors may be contributing to dysfunction and disease. These factors might include diet, lifestyle, and living environment. It is of the utmost importance to remove a patient from surroundings that are associated with illness or to assist the patient in creating an environment more conducive to health.

Factors which provide conditioning that reinforce the disease process can be associated directly or indirectly with one's environment. For example, if animals are returned to situations where their experimental neuroses were induced, their pathological behavior reactivates.^[160] When a patient leaves the offending environment to receive treatment from a physician, the prognosis is correspondingly more favorable.^[12] The physician has the added advantage of a patient's heightened expectation during an office visit – a patient's positive associations with the "healing" environment increases their receptivity to treatment.^[161] If the home or work environment is a source of "dis-ease", and an obstacle to cure, then providing an alternative environment may be a most helpful way to remove the obstacles to cure.

Support the therapeutic relationship

Confidence should surround all aspects of the therapeutic interaction. The patient must have confidence in the doctor's ability to assist a cure, the doctor must have confidence in the efficacy of his or her therapy,^[162] and there must be an understanding or relationship between the doctor and the patient which is mutually conducive to respect, trust, and compassion.

The quality of the doctor/patient relationship is paramount. The therapeutic approach to a patient which optimizes the confidence of the patient in the skill of the doctor stimulates the inherent self-regulating healing mechanisms by relaxing the anxiety the patient has about their illness. Anxiety is a well-known immunosuppressant and aggravates the body's defense mechanism. An optimum therapeutic relationship when combined with the clinical skill to remove the cause of homeostatic dysfunction is the height of therapeutic acumen. As Lewith so accurately states:^[163]

The general practitioner may therefore wish to employ all his knowledge, enthusiasm, consultation technique and

61

sympathy, to create the best possible atmosphere in which to elicit a placebo response from the patient.

Current research on factors contributing to the genesis of the placebo effect consistently documents the importance of the doctor/patient relationship.^{[164] [165] [166]} The healing power of the therapeutic interaction has been demonstrated by the commencement of the placebo effect even before the actual administration of the pill.^[167]

The physician facilitates the cultivation of a sound relationship through developing good communication skills. The art of bedside manner has been recognized throughout history as the primary skill a successful physician needs.^[168] Indeed, the history of medicine is as much a history of the relationship between doctor and patient as it is the evolution of medical technology and techniques. Through centuries when doctors were doing more harm than good, little more than the esteem of their clientele sustained the medical profession. But however little real help the doctor had to offer, it was to him that people turned when illness struck.^[169]

Bedside manner has been found in clinical studies to entirely alter the course of double-blind studies and the quality of a therapeutic encounter to facilitate or disrupt the efficacy of a treatment.^[170] Listening to the patient,^[170] verbal and non-verbal communication of the physician, amount of time spent with the patient,^[171] patient education,^[172] demeanor of the physician,^[173] and interview skills^[171] have been suggested as factors and components of effective physician communication skills.

Touch is an important form of communication and is sometimes forgotten as a key aspect of the doctor/patient relationship. Highly skilled clinicians with many years of experience, such as the late Dr John Bastyr (whose remarkable healing abilities inspired the founding of Bastyr University by those privileged to have been his students), frequently impressed upon clinicians the importance of always using diagnostic and therapeutic touch during a patient visit. The doctor's touch can be diagnostic, therapeutic, and, perhaps most important, a means of communicating that he or she is deeply attuned to the problems, needs, and fears of the patient.^[174] Touch can heal by increasing tissue mobility and fluid exchange (as in massage), and by relieving pain, as demonstrated in research on healers who use their hands.^[175] Touch has also been documented in well-designed double-blind research to extend an unusual healing power which can be transmitted through the hands to plants and animals.^[176]

Regarding other methods of enhancing confidence between the doctor and patient, the setting in which a doctor provides therapy to a patient will also determine its effectiveness. The doctor's office setting is very important for optimum and effective treatment: tools and support systems are more accessible, and a heightened patient response results from seeking out the "healing" environment. In a clinical trial with hypertensive patients, placebo alone was not as effective as when it was administered in conjunction with hospitalization. The visit to the physician represents a search for changes that cannot be found through "self-care" or over-the-counter medicines. According to Frank:^[177]

In short, it appeared that the placebo situation relieved chiefly anxiety and depression, that the degree of relief was unrelated to personality and autonomic measures, and that the patients who responded strongly to a placebo at one time might not at another. In conjunction, these results suggest that the extent of responsiveness to a placebo depends on the interaction of the patient's state at a particular time with certain properties of the situation. The finding that administration of tests and questionnaires seemed to have at least as beneficial an effect as had the pill implies that any interaction between patient and situation that heightens expectations of help may lead to symptom reduction and improvement in mood. The aspects of the situation producing this effect include not only presentation of a symbol of the physician's healing powers (a pill), but any attention and interest shown by professional personal.

This phenomenon was also observed in industry and termed the "Hawthorne effect". As a direct result of the increased attention factory workers received during investigation, the quality of their work improved.^[178] In conclusion, the importance of a doctor/patient relationship and the confidence that this engenders shows that all human beings need to share their feelings and experience the therapeutic benefits of touch: the doctor/patient relationship provides an ideal way to meet these fundamental needs.

Enhance positive emotional states

Love in all its subtleties is nothing more and nothing less than ... the

psychical convergence of the universe upon itself. (*The Phenomenon of Man, Pierre Teilhard de Chardin*)

For optimum enhancement of the psychoneuroimmune system, the physician must assist the patient in developing practices that amplify positive emotional states and reduce negative emotional states. A negative mental state (anxiety, stress, panic, anger, depression, neurotic behavior, self-deprecation, self-destructive feelings and tendencies, and a weak will to live) hinders the ideal functioning of the psycho-neuro-immune-endocrine axis, disrupting homeostasis. Engle has termed this the giving-up/given-up complex:^[179]

Study of the life settings in which patients fall ill reveals that illness is commonly preceded by a period of psychological disturbance, during which the individual feels unable to cope. This has been designated the giving-up/given-up complex and has the following five characteristics: a feeling of giving up, experienced as helplessness or hopelessness; a depreciated image of the self; a sense of loss of gratification from relationships or roles in life; a feeling of disruption of the sense of continuity between past, present, and future; and a reactivation of earlier periods of giving-up. It is proposed that this state reflects the temporary failure of the mental coping

62

mechanisms with a consequent activation of neurally regulated biological emergency patterns. Changes in body economy so evoked may alter the organism's capability to deal with concurrent pathogenic processes, permitting disease to develop.

The importance of reducing negative mental states in acute and chronic conditions has been discussed extensively.^[123] Acute psychological stress is documented to cause various forms of cardiopulmonary dysfunction, even death.^[115]

Chronic mental and emotional strain causes immune system breakdown and disease. The homeostatic processes become overwhelmed by autoimmune, microbial, or neoplastic invasion. Major authors on the subject of acute and chronic stress emphasize the high priority of managing the physiologically and immunologically destructive effects of the human body's response to stress. Pelletier^[180] lists hypertension, arteriosclerosis, migraine headache, cancer, chronic bronchitis, emphysema, asthma, and arthritis as disease processes which are caused or exacerbated by stress physiology. A study researching the relationship between resistance to streptococcal infections in families and stress load in the family found a positive correlation.^[181] Another study on the psychosomatic susceptibility to infectious mononucleosis found that psychosocial factors of high motivation and poor academic performance significantly increased the risk of "disease" infection.^[182] In yet another study, anticipation of mood and menstrual discomfort were positively correlated and manipulated, thereby supporting the suspicion

that expectations act as a determinant of mood.^[183]

The conclusion that there is no acute, chronic, or degenerative disease that is not affected by a patient's mental and emotional state must be drawn from the pervasive immunoendocrine effects generated by the mind and emotions. Wolf^[184] and Cousins^[185] write of the power of panic as a factor in myocardial infarction, Marbach & Dworkin^[150] describe depression as a component in myofascial pain dysfunction, and Shekelle^[186] notes, in a 17-year follow-up study, a twofold increase in the incidence of cancer in depressed patients. The clinical scenarios these observers describe infer that the placebo effect can control the onset and advance of a disease by shutting down the destructive thoughts, images, and feelings that mediate stress.

Enhancing positive emotions is the corollary of controlling the damaging effects of negative mental and emotional states. Laughter,^[187] hope,^[188] acceptance,^[117] and the reduction of suffering^[189] have been shown to speed the course of healing and reduce the level of pain and distress reported by patients. Although pain is sometimes the only language nature can use to adequately communicate to the patient that something is in need of healing: "... the relief of suffering and the cure of disease must be seen as twin obligations of a medical profession that is truly dedicated to the sick".^[189]

Acceptance has been observed to be a key factor that assists patients in greater understanding of their pain.^[117] Acceptance does not mean complacency in the face of disease, but a rational understanding of the situation and the limitations that can sometimes accompany a disease process.

The importance of cultivating hope in a patient also cannot be underestimated.^[190] The fact that a patient seeks the help of a physician or "care giver" already implies a substrate of hope and is a signal that the patient can visualize the potential for recovery. The treatment needs to merely stimulate this willingness to envision a future of health. Hope is an embodiment of the patient's and the doctor's ability to visualize an image of healing and recovery. This process is a recurrent theme in imagery therapy,^[191] visualization therapy,^[192] therapeutic touch,^[193] and psychic healing.^[194] Hope is both an active and a passive placebo. Passive hope placebo is that brought with the patient as the act of seeking help generates a level of unspoken faith in an image or potential for cure. Active hope placebo is generated by the physician, who consciously instills a vision or image of cure in the patient as an adjunct to therapy.

Frank performed a double-blind study where patients were divided into control and induction groups.^[195] The induction group was led through a process whereby their hope was strengthened to conform with the expectations of the therapist.^[177]

It introduces some perceptual clarity into the process of treatment; and to the extent that all our therapists adhered roughly to the insight model of therapy, it helped to bring the patient's expectations in line with what actually occurred in treatment, and also helped him behave in accordance with the therapist's expectations of a good patient.

The induction group were actually being consciously strengthened to a level of optimal

response, while not being led into false expectations.

This type of patient education or active placebo is a necessary and useful tool for framing and directing a positive outlook and prognosis. If a patient can conceive of a state of wellness, then that state of wellness can be achieved. It is the job and domain of the physician to discover those images, emotions, and perceptions which reside in the conscious and subconscious mind of the patient that block the image of a positive state of health. He or she must actively work to control these with the same level of intent as with any presenting gross complaint or physiological dysfunction. Finding these dysfunctional mental substrates and working with the patient to try and change them is fundamental to treating the true cause of disease (see *Tollum causum* on [p. 60](#)).

Research has demonstrated the importance of positive and negative thinking in heart disease and cancer, the two areas of disease which cause the highest death rate. Doctors' health care management protocols should reflect

this research in the same way that attention to proper diet is a part of a management approach to high serum cholesterol. It is now clearly established, for instance, that even low levels of stress trigger the onset of myocardial ischemia.^[196] We also know from the work of Steven Greer et al^[197] and David Spiegel^[198] that the attitude and emotional exploration are critical to breast cancer survival. Knowing these scientific facts, it is imperative that every doctor have strategies for helping their patients explore the areas of stress management, group therapy and support groups and skills in building positive attitude.

Implement therapeutic conditioning or learning

Those who remain at least dimly aware that everything they say or do to a patient conveys a major or minor, positive or negative, helpful or harmful psychological impact are likely to be more effective physicians.^[199]

Conditioning of the mind has been suggested as a mechanism by which the placebo effect becomes a learned response.^{[12] [14] [177]} The future of therapeutic application of placebo will probably hinge primarily on the use of conditioning. A doctor who can understand this will pay close attention to the stimuli of his patients and modify these stimuli in a scientific way to help treat immune and neurological related diseases.

Modern psychology acknowledges two models of conditioning or reinforcement of learning behavior: operant and classical conditioning. Operant conditioning is a behavior response that theoretically occurs in the presence of some stimulus that is a positive reinforcement, e.g. a rat will learn to press a conditioning bar if a food pellet is dispensed as a result. Classical conditioning is a behavior response created by the simultaneous pairing of unconditioned and conditioned stimuli prior to an evoked

response. This is best illustrated by the experiments of Pavlov and his “salivating dog”.

In Pavlov’s experiment with the conditioning of a dog’s salivary response to the ringing of a bell, the bell ring is the conditioned stimuli, the food the unconditioned stimuli. The salivation is the unconditioned response to the food that becomes the conditioned response. When the dog finally associates the bell ring with the food, the ringing alone causes salivation, the conditioned response.

The principle of classical conditioning has far-reaching implications for the diagnosis and treatment of disease because of the pervasive and permeating implications that conditioning has in all the sensory stimuli of daily existence, in sickness and in health:^[200]

Pavlov’s teachings, concepts and basic notions afford the real and ultimately scientific basis for the recognition of the potentialities of medical science attacking diseases from both the psychic and somatic sides.

For the purposes of this discussion, recognize that classical conditioning happens randomly in our environment and is closely linked to health and healing phenomena. Subconsciously, we note random events and associate them with previous events and observations, independent of an intended learning behavior. Operant conditioning happens in the context of reward, and classical conditioning happens in the context of associated stimuli. There is a much greater predominance and range of associated stimuli (classical conditioning) than operant conditioning for the genesis of the placebo effect. This is because the operant depends on reward, although operant conditioning can happen in the medical mode: “Pain killing drugs which I have taken in the past kills pain therefore this capsule which is a painkiller will kill my pain.”

Gliedman et al^[121] note that drugs that affect the CNS are readily conditioned, whereas drugs that affect the peripheral nervous system and are secretory stimulators (e.g. atropine and pilocarpine) do not result in the establishment of a conditioned response. The primary importance of psychological states to central nervous system excitation demonstrates that the pivotal loci of command for conditioning resides within the hypothalamus and the limbic system. Therefore, a doctor who can induce a state of central excitation in the patient can encourage and condition this patient to make those changes that are deemed necessary for the recovery of health.

The conditioning of a patient to a placebo response is modified by learning stimuli associated with the illness, the stimuli of the doctor and the therapeutic setting, the stimuli of the therapy, previous health, medical therapy, and authority-related experiences.^[201] The way that all of these factors interact in the psyche of the patient determines the nature of the placebo response that is achieved.

Satiation obscures the conditioned response, while situations of increased stress seem to potentiate the responsiveness of the placebo effect.^[117] Placebo, conditioning, and learning may therefore be subject to the nature of central excitatory states as well as to levels of stress and distress.

The physiological breadth of the placebo response in humans can now be understood in terms of the variety of interactions and effects that drugs, therapeutic procedures, and sensory phenomena of the medical environment have on the psychosomatic matrix of a patient's consciousness. Rossi^[14] notes that this complicated web of sensory processing reveals how any facet of therapy:

... that alters any aspect of the body's sensory, perceptual or physiological responsiveness on any level can disrupt the more or less fragile state-dependent encoding of symptoms and thereby evoke a "nonspecific" but real healing effect that we call the placebo response.

In fact, the scientific basis of therapeutic applications of psychoneuroimmunology is based on classical conditioning. This research was done by Ader & Cohen^[202] to

64

show that the immune system could be conditioned for therapeutic purposes. Ader & Cohen conditioned immuno-suppression in rats by injecting them with a conditioned stimulus of cyclophosphamide (a potent immunosuppressing agent) while feeding them a saccharine solution as an unconditioned stimulus. The idea of conditioning for immunomodulation in human patients is therefore a promising therapeutic modality. Applying conditioning techniques for the treatment of systemic lupus erythematosus resulted in a delay in the development of the disease using a dosage that normally had minimal results.^[203]

To fully account for the extent of previous and future conditioning in a patient, the physician must take a complete and exhaustive history in order to explore the influences of family, work, accidents, emotional predispositions, past medical history, and neutral stimuli as contributing factors during the onset of an illness. Lifestyle and emotional, behavioral, or physiological factors might contribute to maintaining the state-dependent learning pattern of disease and dysfunction or give clues for a successful therapeutic intervention. A good example of this is Batterman & Lower's^[204] demonstration of increased analgesic effectiveness based on similar previous therapy.

A physician who knows which therapies succeeded, and which failed, can take advantage of the patient's conditioning and encourage biochemical pathways that the body has learned. Drug or therapeutic interventions are not procedures that can be predicted in the same way as can in vivo experimental results. The variables involved in human responses to therapy are clearly underestimated in the current rush of research-oriented therapeutic evaluation.^[55] Therefore, a patient who has been treated by a number of physicians or practitioners for a complaint and received no results or relief has been conditioned to believe that consultation and treatment by a physician will provide no positive changes. When the patient visits the next practitioner, even if this practitioner can offer a diagnosis and treatment that are correct answers to the long-sought cure, there are very real patient conditioning factors that must still be

considered.

Consider the case of a young woman who was undergoing treatment for breast cancer and the clinical course of the ensuing metastases. Each time that she had a positive response to therapy, she experienced a subsequent remanifestation of the cancer. The result of this conditioning was that she came to equate each new course of chemotherapy as a herald of some new manifestation: "... she was torn between a desire to live and the fear that allowing hope to emerge again would merely expose her to misery if the treatment failed."^[205]

The parameters of conditioning in a clinical setting extend to all aspects of the patient's sensory perceptions. Consciously, or unconsciously, the physician is providing an environment for patient learning. Lipkin^[206] points out that every drug, every apparatus, every injection, and every piece of information or advice carries a suggestion of help and hope, regardless of the physiological effects that may accompany it. It is important to realize that the patients are taking in all the information about the surroundings, interactions, and therapy, and making associations that can potentially affect the course of their responsiveness to therapy.

Mower^[135] observed that the "safety signals" of syringes, laboratory coats, and behavioral procedures are all retained in the patient's psyche for future association. A physician can skillfully take advantage of these by encouraging and cultivating response generalization or by associating previous therapeutic situations with subsequent treatments with unconditioned stimuli such as office music, odors, and images. Giving patients some sort of unconditioned stimulus that can be taken home allows them to associate with the conditioned response, eliciting the memory of the therapeutic interaction while away from the doctor's office. These unconditioned stimuli or placebos can be given in multiples at one time,^[131] changed for more powerful stimuli,^[70] and delivered at the end of an induction, suggestion, or imagery procedure. They should not be limited to pills or other apparent medicaments, but should extend to sounds, smells, visualizations, and feelings.

It should be remembered that therapeutic conditioning depends on a perceived physiological shift or change in the patient as described in the theory and research of biofeedback.^[207] This shift can be experienced as a sense of relaxation, increased warmth or circulation, altered autonomic tone, or change in some sensory perception. Patients know immediately when there is no change in their disease or dysfunction after they have been given placebo.^[208] Therefore some patients will need a more active form of therapeutic management that allows for some level of perceived change. Ideally this perception would be a sense of being free from pain, or a state of abnormal physiologic function altered to a state of improved physiologic function. Acupuncture, spinal manipulation, drug therapy, physiotherapy, hydrotherapy, and surgery are all therapies that can create an immediate biochemical impact perceived by the patient.

The optimum model to apply to the concept of conditioning therapy and the selection of an appropriate therapy or modality was proposed by Greene & Laskin^[209] in their evaluation of myofascial pain dysfunction (MPD). During an 11-year follow-up study of MPD patients, they concluded that, when comparing the effectiveness of a wide variety

of reversible and non-reversible (surgical) therapies, conservative and reversible therapies were the most important and appropriate treatment factors for the patient's health and well-being. Focusing on patient communication, educating patients regarding reversibility

of the condition and the nature of muscle dysfunction as it relates to stress–pain–spasm, developing a therapeutic strategy based on increasing patient awareness and self-management skills, and selecting a flexible treatment strategy were all found to be essential for achieving a good initial response which could lead to long-term wellness. The specifics of which therapy was most indicated was not felt to be as important as the need to focus on the nature of presenting musculoskeletal problems and the factors and complexity of the treatment environment.

Routine use of active pharmacological substances reinforces the relationship between conditioned and unconditioned stimuli. However, routine use of unconditioned stimuli in the absence of a conditioned response weakens the therapeutic efficacy of the practitioner and has been described as “placebo sag”.^[13] Therefore, the learning of a conditioned response from unconditioned stimuli could diminish if the conditioned stimuli fail to produce an adequate or reliable conditioned response. Without the intermittent demonstration of active strength, the placebo effect will get weaker and weaker.

The implications of placebo sag for practitioners of alternative medicine, who try to work with the body's own defense mechanisms without overwhelming medical intervention, are that periodic use of perceptually active therapy is needed to support a patient who is not able to respond to, or responds too slowly to, a gentler therapeutic nudge. In this case, the physician must recondition the vital force to open a path to homeostasis.

In a sense, this may be a paradigm of the therapeutic situation where changes towards health are induced in the patient by a doctor who is able to cultivate a basic state of arousal, presumably central in nature. This state of arousal causes the patient to become accessible to the doctor's expectations of him.^[12]

The typical placebo burst, where a therapy is initially effective after a short period, but then wanes, is now understood in terms of the placebo sagging from lack of effective unconditioned stimuli to maintain the conditioned framework.^[70] Physicians who lack the ability to extract themselves from a series of unsuccessful therapies risk eventual placebo sag.^[13]

... therapists who primarily use their active strengths (or unconditioned stimuli) paradoxically will get stronger placebo effects than quacks, will enjoy escalating credibility, and will seem as miracle men – when in fact perhaps only half their miracles can be traced to their active ingredients while the other half is a function of the anticipatory (or conditioned) response elicited

by their conditioned features.

Since the visit to a physician is often initiated by the physical pain of the patient, it stands to reason that skillful pain management is a high priority in establishing a therapeutic conditioned response. Pain management by hypnosis, TENS, therapeutic touch, direct or indirect manipulation, imagery, acupuncture, meditation,^[210] and an understanding that aims to elicit the nature of suffering^[205] can all be valuable therapeutic adjuncts to establishing a therapeutic environment that conditions the patient for full potentiation of their healing capabilities (see [Ch. 56](#) for a full discussion of these techniques.)

With the recent development of standardization, research, and concentration of the active components of plant medicines, vitamins, and biochemical precursors, naturopathic medicine (and other forms of alternative medicine) stands on a stronger therapeutic base because of an ever-growing verification of their pharmaceutical and therapeutic armamentarium. These therapeutic modalities are characterized by safe, yet physiologically active, substances and procedures; therefore they provide some defense against placebo sag.

Utilize altered states of consciousness

Since ancient times, aboriginal humans have recognized the tremendous therapeutic power that lies dormant in the subconscious mind. For thousands of years, shamans and medicine men have used trance states to engage the most subtle aspects of the patient's subconscious to effect factors in disease pathogenesis and prognosis.^[211] In modern medicine, it has been documented that shamanistic healing involving altered states can offer dramatic "spontaneous remissions";^[29] the mechanisms of this process have been explored in the theory and application of hypnosis.^{[1] [128]}

Most currently accepted techniques employed to trigger the subconscious to effect positive changes in somatic or psychic health involve hypnosis. Placebo effect has been linked with hypnosis, or "low arousal states", which are therefore believed to be critical factors in the evaluation of the mechanisms and perimeters of placebo.^[200] A review of the literature documenting the potency of hypnosis and the observed results of placebo clearly demonstrates that these two areas yield remarkably similar clinical results. The inquiry into hypnosis grew out of the simple intent to validate the effectiveness of the mind in healing processes, whereas most placebo literature grew out of the intent to demonstrate a certain percentage of chance, fluke, spontaneous remission, or psychosomatic illness as a factor to be ruled out in the delivery of intelligent, scientific health care. Using these antiquated definitions of placebo and hypnosis, one is led to believe that hypnosis describes a process of healing based on the skillful guidance of a qualified practitioner, while placebo describes a process based on chance, regardless of the professional circumstances. On closer inspection, the distinction between the two blurs: they appear to be much the same process.

Illness, healing, and health states constantly shift in the homeostatic system, a system affected by stimuli

received through the different levels of awareness, and can be accessed, investigated, and modified by a variety of techniques. These include placebo, hypnosis, and induced altered states of consciousness. Rossi^[14] notes that since memory is dependent and limited to the level of awareness in which the memory was acquired, it is “state bound information”:

State dependent memory, learning, and behavior phenomena are the missing link in all previous theories of mind body relationships. ... The major thrust of these hypotheses is that mind-body information and state-dependent memory, learning and behavior mediated by the limbic-hypothalamic system, are the two fundamental processes of mind-body communication and healing. ... The new approach to mind-body healing and therapeutic hypnosis may be conceptualized as processes of accessing and utilizing state-dependent memory, learning and behavior systems that encode symptoms and problems and then reframing them for more integrated levels of adaptation and development.

Some psychosomatic phenomena are coded into the behavior of an individual through state-induced patterning. Until the patient can access the state in which somatic complaints are induced, possibly through hypnosis or other methods which break the sympathetic dominance of “encoded” shock,^[212] the psyche cannot clear them from the soma:^[14]

A person in a traumatic car accident experiences an intense rush of the alarm reaction hormones. His detailed memories of the accident are intertwined with the complex psychophysiological state associated with these hormones. When he returns to his usual or “normal” psychophysiological states of awareness a few hours or days later, the memories of the accident become fuzzy or, in really severe cases ... the victim may be completely amnesic. The memories of the accident have become “state-bound” – that is, they are bound to the precise psychophysiological state evoked by the alarm reaction, together with its associated sensory-perceptual impressions.

In accessing these psychosomatic state-dependent areas of homeostatic dysfunction, the physician must use techniques that relax the conscious mind and allow access to subconscious content for reframing. The nature of the visit to a physician encourages a patient into more accessible unconscious states, as demonstrated by higher placebo effects when patients present to a hospital setting.^[161] These labile states of consciousness are quite natural; humans constantly cycle in and out of different consciousness states.^[161] These cycles, or ultradian rhythms, are described as alternating cycles of hemispherical dominance that change every 1.5 hours.

When these cycles are interrupted by behavioral stress, psychosomatic behavioral responses such as ulcers, gastritis, asthma attacks, and skin rashes develop.^[213] A

change in these rhythms manifests as a period of psychic repose. If an individual is in the midst of performing a task, day-dreaming or the felt need for a rest or coffee break may be the external manifestation of an internally sensed signal of a change in rhythm. This is also a period when one is highly susceptible to hypnotic suggestion. Because these rhythms are very flexible and labile, they can be invoked through hypnosis or, if the physician senses a natural lull indicating a hemispherical switch, a “natural” trance can be induced.

Centuries ago in India, practitioners of hatha yoga observed the effect of mental states on the breathing patterns of an individual. With anger, frustration, and mental instability, the breath reflected a short, arrhythmic pattern which mirrored the disturbed psyche of the person. Conversely, when a person is in a peaceful, relaxed, deep meditative state, the breath is long, rhythmic, and barely perceptible.

Their discovery formed the basis for the development of breathing exercises called *pranayama* (literally, regulation or restraint of the vital energy), which aimed to calm the breath so that deep states of meditation and focused concentration could be attained. Current research has affirmed the powerful effect these exercises have on asthma, diabetes, chronic gastrointestinal disorders, and psychosomatic and psychiatric dysfunction.^[214]

Therapeutic exercises which use somatic stimuli to effect changes in the psyche create fertile environments for stimulating the placebo response. A breathing technique used to decrease sympathetic tone or alter nostril predominance for causing shifts in hemispherical activity,^[215] an exercise to release fascial muscle tension and thereby effect mood-enhancing blood flow in the brain,^{[216] [217]} or a biofeedback treatment that aids in slowing the heart rate and decreasing negative emotional states^[207] are all examples of how the psyche can be accessed by the soma. The whole process of eliciting the placebo response involves an attempt to marshal all the reserves and potential for healing through a doctor/patient interaction, engaging both the patient’s mind and body to re-establish homeostatic equilibrium.

Health care professionals can use the wisdom of psychosomatic therapies as a central part of their therapeutic protocol. In addition to the specific therapeutic regimen, treatment of the whole patient can be achieved through these harmonious techniques. If physicians could persuade patients to care daily for their emotions, minds, and spirits the way they care for their hair or teeth, the effectiveness of any prescribed treatment would be greatly enhanced. As a primary therapeutic adjunct and important basis for preventive medicine, this line of treatment is all too often ignored.

ETHICS

It is important to remember that there are two forms of “conscious” placebo used by the physician. The use of placebo as a gentle therapeutic agent by a practitioner is very different from the use of placebo in a controlled

trial where the possibility of a known therapy is withheld in a treatment group. Some authors feel that the use of placebo in clinical trial breeches the Declaration of Helsinki which states that every patient should be assured of the best proven diagnostic and therapeutic method.^[218] The ethical problems of delivering health care in a research design where there is a possibility of favorable outcome and having half of the group be denied access to this possible favorable outcome is a troubling ethical issue.

The ethical use of placebo has also been questioned in an attempt to determine if a physician should be deceiving patients in the process of healing.^[219] Although there are some authors who advocate a restricted use of pure and impure placebo because of its “deceptive” nature,^[207] it becomes clear in a brief review of the current literature^[4] that any argument for or against the use of placebo assumes that there are medical procedures that are free of potential placebo effect. Brody^[24] concludes that placebo can be called the “lie that heals”. However, on closer examination it can be seen that it is not the lie that does the healing, but rather the relationship between the patient and doctor which stimulates a natural self-healing mechanism via psychologic, symbolic, and biologic intervention:

For some time, medical science has looked almost exclusively at technical means of diagnosis and treatment; the doctor/patient relationship that forms the setting for their application has been naively viewed as a non contributory background factor, relegated to the amorphous realm of the “art of medicine,” or simply ignored. In this setting, the placebo effect has inevitably been viewed as a nuisance variable, interfering with our ability to elicit “clean data” from clinical trials; and deception in medicine has been seen either as an unimportant side issue or as a tolerated means toward an end. But as the doctor/patient relationship is rediscovered as a worthy focus for medical research and medical education, the placebo effect assumes center stage as one approach to a more sophisticated understanding of this relationship.^[24]

While it has been observed that a physician’s correct understanding of the nature of placebo therapy can coexist with its inaccurate use and abuse,^[42] it has been recommended that: ^[219]

- Pure placebo should not be prescribed unless the physician has examined the exact indications even more carefully than when prescribing specific therapy.
- To avoid missing disease process that can be easily treated with an empirically proven protocol (e.g. vitamin B₁₂ -deficient peripheral neuropathy), the physician should not relax a diagnostic protocol because a patient seems to be responding to placebo.

CONCLUSION

Health practitioners need to be equipped with a better understanding of placebo therapeutics.^[6] ^[220] For many years now, the study of placebo has been recommended to doctors and health care professionals. The ideal environment for the dissemination of the therapeutic implications of the doctor/patient relationship is in medical schools as a required part of the curriculum. After finding a pattern of misuse and misunderstanding about the nature and efficacy of placebo, Goodwin^[42] recommended that better education might result in more effective placebo use.

In 1938, Houston^[168] wrote of the need to reaffirm the art of medicine because he perceived a trend in medicine that invested in a concept of the therapeutic doctor/patient interaction as “undisciplined thought”. Houston’s remedy for the intellectual bias that viewed medicine as a “tight, fast-set science” was to emphasize the importance of psychobiology in medical schools:^[168]

One of the most hopeful moves in medical education is teaching to first-year students the elements of psychobiology. A system of belief is implanted best in the young. It would be my suggestion that psychobiology be taught in the premedical years, that the doctor/patient relationship be the beginning of medical studies. A deep insight into this fundamental philosophy is a chief concern of the internist.

Chapter 5 - Women in the history of medicine

Jennifer Booker ND

INTRODUCTION

Traditionally, women have been the healers, caring for their families and neighbors and helping each other through childbirth. Over centuries, women developed and utilized herbal remedies, poultices, diet therapies, water treatments, and techniques for bone setting and the suturing of wounds. Their methods were passed down to form not only the basis of naturopathic medicine, but also much of what is allopathic medicine.

Women have always been at the forefront in providing humane health care, from the venerated women healers of ancient Greece, to the persecuted medieval women lay healers, to the pioneering women of North America. The witch burnings of medieval Europe, the persecution of midwives in the 18th, 19th and 20th centuries, and the discrimination experienced by women in medicine today are all part of the history and development of medicine. To be unaware of women's role in medical history is to be ignorant of half the story of medicine.

Today, health care is primarily in the hands of men, with women playing helpmate roles. The history of women as primary health care givers has been almost completely obliterated. Information about women healers is not part of mainstream knowledge; the interested reader must seek out books specifically about women healers which, until recently, have been generally unavailable. Indeed, women are generally excluded from history books, not only those concerned with medicine (see Spender^[1] for further discussion). This dearth of information is a reflection of the pervasive sexism of our civilization. It is the author's intent to reclaim here part of the history of women in medicine.

Today, 93% of allopathic physicians are male. Through-out the industrialized world there are still only few women physicians: England has 24%^[2] and Canada 10%.^[3] This phenomenon is the culmination of events that date back to early Greece. This chapter investigates the chrono-logical events that have resulted in a medical system dominated

by white, middle- and upper-class males.

FROM ANCIENT GREECE TO 13th-CENTURY ROME

Trotula lived in the 11th century and studied and taught in Salerno. Her gynecological work *De Mulerium Passionibus* (On the Suffering of Women), the earliest known compendium of women's health care, includes the treatments used by Greek, Roman and Arab physicians. During the following 300 years, this text was used across most of Europe. First typeset in 1544, it was reprinted many times in several languages.^[4]

Unfortunately, in allowing women into medical schools and careers, Italy was an exception. The faculty of medicine at the University of Paris absolutely opposed female physicians. Since, in 1220, anyone who was not a faculty member was strictly prohibited by law from the practice of medicine, women were effectively eliminated. There was little need to enforce the law until 1322 when Jacoba Felicie, along with several other women, was charged with examining sick persons, prescribing remedies, curing patients and receiving fees without a license. Although many of Jacoba's patients testified in her favor, and she demonstrated her procedures were the same as those used by licensed physicians, she was still charged and fined. This discrimination continued in France, without remittance, until 1868 (600 years later), when the first woman was allowed entry into the Paris Medical School.

Generally, the tradition of women healers which had begun in the ancient world continued until around the 13th century. Surgery was commonly undertaken by nuns at the local convents or by the "lady of the manor" in wealthy homes as a charitable duty. Some women healers received payment for their skills. Cecelia of Oxford, designated wise woman of the village, was employed as court surgeon by Queen Phillippa, wife of Edward III (1327–1377).

In the 13th century, contact with Arabian scholars stimulated a revival of interest in learning which resulted in two major developments that directly led to excluding women from the healing professions: the appearance of medical schools in universities and the formation of barber-surgeon guilds.^[4]

With the incorporation of medicine into universities, only licensed doctors were given the legal right to practice with the title of physician. With the exception of Italy, all European universities were closed to women. Official recognition of their medical skills was no longer available.

The development of universities and medicine was strictly controlled by church doctrine, and innovation suppressed. Medical students studied Plato, Aristotle, and Christian theology. Medical theory was restricted to Galen and the study of the "complexions" and "tempera-ments" of men. Students rarely, if ever, saw patients, and human dissection was outlawed by the church. Surgery was considered degrading and menial. Treatment

consisted of bleeding, leeches and quasi-religious rituals. For example, the physician to Edward II, an Oxford graduate, prescribed writing “in the name of the Father, the Son and the Holy Ghost, Amen,” on the patient’s jaw for a toothache.^[5]

In contrast, the women healers of this era, practicing illegally, followed the healing methods of Trotula and St Hildegarde of Bingen, Germany. Hildegarde (1098– 1179) wrote a compendium of natural healing methods entitled *Liber Simplicis Medicine*. In it, at a time when male physicians had no use for such advice, she lists the healing properties of 213 plants and 55 trees and asserts the importance of cleanliness for proper treatment.^[6] Although the natural healing methods of these women resulted in their being persecuted and burned at the stake as witches in the Middle Ages, many of these methods continue to be used in naturopathic medicine today.

Viewed from the perspective of the late 20th century, church doctrine was disturbingly misogynist. Pain in labor was perceived as the Lord’s just punishment for Eve’s original sin. In the 13th century, St Thomas Aquinas wrote:^[2]

As regards the individual nature, woman is defective and misbegotten, for the active power in the male seed tends to the production of a perfect likeness according to the male sex; while the production of women comes from defect in the active power, or some material indisposition.... (*Summa Teleologica*)

This attitude towards women climaxed in the 15th century with the burning of witches or lay healers (discussed below).

The second development of the 13th century which served to exclude women from the healing professions was formation of barber-surgeon guilds. These guilds laid down regulations for apprenticeship and membership. In return for guaranteeing standards of practice, members were given exclusive rights to their home town’s needs for surgical care and could prosecute non-guild members who dared to perform surgery. Those most affected were the midwives. Forceps, a surgeon’s invention, could only be legally used by guild members; therefore, a midwife was required to call in a barber-surgeon during a difficult delivery. The surgeon would either remove the infant piecemeal by hooks and perforators or perform caesarian section once the mother was dead.^[7] Occasionally women were allowed admittance into barber-surgeon guilds by patrimony or apprenticeship, but numbers were small.

By the end of the 14th century, organized medicine had effectively excluded women. The church joined in with witch-hunts in the 15th century, and the long tradition of women healers was almost completely eradicated.

By the 14th century, professional, university-trained physicians were in demand by the wealthy. Middle- and upper-class educated women healers were eliminated by excluding them from universities and licensing. This left only the women lay healers of the peasant class as competition. The medical profession appealed to the church for help, and the church responded by persecuting women in one of the most vicious rampages in history. There were two reasons for this victimization: the witch-healer was an empiricist in direct opposition to church doctrine, and women represented sexuality, a betrayal of faith through sensory awareness and alignment with the devil.

The church believed women to be the conduit of all evil. All pleasure was condemned, as the devil was considered the source. Women were associated with sex, and lust in either husband or wife was blamed on the woman. A newborn was immediately baptized by a male priest in order to ensure salvation of its soul, which had been exposed to the wickedness of the woman for 9 months while in the womb. Upon resurrection, it was believed that all humans would be reborn as men.^[8]

Women healers had sins to atone for other than their sex. The so-called witches relied upon their senses and observation in treating their patients. The church believed that to trust one's senses was wrong – the senses were the devil's playground and used by the devil to lure men into the conceits of the intellect, delusions of carnality, and away from the faith.^[8]

The methods of the witch-healer were based on years of experience. She maintained an attitude of active inquiry, learning through trial and error, cause and effect. Her repertoire included herbal remedies such as clary, hyssop, lily, ergot, belladonna and digitalis – many still used by naturopathic physicians today. Codified in the written works of Hildegard of Bingen and Trotula of Italy, her approach was scientific according to today's standards. Even established medicine referred to these works for centuries.^[8]

The approach of medical doctors, deeply anti-empirical with no concern for the material world and empirical observation, was more consistent with church doctrine. They did not search for the natural laws governing physical phenomena but instead abided by the belief that the Lord created the world anew each moment, and hence there was no point in questioning one's surroundings.

The witch-hunts

During the 14th through 17th centuries, witch-hunts spread across Europe. Thousands of executions, usually live burnings at the stake, were carried out, first in Germany and Italy and later in France and England.

In 1484, a witch-hunting manual, the *Malleus*, was written by reverends Kramer and Sprenger, beloved sons of Pope Innocent VIII. It contained specific instructions for conducting witch-hunts and methods of torture for extracting confessions and names of other witches. Witchcraft was defined as political subversion, religious heresy, lewdness, and blasphemy. Women were accused of every conceivable sex crime

against men. They were accused of being organized, of having magical healing powers, and of harming with magic. According to the *Malleus*: “All witchcraft comes from carnal lust which in women is insatiable.... And blessed be the highest who so far has preserved the male sex from so great a crime....”^[8]

Women were often charged and burned at the stake simply for possessing medical knowledge and obstetrical skills. “If a woman dare to cure without having studied, she is a witch and must die” (*Malleus*).^[8] Of course, women could not officially study as they were not allowed into medical schools.

English physicians complained to Parliament about the “worthless and presumptuous women who usurped the profession” and requested that fines and long imprisonment be the punishment for any woman “who dared to use the practice of Fisyk”.^[9] King Henry VIII heard their plea and secured nationwide regulation of medicine and surgery with the Act of 1512, which installed a system of licensing that approved practitioners and punished and suppressed all others.^[7] In Europe, the church was given the responsibility of implementing the program to eliminate women healers and “witchcraft”.

In several German cities, approximately 600 burnings occurred each year, two each day except Sundays. Over 900 “witches” were executed in 1 year in the Wertzberg area and over 1,000 in the area of Como. In Toulouse, 400 women were put to death in 1 day. In the Bishopric of Trier in 1585, so many women were killed that two villages were left with only one woman each. It has been estimated that the total number of executed witches (85% of whom were women) was in the millions.^[8]

The persecution of women healers greatly strengthened the relationship between the church and the medical profession. The doctor was considered the medical expert, providing an aura of authority to the witch-hunt as he decided whether the accused was a witch and what afflictions were the results of witchcraft. The dogma was that if a woman effected a cure, it was with the help of the devil, while if a male priest or doctor effected a cure, it was with the help of God – the Lord worked through male priests and doctors, not through women.^[2]

The majority of witches were the general practitioners of the peasant population. The poor did not have access to hospitals or university-trained physicians and were bitterly afflicted with poverty and disease. The church upheld a double standard in terms of who should receive health care. For the upper classes and nobility, it was a given. For the poor, life experience in the world was

fleeting and unimportant and so was their suffering. The peasants were offered little in the form of relief or even words of comfort from the church:^[8]

You have sinned and God is afflicting you. Thank him and you will suffer so much less the torment in the life to come. Endure, suffer, die. Has not the

church its prayer for the dead?

The witch-hunts deprived the peasantry of the health care that was available to them and helped establish the dominance of a technological and rather violent male-dominated medical profession by eliminating the last of their competition. Not only during the medieval period in Europe, but also until about 1875, university-trained doctors depended on blood-letting and purgatives. Calomel, a mercury salt and the most popular purgative and cure-all medical remedy, was used in large doses for acute problems.^[10] Through the 17th century, they derived their prognoses from astrology and the theory of “complexions and temperaments”, partially treating their patients with incantations and quasi-religious rituals. A common treatment for leprosy was a soup made of black snake caught on dry land among stones.^[5]

In contrast, the approach of the medieval woman healer emphasized the role played by the patient’s innate power of healing – a view still held in naturopathic medicine today. Illness was regarded as part of the life process and an attempt on the part of the organism to regain homeostasis. Her methods included herbs, diet therapy, massage, water cures, poultices, and other gentle health-promoting approaches.^[11] Women healers used their extensive knowledge of physiology, anatomy and herbs gained through experience and observation. Their superior healing abilities were acknowledged by Paracelsus who, in 1527, burned his texts on pharmaceuticals, confessing he “had learned from the Sorceress all he knew”.^[5]

The witch-hunts, however, branded women healers as superstitious and potentially malevolent and so thoroughly discredited women healers among the emerging middle class that, in the 17th and 18th centuries, devastating inroads were made into their last preserve, midwifery.

Discrediting the midwives

The English Act of 1512, which ultimately controlled the licensing of physicians, made no mention of midwives, probably on the basis that midwifery was considered part of surgery.^[7] The system of licensing that did develop for midwives was concerned mainly with social and religious functions, for there was no way for a woman to become educated and therefore no possibility of achieving legitimate status through government licensing. Medical schools and universities were closed to women everywhere in Europe except Italy. The majority of midwives were peasants and could not afford to travel abroad to study. As a result, midwives lacked the knowledge of Latin and Greek necessary to read texts or communicate their knowledge of female anatomy and physiology. The few midwives who did manage to educate themselves, by witnessing dissections and reading medical works, still remained legally unqualified as they could not attain a university degree.^[7]

Midwives in England organized in the mid-18th century to protest the Act of 1512 and the intrusion of male doctors into their realm. They charged doctors with commercialism, damaging infants’ skulls with dangerous overuse of forceps, and causing undue harm to mothers. But as midwives did not know proper medical terminology and many of their members were being burned as witches even as they spoke, their protests were easily

dismissed as “old wives’ tales” based on ignorance and superstition.

So much was their skill and tradition discredited that they lost claim to their own techniques. For example, when Ambroise Pare (1510–1590), surgeon to the King of France, developed an interest in childbirth, he laid claim to discovery of podalic version, the method utilized and described by the woman physician Aspasia of second century Rome.^[4] The male medical profession could now boast of their superior obstetrical methods.

By the early 1600s, male “midwives” began to establish themselves in earnest. They were called in for difficult cases, often with disastrous results. Nevertheless, by the end of the 18th century, throughout Europe childbirth had become the province of male physicians.^[7]

Conclusion

The persecution of witches was a major exercise in medical and social control, eliminating women healers and removing the peasants’ only source of health care. World-views that conflicted with church doctrine, i.e. that recognized the nature principle and the holistic quality of human life, were exorcised from the healing arts, not to be revived until the women’s movement in North America in the 1700s and 1800s.

Perhaps most significant was the effect the witch-hunts had on society’s perception of women, firmly establishing suspicion of evil, black magic and immoral sexuality of women in general, and women healers specifically.

THE BATTLE OF THE SECTS IN 19th-CENTURY AMERICA

Rise of the medical establishment

In early colonial America, the responsibility for healing was in the hands of women as was general family care. University-trained physicians, i.e. allopaths, did not emigrate to the colonies until the late 1700s, and then only a

few came. In the New World, formal education, including medicine, was not available at the university level. In New Jersey, for example, medical practice, except in extraordinary cases, was mainly in the hands of women as late as 1818.^[12] Colonial women brought centuries of healing lore with them handed down from the “witch” healers of medieval Europe. Knowledge of indigenous herbs learned from the American Indians was combined with the European traditions of massage, hydrotherapy, botanicals, and midwifery. Medical practice was open to anyone who could demonstrate healing skills, regardless of formal training, race, or sex.

Then, in the early 1800s, American university-trained doctors, modeled after the established European allopaths, began to become available. The four medical schools established by the turn of the century were far below European standards, and programs were only a few months in length. Most schools lacked clinical facilities and did not require even high school diplomas for entry. As the number of formally trained doctors grew, it became clear that much needed to be done before they could achieve the prestige and economic status of European medical doctors. One of their first tasks was to distinguish themselves from lay healers.

Allopaths were already easily identified as they were male, middle- and upper-class and almost always more costly. Their clientele consisted of middle- and upper-class citizens who could afford the prestige of being under their care. It was fashionable among upper-class women, for example, to employ male doctors for obstetrical care, much to the horror of the general populace who considered it immoral for a woman to expose herself in such a manner to a man.^[12]

The allopaths, however, had little to offer in terms of theory or practice that was superior to what was available through folk medicine. Women healers used gentle botanical medications, offered dietary advice based on generations of experience, and, perhaps most importantly, did little or no harm. Allopathic doctors distinguished themselves by doing a great deal of harm in the form of “heroic medicine”.

Benjamin Rush has been credited with playing a central role in establishing heroic medicine. Along with a small group of elite American medical doctors, he completed his medical education with a few years of study in Great Britain. Here they developed the style of the genteel, highly paid European physicians, and aspired to establish a similar medical model in the New World. To accomplish this, they had to convince the general public that the allopaths were able to offer medical care superior to the inexpensive and efficacious care provided by lay healers and midwives.

An all-encompassing theory and system of therapeutics was developed which resulted in immediate, although extremely dangerous, results. The purpose was to produce the strongest possible visible response in the patient. The stronger a drug or procedure, the greater its therapeutic value was purported to be. Blood-letting, purgatives, laxatives, enemas and blistering were among the most common treatments. A patient was bled until he either fainted or his pulse was no longer palpable. In 1847, one physician, after observing that extensive blistering of children often led to convulsions, gangrene or even death, concluded that blistering “ought to be held in high rank” in the treatment of childhood diseases.^[10] Not all physicians were in agreement with these methods, however. Douglas observed that:^[10]

Frequently there is more danger from the physician than from the Distemper ... but sometimes notwithstanding the Male Practice, Nature gets the better of the Doctor and the patient recovers.

Aside from the lack of effective therapeutic techniques, there was a total void where medical theory should have been. Air was considered the carrier of disease, and getting

wet was thought to enhance susceptibility to disease. Those who listened lived in fear of bathing, sunlight, and breezes. Drinking water was kept from the ill, and windows were kept shut and covered with heavy drapes. Women were advised to keep themselves covered from the sun at all times with parasols and veils.

Heroic medicine gave regular doctors the appearance of being able to keep back disease, winning the “battle” against disease even if it killed the patient. Some of these doctors became very wealthy and gained much influence with statesmen and other influential members of the upper classes. Politically, this was essential to subsequent events in the development of allopathic dominance in North America.

Professions are the creation of the ruling class. To become sole providers of health care and succeed with the sham of heroic medicine, allopaths needed patronage from the ruling class. According to sociologist Elliot Friedson:^[2]

A profession attains and maintains its position by virtue of the protection and patronage of some elite segment of society which has been persuaded that there is some special value in it's work.

Between 1800 and 1820, allopaths used their newly acquired influence to pressure 17 states into passing licensing laws restricting the practice of medicine to their own kind. In 10 states, practicing without a license meant imprisonment.^[13]

Two major unforeseen political problems, however, appeared to disrupt the allopaths' plans. First, the general populace and lower classes did not accept the hazards and pretensions of heroic medicine, preferring the more effective and much less painful and expensive health care provided by lay healers. The second problem was enforcement of licensing laws. The general populace was

not prepared to persecute their own trusted healers, often the women of their own families or a well-known neighbor. The new laws incited public outrage. Fanned by the labor rebellion against upper class elitism and exploitation of burgeoning industrialization, the popular health movement emerged.

The popular health movement

In the early 1800s, the industrial revolution created a deep economic division between the upper and lower classes. Factory employees and unskilled laborers lived in abject poverty on the edge of starvation while working long hours for ridiculously low wages. Single family farmers and owners of small businesses were exploited by banks whose financial manipulations often pushed them into ruin. Upper class industrialists flaunted wealth gained at the expense of the lower classes. From this setting arose the labor movement with its membership of farmers, artisans and factory workers. At the same

time, the women's movement began to take greater hold among working-class women.

In early industrialized society, many women were thrown together, free of the company of men. Women were either confined to home and church or worked in all-women factories such as those in the New England mill towns. Discovering their common aversion to heroic male medicine, women began to develop alternatives.^[14] Among the hundreds of benevolent associations, charitable institutions and mutual support groups was the "Ladies Physiological Society", a feminist health care group. At society meetings, women learned about female anatomy, physiology and personal hygiene; old-time home remedies were recultivated and exchanged; and the lore of botanical healing and other techniques used by the pioneer women healers were recovered. In opposition to the dangerous therapies of allopathic doctors, they emphasized preventive care: frequent bathing, loose-fitting clothing, whole grains, and fresh air – all in direct opposition to the medical dogma of the day. The women's health movement was at the forefront of general social upheaval, a radical assault on medical elitism, and an affirmation of traditional "peoples'" medicine.

Women's outrage against allopathic medicine, shared by working-class men, resulted in a mass movement against medical professionalism and "expertism" of all forms. It was a class war, and the allopathic doctors were on the side of the aristocratic upper class. Regular doctors, with their claim to educational superiority, were denounced, along with the universities that trained them. It was popularly believed that students learned in the universities to look upon labor as "servile and demeaning".^[11]

By the 1830s, the labor and feminist movements had converged into the popular health movement. According to historian Richard Shryock:^[10]

This crusade for women's health was related both in cause and effect to the demand for women's rights in general and the health and feminist movement became indistinguishable at this point.

The health movement was concerned with women's rights, and the women's movement was concerned with health care and access to medical training for women. However, it took a male voice to repeat what women had already said and done before any change took place.

Samuel Thomson is credited with laying the foundation of a theory (see [Chs 2](#) and [35](#)) and practice of folk medicine for the working class and feminists. A poor New Hampshire farmer, he had watched his wife and mother die at the hands of allopathic doctors. Outraged by their violent methods, he began to reconstruct the folk medicine he had learned from a woman healer and midwife named Mrs Benton. According to Thomson:^[13]

The whole of her practice was with roots and herbs applied to the patient, or given in hot drinks, to produce sweating which always answered the purpose. ... By her attention to the family, and the benefits they received from her skill, we became very much attached to her; and when she used to go out and collect roots and herbs, she would take me with her, and learn

me their names, with what they were good for.

Thomson's methodology systemized Mrs Benton's methods, which she in turn had learned from native American Indians and the tradition of women healers before her. In 1822, he published *A New Guide to Health*, which described what was basically her entire healing system. His intention was to provide the public with self-sufficient health care and to remove healing as a commodity from the marketplace. (Although less toxic and more natural than the medical therapies of the day, Thomson's were not always particularly gentle. For example, lobelia was given as an emetic to cleanse the stomach and followed with capsicum to induce fever. He also used steam baths (his followers were often called "steamers") and sought to restore equilibrium through the use of *Myrica cerifera* (bayberry), *Nymphaea odorata* (pond lily), *Pinus canadensis* (spruce), and *Rhus glabrum* (sumac).)^[15]

The Thomsonian Movement was in full swing by 1835, claiming just under one-quarter of the entire US population. There were five Thomsonian journals which included articles concerned with health, women's rights, and affronts to female health inflicted by "heroic" obstetrical practices. He felt that women were natural healers, and strongly believed that doctors, who graduated without ever having witnessed a delivery, should leave obstetrics to midwives. His son, John Thomson, wrote:^[14]

We cannot deny that women possess superior capacities for the science of medicine, and although men should reserve for themselves the exclusive right to mend broken limbs and fractured skulls, and to prescribe in all cares for their own sex, they should give up to women the office of attending upon women.

These ideas were in direct opposition to those of regular doctors, who felt that women had no place in medicine and continued to put much effort into keeping them out. Women were still not allowed into regular medical schools, and the new licensing laws forbade anyone who was not licensed and university educated from practicing the healing arts. Perhaps an extreme example of discrimination against women is that of Henrietta Faber who studied and practiced medicine in Havana, Cuba, disguised as a man. When, in 1820, she revealed her true sex in order to marry, she was sentenced to 10 years in prison.^[16] It wasn't until 1849 that the first woman, Elizabeth Blackwell, entered a United States medical school. (When she was applying to the 42 all-male medical schools, a well-meaning professor at Jefferson Medical College recommended she attend classes disguised as a man.)

Healing systems similar to Thomson's grew in the radical climate of the 1830s. Sylvester Graham founded a movement of physiologically based healing called the Hygienic Movement. The Grahamites were so anti-medicine they rejected the use of botanicals as well as drugs. Instead, the system encouraged a vegetarian diet of raw fruits and vegetables and whole grains, while allopaths held that uncooked produce was

injurious to your health and white bread was a status symbol.

Both the Thomsonians and the hygienists upheld that health care and healing skills belonged to the people and should not be a marketable commodity. Followers of Thomson and Graham fought the new licensing laws for physicians alongside the feminists and working-class activists:^[17]

Any system that teaches the sick that they can get well only through the exercise of the skill of someone else, and that they remain alive only through the tender mercies of the privileged class, has no place in nature's scheme of things, and the sooner it is abolished, the better off mankind will be.

(It should be noted, however, that while the Thomsonians and the hygienists actively recruited women and strongly believed in the importance of women improving their health and that of their families, they were not particularly supportive of feminism.)

By the mid-1830s, every state with restrictive licensing laws had either softened or repealed them. Some states, like Alabama and Delaware, exempted Thomsonians and Grahamites from any restrictions.^[13] Regular doctors now became recognized as just another sect and were revealed as the sect that had attempted to monopolize health care at the expense of the working class. Unfortunately, however, the popular health movement began to decline shortly after its greatest victory.

By the late 1830s, some of the Thomsonian and Grahamian practitioners wanted professionalism and to establish schools and licensing for their graduates, seeking what they had fought so hard against and reversing some of the original tenets of the movement. In-fighting began over the loss of basic principles. Much competition developed between their schools for students, creating a larger rift. Along with these events occurred a loss of public support. Feminists turned away from health issues and refocused their efforts on women's rights in a world controlled by men. The radicalism of the working class trailed off toward Andrew Jackson's Democratic Party and away from socialist revolution. During the lull, allopaths began adopting enough of the principles of natural healing to appear credible.

The reputation of medical doctors was in a terrible state. Their professionalism had been significantly undermined, and uncontrollable growth of their ranks, from a few thousand in 1800 to over 40,000 in 1850, resulted in decreased medical fees and lowered economic status.^[13] Many of the graduates, unable to make a living from their practice, chose to open schools of their own. Allopaths were also experiencing stiff competition from herbalists, hydropaths, midwives, homeopaths, and the eclectics who mixed natural healing with allopathy. Each healing art had its own schools, journals, and dedicated following. Homeopaths were particularly threatening as they appealed to the upper class, the patient population most coveted by allopathic physicians.

In 1847, a small group of allopathic doctors formed the American Medical Association (AMA). Upon surveying their affairs, they concluded:^[13]

No wonder the profession of medicine has measurably ceased to occupy the

elevated position which once it did; one wonders that the merest pittance in the way of remuneration is scantily doled out even to the most industrious of our ranks.

One of the first acts of the newly formed AMA was to extend the length of required study from 4 to 6 months and to require 2 years of approved preceptorship. However, practically all hospitals barred women from internship programs. In 1857, Elizabeth Blackwell, after being barred from all New York hospitals (despite her degree), opened the first woman-dominated hospital in the world, the New York Infirmary for Women. Internships for women continued to be very limited (in the early 1940s, 607 of 712 hospitals would not accept women) until World War II when the shortage of male doctors opened the doors for women.

The problems for women were further aggravated by the AMA's Consultation Clause which barred women from membership in the AMA and prohibited members from providing consultations for irregular doctors.

Although the Consultation Clause was effective, it was not until the early 1900s that allopathic medicine was able to establish supremacy and essentially eliminate women allopaths and natural healers of both sexes from the field. This was accomplished through their adoption of the new religion of "science" and the infusion by the chemical and drug industry (primarily through the

Rockefeller and Carnegie foundations) of millions of dollars into their drug-oriented schools.

The threat of women doctors

From the 1850s through the turn of the century, allopathic doctors relentlessly attacked their competition: the sectarian or irregular and women practitioners. The natural healing-oriented groups were attacked for allowing women among the ranks, and women doctors were attacked for their sectarian methods. But the worst was yet to come.

By mid-century, middle- and upper-class women were aspiring to become regular doctors. They too were motivated by reform, as were the women of the popular health movement, but their spirit of reform was moral rather than social. Middle- and upper-class women were outraged by the implicit indecency of the male doctor treating a female patient. Catherine Beecher, a well-known doctor and journalist of her time, publicly raised charges of seduction and sexual abuse by male doctors.^[18] A women's society in Philadelphia made it quite clear that "the Bible recognizes and approves only women in the sacred office of midwife"^[19] A popular women's magazine, Godey's *Lady's Book*, argued strongly in favor of women physicians:^[19]

We would, in all deference, suggest that, first of all, there will be candor in the patient to the female physician, which would not be expected when a sense of native delicacy and modesty existed to the extent of preferring to suffer rather than divulge the symptoms.

Women began to force their way into allopathic medical schools. Elizabeth Blackwell gained admission into Geneva Medical College in upstate New York in 1849 after having been turned down by 16 other schools. After her graduation, Geneva College quickly passed a resolution barring entry of women.^[19] In the same year, Harriet Hunt was admitted to Harvard Medical College, but the decision was reversed when the all-male student body threatened to riot. Instead, she attended and graduated from an irregular school.^[19]

Emily Howard Jennings returned to Canada from the New York Medical College for Women in 1867 to become the first recognized Canadian woman doctor.^[20] Ironically, the first woman doctor to practice in Canada was actually James Barry, who posed as a man right up to her death. Even in death her sex went unreported by the embalmer; only when her grave was exhumed did her sex become known. The truth had been too embarrassing for the male embalmer to reveal, since women were not believed to have the intellect required to become physicians let alone study (see Shyrock^[10]), yet Barry had become chief military doctor for the country. Through the efforts of the sisters Augusta Jennings Kimball and Ella Jennings, the second and third Canadian women doctors, and those who followed, by 1900 there were approximately 5,000 women doctors in the US and Canada. Over 1,500 women were enrolled in medical colleges exclusively for women: seven in the United States^[19] and two in Canada^[20] (Toronto Women's Medical College and Queens Women's Medical College).

One of the strongest women physicians at the turn of the century, both as a feminist and leader of the natural health movement, was Dr Aloysia Stroebele. In the early 1890s, Stroebele, originally from Sigmaringen, Germany, opened the Bellevue Sanitarium in Butler, New Jersey, a nature cure retreat. As the personal aide to Lady Cooke, the famed suffragist leader, she became a strong advocate of "feminine independence and the emancipation of women".^[21] During the several years she spent with Lady Cooke, she made three trips around the world, and in the process met with several natural healers, one of whom, Rickli, influenced her greatly. Her accomplishments were many: co-founding the first naturopathic college, co-founding the famed Yungborn sanitarium, funding the journal *Naturopath*, and authoring several articles and books. She married Benedict Lust, the founder of naturopathic medicine, in 1901 and changed her name to Louisa Lust. Her most telling contribution, besides her famous cures at "the Bellevue" through her integration of diet therapy, hydrotherapy, and the Rickli air cure, were the funds she contributed to fight 17 legal actions taken against practitioners of naturopathy.^[22]

The male medical profession understood all too well the economic threat of these women physicians. Any middle- or upper-class woman who found the idea of revealing herself to a male doctor too repulsive could turn to a woman who was a regular, allopathic physician – still the preferred healers of the upper classes. She no longer had

to quibble over going to see “irregular” women physicians. Male physicians fought back with all the misogynous slander they could muster.

They argued that women were too frail to practice medicine, incapable of operating while menstruating, and unable to survive the vulgarities of anatomy class or the shocking truths of reproduction.^[19] The idea that women were too delicate and modest to survive medical training, let alone desire it, meant that women who insisted upon their rights were not really women at all. Alfred Stille, president of the AMA in 1871, explained the phenomenon of women in medicine in his presidential address:^[10]

Certain women seek to rival men in manly sports ... and the strange-minded ape them in all things, even in dress. In doing so they may command a sort of admiration such as all monstrous production inspires, especially when they tend towards a higher type of their own.

The editor of the *Buffalo Medical Journal* was more explicit: ^[17]

If I were to plan with malicious hate the greatest curse I could conceive for women, if I could estrange them from the

81

protection of men, and make them as far as possible loathsome and disgusting to man, I would favor the so-called reform which proposes to make doctors of them.

In other words, women who became physicians, or even desired to become physicians, were not only less than women, they were less than human.

In addition to public slander, male MDs and medical students did all they could to make the lives of women aspiring to medical careers as miserable as possible. In class they were harassed with insolent and offensive language, and missiles of tobacco quid and garbage were thrown at them. Anatomy teachers often refused to lecture if women were present.^[19] An 1848 obstetrics textbook explained how: “She (woman) has a head almost too small for intellect but just big enough for love.”^[10]

Once graduated, women doctors were allowed into few hospitals, and internships were almost non-existent. Nor were women doctors allowed to join medical societies or to publish in medical journals. Not until 1915 did the AMA admit its first female physician.

The entry of women into medicine was fiercely resisted by male doctors, not only because of their deeply rooted misogyny dating from the beginnings of Christianity and the economic threat they posed, but also because of their association with the popular health movement. The integrity of allopaths had been assaulted by the general public and the popular health movement in which women and feminism played a central role. The irregular schools of nature cure continued to welcome women students, and many of the irregular doctors were women providing a gentle and viable alternative to the

dangers of regular health care. During the late 18th and early 19th centuries, women applying to medical school were considered guilty by association of being in opposition to regular medicine and of being feminists.^[2]

Hydrotherapy: a haven for women

In terms of women's liberation and medical thought, the most revolutionary alternative system of healing was the hydrotherapy movement, or hydropathy as it was known in 19th century America. The original system consisted of using hot and cold water for bathing, wrapping, douching, and spritzing (spraying all or parts of the body). Allopathic medicines were excluded. Instead, a vegetarian diet, fresh air, exercise, regular bathing with cold water, and drinking numerous glasses of pure water were considered the pathways to health. Later, the principles of hydrotherapy were combined with those of the hygienic, Graham, and eclectic systems to form naturopathic medicine.

The formal practice of hydrotherapy began with Vincent Priessnitz who opened a water cure clinic in Graefenburg, Germany, in 1829.^[23] A medical doctor, Joel Shew, and his wife, Mary Louise Shew, introduced hydrotherapy to the United States in 1843, where the cause was most visibly carried forward by Mary Gove Nichols and Russell Thatcher Trall.^[23]

Women played a major role in hydrotherapy as practitioners, educators, and leaders in health reform and women's rights. Many women worked alongside husbands or male professionals, specializing in the care of obstetric and gynecological patients. Most prominent was Mary Gove Nichols who, in 1846, opened her own water cure establishment in New York.^[23] In 1851, she and her physician husband Thomas Nichols opened a medical school based on water cure principles in New York. Other prominent water cure partners included Racheal Brooks Gleason and her physician husband Silas Gleason, James Jackson and Thodoria Gilbert (who opened the Glen Haven Water Cure), and Harriet Austin who later worked with Jackson.^[23]

The concept of women as protectors of the family's health and morality was one of the major tenets guiding the hydrotherapist's insistence that women take control of their own health and personal power. They believed that by developing a healthy lifestyle and independence, women could work alongside men to improve society. These ideas were in direct opposition to the dominant social ethics and medical thought of the day.

Allopaths viewed puberty, menses, pregnancy, childbirth, and menopause as a series of potentially dangerous pathological events. Women were relegated to the domestic sphere due to their supposed weak physical and intellectual nature. In the home, they could be protected by the man.^[24]

In contrast, the hydropaths viewed women's physiology and reproductive functions as normal, healthy processes. Water cure establishments provided a haven where women could receive sympathetic care, find relief from constant pregnancies, and receive psychological and emotional support.^[24] Women were inspired to achieve beyond the

domestic realm, and many went on to become hydropaths themselves.

Taking the cure at the hydrotherapy establishments became fashionable amongst the wealthy during the late 19th century. Between 1843 and 1900, 213 water cure sanitariums opened.^[23] Numerous journals, books, and magazines devoted to the tenets of water cure and a natural lifestyle were published during this time. They became forums for disseminating hydropathic ideals of the perfect society where women no longer wore tight corsets, long dresses, or suffered the ill effects of the allopaths' over-medication with mercury (for postpartum hemorrhage), lead (for dyspepsia), opium, leeches, and blood-letting. Women were encouraged to avoid the meat-, salt- and stimulant-rich diet of the day. In the vision of the hydropaths, women were free to pursue any career they chose, with hydrotherapy and medicine being the most noble.^[23]
^[24] ^[25]

Thomas Nichols' statement in the *Water Cure Journal* clearly states their intent: "Never has woman had such an opening for usefulness and influence as this. No water cure establishment is complete without a qualified woman physician."^[26]

Mary Gove Nichols, in her inaugural address at the opening to the American Hydropathic Institute, professed: "Women are peculiarly fitted to the art of healing because of their tenderer love, the sublime devotion, the never to be wearied patience and kindness of woman."^[27]

Women comprised between 30 and 50% of the graduates from the hydrotherapy schools. They worked diligently as the heads of the ladies' departments of the water cure establishments, attending to all facets of women's and children's health care. They provided prenatal care where allopaths had little to offer, recommending a diet of fruit, vegetables, whole grains, and milk. Loose clothing, daily exercise, and cold baths were recommended to tone the body in preparation for childbirth.^[23] After the birth, women were encouraged to get out of bed within days, if not the same day, thus decreasing the risk of postpartum blood clots and pulmonary embolism. Women were taught to experience childbirth as an empowering, natural and holy function, rather than as an event to be dreaded as risking imminent death.

Hydrotherapy, more than any other 19th century medical sect, had the strongest connection with the women's movement.

Victory for a male profession

Until the early 20th century, allopaths had little to offer that was superior to the other types of health care practices. They had neither economic dominance nor elevated social status over the irregular or natural health care practitioners. In spite of the AMA's valiant attempts to establish allopathy as the only legitimate form of healing, only 8,000 out of 125,000 doctors in the United States were members of the AMA at the turn of the

century.^[28]

European allopaths had better success in establishing themselves among the upper class. With the introduction of the germ theory by French and German scientists came the first scientifically demonstrable basis for disease prevention and treatment. European medical men were the first to adopt scientific methodology into medical practice and education. This served to further enhance their already elevated status. Science had become the new religion of the general public and was held up as the answer to all social, economic and health problems. The new religion was received in North America with tremendous enthusiasm.

Science in North America became a national moral value; any discipline which wanted to justify its existence had to adopt scientific doctrine. Social work, philanthropy, housekeeping, child-rearing, business management, public administration, law, and medicine all began to search for a scientific basis. The adoption of scientific principles was synonymous with reform.^[2]

In the late 19th century, a small group of American doctors traveled to German and French medical universities for further training and returned determined to install an elite medical educational system that would elevate their professional status. In 1893, they founded Johns Hopkins University, the first medical school in North America with laboratories and full-time professors. Eight years later, the Rockefeller Institute for Medical Research was opened. The institute was, and is still today, solely concerned with pure research and helped to exalt the mystery of European scientism. One of the founders of the institute and a close friend of the Rockefellers, described the place as “a theological seminary, presided over by the Reverend Simon Flexner, M.D.”^[29]

Having finally created a credible academic and research model for medical education, the AMA began to effectively utilize economic and political pressure to ensure that all schools providing a medical education either ascribed to the model provided by the Rockefeller Institute and Johns Hopkins University or were closed.

This was accomplished through a cooperative effort between the AMA’s Council on Medical Education (made up of faculty from the medical schools modeled on the Johns Hopkins prototype) and the Carnegie and Rockefeller Foundations. The Carnegie Foundation ostensibly agreed to conduct a study of the educational institutions found in the various healing professions. The results were then utilized to determine which schools and sects were to receive a portion of \$150 million in endowments.

The study was conducted by Abraham Flexner, brother of the director of the Rockefeller Institute, Simon Flexner MD, a graduate of Johns Hopkins University. In the survey, schools such as Harvard were seen to be conforming to the new scientific model quite well, as they had the money (granted them by the foundations) to employ full-time professors and install expensive laboratories. These schools were given large endowments. The smaller, poorer schools, which provided medical education for women, blacks and those interested in natural healing, did poorly in meeting allopathic requirements and hence received no funds from the Rockefeller and Carnegie foundations. According to Flexner’s report, these schools were not worth saving and

their closure would be no loss.

Despite the 10 medical colleges in existence at the time that provided medical education solely for women, Flexner also decided that few women doctors were needed. He perceived a lack of “any strong demand for women physicians or any strong ungratified desire on the part of women to enter the profession”!^[30] Flexner did deduce that some black doctors were needed, but only enough to check the spread of disease from black to white

neighborhoods for “ten millions of them live in close contact with sixty million whites”.^[30] Due to both economic and philosophical reasons, the irregular schools, which had been a haven for women, and women’s medical colleges did not conform to the new allopathic model and were discredited by the Flexner report.

From 1904 to 1915, 92 medical schools closed or merged: five out of seven all-black medical schools closed, seven out of 10 medical schools for women shut their doors, and the majority of the alternative medical schools were eliminated. As a direct result, the number of women graduates from allopathic medical schools dropped from 4.3 to 3.2%. In the meantime, from 1910 to 1930, over \$300 million was poured into the medical schools that ascribed to the Johns Hopkins model.^[31] Not only women and blacks were affected by these events, for scientism became the domain of the upper classes.

The reforms which ruled the existence of medical schools included an entrance requirement of 2 years of university training. This effectively made a medical career impossible for all but the middle and upper classes due to the expense. Medical schools that had been economically accessible to the working class ceased to exist, and the entrance of blacks into medical schools was limited by racial discrimination. Women suffered sex discrimination in their attempts to enter the remaining medical colleges,^[2] with percentages steadily shrinking until the 1970s and the resurgence of feminism.^[32] The medical profession had become an institution composed almost entirely of white, middle- and upper-class males confirmed in their opposition to women and natural healing methods.

It is true that turn-of-the-century medicine needed some form of standardization of education and health care. However, in the fervor of scientism, sexism, racism, and the allopaths’ rush for economic control, the alternatives to allopathic medicine were effectively eliminated. Despite the new reforms, the quality of medical care was not necessarily improved. The new system of lengthy scientific training did not guarantee that physicians were any more effective or humanely empathic than the irregular healers they replaced – in fact quite the opposite appears to have been the case (see Ivan Illich, *Limits to Medicine* ^[33] and other chapters of this textbook). While the scientific method has much to offer, it is arguable that, in the context of the stifling, one-dimensional philosophy and male elitism of the medical profession, the use of the banner of

scientism to establish political and economic protection from competing ideas actually inhibited the development of health care in this country.

Midwives: the last of the women healers to fall

In 1900, approximately 50% of all births in North America were attended by midwives.^[2] Middle- and upper-class women had their babies delivered by licensed MDs. Lower-class blacks and European immigrants could not afford MDs, nor did they want them. Midwifery was a respected tradition held in high esteem, particularly by Africans and Europeans. This meant fewer obstetrical cases for teaching medical students, as upper-class women certainly did not want a room full of men, medical students or not, witnessing their birthing efforts. Therefore, it was said that midwives, by providing affordable and readily available obstetrical care to the lower class, were depriving medical students of valuable learning experiences.

To remedy the situation, medical schools began to associate themselves with local charity hospitals, offering medical trainees as staff in return for patients they could learn on. In the meantime, the medical profession put considerable energy into making midwifery illegal. An editorial in the *Journal of the American Medical Association* by Charles Ziegler stated the situation:^[11]

It is at present impossible to secure cases sufficient for the proper training in obstetrics, since 75% of the material otherwise available for clinical purposes is utilized in providing a livelihood for midwives.

The “material,” of course, was the bodies of pregnant women.

A campaign was launched to rally support among members of the profession to outlaw midwifery by appealing to their sense of what was best for medical education and by portraying midwives as “hopelessly dirty, ignorant and incompetent relics of a barbaric past” who could do only harm to mother and child:^[34]

They may wash their hands, but oh what myriads of dirt lurk under their fingernails. Numerous instances could be cited and we might well add to other causes of pyosalpinx “dirty midwives.” She is the most virulent bacteria of them all and she is truly a micrococcus of the most poisonous kind.

An obvious solution to the problem of the “dirty and ignorant midwives” would have been to educate them in hygiene, in the use of an eyedropper to prevent gonococcal eye infections in the newborn, and in the use of forceps in difficult births. However, the medical profession wanted obstetrical “material”, not to train midwives to further increase their effectiveness and legitimacy. Through cooperation with them, the MDs could have learned much about childbirth and improved their own reputations.

The medical doctors’ version of childbirth was dangerous. If the labor was going too slowly for his schedule, he used forceps and caesarian section with considerable risk to mother and child.^[7] In teaching hospitals, there was a definite bias in favor of surgery to

provide experience for students in abnormal deliveries.^[11] In fact, a 1912 study by Johns Hopkins University found the majority of American doctors less competent than the midwives they had replaced. According to the study, they were less

experienced, less observant and less likely to be present at the critical moment.^[35]

It appears that the MDs realized they could not fill the void of service left if midwives were eliminated. One obstetrician in 1915 admitted that of all births in New York State, 25% would be entirely deprived of assistance once midwifery was eliminated.^[34] Yet between 1900 and 1930, midwives were almost totally eliminated from North America. With the demise of the midwife, American women lost their last independent role as healers.

More than one historian has referred to the years from 1900 to 1965 as the Dark Ages in terms of the progress of women in the healing arts.^[36] Although there were women allopathic physicians, their numbers were small. In 1900, women comprised 5% of all physicians of all sects, and by 1926, they made up only 2%. Not until the 1970s, with the resurgence of feminism, did the number of women in allopathic medical schools approach even 6%.^[32] The remaining irregular schools had continued accepting women students without discrimination, although the numbers were not as high as they are now. In the early 1970s, the naturopathic student body was approximately 33% female.

WOMEN IN MEDICINE TODAY

Today's dominant form of medicine is a refined form of the heroic techniques of turn-of-the-century allopaths, and women have only recently begun to make real progress in entering the ranks of male-dominated technological medicine. From 1968 to 1978, the number of women enrolled in regular medical schools has increased dramatically, from 7 to 25%. At McMaster Medical School in Hamilton, Ontario, more than 50% of the 1978 graduating class were women – the first time in North America that the number of women in an allopathic medical school was greater than that of men.^[37] Discrimination against women in medicine persists, however.

According to a 1985–86 survey conducted by the AMA, women earn 62% of the salary of their male colleagues.^[38] Women also fill less than 3% of administrative positions in medical schools, and, as of 1987, only two American medical colleges have a female dean. Academic ranking also shows discrimination as women make up 23.6% of assistant professors as compared with only 6% of full professors.^{[38] [39]}

Barriers to admitting women into medical schools have been lowered considerably for several reasons: the adoption of civil rights and affirmative action legislation, and resolutions on equal opportunity in the United States and Canada. The women's movement has encouraged women to seek non-traditional careers and to assert their rights to pursue them.^[40] Although the number of women in medicine is increasing,

sexist attitudes seem to have changed little since the turn of the century.

Ramey, referring to the scarcity of women in administrative positions, commented in 1980 that “women are prone to emotions, verbosity, pettiness and pregnancy”.^[41] In this author’s opinion, the final proof of the continued existence of discrimination against women in allopathic medicine is this statistic: women comprise only 10% of practicing allopathic physicians. In contrast, they comprise 40% of practicing naturopathic physicians.

Continuing discrimination against women in medicine has manifested itself in many ways:^[41] ^[42] ^[43] ^[44]

- There is no school-supported recruitment of women such as there is for minority students.
- There is a reluctance to admit married women, as they may become pregnant and, if they have families, may not utilize their education.
- There is overt discrimination in the classroom, including baiting, hostility, and derogatory comments.

It has been documented that lecturers, in dealing with problems in medical practice, direct all of their questions and comments to male students.^[43] ^[45] The prevalence of stereotyping women as sex objects within the profession is exhibited by the number of female students who have been sexually embarrassed, harassed or abused by their male instructors. Reports of such incidents at a conference on women in medicine in Toronto in 1985 were too frequent to be considered extraordinary.^[42] A 1988 study of the gender climate in medical school found that 80% of women students reported discrimination by faculty and other physicians, with faculty displaying subtle to blatant sexism.^[43] Another recent study at a Midwest medical school indicated that gender discrimination increased in intensity as the women moved closer to graduation and licensing.^[43] The types of discrimination reported included sexual remarks, jokes and innuendoes relegating women into stereotyped roles, sexual advances by married mentors, and blatant sexual manipulation.^[44] The same study also found that two-thirds of practicing male physicians admitted they did not accept women as professional peers.

A prevalent argument used to justify reluctance in allowing women into allopathic medical school is that women MDs are less productive.^[36] Evidence, however, suggests the opposite is true. The January 1976 *Bulletin of the Professional Corporation of Physicians of Quebec* indicated that although women doctors work only 66% of the hours that male doctors do, they provide 92% of the patient care that male doctors provide. While it is true that not all women physicians continue to practice throughout the entire span of their potential working years, it is also true that women doctors are still expected to carry on with traditional family roles – a continuing societal problem. A study of women doctors in Detroit indicated that only 59% had worked without interruption since graduation and that 76% of women physicians are

still doing all of the cooking, shopping, housekeeping, and childcare.^[44] ^[46] Women's advancement within the profession is inversely related to marital status and family size.^[36] As a direct result of carrying the lion's share of family responsibility, and the discrimination they experience in obtaining an education and competing for career opportunities, women allopathic physicians are severely underrepresented in private practice, surgical specialties, and administrative and policy-making positions.

Still, the future of women in allopathic medicine looks brighter since their numbers are increasing. It has been predicted that women will make up 35% of the medical profession within the next decade or two.^[42] As to the types of medicine women will be practicing, it seems that women are returning to their traditional role of providing preventive health care. According to Spiro:^[47]

The long standing interest of women in preventive medicine, and the current public dissatisfaction with crisis-oriented care have led still others to predict that one contribution of women may be a more 'health-oriented' medical practice.

When one considers the percentage of women in naturopathic medicine, his statement is irrefutable.

The return of women to their role as primary providers of humane, holistic health care can be attributed to several events:

- the resurgence of irregular and naturopathic medicine in North America and Europe as indicated by the increasing number of colleges and institutions providing training in massage, herbal medicine, midwifery, acupuncture, homeopathy, and naturopathy
- the revival of the feminist movement since the late 1960s
- the increasing interest women are taking in self-health care as reflected by the growing number of women's organized health information groups
- the growing dissatisfaction of the general public with allopathic medicine, recognizing it as expensive and potentially dangerous to one's health.

(For further discussion, see Illich,^[33] Mendelsohn,^[48] and McKowen.^[49])

These events and social conditions have created an atmosphere similar to the one in which the popular health movement became successful in the early 1800s. Now, as during that time, there is considerable public discontent with heroic medicine and a recultivation of folk medicine, with women at the forefront of the revolution in health care.

Today, women make up over 50% of the student bodies at Bastyr College and National College of Naturopathic Medicine. Much of the philosophy and therapeutic approach of naturopathic medicine has been derived from the work of women healers dating back to

ancient Greece and the Roman empire. History seems to be repeating itself, with women once again playing a major role in providing preventive holistic health care.

CONCLUSION

The history of women in medicine is not well known outside of their traditional roles as helpmates and nurses to male physicians. It is not generally known that women have been primary health care providers from ancient Greece through the beginning of the 19th century. Many factors have created the low percentage of women in the medical profession today. Throughout the ages, women have been intensively persecuted for practicing medicine: Aspasia by Roman law, women folk healers of medieval times who were burned as witches, English midwives who were legislated out of practice in 1512, and women healers of all kinds in early America who were virtually barred from entering allopathic medical schools in North America until the end of the 19th century, and then allowed only in very limited numbers.

Today, women have made substantial progress in breaking into the allopathic medical profession despite continuing discrimination. The real changes for women in medicine may come with recent trends towards natural therapies and preventive health care, and the resurgence of midwifery and naturopathic medicine. Along with increasing public interest in irregular medicine and the resurgence of colleges providing credible training in alternative health care, an increasing number of primary health care givers are, once again, women.

Chapter 6 - Apoptosis assessment

Aristo Vojdani PhD MT

INTRODUCTION

Apoptosis is a distinct form of cell death controlled by an internally encoded suicide program. It is believed to take place in the majority of animal cells. It is a distinct event that triggers characteristic morphological and biological changes in the cellular life cycle. It is common during embryogenesis, normal tissue and organ involution, and cytotoxic immunological reactions and occurs naturally at the end of the life span of differentiated cells. Apoptosis can also be induced in cells by the application of a number of different agents, including physiological activators, heat shock, bacterial toxins, oncogenes, chemotherapeutic drugs, a variety of toxic chemicals, and ultraviolet and gamma radiation. When apoptosis occurs, the nucleus and cytoplasm of the cell often fragment into membrane-bound apoptotic bodies which are then phagocytized by neighboring cells. Alternatively, during necrosis, cell death occurs by direct injury to cells, resulting in cellular lysing and release of cytoplasmic components into the surrounding environment, often inducing an inflammatory response in the tissue. A landmark of cellular self-destruction by apoptosis is the activation of nucleases and proteases that degrade the higher-order chromatin structure of the DNA into fragments of 50–300 kilobases and subsequently into smaller DNA pieces of about 200 base-pairs in length. Using fluorescent-labeled reagents, it is possible to tag the DNA break and identify the percentage of apoptotic cells with a high degree of accuracy.^{[1] [2] [3] [4] [5] [6]}

Measurable features of apoptosis

One of the most easily measured features of apoptotic cells is the break-up of the

genomic DNA by cellular nucleases. These DNA fragments can be extracted from apoptotic cells and result in the appearance of DNA laddering when the DNA is analyzed by agarose gel electrophoresis. The DNA of non-apoptotic cells, which remains largely intact, does not display this laddering

90

on agarose gels during electrophoresis. The large number of DNA fragments appearing in apoptotic cells results in a multitude of 3'-hydroxyl termini of DNA ends. This property can also be used to identify apoptotic cells by labeling the DNA breaks with fluorescent-tagged deoxyuridine triphosphate nucleotides (F-dUTP). The enzyme terminal deoxynucleotidyl transferase (TdT) catalyzes a template-independent addition of deoxyribonucleotide triphosphates to the 3'-hydroxyl ends of double- or single-stranded DNA. A substantial number of these sites are available in apoptotic cells, providing the basis for the single-step fluorescent labeling and flow cytometric method. Non-apoptotic cells do not incorporate significant amounts of the F-dUTP owing to the lack of exposed 3'-hydroxyl DNA ends.

Apoptosis can also be characterized by changes in cell membrane structure. During apoptosis, the cell membrane's phospholipid asymmetry changes – phosphatidylserine (PS) is exposed on the outer membrane, while membrane integrity is maintained. Annexin V specifically binds phosphatidylserine (PS), whereas propidium iodide (PI) is a DNA-binding fluorochrome. When a cell population is exposed to both reagents, apoptotic cells will stain positive for annexin V and negative for PI; necrotic cells will stain positive for both and live cells will stain negative for both.^[3]

This process of apoptosis and its analysis by flow cytometry are shown in [Figures 6.1](#) and [6.2](#).

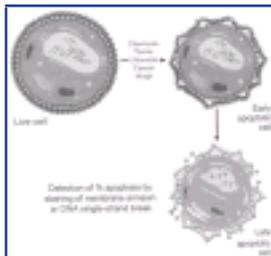

Figure 6-1 Detection of apoptosis using damaged membrane or DNA single-strand break and flow cytometry.

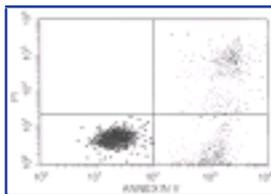

Figure 6-2 Separation of cells by flow cytometry and detection of apoptotic

population.

Different stages of apoptosis

The process of apoptosis is divided into three different stages:

- induction
- sensing or triggering
- execution.

These stages of apoptosis are depicted in [Figure 6.3](#) . Induction represents the initial events that signal a cell so that apoptosis may begin. This induction phase may

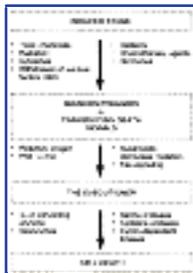

Figure 6-3 Various stages of “inside out” cell death or apoptosis.

be induced by a variety of physical agents such as toxic chemicals, radiation, chemotherapy agents, hormones and CD95 or Fas ligation. However, in a series of our recent experiments, we demonstrated that this induction stage of apoptosis is prevented by many antioxidants (vitamin C, beta-carotene and vitamin E) and also by a variety of biological response modifiers, including lentinan, thymic hormones, viral antigens and cytokines.

The induction stage is followed by a decision on whether or not the cell will undergo apoptosis. The decision to die is under the control of a number of different pathways or cellular sensors that induce the apoptosis signal which then triggers the central mechanisms. During this stage, several enzymes, such as IL₁-β* converting enzymes, serine protease, cysteine protease, granzymes and cyclin-dependent kinases, become activated. Once activated, these enzymes dismantle the cell and trigger the cell surface changes that cause direct cell recognition and engulfment of the dying cells by phagocytes. These central events are prevented by a variety of antioxidants and biological response modifiers.

Apoptosis is induced by chemicals to control malignancy

Many chemicals have the capacity to bind to DNA, form DNA adducts or cause DNA

single-strand breaks, possibly leading to cancer. However, the body is equipped with many factors, enzymes, suppressor genes and cellular sensors, all with the capacity to prevent this action of chemicals on DNA by activating apoptosis-inducing signals.

The role of apoptosis in regulating tissue growth is readily apparent in the simple equation in which the rate of growth is equal to the difference between the rates of cell proliferation and cell death. Thus, tissues expand if the rate of proliferation exceeds the rate of cell death. This is one of the reasons for suggesting that defects in apoptosis may contribute to the transformed state.

An important prediction of the relevance of apoptosis to malignancy is that the rate of apoptosis versus mitosis should influence the behavior of a tumor. Recently, the relationship between the apoptotic and mitotic indices in a tumor was demonstrated predictive of outcome: higher ratios correlate with positive prognosis. Further, it was found that this is not simply a function of cell death per se. Tumors with a high incidence of necrosis rather than apoptosis were correlated with poor prognosis. It therefore follows that treatments or conditions that favor apoptosis should have desirable effects, and that defects in the pathway(s) leading to apoptosis are likely to play important roles in the process of oncogenesis.^{[4] [5]}

Many reactive chemicals and drugs, such as acetaminophen, diquat, carbon tetrachloride, quinones, cyanide, polyhydroxyl polyether, methyl mercury, organotin and others, have been implicated in apoptosis (programmed cell death) and necrosis (toxic cell death).^{[7] [8] [9] [10] [11] [12] [13] [14]}

Most of the research on chemical induction of apoptosis is carried out with primary cultures of cell lines (neurons, thymocytes, carcinoma cells, leukemia cells, neuroblastoma, breast cancer cells, lymphoma and others); little has been published on the in vivo effects of chemicals on apoptotic cells in animal models and none in humans. Therefore, it was of interest to examine the effects of exposure to low levels of benzene, as well as through drinking water concentrations of up to 14 ppb on the apoptotic cell population, and to examine possible changes in the cell-cycle progression.^[7]

There is sufficient evidence for the carcinogenicity of benzene in humans; therefore, there is no safe level of exposure to this chemical or its metabolites. Published case reports, a case series, epidemiological studies, and both cohort and case-control studies have shown statistically significant associations between leukemia and occupational exposure to benzene and benzene-containing solvents.^{[15] [16]}

It is indicated that possibly 800,000 persons are exposed to benzene from coke oven emissions at levels greater than 0.1 ppm, and 5 million may be exposed to benzene from petroleum refinery emissions at levels of 0.1–1.0 ppm. Since then, numerous chemicals have been implicated in apoptosis (or programmed cell death) which arises from damage to DNA. We hypothesized that in individuals with a certain genetic make-up, benzene or its metabolites act as haptens, which may induce programmed cell death. The study involved a group of 60 male and female subjects who were exposed to benzene-contaminated water (at concentrations up to 14 ppm for a period of 3–5 years). For comparison, we recruited a control group consisting of 30 healthy males

and females with a similar age distribution and without a history of exposure to benzene. Peripheral blood lymphocytes of both groups were tested for percentage of apoptotic cell population, using flow cytometry. When exposed individuals were compared with the control group, statistically significant differences between each mean group were detected (27.5 ± 2.4 and 10 ± 2.6 , respectively), indicating an increased rate of apoptosis in 86.6% of exposed individuals ($P < 0.0001$, Mann–Whitney U-test). Flow cytometry analysis of apoptosis in a healthy control and a patient with CFS is shown in [Figure 6.4](#) .

We have already shown that benzene induction of apoptosis is caused by a discrete block of the cell cycle progression. Since it was shown that the ratio of apoptosis to mitosis is predictive of tumor growth, with increased apoptosis favoring positive prognosis, we analyzed our data and expressed them in terms of this ratio.^[5]

As shown in [Table 6.1](#) , about 10% of the chemically exposed individuals demonstrated a rate of mitosis

92

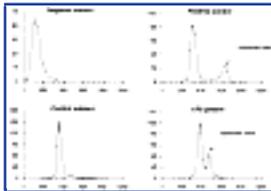

Figure 6-4 Enhanced apoptotic cell population in benzene-exposed CFS individuals. Flow cytometry analysis of apoptotic cell population in negative control cells (HL-60 leukemic cell line), positive control cells (HL-60 leukemic cells treated with the apogen camptothecin), control subjects and benzene-exposed individuals. PBL were isolated, cultured for 12 hours paraformaldehyde-fixed, F-dUTP-labeled and analyzed for apoptosis by flow cytometry.

greater than that of apoptosis, which is predictive of cancer development. Therefore, the tendency of normal cells to commit suicide when deprived of their usual growth factors, or of physical contact with their neighbors due to chemical exposure, is probably a built-in defense against metastasis. Prompt activation of apoptosis in tumor cells that leave their native tissue presumably eradicates many metastatic cells before they have a chance to proliferate. In cancer, it is tumor cells that neglect to sacrifice themselves or forget to die. Indeed, researchers increasingly describe cancer as a disease involving both excessive proliferation of cells and abandonment of their ability to die.

Cancer develops after a cell accumulates mutations in several genes that control cell growth and survival. When a mutation seems irreparable, the affected cell usually kills itself rather than risk becoming deranged and potentially dangerous. But if the cell does not die, it or its progeny may live long enough to accumulate mutations that enable it to divide uncontrollably and metastasize, to break away from the original tumor and establish masses at distant sites.

In many tumors, genetic damage apparently fails to induce apoptosis because the constituent cells have inactivated the gene that codes for the P53 protein. This protein, it will be recalled, can lead to activation of the cell's apoptotic machinery when DNA is injured by environmental agents such as benzene or its metabolites. Therefore, it is very important to study cell suicide in health and diseases.

CLINICAL APPLICATIONS

Apoptosis in autoimmune diseases

In cancer, it is the tumor cells that forget to die – in autoimmunity, immune cells fail to die when they are supposed to. Virtually all tissues harbor apoptotic cells at one time or another. Damaged cells usually commit suicide for the greater good of the body; when this does not occur, disease may develop. Autoimmunity occurs when the antigen receptors on immune cells recognize specific antigens on healthy cells and cause the cells bearing those particular substances to die. But true autoimmune diseases that involve apoptosis do exist. Under normal conditions, the body allows a certain number of self-reactive lymphocytes to circulate. These cells normally do little harm, but they can become overactive

TABLE 6-1 -- Ratio of apoptosis to mitosis in patients exposed to a carcinogenic chemical (benzene). In patients 11 and 14, the rate of mitosis is twice that of apoptosis, yielding a ratio of apoptosis to mitosis very close to 0.5. Others present ratios close to 1, which indicates normal homeostasis

| Sample no. | Percentage apoptosis | Percentage mitosis | Ratio of apoptosis/mitosis |
|------------|----------------------|--------------------|----------------------------|
| 1 | 34 | 18.3 | 1.9 |
| 2 | 29 | 25 | 1.2 |
| 3 | 48 | 46 | 1.05 |
| 4 | 47 | 52 | 0.9 |

| 20 | 10 | 11 | 0.9 |

through several processes. For instance, if these reactive lymphocytes recognize some foreign antigen such as microbes on food and haptenic chemicals, then exposure to that antigen causes them to become excited. If, due to molecular mimicry, these antigens are similar to normal tissues, the activated cells may expand their numbers and attack the healthy tissue, thus causing an autoimmune disease.^{[1] [17] [18]}

Autoimmune reactions usually are self-limited – they disappear when the antigens that originally set them off are cleared away. In some instances, however, the autoreactive lymphocytes survive longer than they should and continue to induce apoptosis in normal cells. Some evidence in animals and humans indicates that extended survival of autoreactive cells is implicated in at least two chronic autoimmune syndromes – systemic lupus erythematosus and rheumatoid arthritis. In other words, the lymphocytes undergo too little apoptosis, with the result that normal cells undergo too much.^{[19] [20]}

Apoptosis during viral infection

Disturbance in the regulation of apoptosis participates in a variety of diseases. Viral illnesses are among the diseases caused by apoptosis dysregulation. After entering a cell, viruses attempt to shut down the cell's ability to make any proteins except those needed to produce more virus. This act of stalling host protein synthesis is enough to induce many kinds of cells to commit suicide. If the host cell dies, the virus is also eliminated. Therefore, certain viruses have evolved ways to inhibit apoptosis in the cells they infect.

Epstein–Barr virus, which causes mononucleosis and has been linked to lymphomas in humans, uses a mechanism that has been seen in other viruses. It produces substances that inhibit apoptosis. Other viruses, such as P53, inactivate or degrade the induced apoptosis. Papillomavirus, a major cause of cervical cancer, is one example. Cowpox virus, a relative of which is used as the smallpox vaccine, is another. Both elaborate a protein that prevents proteases from carrying out the apoptotic program. Investigators interested in antiviral therapy are now exploring ways to block the activity

of the anti-apoptotic molecules manufactured by viruses.^[19]

Apoptosis in AIDS

Induction of apoptosis by viruses in healthy cells is believed to contribute to the immune deficiency found in AIDS patients. In these patients, infection with human immunodeficiency virus (HIV) causes T-helper cells to die. As T-helper cells gradually disappear, cytotoxic cells, such as NK cells, perish as well through apoptosis, since they cannot survive without the growth signals produced by T-helper cells. When the number of T-cells dwindles, so does the body's ability to fight infections, especially viral and parasitic. Researchers have shown that many more helper cells succumb than are infected with HIV. It is also highly probable that a large number of the cells probably die through apoptosis. Apparently, Fas plays a crucial role in this process.

Normally, T-cells make functional Fas only after they have been active for a few days and are ready to die. But helper cells from AIDS patients may display high amounts of functional Fas even before the cells have encountered an antigen. This display of Fas would be

expected to cause the cells to undergo apoptosis prematurely whenever they encounter Fas ligand on other cells (such as on T-cells already activated against HIV or other microbes). In addition, if the primed cells encounter the antigen recognized by their receptors, they may trigger their own death.

It is also possible that oxygen free radicals trigger the suicide of virus-free T-cells. These highly reactive substances are produced by inflammatory cells drawn to infected lymph nodes in HIV patients. Free radicals can damage DNA and membranes in cells. They will cause necrosis if they do extensive damage, but they can induce apoptosis if the damage is more subtle. In support of the free-radical theory, researchers have found that molecules capable of neutralizing free radicals will prevent apoptosis in T-cells obtained from AIDS patients.^{[19] [20]}

Therapies with anti-apoptotic medication, such as Trolox, a water-soluble analog of vitamin E which prevents oxidative stress, and pyrrolidine dithiocarbamate, a potent inhibitor of nuclear factor kB (NF-kB), are now the focus of AIDS and autoimmune disease studies.^{[21] [22]}

Apoptosis in the heart and brain

In contrast to cancer, where cells forget to die and insufficient apoptosis occurs, excessive apoptosis accounts for much of the cell death that follows heart attacks and strokes. In the heart, vessel blockage decimates cells that were fully dependent on the vessel. Those cells die by necrosis, partly because they are catastrophically starved of the oxygen and glucose they need to maintain themselves and partly because calcium

ions, which are normally pumped out of the cell, rise to toxic levels.

Over the course of a few days, cells surrounding the dead zone – which initially survive because they continue to receive nourishment from other blood vessels – can die as well. Later on, however, many cells die by necrosis after being overwhelmed by the destructive free radicals that are released when inflammatory cells swarm into the dead zone to remove necrotic tissue. The less injured cells commit suicide by apoptosis.

If the patient is treated by restoring blood flow, still more cells may die by necrosis or apoptosis, because reperfusion leads to a transient increase in the production of free radicals. Similarly, in strokes due to inflammation, release of such neurotransmitters as glutamate lead to necrosis and apoptosis. Understanding of the factors that lead to the tissue death accompanying heart attack, stroke, and reperfusion has led to new ideas for treatment. Notably, cell death might be limited by drugs and other agents that block free-radical production or inhibit proteases.

Apoptosis also accounts for much of the pathology seen in such diseases as Alzheimer's, Parkinson's, Huntington's and amyotrophic lateral sclerosis (Lou Gehrig's disease), which are marked by the loss of brain neurons. Elevated apoptosis in these neurological diseases seems to be related to lack of production of the nerve growth factor and to free radical damage. It seems likely that a combination of such factors could cause many cells to destroy themselves. Manipulation of this process of cell killing may help in treating these neurological diseases. In fact, studies in animal models imply that long-term delivery of nerve growth factors could protect against programmed cell death in these conditions. Therefore, a greater understanding of the mechanisms involved in cell death should greatly enhance those important steps.^{[17] [21] [23]}

CONCLUSIONS

Apoptosis and cell proliferation play an important role in development, differentiation, homeostasis, and aging.^{[2] [3] [4] [5] [6]} The balance established between these two processes depends on a variety of growth and death signals which are influenced by diet, nutrition, lifestyle and other environmental factors.

When the equilibrium between life and death is disrupted by aberrant signals (e.g. low levels of antioxidants in the blood or tissue cells), either tissue growth or atrophy occurs.

Under normal conditions with optimal nutritional factors, tissue homeostasis is sustained by balancing the effects of mitosis and apoptosis. The importance of this

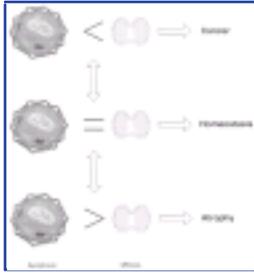

Figure 6-5 Balance or imbalance between the rate of apoptosis and mitosis determines tissue homeostasis, atrophy, cell proliferation, and development of cancer.

balance can clearly be seen when one of these processes becomes predominant (see [Fig. 6.5](#)).

During viral or chemical exposure and in pre-neoplastic tissue, the number of cells undergoing apoptosis increases, possibly to compensate for an increase in proliferation.

As the cell loses functional tumor-suppressor genes (the P53), the propensity to undergo apoptosis decreases and the population of tumor cells grows. Inefficient immune function such as low NK activity due to stress or antioxidant deficiencies may contribute further to this mitosis and apoptosis imbalance, which results in additional tumor cell growth.

Chapter 7 - Bacterial overgrowth of the small intestine breath test

Stephen Barrie ND

INTRODUCTION

Bacterial overgrowth of the small intestine is a serious digestive disorder that is treatable after proper diagnosis. Although widespread, it is frequently unsuspected in cases of chronic bowel problems and carbohydrate intolerance because its symptoms often mimic other disorders.^[1]

The incidence of bacterial overgrowth of the small intestine increases with age, particularly in people aged 80 years and more.^[2] Elderly patients may develop mal-absorption secondary to bacterial overgrowth. It has been suggested as the major cause of clinically significant malabsorption in the elderly and linked to the “failure to thrive syndrome” seen in older patients.^[3]

Breath testing is a very useful procedure for distinguishing bacterial overgrowth of the small intestine from other problems with similar symptoms.

Symptoms of bacterial overgrowth

By inhibiting proper nutrient absorption, bacterial overgrowth of the small intestine can lead to systemic disorders such as altered permeability, anemia and weight loss, osteomalacia and vitamin K deficiency.^[3] Bacterial overgrowth of the small intestine may also contribute to maldigestion and malabsorption. It frequently is a complication of parasitic infection. Patients with pancreatic insufficiency secondary to chronic pancreatitis are prone to developing bacterial overgrowth of the small intestine.^[4]

As can be seen from [Table 7.1](#) , the signs and symptoms

TABLE 7-1 -- Symptoms of bacterial overgrowth

-
- Abdominal cramps

 - Bloating

 - Diarrhea

 - Gas

 - Steatorrhea

 - Vitamin B₁₂ malabsorption and deficiency

 - Weight loss
-

of bacterial overgrowth are commonly seen in a clinical practice.

Causes of bacterial overgrowth

Normally, far fewer bacteria inhabit the small intestine than the ample growth found in the colon. Gastric acid secretion and intestinal motility keep the small intestine relatively free of bacteria. A wide range of abnormalities and malfunctions, however, can encourage bacteria to multiply in the small intestine.

The most common causes relate to a decrease in the production of hydrochloric acid or pancreatic enzymes, thereby creating an unsterile environment for the small intestine. Other causes of bacterial overgrowth of the small intestine include intestinal obstructions caused by Crohn's disease, adhesions, radiation damage and lymphoma (see [Table 7.2](#)). Many years may pass between the development of diverticula and symptoms of bacterial overgrowth.^{[5] [6]}

EFFECTS ON THE BODY

Bacterial flora function as small biochemical factories, which explains most of the effects of bacterial overgrowth of the small intestine.^[7] The flora contain very high concentrations of different enzymes which act upon substrates presented through the diet. Some of these enzymes produce toxic fermentation products normally not found in the small intestine.

Gut flora metabolize biliary steroids, which contribute to the diarrhea common in bacterial overgrowth and which may contribute to colon cancer. As can be seen in [Table 7.3](#), overgrowth of flora in the small intestine can have a wide variety of damaging effects to the intestines and health.

TESTING METHODS

While intubation and culture of intestinal aspirates are the standard for determining bacterial overgrowth of the

TABLE 7-2 -- Causes of bacterial overgrowth of the small intestine

-
- Achlorhydria, hypochlorhydria or drug-induced hypoacidity

 - Crohn's disease

 - Diabetes mellitus

 - Giardiasis and other parasitic infections

 - Immunodeficiency syndromes (particularly sIgA)

 - Intestinal adhesions

 - Systemic lupus erythematosus

 - Malnutrition

 - Chronic pancreatitis

 - Reduced motility in elderly patients

 - Scleroderma

 - Stasis due to structural changes – diverticulitis, blind loops, radiation damage

TABLE 7-3 -- Health effects of floral overgrowth in the small intestine

-
- Inactivate pancreatic and brush border digestive enzymes due to production of proteases

 - Destroy dietary flavonoids, which serve as important natural antioxidants but are rapidly broken down and hydrolyzed by gut flora

 - Hydrogenate polyunsaturated fatty acids

 - Deconjugate bile salts

 - Consume vitamin B₁₂

 - Produce vitamin B₁₂ antagonists

 - Produce nitrosamines

small intestine, the less invasive breath trace-gas analysis is an attractive and effective alternative. [\[5\]](#) [\[8\]](#) [\[9\]](#) [\[10\]](#)

Endoscopy and intestinal fluid culture have the advantages of providing a definitive diagnosis, but the method is expensive and requires invasive intubation. In addition, it assesses only one or a few sites and may miss flora elsewhere, leading to false-negative results.

On the other hand, hydrogen/methane breath tests are simple to administer and offer greater patient comfort and convenience. In addition, these breath tests have good sensitivity and specificity.

However, hydrogen/methane breath tests are not effective in patients who don't produce hydrogen or methane in response to carbohydrate challenge dose (less than 5%).

The bacterial overgrowth of the small intestine breath test uses a challenge dose of lactulose or glucose that the patient takes after an overnight fast. If bacteria exist in the small intestine, the bacteria will ferment the challenge substance and produce increases in breath hydrogen and methane. Each substance has advantages and disadvantages.

Lactulose challenge

Lactulose, a synthetic disaccharide not absorbed by the digestive system, produces hydrogen after contact with bacteria in the gut.^[11] In the lactulose challenge test, patients collect a fasting breath sample, drink a 10g lactulose solution, and collect breath samples every 15 minutes for 2 hours.^[1]

Advantages

- Good sensitivity, because the challenge dose is carried farther toward the jejunum than glucose, so it checks for bacterial overgrowth farther down the intestinal tract
- Good specificity for bacterial overgrowth of the small intestine
- Suitable for patients with diabetes, hypoglycemia, and other blood sugar disorders because lactulose isn't absorbed.

Disadvantages

- Some difficulty in interpretation due to the possible late peak of colonic fermentation of lactulose
- Possible mild discomfort or diarrhea in some patients, although usually at higher doses than those used in the breath test.

Glucose challenge

Glucose is normally absorbed before it reaches the large intestine. If bacteria are present in the small intestine, the bacteria will metabolize glucose before it can be absorbed, producing breath gases. This test requires ingestion of a 75g glucose solution.

Advantages

- Good sensitivity and specificity
- Easy to interpret because patients who don't have bacterial overgrowth of the small intestine absorb glucose and don't produce an increase in breath gases
- Can be performed at the same time as a glucose tolerance test (if both are medically indicated).

Disadvantages

- Test is not suitable for patients with diabetes, hypoglycemia, or other blood sugar disorders
- If the presence of yeast in the colon is regarded as a medical condition, ingestion of sugar may be inadvisable due to its potential for promoting yeast growth
- Sensitivity is reduced for distal ileum activity of bacterial overgrowth.^[12]

Interpreting the results

Baseline responses

The typical fasting breath sample contains less than 10 ppm of breath hydrogen or methane. A high breath hydrogen or methane level greater than 20ppm is likely in patients with bacterial overgrowth.

Because the fasting breath hydrogen level can be suppressed by methanogenic bacteria, testing for both hydrogen and methane is more sensitive than testing for hydrogen only.^[1]

Lactulose response

The lactulose challenge typically causes a two-phase response. During the test, hydrogen increases early as lactulose comes into contact with bacteria in the small intestine. This rapid response distinguishes bacterial overgrowth from normal colonic flora, which produce a later, more prolonged increase in breath hydrogen.^{[1] [12]} The test monitors breath gas during the first 2 hours, so colonic fermentation either is not detected or is seen as a rise in the final breath specimens.

A breath hydrogen peak greater than 12 ppm above the fasting level within 30 minutes of ingesting lactulose and preceding the colonic excretion response by 15 minutes is considered indicative of bacterial overgrowth of the small intestine.^{[1] [12] [13]}

Glucose response

With the glucose challenge, a rise of 12 ppm in breath hydrogen within 1 hour suggests bacterial overgrowth.^[1] The 1 hour period avoids confusion between an increase in

breath hydrogen due to bacterial fermentation and early colonic generation of breath hydrogen due to rapid transit.^[14]

Combining the observation of elevated fasting breath hydrogen (greater than 20ppm) and a positive hydrogen response (greater than 15ppm) reduces the chance of false-positive responses.^[1]

False-positives

The majority of false-positives reported in bacterial overgrowth of the small intestine breath test can be eliminated if patients follow proper instructions and preparation.^[1] Typical problems include:

- Eating high-fiber foods within 24 hours of the test. This elevates the level of fiber in the colon at the beginning of the test and increases breath hydrogen production. No starches except rice should be eaten the night before the test. A protein and rice meal, such as beef, poultry, fish or tofu, should be eaten the night before. Fiber supplements should be discontinued 24 hours before the test.
- Smoking. Smoking in the area of the test produces high hydrogen levels and unstable baseline results. Breath samples should not be collected where patients are exposed to tobacco smoke.
- Sleeping. Sleeping during the test increases both hydrogen and methane levels due to the slow-down in removal of breath trace gases from blood.

False-negatives

False-negative results can be caused by severe diarrhea or recent use of an antibiotic, laxative, or enema. Any of these may inhibit bacterial fermentation of carbohydrates and thus production of breath trace gases.^{[15] [16] [17] [18] [19]}

To reduce the possibility of false-negative results, patients should wait at least 1 week following completion

of antibiotic treatment or after recovery from severe diarrhea to re-establish colonic flora. Hyperacidic colon contents do not affect the lactulose challenge because the test reports bacterial fermentation in the small intestine.^[1]

CLINICAL APPLICATION

Once bacterial overgrowth of the small intestine has been diagnosed, two steps are necessary:

- treat the overgrowth symptoms

- investigate the underlying causes to keep bacterial overgrowth from recurring.

Antimicrobials

While tetracycline (250mg four times daily) is the traditional antibiotic choice, research indicates that up to 60% of patients with bacterial overgrowth no longer respond to it.^[5] Several broad-spectrum antibiotics have been used effectively. Augmentin (250–500mg three times daily) is generally effective and well tolerated. Acceptable alternatives include the cephalosporin Keflex (250mg four times daily) and Flagyl (250 mg three times daily).^[5]

Antimicrobials such as penicillin, ampicillin, neomycin, kanamycin, and oral aminoglycosides are ineffective in treating bacterial overgrowth because of their poor activity against anaerobes. A non-absorbable rifamycin derivative, Rifaximin, has been used effectively against anaerobic intestinal bacteria in Italy.^[20]

Several natural antimicrobials may be useful in the treatment of bacterial overgrowth syndromes. These include:

- bismuth, a broad-spectrum antimicrobial absorbed in the gut
- bentonite, which inhibits bacterial growth and activity, absorbing many by-products that bacteria produce
- berberine, an alkaloid from *Hydrastis canadensis*, with antimicrobial, antifungal and antiprotozoan activity
- herbal mixtures containing gentian and sanguinaria, which have very strong broad-spectrum antimicrobial activity.

Nutrition

A low-starch or low-sugar diet may be helpful in reducing diarrhea and steatorrhea. Whether starch or sugar needs to be restricted depends on the location of bacterial overgrowth. If bacteria are in the jejunum, patients tend to be more intolerant of sugars. If bacteria are in the ileum, starch may affect patients more.

Soluble fiber may exacerbate abnormal gut ecology. A diet free of cereal grains is generally helpful. Potential deficiencies of nutrients such as vitamin B₁₂, vitamin K, and calcium should be considered (see [Ch. 19](#)).^[5]

Treatment of underlying causes

Bacterial overgrowth of the small intestine may recur if the root causes are not eradicated ([Table 7.2](#)). Hypochlorhydria and achlorhydria limit the body's ability to utilize nutrients from food and supplements. With low gastric acid, ingested food is not adequately sterilized, and normal colonic bacteria may move upstream into the small intestine, causing the return of bacterial overgrowth. Numerous studies have shown that acid secretion decreases with age, possibly due to atrophy of various digestive functions (see [Ch.19](#)). Betaine hydrochloride may be useful in replacing hydrochloric acid in

patients not producing sufficient amounts.

A sluggish digestive tract keeps food lingering in the intestinal system. Reduced motility may be caused by inadequate water intake, a low-fiber diet, or aging. Addition of insoluble fiber helps to create bulk and encourage motility.

SUMMARY

Bacterial Overgrowth of the Small Intestine Breath Test is a useful procedure for patients with chronic gastrointestinal problems. [Table 7.4](#) lists the most appropriate clinical indications.

TABLE 7-4 -- Clinical conditions for the bacterial overgrowth of the small intestine breath test

-
- Patient has abdominal gas, bloating or diarrhea, usually within 1 hour of eating

 - Patient cannot tolerate carbohydrates or starchy foods, fiber supplements and/or friendly flora supplements

 - Evidence of hypochlorhydria and/or low transit time as indicated by patient history or the comprehensive digestive stool analysis

 - When CDSA indicates maldigestion or malabsorption, patient is treated but symptoms persist. Also, when the CDSA suggests alkaline pH or dysbiosis

 - Lactose intolerance is suspected but ruled out by lactose intolerance breath test

 - Patient has abdominal symptoms coupled with unexplained symptoms such as vitamin B₁₂ deficiency, chronic weight loss or chronic skin problems

Chapter 8 - Cell signaling analysis

Aristo Vojdani PhD MT

INTRODUCTION

Signaling pathways in normal cells consist of growth and controlling messages from the outer surface deep into the nucleus. In the nucleus, the cell cycle clock collects different messages, which are used to determine when the cell should divide. Cancer cells often proliferate excessively because genetic mutations cause induction of stimulatory pathways and issue too many “go ahead” signals, or the inhibitory pathways can no longer control the stimulatory pathways.^[1]

Over the past 5 years, impressive evidence has been gathered with regard to the destination of stimulatory and inhibitory pathways in the cell. These pathways converge on a molecular apparatus in the cell nucleus that is often referred to as the cell cycle clock. The clock is the executive decision-maker of the cell; apparently, it runs amok in virtually all types of human cancer. In a normal cell, the clock integrates the mixture of growth-regulating signals received by the cell and decides whether the cell should pass through its life cycle. If the answer is positive, the clock leads the process.

THE CELL CYCLE

A scheme of the classical cell cycle is shown in [Figure 8.1](#). The cell cycle compartments are drawn such that their horizontal position reflects their respective DNA content. Cells that contain only one complement of DNA from each parent (2C) are referred to as diploid cells. Cells that have duplicated their genome, and thus have 4C amounts of DNA, are called tetraploid cells.

The cell cycle is classically divided into the following phases:

- G_0
- G_1
- S

- G₂
- M.

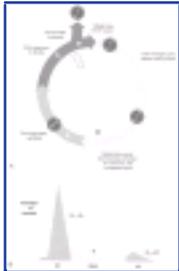

Figure 8-1 Stages of cell cycle (G₀, G₁, S, G₂, and M phases) (A) and DNA histogram (B) generated by flow cytometry.

The cell cycle phase of G₁ was historically considered to be a time when diploid (2C) cells had little observable activity. Since this time precedes DNA synthesis, the term Gap 1 (G₁) was coined. We now know that there is quite a bit of transcription and protein synthesis during this phase. At a certain point in the cell's life, the DNA synthetic machinery turns on. This phase of the cell's life is labeled "S" for synthesis. As the cell proceeds through this phase, its DNA content increases from 2C to 4C. At the end of S, the cell has duplicated its genome and now is in the tetraploid state. After the S phase, the cell again enters a phase that was historically thought to be quiescent. Since this phase is the second gap region, it is referred to as G₂. In the G₂ phase, the cell is producing the necessary proteins that will play a major role in cytokinesis. After a highly variable amount of time, the cell enters mitosis (M). DNA content remains constant at 4C until the cell actually divides at the end of telophase.

The enlarged parent cell finally reaches the point where it divides in half to produce its two daughters, each of which is endowed with a complete set of chromosomes. The new daughter cells immediately enter G₁ and may go through the full cycle again. Alternatively, they may stop cycling temporarily or permanently.^{[2] [3] [4]}

FLOW CYTOMETRY TO ASSESS CELL CYCLE STATUS

Flow cytometry is a method of measuring cell properties as they "flow" through a detector while being illuminated with intense light. Tissues are generally disaggregated into single-cell suspensions and stained with one or more fluorescent dyes. The cells are forced to flow within a sheath of fluid, eventually being intersected and interrogated by an intense light source such as a laser beam. As the cell enters the laser beam, it scatters light in all directions. The measurement of light scattered in the forward direction yields information on the particle's size. Scattered light at right-angles to the incident light beam provides information on the internal granularity of the cell. If the cell has been stained with one or more fluorescent dyes, a correlated measurement of more

than one cellular parameter can be achieved.

CLINICAL APPLICATION

Patients exposed to carcinogenic chemicals and patients with chronic fatigue syndrome

To determine whether peripheral blood lymphocytes (PBL) isolated from chronic fatigue syndrome (CFS) individuals and chemically exposed patients represent a discrete block in cell cycle progression, PBL isolated from CFS and control individuals were cultured, harvested, fixed, PI-stained, and analyzed by flow cytometry. The non-apoptotic cell population in PBL isolated from CFS individuals consisted of cells arrested in the late S and G₂/M boundaries, as compared with healthy controls. The arrest was characterized by increased S and G₂/M phases of the cell cycle (from 9 to 33% and from 4 to 21%, respectively) ([Table 8.1](#) , [Fig. 8.2](#)) at the expense of G₀/G₁ . Such an abnormality in cell cycle progression is an indication of abnormal mitotic cell division in patients who have been exposed to chemicals and who suffer from chronic fatigue syndrome. From these results, we concluded that PBLs of patients with chemical exposure

TABLE 8-1 -- Percentage of different phases of cell cycle in healthy controls and patients exposed to chemicals

| Phase | Healthy controls | Chemically exposed |
|--------------------------------|------------------|--------------------|
| G ₀ /G ₁ | 88.6 ± 1.4 | 51.7 ± 2.4 |
| S | 8.6 ± 1.2 | 33.2 ± 4.3 |
| G ₂ /M | 3.6 ± 0.82 | 21.0 ± 2.6 |

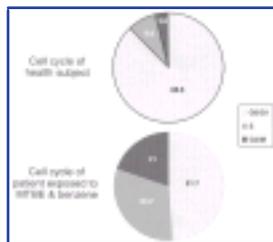

Figure 8-2 Cell cycle analysis of peripheral blood lymphocytes from healthy controls (A) and patients exposed to benzene (B). Note that in patients' samples, the majority of cells switched from G₀/G₁ to S and G₂/M phases.

and chronic fatigue syndrome grow inappropriately, not only because the signaling pathways in cells are perturbed, but also because the cell cycle clock becomes deranged and stimulatory messages become greater than the inhibitory pathways. ^[5] ^[6]

However, in order to limit cell proliferation and avoid cancer, the human body equips cells with certain back-up systems that guard against runaway division. One such back-up system present in lymphocytes of CFS patients provokes the cell to undergo apoptosis. This programmed cell death occurs if some of the cell's essential components are deregulated or damaged. For example, injury to chromosomal DNA can trigger apoptosis.^{[1] [5] [6]}

Chapter 9 - Comprehensive digestive stool analysis

Stephen Barrie ND

INTRODUCTION

Nutrition and digestion are undeniably important to good health. We are, essentially, what we eat and then absorb. Over the long haul, excellent health is impossible without good nutrition. However, without adequate breakdown and assimilation, even the best diet offers little help. Additionally, incomplete or faulty digestive processes may lead to a variety of chronic disorders.

Gastrointestinal (GI) disorders have a major impact on health. One recent study found that, during a 3 month period, nearly 70% of American households experienced one or more gastrointestinal symptoms.^[1] Maldigestion, malabsorption and abnormal gut flora and ecology, as well as many complex chronic illnesses and symptoms, lie at the root of most common GI complaints. Thus, nutrition and digestive processes are central to long-term health. The comprehensive digestive stool analysis (CDSA) provides clinicians with a critical tool for evaluating the status of the GI tract.

This assay helps to pinpoint imbalances, to provide clues about current symptoms and to warn of potential problems should the imbalances progress. With an accurate assessment, custom-tailored treatment can be easily applied, greatly increasing the chances for therapeutic success.

The CDSA is used in the evaluation of various gastrointestinal symptoms or systemic illnesses that may have started in the intestine. Because illnesses are often not discernible from symptoms, the CDSA is a valuable screen for all patients and frequently reveals critical imbalances previously unsuspected.

THE GASTROINTESTINAL TRACT

As most food molecules cannot be absorbed or utilized in their native state, a primary function of the gastrointestinal system is to break down complex molecules and absorb

nutrients. This is a complex process, taking place primarily in the gastrointestinal mucosa, where the

battle for health – to absorb nutrients and exclude toxins – is fought. The gastrointestinal mucosa does this through a combination of physical barriers to diffusion, mucosal fluids and active immune processes.^[2]

The digestive process

Mouth

Teeth break up food and mix it with saliva. Saliva in turn helps to form a bolus and protects the pharyngeal and esophageal mucosa, primarily with secretory IgA antibodies. Saliva also helps to remineralize the teeth with calcium salts. The enzymes lingual lipase, salivary amylase and ptyalin initiate fat and starch digestion.^[3]

Stomach

The stomach mechanically churns food, breaks up and emulsifies fats and exposes molecules to additional enzymes. In doing this, it produces 1–2 L of gastric juices per day.^[4]

Gastric juice has several components:

- Hydrochloric acid is secreted by the parietal cells. It activates pepsinogens to convert to pepsin and renders some minerals (e.g. calcium and iron) more absorbable. Stomach acid also prevents bacterial overgrowth by creating an essentially sterile environment (a potential exception is *Helicobacter pylori*).
- Mucus forms an acid- and pepsin-resistant coating of the stomach lining.
- Gastric lipase begins the hydrolysis of fats.

Small intestine

Most digestion and absorption takes place in the small intestine and is mediated by pancreatic enzymes and bile.^[4] The process involves several steps:

1. Secretion of pancreatic juices (about 2.5 L/day), which is controlled by the vagus nerve and the duodenal hormones secretin and cholecystinin. Hormone production, in turn, is stimulated by the presence of fat, protein and acid chyme.
2. Secretion of bicarbonate which neutralizes stomach acid.
3. The proteases trypsinogen, chymotrypsinogen and procarboxypeptidase are activated to trypsin, chymotrypsin and carboxypeptidase. These enzymes digest proteins to oligopeptides and amino acids.

4. Amylase splits starch to maltose.
5. Lipase hydrolyzes diglycerides and triglycerides, producing long-chain fatty acids.
6. Bile secreted by the liver (about 700 ml daily) is stored in the gall bladder. Bile salts solubilize and emulsify fats, enabling enzymatic hydrolysis.

The crypts of Lieberkühn of the intestinal mucosa also produce immunoglobulins (which protect the gastric mucosa from microbes) and small amounts of digestive enzymes such as peptidase and disaccharidases.

Large intestine

A primary role of the large intestine is the absorption of water, about 1 L daily. The large intestine also provides an environment for microbial fermentation of soluble fiber, starch, and undigested carbohydrates.

Anaerobic colonic fermentation results in the production of short-chain fatty acids (SCFAs), the main energy source for colonic epithelial cells. It is these SCFAs, in combination with amines derived from protein degradation, that provide buffering and create the slightly acidic pH of fecal matter.

Absorption of specific nutrients^[5]

Carbohydrate digestion

Salivary amylase initiates starch digestion in the mouth. However, this activity is short-lived as the enzyme is denatured by low gastric pH. In the duodenum, oligosaccharides and starch polymers undergo hydrolysis by pancreatic amylase. Specific disaccharides are hydrolyzed by brush border enzymes (lactase, maltase, sucrase) located on the enterocyte microvilli. Resulting monosaccharides are absorbed by specific sodium-dependent transport carrier mechanisms.

Protein digestion

Gastric acid and pepsin initiate the digestion of dietary protein. This is followed in the duodenum by hydrolysis into oligopeptides and amino acids by proteolytic pancreatic enzymes. Final protein digestion is accomplished by intestinal brush border peptidases. Dipeptides, tripeptides, free amino acids, and other short-chain peptides are then absorbed.

Fat digestion

Processing of dietary fat is the most complex of the digestive and absorptive processes. Fat is water-insoluble, so the GI tract must transform large water-insoluble particles into a soluble, absorbable form.

Digestion begins in the mouth with secretion of lingual lipases. The stomach disperses

fat globules into an evenly divided phase, called chyme. Pancreatic enzymes then split triglycerides into fatty acids and monoglycerides, which then combine with bile acids and phospholipids to form micelles. This process transforms water-insoluble lipids into a water-soluble form absorbed in the proximal small intestine.

After absorption, fatty acids and other lipids are re-esterified in the intestinal cell to form chylomicrons, which are then secreted into the lymphatic system. Medium-chain triglycerides can be absorbed directly in the jejunum without forming chylomicrons.

DIGESTIVE ABNORMALITIES^[6] ^[7] ^[8]

As discussed in [Chapters 19](#) and [55](#) , inadequate digestion and absorption of nutrients is a far more common problem than is generally recognized by clinicians. Not only does ingestion of even the best nutritional substances provide little benefit when breakdown and assimilation are inadequate, but also incompletely digested macromolecules can be inappropriately absorbed into the systemic circulation. This can lead to food allergy, immune complex deposition diseases, and toxic overload of the liver.

Maldigestion

Hypochlorhydria

Gastric acid secretion is a fundamental step in digestion and assimilation. Many clinical conditions originate with decreased gastric acidity ([Tables 9.1](#) and [9.2](#)). Acid secretion decreases with age, and low stomach acidity is found in more than 50% of patients over the age of 60.^[22] ^[23] Researchers speculate that malabsorption of nutrients in the elderly is due to atrophy of various digestive organs because of hypochlorhydria.^[24]

Gastric acid has a fundamental role in activating pancreatic proenzymes and converting them from inactive precursors (chymotrypsinogen, trypsinogen, etc.) to their active forms (chymotrypsin, trypsin). Intestinal peristalsis and gastric acid secretion normally prevents excessive growth of bacteria in the small intestine. Bacterial overgrowth appears to interfere with fat digestion and irritate the intestinal mucosa.

Pancreatic exocrine insufficiency

Inadequate delivery of pancreatic lipases and proteases to the small intestine can lead to inadequate breakdown

TABLE 9-1 -- Symptoms of low gastric acidity^[9] ^[10]

- Bloating, belching, burning, and flatulence immediately after meals
 - Sense of fullness after eating
-

- Indigestion, diarrhea, or constipation
- Systemic reactions after eating
- Nausea after taking supplements
- Rectal itching
- Weak, peeling or cracked fingernails
- Dilated capillaries in cheeks and nose (in non-alcoholics)
- Post-adolescent acne
- Iron deficiency
- Chronic intestinal infections, parasites, yeast, bacteria
- Undigested food in stool

of fats and protein. The net effect is a failure to obtain nourishment from protein, carbohydrate and fiber foods and an unhealthy environment for the flora of the large colon. It has been argued that even small decreases in pancreatic output can contribute substantially to maldigestion and have far-reaching effects in chronically ill patients.

Malabsorption

Malabsorption is characterized by abnormal fecal excretion of fat (steatorrhea) and variable malabsorption of fats, fat-soluble vitamins, other vitamins, proteins, carbohydrates, minerals and water. Common causes are listed in [Table 9.3](#) .

Important clinical diseases strongly associated with and possibly causal of mucosal malabsorption are listed in [Table 9.4](#) .

TABLE 9-3 -- Common causes of malabsorption

-
- Defective protein, fat, or carbohydrate breakdown
-
- Inadequate solubility of fatty acids (inadequate bile salts)
-
- Rapid transit (e.g. diarrhea), which doesn't allow sufficient time for absorption
-
- Mucosal cell abnormality and inadequate surface area
-
- Intestinal infection

TABLE 9-4 -- Diseases associated with mucosal malabsorption

-

Clinical considerations of malabsorption

The signs and symptoms of malabsorption, which increases with age, are varied.^[25] Amino acids, carbohydrates, fats, vitamins, and trace elements may be absorbed by

different processes, so an individual may suffer malabsorption of one nutrient but not of others. In fat malabsorption, essential fatty acid deficiency may result in addition to the loss of the highest dietary source of calories.

MICROBIOLOGY

Bacteria

Because the oxygen content of the colon is low, the vast majority of bacteria are anaerobes. There are, however, hundreds of varieties of anaerobic flora in vastly different concentrations, all growing very slowly. The significance of most of these flora remains largely unknown. Most researchers, therefore, utilize the aerobic flora as an indication of bacterial health. Two frequently identified organisms, *Lactobacilli* sp. and *Escherichia coli*, are employed as indicators of eubiosis or healthy overall flora. Many researchers believe these two organisms have intrinsic benefit and aid digestion while helping to prevent overgrowth of abnormal flora.

Bacterial cultures also identify and show potential pathogens. The term “potential pathogens” is used because individuals may harbor traditional pathogens and appear healthy, while others harbor weak or questionable pathogens and have gastrointestinal complaints. While not necessarily causing acute GI tract disturbances, some intestinal bacteria may be involved in the etiology of various chronic or systemic problems. These include *Klebsiella*, *Proteus*, *Pseudomonas* and *Citrobacter*. These organisms may be involved, through molecular mimicry, in various autoimmune diseases. This has been reported in diabetes mellitus, meningitis, thyroid disease, ulcerative colitis, arthritis, ankylosing spondylitis and systemic lupus.^{[26] [27]} Some potential pathogens may cause clinical and subclinical malabsorption of nutrients and increase bowel permeability to large macromolecules. A number of clinicians speculate that this is directly related to the etiology of food and chemical sensitivity and intolerance.

Whipple’s disease, although rare, presents an interesting model of the interaction of bacterial infection, absorptive processes and systemic health. This disease is known to be caused by an unusual bacteria which resists attempts to culture it in vitro. Symptoms include severe alterations in intestinal permeability and chronic fatigue.^[28] There is strong scientific support for the profound relation between GI tract flora, malabsorption, permeability changes and overall health.

Yeast

In the last few years, colonic yeast infections have

TABLE 9-5 -- Diseases associated with *Candida albicans* overgrowth^{[30] [31] [32] [33] [34] [35]}

-
- Food allergy
-
- Migraine headache
-
- Irritable bowel syndrome
-

- Asthma

- Indigestion and gas

- Depression related to PMS

- Vaginitis

- Chronic fatigue

attracted attention and controversy as a possible cause of chronic complex illness.^[29] Many investigators suggest that an intestinal overgrowth of *Candida albicans* (and other intestinal yeast) may be involved in several diseases, as listed in [Table 9.5](#) .

Although others have dismissed these claims as speculation, part of the problem is focusing on the terms “pathogen” and “commensal”. It may be more accurate to use the terms “strong pathogen” and “weak pathogen”. While it is obvious that yeasts are not strong pathogens, large amounts of weak pathogens are also a problem. A significant and surprising amount of peer-reviewed literature supports yeast as a weak pathogen.^{[36] [37] [38]}

While the normal GI tract harbors small amounts of yeast, overgrowth may occur as a consequence of the wide use of antibiotics, corticosteroids, birth control pills and increased dietary carbohydrates.^[39] Odds’ text on *Candida* summarized more than 20 published studies which found that patients had a frequency of *C. albicans* in their feces more than twice as often as normal controls.^[40] One study reported that chronic diarrhea and abdominal cramps may be caused by large numbers of dead or damaged yeast, as found in feces.^[41] Other research indicates *Candida* as a cause of colitis in patients with AIDS, neoplastic disease and renal transplants.^{[42] [43] [44]}

While the yeast pathogenicity debate continues, high-quality laboratory work is essential. Yeast may be observed directly via a microscope or indirectly through a culture. Both are necessary for proper analysis.

Dysbiosis

Dysbiosis is the state of disordered microbial ecology that causes disease. It may exist in the oral cavity, gastrointestinal tract or vaginal cavity. In dysbiosis, organisms of low intrinsic virulence, including bacteria, yeasts and protozoa, induce disease by altering the nutrition or immune responses of their host.^[45] The major causes of intestinal dysbiosis are given in [Table 9.6](#) .

The concept of intestinal flora having a major impact on human health has increasingly gained support, particularly as the widespread use of antibiotics has been observed to disrupt the normal flora ([Fig. 9.1](#) shows the microecology relationships). Published research has implicated

Figure 9-1 Microecology relationships.

TABLE 9-6 -- Major causes of intestinal dysbiosis^[45] ^[46] ^[47]

- Poor diet/nutritional status (high fat, simple carbohydrates)
- Stress
- Antibiotic/drug therapy
- Decreased immune status
- Decreased gut motility
- Maldigestion
- Intestinal infection
- Presence of xenobiotics
- Increased intestinal pH

intestinal dysbiosis as contributing to vitamin B₁₂ deficiency, steatorrhea, irritable bowel syndrome, inflammatory bowel disease, autoimmune arthropathies, colon and breast cancer, psoriasis, eczema, cystic acne and chronic fatigue.^[48] ^[49] ^[50] ^[51] ^[52] ^[53]

GI tract and arthritis

Researchers increasingly acknowledge that there is a link between digestive processes and arthritis. In patients with altered bowel anatomy, chronic bacterial overgrowth can lead to the formation of circulating immune complexes and synovitis.^[54] Changes in bowel permeability due to local gut inflammation may expose the host immune system to microbial or food antigens and even bacterial translocation.^[55] ^[56] In some cases, toxins derived from enteric organisms (e.g. *Clostridium difficile*) may play a direct role in the induction of arthritis.

Food allergy

Food allergy is a well-documented problem, although its prevalence, testing methods

and treatment modalities are controversial. Some researchers have proposed that food allergy is not an immunological disease but a disorder of bacterial fermentation in the colon. The combined mechanisms of reduced gut enzyme concentrations, imbalanced bacterial flora and increased permeability may account for many cases of food intolerance.^[57]

Four patterns of dysbiosis

Leo Galland MD has advanced the idea of four interlocking patterns of bacterial dysbiosis: putrefaction, fermentation excess, deficiency and sensitization.

Putrefaction

This is the Western degenerative disease pattern which results from diets high in fat and meat and low in insoluble fiber. This type of diet produces increased concentrations of *Bacteroides* sp. and induces bacterial urease and beta-glucuronidase activity. These enzymes may then metabolize bile acids to tumor promoters and deconjugate excreted estrogens, raising the plasma estrogen level. The fecal pH may increase as a result of increased ammonia production.

Epidemiologic data implicates this type of dysbiosis in the pathogenesis of colon cancer and breast cancer. It is usually corrected by decreasing dietary fat and animal flesh, increasing fiber consumption and consuming probiotic preparations.

Fermentation excess

This is a condition of carbohydrate intolerance induced by an excess of normal bacterial fermentation usually resulting from small bowel or fecal bacterial overgrowth. Abdominal distention, flatulence, diarrhea, constipation and feelings of malaise are commonly described. In small bowel bacterial overgrowth, degradation of intestinal brush-border and pancreatic enzymes by bacterial proteases may cause maldigestion.

Fecal short-chain fatty acids may be elevated. Patients with fermentation excess are usually intolerant of fiber supplements and often benefit from a reduction of carbohydrate consumption and antimicrobials.

Deficiency

Exposure to antibiotics or a diet depleted of soluble fiber may create a deficiency of normal fecal flora, including *Bifidobacteria*, *Lactobacillus* sp., and *E. coli*. Direct evidence of this condition is seen in stool cultures when concentrations of any of these organisms are reduced. This condition has been described in patients with irritable bowel syndrome and food intolerance.

Deficiency and putrefaction dysbiosis often occur together and respond to the same treatment. Probiotic supplementation as well as fructo-oligosaccharides are often helpful

in re-establishing a normal flora.

Sensitization

Abnormal immune responses to components of the normal indigenous intestinal microflora may contribute to the pathogenesis of inflammatory bowel disease, spondyloarthropathies, and other connective tissue diseases or skin disorders such as psoriasis or acne. Endotoxins may activate the alternative complement pathway and sensitization may complement fermentation excess. Similar treatments may benefit both conditions.

THE CDSA MARKERS

The comprehensive digestive stool analysis provides diagnostic tools for analysis of digestion, colonic environment and absorption.

Digestion

The Great Smokies Diagnostic Laboratory (GSDL) has developed unique detergent extraction and enzymatic analysis procedures that allow quantitative, precise, and accurate measurements of digestion efficacy.^[58] ^[59] These methods give physicians the tools for differential diagnosis of digestive conditions as they relate to acute and chronic illness.

Triglycerides

Triglycerides are the major dietary fat component. Elevated fecal amounts reflect incomplete fat hydrolysis and suggest pancreatic insufficiency.

Chymotrypsin

Fecal chymotrypsin is a sensitive, specific measure of proteolytic enzyme activity.^[60] ^[61] Decreased values suggest diminished pancreatic output (pancreatic insufficiency), hypoacidity of the stomach, or cystic fibrosis. Elevated chymotrypsin values suggest rapid transit time, or, less likely, a large output of chymotrypsin from the pancreas.

Iso-butyrate, iso-valerate and n-valerate

New research suggests that these short-chain fatty acids (SCFAs) can be produced through bacterial fermentation of protein, thus reflecting the presence of undigested protein in the bowel. In a healthy colon, these SCFAs constitute less than 10% of the total concentrations of SCFAs due to the sparse amounts of polypeptides present in the

large intestine compared with undigestible carbohydrates. However, an increase in the load of protein in the colon will alter these concentrations. Causes may include pancreatic insufficiency (insufficient proteases), malabsorption or gastrointestinal disease, leading to mucosal desquamation.^[62]

Meat and vegetable fibers

These are microscopic, qualitative, indirect indicators of maldigestion from either gastric hypoacidity or diminished pancreatic output. Several studies report that fecal meat fibers were equal to other methods for non-specific maldigestion.^[60] ^[63] ^[64] One study reported a correlation between excessive fecal meat fibers and hypochlorhydria or achlorhydria as measured by direct radiotelemetry.^[65]

Absorption

Total fecal fat

This parameter is the sum of all the lipids except short-chain fatty acids. Elevation can be indicative of maldigestion or malabsorption. Elevated long-chain fatty acid levels may reflect malabsorption, and elevated triglyceride levels reflect maldigestion.

Long-chain fatty acids

These free fatty acids are readily absorbed by healthy mucosa. In cases of malabsorption, however, they accumulate and reach substantially elevated levels in the feces. Elevation can also indicate pancreatic insufficiency.

Cholesterol

Fecal cholesterol comes from both dietary sources and mucosal epithelial cell breakdown. Some of this cholesterol is absorbed, stored and used by the body, but some is excreted. The fecal cholesterol level remains surprisingly constant during fluctuating exogenous intake. An elevated cholesterol level in feces is abnormal and may reflect mucosal malabsorption.

Total short-chain fatty acids

A special property of colonic bacteria is their fermentation of soluble fibers to short-chain fatty acids (acetate, propionate, butyrate and valerate).^[66] These molecules are normally readily absorbed so that fecal levels reflect a balance between production and absorption. SCFAs provide up to 70% of the energy for colonic epithelial cells.^[67] SCFA production may be an important factor in establishing and maintaining a balanced ecosystem in the colon and may prevent establishment of pathogenic microbes such as *Salmonella* and *Shigella* spp. One interesting report suggests that diversion colitis might be successfully treated with rectal irrigations of SCFAs.^[68] Elevated levels of the four main SCFAs may reflect colonic malabsorption or bacterial overgrowth. Elevated levels

are also found in active colitis.^[69] Decreased levels may reflect insufficient dietary fiber or disruption of the normal colonic flora.

Microbiology

Beneficial bacteria

Healthy amounts of *Lactobacilli*, *Bifidobacteria* and *E. coli* are essential to the maintenance of a healthy colon. *Lactobacilli* and *Bifidobacteria* spp., in particular, have long been noted for their contributions to intestinal health – from the inhibition of gut pathogens and carcinogens, control of intestinal pH and the reduction of cholesterol to the synthesis of vitamins and disaccharidase enzymes.

In a healthy gut, these organisms make up a substantial portion of the 400-plus species of bacteria; *Bifidobacteria* alone comprises up to one-quarter of the total flora in a healthy adult. Reduced numbers of these organisms, resulting from the use of broad-spectrum antibiotics, chronic maldigestion or bacterial overgrowth, leave the intestine susceptible to invasion by pathogens and production of carcinogens. Low levels may indicate the need to supplement with “friendly bacteria” to restore these important properties. While *E. coli* do not share some of these direct beneficial effects, clinical observation suggests that ample amounts of these organisms are present in healthy intestines.^[70]

Additional bacteria

Bacteriology cultures quantitate normal flora (*Lactobacilli*, *Bifidobacteria*, *E. coli* and other frequently isolated organisms), imbalanced flora and potential pathogens. Serotyping for toxigenic *E. coli* and *Campylobacter* cultures is performed on diarrhetic specimens (see [Tables 9.7](#) and [9.8](#)).

Mycology

The CDSA includes a mycology culture that identifies and quantitates fecal yeast. Some of the more commonly

TABLE 9-7 -- Common potential pathogens

- Mucoid *E. coli*

identified species are *C. albicans*, *C. tropicalis*, *Rhodotorula* and *Geotrichum*. Broth dilution sensitivity analyses are performed on all yeast cultures of 2+ or greater, utilizing both pharmaceutical and natural substances. Quantitative MIC analysis determines the relative potency of differing antimycotic agents. This provides more information on the effective agents and dosages for each yeast.

Metabolic markers

n-Butyrate

Butyric acid is a key SCFA because it is the main energy source for colonic epithelial cells. Adequate amounts are necessary for healthy metabolism of the colonic mucosa. A possible mechanism for the anticancer action of dietary fiber is the increased fermentation of fiber to butyrate. It has been suggested that failure to use butyric acid by colonic mucosal cells or inadequate amounts available in the colon could be a primary factor in the etiology of ulcerative colitis, inflammatory bowel disease and colon cancer.^{[66] [71] [72]}

Beta-glucuronidase

Beta-glucuronidase is a bacterial enzyme, the activity of which serves as a valuable marker of cancer risk. This enzyme is elaborated by several microorganisms, including *E. coli*, *Bacteroides* and *Clostridium*. Via the uncoupling of glucuronides (compounds detoxified through the hepatic glucuronidation pathway), this enzyme catalyzes reactions which may result in the formation of carcinogens in the bowel as well as the persistence of certain hormones and drugs in the body. Thus, excess

beta-glucuronidase activity correlates with increased cancer risk, including estrogen-related cancers through the enhanced enterohepatic recirculation of estrogen in the body. The activity of this enzyme is strongly influenced by diet, levels of *Lactobacilli* and *Bifidobacteria*, intestinal pH and nutrients such as calcium gluconate.^[73]
^[74] ^[75] ^[76]

pH

Fecal pH appears to be an indicator of the health or status of the colonic digestive processes. Abnormally acidic or alkaline pH usually reflects an abnormality in either acid production or absorption. There is increasing evidence that fecal pH is a useful indicator of risk for colon cancer.^[77] ^[78] ^[79] There appears to be a correlation between alkaline pH and decreased short-chain fatty acids (particularly butyrate).^[80] Elevated fecal pH and diminished SCFAs suggest inadequate digestion of fiber and/or inadequate intake of dietary fiber.

Short-chain fatty acid distribution

Adequate amounts and proportions of the different

SCFAs reflect the basic status of intestinal metabolism. The ratios of the individual SCFAs remain relatively constant in healthy colons, but become imbalanced in various disease states. Imbalanced ratios of the SCFAs reflect imbalanced metabolic processes due to disordered bowel flora. Researchers are beginning to identify unique SCFA “fingerprints” with specific bacterial infections.^[71] The ratio among SCFAs has diagnostic value as a screening test for intestinal infections.^[72] A significantly higher ratio of acetate/total SCFAs and a lower ratio of butyrate/total SCFAs have been found in the feces of patients with large bowel adenomas and cancer compared with control groups.^[71]

Immunology

Fecal sIgA

Secretory IgA, derived from lymphoid tissue within the intestinal mucosa, acts as the first line of immunological defense against microbes and antigens in the GI tract. SIgA works by binding with pathogenic microorganisms, allergenic food proteins and carcinogens to form immune complexes which prevent them from binding to the surface of absorptive cells.

SIgA has been demonstrated to prevent the adhesion of *Vibrio cholerae* to mucosal epithelium, to neutralize cholera toxin and polio virus, and to reduce the absorption of ovalbumin and other allergenic food proteins. In patients with selective IgA deficiency,

high titers of antibodies against food antigens can be detected. Depressed sIgA has also been observed in healthy, asymptomatic individuals, presumably from high antigenic exposure. Over time, this decreased resistance can lead to dysbiosis and increased risk for infection and allergy. ^{[81] [82] [83] [84] [85]}

Macroscopic observations

The color of feces provides important insight into various conditions, as listed in [Table 9.9](#).

The presence of mucus or pus can indicate irritable bowel syndrome, intestinal wall inflammation (caused

TABLE 9-9 -- Clinical interpretation of fecal color

| Color | Probable significance |
|----------------------|--|
| Light brown to brown | Normal |
| Yellow or green | Diarrhea or a bowel sterilized by antibiotics |
| Black | Upper GI tract bleeding |
| Tan or gray | Blockage of the common bile duct, pancreatic insufficiency (greasy stool) or steatorrhea |
| Red | Beets in diet; lower tract bleeding |

by infection – typhoid, *Shigella* or amoebic), diverticulitis or other intestinal abscess. Absence of mucus and pus is normal.

The CDSA also includes an occult blood test. Although a positive result might be due to hemorrhoids or eating too much red meat, occult blood is a possible indicator of colon cancer. Follow-up is recommended, perhaps a second test using a meat-free diet or a sigmoidoscopic exam.

Dysbiosis index

Intestinal dysbiosis is marked by many indicators. Relevant results are weighed and an index is calculated to provide a quick assessment of the patient’s GI tract. Factors used to determine the index include metabolic and microbiological markers.

SUMMARY

The CDSA’s battery of integrated tests evaluates digestion, colonic environment, and absorption. It enables therapeutic intervention based not only on single test results, but also on patterns and relationships. The CDSA provides clinical insights not available

with other diagnostic procedures, insights not limited to the gastrointestinal system. According to Mitch Kaminski MD: “More than 50% of the immune system takes its signals from the gut. Immune modulation, the cytokines, commonly produce oxidative stress. Free radicals cause aging and chromosomal damage associated with cancers.”

Chapter 10 - ELISA/ACT test

Patrick M. Donovan ND

INTRODUCTION

Antigens from the enteric environment are among the most common and constant challenges to our immune defense and repair systems, and hence to overall health and vitality.^{[1] [2] [3] [4] [5]} Challenges can be from enteric organisms and seemingly innocuous, commonly encountered substances such as foods, chemicals, and microbial toxins (endo- and exotoxins). Maldigestion and increased intestinal permeability increase such exposure.^{[6] [7] [8] [9] [10] [11] [12] [13] [14] [15] [16] [17] [18] [19] [20] [21] [22] [23] [24] [25] [26] [27] [28] [29] [30] [31] [32] [33] [34] [35] [36] [37] [38] [39] [40] [41]}

The adaptive mechanisms for human immune defense and repair can be overwhelmed by these reactive substances. This enhances susceptibility to both infectious disease and hypersensitivity reactions. Clinically important immune overload dysfunction can then occur and present as recurrent infections, multisystem chronic inflammation, and/or autoimmune syndromes.^{[36] [37] [38] [39] [40] [41] [42] [43] [44] [45] [46] [47] [48] [49]}

Identifying the commonly encountered substances (foods, food additives, soaps, detergents, environmental chemicals, and pharmaceuticals) that cause delayed hypersensitivity reactions in an individual is often clinically challenging due to the time-delayed or late-phase reactions they elicit. The individual may slowly adapt to the impaired function and reduced performance caused by daily onslaught of reactive substances without being fully aware of the tax on his/her inner economy.^[41] The identification of these reactive substances and their mitigation or elimination is the first step in preventing or correcting immune overload dysfunction and chronic inflammatory, degenerative or autoimmune diseases. A comprehensive, and clinically useful test for identifying such foreign reactants is the enzyme-linked immunosorbant assay.^{[50] [51] [52]}

Reducing immunologic load allows an individual's physical economy to move from a state of "red alert" and hyperactivity to one of balance, regeneration, and repair. This shift is essential to the restoration of health.

REACTANTS AND THE IMMUNE RESPONSE

Chemical reactants are usually antigens, i.e. compounds that induce an immune response. The criteria are that the reactant be:^[1] ^[2] ^[3] ^[4]

- identified by the host organism as foreign
- of large enough molecular weight to be detected by the immune system
- of sufficient chemical complexity to induce a reaction.

Foreignness. Generally, the immune system does not respond to the body's own normal tissues (i.e. self-antigens), but it does respond to those antigenic compounds identified by the body as non-self or foreign. Autoimmune conditions are the exception where normally sequestered self-antigens are exposed to the immune system and treated as foreign. This is usually due to tissue damage significant enough to breach normal compartmentalization, decreased tissue repair, and increased tissue permeability which exposes antigens normally restricted from the circulation in states of health.

High molecular weight. A compound must have a certain molecular size to be antigenic. Low molecular weight compounds, such as many drugs and chemicals, can only be antigenic when they bind with a high molecular weight carrier such as a protein (haptization).

Chemical complexity. There also must be a certain degree of structural and chemical complexity for a compound to be antigenic.

Classes of antigens

There are four major classes of antigens:

- polysaccharides
- lipids
- nucleic acids
- proteins.

These four are usually combined in reactive antigens, e.g. lipopolysaccharides, glycopeptides, nucleoproteins, etc.

Polysaccharides are part of more complex molecules found on the surface of most animal and human cells. They are also a major constituent in the cell walls of plants and microorganisms. Lipids are not antigenic of themselves. They are only antigenic when combined with other molecules such as polysaccharides, forming lipopolysaccharides (LPS). Lipopolysaccharides are products of many bacterial (endotoxins), fungal, and

plant cell walls which can activate the immune system. Nucleic acids are also usually not themselves antigenic, but can become so when combined with protein carriers (histones). Proteins, especially glycopeptides, are the most antigenic of all compounds; virtually any protein can induce an immune response given the appropriate circumstances.

When an antigen enters the body, the healthy immune system is stimulated to respond. White blood cells such as macrophages, neutrophils, eosinophils, basophils, and lymphocytes, e.g. helper or natural killer (NK) cells, respond by phagocytosing and processing the antigen. Proinflammatory compounds and immunostimulating chemicals (interferons, interleukins, cytokines, and other growth factors and cellular modulators) play essential roles in modulating the immune response. Antibodies are produced from activated B-class lymphocytes which attack/bind to the antigen and stimulate complement amplification of the response. Immune complexes occur when humoral response exceeds cellular processing capacity. The reticuloendothelial system (RES), especially the Kupffer cells of the liver, is responsible for removing immune complexes or cells with bound/absorbed immune complexes from the circulation.^{[1] [2] [3] [4]}

Hypersensitivity reactions

An amplified immune response to an antigen can occur, resulting in hypersensitivity reactions.^{[1] [2] [3] [4] [5] [25] [31] [34] [41] [49]} In a hypersensitive reaction or condition, the normally beneficial immune response becomes inappropriately over-responsive to normally innocuous, commonly encountered antigens, causing inflammation and tissue damage through the release of proinflammatory compounds. This can cause acute crises or lead to chronic allergies, asthma, autoimmune and inflammatory diseases, as well as other “environmentally sensitive” conditions. These reactions are increasingly common in the industrialized world where chemical dependence, environmental pollution, restructured diet patterns, and habitual distress are endemic.^{[5] [28] [34] [37] [39] [40] [41] [48] [49]}

There are four basic types of hypersensitivity (allergic) responses (defined by Gel & Coombs in the 1960s). These responses are mediated by the release of proinflammatory compounds induced either by an antigen–antibody, cell-cytotoxic, or T-cell-mediated response. Delayed-type reactions (types II–IV) are not as easily identified clinically nor as closely linked to disease conditions due to their delayed nature and the variety and chronicity of the symptoms they cause. Type I reactions are typically readily identified as the reactions are immediate.

Type I: immediate hypersensitivity or immediate

This reaction is mediated by immunoglobulin E (IgE) which binds to the antigen and causes the release of pharmacologically active amines and cytokine compounds, most notably histamine. The classic allergic reaction of itchy eyes, runny nose, swelling and edema,

hives, and bronchoconstriction, or more severe responses such as asthmatic attacks and anaphylaxis, can occur. It happens immediately (within minutes) on exposure to the antigen and can be life-threatening.

Type II: antibody-dependent cytotoxic hypersensitivity

This reaction occurs when antibodies (IgA, IgG, or IgM) are provoked against cellular antigens (this can be an antigen on an individual's own cells) leading to cell/tissue destruction via the activation of immune cells and proinflammatory compounds. This delayed reaction may take hours or days to develop. ABO and Rh incompatibility reactions, drug-induced reactions (via haptization with cellular and/or circulating blood proteins), and many autoimmune conditions are examples.

Type III: immune complex-mediated hypersensitivity

This reaction occurs when immune complexes are formed when antibodies (IgG, IgM, or IgA) and antigens coalesce. These complexes deposit in the tissues causing the release of immunologically active cells and proinflammatory chemicals that damage those tissues. This delayed reaction may take hours or days to develop. The classic Arthus reaction, serum sickness, and autoimmune/infection-associated immune complex diseases (rheumatoid arthritis, rheumatic fever, glomerulonephritis, etc.) are examples of this type of reaction.

Type IV: T-cell-mediated hypersensitivity

This reaction is mediated by T-cells which have been previously sensitized to a specific antigen. The T-cells release lymphokines (interleukins) which induce an inflammatory reaction. This type of reaction is seen in the TB skin test, contact dermatitis, and tissue or organ rejection reactions. The classic delayed reaction can take days to develop.

Cross-reactive, cytotoxic antibodies, and disease

An antibody-dependent cytotoxic reaction directed against self-antigens can be initiated and propagated by environmental antigens (viruses, bacteria, food protein, chemical, etc.), similar enough to self-antigens to stimulate cross-reactive antibodies to self. When this occurs, chronic exposure to the environmental antigen can potentiate this self-directed immune response by provoking continual production of cross-reactive antibodies – hence, the possible relationship between environmental antigens and autoimmune diseases.^{[1] [2] [3] [4] [41] [53] [54] [55]}

Immune complex-mediated diseases

High levels of circulating immune complexes can result in their deposition in susceptible

tissues. This deposition can damage these tissues and organs and result in:

- metabolic dysfunction
- inflammation
- pain
- swelling
- fibrosis
- exposure of normally sequestered self-proteins to immunological recognition
- release of free radical and acidic oxidative products.

Chronic antigen exposure and systemic antigen load resulting in a delayed hypersensitivity response and immune complex deposition can often lead to autoimmune and chronic diseases, accelerated aging, and organ dysfunction and failure, if not corrected.^{[1] [2] [3] [4] [56] [57] [58] [59] [60] [61]}

These diseases/pathologies can be placed broadly into three groups (see [Table 10.1](#)) according to the source of the antigen and the organs most frequently affected.^[3]

Persistent infection

When a low-grade persistent infection occurs with a weak antibody response, chronic immune complex formation can result. These complexes may then deposit in various tissues, producing such conditions as endocarditis, hepatitis, glomerulonephritis, and arthritis.

Autoimmunity

Immune complex-mediated inflammatory disease is a frequent complication of autoimmune disease. Such autoimmune diseases include rheumatoid arthritis and

TABLE 10-1 -- Immune complex-mediated diseases

| Cause | Antigen | Sites of complex deposition |
|-------------------------------|--|---|
| Persistent infection | Microbial antigen | Infected organ(s), kidneys, joints, heart |
| Autoimmunity | Self-antigen | Kidneys, joints, arteries, muscles, brain, lungs, liver, skin, bowel, connective tissue |
| Extrinsic or exogenous source | Environmental antigen (food, drugs, chemicals, etc.) | Generally the same as for autoimmunity |

Modified from Roit et al ^[2] (p. 21).

other inflammatory joint diseases, systemic lupus, polyarteritis, vasculitis, polymyositis, glomerulonephritis, multiple sclerosis, colitis, Crohn's, and many of the mixed connective tissue diseases.

Extrinsic or exogenous antigens

Environmental antigens are generally contacted by the skin and mucosal surfaces (inhaled or ingested) and form immune complexes either at the body surfaces or in the tissues after absorption. Such antigens may include chemicals, drugs, endotoxins, food proteins, and antigenic material from moulds, plants, or animals. Prolonged immune complex formation and the production of cross-reactive autoantibodies may occur from chronic daily exposure to reactive environmental antigens leading to overload of the reticuloendothelial system and tissue deposition.

INTESTINAL ANTIGENS AND TOXICANTS

The most common portals of entry for foreign antigens are the skin and mucosal surfaces of the genitourinary, respiratory, and gastrointestinal tracts. Of primary clinical importance is the gastrointestinal tract because of its constant contact with a plethora of dietary materials, proteins, chemicals, and bacteria.^{[1] [2] [3] [4] [6] [7] [8] [9] [10] [27] [32] [34] [36] [37] [38] [39]}

Observations by clinicians since the time of Hippocrates and reports in the current scientific literature document the role of the colon and bowel in the etiology and propagation of many diseases and pathological conditions. This is due to the local and systemic effects of bowel antigens ("toxicants") in different tissues and organs, often mediated through a delayed hyperreactive mechanism.^{[6] [26] [28] [29] [32] [41] [49] [56] [57] [58] [59] [60] [61]}

There is a significant release of toxicants from the bowel into systemic circulation when:

- colon health is compromised in any way (infection, irritation, inflammation, or ulceration)
- the microfloral homeostatic environment is disturbed (dysbiosis) resulting in overgrowth of pathogenic organisms
- there exists a hospitable environment for parasitic infection
- putrefaction occurs as a result of prolonged fecal transit time (constipation)
- prolonged distress has compromised normal protective mechanisms such as secretory IgA.

This release results in immune activation, delayed hypersensitivity, inflammation, and host disposition to chronic disease.

Antigenic bowel toxicants include dietary macromolecules (undigested or partially digested food proteins and other by-products of incomplete digestion), various food additives and chemicals, and microbial toxicants (bacterial lipopolysaccharides).^{[6] [7] [8] [9] [10] [13] [19] [32] [34] [36] [37] [38] [39] [54] [55] [56] [58] [62]} The bowel is partially permeable to these toxicants and many, particularly food, macromolecules can traverse the normal intestine in sufficient quantities to exceed the lymphatic system's surveillance capacity, resulting in their immunological recognition as foreign invaders.^{[6] [7] [8] [9] [10] [32] [56] [58] [62]} This recognition causes activation of the body's immune mechanisms, particularly the activation of lymphocytes, resulting in the production of anti-bodies (IgA, IgG, IgE, IgM), the formation of immune complexes, and delayed hypersensitive reactions.

Food antigens

Normally, the digestive process completely breaks down foods into their component amino acids, tiny peptides, glycerides, and saccharides. All too often, however, digestion is not complete. In fact, appreciable quantities of these digestion remnants can penetrate the normal intestinal mucosal barrier and enter systemic circulation, where they provoke immune response.^{[6] [7] [8] [9] [10] [32] [56] [58] [62]} Individuals with allergic conditions, gastrointestinal disease, poor digestive functions (especially low hydrochloric acid activity in the stomach and pancreatic insufficiency), constipation, and diets high in refined foods can absorb significant amounts of these food antigens, with resultant delayed hypersensitivity reactions.

These reactions are becoming more common.^[28] Some researchers claim that they are the leading cause of many undiagnosed symptoms, and that at least 60% of the American population suffers some degree of disability from associated symptoms. Diet-induced hypersensitivity reactions are associated with:^{[25] [26] [27] [28] [29] [30] [31] [32] [33] [34] [18] [19] [20] [62] [63] [64] [65] [66] [67] [68] [69] [70] [71] [72] [73] [74] [75] [76] [77] [78] [79] [80]}

- migraine headache
- eczema
- arthritis
- systemic lupus erythematosus
- inflammatory bowel disease
- gall bladder disease
- asthma
- irritable bowel syndrome
- childhood hyperactivity
- disturbances of behavior
- sinus congestion
- indigestion
- intestinal gas
- diarrhea/constipation
- general fatigue.

Primary protective mechanisms against systemic antigen overload from the

bowel

Secretory immunoglobulin A (sIgA)

Secretory IgA is found primarily in bodily secretions

121

(saliva, tears, breast milk, and gastrointestinal and respiratory mucus). Secretory IgA acts as a major protective mechanism in these areas by neutralizing biologically active antigens such as viruses, bacteria, enzymes, and toxins. It binds antigens crossing the mucosal barrier and mediates their transport from portal circulation through the liver into the bile for elimination, thus limiting the immunological response.^{[81] [82] [83] [84]}

Any deficiency of sIgA, transient or chronic, either from decreased production (immunodeficiency) or from overwhelming the sIgA system by repeated antigen exposure, can cause an influx of bowel antigens into the portal circulation. This influx, if prolonged and sufficient, can overwhelm the second line of defense: the liver's phagocytosis of these substances. When this occurs, the toxins enter systemic circulation and initiate both immediate and delayed reactions, immune complex deposition, complement activation, inflammation, tissue damage, and disease.^{[85] [86] [87] [88]} The increased levels of antibodies to dietary antigens found in patients with IgA deficiency (which occurs in one of 600 individuals of European origin)^[53] further support the importance of this class of immunoglobulin in limiting the absorption of food macromolecules.^[88] It is important to note that sIgA deficiency is the most common primary immunodeficiency.

Liver

The liver plays a crucial role by filtering the portal circulation and preventing antigen and immune complex entrance into systemic circulation. The Kupffer cells of the liver, with the help of sIgA, phagocytize, process, and eliminate these toxins in the bile. However, if the liver is compromised in any way, either from (1) inflammation (e.g. hepatitis), (2) fatty infiltration and degeneration (e.g. cirrhosis), (3) excessive alcohol consumption, (4) drugs, and/or (5) chronic toxin overload, then these bowel antigens will more readily enter systemic circulation and generate disease.^{[81] [82] [83] [84] [89]}

IDENTIFYING THE ANTIGENIC TOXICANTS OF DELAYED HYPERSENSITIVITY

The classic way of testing for delayed reactions to food and other environmental antigens is by the subjective method of provocative challenge.^{[5] [25] [31] [34]} Exposure to the reactive substance (food, chemical, etc.) will elicit various signs and symptoms. Often, as in the case of foods, it is necessary to eliminate the suspicious substance from the individual's immediate environment for 4 or more days, keeping all other variables

constant, before reintroducing it (challenge). When multiple foods and other substances are suspected (as is usually the case), this process can be time-consuming and painfully frustrating to both patient and doctor. In such a case, an objective laboratory test may be the best method; however, no “gold standard” test has been developed which consistently recognizes all delayed reactions.

The tests currently available for delayed hypersensitivity reactions include:

- *the modified radioallergosorbent test (RAST)* – a solid-phase radioimmunoassay classically used to detect IgE (type 1) reactions modified for IgG
- *the radioallergosorbent procedure (RASP)* – a variant of the RAST, this is also a solid-phase radioimmunoassay classically used to detect IgE (type I) reactions but thought to be more sensitive to IgG reactions than the classic RAST
- *the food immune-complex assay (FICA)* – a solid-phase radioimmunoassay specific for IgG allergens and immune complexes
- *the IgG ELISA* – a solid-phase, monoclonal antibody test for an IgG subclass (IgG₄) reaction utilizing the ELISA technique (see below)
- *the ELISA/ACT* – a modification of the ELISA method which combines enzyme amplification with lymphocyte blastogenesis.

Of these tests, the ELISA/ACT appears to be the only one capable of testing for all (types II–IV) delayed hypersensitive reactions (see [Fig. 10.1](#)).^{[4] [5] [25] [31] [34] [50] [51] [52]}

The ELISA method

The ELISA method of immunologic testing is a solid-phase immunoassay (as are radioimmunoassays such as the RAST) which employs an enzyme-linked reactant (classically an anti-immunoglobulin). Positive results are obtained when the enzyme is activated in the presence of a substrate producing a measurable color change. The intensity of the color change can also be read to determine the strength of reaction. According to Benjamini & Leskowski:^[4]

The ELISA method is rapidly replacing many assays in which a radioactive label is used because it is less expensive. Also, it does not require the special precautions for the handling of radioactivity, and it is, in general, just as sensitive.

ELISA/ACT

The ELISA/ACT is a modification of the ELISA method. It combines enzyme amplification with lymphocyte blastogenesis (instead of monoclonal or anti-antibody binding) in an autologous environment (whole plasma, as opposed to serum, with all the immunologic constituents intact and inducible) to test for all phases (types II–IV) of delayed reactivity (see [Fig. 10.1](#)).^{[50] [51]} It is, in a sense, an *ex vivo* window on the immune system which can provide an “immunologic fingerprint” of an

Figure 10-1 The immune response pie.

individual's delayed reactivity via the pattern of reactivity to a large number of substances (see [Tables 10.2](#) and [10.3](#)). One of the key advantages of this procedure over other laboratory methods is its ability to measure IgG₄ antibodies. Although initially thought to act as a blocking antibody, thereby exerting protective effects against allergy, it now appears that IgG₄ antibodies are actually involved in producing allergic symptoms. ^[52]

As shown in [Table 10.3](#) , a positive result on the

TABLE 10-3 -- Meaning of positive results

-
- Immune recognition
-

- Contaminant recognition

- Contingent recognition

- Cross-reaction to:
 - gut pathogen (identical epitope)

 - related food family (identical epitope)

 - patient’s tissue (identical epitope)

ELISA/ACT test (lymphocyte blastogenic reaction) can be due to one of four causes:

- immune recognition of a particular antigen specific to the compound tested
- immune recognition of a contaminant (such as a pesticide) not normally a constituent of the specific compound tested
- immune recognition contingent upon the presence of a specific hapten
- immune recognition of an identical epitope to another antigen.

While the common serum-based ELISA test, through several steps, builds up a molecular sandwich to improve the detection of small amounts of reactive substance, the ELISA/ACT is a one-step procedure taking unique advantage of the reactive cell surface on which enzymes become active when a substance is recognized as foreign. This reduction in steps contributes to greater precision.^{[50] [51] [52]}

Lymphocyte blastogenesis

Lymphocyte blastogenesis occurs during the early phase of all delayed hypersensitivity reactions. It represents lymphocyte activation from antigen/cytokine (see [Table 10.4](#)) stimulation where the lymphocytes are in a state of hyperactive metabolism resulting in a rapid increase in size and synthesis of DNA, RNA, and protein. By linking the enzyme reaction to lymphocyte blastogenesis (release of membrane-sequestered compound during the blastogenic reaction), the ELISA becomes an activated cell test (ACT) specific for all delayed responses.^[52]

A blastogenic reaction can take place within hours as demonstrated by a change in the rate of protein formation. The measurement of such a reaction has traditionally taken up to 4–5 days using tests for thymidine and uptake of radiolabeled purine and pyrimidine. Because of a new technique, ELISA/ACT measures blastogenesis within hours, allowing for much quicker evaluation of sensitivity.^{[50] [51] [52]}

Validity, reproducibility, sensitivity, and specificity

The classic way of determining the validity (the degree to which the results of a measurement correspond to

TABLE 10-4 -- Substances capable of eliciting a lymphocyte blastogenic response (positive result)

-
- Antigen
 - Hapten
 - Oxidant
 - Lectin
 - Other
-

the true state of the phenomenon being measured)^[89] of a test is by comparing the observed measurement or results to some accepted, objective, physical standard (the “gold standard”). However, there is no such standard for determining delayed hypersensitivity reactions. Therefore, validity must be established by showing that the test results are predictive of or are directly related to clinically measurable or observable phenomena (signs and symptoms).^[89]

To determine its validity (based on the predictive value of clinical phenomena), the ELISA/ACT was performed on a very refractory population: 81 patients suffering from an autoimmune or chronic viral syndrome for more than 5 years that had been progressive and had not responded more than briefly to any of several therapeutic interventions. Each patient filled out two symptom questionnaires (the Cornell Medical Index Questionnaire and a questionnaire prepared by Serammune Physicians’ Laboratory) and rated the intensity of their primary symptoms on a scale of 1–100 prior to beginning the recommended ELISA/ACT program based on their test results. At 6–30 months after beginning the program, they again rated the intensity of their primary symptoms (these data are based on follow-up results regardless of how carefully the person followed the recommendations). The results showed a primary symptom intensity of 77.4 ± 14.5 before and 26.4 ± 18.2 after following

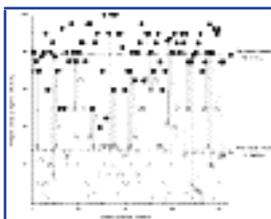

Figure 10-2 Response of autoimmune syndromes to ELISA/ACT – patient report (6–36 month follow-up)

the program ($p < 0.0001$), demonstrating a significant improvement (see [Fig. 10.2](#)).^[90]

These results suggest a strong correlation between the reduction of symptom intensity and the elimination of the reactive foods and substances (as determined by the ELISA/ACT), and incorporation of the ELISA/ACT program, supporting the validity of the

ELISA/ACT test and program.

During the 3 year development phase of the ELISA/ACT, two procedures were utilized to establish reliability (the extent to which repeated measurements of a relatively stable phenomenon fall closely to each other):^[89]

1. In over 100 separate instances, multiple samples were taken at the same time, from the same subject, and analyzed with the technician blinded. Results replicated with $R > 0.999$ with only occasional differences where a strong reaction was read as an intermediate or a marginal intermediate was read as not reactive.
2. Many of the more than 3,000 different subjects tested were retested weekly, sometimes for months at a time. The results replicated with an $R = 0.998$.^[91]

Determination of sensitivity (the proportion of positive reactions that are confirmed as truly positive – the greater the sensitivity, the fewer the false-positives)^[89] and specificity (the proportion of negative reactions that are

TABLE 10-5 -- Measures to reduce error

| Sources of error | Measures to reduce error |
|--|---|
| Glass contact | Sample drawn and shipped in plastic |
| Vacuum draw of sample | Sample drawn slowly using syringe |
| Tissue thromboplastin activated | Initial 3 ml of blood discarded |
| Heat | Sample refrigerated and shipped with ice pack |
| Leukopenia (<500 total WBC) | If suspected, must be checked for with CBC |
| Drugs (steroids, theophylline, anti-provided histamines, and all aspirin-containing compounds) | Detailed pre-test instructions |

confirmed as truly negative – the greater the specificity, the fewer the false-negatives)^[89] of a test like the ELISA/ACT is difficult. The physician is again faced with the lack of a “gold standard” to confirm a truly positive (induction of lymphocyte blastogenesis) or a truly negative (no induction of lymphocyte blastogenesis) result. At best, confirmation of such results can only be achieved by demonstrating the presence or absence of clinical signs and symptoms to the substances in question (provocative challenge test). However, reactivity to a substance does not always yield clinical signs and symptoms, so their elicitation may be due to a type 1 hypersensitivity reaction (not tested for with ELISA/ACT) or a psychologically programmed (dis-stress) response. Therefore, there

are no clear-cut, confirming statistics available to determine the degree of sensitivity and specificity of the ELISA/ACT.

SUMMARY

The ELISA/ACT is a useful tool for the clinician in the treatment of autoimmune, chronic viral, and inflammatory conditions. It provides a comprehensive “immunologic fingerprint” of the substances to which a patient displays a delayed hypersensitivity reaction. After these substances are clearly identified, they can be eliminated from the patient’s immediate environment, thereby reducing the immunologic stress and resultant pathology (immunologic disrepair, inflammation, and tissue destruction) induced by delayed hypersensitivity reactions.

Although the validity and sensitivity of the ELISA/ACT procedure must still be evaluated by other researchers, its theoretical premise and clinical relevancy for diagnosing late-phase hypersensitivities look very promising.

Chapter 11 - Erythrocyte sedimentation rate

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

The erythrocyte sedimentation rate (ESR), the rate at which erythrocytes settle out of unclotted blood in one hour, has been one of the most widely performed laboratory tests for the past 50 years. Used primarily to detect occult processes and monitor inflammatory conditions, the ESR has undergone very little change since 1918, when Fahraeus discovered that erythrocytes of pregnant women sedimented in plasma more rapidly than they did in non-pregnant women. Since its incorporation into standard laboratory diagnosis, the ESR has been shrouded with medical myths and is often misinterpreted or misused. This chapter provides a rational guideline for its use as a non-specific measure of inflammatory, infectious, and neoplastic diseases.^{[1] [2] [3]}

Normally, erythrocytes settle quite slowly, as the gravitational force of the erythrocyte's mass is counteracted by the buoyant force of the erythrocyte's volume. However, when erythrocytes aggregate, they sediment relatively rapidly because the proportional increase in their total mass exceeds the proportional increase in their volume.^{[1] [2]}

Therefore, the major determinant in the sedimentation rate of erythrocytes is erythrocyte aggregation, which usually occurs along a single axis (rouleaux formation). The aggregation of erythrocytes is largely determined by electrostatic forces. Under normal circumstances, the erythrocytes have a negative charge, and therefore repel each other. However, many plasma proteins are positively charged and neutralize the surface charge of erythrocytes, thereby reducing repulsive forces and promoting aggregation.^{[1] [2] [3]}

The relative contribution of the various "acute-phase" reactant proteins to aggregation is shown in [Table 11.1](#). One protein that has no direct effect on the ESR in physiological concentrations, but which is associated with certain inflammatory, degenerative, and neoplastic diseases, is the C-reactive protein. Its major function is

TABLE 11-1 -- Relative contribution of acute-phase reactant proteins to erythrocyte aggregation

| Blood constituent | Relative contribution |
|-------------------|-----------------------|
| Fibrinogen | 10 |
| Beta-globulin | 5 |
| Alpha-globulin | 2 |
| Albumin | 1 |

facilitation of the complement system. Like the ESR, measurement of the C-reactive protein is used in the monitoring of patients with chronic inflammatory conditions.^[1] An elevated C-reactive protein provides evidence of an inflammatory process despite a normal ESR. Therefore, when used in conjunction with the ESR, it greatly increases the sensitivity in detecting inflammatory / infectious processes, especially when variables, such as anemia, confound the ESR.

The ESR will also be elevated in patients with proteinemias (myeloma, macroglobulinemia, cryoglobulinemia, and cold agglutinin disease).^{[1] [2] [3]} Disorders of erythrocytes, such as anemias, alter the ESR and may interfere with accurate interpretation.^{[1] [2] [3]} Since the ESR is directly proportional to the mass of the erythrocyte and inversely proportional to its surface area, large erythrocytes sediment more rapidly than smaller cells. Therefore, in macrocytic anemia there is an increased ESR, and in microcytic anemia there is a decreased ESR.

PROCEDURES

Various methods for determination of the ESR have been developed. Currently the Westegren method is recommended by the International Committee for Standardization in Hematology.

Westegren method

In the standard Westegren method, the following procedure is used:

1. Dilute venous blood 4:1 with anticoagulant sodium citrate.
2. Put in a 200 mm long, 2.5 mm internal diameter, glass tube (Westegren tube).
3. Allow to stand in a vertical position for 1 hour.
4. At the end of 1 hour, the distance from the meniscus to the top of the column of erythrocytes is recorded as the ESR.

The modified Westegren method uses edetic acid (EDTA) rather than sodium citrate as

an anticoagulant and is more convenient, since the same tube of blood can be used for other hematological studies. The standard and modified methods give identical results.^[1]
^[2] ^[3]

Wintrobe method

The second most commonly used method is the Wintrobe method. This method is performed with a 100 mm tube (Wintrobe tube) containing oxalate as the anticoagulant. It is more sensitive than the Westegren method in the “normal” to “mildly elevated” range; however, in the more highly elevated ESR, the short tube leads to relatively insensitive readings due to packing of cells.^[2]

Results

- Westegren (normal results)
 - men: 0–10 mm/hour

 - women: 0–15 mm/hour

 - children: 0–10 mm/hour

- Wintrobe (normal results)
 - men: <6.5 mm/hour

 - women: <16 mm/hour.

INTERPRETATION

Several factors may result in false ESR values; the more significant of these are listed in [Table 11.2](#) . In addition, it is important to recognize that in acute disease, the change in rate may lag behind the temperature elevation and leukocytosis for 6–24 hours, and in *unruptured* acute appendicitis the rate may be normal. In convalescence, the increased rate tends to persist longer than the fever or leukocytosis. [Table 11.3](#) lists the most common clinical implications of changes in the ESR.

TABLE 11-2 -- Factors interfering with the ESR^[1] ^[4]

False increase

- Elevated levels of fibrinogen, globulins, and cholesterol

- High room temperature

- Macrocytic anemia

- Menstruation

- Pregnancy

- Running a refrigerated blood sample before it has returned to room temperature

- Tilted ESR tube

- Certain drugs: dextran, methyldopa, methylsergide, OCA, penicillamine, procainamide, theophylline, trifluoperidol, vitamin A

False decrease

- Cachexia

- Clotting of blood sample

- Elevated bile salts

- Elevated phospholipids

- Greater than 2 hour delay in running the test

- High doses of adrenal steroids

- Hypofibrinogenemia

- Hyperglycemia

- Hyperalbuminemia

- Leukocytosis

- Microcytic anemia

- Newborn

- Certain drugs: ACTH, cortisone, ethambutol, quinine, salicylates

TABLE 11-3 -- Clinical implications of changes in the ESR

Increased rate

- Acute heavy metal poisoning

- All collagen diseases

- Carcinoma

- Cell or tissue destruction

- Gouty arthritis

- Infections

- Inflammatory diseases

- Leukemia

- Myocardial infarction

- Multiple myeloma

- Nephritis

- Pneumonia

- Rheumatoid arthritis

- Syphilis

- Toxemia

Decreased rate

- Congestive heart failure

- Polycythemia

- Sickle cell disease

Elevated ESR

Asymptomatic patients

The presence of an elevated ESR as the only manifestation of a disease process is quite rare. However, when present, it can be highly significant. For example, in one study of 17 patients whose increased ESR was the sole initial clue to disease, two had tuberculosis and one had colon cancer (both of which are diseases whose outcome is improved by early detection), one had systemic lupus erythematosus and three had ankylosing spondylitis (diagnoses that become apparent only after several years of observation), and four men had a persistently elevated ESR several years before a myocardial infarction. The remaining patients developed myeloma, prostate cancer, psoriasis, benign monoclonal gammopathy, and pancreatic cancer.

Although, in general, the ESR makes a very small contribution to disease detection in asymptomatic persons, the presence of an elevated ESR as the only clue to illness in an asymptomatic indicates the need for a careful diagnostic work-up; it may be the first sign of an occult malignancy or a chronic inflammatory disease. Laboratory evaluation for an asymptomatic patient with an elevated sedimentation rate should include CBC with differential, BUN and creatinine, alkaline phosphatase measurement, serum protein electrophoresis, urinalysis, guaiac tests of stool, and chest X-ray.^[1]

An ESR that exceeds 100 mm/hour is definitely associated (predictive value of greater than 95%) with infection, malignancy, or connective tissue disease. Rarely does disease remain undiagnosed when the ESR is greatly elevated.^{[1] [2] [3]}

If, after further clinical evaluation, an elevated ESR cannot be explained, the ESR should be repeated in one month. In one study where 43 patients with an elevated ESR remained undiagnosed, the elevation was transitory in 32. The remaining 11 were followed for a period of 10 years: two developed cancer, one had a benign

dysproteinemia, and no diagnosis was ever made for the remaining nine.^[1]

Predictor of coronary artery disease. An elevated ESR in white men aged 45 to 64 years was found to be an independent risk factor for coronary heart disease in the National Health and Nutrition Examination Survey I. The risk was highest when the ESR was >22 mm/hr. It was hypothesized that an elevated ESR in these men reflected an elevated blood fibrinogen level (see [Chapter 13](#) for further discussion of fibrinogen).^[3]

Symptomatic patients

The ESR is sometimes used to provide confirmation of a disease process when the history and physical findings point toward a specific diagnosis. Although the ESR itself is not a specific test, when combined with information gathered in a history and physical, as well as in conjunction with other laboratory tests, it can be a great help in the formation of a specific diagnosis.

In patients with vague, unsubstantiated illness, the ESR offers limited benefit due to the lack of specificity and the presence of a normal ESR in a wide variety of illnesses. However, the ESR offers great diagnostic benefit when other signs, symptoms, and laboratory findings are present. This is particularly true in malignancies, temporal arteritis and polymyalgia rheumatica, inflammatory arthritis, and suspected infection.

ESR in cancer

Malignancy is quite common in symptomatic patients with an elevated ESR. In one study, 70 (or 8.8%) of 790 clinic patients with an elevated ESR had cancer.^[4] However, of the 70 patients with malignancy and an increased ESR, 68 had local signs that led directly to the diagnosis. Thus, occult malignancy was present in only two of the 790 subjects. In addition, the ESR is often normal in patients with cancer, indicating that the ESR should not be relied upon as a test to exclude occult malignancy in patients with vague symptoms.

In a prospective follow-up of 300 patients with prostate cancer, an ESR greater than 37 mm/hr was associated with a higher incidence of disease progression and death. These findings paralleled other prognostic indicators such as M and T categories, grade, performance status, and age, but nonetheless indicate that ESR does provide additional value in the monitoring of these patients and presumably others with invasive cancer.^[5]

Temporal arteritis and polymyalgia rheumatica

Temporal arteritis and polymyalgia rheumatica are

related syndromes that can occur together or alone. Both occur in older individuals and

are associated with an increased ESR. Symptoms of temporal arteritis include unilateral throbbing headache, scalp sensitivity, visual symptoms, jaw claudication, and localized thickening or loss of pulsation of the temporal artery. Polymyalgia rheumatica is a fast-developing condition characterized by pain and stiffness of the pelvis and shoulder girdle, in association with fever, anemia, malaise, and weight loss. It is typically self-limited to 1–2 years.

Determination of the ESR is of critical importance in the diagnosis and management of patients with temporal arteritis, a condition that can result in blindness due to obstruction of the ophthalmic arteries. When the clinical evidence for temporal arteritis is limited, a normal ESR reduces the probability of the disease to less than 1%. When the clinical evidence is strong, it is extremely rare to have a normal ESR. Achievement of a normal ESR by the use of anti-inflammatory agents, such as cortisone or the natural medicines discussed in Section 5, greatly reduces the risk of developing blindness.^{[1] [2]}

Inflammatory arthritis

The ESR is sometimes used to distinguish inflammatory arthritis from other causes of joint symptoms. This is particularly true in the differentiation of rheumatoid arthritis, which has an elevated ESR, and osteoarthritis, which typically has a normal ESR. It is not appropriate to place much value on the ESR as an independent diagnostic predictor of rheumatoid arthritis. An elevated ESR in patients with joint symptoms simply indicates an active inflammatory process.^{[1] [2]}

Suspected infection

Leukocytosis and fever are better indicators than the ESR of an acute infectious process, as the ESR is typically normal during the first stages of infection. However, the ESR is of some value in the differentiation of an intact versus ruptured appendix. Researchers demonstrated that only two of 25 patients with non-ruptured appendicitis had an ESR of greater than 20 mm/hour. In contrast, 67% of patients with ruptured appendixes had an elevated ESR.^[1]

Decreased ESR

The causes of a very low ESR (0–1 mm/hr) are listed in [Tables 11.2](#) and [11.3](#). In one study of patients with a low ESR, 38% had no evidence of disease, and only 6% had one of the diseases commonly associated with a very low ESR. The remaining patients had a wide variety of diagnoses. A low ESR is generally of little significance and may actually indicate a healthy state.^{[1] [2] [3]}

Monitoring of disease activity

The ESR is well recognized as an aid in monitoring the activity of such inflammatory diseases as temporal arteritis, polymyalgia rheumatica, and rheumatoid arthritis.^{[1] [2]}

Temporal arteritis and polymyalgia rheumatica

The ESR is the most widely used test for assessing disease activity in patients with temporal arteritis and polymyalgia rheumatica, because these conditions have few specific clinical indicators of disease activity. However, both the ESR and clinical status need to be monitored in these patients and appropriate therapy instituted if the ESR increases or if there is a worsening in the clinical picture.^{[1] [2]}

Rheumatoid arthritis

Although 5–10% of patients with rheumatoid arthritis have a normal ESR, the ESR generally parallels disease activity. Therefore, monitoring the patient's ESR provides invaluable feedback on therapeutic effect. An isolated elevated ESR is not useful for prognosis, but sustained extreme elevation of the ESR is associated with a very poor prognosis.^{[1] [2]}

Other inflammatory diseases

Other inflammatory diseases, particularly collagen diseases, such as systemic lupus erythematosus, can be monitored by the ESR in a fashion similar to that for rheumatoid arthritis.^{[1] [2]}

SUMMARY

The ESR is a simple, valuable, and useful laboratory procedure. Although it is a non-specific indicator, an elevated ESR (i.e. greater than 80 mm/hour) indicates the presence of significant disease in over 95% of individuals. The ESR should never be used as the sole diagnostic test. Clinical presentation, comprehensive history, laboratory investigation, and other diagnostic procedures should always be considered when interpreting ESR results. The ESR may be used as a non-specific gauge of therapeutic efficacy and as a monitoring tool in several inflammatory conditions, including temporal arteritis, polymyalgia rheumatica, rheumatoid arthritis, and certain malignancies.

Chapter 12 - Fantus test for urine chloride

Dirk Wm Powell ND

INTRODUCTION

The Fantus test is a simple test for measuring urinary output of chlorides. It is generally used to estimate dietary sodium chloride intake. For this purpose, it has been shown to give accurate results if two factors are taken into consideration:^{[1] [2] [3]}

- The concentration of urinary chloride is generally proportional to urinary sodium except when the patient is taking chloride salts without sodium, i.e. NH_4Cl or KCl .
- The urinary output of NaCl is indicative of intake, except when the patient is suffering from a salt-wasting disorder (see [Table 12.1](#)).

CLINICAL APPLICATION

This test was first described by J. B. Fantus in 1936.^[4] Since then it has been used mainly in the diagnosis and treatment of salt and water depletion and edema.^[5] However, one of the most useful applications of this procedure may be in the monitoring of patients with blood pressure disorders.

Since 1904 when Ambard & Beaujard^[6] first implicated salt as a major factor in the pathogenesis of hypertension, conflicting opinions and data have confused this issue. In 1944, Kempner^[7] published a classic article describing the effective treatment of essential hypertension using a very low-salt “rice diet”. Since then, many studies have demonstrated the effectiveness of salt-restricted diets in hypertension.^{[8] [9] [10] [11] [12]} There is now substantial evidence that sodium alone does not raise blood pressure as was commonly thought, but rather that chloride also

TABLE 12-1 -- Sodium-wasting conditions in which salt restriction can be deleterious

- Adrenal insufficiency
 - Salt-wasting renal disease
-

- Heavy sweating or exercise
 - Unusual losses via the GI tract
-

plays an important role in the elevation of blood pressure when consumed concomitantly as common table salt.^[13] ^[14] (See [Ch. 178](#) for further discussion of the relative roles of dietary sodium and chloride.)

Since the Fantus test, which has been called an indirect test for sodium, actually measures chloride, it may therefore be preferable to direct tests of sodium in the management of hypertension.^[13] ^[14]

Two difficulties arise in the treatment of hypertensive patients with salt restriction:^[15]

- salt must be carefully restricted to low levels, 3–6 g/ day, as compared with the 6–18 g/day commonly consumed
- strict salt restriction is difficult to obtain and maintain because of the prevalence of salt in convenience and prepared foods, and the customary intake of large amounts of salt.

These problems make monitoring salt intake important and the Fantus test a valuable clinical tool.

The Fantus test may be used in other conditions where salt restriction is useful, i.e. congestive heart failure, premenstrual syndrome, edema, chronic kidney disorders, and where salt depletion may be contributing to the disorder, i.e. hypotension. It is important to recognize, however, that salt restriction is not always appropriate, as in the conditions listed in [Table 12.1](#) .

Another application is the identification of people who are ingesting excessive amounts of salt, but who are without overt disease. It has been observed that a high intake of sodium decreases longevity in animals,^[16] and salt-induced angiotensin elevation may adversely affect the myocardium in humans, even though the blood pressure remains within normal limits.^[17] The effects of excess salt may persist long after salt is withdrawn.^[18] ^[19]

Identifying those people at risk due to excessive salt consumption is a significant aspect of preventive medicine. People with risk factors for hypertension should restrict salt intake.^[20] Included in this group are patients with chronic renal disease, those with one or both hypertensive parents, and most people over the age of 50.^[20]

The potential benefits of identifying those people with excess salt intake suggest the

usefulness of this non-invasive, low-cost test.

PROCEDURE

The Fantus reagent is prepared so that the number of drops of silver nitrate used in the titration step can be recorded as grams of NaCl per liter of urine (g NaCl/L urine).

Method

1. Collect a 24 hour urine sample
2. Measure and record volume (in L)
3. Add one drop of K_2CrO_4 solution to 10 drops of urine
4. Titrate (one drop at a time) with the $AgNO_3$ solution
5. Record the number of drops needed to turn color from yellow to brown.

(If chloride is present in too low a concentration, use 20 drops of urine. Each drop of $AgNO_3$ is then equal to 0.5 g NaCl/L.)

Reagents

- $AgNO_3$: 2.9% solution
- K_2CrO_4 : 20% solution.

Results

- Typical Western diet: 12–27 g/24 hours
- Salt-restricted diet: 0.6–3.5 g/24 hours.

INTERPRETATION

Normally, urinary NaCl varies considerably, reflecting the salt content of the typical Western diet: 80–180mEq/ 24 hours (12–27g/24 hours).^[21] On a salt-restricted diet, the goal is usually to reduce 24 hour urine NaCl to close to the minimum considered safe, i.e. 0.6–3.5 g/24 hours.^[20] Water consumption is typically closely related to salt intake, and a salt intake of 3g/day corresponds to an intake of 2,750ml of water from both solids and fluids, which is the average water turnover for a 70kg adult. After evaporation from the lungs and other losses, the urine volume is approximately 1500ml/24 hours.^[5] This would yield a urine NaCl of 2g/L or 3g/24 hours.

Chapter 13 - Fatty acid profiling

Richard S. Lord PhD
J. Alexander Bralley PhD

INTRODUCTION

The analysis of fatty acids in blood provides useful information about fatty acid deficiencies and imbalances and can also reveal a functional need for certain vitamins and minerals. Clinical interventions involve changes in food selection or supplementation with selected nut or seed extract oils and required micronutrients. Laboratory reports of fatty acid profiles typically list the fatty acids by structural type in the following order: ω -3-polyunsaturates, ω -6-polyunsaturates, mono-unsaturates, even-numbered saturates, odd-numbered saturates, and, finally, *trans* mono-unsaturates. Several ratios may be calculated, and for plasma, the total fatty acid concentration may be calculated by summing the individual components and expressing the total in mg/dl, consistent with the units for serum triglycerides which are directly related to total fatty acid content.

METHODOLOGICAL ISSUES

A plasma fatty acid profile is an amplification of the standard serum triglyceride analysis. In both cases, the fatty acids are present in lipoprotein particles. Instead of measuring only the total of all fatty acids present, the profile test reports the individual concentrations of each fatty acid. An individual with high serum tri-glycerides will have higher levels of many individual fatty acids in plasma. Of course, any condition indicated by elevated serum triglycerides will likewise be revealed as elevated fatty acids. The pattern of the high and low levels will depend on recent dietary intake and, depending on the length of fasting state, the type of stored fatty acids.

Plasma vs. erythrocyte fatty acid profiles

Erythrocyte membrane fatty acid profiling is the most commonly used test to determine

the presence of long-term insufficiencies and imbalances. The erythrocyte

membrane is 45% fatty acids in the form of various phosphatides and glycolipids. The procedure used for profiling measures total concentrations of individual fatty acids. Erythrocyte data are generally preferred for assessing overall body status of fatty acids because the levels reflect those present in most tissues. For example, the fatty acid composition of brain has been found to be directly correlated with that in red blood cells in rat and primate studies.^[1]

The triglyceride-lowering drug, gemfibrozil, causes a profound suppression of erythrocyte unsaturated fatty acids, even in the presence of high concentrations of the same compounds in plasma. The effect is apparently due to stimulation of the peroxisomal beta-oxidation system.^[2]

Concentration vs. percentage

Prior to 1996, virtually all clinical laboratories reporting fatty acid fractionations had little choice but to express each fatty acid as a percentage of the total fatty acids present. Actual concentrations could not be reported due to the lack of pure standards necessary to build calibration curves. The reporting of “relative area” data has some utility but leaves important points obscured. The most abundant fatty acids are present at concentrations 50 times higher than those of the lesser components.^[3] In percent area calculations, variations in the most abundant components have disproportionate impact. If linolenic acid is the same in two cases, for example, while palmitic acid is low in the first and high in the second, the percent linolenic can appear high in the first and normal in the second. This is due to the fact that palmitic acid makes up so much of the total, and the ratios of the minor components such as linolenic acid are calculated by dividing by the total.

With the availability of pure standards, it is now possible to measure the actual concentrations of each fatty acid. Since the molecular weights span a range of over 70-fold for these homologous compounds, molar units allow more meaningful comparisons. This unit also simplifies interpretation of plasma fatty acids where the total of all fatty acids is directly proportional (and closely equivalent) to the values for total triglycerides from a standard serum chemistry assay. For erythrocytes, the μM concentrations are based on packed cell volumes.

INTERPRETATION OF ABNORMAL FATTY ACID RESULTS

[Table 13.1](#) provides a brief overview of the various fatty acid abnormalities. [Table 85.4](#) (p.729) lists the typical symptoms and diseases associated with various fatty acid abnormalities. The significance of abnormal levels and ratios of fatty acids is discussed

below.

Individual fatty acids

Alpha-linolenic acid (ALA) (18:3?3)

This polyunsaturated fatty acid is produced by many plants, but because of the small amounts of fresh vegetables consumed, it is one of the least abundant of the essential fatty acids in most diets. It is found in flax, hemp, rape (canola) seed, soybean, and walnut oils, and in dark green leaves and it must be supplied by such foods. Dietary insufficiencies and imbalances of this fatty acid and its counterpart, GLA, play a central role in many disease processes (see [Tables 85.4](#) and [85.5](#), pp.729 and 730). The wide range of symptoms and disease associations is due to the function of this fatty acid in critical cell processes of membrane integrity and eicosanoid local hormone production. The latter function utilizes the fatty acid eicosapentaenoic acid (EPA, see below), which can be produced from ALA by elongation and desaturation. This conversion is very efficient in most individuals. An inadequate conversion is indicated by low EPA and DHA in the presence of normal ALA.

Eicosapentaenoic acid (EPA) (20:5?3)

Insufficiencies of EPA are likely the most prevalent fatty acid abnormality affecting the health of individuals in Western societies. Low levels in plasma or especially in erythrocytes are indicative of insufficiency. Arthritis and heart disease, as well as excessive aging, result from direct or indirect effects of unchecked inflammatory response. Supplementation with EPA-rich fish oils aids in the prevention of cardiac arrhythmias.^[4] Significant reduction in total cholesterol and triglyceride has been achieved with a combination of garlic concentrate (900mg/day) and fish oil supplementation.^[5] EPA is the parent of the 3-series prostanoids and leukotrienes which moderate the proinflammatory effects of the 2-series derived from arachidonic acid (see below). Although EPA can be produced from the essential fatty acid, ALA, dietary intake of this fatty acid is generally poor. The conversion also requires the action of the $\Delta 6$ desaturase enzyme, which may be low due to inadequate Zn, Mg, or vitamins B₃, B₆, and C. Such an enzyme impairment would be indicated if EPA is low and ALA is normal or high. High levels of saturated, mono-unsaturated, and *trans* fatty acids, and cholesterol also slow the conversion of ALA to EPA (as well as GLA to DGLA). Fish oils are rich sources of EPA.

Docosapentaenoic acid (DPA) (22:5?3), docosahexaenoic acid (DHA) (22:6?3)

The growth and development of the central nervous system are particularly dependent upon the presence of an adequate amount of the very long-chain, highly

TABLE 13-1 -- Overview of fatty acid abnormalities

| Name | Levels | Metabolic association | Potential responses* |
|--------------------------------|------------------------|---------------------------------|------------------------------|
| Omega-3 polyunsaturated | | | |
| Alpha linolenic | L | Essential fatty acid | Add flax and/or fish oils |
| Eicosapentaenoic | L | Eicosanoid substrate | |
| Docosapentaenoic | L | Nerve membrane function | Add fish oils |
| Docosahexaenoic | L | Neurological development | |
| Omega-6 polyunsaturated | | | |
| Linoleic | L | Essential fatty acid | Add corn or borage oil |
| Gamma linolenic | L | Eicosanoid precursor | Add evening primrose oil |
| Eicosadienoic | H | Desaturase inhibition | Zn; 50 mg/day |
| DGLA | L | Eicosanoid substrate | Add borage oil |
| Arachidonic | H H } H H } | Eicosanoid substrate | Reduce red meats |
| Docosadienoic | | | |
| Docosatetraenoic | H | Increase in adipose tissue | EFA and glycemic control |
| Mono-unsaturated | | | |
| Vaccenic | H | Biotin deficiency | Biotin; 50 mg BID |
| Myristoleic | H H H H } H H H H } | | |
| Palmitoleic | | Membrane fluidity | See discussion |
| Oleic | | | |
| 11-Eicosenoic | | | |
| Nervonic | L | Neurological development | Add fish or canola oils |
| Erucic | L | Nerve membrane function | Add peanut oil |
| Saturated | | | |
| Capric acid | H H H } H H H } | Multiple AcylCoA disorder (MAD) | |
| Lauric | | | Riboflavin; 50mg TID |

| Palmitelaidic | H H } | Eicosanoid interference | Eliminate hydrogenated oils |
| Elaidic | | | |
| Ratios and indexes | | | |
| LA/DGLA | H L } | ? 6 desaturase enzyme | Add blackcurrant oil |
| DGLA/EPA | | | Add fish oils |
| | H | Eicosanoid imbalance | Add borage oil |
| AA/EPA | H | | Add fish oils |
| P/S Ratio | H | Overall fatty acid status | Add dietary unsaturates |
| Stearic/oleic (rbc) | L | Cancer marker | See comments |
| Total fatty acids (pl) | H | Serum triglyceride (VLDL) | Evaluate hyperlipidemias |

* Fatty acids are usually supplemented in the range of 1–3 g/day in the form of extracted nut and seed oils that may contain 30–60% of the fatty acid by weight.

unsaturated fatty acids, DPA and DHA.^{[6] [7]} Attention deficit hyperactivity disorder and

failures in development of the visual system in essential fatty acid deficiencies are two examples of this dependency.^[9] DHA is an important member of the very long-chain fatty acids (C22–C26) which characteristically occur in glycosphingolipids, particularly those in brain. Since this fatty acid is so important in early development, it is worth noting that the levels in breast milk are correlated with the mother's intake of fish oils, which are rich sources of DHA and EPA.^[9]

Linoleic acid (LA) (18:2 ω 6)

LA is by far the most abundant polyunsaturated fatty acid in most human tissues. It is one of the essential fatty acids because it contains a double bond at the ω 6 position which is beyond the reach of the human

desaturase enzyme. Low levels indicate dietary insufficiency, which leads to a variety of symptoms (see [Table 85.4](#), p.729). Some of these symptoms result from a lack of linoleic acid in membranes, where it has a role in structural integrity. Most, however, are from failure to produce the 1-series and 3-series local hormones known as prostanoids. Linoleic acid is the starting point for this pathway. Normal neonatal status of this fatty acid is marginal, if not insufficient. Fetal linoleic and eicosonic acid (DHA) are correlated with maternal RBC levels.^[10] Since dietary sources (especially corn oil) are abundant, however, linoleic acid may be found to be above normal in some adults. Because of the need for balanced prostanoid and leukotriene synthesis, excessive linoleic acid can contribute to an overproduction of the proinflammatory 2-series local hormones. Compared with other fatty acids, linoleic acid caused growth inhibition of *Helicobacter pylori*, the bacterium thought to cause gastric ulcer.^[11]

Gamma linolenic acid (GLA) (18:3 ω 6)

GLA is the precursor of DGLA, the parent of the 1-series prostanoids, as well as the precursor of arachidonic acid, the parent of the 2-series prostanoids. It is found in hemp, borage, blackcurrant, and evening primrose oils. It can be produced in human tissues by the action of desaturase enzymes on linoleic acid. Use of 1.4g/day in the form of borage seed oil resulted in a clinically important reduction in the signs and symptoms of rheumatoid arthritis^[12] (see [Table 85.4](#), p.729 for other clinical associations). In cases of cancer, it is especially important that low levels of GLA should not be supplemented without added ω 3 fatty acids, because ω 6 fatty acids enhance tumor formation and growth, while ω 3 fatty acids inhibit tumors.^[13] Gamma linolenic acid corrects most of the biological effects of zinc deficiency, indicating that the requirement of the ω 5 desaturase enzyme for zinc is a first-order essential function of zinc.^[14]

Dihomogammalinolenic acid (DGLA) (18:3 ω 6)

Diets low in the essential fatty acid LA are almost universally also low in DGLA. The 1-series prostanoids and leukotrienes are derived from DGLA, so an insufficiency of this

fatty acid impairs a wide range of cellular functions and tissue responses. The 1-series compounds act like the 3-series derived from ALA to moderate the proinflammatory 2-series. In tumor response, however, they are unique in being promoters of growth where the 3-series are inhibitors. When testing reveals low levels of DGLA, supplementation with borage or evening primrose oils should be considered, but if a history of tumor formation is known, always consider ALA sources (blackcurrant) as well. See EPA above (p.136) for other factors affecting the desaturase enzyme required for conversion of GLA into DGLA.

Arachidonic acid (AA) (18:4?6)

Because of the prevalence of corn and corn oil products in feed for cattle and hogs, diets high in these red meats are rich in AA. AA is a 20-carbon or eicosanoate fatty acid that serves as substrate for the cyclooxygenase and lipoxygenase enzymes, leading to the production of the 2-series prostanoids and leukotrienes. Several of these products have potent proinflammatory and thrombogenic activity. High AA also promotes gallstone formation by stimulating mucin production in the gall bladder mucosa.^[15]

Docosadienoic acid (22:2?6), docosatetraenoic acid (22:4?6)

When ?6 dietary fatty acids are constantly supplied in overabundance, the intermediate products of further desaturation and elongation are not utilized as fast as they are produced. Under these conditions, the process of modification can continue through docosadienoic acid to the 22-carbon, four double bonded docosatetraenoic acid (DTA). These fatty acids can then accumulate in adipose tissue. Data from our own studies indicate a strong association of DTA acid in plasma with obesity. Apparently this fatty acid accumulates in adipose tissue from which it is mobilized in the fasting state. No such association has been seen in erythrocyte fatty acid profiles, indicating rapid utilization of these fatty acids once they are mobilized.

The level of DTA in plasma may be useful in monitoring the metabolic aspects of weight control and especially in avoiding the risk of essential fatty acid deficiencies while maintaining a very low-fat diet. A low level of DTA in an individual who is on a fat-restricted weight loss program may indicate a state of essential fatty acid deprivation.

Myristoleic acid (18:1?7), palmitoleic acid (16:1?9), vaccenic acid (18:1?9)

The ratio of vaccenic acid to palmitoleic acid has been reported to be a valuable indicator of biotin deficiency.^[16] Vaccenic acid also seems to have large effects on membrane fluidity, possibly due to the fact that the ?7 double bond does not align with the much more abundant ?9 positions of the majority of fatty acids present in the membrane. Inhibition of tumor growth in cell culture has been reported for vaccenic acid.^[17]

Oleic acid (18:1?9)

Oleic acid is present in all foods that contain fat and is

easily produced by the fatty acid synthetic pathways present in normal human hepatic cells. It constitutes 15% of the fatty acids in erythrocyte membranes. Because of the presence of the double bond in the center of the molecule, it helps to govern the critical nature of fluidity of the membrane matrix.

The pathogenesis of atherosclerosis involves accumulation of foam cells along the arterial wall. Lipids that transform macrophages into these foam cells are provided by oxidized low-density lipoproteins (LDLs). Oleic acid is the principal lipid of a class that makes LDLs resistant to oxidation, and thus a diet rich in this fatty acid reduces foam cell accumulation rates and thereby lowers the chances of atherosclerosis^[18] (see [Ch.133](#) for a more complete discussion).

In tumors, the net result of modification in fatty acid enzymes is low stearic acid and high oleic acid, causing a profound shift in the ratio of stearic to oleic acids.^[19] One likely outcome of this shift is an increased fluidity of the tumor cell membrane, resulting in more rapid movement of nutrients and waste products and allowing for faster metabolic rate. The stearic/oleic ratio is used as a monitor of the effectiveness of therapy.^[20]

High oleic acid intake (usually as olive oil) can raise total oleic acid content of plasma above the reference range. This finding alone is not highly significant since oleic acid is a cholesterol neutral fatty acid and is produced in humans from stearic, so it is not an essential fatty acid.

Erucic acid (22:1?12)

This fatty acid is apparently one of the components responsible for the favorable response of individuals with adrenal leukodystrophy to preparations containing rape and mustard seed oils.^[21] Other studies using Lorenzo's oil containing glycerol trierucate revealed no appreciable changes in brain lipid content.^[22] In Zellweger syndrome, where peroxisomes are absent, erucic and adrenic (docosatetraenoic) acids accumulate. It is speculated that either the anabolic enzymes are inhibited from producing sphingolipids or the catabolic enzymes are stimulated to faster clearance of the offending products.^[23]

Capric acid (10:0), lauric acid (12:0), myristic acid (14:0)

These medium-chain fatty acids correspond to the dicarboxylic acids that accumulate in the fatty acid catabolic disorders known as multiple acyl-coenzyme A dehydrogenation disorders (MAD).^[24] One type of this enzyme defect is responsive to riboflavin at levels far above normal intakes.^[25] A pattern of low levels of the shorter chain fatty acids and high levels of longer chain fatty acids may indicate a fatty acid-restricted diet, in which

case there is a stimulation of hepatic synthesis and elongation enzymes.

Palmitic acid (16:0)

The liver can convert fatty acids into cholesterol. Although any fatty acid can enter this pathway, palmitic acid is the most stimulatory one known and high levels lead to increased serum cholesterol levels and thus to increased risk of atherosclerosis, cardiovascular disease, and stroke. Most other fatty acids are either cholesterol neutral or have reverse effects, as in the case of EPA. Palm kernel and coconut oils are rich sources of palmitic acid. Palmitic is also the principal fatty acid product of human fatty acid synthesis, which is stimulated by dysinsulinemia and by diets high in simple carbohydrates.

Stearic acid (18:0)

Stearic acid is a saturated fatty acid that is two carbon atoms longer than palmitic and is similarly cholesterologenic. High levels in plasma are therefore a risk factor in atherosclerotic vascular disease (see 'Palmitic acid' above). Abnormal levels in erythrocyte membranes cause alteration in membrane fluidity with numerous consequences. Low levels give increased fluidity, which is associated with active tumor proliferation.

Arachidic acid (20:0)

Arachidic acid (20:0) can be utilized as an energy source or 1-position phospholipid, but it serves no other special function. Its accumulation is most likely to exacerbate essential fatty acid metabolism as it binds to the Δ^6 desaturase enzyme and inhibits the insertion of double bonds needed to produce DGLA, EPA and AA.

Behenic acid (22:0), lignoceric acid (24:0), hexacosanoic acid (26:0)

Accumulation of certain very long-chain fatty acids is associated with degenerative diseases of the central nervous system such as adrenal leukodystrophy. There are a large number of known genetic disorders involving accumulation of sphingolipids, usually due to the lack of enzymes needed to maintain the turnover of membrane components. Behenic, lignoceric, and hexacosanoic acids, as well as the unsaturated members of the C22–24 classes, especially nervonic, are found elevated in such cases.

Pentadecanoic acid (15:0), heptadecanoic acid (17:0), nonadecanoic acid (19:0), heneicosanoic acid (21:0), tricosanoic acid (23:0)

Since the normal synthetic pathway for fatty acids leads to only even numbers of carbon atoms in the products,

it may seem curious to find any odd-numbered chains present in human tissues. Fatty acids with odd numbers of carbon atoms are produced primarily by initiating the synthetic pathway with the three carbon compound, propionic acid. Vitamin B₁₂ is required for the conversion of propionate into succinate for oxidation in the central energy pathways.^[26] Deficiency of vitamin B₁₂ results in accumulation of propionate and subsequent build-up of the odd-numbered fatty acids.

The bacteria in the gut of ruminants produce large amounts of propionate, which is absorbed and enters the metabolism. Consequently, the intake of animal and dairy products favors higher levels of odd-numbered fatty acids. Alternatively, it is possible that the bacteria in the human gut could produce sufficient amounts of propionate to lead to an elevation in the odd-carbon fatty acids. This would only occur under conditions of significant gut dysbiosis.

The association between vitamin B₁₂ and abnormal fatty acid synthesis provides a rationale for the neuropathy of cobalamin deficiency. Odd-chain fatty acids would build up in membrane lipids of nervous tissue, resulting in altered myelin integrity and demyelination, leading eventually to impaired nervous system functioning.^[27]

Palmitelaidic acid (16:1ⁿ⁻⁷), elaidic acid (18:1ⁿ⁻⁷)

The *trans* fatty acids, elaidic and palmitelaidic acid, are prevalent in most diets because of the widespread use of hydrogenated oils by manufacturers of margarine, bakery products, and peanut butters. These fatty acids contain one double bond and thus are included in the unsaturated category. Because of the geometry of the *trans* bond, however, they behave like saturated fats on the one hand, leading to higher cholesterol levels.^[28] On the other hand, they mimic unsaturated fats in binding to desaturase enzymes and interfering with the normal production of critical products. The net effect is to raise plasma LDL and lower HDL.

The growing consensus among experts in lipid nutrition is that foods containing hydrogenated oils are to be avoided. These fatty acids are also produced by the bacteria in the gut of ruminant animals, which is the reason that beef and milk contain small amounts (1–3%) of elaidic acid. Moderate use of these foods is unlikely to provide *trans* fatty acids at levels that are of concern. If these synthetic fatty acids are elevated, foods containing hydrogenated oils may need to be avoided. Foods that generally contribute the greatest amounts of *trans* fatty acids include stick margarine, peanut butters, and bakery products such as breads, rolls, cookies, crackers, pies, and cakes. Products with labels that say simply “vegetable oil” should be substituted, avoiding those containing hydrogenated oils.

Fatty acid ratios

As with all ratios of reported laboratory values, the calculated value allows a comparison of the relative magnitudes of the two individual measurements. The added value lies in the use of the ratio as a quick guide to the balance between two parameters. Sometimes valuable insights into imbalances are found in ratio values, even though the individual components are normal.

The LA/DGLA ratio

The ratio of LA to DGLA increases when the $\Delta 6$ desaturase enzyme is inhibited by zinc deficiency or excesses of saturated, monounsaturated, or *trans* fatty acids. Under these conditions, the enzyme cannot convert the substrate (LA) to the product (DGLA) fast enough. The production of all desaturation products is affected, including EPA and AA. These longer chain polyunsaturated fatty acids then must be supplied from the diet or supplemented forms.

The DGLA/EPA ratio

The balance of 20-carbon or eicosenoic fatty acids is critical for proper supply of the prostanoid and leukotriene 1-, 2-, and 3-series local hormones that control a host of cellular functions and responses. The DGLA/ EPA ratio is typically high due to DGLA being elevated relative to EPA, indicating a need for EPA sources such as fish oils. When the ratio is low, sources of DGLA (borage or evening primrose oil) are indicated.

The AA/EPA ratio

This ratio allows a quick comparison of the relative amounts of these two eicosanoid precursors. An abundance of AA is quite common in Western diets high in meat and corn oil and can result in the elevation of the AA/EPA ratio. This is one of the indicators that extra $\Delta 3$ fatty acids, including EPA of fish oils, would be beneficial.

Red cell stearic/oleic index

The ratio of stearic to oleic acids in red cell membranes has been found to be a strong indicator of the presence of malignant tissue, as it reflects the lowered ratio found in malignant tissue cell membranes.^[29] Values below 1.1 are associated with the presence of malignancy. The ratio was found to respond to hormonal therapy for prostatic cancer and, in studies following surgical cures, individuals who maintained this ratio above 1.1 had no tumor recurrences.

The polyunsaturated to saturated fatty acid ratio (P/S)

Originating primarily as a measure of the quality of dietary fats, this ratio is sometimes

used also as a general measure of physiological fatty acid balance. This ratio increases markedly during exercise, as the saturated fatty acids are preferentially utilized as energy sources, causing plasma levels to fall relative to the unsaturated fatty acids.^[30] The availability of individual fatty acid data allows the inclusion of *trans* fatty acids in the saturated group since their physiological behaviour is the same. This has not normally been done in the food industry to date, giving misleadingly favorable ratios on labels. The overall effect of higher levels of the polyenoic fatty acids is suppression of hepatic lipogenesis.^[31]

Total fatty acid concentration (calculated)

When the concentrations of total fatty acids present in plasma are summed and expressed in units of mg/100dl, the result is closely equivalent to that of the routine serum triglyceride assay. In both cases, the fatty acids are normally present in the form of very low-density lipoprotein particles. The treatment of elevated levels by various actions involving dietary restriction of fats, the use of pharmacological doses of niacin and lipid-lowering drugs is in common practice, depending on the class of hyperlipidemia found by studies of lipoprotein subclasses and cholesterol levels.

When total fatty acids are low, there is the possibility of stimulation of peroxisomal oxidation of fatty acids. A number of structurally diverse chemicals have been found to cause proliferation of peroxisomes in liver and other tissues.^[32] Paradoxically, high-fat diets also cause such proliferation. The increased oxidative activity leads to higher levels of hydrogen peroxide and development of liver tumors in laboratory animals.^[33] In humans, the related disorder, hypobetalipoproteinemia, is associated with increased risk for a variety of cancers, pulmonary, and gastrointestinal diseases.^[34]

SUMMARY

Recent advances in laboratory methodologies now allow measurement of absolute, as well as relative, levels of essential, non-essential and potentially damaging types of fatty acids in the blood. The research literature now provides guidance for interpretation of the clinical significance of various fatty acid patterns. Fatty acid manipulation through diet and supplementation is a very powerful therapeutic resource (see [Ch. 85](#)).

Chapter 14 - Folic acid status assessment

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

Folic acid is the nutritionally essential precursor of a large family of compounds collectively referred to as folates. It is a pteridine derivative linked through a methylene bridge to a molecule of para-amino-benzoyl-glutamic acid.

Folate coenzymes are widely distributed in the body and are involved in a diverse variety of metabolic processes: single carbon transfer reactions; biosynthesis of purines, the pyrimidine, thymidate (which is necessary for the formation of DNA), methionine, and choline; histidine degradation; methylation of biogenic amines, such as serotonin; the hydroxylation of proline for collagen formation; and the maturation of erythrocytes and leukocytes.^[1]

Although widely distributed in nature, folic acid is thought to be the most common hypovitaminosis of humans, particularly of indigenous populations.^[2] Deficiency is common during pregnancy (20% of women with otherwise normal pregnancies have been shown to have low folate levels),^[3] lactation, early infancy, and adolescence;^[4] and in those taking a wide range of anti-tumor, antimalarial, antibacterial, anticonvulsive, and contraceptive drugs.^[1]

CLINICAL APPLICATION

Clinical conditions which can be caused by a folate deficiency include megaloblastic anemia, glossitis, diarrhea, affective disorders such as depression, and weight loss. Signs and symptoms may include ulcerative stomatitis, hyperpigmentation of the skin, cervical dysplasia (see [Ch. 142](#)), hepatomegaly, splenomegaly, ankle edema, and the typical non-specific signs of anemia, such as palpitations, angina, light-headedness, and faintness.^[1] ^[5] Folate deficiency has also been shown to impair the phagocytosis and

bactericidal activity of neutrophils.^[6]

A prolonged dietary folic acid deficiency, or the presence of folate antagonists, results in the progressive development of biochemical and hematological abnormalities,

TABLE 14-1 -- Progressive manifestations of folate deficiency^{[7] [8]}

| Duration (weeks) | Abnormality |
|------------------|---------------------------------|
| 2–6 | Decreased serum folate levels |
| 6–11 | Neutrophil hypersegmentation |
| 13 | High urinary formiminoglutamate |
| 17 | Low RBC folate |
| 18 | Macro-ovalocytosis |
| 19 | Megaloblastic marrow |
| 20 | Megaloblastic anemia |

as shown in [Table 14.1](#) . As can be seen, although an abnormal folate status is traditionally suspected by the presence of a megaloblastic anemia, this is a late-stage development. The measurement of neutrophil hypersegmentation is a far better indicator of incipient folate deficiency,^[9] and is an inexpensive test that can be added to the repertoire of the nutritionally oriented doctor. Serum folate is somewhat unreliable since a vitamin B₁₂ deficiency will result in invalidly high levels, and although RBC folate is more accurate, it is not widely available, expensive to run, and gives abnormally low values in patients with a vitamin B₁₂ deficiency.^[10]

[Table 14.2](#) lists the typical causes of folic acid deficiency by mechanism.

PROCEDURE

The measurement of neutrophil hypersegmentation is a useful test that correlates well with serum folate levels ($R = -0.772$), and is easily performed in a clinical laboratory.^[9]

Method

1. Take a standard peripheral blood smear on a 1 inch by 3 inches glass slide.
2. Stain with Leishman or other convenient stain.
3. Count the lobes on 100 neutrophils using an oil immersion objective.
4. Calculate the segmentation index (SI):

$$SI = \text{neutrophils with 5+ lobes} \times \frac{100}{\text{neutrophils with 4 lobes}}$$

TABLE 14-2 -- Causes of folic acid deficiency^[11]

| Mechanism | Cause |
|------------------------|--|
| Inadequate intake | Alcoholism |
| | Dietary insufficiency |
| Increased requirements | Pregnancy |
| | Severe hemolysis |
| | Chronic hemodialysis |
| Inadequate absorption | Tropical sprue |
| | Gluten-sensitive enteropathy |
| | Crohn's disease |
| | Lymphoma of small bowel |
| | Amyloidosis of small bowel |
| | Diabetic enteropathy |
| | Intestinal resection or diversion |
| | Drugs that block absorption |
| | —cholestyramine |
| | —phenobarbital |
| —biguanides | |
| Impaired metabolism | Drugs blocking action of dihydrofolate reductase |
| | —methotrexate |
| | —trimethoprim |
| | —pyrimethamine |
| | —anticonvulsants |
| | Drugs interfering by other means |
| | —phenytoin |
| | —ethanol |
| —antituberculous drugs | |
| —oral contraceptives | |

Results

- Normal: SI = 2–30%
- Folate-deficient: SI = 31.5–116%

INTERPRETATION

Although abnormal folate levels are responsible for 90% of patients with neutrophil hypersegmentation in the absence of macrocytic anemia, other causes must be considered. It is seen in uremia, and 7% have a vitamin B₁₂ deficiency.^[12] It is also a congenital condition in as much as 1% of the population.^[13]

Chapter 15 - Food allergy testing

Stephen Barrie ND

INTRODUCTION

The purpose of food allergy testing is to determine, in a reliable and reproducible manner, a patient's food sensitivities. When used in conjunction with a comprehensive history and food diary, the tests discussed here can help to determine what foods or chemicals an individual might be sensitive to.

Often, patients are unaware that they are sensitive to one or more foods because their reactions are either "masked" or "lost in the crowd". There are several well known immunological mediators of food sensitivity: IgE and IgG (immediate and delayed), and various immune complexes, as well as one or more unknown mechanisms of food allergy or food intolerance (see [Ch. 51](#)). ^[1] ^[2]

There are two broad categories of applicable tests commonly used:

- laboratory methods that attempt to measure immune complex formation in a variety of ways (both in vitro and in vivo)
- experiential clinical tests which challenge the patient with suspected allergens while carefully monitoring for reactions.

LABORATORY METHODS

Enzyme linked immunosorbent assay (ELISA)

The ELISA is an in vitro test that requires serum from the patient (it is fully described in [Ch.10](#)). This immunological procedure uses an enzyme bonding process to detect antibody levels and has been hailed as a "safe, economical, and highly sensitive test". It is currently the most popular method in use. The ELISA can measure IgE, IgG, IgG₄ and IgA antibodies, therefore identifying both immediate and delayed hypersensitivity reactions. In general, the ELISA method has replaced radioactive testing methods

because it is less expensive and avoids the use and exposure to radioactive material, as used, for example, in RAST and RASP tests (discussed below).

In addition to the procedural advantages, one of the key advantages of the ELISA over other laboratory methods is its ability to measure IgG₄ antibodies. This subclass of antibody was initially thought to act as a blocking antibody, thereby exerting protective effects against allergy. However, it now appears that IgG₄ antibodies are actually involved in producing allergic symptoms.^[3] For example, in a study in asthmatics it was demonstrated that asthma in these patients could be produced in response to inhaled antigens that did not bind to IgE antibodies, but did bind to IgG₄.^[4] These results suggested that IgG₄ antibodies play a major role in atopic disease. In short, IgG₄ has been shown to act as an anaphylactic antibody, especially to food antigens.^[5]

With regard to food allergy testing, it has been shown that the “combination of specific IgE and specific IgG₄ is a better correlate to positive food challenge than is skin testing alone”.^[6]

Radioallergosorbent test (RAST)

This is an in vitro test that requires serum from the patient. Suspected allergens are coupled to a solid matrix, followed by application of a sample of the patient's serum. If the patient's serum or plasma contains an antibody specific to the antigen, it will couple with the antigen, thus becoming attached to the solid matrix. A minute amount of radioactive-polyclonal antireaginic-antibody is then added. After incubation and subsequent washing, the residual radiation is measured to determine what percentage of the radioactive antibody became bound to the allergen-antibody solid matrix. The higher the radioactive bond, the greater the amount of reagenic antibody specific to the allergen tested is present in the patient's serum.^[7]

The underlying assumption in this test is that a person without food sensitivity will have little or no food antigen specific antibodies in their blood. The RAST primarily measures immediate IgE-mediated sensitivities (i.e. type I reactions which occur in less than 1 hour). While traditional allergists believe that most food allergy is IgE-mediated, there is growing evidence that other immunological factors, especially IgG, may be considerably more important.^[8] ^[9] ^[10] RAST seems to have better specificity and sensitivity for inhalants than for foods. Some studies have shown a poor correlation of RAST results with individual food challenge,^[11] while others have demonstrated a positive correlation.^[12]

RAST results are not influenced by B-receptor stimulants, ephedrine, antihistamines, or steroids, which can sometimes influence other tests (e.g. the skin scratch test). Results can be available within several days or up to several weeks, depending on where the laboratory is located (serum can be mailed without affecting the results). Many

commercial laboratories offer the test, and it is available in kit form for in-office laboratories. Pharmacia was the first to market test kits for specific IgE (called Phadebas RAST). RAST results contain more false-negatives than false-positives.

A variant of this radioimmune assay (RIA) procedure is the enzyme immunoassay (EIA). In EIA, the same principles as in RIA are used. Using colorimetry or spectroscopy, EIA measures the enzyme broken off at the disulfide bridge on the anti-IgE to which the enzyme was tagged. Pharmacia offers EIA as Phadezym IgE (PRIST).

Radioallergosorbent procedure (RASP)

The RASP is a variant of the RAST, although it follows a slightly different protocol. It has been shown to have a higher degree of sensitivity and specificity for food allergens than the RAST.^[9] ^[11] In clinical practice, it appears to uncover a much higher degree of food allergy. Recent information suggests that the RASP may be measuring some IgG complexes in addition to IgE, which helps to explain the increased sensitivity.

Provocation-neutralization and serial dilution titration tests (P-N, S-D)

These controversial techniques are employed primarily by clinical ecologists. P-N testing is an in vivo technique which diagnoses a sensitivity by assessing the ability of a test dose to evoke symptoms and induce wheal growth. In the P-N method, 0.5 ml serial dilutions (in a 1:5 ratio) of each whole extract antigen dissolved in glycerin, phenol, or distilled water are administered intradermally.^[13] The goals of this method are, first, to identify substances that provoke symptoms, and second, to discover which dilutions of those substances are appropriate for treatment (see [Ch. 51](#)).

Empirically, it has been found that certain dilutions of an offending substance will provoke, while other dilutions will relieve, various of the patient's characteristic symptoms during a 10 minute test period after each dilution.^[14] The P-N method is applicable for a wide range of allergens – foods, pollens, dusts, molds, and chemicals.^[15] In the P-N method, the neutralizing dose is a symptom-relieving dilution. Both stronger and weaker dilutions can provoke symptoms. Thus, the dose– response curve is often non-monotonic (i.e. biphasic). The P-N method may be used with wheal response alone, or in combination with symptom response.

A variant (especially useful in children) involves provocation through sublingual drops. With this approach, symptom provocation and neutralization are the only criteria for diagnosing sensitivities. Sublingual P-N is frequently used for testing food colorings and certain food chemicals, and is frequently effective for diagnosing

sensitivities in hyperkinetic children.^[16] While there have been both positive and negative studies, the P-N technique enjoys wide clinical use.^[17] ^[18] ^[19] Due to its expense, patient time requirements (3 hours for four foods), and potential patient discomfort, the P-N is

not a practical broad-screening technique for foods, except in special circumstances.

The serial dilution (S-D) technique is similar to the P-N technique. This titration method uses wheal changes alone to identify, and then neutralize, natural inhalants such as pollens, dusts, and molds.^[20]

EAV acupuncture technique

The electroacupuncture diagnostic method utilizes a galvanometer designed to measure the skin's electrical activity at designated acupuncture points. Electro-acupuncture, according to Voll (EAV), has been used in Europe for many years to determine the abnormalities or energy imbalances of the body. Proponents claim that allergy is a pathogenic and measurable entity. This controversial technique purports to measure both general allergic pathology and specific food sensitivity.^[21] The patient holds a negative electrode in one hand, and the positive electrode probe is used to press selected acupuncture points. When a suspected food is placed on an aluminum tray which is connected into the circuit, certain galvanometer reading changes indicate sensitivity. If the appropriately diluted form of the extract is then placed on the tray, equilibrium of the reading should occur.

In order for this technique to gain wider acceptance, more research and clinical trials will have to be conducted, and a scientifically satisfactory explanation of its mode of operation will have to be developed.

Kinesiologic

Practitioners of applied kinesiology (AK) claim that kinesiologic muscle testing can diagnose food allergies. After either the patient has ingested a small amount of the antigen, or the antigen has been placed on the surface of the patient's body, certain of the muscles are tested kinesiologically for strength and weakness. This technique is widely used by AK practitioners (particularly chiropractors), and, if it is effective, does have the advantage of being inexpensive and fast.

More research needs to be done in order to confirm the limited clinical claims, and, as with the EVA technique, a satisfactory explanation of its mode of action must be developed.

EXPERIENTIAL CHALLENGE METHODS

Many physicians believe that oral food challenge is the definitive method ("gold standard") for diagnosing food sensitivities. Orthodox practitioners, clinical ecologists and naturopathic physicians agree that food challenge is an accurate and useful procedure when used with an appropriate patient. This is especially true considering research reports of food intolerance which is not detected by current immunological assessments.

For example, a recent study carefully evaluated antibody levels in four infants who had

rice intolerance with symptoms which include shock, vomiting, diarrhea, and positive occult blood tests.^[22] None of the immunologic tests was positive. All the symptoms disappeared during 6 weeks of a diet free of rice and flour. Histologic changes in the intestinal mucosa were noted after rice was reintroduced. This information is especially important since rice is commonly suggested as a component of an elimination diet in patients with food allergy.

When the relationship between ingestion of certain foods and resulting symptoms is unclear, the use of food challenge methods is warranted. There is, of course, a wide variety of protocols and indications among the physicians using these methods.

There are two broad categories of food provocation challenge testing:

- elimination or oligoantigenic diet, followed by food reintroduction
- pure water fast, followed by food challenge.

Food challenge may be performed in an open, single-blind, or double-blind manner.

Note. Food challenge testing should *not* be used in patients with symptoms that are potentially life threatening (such as airway constriction or other severe anaphylaxis).

Challenge/oligoantigenic diet method

The patient is placed on a limited diet; common foods are eliminated and replaced with either hypoallergenic and rarely eaten foods, or special hypoallergenic formulas (such as Vivonex).^[23]^[24] The fewer the allergic foods, the greater the ease of establishing a diagnosis with an elimination diet. The patient stays on the limited diet for at least 1 week (up to 1 month). The first 4 days are considered the “cleansing period”, with the GI tract being cleared of previously ingested foods, thus decreasing food sensitivity reactions. On the fifth or sixth day, symptoms due to food allergy usually disappear (if the food was eliminated), and the patient generally feels better. Care must be taken to ensure that suspected foods are not hidden in other foods and thus unknowingly consumed.

Beginning on day 7, individual foods are reintroduced according to some type of plan. Methods range from having the patient reintroduce only a single food every

2 days, to one every one or two meals. A careful record is made of any symptoms that may reappear.^[25]

It can be useful to have patients track their wrist pulse during the trial, as it has been shown that pulse changes can occur in some people when a sensitive food is ingested.^[26] During the cleansing period, the patient will typically develop an increased

intolerance, or “hyperreactivity”, to sensitive foods. This explains why the reintroduction of foods may produce a more severe or recognizable symptom than before.

The challenge/elimination diet has proven clinically very useful in several studies. For example, one group of researchers studied 322 children under 1 year of age, 99% of whom had allergic rhinitis symptoms, while 85% had bronchial asthmatic symptoms.^[27] The children, who were negative for inhalant skin tests, were placed on a 6 week hypoallergenic diet consisting of a meat-based formula: beef, carrots, broccoli, and apricots. Two hundred and ninety-two, or 91%, experienced improvement of respiratory symptom scores during the trial. Oral food challenge produced symptoms in 51% of the children. Milk, eggs, chocolate, soy, legumes, and cereals, in that order, were the most commonly offending foods. Only 6% of the children showed any evidence of food hypersensitivity 5 years later.

For patients with limited financial resources, as well as those with less severe health problems, elimination diets offer a viable means of detection. Because the patient can sometimes dramatically experience the effects of food reactions, motivation for therapy can be improved. The procedure is time-consuming and requires patient discipline and motivation.

Dietary fast with food challenge

A refinement which yields more results than the simple elimination diet is the 5 day water fast with subsequent challenge. Proponents of this approach believe that it is necessary for the patient to fast for at least 5 days in order to “clear” the body of all allergic responses.^[28] This procedure can be performed on an outpatient basis, or in a hospital clinical ecology unit.^[15] During the fast, patients are likely to experience “withdrawal” symptoms which will usually subside by the fourth day. As in the elimination diet, symptoms caused by food allergy will diminish or be eliminated after the fourth day.

After the 5 day fast, individual foods are singly reintroduced, with the patient monitoring symptoms and pulse. Due to the hyperreactive state, symptoms tend to be more acute and pronounced than before the fast. This method can produce dramatic results, greatly motivating the patient to follow whatever therapeutic procedures are appropriate.

This method is only advisable for people who are physically and mentally capable of a 5 day water fast. Close patient monitoring during the fast is a necessity.

TABLE 15-1 -- Advantages and disadvantages of the food allergy testing methodologies

| Procedure | Advantages | Disadvantages |
|------------------|---------------------------------------|---------------------------------|
| ELISA | Patient convenience | Limited research substantiation |
| | Detects both IgE and IgG ₄ | |
| | Good sensitivity | |

| | | |
|--------------------|--|-------------------------------------|
| RAST | Patient convenience | Low sensitivity |
| | Good for inhalants | Expensive |
| | Office kits available | Detects IgE only |
| RASP | Patient convenience | Expensive |
| | Good sensitivity | Not widely available |
| | | Detects IgE and only some IgG |
| Skin prick | Widely available | Poor sensitivity |
| | Good for inhalants | Inconvenient |
| Provocation | Good for chemicals | Expensive |
| | Office procedure | Time-consuming |
| | Aids therapy | |
| EAV acupuncture | Inexpensive | No scientific basis |
| | Easily applied | Few clinical studies |
| Kinesiologic | Inexpensive | No scientific basis |
| | Easily applied | Few clinical studies |
| Oligoantigenic | Sensitive to all types of food intolerance | Requires highly compliant patient |
| | Inexpensive | Can be dangerous if severe reaction |
| | Improved patient motivation | Susceptible to irrelevant events |
| Fast/challenge | Sensitive to all types of food intolerance | Requires highly compliant patient |
| | Inexpensive | Can be dangerous if severe reaction |
| | Improved patient motivation | Susceptible to irrelevant events |

At times, careful interpretation of results is needed, due to the occurrence of delayed reactions.

SUMMARY

There is a wide variety of diagnostic food allergy test methods available. These procedures encompass a broad range of accuracy, sensitivity, specificity, patient economics, risk factors, suitability, and comfort, not to mention “medicophilosophical”

paradigms. [Table 15.1](#) summarizes the advantages and disadvantages of each methodology.

Each practitioner will have to develop his or her own operating plan, bearing in mind that different procedures are suitable in certain conditions and that new procedures are constantly being developed. No matter which methods are used, there is a wonderful cross-check for results: if the offending food is eliminated, the patient feels better; if it isn't, he/she doesn't!

Chapter 16 - Functional assessment of liver phase I and II detoxification

Dan Lukaczer ND

INTRODUCTION

The concept that toxins accumulate in the body and are the cause of various health problems has long been a fundamental tenet of traditional health care systems around the world. For centuries, societies have valued therapies which have promoted the idea of cleansing and detoxifying. From the simple water fast used since antiquity to the sometimes elaborate detoxifying regimens of spas, saunas, enemas, hydrotherapy treatments, and dietary modifications, detoxification as a therapeutic goal has long been pursued. In the late 20th century, as society has increasingly been exposed to toxic compounds in the air, water, and food, it has become apparent that an individual's ability to detoxify substances to which they are exposed is of critical importance in their overall health.

In any large population exposed to the same low levels of carcinogens, some individuals will develop cancer while others will not. The variability that one finds here and in other diseases appears to be associated, in part, with the individual's ability to detoxify various pro-carcinogens and other xenobiotics.^[1] It is then not only the level of the toxin in the environment, but the individual's response that is significant. Until recently, science has had difficulty calculating and objectively analyzing the individual response to toxic compounds. New functional assessment tools have become available to the health professional which significantly enhance our understanding of interindividuality in detoxification. These tools allow clinicians to quantitatively analyze the body's ability adequately and properly to detoxify compounds to which it is exposed. In fact, new research suggests that the ability of the body to adequately transform toxic metabolites formed from both internal metabolism and external xenobiotic exposure may be related causally to various puzzling disease entities such as chronic fatigue syndrome, fibromyalgia, and multiple chemical sensitivities.^[2] Research has also begun to validate the hypothesis that the dysfunction of the body's detoxification ability

may underlie various chronic neurologic diseases such as Parkinson's and Alzheimer's.^[3]

THE HEPATIC DETOXIFICATION SYSTEM

The process of conversion and excretion of toxic substances to non-toxic metabolites takes place at two major sites: the intestinal mucosal wall and, more significantly, the liver. There are two distinct phases in the biochemical processes related to detoxification. These two processes, traditionally known as phase I and phase II, chemically biotransform toxins into progressively more water-soluble, and hence excretable, substances, through a series of chemical reactions (see [Figure 16.1](#)).

Phase I detoxification

The phase I reactions usually involve oxidation, reduction, or hydrolysis, the most important of which is performed by a family of enzymes commonly referred to as cytochrome P450 mixed function oxidases.^[4] This system is actually a group of many isoenzymes which have specific affinity for differing substrates. They are responsible for beginning the process of detoxifying xenobiotics such as petrochemical hydrocarbons and medications, and endogenous substances such as steroid hormones and other end-products of metabolism, which would also be toxic if allowed to accumulate. In phase I, the biochemical reaction involves the adding or exposing of a functional group to the toxic molecule. In most cases, this biotransformation allows the phase I compound to undergo phase II conjugation reactions. In some cases, the compound may be eliminated directly after the phase I reaction.^[5]

As is evident in [Figure 16.1](#) , a significant consequence of this biotransformation is the increase in oxidant stress and free radical generation.

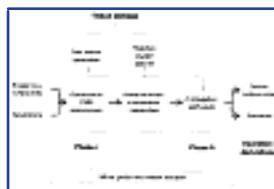

Figure 16-1 The major hepatic detoxification pathways.

Phase II

In the more common scenario, the phase I reaction produces an intermediate to be further transformed by phase II conjugation. This intermediate step in the process of transforming toxins to excretable harmless metabolites is referred to as “bioactivation”. These biotransformed intermediates can be highly reactive and are, in fact, often more toxic than the original compound. Because of this, the more promptly and efficiently

these metabolites are acted upon by the phase II reactions, the less tissue damage will occur. Therefore, of fundamental importance in detoxification is the balance of activities between the phase I and phase II processes. If phase II reactions are inhibited in some way, or if phase I has been upregulated without a concomitant increase in phase II, that optimal balance is compromised.

Whereas the primary phase I reactions are a family of isoenzymes, phase II reactions, in which various biotransformed molecules are conjugated, are distinct reactions. The main conjugation reactions are glucuronidation, amino acid conjugation, sulfation, glutathione conjugation, acetylation, and methylation.^[6] These conjugation reactions involve the addition of a molecule to the intermediate metabolite to further increase its hydrophilic qualities, allowing for final elimination in the urine or bile.^[7]

PROCEDURE

In assessing the liver's detoxification ability, one is evaluating the functional capacity of this organ system. Measuring functional capacity and performance of an organ system is not new. Exercise EKG and the oral glucose tolerance tests are two examples in which the functional capacity, and therefore organ reserve, is appraised. Assessment of the activity of hepatic detoxifying systems is a new example of this challenge method. These tests differ substantially from the normal liver tests found in most panels, such as SGOT, GGPT, and SGPT. Those tests measure liver pathology, not liver metabolic function.^[8] Elevation in the serum of these enzymes occurs as a consequence of necrosis of hepatic tissue. Functional liver testing, on the other hand, measures the detoxifying ability of the liver when challenged with a test substance. These tests allow assessment of the metabolic capacity of the liver, and thus provide a window to an individual's facility to adequately deal with his or her environment.

Laboratory assessment of the liver's detoxifying ability has been extensively studied.^[9] To evaluate the various metabolic pathways of detoxification discussed above, probe substances, whose detoxification pathways are well established, are ingested, and their metabolites are measured in the urine, blood, or saliva.

Phase I assessment

Research over the past 20 years has shown that caffeine is a model substance for testing the phase I P-450 system.^[10] A measured amount of caffeine is ingested, and then timed saliva samples are taken over the next 8 hours. Caffeine is almost completely absorbed by the intestine and is metabolized in the liver primarily by the isoenzyme P-4501A2. (To date, at least 20 different P450 isoenzymes have been identified.^[11]) Its rate of clearance, as measured in saliva, has proven to be an ideal non-invasive way to assess activity of this P450 enzyme.^[12] ^[13] Genetics, nutrition,^[14] ^[15] ^[16] medications, ^[17] and environmental factors^[18] ^[19] such as alcohol, heavy metals, and smoking can all influence the inducibility of this enzyme system.^[20] Elevation or

depression of the rate of caffeine clearance suggests up- or downregulation. Dietary elimination of caffeine-containing foods and medications is instituted 24 hours before the test.

Phase II assessment

As mentioned above, phase II reactions involve a number of distinct conjugating substances. The most important appear to be glycine conjugation, glutathione conjugation, glucuronidation, and sulfation. To accurately assess these pathways, two additional probe substances – acetaminophen and either aspirin or sodium benzoate – have been employed. Acetaminophen is metabolized through three phase II pathways: glutathione conjugation, sulfation, and glucuronidation to form urinary acetaminophen mercaptuates, acetaminophen sulfate, and acetaminophen glucuronide, respectively (see [Fig. 16.2](#)).^[21]

Aspirin is readily degraded into salicylic acid, which is eventually conjugated and metabolized through glycine conjugation and glucuronidation to form salicylic acid and salicyl glucuronide, respectively.^[22] Alternatively, in individuals with salicylate sensitivities, the common food preservative, sodium benzoate, can be used to assess phase II glycine conjugation.^[23] Either way, the metabolites are then measured in the urine.

These probe markers therefore serve as useful, well researched challenge substances for the functional evaluation of four important phase II detoxification pathways.^[24] As with the caffeine challenge above, foods and medications containing aspirin, acetaminophen and sodium benzoate are eliminated 24 hours prior to the test.

Alternative pathways

Using these probe substances, one is provided with a tool for assessing the body's detoxification capacity which gives the clinician insight into the unique sensitivities the patient may have to his or her environment. For most toxins in need of detoxification, multiple pathways are utilized. Under optimal conditions, there is a particular affinity of a xenobiotic for a particular pathway.

When a pathway is underdeveloped, saturated, or bottlenecked, other pathways will be utilized in the metabolism of toxins. However, the alternative pathway may be less desirable because of incomplete detoxification or accumulation of toxic intermediates. A good example of this is the metabolism of acetaminophen. The usual pathways for this compound are primarily glucuronidation and sulfation. If these pathways are inhibited or depleted, an alternative pathway is through glutathione conjugation after acetaminophen is biotransformed by the phase I pathway. This biotransformed intermediate, *N*-acetyl-*p*-benzoquinoneimine (NAPQI), is a highly neurotoxic substance and, if not rapidly cleared by glutathione conjugation, can result in severe toxicity.^[25] Not only are the sufficiencies of the various individual pathways of importance, but the relative balance of phase I and phase II detoxification is critical, as this determines the longevity

of the biotransformed intermediates.

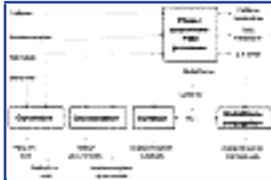

Figure 16-2 Degradation of acetaminophen and other probe substances.

TABLE 16-1 -- Interpretation of phase I and II marker excretion rates

| Result | Interpretation | Possible causes | Possible consequences |
|-------------------------------|---|---|--|
| Low caffeine clearance | Impaired phase I | Drugs (e.g. antihistamines, benzodiazapine antidepressants, amphetamines, H ₂ blockers, isoniazid, oral contraceptives), deficiency (e.g. copper, magnesium, zinc or vitamin C), grapefruit juice, aging, spice curcumin | Increased susceptibility to toxins |
| High caffeine clearance | Overactive phase I | Drugs (alcohol, nicotine, phenobarbital, sulfonamides, steroids), heavy toxin exposure, charcoal broiled meats, herb sassafras | Excessive production of activated intermediates, increasing their potential for toxicity and carcinogenesis Depleted glutathione |
| Low salicylic acid | Impaired phase II glycine conjugation | Deficiency of glycine, low-protein diet | Increased susceptibility to toxins |
| Low acetaminophen mercaptates | Impaired phase II glutathione conjugation | Deficiency (glutathione, vitamins B ₂ , B ₆ , selenium, zinc), excessive exposure to toxins, fasting | Poor detoxification of acetaminophen, nicotine from cigarette smoke, organophosphates, epoxides |

| | | | |
|-------------------------------|-----------------------------------|---|--|
| Low acetaminophen sulfate | Impaired phase II sulfation | Deficiency (cysteine, methionine or molybdenum), drugs (NSAIDs), tartrazine, diet low in sulfur compounds (e.g. egg yolks, peppers, garlic, onions) | Increased susceptibility to neurotoxins, poor detoxification of neurotransmitters, estrogen, aniline dyes, coumarin, acetaminophen, methyl-dopa, increased risk of Parkinson's disease, Alzheimer's disease and rheumatoid arthritis |
| Low acetaminophen glucuronide | Impaired phase II glucuronidation | Deficiency (glucuronic acid), drugs (aspirin, probenecid), excessive oxidative stress | Poor detoxification of acetaminophen, morphine, diazepam, digitalis |

INTERPRETATION

[Table 16.1](#) lists the interpretation, possible causes, and possible consequences of the abnormal rates of phase I and II detoxification. As genetic variability affects all the detoxification pathways, it is not listed as a possible cause.

CLINICAL APPLICATIONS

Over the past 10 years, extensive research into the detoxification ability of the individual has resulted in the continuing evolution of our understanding.^[26] ^[27] Sluggish, imbalanced or impaired detoxification systems can result in the accumulation and deposition of metabolic toxins, increased free radical production and its ensuing pathology, and impairment of oxidative phosphorylation and consequent reduced energy production. Substances that upregulate phase I, such as alcohol, smoking, and certain medications, can have a deleterious effect upon this balance, because the phase II pathways may be unable to keep up with the demand. Conversely, various medications such as antidepressants (e.g. Prozac), oral birth control pills, and H₂ blockers (e.g. Tagamet) may inhibit phase I. This may also create problems, as endogenous and exogenous toxins may go unchanged and therefore lead to toxic reactions.

Cancer

The relative detoxification ability in an individual plays an important role in the toxicity or carcinogenicity of a specific substance. Upregulation of various P450 isoenzymes may be detrimental, as most chemical carcinogens are not capable of causing genetic damage by themselves, but require activation to electrophilic species.^[28] For example, it has been shown that the risk for hepatic carcinoma is associated with the degree or

activity of a particular isoenzyme of the cytochrome P450 system.^[29] Elsewhere, it was shown that evaluations of detoxification rates were predictive of bladder cancer incidence when other factors were held constant.^[30] Individuals with a high inducibility phenotype for P4501A1 appear to have a higher risk for cancer, regardless of exposure to smoking or other known carcinogens.^[31] As the majority of all cancers can be related to environmental exposure or dietary intake, it is apparent that individual detoxification ability can be an important factor for their development.^[32]

Gilbert's syndrome

Variability of detoxification may be involved in diseases previously thought to be benign. Gilbert's syndrome (GS), thought to be a condition with little morbidity, is a genetically induced, nutritionally exacerbated metabolic disorder determined to be caused by a deficit in the glucuronosyl transferase enzyme which catalyzes the phase II conjugation step of glucuronidation.^[33] Recently, however, it has been seen that GS can predispose people to the bioactivation, and potentially the toxicity, of drugs for which glucuronidation constitutes a major, alternate pathway of elimination.^[34] There is some evidence that

nutritional support in GS patients improves a wide variety of symptomatology which previously had not been associated with this disorder.^[35] Although further research is in order, this line of inquiry may open up a window to exploring how other detoxification "defects" may impinge upon health.

Chronic fatigue immunodeficiency syndrome

Current research on the etiology of chronic fatigue immunodeficiency syndrome (CFIDS) suggests that there may be a relationship between impairment in detoxifying pathways and symptomatology,^[36] and that CFIDS may be a result of toxic exposure.^[37] Correction of these imbalances and deficiencies has proven to be of significant benefit in alleviating some patients' symptoms.^[38] A recent trial using nutritional modulation to support detoxifying pathways and a food elimination diet resulted in significant improvement in subjective symptom evaluation as well as objective improvement of phase I and II balance.^[39]

Neurological diseases

Detoxification has clinical implications for chronic degenerative diseases as well. Research into the etiology of Parkinson's disease has discovered defects in patients' abilities to adequately metabolize sulfur-containing xenobiotics.^[40] Altered detoxification, then, may render susceptible individuals at higher risk to neurotoxicity when exposed to sulfur-containing compounds.^[41] A combination of genetic susceptibility, reduced detoxification capacity, and increased exposure to neurotoxins creates an increased risk of damage which, over the course of time, may lead to clinical disease. Connections

with Alzheimer's and other motor neuron diseases have also been made.^[42] Certainly genetic determination is but one factor and must be looked at in light of the strong support that has been found for the role of nutritional and environmental factors.^[43]

Autoimmune disease

Emerging research is now showing a possible relationship role for altered hepatic detoxification ability in lupus erythematosus and rheumatoid arthritis.^[44]

Endocrine disorders

As noted, various drugs or chemicals may have an inhibitory or stimulatory effect on the detoxification capacity. Because of this, other molecules detoxified through the same pathway may be slowed down or speeded up. For example, cigarette smoking upregulates certain phase I P450 isoenzymes. These same enzymes are involved in the detoxification of estrogen. As a consequence, it has been noted that serum estrogen levels are lower in women who smoke. This fact may in part explain the increased incidence of osteoporosis and menopausal symptoms in women smokers as compared with non-smokers.^[45]

CONCLUSION

The consequences of defective drug metabolizing enzymes and pathways are varied. They may lead to:^[46]

- functional overdose due to inefficient elimination of an active drug
- lack of efficacy due to inefficient activation of a drug
- idiosyncratic toxicity unrelated to the intended drug effect
- associations with apparently spontaneous diseases.

This opens up a huge field of inquiry to the identification and proper counseling of individuals, and dietary, environmental, or supplemental modification to take those biochemical individualities into account.

As we are increasingly exposed to higher levels of xenobiotics in the food we eat, the water we drink, and the air we breathe, as well as the increased endogenous load from faulty digestion, detoxification and our "detoxification personalities" will become increasingly important. Studies of detoxification function show that the enzymes that control the various phase I and phase II processes may vary significantly from person to person, with a wide variability in apparently healthy people.^[47] ^[48] There are numerous pharmacogenetic variants affecting drug disposition and which are manifested only upon drug or environmental challenge. This new understanding of detoxification brings us back full circle to a greater appreciation of Roger Williams' work some 40 years ago and his popularization of the term and concept of "biochemical individuality".^[49] Differences among individual detoxification capacities based upon individual genetic disposition, environmental exposure and nutritional insufficiencies can have a profound effect upon susceptibility to a wide variety of diseases. Xenobiotics may act as

immunotoxic agents, suggesting a biochemical connection between the immune, nervous, and hepatic detoxification systems.^[50] The intriguing question is how many diseases we now consider idiopathic, or disorders of unknown origin, may be linked to atypical detoxification reactions? Disordered detoxification may have wide-ranging impact upon hepatic, renal, cardiovascular, neurological, endocrine, and immune system function. Certainly, the complicated interrelationship among exposure to various substances, genetically determined detoxification pathways, alteration of the pathways by foods, drugs, and chemicals, and sensitivity of tissues

to secondary metabolites from toxins play an under-recognized role in contributing to the appearance of many health problems.

Identifying slow, fast, or otherwise imbalanced steps in the individuals' detoxification pathways can be extremely important to the clinician. Laboratory assessment of hepatic detoxification gives the health professional more precise and definitive assessment tools, an ability to define an individual's unique metabolic detoxification capacity, and then the opportunity to tailor nutritional support and environmental factors to reduce symptoms associated with metabolic toxicity.

Chapter 17 - Hair mineral analysis

Steve Austin ND
Nick Soloway LMT DC LAc

INTRODUCTION

Despite several research studies since the original publication of this chapter in 1985, there has been little change in the *diagnostic* value of hair analysis (HA). Outside its accepted use for diagnosis of heavy metal toxicity (see [Ch. 18](#)), HA still has, at this time, only limited clinical application.

In recent years, several attempts have been made to standardize hair analysis testing techniques^[1] and broaden the non-specific screening uses for which HA may be employed. However, its accepted use is still only in testing for heavy metal contamination.

Many conditions and diseases have been tested for abnormal HA patterns, and, indeed, a number have been shown to have patterns differing significantly from the norm, including, among others:

- learning disabilities^[2] ^[3]
- birth defects^[4]
- hyperactivity ^[5] ^[6]
- Down's syndrome^[7] ^[8]
- neurosis and psychosis^[9]
- senile dementia ^[10]
- autism^[11]
- alopecia areata^[12]
- insulin-dependent diabetes mellitus^[13] ^[14]
- cystic fibrosis^[15]
- beta-thalassemia. ^[16]

More recently, HA has been used successfully to test for drug abuse,^[17] ^[18] although the

indices measured (drug metabolites) are not found on most commercial hair analyses.

In a few of the above-mentioned conditions, HA appears to offer real potential as a diagnostic tool. For example, the high hair sodium in infants with cystic fibrosis shows very little overlap with controls, and one study demonstrated that children with learning disabilities can be diagnosed with 98% accuracy due to a consistent pattern of high hair cadmium, manganese and

chromium, in conjunction with low lithium and cobalt.^[2] As a result of this progress, the non-invasive nature of the procedure, its low cost, and the philosophical relevance of mineral balance, HA has remained popular with nutritionally oriented practitioners.

Hair analysis' usefulness as a research tool can hardly be questioned. Significant controversy exists, however, over the use of HA for the clinical diagnosis of diseases, other than heavy metal toxicity, and as an indicator of nutritional status. The difference between research and clinical use is a significant one. Whereas it may be of interest in a research setting that patients with various skin conditions have lower mean levels of hair magnesium than controls, the two groups overlap so much that the procedure is useless diagnostically.^[12] Moreover, even when an altered HA pattern has been associated with a disease, there is generally no investigation as to whether mineral supplementation would affect the clinical condition or even revert the hair mineral pattern to normal.

Wide overlap of disease and control groups is frequently the case with HA, resulting in excessive false-positives and -negatives. For example, mentally retarded patients have been found to have lead, sodium, and potassium hair levels approximately twice those of controls,^[7] but when we consider the enormous standard deviations (for sodium, 1644.71 ± 1814.93 vs. 744.43 ± 1987 ;^[12] and for potassium, 870.15 ± 1009.19 vs. 408.35 ± 689.99), we again see a pattern of overlap greatly reducing the clinical use of HA. In addition, many of the altered HA patterns associated with the diseases listed above are as yet unconfirmed.

SPECIFIC MINERALS

Calcium and magnesium

The literature on hair levels of calcium and magnesium is surprisingly sparse. Low magnesium levels have been found in autistic children^[11] and in patients with various skin disorders,^[12] while high levels have been reported with dyslexia,^[19] and Prader–Willi syndrome.^[20] The significance of these data is unknown. Elevations in both calcium and magnesium were correlated with a low dietary Ca/P ratio in one study whose author suggested that this may be indicative of an induced hyperparathyroidism.^[21] Although there was little overlap between the groups, once again large standard deviations mar the clinical usefulness of these results. Passwater & Cranton^[22] reviewed the limited

literature on hair magnesium and calcium, but few if any conclusions can be drawn.

There is little evidence to support the use of hair calcium and magnesium in clinical diagnosis at this time.

Chromium

Hair chromium is low in insulin-dependent diabetics,^[14] although there is much overlap with normals. Hair and tissue chromium levels vary greatly during pregnancy, being very high during the first few months of normal pregnancy and subsequently decreasing.^[23]^[24] Late in pregnancy, hair chromium typically becomes low,^[25] suggesting deficiency.^[17] However, high hair chromium in pregnancy is associated with low-birth-weight infants^[26] and gestational diabetes. Increasing dietary chromium has been linked to increasing hair chromium,^[27] while supplemental chromium does not seem to alter hair levels.^[23] ^[28]

Although normal and deficiency ranges need to be more clearly defined, hair chromium appears to have potential future use in clinical settings.

Copper

Oral contraceptive use is associated with decreased hair copper and increased serum copper.^[29] High hair copper is associated with being female, lactation,^[30] idiopathic scoliosis,^[31] and pregnancy in some,^[30] but not all,^[32] studies.

Unfortunately, conditions which affect systemic copper status have been shown not to affect hair levels. Copper deficiency,^[33] Wilson's disease,^[34] and cirrhosis^[35] do not significantly alter hair copper. Copper levels also vary with geographical location.^[36] However, fur and liver copper have been found to correlate in rats,^[35] and one study has reported that supplemental copper raises hair levels.^[37]

At this time, hair copper appears unreliable for clinical application.^[30]

Manganese

Levels of hair manganese in mothers of infants with congenital malformations and their offspring were significantly decreased in one study,^[4] which may allow maternal hair levels to be used as an indicator of the risk of malformations. Altered levels of manganese were also found in epileptics,^[38] although the difference was not significant. Hair manganese levels were elevated in violent behavior with varying levels of significance.^[39] ^[40] Evidence that manganese supplementation will affect behavior does not appear to exist at present.

Hair manganese may serve as a useful research tool in the study of altered behavior, but the most promising value of hair manganese may lie in the prediction of congenital malformations.

Selenium

Well water and hair selenium levels show good correlation.^[41] High hair levels are seen in toxicity,^[42] and low levels are seen in deficiency.^[43] Tissue values reflect short-term variations in intake^[36] and hair levels increase significantly after supplementation.^[44]

161

As with chromium, insufficient data are now available to establish reliable norms and the incidence of false-positives and -negatives remains unknown. When these problems are resolved, hair selenium shows promise for clinical use.

Sodium and potassium

It is generally accepted, even by HA proponents, that hair sodium and potassium do not reflect dietary status.^[45] Very high elevations of hair sodium may be diagnostic in cystic fibrosis,^[15] but require confirmation. A relatively low Na/K ratio has been reported in celiac disease.^[46] Although many HA advocates site low hair sodium and potassium as indicative of “adrenal exhaustion”, the only (preliminary) study on the subject reported that hair sodium and potassium do not correlate with adrenal function.^[47]

Except for cystic fibrosis, hair sodium and potassium appear to hold little promise for clinical use.

Zinc

Hair zinc levels have received more research attention than any other mineral. Low hair zinc has been associated with zinc deficiency,^[48] anorexia nervosa,^[49] hyperactivity,^[6] gender,^[50] age,^[51] atherosclerosis,^[52] beta-thalassemia,^[16] vege-tarianism,^[53] short stature in childhood,^[54] ^[55] ^[50] poverty,^[56] ^[57] ^[58] and insulin-dependent diabetes mellitus.^[13]

Because a few of these conditions have been associated with potential zinc deficiencies and supplemental zinc has been shown to increase hair zinc levels,^[48] ^[49] ^[55] ^[59] practitioners who use HA often rely on hair zinc as an indicator of zinc status.

Unfortunately, shampooing and dying affect hair zinc levels,^[60] as does the sex of the subject^[60] ^[61] ^[62] ^[63] and hair growth rate. Malnourished children have shown both low,^[57] ^[64] ^[65] and high^[66] hair zinc. Poor correlations between hair zinc and height, weight and zinc consumption have also been reported.^[37] ^[61] Although very low hair zinc levels have been reported in patients with insulin-dependent diabetes mellitus,^[59] there is, in general, considerable overlap between cases and controls.

At this time there is no definitive explanation or correlations for hair zinc levels. The speculative interpretation is that high hair zinc levels reflect acute deficiency while low

levels indicate chronic deficiency, an hypothesis which has yet to be proven.

Drug abuse

Recently, HA has been used to detect drugs of abuse and their metabolites when urine tests were negative.^[17] Hair analysis has been used as evidence in a court of law concerning past drug abuse.^[18] Although there are concerns about the role of HA in testing for drug abuse,^[67] HA does seem to be a valuable tool in drug screening. As mentioned above, drug metabolites and not mineral levels are measured in these trials.

Ratios

The experimental documentation for the majority of the ideal ratios that have been published by several HA companies has not been found. The Zn/Cu ratio has been reported to be altered in violent patients.^[40] This ratio was also elevated in survivors of myocardial infarcts,^[68] but the clinical significance is not known.

DISCUSSION

Hair mineral analysis is conceptually very enticing and potentially a valuable clinical tool. However, problems abound. Many variables affect the results (see Austin^[69] for a comprehensive review):

- gender
- hair color
- cold waving
- bleaching
- exogenous contamination
- variations in mineral content within a given sample, etc.

This is further aggravated by the reporting of different results on the same sample from different laboratories.^[70] The distribution of elements within the lipid and non-lipid portions of hair and the treatment of the sample prior to testing may explain the variance.^[71] As noted above, dietary intakes do not necessarily correlate with hair levels; and hair color, sex, age, and other variables appear important for some minerals. Separate norms are only now being established and reviews of the literature attempting to establish reference values show a large variance in mean values, standard deviations and ranges.^[36] ^[72]

As a result of the gulf between available information on the one hand, and the clinical interest by some practitioners on the other, several articles have appeared decrying the misuses of HA.^[73] ^[74] ^[75] Hambidge ^[74] says:

There is a wide gulf between the limited and mainly tentative justification for their use on an individual basis and the current exploitation of multielement

chemical analysis of human hair.

Klevay et al^[76] acknowledge the experimental usefulness of HA but go on to say that "... its use in clinical medicine for diagnosis, prognosis, and therapy will remain limited until validation by the standard methods of clinical investigation is achieved".

Widespread use of speculative diagnostic procedures

162

invites condemnation, especially when the burden of these speculations falls on the pocketbook and psyche of the patient. HA is a valid and useful screening tool for toxic metal exposure (lead, mercury, cadmium, arsenic, and selenium). It has the potential of becoming a clinical tool of considerable use in other areas. Current abuse is perhaps as likely to hinder this development as to help it.

Chapter 18 - Heavy metal assessment

Stephen Barrie ND

INTRODUCTION

With the enormous amounts of toxic metals in the environment, assessing patients for heavy metal exposure is increasingly important. Consequently, elemental analysis is one of the most rapidly advancing fields in medicine. Rapid development of new technologies and the attendant possibility for new exposure patterns are a practical concern for the astute physician. In this chapter, the status of hair, urine and blood elemental analysis for providing a precise gauge of element exposure is examined.

Although measuring blood and urine are the traditional element assessment tools, the significance of measuring element concentrations in scalp hair has now been studied for more than 30 years. While blood and urine reflect the body's dynamic equilibrium, hair acts as a depot and indicates element storage over time. Numerous studies correlate elements in hair with environmental exposure (such as to smelters and mines) and with disease and physiologic or pathologic effects. Additionally, geographic variation and historical trends in hair element levels have been published, and hair analysis is used in forensic medicine. Consequently, hair analysis provides a long-term record that reflects normal and abnormal metabolism, assimilation, and exposure.^{[1] [2] [3]}

ASSESSMENT METHODOLOGIES

Each of the three tissues regularly used to assess heavy metal load has its advantages and disadvantages. Hair is perhaps the best sample to screen patients for suspected heavy metal toxicities. It provides good long-term exposure assessment, is non-invasive, inexpensive and allows for investigation of nutrient/toxic interactions. Urine shows what elements the body is currently excreting. It provides good qualitative information if a person has been recently exposed to a toxic element (days–weeks), and gives quantitative information of excreted elements before, during and after provocative challenge. Blood provides information about what the

body has recently (hours–days, in some cases weeks) absorbed. This is largely independent of tissue deposition. Blood levels vary according to the actual component analyzed (plasma, serum, RBCs). They can be transient in nature, and are subject to the body's homeostatic mechanisms.

Hair analysis

Numerous papers have been published evaluating the accuracy and efficacy of hair testing, particularly for toxic metals.^[4] ^[5] The EPA published a study in 1979 in which more than 400 reports on hair testing were reviewed. The authors concluded that hair is a “meaningful and representative tissue for biological monitoring of most of the toxic metals”.^[6] Hair element testing is best viewed as a screen and shouldn't be used to diagnose the presence or absence of disease, but rather to monitor element imbalances and environmental toxicity. Follow-up blood testing or provocative urine testing is useful to confirm hair element findings.

To understand how hair retains elements, it is important to know the structure of hair and how hair protein is synthesized and traps minerals. The hair shaft is a filament formed from the matrix of cells at the bottom of the hair follicle deep in the epidermal epithelium. Each follicle is a miniature organ that contains both muscular and glandular components. Human hair is composed of 80% protein, 15% water, and small amounts of lipids and inorganic materials. The mineral content of the hair is 0.25–0.95% of dry ash.^[7] Of the approximately 100,000 hairs in the average human scalp, 10% are in the resting phase. During the growth phase, the scalp follicles produce hair at a rate of 0.2–0.5 m/day or about 1 cm each month.

The growing hair follicle is richly supplied with blood vessels, and the blood that bathes the follicle is the transport medium for both essential and potentially toxic elements. These elements are then incorporated into the growing hair protein. Unlike other body tissues, hair is a metabolic end-product that incorporates elements into its structure while growing. As hair approaches the skin surface, it undergoes a hardening process, or keratinization, and the elements accumulated during its formation are sealed into the protein structure of the hair. Thus, element concentrations of the hair reflect concentrations in other body tissues.

Hair has a long history in human and animal studies of revealing chronic exposure to toxic metals. Because hair is biologically stable, accurate assays can be performed, even on hair that is hundreds of years old. For instance, hair samples taken from Napoleon were tested for arsenic poisoning.^[8] In recent years, hair screening for toxic elements such as lead, mercury, cadmium, and arsenic has received substantial scientific validation.

Environmental exposure to toxic metals may be infrequent and highly variable, and hair element concentrations are most meaningful when cumulative intake and exposure over

time are the case.^[9] ^[10] ^[11] Research suggests that hair metal content provides a better estimate for long-term risk when compared with blood metal levels.^[12] Hair is an excellent medium because concentrations often are up to 300 times higher than those of serum or urine. Because hair stores these elements, it is a barometer of early, chronic exposure and often reflects excess exposure before symptoms appear.

Urine analysis

Urine element testing is currently receiving a considerable amount of research attention.^[13] ^[14] The urine is an appropriate sample to assess the excretion of potentially toxic elements, providing a window on levels retained in the body and duration of exposure. As astutely stated by one researcher of heavy metal exposure in Denmark, a reasonable example of developed countries: "... high-dose environmental or occupational trace element exposure rarely occurs and health risk assessment is mainly pertained to the health effects of long-term low-dose exposure."^[13] Under certain conditions, urine samples are optimal to gauge the effects of long-term, low-dose type deposition of toxic elements.

Provocative testing can help to determine toxic element deposition and provide the clinician with clear therapeutic direction and accurate monitoring of treatment response. In this technique, a strong excretory inducer is administered to the patient after a pretreatment urine sample is obtained. After a given time frame, dependent upon the agent used and the analytical technique applied, a second urine sample is collected and the post-treatment excretion of elements calculated. This method allows sampling of the stored deposits of toxic elements which have been sequestered from the blood.

Blood analysis

Minerals can be stored in various tissues where they may cause damage or metabolic interference in the depot structures (e.g. kidney, bone, nerve tissue) without causing particularly elevated blood levels. Cadmium, for example, accumulates in the renal tubules where it eventually reaches a threshold above which it causes damage and the potential for hypertension. The blood levels reflect only the last 2–3 months of absorption, whereas urine elemental analysis shows cadmium storage, mostly from the kidneys. Since cadmium has a biological half-life in humans of greater than 10 years, the cumulative deposition of this element can be of significant concern.^[15]

The ability of the blood to counter changes in element concentration keeps many toxic levels within a narrow range, unless under heavy exposure. This homeostatic response illustrates the effective clearance mechanisms in the blood, and largely explains why blood analysis is best used only for short-term exposure. Exploring the depot storage of toxic metals is better met by urine and hair testing.

TOXIC METALS

Toxic metals used in industrial processes have increased human exposure dramatically during the last 50 years. These toxins can lead to a variety of symptoms (see [Ch. 37](#)).

Toxic elements have detrimental effects, even at minute levels, but the effects vary with the mode and degree of exposure and with individual metabolism and detoxification. Mechanisms of toxicity are multiple and include:

- enzyme or cofactor inhibition
- enzyme potentiation
- disruption of membrane and other transport processes
- decreases in neuronal functioning or nerve conduction processes.

Some of these effects are synergistic among elements or with toxic chemicals. Studies confirm that toxic elements can directly influence behavior by impairing brain function, influencing neurotransmitter production and utilization, and altering metabolic processes. The gastrointestinal, neurological, cardiovascular and urological systems are particularly sensitive to heavy metal-induced impairment and dysfunction.

The level of toxicity of these elements and corresponding adverse effects vary among individuals. Chronic, subacute exposure may lead to subtle or overt long-term problems in selected individuals and is of particular concern in children. Lead and mercury, in particular, show deleterious effects in children, in part due to their high growth rates and low body mass. The toxic elements may impair various enzymatic and neurologic processes gradually and progressively.

Below are some relationships that have been made between toxic elements and various types of dysfunction. Since hair analysis often serves as an easily available and inexpensive screening procedure, most of the following discussion focuses on this tissue for toxic element evaluation.

Aluminum

Aluminum is ubiquitous, being the most prevalent element in the Earth's crust. Sources of exposure may include drinking water (especially from areas exposed to acid rain), aluminum cookware, and aluminum-containing medications such as antacids. Urine levels of aluminum are observed to be elevated in people with a history of antacid intake.^[16] The estimated half-life of aluminum found in the urine is 7.5 hours; however, the excretion kinetics vary according to the form of aluminum to which the patient was exposed.^[17]

A disturbing pattern of aluminum accumulation and interference with normal neurological function appears to be supported in the literature. Dyslexic children have been shown to have higher levels of aluminum in their hair compared with controls, and other behavioral difficulties in school also correlated with elevated levels of this

element.^[18] ^[19] There are geographical links with Alzheimer's disease and high aluminum in drinking water. Elevated hair aluminum has been observed in Alzheimer's patients, and some Alzheimer's patients experience stabilization of their symptoms upon treatment with the aluminum-chelating agent desferioxamine. Amyotrophic lateral sclerosis, another neurodegenerative disease, may also be linked with aluminum content of water supplies.^[20] ^[21] Aluminum also can interfere with phosphate absorption leading to hypophosphatemia.

Antimony

Antimony accumulates in the hair of exposed workers and their children, with higher levels accumulating in the children's hair.^[22] Local environmental pollution (i.e. via airborne particles from phosphorus fertilizer production and smelting processes) leads to these elevated hair levels.^[23] The smaller body mass of children combined with greater accumulations of antimony is perhaps cause for concern regarding potential toxicities in areas of high exposure. Antimony salts have in the past been used for the treatment of a wide range of parasitic infections, but, because of high toxicity, are now only used for the treatment of leishmaniasis. Chronic industrial exposure results in:

- itching skin pustules
- bleeding gums
- conjunctivitis
- laryngitis
- headache
- weight loss
- anemia.

Arsenic

Arsenic toxicity has been recognized for centuries. This toxicity manifests in a number of ways including muscular weakness and sensorimotor polyneuropathy, and in subacute exposure may lead to macrocytosis,

anemia, jaundice, brown cutaneous pigmentation, hyperkeratosis of palms and soles, and white transverse banding of nails (Mee's lines). Continuing research is discovering new disease associations. One study which evaluated bladder cancer mortality over a 5-year period in 26 counties in the US, found that bladder cancer was significantly higher in counties with documented arsenic exposure. There was a dose-response relation between inorganic arsenic exposure from drinking water and bladder cancer.^[24] Another study found a strong, dose-dependent relationship between ischemic heart disease and arsenic exposure.^[25] Hair arsenic shows significant correlation with intake.^[26]

Cereals are a major source of arsenic during infancy, and changes in hair arsenic levels

during infancy correspond to the introduction of cereals in the diet.^[27] Disturbing sources of arsenic, and other heavy metals, are a few contaminated, or adulterated, Chinese and Ayurvedic herbal remedies. In one study, imported traditional Chinese herbal balls used for fever, rheumatism, apoplexy and cataracts showed an arsenic level of 0.1–36.6 mg/ball. The recommended dose of two herbal balls daily could theoretically provide a daily dose of 73 mg of arsenic.^[28]

Barium

The insoluble form of this element, barium sulphate, is used as an X-ray contrast medium and is non-problematic. Absorbable barium salts (hydroxide, chloride, or carbonate) may occur in some pesticides.^[29] Few studies relate barium levels in the hair to pathologic processes; however, one retrospective study indicated that high levels in the hair along with an elevated calcium/magnesium ratio correlated with myocardial infarction.^[30]

Cadmium

Cadmium is another toxic metal with a long history of detrimental effects. Industrialization has brought much higher levels of cadmium into the environment as a result of zinc and lead smelting, as well as industrial waste exposure, plastics production, paints, antiseptics and fungicides, and cigarette smoking. Cadmium exposure has been associated with hypertension, and studies show that hair levels of hypertensives are higher than controls.^[31] Hair cadmium has also been shown to be significantly and inversely related to the activity of erythrocyte Na^+/K^+ ATPase among a group of male smokers. This enzymatic inhibition by cadmium was noted at levels far below toxic levels and may provide additional insight into the link between hypertension and cadmium exposure.^[32] Cadmium appears to inhibit sulfhydryl-containing enzymes so that relatively low doses depress levels of norepinephrine, serotonin and acetylcholine.^[33] Hair analysis is useful for evaluating cadmium in smoker and non-smoker populations of industrially non-exposed urban and rural areas.^[34] Smoking itself causes significant elevation of toxic element levels in hair, particularly cadmium, lead, and nickel.^[35] The urine level of cadmium is also a good measure of body stores, particularly relating to the kidney.^[36] As it has been established that renal toxicity occurs once a threshold is exceeded, measurement of urine levels is a clinically useful technique.^[37]

Lead

Lead is the best-known example of health problems associated with chronic low-level toxic element exposure. Studies show that lead toxicity is associated with deficits in central nervous system functioning that can persist into young adulthood.^[38] Hair lead and cadmium are correlated with both reduced intelligence scores and lowered school achievement scores.^[39] A recent study with 277 first-grade children gave some indication of the profound effects of lead on learning and behavior. There was a highly significant ($P < 0.0001$) relationship between hair lead and children with a high deficit rating in teacher questionnaires relating to concentration and task completion.^[40] One study on lead noted a sevenfold increase in failure to graduate from high school.^[41] The

accepted level for lead-engendered neurotoxicity in children has declined steadily over the past decade as more sophisticated studies have been conducted. Sources are primarily from leaded solder joints, lead-based paint, and inner city urban environment.

Mercury

No metabolic functions are known for which mercury is required. Mercury is considered to be toxic at any level in the body, and at high concentrations causes liver and kidney damage and neurological symptoms.^[42] Symptoms of mercury poisoning include:

- salivation
- stomatitis
- diarrhea
- neurologic signs (trembling, dysarthria, ataxia, irritability)
- changes in mood and affect.

Interest has grown in the possible ill health effects of mercury liberated from dental amalgam fillings as well as the increased consumption of fish contaminated with mercury.^[43] ^[44] Another potentially significant source may be contaminated or adulterated Chinese and Ayurvedic herbal medicines. One disturbing study of imported traditional Chinese herbal balls used for fever, rheumatism, apoplexy, and cataracts showed a mercury

content ranging from 7.8 to 621.3 mg. The recommended dose of two herbal balls daily could theoretically provide more than 1,200 mg of mercury. Chronic mercury sulfide poisoning from ethnic Ayurvedic remedies has also been documented.^[28]

There is intriguing evidence correlating increased hair mercury levels with certain disease conditions.^[45] ^[46] For instance, chronic mercury ingestion may be a risk factor for cardiovascular disease. Recent data suggest that a high intake of mercury from non-fatty freshwater fish and the consequent accumulation of mercury in the body is associated with an increased risk of acute myocardial infarction, as well as death from cardiovascular disease in general. This increased risk has been proposed to be due to the promotion of lipid peroxidation by mercury.^[47]

Collaborative evidence for this finding comes from a Finnish case-controlled study in which higher numbers of dental fillings in individuals were associated with an increased risk of acute myocardial infarction.^[48] There is other support that mercury from dental fillings results in increasing body burden: scalp hair mercury levels of British dentists and dental hygienists were two to three times higher than those of the support staff.^[49] A study of dentists, dental nurses, and assistants showed that the average elevation of urine mercury levels were significantly related to the number of amalgam fillings the subjects had.^[50]

Both hair and urinary mercury have been associated significantly with elevated titers of immune complexes containing oxidized LDL.^[51] This supports other evidence which shows that mercury can induce autoimmune disease in both humans and experimental animals.^[52] Mercury from dental fillings may also be a factor in multiple sclerosis, as hair mercury was found to be significantly higher in MS subjects than in the non-MS controls.^[53] The above studies support the utility of hair and urine mercury measurement in situations of dietary, dental or environmental exposure.

Nickel

Nickel accumulates with age and smoking, perhaps explaining why tissue levels are highest in patients who died of cardiovascular disease.^[54] ^[55] Hair appears to be an accurate medium for evaluation of total tissue burden of nickel. Findings of elevated IgG, IgA, and IgM, and decreased levels of IgE have been observed in patients with high hair levels.^[56] Most exposure leading to elevated hair levels is via dust from nearby industries including electrometallurgical emissions.^[57] ^[58]

Given nickel's ability to cause contact dermatitis, and its observed perturbation of immunoglobulin levels, elevated hair levels may serve as a warning sign for immune dysfunction along with its potential as a helpful marker of cardiovascular risk.

Uranium

Increased exposure to uranium dust has long been associated with increased incidence of lung cancer.^[59] Although there are no strong studies linking hair uranium with either cancer risk or radon exposure, hair levels (measuring U238) do correlate with environmental exposure to this element. The accumulation of uranium in the hair may be related to blood group, with types AB and B having a higher apparent affinity for the element.^[60] In animal studies, a condition of low iron nutriture led to greater retention of uranium as evidenced by hair levels.^[61]

Vanadium

Correlations between hair vanadium levels and bipolar disorder indicate that the elevated vanadium found among patients with active symptoms tends to normalize during recovery.^[62] Vanadate is reported to inhibit Na/K ATPase. This effect is decreased by a number of psychotropic drugs used to treat bipolar disorders and depression which catalyze the vanadate–vanadyl reaction. This results in a less inhibitory impact on the enzyme system and clinical improvement.^[63] Here we see a correlation between changing hair levels of an element and movement toward clinical recovery, an affirmation of homeodynamic response mechanisms at work.

CONCLUSION

Research during the past three decades suggests that the relationship between hair, blood and urine element concentrations and human health is an important and complex

process. Variables of key clinical relevance include exposure sources, absorption dynamics and tissue distribution of the various essential and toxic elements. As our understanding of the sophisticated relationships among nutrient and toxic elements grows, so will the utility of tissue elemental analysis for diagnosis and treatment applications.

Chapter 19 - Heidelberg pH capsule gastric analysis

Stephen Barrie ND

INTRODUCTION

Proper digestion is a prerequisite for optimum health, and incomplete or disordered digestion can be a major contributor in the development of many diseases. The problem is not only that ingestion of the best nutritional substances may be of little benefit when breakdown and assimilation are inadequate, but also that incompletely digested macromolecules can be inappropriately absorbed into the systemic circulation. This can lead to various immune complex deposition diseases, and this process is now theorized to be an integral part in the etiology of food allergies.

Adequate gastric HCl is also necessary for protection of the gastrointestinal tract from ingested pathogens and for the maintenance of proper bowel flora. A healthy flora is known to be important for proper immune function, vitamin absorption, and the prevention of opportunistic infections, such as *Candida albicans*, in the gut.

The Heidelberg gastric analysis technique was developed to measure the pH of the digestive tract and determine the acid secretory ability of the parietal cells. Its use of radiotelemetry allows the gathering of this important information in a convenient and accurate manner.

The Heidelberg pH capsule system had its origin over 30 years ago at Heidelberg University in Germany. In research sponsored by Telefunken, a West German electronics firm, the inventor H. G. Noeller studied gastric acidity in 10,000 people. Since then, over 100 studies have utilized the Heidelberg system to investigate various aspects of digestion.^{[1] [2] [3] [4] [5] [6] [7]} Physicians and researchers now utilize this technique for measuring the pH of the digestive system.

PHYSIOLOGY OF DIGESTION IN THE STOMACH

The epithelium of the stomach contains many gastric

174

glands. These tubular glands consist of parietal, chief, and mucous cells. The antral portion of the stomach produces the digestive hormone gastrin whose release is stimulated by

- vagal nerve stimulation
- the physical bulk of the ingested food distending the stomach
- partially digested proteins.

After gastrin is absorbed into the bloodstream, it is carried to the gastric glands where it stimulates the parietal cells to produce hydrochloric acid and, to a lesser extent, the chief cells to produce digestive enzymes (such as pepsin and intrinsic factor). With adequate stimulation, the parietal cells increase their production of HCl by as much as eightfold.

When the pH of the stomach reaches about 2.0, the gastrin mechanism becomes blocked, and feedback causes the parietal cells to decrease production of HCl. This concentration of hydrogen ions (by a factor of 100,000) is a very energy-dependent process.

Dietary protein is composed of amino acids held together by peptide linkages. Pepsin A, the major gastric protease, cleaves these in the stomach and is most active at pH values of between 2.0 and 3.0. It is inactive at a pH of 5.0 and above. Consequently, in order to have any significant digestive effect in the stomach, the gastric juices must be acidic.

Trypsin (a protein-splitting enzyme secreted by the pancreas) completes the process, yielding amino acids and dipeptides. The biochemical messenger which stimulates this pancreatic secretion is the acidic bolus of food moving from the stomach into the duodenum.

PROCEDURE

Equipment

The Heidelberg system consists of the following equipment:

- Radiotelemetry capsule – a hard plastic capsule (about 2 cm long × 0.8 cm in diameter) which contains a miniature radio transmitter, a pH sensing device and a saline activated battery.
- Waistband antenna – receives the signal from the capsule and relays it to the

receiver.

- Receiver/recorder – receives and translates the signal. The pH reading is displayed on a meter and recorded by a continuous printer for a permanent record. The receiver also contains a calibration probe used to calibrate each capsule with known pH 1.0 and 7.0 solutions.
- Heater block – maintains the calibrating solutions at 37°C.

Methods

There are two ways in which to conduct the test: the tethered capsule repeat challenge and the flow-through method. Each gives different information and has its advantages and disadvantages. For both procedures, the test begins after the patient has fasted (food and liquid) for 8 hours.

The tethered capsule repeat challenge

In this procedure, the capsule is tethered so that it remains in the stomach while the stomach is challenged by the ingestion of a saturated sodium bicarbonate solution (NaHCO_3 , i.e. baking soda).^[8] The challenge solution triggers a rise in stomach pH and a subsequent attempt by the parietal cells to re-establish appropriate acidity. The majority of people have a normal initial pH of between 1.0 to 2.3. Abnormalities of stomach secretions are usually found only after the stomach is challenged. (A more involved protocol can be found in Wright.^[8])

The procedure is as follows:

1. The waistband antenna is fastened around the patient's waist and the receiver/recorder is turned on and calibrated.
2. The patient swallows the capsule, which is attached to a 1 m long, thin cotton thread (a small amount of distilled water is allowed). The pH reading typically starts at 7.0 and falls towards 1.0. After about 5 minutes, the capsule reaches the bottom of the stomach (which normally displays a pH of between 1 and 2) and the remaining thread is taped to the cheek in order to prevent movement of the capsule out of the stomach and into the intestine.
3. If the fasting pH is normal, the patient swallows the first challenge of 5 ml of the alkaline solution. Within 30 seconds, the pH will normally rise to 7.0 and the patient is asked to lie down on his/her left side (to keep the stomach contents in as long as possible).
4. If stomach function is normal and acid is secreted sufficiently in response to the alkali challenge, the pH returns to normal (between 1.0 and 2.0) within 20 minutes.
5. The challenge is repeated up to four times, as long as the response time is within 20 minutes.

Flow-through capsule

In this procedure, the capsule is not tethered to a thread and is allowed to move freely from the stomach into the duodenum and the rest of the small intestine. The proponents

of this method claim that this allows measurement of the gastric emptying time and intestinal pH, both of which are important parameters.

INTERPRETATION

Results may be classified as normal, hypochlorhydria, achlorhydria, and hyperchlorhydria.

Normal. The patient successfully reacidifies after four challenges (see [Fig. 19.1](#)). No. 1 shows the capsule entering digestive tract; no. 2 shows the capsule reaching bottom of stomach and alkaline challenge occurring; and no. 3 shows a pH rise after swallow and subsequent reacidification within 20 minutes.

Hypochlorhydria. The patient requires more than 20 minutes to reacidify (see [Fig. 19.2](#)). No. 4 shows a pH of 1.0 being reached after 30 minutes. Note that on the third challenge, the pH comes back only to about 5.0.

Achlorhydria. The patient's stomach shows little acid secretion and is not able to secrete enough acid to bring the pH below 4.0, even on the first challenge (see [Fig. 19.3](#)). The pH remains at about 4.2 for almost 2 hours.

Hyperchlorhydria. The gastrogram would show extremely rapid reacidification (within 5 minutes) after each challenge.

Depending on specific curve components, some investigators believe that mucous quantity, fresh or chronic ulcers, and acute gastritis conditions can at times be identified.

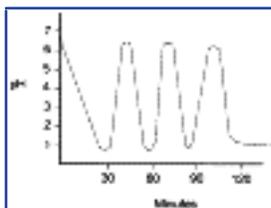

Figure 19-1 Normal Heidelberg gastrogram.

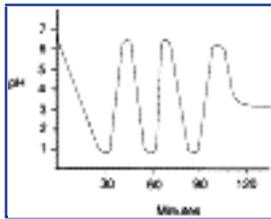

Figure 19-2 Hypochlorhydric gastrogram.

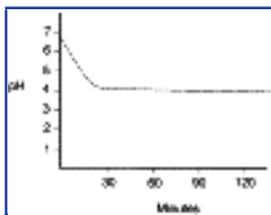

Figure 19-3 Achlorhydric gastrogram.

CLINICAL APPLICATION

Although much is said about hyperacidity conditions, probably more significant health problems are caused by hypochlorhydria and achlorhydria. Direct measurement of gastric acid secretion through intubation and aspiration is uncomfortable and unacceptable to many patients. The Heidelberg pH capsule system offers a convenient and accurate outpatient testing system to clinicians interested in evaluating gastric function.

Hydrochloric acid, pepsin and intrinsic factor are involved directly in digestion and contribute to the chemical changes in the intestines that assist in the absorption of many nutritional factors. For example, vitamin B₁₂ absorption requires intrinsic factor, while zinc, calcium, and iron are poorly assimilated when gastric acidity is low.^{[9] [10] [11]}

Indications

There are many symptoms and signs that suggest impaired acid secretory ability, and a number of specific diseases have been found to be associated with achlorhydria and hypochlorhydria (particularly HLA-B₈ -related autoimmune diseases). These are listed in [Tables 19.1](#) , [19.2](#) and [19.3](#) .

Aging

Numerous studies have shown that acid secretory ability decreases with age. Low stomach acidity has been found in over half of those over the age of 60.^{[24] [25]} One study of

TABLE 19-1 -- Common symptoms of low gastric acidity^[12]

-
- Bloating, belching, burning, and flatulence immediately after meals
-
- A sense of “fullness” after eating
-

- Indigestion, diarrhea, or constipation
- Multiple food allergies
- Nausea after taking supplements
- Itching around the rectum

TABLE 19-2 -- Common signs of low gastric acidity^[12]

- Weak, peeling and cracked fingernails
- Dilated capillaries in the cheeks and nose (in non-alcoholics)
- Post-adolescent acne
- Iron deficiency
- Chronic intestinal parasites or abnormal flora
- Undigested food in stool
- Chronic candidal infections
- Upper digestive tract gassiness

the elderly found that their tissue nutrient levels could be saturated only through the use of intramuscular supplementation; oral supplementation was ineffective. The authors speculated that this was due to atrophy of various digestive organs.^[26]

CONCLUSION

The Heidelberg pH capsule system is an effective and convenient method to determine gastric acid secretory ability under conditions simulating ingestion of food. Results are extremely valuable in identifying the large

TABLE 19-3 -- Diseases associated with low gastric acidity^{[13] [14] [15] [16] [17] [18] [19] [20] [21] [22] [23]}

Chapter 20 - Immune function assessment

Aristo Vojdani PhD MT

INTRODUCTION

The human immune response is dependent on a diverse army of cells and molecules working in concert to protect the body against invaders. The ultimate target of all immune responses is an antigen, which is usually a foreign molecule from an invading microorganism or cancer cell. The immune system is composed of essentially two aspects: non-specific defenses, called cell-mediated immunity, and specific defenses, called humoral immunity.

Cell-mediated immunity, the first strike force, involves special white cells (typically T-cell lymphocytes and neutrophils) which immediately attack the invader and either prevent its entry into the body, or, if the invader manages to gain a foothold, quickly destroy it. Cell-mediated immunity is especially important in the body's ability to resist infection by yeasts (such as *Candida albicans*), fungi (such as athlete's foot), parasites (worms), and viruses (such as herpes simplex and Epstein-Barr). Cell-mediated immunity is also critical in protecting against the development of cancer and is commonly involved in allergic reactions.

Humoral immunity involves sensitized white cells and antibodies. Formed to uniquely match the surface of invaders, the humoral immunity team either damages them directly (sometimes by making them clump together) or alerts and activates other white cells to attack the pathogen. Although powerful, since these sensitized white cells and antibodies are tailored just to suit a specific invader, they take several days to develop.

Specialized antigen-presenting cells such as macrophages roam the body, ingesting the antigens they find and fragmenting them into antigenic peptides. This activates circulating T-cells that recognize the specific antigen. For a cell-mediated immune response to occur, antigen-specific T-cells must be stimulated. Interleukin-1, a product of activated macrophages, enhances this T-cell response. T-cell stimulation results in the clonal proliferation of helper T-cells, cytotoxic (killer) T-cells,

suppressor T-cells and memory T-cells. When activated, T-cells produce and secrete a wide variety of immune chemicals, including interleukin-2, gamma-interferon and B-cell growth factors. These chemicals, known as cytokines, recruit and activate non-specific destructor cells such as natural killer (NK) cells, polymorphonuclear phagocytes (PMNs) and macrophages. Cytokines also stimulate the further growth and differentiation of T-cells and B-cells. In the presence of antigen and activated T-cells, B-cells will rapidly proliferate and differentiate into plasma cells. Plasma cells secrete antibody into the blood and lymph. The antibody binds to the antigen that stimulated its production. This response, also antigen-specific and known as humoral immunity, is shown in [Figure 20.1](#).

Recent advances in immune function assessment

Unraveling the immune system's intricacies and finding better methods for diagnosing and treating its disorders are two of the most formidable challenges facing contemporary medicine. The best way to meet these challenges is through painstaking research that draws upon and combines the expertise of diverse disciplines. Only through leadership in research can a brighter future be anticipated by the estimated 65 million Americans with dysfunctional immune systems. Research into the immune system, how it functions and its relationship to health and disease, is therefore vital to identifying the cause and potential cure of the immunologically mediated diseases.

In the last several years, immunology as a section of the diagnostic clinical laboratory has increased in scope tremendously. New knowledge about cellular immunity, including lymphocyte subsets and advances in protein chemistry, bacteriology and cell biology has increased our understanding of human immunopathology and, at the same time, has made available clinically useful antigens and antibodies with great specificity and sensitivity. The developing technologies of monoclonal antibody production and genetic engineering have had tremendous impact on the quality of reagents available to the research and clinical laboratories.

Recognizing the need for research as well as the importance of education, the National Coalition on Immune System Disorders (NCISD) was established in 1987 to represent the millions of adults and children afflicted with immune system-related disorders and diseases. Since 1987, significant achievements in the field of immunology have been made which have contributed to the advancement of biomedical science. Based on these achievements, "our science is maturing, and the power of using the immune system for diagnosis and treatment of diseases is in place". Some of these developments of most interest are the ability to monitor T-helper 1, T-helper 2, T-suppressor 1, and T-suppressor 2 involvements in immune dysregulation, lymphokines and cytokines produced by these lymphocyte subsets, and the capability

Figure 20-1 Humoral immunity.

of measuring these lymphocytes at the message as well as at the protein level.

All these are now possible, thanks to development of two major discoveries of the 1970s and 1980s in the field of molecular immunology: the monoclonal antibody and polymerase chain reaction.

Polymerase chain reaction (PCR) technology enables laboratories to detect genomes of many infectious agents at the level of femtograms. This makes PCR the most sensitive method of detection for viral and bacterial genomes in a clinical setting. Since many infectious agents have been implicated in immune dysregulation and immune dysfunction, early detection by PCR will help in the treatment of many immune disorders.

Disorders of the immune system underlie many diseases and disorders

Disorders and diseases of the immune system affect the health and quality of life of approximately one in four Americans. The data in [Table 20.1](#) exemplify the magnitude of this problem.

Listing the incidence of these immune dysfunction diseases does not begin to estimate their costs in terms of number of work and school days lost, cost of medication, hospitalization, diminished quality of life and involvement of family and friends during illness. Although these diseases differ in terms of their severity, most have their roots in an immune system that has either failed to develop or gone awry.

The integrity of the immune system can be assessed in two different ways: by evaluation of cell number and by testing cell function.

MONOCYTE AND LYMPHOCYTE ENUMERATION

The number and functional capacity of circulating peripheral blood leukocytes reflects the overall state of immune competence of an individual. In a variety of clinical situations, tests for granulocyte, lymphocyte and monocyte number and function have become routine

TABLE 20-1 -- Incidence of immune disorders in Americans

-
- 73 million have chronic respiratory problems

 - 43 million have asthma or allergic disease

 - 38 million, of which 250,000 are children, have arthritis

 - 11 million have diabetes

 - 2 million have ileitis and colitis

 - 1 million are infected with the HIV virus

 - 500,000 have systemic lupus erythematosus (8:1 are women)

 - 250,000 have multiple sclerosis

 - Over 200,000 have AIDS (the CDC has counted more than 500,000 AIDS cases since 1981 and 311,381 deaths; as of 1993, between 630,000 and 897,000 Americans were alive with HIV infection)

 - 250,000 have a primary immune deficiency disorder

in the diagnosis of disease and in monitoring immunosuppressive and immunorestorative treatments. In recent years, flow cytometric tests for lymphocyte subsets have begun to take their place as useful diagnostic and prognostic indicators in several clinical situations, including bone marrow and organ transplantation, diagnosis of leukemias and lymphomas, and evaluation of immune deficiency disorders. Flow cytometric measurements allow the enumeration of different types of lymphocytes which are known to have distinctive functional activities.^{[1] [2] [3]}

The techniques available to enumerate lymphocytes of various types have improved as a result of the development of monoclonal antibodies against cell surface differentiation antigens. These reagents are especially valuable when used in conjunction with flow cytometry to define lymphocyte cell surface phenotypes. T-lymphocytes, B-lymphocytes and natural killer (NK) cells, as well as subsets of these populations, can be discriminated. The close correlation of lymphocyte phenotype with function results in part from the fact that some of the molecules in the cell membrane of lymphocytes play a role in the specific functions that these cells perform. Such functions include recognition of antigen or other cells in the immune system, regulation of the immune response, cytotoxicity and a variety of other cellular interactions. Many of the monoclonal antibodies against lymphocytes react with molecules which play a role in one or more of these lymphocyte functions. Other monoclonal antibodies which are valuable in characterizing lymphocyte subpopulations react with receptors for soluble molecules which regulate the immune system. Overall, the cell surface phenotype of lymphocytes may reflect their lineage, differentiation state and immunological potential.^{[1] [2] [3] [4] [5] [6] [7] [8] [9]} Enumeration of lymphocytes is done by the most reliable technique – flow cytometry.

Flow cytometry in clinical medicine

Flow cytometry in conjunction with monoclonal antibody staining has a number of advantages over alternative methods of lymphocyte enumeration. The technique is

quick, precise, reproducible, and quantitative. Furthermore, it can be subjected to stringent quality control and standardization.

The lymphocyte population of human peripheral blood is composed of three cell types: T (thymus-derived), B (bone marrow-derived) and null cells. These cells are morphologically indistinguishable by microscopy but can be identified by characteristic antigenic differences in their cell membranes.^[6] ^[7]

Flow cytometry is a technique that enables rapid, multiparameter, correlated analysis of a large number of single cells. This method has been of particular importance in clinical immunology when used for the

identification of human lymphocyte subsets based on the expression of cell surface antigens. This application has expanded over the past decade as a result of the development of specific monoclonal antibodies with specificity for lymphocyte surface antigens.

For preparation of flow cytometry samples, whole blood lysis is the most common technique used in the clinical laboratories. This method consists of mixing a fixed volume of whole blood with one or more directly conjugated monoclonal antibodies, then incubating the mixture at a designated temperature and time. Next, the red blood cells are lysed using Tris ammonium chloride or a hypotonic buffer. The sample is washed and then run into the flow cytometer, usually after being fixed in paraformaldehyde, which decreases the infectious risk of the sample and increases its stability.^[7]

The LeucoGATE™ reagent is used to stain the first aliquot of whole blood from each subject with CD45 and CD14. The four parameters measured on this tube – two light scatter and two fluorescence – allow the SimulSET™ software to determine an optimal light scatter “gate”, which identifies the lymphocyte cluster in all subsequent tubes from the same sample. This LeucoGATE™ analysis identifies lymphocytes, monocytes, and granulocytes by a combination of antigen expression and light scatter characteristics (shown in [Fig. 20.2](#)).

The use of this automated multiparameter procedure for setting the lymphocyte acquisition gate provides a significant advantage over operator-defined light scatter gating, because some overlap exists between the different cell lineages when light scatter is used as the sole criterion to identify lymphocytes.

Furthermore, with LeucoGATE™ analysis, uniform and reproducible acquisition gating is possible, and consistently more than 95% of the total lymphocytes can be located and evaluated with less than 10% contamination by either debris, granulocytes, or monocytes.

Macrophages play a central role in cell-mediated immunity because they are involved

both in the initiation of responses as antigen-presenting cells and in the effector phase as inflammatory, tumoricidal and microbicidal cells. Using CD14 monoclonal antibodies, it is possible to define the percentage of monocytes in the blood.

Monoclonal antibodies for routine clinical enumeration of lymphocyte subpopulation

The nomenclature adopted by the International Leukocyte Differentiation Antigen Workshop is used in this chapter to designate the antigens with which various monoclonal antibodies react.^{[7] [8] [9] [10] [11] [12] [13]} The following cluster designations (CDs) are used for determination of the lymphocyte subpopulation.

CD11 for identification of T-lymphocytes

The CD4 antigen is associated with the E-rosette receptor and has a molecular weight of 50 kDa. The T11 antigen normally is present on greater than 9% of thymocytes and 100% of E-rosetting positive lymphocytes, including T-lymphocytes and a fraction of null cells. It is also found on greater than 90% of tumor cells from patients with T-cell acute lymphoblastic leukemia (ALL) and Sezary syndrome, and in a rare leukemic population of myeloid lineage. The CD4 antigen is not present on non-T-cell acute lymphoblastic leukemia cells.

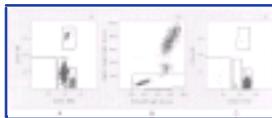

Figure 20-2 Lymphocyte gates set using LeucoGATE™. Lymphocyte gates for data acquisition were established using SimulSET™ software. Acquisition gates are defined by combining the fluorescence parameters from the LeucoGATE™ tube (A) with the forward- and right-angle light-scattering parameters (B). The light scatter gate (region 5, panel B) was set to include at least 95% of the lymphocytes. The cells of other lineages that also were included in this gate can be identified and enumerated by their characteristic immunofluorescence (C). Lymphocytes are confined to region 1, monocytes are found in region 2, while granulocyte and debris fall in regions 3 and 4, respectively. The analysis of subsequent tubes can be corrected by using the numbers of cells with each of the regions defined in (C), to obtain more precise values for enumeration of lymphocyte subsets.

Clinical relevance. The CD4 monoclonal antibody is used to quantitate total T-lymphocytes in circulating blood (both mature and immature) and to determine T-cell lineage of lymphoid tumor cells. Decreased numbers of T-lymphocytes are found in patients with autoimmune disorders including multiple sclerosis, systemic lupus erythematosus, and eczema. Thymic aplasia (DiGeorge syndrome) is associated with a decreased number of T-lymphocytes. Increased numbers of T-lymphocytes are noted in patients with acute infectious mononucleosis and some forms of acquired agammaglobulinemia due to the presence of activated suppressor cells.^[14]

CD19 for identification of B-lymphocytes

The CD19 antigen defines a bimolecular structure of 40 and 80 kDa. The specificity of the CD19 monoclonal antibody for surface immunoglobulin of the B-lymphocyte was determined by removal of the CD19 positive population from peripheral blood by sorting the cell population that is induced to differentiate into Ig-secreting plasma cells in a pokeweed mitogen-driven system. The CD19 monoclonal antibody recognizes the CD19 antigen on human B-lymphocytes. The CD19 antigen is expressed on all normal B-lymphocytes, follows the Ia antigen in B-cell ontogeny and is only lost prior to the plasma cell. The CD19 antigen is present on all B-cells isolated from lymphoid organs and on approximately 5% of normal adult bone marrow cells. In addition, CD19 is expressed on greater than 95% of non-T-cell acute lymphoblastic leukemias (ALL), and on 90% of B-cell lymphomas and B-cell lymphocytic leukemias (CLL), but is not expressed on T-cell or myeloid tumors. The CD19 antigen appears to be the earliest B-cell-associated antigen demonstrated in fetal tissues.

Clinical relevance. The CD19 monoclonal antibody appears to be useful in defining the cellular lineage of non-T-cells. ALL cells and chronic myelogenous leukemia (CML) blast crisis cells and ALL non-T-cell and CML blast crisis cells are reactive with this antibody, suggesting a B-cell origin of these tumor cells. The CD19 monoclonal antibody may also be useful in defining early B-cells and in the study of immunodeficiency diseases.^[15]

CD4 for identification of T-helper cell

Two main types of T-lymphocytes can be distinguished according to their function and surface proteins. These are the inducer/helper (CD4+) and suppressor/cytotoxic (CD8+) T-lymphocytes.

The CD4 antigen has a molecular weight of 62 kDa. It is normally present on a majority of thymocytes (approximately 80%) and approximately 60% of peripheral blood T-lymphocytes. The CD4+ lymphocytes play a central role in regulating the immune response. In peripheral blood, the CD4+ lymphocytes provide an inducer function for T-T, T-B and T-macrophage interaction. The CD4+ antigen reacts with the class II major histocompatibility complex (MHC) antigen on target cells.

Clinical relevance. Identification of abnormal levels of CD4+ lymphocytes may aid in the diagnosis and/or prognosis of immunodeficiency diseases such as agammaglobulinemia, thymic aplasia (DiGeorge syndrome), severe combined immunodeficiency and acquired immunodeficiency syndrome (AIDS). Measurement of CD4+ lymphocytes may also aid in phenotyping certain T-cell leukemias. Examples of these diseases include adult T-cell leukemia/lymphoma, T-cell acute lymphoblastic leukemia, and chronic T-cell leukemia.

Infection with human immunodeficiency virus (HIV), the etiologic agent of AIDS, results in profound immunosuppression due predominantly to a selective depletion of the CD4+ lymphocytes that express the receptor for the virus (the T4 antigen). Progressive clinical

and immunologic deterioration generally correlates with a falling CD4+ lymphocyte count.^[16]

CD8 for identification of T-suppressor cell

The CD8 antigen has a molecular weight of 76 kDa. It is normally present on a majority of thymocytes (approximately 80%) and approximately 30–35% of peripheral blood T-lymphocytes. The CD8+ lymphocytes play a central role in regulating the immune response through suppressor and cytotoxic action. The CD8 antigen reacts with the class I major histocompatibility complex (MHC) antigen on target cells.

Clinical relevance. Identification of abnormal levels of CD8+ lymphocytes may aid in the diagnosis and/or prognosis of immunodeficiency diseases such as agammaglobulinemia, thymic aplasia (DiGeorge syndrome) and severe combined immunodeficiency. Measurement of CD8+ lymphocytes may also aid in phenotyping certain T-cell leukemias. Examples of these diseases include adult T-cell acute lymphoblastic leukemia and chronic T-cell leukemia. The finding that increased levels of CD8+ cells are associated with viral infections such as hepatitis B, Epstein–Barr and cytomegalovirus may also be of diagnostic and/or prognostic significance.^[17]

Ratio of CD4/CD8 for determination of T-helper/ T-suppressor ratio

Disease-related changes in CD4+ and/or CD8+ lymphocyte levels may alter the CD4/CD8 inducer to suppressor/ cytotoxic cell ratios. As a result, CD4 to CD8 ratios may also be useful as diagnostic and/or prognostic indicators of immune competence.

Clinical relevance. CD4/CD8 ratios in conjunction with CD4+ lymphocyte cell numbers have been the most

widely used laboratory parameters for the evaluation of AIDS-related complex and AIDS. CD4/CD8 ratios fall toward zero in advanced AIDS patients with no detectable levels of CD4+ lymphocytes. In such cases, CD8+ lymphocyte levels may be normal, increased or decreased.

Modulations in CD4/CD8 ratios and CD4+ and T8+ lymphocyte levels may occur in autoimmune diseases such as multiple sclerosis (MS) and systemic lupus erythematosus (SLE). Increased CD4/CD8 ratios and decreased numbers of CD4+ and CD8+ lymphocytes have been observed in patients with progressive (active) MS. The lymphocyte response pattern in SLE, however, appears to reflect clinical disease activity and the level of organ involvement in the SLE disease process. For example, high T4/T8 ratios and elevated CD4+ lymphocyte percentages have been found in active/inactive SLE patients with multisystem disease including lymphadenopathy, but little or no renal disease. High T4/T8 ratios but decreased percentages of CD8+

lymphocytes have also been documented in similar active SLE patients. Further, high CD4+ and low CD8+ lymphocyte percentages have been measured in active SLE patients with central nervous system disease but no renal disease. In contrast, low CD4/CD8 ratios and decreased CD4+ lymphocyte percentages have been noted in active/ inactive patients with SLE, manifested by severe renal disease and/or thrombocytopenia. In other active/inactive SLE patients, both low CD4+ and high CD8+ lymphocyte percentages have been recorded. Finally, normal CD4/CD8 ratios have been obtained in patients with widespread multisystem SLE, which often includes the renal and central nervous systems.

Increased CD4/CD8 ratios with high CD4+ and low CD8+ lymphocyte percentages have been reported in head and neck cancer patients with elevated circulating IgA and generalized hypergammaglobulinemia.

Decreased CD4+ and increased CD8+ lymphocyte percentages without significant changes in CD4/CD8 ratios have been observed in patients with stable renal allograft function after transplantation. Similar findings have been reported in patients with B-cell chronic lymphocytic leukemia, except that CD4/CD8 ratios were decreased.^{[16] [17] [18] [19]}

CD4+CD29 for determination of helper/inducer subpopulation of lymphocytes

The CD29 cell surface antigen has a molecular weight of 134 kDa and defines a common B1 subunit of the heterodimeric glycoprotein family called VLA. It appears on approximately 41% of unfractionated human T-lymphocytes, 41% of CD4+ inducer lymphocytes, 43% of CD8+ suppressor/cytotoxic lymphocytes, 5–30% of B-lymphocytes and over 30% of null cells, macrophages, and thymic lymphocytes. The CD29 antigen is not present on granulocytes. The monoclonal antibody identifies the helper/inducer (CD4+CD29) subpopulation of CD4 lymphocytes.

Research relevance. Disease-related changes in CD4+ lymphocyte levels may alter levels of the CD4+CD29 helper/inducer and suppressor/inducer subpopulations.

The presence of CD4+CD29+ cells in the joints of rheumatoid arthritis has been reported and may account for the inflammatory process. More recently, decreased numbers of these cells have been observed in HIV-positive patients in the early phases. Accumulation of CD4+CD29+ cells in tissues has also been reported in patients with tuberculoid leprosy and multiple sclerosis.^[19]

CD16 and CD56 for determination of natural killer cells

NKH-1 (CD56 and CD16) defines a human natural killer cell antigen with a molecular weight of 200–220 kDa. It is expressed on a subpopulation of peripheral blood large granular lymphocytes (LGL) that demonstrate natural killer activity. More than 95% of cells capable of mediating spontaneous non-MHC restricted cytotoxicity in peripheral blood are contained within the 10–12% of peripheral blood mononuclear cells (PBMC) that express NKH-1. Seventy-five to 80% of NKH-1 cells co-express CD3 and T-cell receptor gene products. This latter population, which represents approximately 2% of

PBMC in normal individuals, also mediates non-MHC restricted cytotoxic activity. NKH-1 is not expressed on other T or B-lymphocyte, monocyte, granulocyte, or erythrocyte populations.

Research relevance. The NKH-1 antibody can aid in the detection and enumeration of natural killer cells in normal and disease states. For example, low numbers of NKH-1⁺ T3⁻ cells have recently been found in patients with chronic fatigue syndrome. When used with T3 antibodies, NKH-1 can be used to define distinct subsets of non-MHC restricted cytolytic cells within the NKH-1 population, i.e. NKH1⁺ CD3⁻ and NKH-1⁺ CD3⁺. Also, this antibody can be used in the identification and enumeration of lymphoproliferative diseases involving NK cells and may be used in the purification of human NK cells and lymphokine-activated killer (LAK) cells.^[20]

MEASUREMENT OF ACTIVATION MOLECULES AND LYMPHOCYTES

Many lymphocytes can be differentiated by measuring the level of activation markers on their surfaces.

CD25 antigen (Tac). Tac is a single-chain glycoprotein with a molecular weight of 55 kDa which is the low affinity receptor for IL-2. It is found on activated T- and B-cells, on activated macrophages and on T-cell clones. It is absent on thymocytes, resting T-cells, B-cells, and null cells.

CD26 (TA1). TA1 antigen has a molecular weight of 105 kDa and is a lymphocyte surface antigen. It is strongly expressed on activated human T-cells and IL-2-dependent human T-cell lines and clones. It is also weakly expressed on a small fraction of peripheral blood T-cells. This activation marker was found to be elevated in 80% of patients with chronic fatigue syndrome and in a high percentage of patients with a history of exposure to toxic chemicals.

CD69 antigen. CD69 antigen is a 60 kDa homodimer phosphorylated glycoprotein known as an activation inducer molecule (AIM). This structure contains two polypeptide chains of molecular weights 32 and 28 kDa. This activation antigen appears very early (before other activation antigens such as IL2-R) after T- or B-cell activation. It is also expressed by activated macrophages and by NK cells, but is absent in resting lymphocytes.

CD45RA epitope. The CD45RA epitope is present on all the CD45 restricted molecules in which the A axon is expressed. CD11 recognizes some peripheral T-cells, CD4⁺ T-lymphocytes and CD8⁺ T-lymphocytes, but specifically non-naive lymphocytes. The co-expression of CD4 and CD45RA antigens allows the identification of the suppressor/inducer subpopulation of CD4 lymphocytes. It also reacts with B-cells, monocytes, and granulocytes. This marker was found to be elevated in patients with

rheumatoid arthritis.

CD45RO molecule. The CD45RO molecule is the 180 kDa isoform of the leukocyte common antigen. This isoform is the CD45 restricted form of the lowest molecular weight. CD45RO is a single-chain glycoprotein which is expressed by thymocytes, the CD4+ memory T-cell subset and activated T-cells. The CD45RO+, CD4+ T-cells which provide the helper-inducer function were found to be elevated in synovial tissue of patients with arthritis.

CD11a antigen. CD11a antigen (leukocyte function associated molecule-1 or LFA-1) is the 180/95 kDa integrin α L-chain, non-covalently associated with the 95 kDa CD19 (integrin β 2). It promotes adhesion between lymphoid cells and the adhesion of lymphoid cells to the vascular endothelium. LFA-1 can interact with various ligands, the intercellular adhesion molecules: ICAM-1 (CD54), ICAM-2 (CD102) and ICAM-3 (CD50). CD11a antibodies have a strong reactivity with all leukocytes but do not recognize platelets. This antibody reacts with most peripheral blood T- and B-cells and with a portion of monocytes and granulocytes.

CD11b antigen (Mac1). Mac1 is the 165/95 kDa integrin α M chain, non-covalently associated with CD18 (integrin β 2). It has been identified as the C3bi complement receptor (CR3). As a member of the β 2 integrin family of adhesion molecules, Mac-1 mediates PMN and monocyte adherence to the endothelium. Additional CD11b ligands are ICAM-1 (CD54), factor X, fibrinogen, and endotoxin. CD11b antibodies mainly react with myeloid and natural killer cells. The Bear1 antibody recognizes some peripheral blood lymphocytes and a subset of T-cells (a portion of CD11b+ cells is also positive for CD8). It also reacts with granulocytes and monocytes. This population of CD8+CD11b lymphocytes is reported to be lower than normal in patients with chronic fatigue.^{[21] [22] [23] [24]}

I3 (HLA-DR antigen). The MHC class II HLA-DR antigen is expressed by human monocytes, macrophages, B-lymphocytes, and activated T-lymphocytes. Anti-I3 is used for classification and enumeration of Ia-positive B-cell lymphoproliferative malignancies (acute and chronic lymphocytic leukemias, non-Hodgkin lymphomas, etc.), acute myelogenous leukemias and identification of states of T-lymphocyte activation due to viral illnesses. Therefore, the number of HLA-DR+ positive cells is significantly increased in patients with chronic fatigue syndrome.

CD38. CD38 is a protein with a molecular weight of 45 kDa which is expressed on thymocytes, activated T-cells and plasma cells. Because of an increase in activated T-cells in chronic fatigue syndrome, the population of CD8 lymphocytes which carry the CD38 receptor are significantly elevated.^[24]

Summary of lymphocyte enumeration

Immunophenotyping by flow cytometry is common in most larger clinical laboratories. The application of this technology has moved forward in response to significant

improvements in instrumentation and an increase in the availability of reagents.

Properly performed, flow cytometry can identify lymphocyte subpopulations rapidly and accurately. The primary clinical uses of immunophenotyping are to quantitate CD4 T-cell counts in HIV infection and to assign lineage and/or monoclonality in leukemias and lymphomas. Additional uses include characterizing immune deficiency disorders, evaluating immunemediated inflammatory diseases and assessing patients before and after organ transplantation.

Although certain surface antigens are associated with functional status, such as the isoforms of CD45 which appear to identify naive (CD45RA) or memory (CD45RO) T-cells, these classifications are not absolute and must not be considered determinants of cell function.

Immunophenotyping is a means of identifying cells, but it is not the equivalent of a functional evaluation. Therefore, for functional leukocyte capacity, macrophage function, NK cytotoxic activity, and T- and B-cell function should be measured.^{[21] [22] [23] [24] [25] [26]}

In many patients, lymphocyte subpopulation numbers are normal, but their functional capacity for killing bacteria or tumor cells and reaction to antigens are completely abnormal. Hence, the major emphasis of this chapter is on the functional capacity of lymphocytes.

ASSESSMENT OF MONOCYTE AND MACROPHAGE FUNCTION

The major function of monocytes and macrophages is host defense against the microorganisms, removal of necrotic and cellular debris, and interaction with lymphoid components in the generation and effector phase of immune responses. Patients suspected of having a deficiency of cell-mediated immunity are candidates for evaluation of monocyte functions, even if the number and function of T- and B-cells are normal. Various assays of monocyte competence are performed in the immunology laboratory, including mediating tumor cell-dependent cellular cytotoxicity, microbial killing, production of prostaglandins, generation of respiratory burst and the ability of monocytes' antigen-induced activation of T-cells and production of interleukin-1 (IL-1).

The test for IL-1 production, representing accessory function and antigen presentation, is the most useful in evaluating immunodeficiency. Other tests such as microbial killing, cytotoxicity, prostaglandin and generation of peroxide are more useful in the evaluation of patients suffering repeated infections by fungi, protozoans, saprophytic microorganisms and atypical mycobacteria.^{[27] [28] [29] [30]}

Production of IL-1 by monocytes

Measuring IL-1 production represents an important assay of monocyte function as it directly relates to accessory function and interaction with T-helper cells.

IL-1 is produced by monocyte-macrophages, endothelial cells and other non-leukocytic cell types. Monocytes can also release IL-1 in response to stimulation with the neuropeptide substance P, providing a potential link between the nervous system and immune system. The IL-1 family includes three peptides: IL-1 α , IL-1 β and IL-1 receptor antagonist (IL-1ra). IL-1 has numerous diverse effects including induction of fever, hypotension, sleep, and stimulation of T-cells and B-cells; IL-1ra binds the IL-1 receptor but does not activate it; and IL-1ra may diminish the disease-mediating effects of IL-1. [29]

IL-1 production can be measured by enzyme immunoassay and IL-1 messenger. RNA can also be measured by PCR with much higher sensitivity. In many clinical conditions, the message of cytokines may be abnormal but the protein level will be within the normal range. Therefore, a combination of both measurements (protein and message) is the logical step.

Procedure

Monocytes are isolated from peripheral blood mononuclear leukocytes by sequential buoyant density centrifugation over Ficoll-Hypaque, Percoll or similar gradients and adherence to glass or plastic surfaces. The buoyant density of monocytes is similar to that of other peripheral blood mononuclear leukocytes but is considerably less than that of polymorphonuclear leukocytes and erythrocytes. In separating monocytes from lymphocytes with similar density, advantage is taken of the greater adherent properties of the mononuclear phagocyte.

Heparinized venous blood is diluted with an equal volume of PBS or HBSS and carefully layered over 2 ml of Ficoll-Hypaque in sterile culture tubes. The diluted blood is added carefully so as to avoid turbulence which would disturb the interface. The tubes are centrifuged at approximately $500 \times g$ at room temperature for 30 minutes. When the tubes are removed from the centrifuge, a distinct band can be seen between the plasma layer and the Ficoll-Hypaque layer. The top layer containing plasma is pipetted and discarded, and the bottom layer above the Ficoll-Hypaque is harvested with a sterile Pasteur pipette; the top one-third of the Ficoll-Hypaque layer is taken up in addition to the cells. The bands from several tubes are then combined in another tube and the cells are washed with either HBSS or PBS two or more times by centrifuging at $10^3 \times g$ for 8 minutes. This cell pellet should be relatively free of platelets and erythrocytes and should contain about 60–80% lymphocytes and 20–40% monocytes. The mixture of lymphocytes and monocytes is suspended in an RPMI medium with 10% human AB serum or fetal calf serum at a concentration of 2×10^6 /ml in the presence or absence of endogenous activators such as bacterial lipopolysaccharide (LPS) with a concentration of 10 to 20 $\mu\text{g/ml}$. The cultures are kept in a CO_2 incubator for a period of 72 hours, and supernatant-containing cytokines are removed and measured for IL-1 concentration using ELISA methodology. Results are expressed as IL-1 picograms/million lymphocytes and used in a culture in the presence or absence of an endogenous

activator (LPS).

Bacterial phagocytosis and killing by monocytes

The capacity of monocytes to ingest and digest bacteria is generally determined using a method in which the monocytes are allowed to ingest and subsequently kill a measured number of microorganisms. Once inside the monocyte, the microorganism is exposed to the microbicidal components of the cell. After an appropriate time, the monocytes are lysed and the intracellular organisms are released and assayed by a colony-counting method to determine the number of viable organisms remaining within the cell. Microbial killing is enhanced when resting monocytes undergo activation.

Procedure

The procedure for the microbial killing assay involves

185

preparation of a suspension of adherent monocytes in a glass Petri dish. Bacterial suspensions are prepared using either *Staphylococcus aureus* or *Streptomyces albus* and are cultured for 16–24 hours at 37°C in Trypticase soy broth. The bacterial culture is centrifuged, washed twice in PBS and adjusted to a concentration of approximately 10⁸ bacteria/ml by measuring turbidity. The bacterial suspension is eventually diluted with HBSS to obtain a final working concentration of 10⁷ bacteria/ml. Autologous or normal pooled AB serum can be used as a source of opsonin for the bacteria. In plastic culture tubes, 0.1 ml of medium, 0.2 ml of bacterial suspension at 10⁷ bacteria/ml and 0.5 ml of monocyte suspension (10⁶ monocytes/ml) are mixed. This mixture, along with proper controls, is then incubated for 1–2 hours at 37°C. Before culturing, a sample of the suspension is taken out for bacterial counts. After the 2 hour incubation, the cells are resuspended and colony counts are performed once more to determine the total amount of bacteria remaining. The tubes are then centrifuged and colony counts are performed on the supernatant using classical microbiology techniques. The colony-forming units are counted to quantitate the remaining viable bacteria.^{[31] [32] [33]} The percentage of bacteria ingested and killed by the monocytes is calculated using the following formula:

$$\frac{(\text{CFU at zero time} - \text{CFU in 15 min sup.}) - (\text{CFU at 1 hour total} - \text{CFU in 1 hour sup.})}{\text{CFU at zero time} - \text{CFU in 15 min sup.}}$$

Measurement of bacterial phagocytes by flow cytometry

Similar measurements of bacterial engulfment and killing are possible using flow cytometry. For the assessment of phagocytosis by flow cytometry, 100 µl FITC-labeled yeast cells (5 × 10⁶ /ml) are mixed with 100 µl autologous plasma, 200 ml PBS and

100ml granulocytes (1×10^6 /ml). After incubation at 37°C with continuous agitation for 1 hour, 1 ml of ice-cold PBS is added. After incubation at 20°C for 10 minutes, the cells are washed twice in ice-cold PBS. The cells are then taken up by the flow cytometer in 0.5 ml of PBS. The number of granulocytes showing green fluorescence (i.e. phagocytosing cells) is evaluated using the FACScan flow cytometer (Becton-Dickinson, USA). The gates are set around the granulocyte cluster in a cytogram, simultaneously evaluating forward-angle and right-angle light-scattering properties of the cell passing through the focused laser beam. The percentage of granulocytes with green fluorescence containing engulfed yeast cells in the histogram is determined on the FL1 channel (FITC filter transmission, 530 ± 30 nm) of the FACScan. Using this methodology, we found that the percentages of phagocytosing cells in healthy subjects were between 45 and 55%. Significant reduction in the percentage of phagocytosing cells was found in patients with chronic illnesses, including chronic fatigue immune dysfunction syndrome.^{[31] [32] [33] [34]}

In order to assess the percentage of yeast cells killed after phagocytosis, 100 μ l of the yeast cell suspension (1×10^6 /ml), are mixed with autologous plasma (100 μ l), PBS (100 μ l) and 100 μ l of granulocyte (1×10^6 /ml). A control consisted of 100 ml of yeast cells mixed with 100 ml of autologous plasma and 200 μ l of PBS in the absence of cells. After incubation at 37°C with continuous agitation for 2 hours, 100 μ l cold 0.5% Triton X-100 are added to lyse leukocytes. To remove DNA released from the lysed granulocytes, 1 ml of a warm (37°C) DNase solution (40 μ g deoxyribonuclease 1 from bovine pancreas = 2000 Kunitz units dissolved in PBS) is added and the mixture is incubated for 5 minutes with periodic agitation. The tubes are centrifuged ($500 \times g$ for 5 minutes) and the cell pellet is resuspended in 1 ml of PBS; 20 μ l of propidium iodide (red fluorescence) 0.05 mg/ml is then added, and the tubes are incubated for 5 minutes at 4°C. The gate is set around the yeast cell cluster on the FL1 channel. The percentage of yeast cells showing red fluorescence (i.e. killed cells) is evaluated on the FL3 channel of the FACScan (red pass filter, transmission 650 ± 30 nm) within the gated region. The percentage of yeast cells killed is expressed as the percentage of cells killed in the test sample minus the percentage of cells killed in the control test tube.^{[35] [36] [37]} In healthy controls examined in our laboratory, between 25 to 30% of yeasts were killed by this method, while in patients with chronic illnesses, these numbers may drop to below 10%.

Measurement of oxidative burst in monocytes

Phagocytosis and its associated oxidative burst are essential for certain monocyte functions. During the respiratory burst of hydrogen peroxide, hydroxyl radicals, nitric oxide and superoxide anion are produced as toxic oxygen metabolites.

Hydrogen peroxide released from monocytes can be measured as a function of oxidative burst activity in response to stimulation. Hydrogen peroxide can be assayed by a fluorescent scopoletin assay or by a photometer-based microassay requiring the horseradish peroxidase-dependent oxidation of phenol red. Hydrogen peroxide release is measured after in vitro stimulation by inducers of the oxidative burst such as phorbol myristate acetate (PMA) or serum-opsonized zymosan, which contains cell walls of *Saccharomyces cerevisiae*.

Recent studies have demonstrated that the production of nitric oxide (NO) by macrophages is important in the killing of intracellular parasites. Several different pathogens including *M. bovis* BCG and *Mycobacterium tuberculosis* are reported to be susceptible to NO. Furthermore, it is reported that activated macrophages contribute to

the suppression of Ag-specific T-cell proliferation through their NO production during primary listerial infection. The suppressive effect of NO is also observed in Con A responsiveness and IFN- γ - and IL-2-induced production of T-cells. These findings suggest that NO is not only the molecule responsible for the tumoricidal and microbicidal effects, but also one of the crucial factors controlling immunologic responses.

In macrophages, NO is generated from oxidation of the terminal guanidino nitrogen atom of L-arginine by inducible NO-synthase (iNOS), an enzyme known to be induced by cytokines such as IFN- γ , TNF- α , IL-1 and LPS. Expression of iNOS is also inducible by infection with *L. monocytogenes*, *M. tuberculosis* and BCG in mice and by *M. avium* in humans. Therefore, measurement of NO is not only a measure of phagocytosis but also a measure of normal or abnormal immunologic responses. For measurement of nitric oxide generation, Ficoll-Hypaque-separated mononuclear cells (2×10^6 /ml) are cultured in C-RPMI for 24 hours at 37°C. The non-adherent cells are removed by gentle washing with Hanks balanced salt solution (HBSS) and adherent cells are used as macro-phages. Macrophages are stimulated with 10 μ g/ml of LPS or 1×10^6 CFU/ml of BCG for 2 days at 37°C. After removal of the supernatant, the level of NO is measured by determining the amount of nitrite using Greiss reagent. Briefly, a 300 μ l aliquot of each sample is mixed with an equal volume of Greiss reagent (0.5% sulfanilamide, 0.05% naphthylethylenediamin and 2.5% H₃ PO₄) and absorbance at 550 nm is determined after 10–15 minutes' incubation at room temperature. Sodium nitrite is used as a standard. Results are expressed by nanogram of nitric oxide produced by 1 million monocytes.^[38]

Defects in monocyte phagocytosis are reported in a variety of clinical conditions including systemic lupus erythematosus (SLE), monocytic leukemia and congenital deficiency of membrane-adherence glycoproteins (CD11-CD18 complex).

Impaired oxidative burst activity and defects in microbicidal activity characteristically involve the neutrophil and monocyte in chronic granulomatous disease (CGD). Generation of toxic oxygen intermediates may also be impaired by some malignancies and infectious diseases.

For the above reasons and for the general assessment of the immune function, monocyte phagocytosis should be recommended. Performance of this test will also be instrumental in evaluation of augmentative therapy using different biological response

modifiers including antioxidants.

ASSESSMENT OF T- AND B-CELL FUNCTION

Assessment of T- and B-cell function is done by the standard lymphocyte proliferation assay or by the newly developed fast immune assay system of Becton-Dickinson using flow cytometry.

Lymphocyte proliferation or transformation is the process whereby new DNA synthesis and cell division takes place in lymphocytes after a stimulus of some type, resulting in a series of changes. The lymphocytes increase in size, the cytoplasm becomes more extensive, the nucleoli are visible in the nucleus and the lymphocytes resemble blast cells. The term “blast transformation” is also sometimes applied to this process. Lymphocytes from humans proliferate in response to antigens to which they are sensitized. This in vitro response correlates with the existence of delayed-type hypersensitivity in the host. Lymphocyte proliferation also occurs in response to different histocompatibility antigens when leukocytes from two donors are mixed in a mixed leukocyte culture. Mitogens, including pokeweed mitogen, phytohemagglutinin (PHA), LPS and concanavalin A, will induce proliferation of normal cells in culture.

Evaluation of lymphocyte proliferation can be quantitated by determination either of the percentage of lympho-blasts or of increased DNA synthesis. This evaluation may be achieved by the addition of a radiolabeled precursor of DNA (usually tritiated thymidine) to the culture medium and the subsequent detection of the amount of radioactivity incorporated into the cells. The assay involves the in vitro culture of a lymphocyte population in the presence or absence of a selected stimulus for various periods of time. The changes induced in the stimulated groups are compared with changes in the unstimulated cell populations. Radiolabeled amino acids are used most commonly for these comparisons, as they offer a means of quantitating the changes in a simple, reproducible manner. The use of automated harvesting procedures results in greater reproducibility and ease of performance of the assay.^{[39] [40] [41]}

Lymphocyte proliferation assay procedure

After Ficoll-Hypaque separation, peripheral blood mononuclear cells are counted and adjusted to the concentration of 1×10^6 /ml. Cells are cultured in quadruplicate in flat-bottom microtiter plate wells with 10 μ g/ml of T-cell mitogens (PHA, CONA) or 5 μ g/ml of B-cell mitogens (LPS or pokeweed). After 48 hours of incubation at 37°C in a water-saturated atmosphere of 95% air and 5% CO₂, cells are pulsed with 2 μ ci/well of tritiated thymidine for 16–18 hours. Incorporation of ³H-thymidine into cellular DNA is determined by harvesting the cultures in a Mash II unit harvester. Radioactivity is measured by liquid scintillation counting.

The percentage of induction of ³H-uptake is determined by the following formula:

counts/minute in the presence of mitogen
counts/minute in the absence of mitogen

Optimal DNA synthesis in response to mitogens is usually detected in 2–4 days, whereas 5–7 days are necessary to detect optimal responses to antigens and mixed allogenic leukocytes. Under suboptimal conditions (either low cell numbers or low concentrations of mitogen), the response to mitogens also peaks after 4 days, which suggests a relationship between the number of responding cells and the rate of DNA synthesis.

This method is not only lengthy, labor-intensive and involving radioactive material but also does not provide information about individual lymphocyte subsets responding to particular stimuli. In contrast, multiparameter flow cytometry offers the potential to analyze selected lymphocyte subset responses to a variety of stimuli (e.g. pathogens and bioresponse modifiers).

The graph in [Figure 20.3](#) compares CD69 expression and ³H-thymidine incorporation and suggests that T-cell activation, as measured by the expression of CD69 on CD3-positive cells, parallels the proliferative response determined by ³H-thymidine incorporation.

In most cases, activation of T-cells requires the presence of accessory cells or antigen-presenting cells (APCs). Under appropriate conditions, in vitro, antigenic or mitogenic stimuli activate T-cells via the T-cell receptor complex. This results in a number of biochemical and morphological changes that culminate in T-cell differentiation and proliferation and expansion of memory cells.

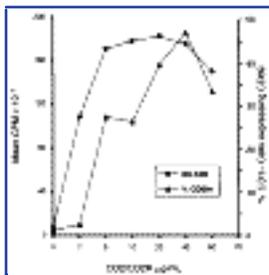

Figure 20-3 CD69 Expression vs. tritiated thymidine incorporation. Incorporation of ³H-thymidine was compared with CD69 expression as a measure of T-cell response to varying concentrations of a co-mitogenic pair of antibodies, CD2 and CD2R. Tritiated thymidine incorporation was measured after 3 days of stimulation of PBMCs in media plus autologous plasma; the percentage of CD69 expression was measured by flow cytometry after 4 hours of stimulation under identical conditions.

One of the earliest changes noted is the expression of the activation antigen CD69, reaching peak expression within 8 hours of stimulation. Other activation markers,

including CD25 (IL-2 receptor), CD71 (transferrin receptor) and HLA-DR, which are expressed later during this process, are shown in [Figure 20.4](#) .

Since expression of CD69 does not reflect some of the downstream events involved in signals for proliferation, such as IL-2 receptor expression, we use a combination of CD69+CD25 to cover the early and late signals involved in lymphocyte proliferation.

These properties suggest that the CD69+CD25 markers presented in [Figure 20.3](#) are generic markers for lymphocyte

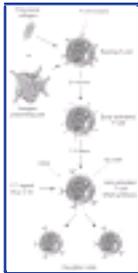

Figure 20-4 Expression of different activation markers on T-lymphocytes after polyclonal mitogenic stimulation.

activation and are well suited to rapid analysis of functioning lymphocytes.

The assay utilizes fluorescence triggering on CD3-positive lymphocytes in the FL3 channel and subsequent two-color analysis of the activation marker (CD69 PE) versus the subpopulation marker (such as CD4 FITC or CD8 FITC). T-cell activation is measured as a function of the percentage of T-cell subsets (FL1) that express CD69 (FL2).

The FASTIMMUNE system includes a two-color reagent, CD69 PE/CD3 PerCP, that allows customized subset analyses. The functions of specific T-lymphocyte subpopulations may be studied by adding FITC-labeled T-cell subset markers to the two-color reagent. The open system utilizes isotype and activation controls.

Isotype control, ?1, FITC/?1, PE/CD3 PerCP, is used to set the boundaries between positive and negative results for the FL1 and FL2 channels. The activation control, CD2/CD2R, is a combination of comitogenic monoclonal antibodies that assure that the activation system is working properly.^{[41] [42]}

Basic procedure

Sample preparation and mitogenic stimuli

1. Whole blood is collected using a sodium heparin anticoagulant.
2. Mitogenic or antigenic ligands and the FASTIMMUNE activation control are added to separate 200–500 µl aliquots of heparinized whole blood.
3. Stimulated samples and unstimulated control samples are incubated for 4 hours at 37°C in a water bath or an incubator.

Three-color immunofluorescent staining

1. FASTIMMUNE three-color antibody conjugate combinations, including fluorochrome-labeled isotype-matched staining controls, are added to 50 µl aliquots of stimulated and control samples.
2. Cells are stained for 15 minutes at room temperature.
3. Samples are lysed and fixed with 450 µl of FACS® lysing solution for 15–60 minutes at room temperature to analyze the percentage of activated lymphocytes by flow cytometry.

Clinical application

The lymphocyte transformation test has a broad range of applications, including:

- assessment and monitoring of congenital immunological defects
- assessment of either immunosuppressive or immunoenhancing therapies
- determination of histocompatibility matching in transplantation
- identification of serum or plasma factors which may suppress or enhance reactivity
- diagnostic testing for detection of previous exposure to a variety of antigens, allergens or pathogens
- determination of a variety of cytokines.

A wide variety of acquired conditions have been shown to have impaired lymphocyte transformation. These conditions include a variety of bacterial and viral infections as well as chemotherapy and autoimmune diseases such as Sjögren's syndrome and systemic lupus erythematosus. A variety of other clinical conditions have also been shown to affect lymphocyte transformation, including surgery and anesthesia, stress, aging, malnutrition, a variety of malignancies, uremia and major burns.

In patients with congenital immunological defects, lymphocyte transformation ranges from complete lack of function, as in severe combined immunodeficiency disease and DiGeorge syndrome, to a partial deficit, as in ataxia telangiectasia, Wiskott–Aldrich syndrome and chronic mucocutaneous candidiasis, to normal reactivity, as in X-linked hypogammaglobulinemia.

Lymphocyte transformation has also been used to monitor sequential samples from patients undergoing a variety of immunoenhancing or immunosuppressive therapies in the treatment of diseases states. This approach is especially sensitive when patients show nearly complete deficits before initiation of therapy, such as in immunodeficient

subjects requiring bone marrow transplantation. Patients undergoing immunoenhancing therapy with lymphokines, such as recombinant interferon or the interleukins for cancer, can be monitored for increased reactivity after therapy.^{[39] [40] [41] [42] [43]}

Therefore, enhancement of T- and B-cell function is the best screening method for selection of biological response modifiers, including botanicals.

T-HELPER 1 AND T-HELPER 2 FUNCTION

T-helper lymphocytes can be divided into at least two functionally distinct subpopulations, defined on the basis of clonal analysis as T-helper 1 (TH1) and T-helper 2 (TH2). However, at present, no phenotypic markers exist to distinguish between the TH1 and TH2 cells or between those that generate type 1 and type 2 responses. Thus, type 1 and type 2 responses are dependent on functional parameters that are more complex than the phenotypic markers based on cell surface analysis.^{[44] [45] [46] [47]}

TH1 lymphocyte clones are characterized by the production of type 1 cytokines or IL-2 and INF-d. The TH2 lymphocyte clones produce type 2 cytokines, which are IL-4, IL-5, IL-6, IL-10 and IL-13. Therefore, measurements

of these cytokines is an indirect way to assess T-helper 1 and T-helper 2 function.

The TH1–TH2 concept has been broadened to include the type 1 and type 2 responses, which reflect the functional profiles of interacting cell populations of the immune system and summarize the two modalities by which the immune system responds to antigenic stimuli. A type 1 response can be defined as a cytokine profile in which there is appreciable production of TH1 cytokines and/or expression of cytokine messenger RNA. This response is characterized by the activation of cell-mediated immunity and by certain isotypes of antibody. Type 2 responses can be defined as a cytokine profile characterized by a polarized production of TH2 cytokines, which induce strong humoral immunity and antibody production, including immunoglobulin, and switch from IgG to IgE production. Type 1 responses are negatively regulated by IL-4 and IL-10, and type 2 responses are down-modulated by INF-d and IL-12. Increase in production of type 2 cytokines and decrease in production of type 1 cytokines have been described in a variety of immunological conditions, including immunodeficiencies and immune activations.

Clinical application

Evidence is accumulating that the pathogenesis of some human diseases may be conceptualized in terms of type 1 and type 2 helper cell cytokine profiles. Many of these

diseases are due to infectious agents, including:

- viruses such as HIV-1 and the measles paramyxovirus
- mycobacteria such as *Mycobacterium leprae* (leprosy) and *M. tuberculosis*
- spirochetes such as *Treponema pallidum* (syphilis) and *Borrelia burgdorferi* (Lyme disease)
- parasitic diseases such as leishmaniasis and filariasis
- mycoplasma such as *M. fermentans* which have been described as a cofactor in AIDS and as one possible cause of chronic fatigue syndrome.

In this population of patients, a switch in the pattern of helper-1 to helper-2 population has been observed.

Stimulation of lymphocytes to produce INF- γ or other type 1 cytokines, but not IL-4, is the best method of screening biological response modifiers and botanical immunomodulators for treatment of immune diseases.^{[44] [45] [46] [47]}

NATURAL KILLER CELL CYTOTOXICITY

Natural killer (NK) cells are large granular lymphocytes which play an important role in a variety of human diseases. Compromised or absent natural immunity, as measured in vitro by decreased NK activity and/or depressed absolute numbers of circulating NK cells, has been linked to the development and progression of cancer, chronic and acute viral infections, including the acquired immunodeficiency syndrome (AIDS), chronic fatigue syndrome, psychological dysfunction, various immunodeficiencies, and certain autoimmune diseases.^{[1] [2] [3] [4]} Recent evidence indicates that NK cells are involved in multiple effector, regulatory, and developmental activities of the immune system and that deficiencies or abnormalities in NK cell function may contribute to, or be a biologic marker for, disease. For the above reasons, it is important to reliably detect abnormalities in NK cell function and monitor prognosis of chronic illnesses after therapy with biological response modifiers or other agents.^{[48] [49] [50] [51] [52] [53]}

T killer cell on the warpath

Although the main task of the immune system is to protect against the multitude of external microorganisms and other foreign perils, some of its weapons are reserved for combating abnormal cells. Their task is strongly reminiscent of the secret police in a dictatorship. Killer cells move constantly through the body's tissues, combing the tissues for deviant cells. T-lymphocytes originate in the bone marrow, enter the bloodstream, and settle in the thymus for a while. Here, they become immune-competent. Some of them are classed as helper T-cells, others as suppressors, and a third, exceedingly aggressive category as killer cells. The killer cells are equipped with special weapons which can kill the deviant cells.

While most white cells of the immune system react to foreign antigens on the surfaces of invading microorganisms, the killer cell reacts to both foreign antigens and the body's own antigens. Very often, for example, a virus conceals itself inside body cells, safe

from antibodies, complement factors and scavenging cells. It is protected by the antigens of the infected cell, to which the body's defenses do not respond. The killer cell, however, detects the virus as the infected cell bears on its surface both the body's own antigens and foreign virus antigens.

Characteristics of NK cells

Morphologically, NK cells belong to a subset of large granular lymphocytes (LGLs). Using monoclonal antibodies, NK cells can be distinguished from other lymphocytes because they express a characteristic set of surface markers; they are CD3⁻, CD2⁺, CD16⁺ and CD56(NKH1)⁺. They do not productively rearrange T-cell receptor genes and do not express the CD3 complex. NK cells are cytotoxic effectors that are capable of spontaneously killing tumor or virus-infected cells.^{[18] [19]} Their cytolytic activity is not restricted by or dependent upon expression of the major histocompatibility complex (MHC) on target cells. Although the basis for target cell recognition by NK cells

190

is not clear at this time, they are capable of distinguishing and sparing most normal tissue cells.^{[54] [55]}

Determination of NK activity

The number of NK cells in the blood or cellular suspensions is determined by staining mononuclear cell populations with monoclonal antibodies against surface antigens on NK cells such as CD56 or CD16.

NK activity is measured in a 4 hour cytotoxicity assay using cultured tumor cells as targets and mononuclear cells isolated from the blood or tissues as effectors. Tumor cells used as targets are sensitive to human NK cells and K562, a cell line derived from a patient with chronic myelogenous leukemia in blast crisis. The targets are first labeled with radioactive chromium (⁵¹Cr) and extensively washed to remove any unbound radioisotope. The K562 line is maintained in culture in the presence of 10% (v/v) fetal calf serum (FCS) and is provided regularly with fresh medium to assure that cells used as targets are in the log phase of growth; this is important to ensure high viability and good uniform uptake of the radioisotope.

NK activity in the blood is measured by using unfractionated mononuclear cells. These are prepared fresh and maintained in medium supplemented with 5% (v/v) FCS prior to the assay. A constant number (usually 5×10^3) of ⁵¹Cr-labeled K562 target cells is mixed with graded numbers of effector cells in triplicate wells of U-shaped microtiter plates. These plates are centrifuged briefly to bring effectors and targets into contact with each other, and then they are placed in a 37°C incubator for 4 hours. Killed targets are quantitated by measuring the amount of ⁵¹Cr released into the supernatant

following the 4 hour incubation of effectors and targets.

Each plate contains wells for determination of the spontaneous chromium release from target cells (i.e. target cells in medium only) and of the maximal chromium release from lysed tumor cells by adding acid or detergents. The harvested supernatants from control and experimental wells are counted in a gamma counter. The amount of ⁵¹Cr released into the supernatant is directly related to the proportion of target cells killed by effector cells. [56] [57] [58]

Calculation of results in NK activity assay

Results of the NK cell assay for each effector/target (E:T) ratio can be expressed as a percentage of specific lysis, but more commonly NK activity is expressed in terms of “lytic-units” (LUs).

To calculate LUs of NK activity, we combine the percentage of specific lysis at all the measured E:T ratios. First, the E:T ratio yielding 20% lysis (E:T₂₀) is estimated from these measurements. The standard number of effectors (E_{std}) is typically chosen to be 10⁷, and the standard number of target cells (T_{std}) is typically 5 × 10³. Then the lytic activity is reported as:

$$\text{number of LUs} \times \frac{E_{\text{std}}/T_{\text{std}}}{E:T_{20}} = \frac{T:E_{20}}{T_{\text{std}}/E_{\text{std}}}$$

The size of a lytic batch, which is (E:T₂₀) (T_{std}) effector cells, represents 1 LU.

Therefore, since lytic units (LUs) are a convenient way to quantitatively compare the relative cytotoxic activities of effector cell populations from different individuals or from the same individual over time, we use LUs to express NK activity of our clinical specimens. For this type of reproducibility, it is necessary to compare the percentage of specific lysis at all the measured E:T ratios.

First, the E:T ratio yielding 20% lysis (E:T₂₀) (20) is estimated from these measurements. The choice of 20% as a reference level of lysis is arbitrary; however, it is quite common and seems to be a good choice, since experimental E:T ratios can be chosen so that the calibration will rarely require extrapolation beyond the range of the experiment. The estimation of E:T₂₀ is usually accomplished by fitting a curve to the measured points on the graph of percentage of lysis versus E:T ratio and calibrating.

One feature of the LU, in contrast with using the percentage of lysis at a single E:T ratio, is that four values at four distinct ratios are used, implying greater amounts of information and, therefore, greater precision. For example, the mean of four measurements has half the standard deviation of a single measurement. Also, LUs provide a measure of potency and dosage, when effector cells are infused in a clinical trial or experiment. The total activity of a bolus of cells might be well represented as the

size of the bolus divided by the size of a LU.^[57]

These optimal conditions for NK cell cytotoxic assay and criteria for a reproducible assay were first established in Dr Herberman's laboratory at the Pittsburgh Cancer Institute in 1990.^[57] Based on these criteria, we established conditions for obtaining a reproducible assay using 24-hour-old blood drawn in a yellow-top (ACD) tube and computer program; lytic units are calculated from 12 tubes used for each patient.

Examples of lytic units calculations for healthy subjects and patients are shown in [Figures 20.5](#) , [20.6](#) , [20.7](#) .

NK cell activity in human diseases

The biological roles of natural killer cells are shown in [Table 20.2](#) . As indicated in this table, NK cells are involved not only in defense against pathogens and elimination of metastases, but also in a variety of other biological interactions.

It has been well established that patients with a variety

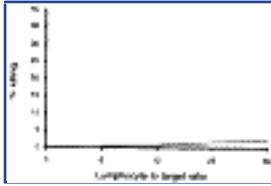

Figure 20-6 Very low natural killer cell activity of a cancer patient. Lymphocyte to target ratio giving 20% killing = 458.27. Results: lytic units = $1,000/458.27 = 2.18$.

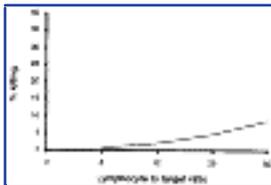

Figure 20-7 Low natural killer cell activity of a patient with chronic fatigue syndrome. Lymphocyte to target ratio giving 20% killing = 109.55. Results: lytic units = $1,000/109.55 = 9.13$.

of solid malignancies and large tumor burdens have decreased NK activity in the circulation and that this low NK activity may be significantly associated with the development of distant metastases. Furthermore, in patients treated for metastatic disease, the survival time without metastases correlates directly with levels of NK activity.^[59] In patients with hematologic malignancies, there appears to be a correlation between NK activity and the status of disease; the more advanced the disease, the lower the NK activity. Decreased NK activity may also be an important risk factor for the development of malignancy in humans. The prognostic significance of low NK activity in patients with cancer has been recently established; thus, low NK activity may have prognostic value in predicting relapses, poor responses to treatment and, especially, decreased survival time without metastases.^{[51] [52] [53]}

NK cells are sensitive indicators of activation by biologic response modifiers and their monitoring has been used to document alterations in the activity of circulating immune cells during therapy with these agents. In cancer patients treated with radiation or chemotherapy, NK activity becomes depressed as a result of the therapy. Given a role for natural immunity in tumor control, it may be clinically important to monitor the extent and duration of suppression of NK activity in order to minimize it through adjustments to the extent and/or duration of cyto-reductive therapy. In human bone marrow transplantation, NK cells may influence the outcome by helping in engraftment and controlling viral infections and may mediate anti-leukemic effects important for the elimination of residual tumor cells. On the other hand, there is also evidence for the ability of NK cells to suppress hematopoietic development.^[59] Furthermore, recent evidence indicates that there is a relationship between an individual's reaction to emotional stress and NK activity. Attempts are being made to define the mechanism responsible for low NK activity in individuals who have difficulties in handling stress and in those suffering from behavioral disorders.^{[60] [61] [62]}

The role of NK cells in viral disease has been known for a long time. The correlation between low NK activity and serious viral infections in immunocompromised hosts, e.g. in AIDS, after transplantation and in certain congenital immunodeficiencies, has been well documented. Abnormalities in NK function have been described in a variety of

autoimmune diseases, and since these diseases are frequently associated with serious viral infections and malignancy, low levels of NK activity may be biologically important in individuals with autoimmune disorders.^[56] Finally, chronic fatigue immune dysfunction syndrome (CFIDS) is characterized by a number of immunologic abnormalities, the most consistent being a significant depression of NK activity.^[61] ^[62] A similar phenomenon (low NK cytotoxic activity) was recently

reported by our laboratory in patients who have a history of toxic chemical exposure or silicone breast implants.^[61] ^[62] ^[63] ^[64] ^[65] ^[66] ^[67]

Enhancement of NK cell activity by buffered vitamin C (ultra-potent C) in chronic fatigue syndrome patients exposed to toxic chemicals

After exposure to numerous toxic chemicals, NK function can be decreased significantly. Weeks or months later, NK function can rebound to normal levels in some persons and be suppressed for prolonged periods of time in others.

In view of these results, we decided to study the effect of buffered vitamin C on NK, T- and B-cell function in patients who had been exposed to toxic chemicals. After the first blood draw, 55 patients immediately ingested granulated buffered vitamin C in water at a dosage of 60 mg/kg body weight. Exactly 24 hours later, blood was again drawn for a follow-up study of NK, T- and B-cell function. In 78% of patients, vitamin C in a high oral dose enhanced NK activity up to 10-fold. Lymphocyte blastogenic responses to T- and B-cell mitogens were restored to the normal level after vitamin C usage. Signal transduction enzyme protein kinase C (PKC) appeared to be involved in the mechanism of induction of NK activity by vitamin C. We concluded that immune functional abnormalities after toxic chemical exposure can be restored by oral usage of vitamin C. The enhancement of NK activity in patients exposed to chemicals is shown in [Figure 20.8](#).

We used a buffered preparation of vitamin C or ultra-potent C concentration of 60 mg/kg. This preparation was found to be very well tolerated at high doses. So far, a large number of patients have been followed by physical examination, hematology, and blood chemistry, including liver enzyme and complete urinalysis for a period of 3 years of post-ultra-potent C usage; no signs of tissue toxicity (liver or kidney) or other abnormalities were detected. While vitamin C was capable of enhancing the NK, T- and B-cell function, non-significant improvement in the described symptoms was observed. However, enhancement in functions of NK, T- and B-cells by vitamin C may prevent or delay infections or other health problems in patients who are at increased risk from toxic chemical exposure.

In our study, we proposed that immune function testing should become routine, not only in patients after toxic chemical exposure, but also in patients who suffer from malignant diseases and are undergoing chemotherapy and radiation therapy. These treatment

modalities may further impair immune function; thus, the body's capacity to fight malignant cells will be reduced. In these patients, immune modulation or stimulation should be attempted. In our case, this was successfully accomplished with ultra-potent C in a majority (78%) of the patients studied. Other biological response modifiers, such as lentinan interleukin-2 and other cytokines, should be examined and then may be recommended for the other 22% of patients whose immune function did not respond to vitamin C.^[68]

CONCLUSION

A collection of these tests not only reflects the function of the immune system but also represents the most important markers for detection of oxidative stress. Under normal conditions, T-cells, B-cells and natural killer cells maintain a suitable redox equilibrium by balancing cytoplasmic levels of oxidants and antioxidants.

Following activation by infectious agents, especially their superantigens and haptenic chemicals through different receptors, mitochondrial respiration increases, which results in higher levels of reactive oxygen intermediates.

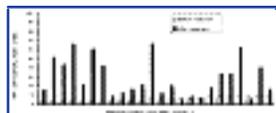

Figure 20-8 Effect of buffered vitamin C on NK cell activity in patients exposed to chemicals.

When cellular antioxidant levels are insufficient or cellular exposure to reactive oxygen intermediates occurs, oxidative stress may be invoked. This leads to activation of PKR, NF-kB, and finally, DNA damage.

Oxidative damage to DNA and activation of PKR and NF-kB first lead to malfunction of natural killer, T- and B-cells and then to the activation of death genes, which leads to a change in cell signaling (see [Ch. 8](#)) and programmed cell death (or apoptosis – see [Ch. 6](#)). Therefore, the measurement of NK cell activity along with cell cycle and apoptosis as shown in [Figure 20.9](#) in patients with chronic illnesses will enable clinicians to simultaneously assess the function of the immune system and evaluate the cellular level of oxidative stress. Moreover, these tests are extremely important for the follow-up treatment and prognosis of diseases using biological response modifiers, antioxidants, growth hormone, cytokines, plant extracts and other modalities. In many chronic illnesses, the final goal of many clinicians is to reverse tissue abnormalities and sustain tissue homeostasis, and this could only be documented by laboratory examinations described in this chapter.

Chapter 21 - Intestinal permeability assessment

Martin J. Lee PhD

INTRODUCTION

The small intestine has the paradoxical dual function of being a digestive/absorptive organ as well as a barrier to permeation of toxic compounds and macromolecules ([Fig. 21.1](#)).^{[1] [2] [3]} Either one of these functions may be disrupted by various mechanisms, resulting in local as well as systemic problems.

In certain disease states of the small intestine, such as gluten-sensitive enteropathy, permeability to large molecules may increase while permeability to small molecules decreases. The explanation of this apparent paradox lies in the different routes of entry for readily absorbed, water-soluble molecules, such as mannitol, and normally excluded molecules like lactulose. Transcellular uptake of mannitol relies on properties of the luminal cell membrane, a relatively huge area compared to the minute intercellular junctional complexes or tight junctions. Increased porosity of tight junctions has little effect on mannitol uptake, but villous atrophy decreases mannitol diffusion into mucosal cells. Thus, decreased transcellular permeability to small, water-soluble molecules may lead to malnutrition. In contrast, increased porosity of junctional complexes may lead to increased uptake of food antigens and bacterial toxins, correlating with increased susceptibility to food allergies and autoimmune conditions such as rheumatoid arthritis.

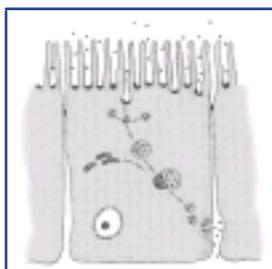

Figure 21-1 The intestinal barrier.

The large intestine contains numerous dietary and bacterial products with toxic properties. These include viable bacteria, bacterial cell wall polymers, chemotactic peptides, bacterial antigens capable of inducing antibodies which cross-react with host antibodies, and bacterial and dietary antigens which can form systemic immune complexes.^[4] Abnormalities of the immune or mechanical barriers may lead to enhanced uptake of inflammatory luminal macromolecules and pathogenic bacteria. With intestinal injury, mucosal absorption of normally excluded substances increases dramatically. Intestinal inflammation enhances the uptake and systemic distribution of potentially injurious macromolecules.^[4] Peters & Bjarnson^[5] noted: "Measurement of intestinal permeability will play an increasing role in clinical investigation and monitoring of intestinal disease."

MEASURING INTESTINAL PERMEABILITY

Gut permeability has traditionally been measured by ingesting a non-metabolizable monomeric sugar and observing the degree to which it is adsorbed. The marker of absorption must be inert, so that it can be an indicator of the passive diffusion and uptake of nutrients. Xylose is an example of a molecule that fulfills this criteria.

Unfortunately, xylose absorption turns out to be a very insensitive test. There are two basic reasons for this. First, the amount of xylose absorbed is a function of the transit time and the contents of the gastrointestinal tract (osmotic strength, mucous flows, etc.). Thus, there is considerable within-individual biological variation. Secondly, and more importantly, it is incorrect and simplistic to view absorption with a model of a simple sieve.

Absorption can, in fact, be divided into transcellular (through the cell) and paracellular (between the cell) processes. A useful analogy to help understand this process is that of a train containing a number of boxcars, with each car representing a cell. Now, imagine that each boxcar was the length of a football field and each boxcar was held together with heavy-duty springs having an average distance between boxcars of perhaps 1 foot. Small molecules – monomers such as simple sugars, glycerol, amino acids, and many vitamins and nutrients – can go into the cells and be absorbed directly into the cells (boxcars). Large molecules, however, are excluded.

Interestingly, the spaces between the cells are not static. They vibrate with the springs that hold the cells together. These springs – called the tight junctions – are usually sufficient to keep out anything bigger than very small molecules. Some dipeptides and tripeptides can be absorbed, but larger peptides, disaccharides and larger carbohydrates cannot normally enter the body. However, when the cellular health is less than optimum, when nutrition is poor or digestive processes are compromised, in the presence of and possibly etiologically related to many gastrointestinal disorders, the tight junctions become less tight, the spaces between the cells become effectively

larger, and bigger – even much bigger molecules can enter the body.

Thus, it can be seen that in many people there can be a paradoxical leakiness to gut antigens, proteins, food molecules and even bacteria, while at the same time there may be malabsorption of nutrients and vitamins when damage to the intestinal cells interferes with transcellular absorption of required nutrients.

An elegant method to evaluate this permeability and account for osmotic and biological variation has been developed in recent years. This system employs two non-metabolized molecules: mannitol, a monomeric sugar, and lactulose, a dimeric sugar. Mannitol, the monomer, is readily absorbed and serves as a marker of transcellular uptake. Lactulose is only slightly absorbed and serves as a marker for paracellular permeability. The ratio has been found in numerous clinical studies to be an exquisite marker of subtle changes in intestinal permeability. To perform the test, the patient ingests a pre-measured amount of lactulose and mannitol. Urine is then collected, usually for 6 hours, and the amount of each sugar recovered in the urine is then measured.

CLINICAL APPLICATIONS

Increased permeability of the intestinal mucosal barrier appears to correlate with a number of frequently seen clinical disorders, while decreased permeability appears to be a fundamental cause of malnutrition, malabsorption and failure to thrive. Increased permeability is seen in many disorders ([Table 21.1](#)).^[6] Several of these disorders are discussed in detail below.

Inflammatory bowel disease

Increases in permeability have consistently been reported with small bowel inflammation.^[7] In 1972, Shorter et al^[8] proposed that a breach of the intestinal barrier is fundamental to the development of intestinal inflammation. Most current hypotheses about the pathogenesis of Crohn's disease posit the prime importance of mucosal

integrity in maintaining a healthy state, and suggest that increased mucosal permeability underlies the inflammatory process. Studies show Crohn's disease to be more extensive than is sometimes apparent using macroscopic approaches.^[9] Pearson et al^[10] showed a sixfold increase in permeability in people with Crohn's disease. When patients with Crohn's disease were placed on an elemental diet, their permeability improved significantly, coinciding with marked clinical improvement.^[11] (See [Ch. 163](#) for a full discussion.)

Inflammatory joint disease

The concept that the underlying etiology of inflammatory arthritides (including rheumatoid arthritis) is related to pathology in the gut has become accepted by many researchers.^[12] ^[13] All material that traverses the mucosa is inspected by the immune system and it is here that the immune system may have its greatest antigenic exposure. Increased gut permeability can permit exogenous antigens to enter the systemic circulation. If the antibodies generated against gut antigens cross-react with the body's own immunologically similar tissues, the resulting process may manifest itself as an autoimmune disease.^[14]

Studies have demonstrated that patients with ankylosing spondylitis, rheumatoid arthritis and vasculitis have increased intestinal permeability; and suggest that this may be an important factor in the pathogenesis of these disorders.^[13] ^[15] ^[16] ^[17] There is a strong association between enteric infection and Reiter's syndrome or reactive arthritis. Intestinal infections of *Shigella*, *Salmonella*, *Yersinia*, and *Campylobacter* are known to cause this type of disorder. It has been suggested that the arthritis from these infections may be due to tissue deposition of circulating immune complexes arising from increased permeability of source antigens.^[18] ^[19] Darlington & Ramsey,^[20] after studying the influence of diet on arthritis, concluded: "The mechanism by which fasting leads to improvement of rheumatoid arthritis may be a reduction in gut permeability". Mielants and co-workers^[15] ^[21] suggest that the joint disease in spondylarthropathies is triggered through the gut (see [Ch. 185](#) for further discussion).

Food allergy

Development of food allergies depends on heredity, intestinal permeability, immune responsiveness, and exposure to food.^[22] Food *sensitivity* is used to refer to all adverse reactions to the ingestion of food, including allergic, idiosyncratic, toxic, metabolic, and pharmacological. Food *allergies* are distinguished by being mediated by an immunologic mechanism, consistently reproduced by blinded food challenge and

causing functional changes in target organs.^[23]

In general, the intestinal tract provides an effective barrier against the excessive absorption of food antigens. When this mechanism is ineffective, antigens enter the system in excessive amounts, which leads to sensitization of the immune system in some individuals. Increased permeability is implicated in type I, type III and type IV allergies.^[22] Andre et al,^[24] in a study of food allergy, concluded that “evaluation of intestinal permeability ... provides an objective means of diagnosing food allergy and assessing the effectiveness of anti-allergic agents”. Their research has shown that people with food allergy have increased permeability during a fasting state; and that the permeability further increases after ingestion of an offending allergen. They concluded that using lactulose and mannitol to measure intestinal permeability allows objective diagnosis of food allergy. They also observed that permeability increases even after ingestion of an amount of food that is not large enough to cause a clinical reaction.^[25]

Other researchers studied children with cow’s milk allergy and found that the majority of children displayed changes in permeability after challenge, and that pretreatment with sodium cromoglycate diminished the changes.^[26] Cromoglycate is believed to stabilize mast cells and IgE-producing plasma cells in the lamina propria of the gut, and thus to reduce the local inflammation which contributes to the increased intestinal permeability. Urticaria and atopic dermatitis can be caused by the ingestion of certain foods.^[27] People with atopic dermatitis and those with urticaria demonstrated increased permeability when given an oral challenge of food that provoked symptoms^[25] (see [Chs 15](#) and [51](#) for further discussion).

Celiac disease

Intestinal permeability has been studied in patients with celiac disease.^{[10] [28] [29] [30]} Children with celiac disease suffer a significant alteration in permeability due to reduced absorption.^[10] After exposure to a single oral dose of gluten, the intestinal permeability of people with celiac disease became transiently abnormal, returning to normal within 1 week.^[28] Hamilton et al^[28] concluded that the sugar ratio test is of value in assessing the response to gluten withdrawal and in monitoring patients who are already established on a gluten-free diet by detecting dietary lapses and “non-responders”. In another study, a persistent functional and/or structural abnormality of the small intestine was found to be associated with celiac disease along with possible etiological implications.^[29]

Non-steroidal anti-inflammatory drugs (NSAIDs)

Numerous studies have shown that NSAID usage disrupts the intestinal barrier function and causes increased permeability.^{[31] [32] [33]} This is of particular importance in those

people with arthritis who are being treated with NSAIDs, because the increased permeability may be a key factor in their disease process. The hypothesis that various

bacterial and viral intestinal infections can cause altered permeability is well supported.^[34]^[35] Studies show that host responses to infections are related to increased passage of microorganisms and endotoxins into the systemic circulation.^[36] Several authors have claimed that this breach of the mucosal barrier is an important aspect in both acute and chronic systemic effects of intestinal infection. Deitch^[37] reported that bacteria translocate across the mucosal barrier and cause systemic infections and various immunologic sequelae. Factors that promote translocation of bacteria include disruption of the ecologic balance of normal indigenous microflora (dysbiosis), bacterial overgrowth, impaired immune defense, trauma, and endotoxemia.

HIV infection and AIDS

Investigation has begun into intestinal permeability in patients testing positive for human immunodeficiency virus (HIV) and patients with acquired immunodeficiency syndrome (AIDS). One recent study evaluated intestinal permeability in HIV-positive patients and AIDS patients with and without diarrhea.^[38] The researchers found that patients with AIDS and diarrhea have altered intestinal permeability and theorized that this alteration could allow increased transmucosal passage of opportunistic pathogens. Mannitol recovery decreased and lactulose/mannitol ratios increased incrementally as the disease progressed, suggesting that as HIV disease progresses, there is loss of functional absorptive capability, possibly contributing to the malnutrition that often characterizes AIDS.

Pancreatic insufficiency

Intestinal permeability was studied recently in patients with cystic fibrosis or pancreatic insufficiency.^[39] Lactulose permeation increased with exocrine pancreatic insufficiency. The degree of increased intestinal permeability correlated with the level of duodenal trypsin and with the degree of undigested fat in the stool. The authors suggested that urinary lactulose might be useful in evaluating exocrine pancreatic function.

Malabsorption, malnutrition

Recent studies have shown that damage to the small intestine mucosa (resulting in decreased permeability) is linked to poor growth rates and failure to thrive in children. The intestinal damage is typically a result of infection and resulting diarrhea.^[40]^[41]

Alcoholism

Studies of intestinal permeability in alcoholics have shown elevated intestinal permeability.^[42] In many, the abnormality persisted for up to 2 weeks after cessation of drinking. This increased permeability may account for some of the extraintestinal tissue damage common in alcoholics. Gut-derived endotoxins may play a role in the initiation and aggravation of alcohol-induced liver disease.

Aging

In an intriguing study on aging, the authors concluded that “the intestinal barrier to the absorption of potentially harmful environmental substances may be less efficient in aging animals”.^[43] Various studies show that aging rats have diminishing capacity to prevent larger size molecules from penetrating the intestinal mucosa, possibly allowing antigenic or mutagenic compounds to reach the systemic circulation.^[44]

Chemotherapy

Cytotoxic treatment has been shown to decrease permeability, a possible factor in malnutrition of cancer patients.^[45]

CONCLUSION

Intestinal permeability is a widely applicable test. It measures the fundamental health of the mucosal epithelial membrane and its ability to carry out two of its primary functions: absorption of nutrients and the exclusion of toxic bowel constituents. Whenever digestive or nutritional dysfunction are suspected to impact systemic conditions, symptoms, or overall health, the measurement of intestinal permeability should be considered to provide information on this basic process.

Chapter 22 - Laboratory tests for the determination of vitamin status

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

Laboratory assessment of vitamin status is a significant challenge for the clinician. Although measurement of blood and serum levels is easily available, their clinical value is limited to the detection of severe deficiencies. Detection of functional deficiencies requires far more sophistication.

ASSESSMENT OF VITAMIN STATUS ([Table 22.1](#))

Ascorbic acid

Assessment of vitamin C is particularly difficult as ascorbate readily oxidizes in assay samples. In addition, serum levels reflect recent dietary uptake rather than actual tissues levels. Leukocyte levels are not as susceptible to dietary levels, but are also readily affected by infection, hypoglycemia and many common prescription and over-the-counter drugs. The popular lingual ascorbate test does not appear to be reliable as it does not correlate very well with leukocyte or serum levels. The loading test, if carefully controlled, is probably most accurate, although good standard ranges have yet to be determined.

Folate

Serum folate is also greatly affected by recent consumption. The neutrophil hypersegmentation test is a useful functional test. A deficiency of folate (as well as vitamin B₁₂) will cause an over-aging of white cells which results in increased lobulation of their nuclei. The test is not, however, reliable during pregnancy.

Niacin

While measurement of nicotinic acid in the blood is not very reliable, measurement of metabolites provides a clinically useful function assessment. Several metabolites tests are now available.

TABLE 22-1 -- Laboratory tests and optimal ranges for common vitamins^{[1] [2] [3]}

| Nutrient | Test | Acceptable level |
|---------------|--------------------------------------|------------------------------|
| Ascorbic acid | Serum | >0.3 mg/dl |
| | Leukocyte | 30 ug/10 ⁸ WBCs |
| | Load test | 0.3–2.0 mg/h in control |
| | | 24–49 mg/h after 500 mg |
| Folate | RBC folacin | >160–650 ng/ml |
| | Neutrophil hypersegmentation | <30% with five or more lobes |
| Niacin | Urinary <i>N</i> -methylnicotinamide | >1.6 mg/gm creatinine |
| | RBC NAD/NADP | >1.0 |
| Pyridoxine | Serum level | >50 ng/ml |
| | Tryptophan load | <35 mg/24 h xanthurenic acid |
| | Transaminase index | |
| | EGOT | <1.5 (ratio) |
| | EGPT | <1.25 |
| | Plasma pyridoxal | >8 ng/ml |
| Riboflavin | RBC glutathione reductase | |
| | FAD-effect | <20% increase |
| Thiamine | RBC transketolase | <15% increase |

| | | |
|-------------------------|--|---------------------|
| Vitamin A | Plasma retinol | 15–60 ug/dl |
| | 0–5 months | >20 |
| | 6 months–17 years | >30 |
| | Adult | >20 |
| | Plasma carotene | 80–400 ug/dl |
| | 0–5 months | >10 |
| | 6–11 months | >30 |
| | 1–17 years | >40 |
| | Adult | >40 |
| | Pregnancy | >80 |
| Vitamin B ₁₂ | Serum B ₁₂ | >150 pg/ml |
| | Urinary methylmalonic acid | <5 ug/mg creatinine |
| Vitamin D | Cholecalciferol (D ₃) | 10–80 ng/ml |
| | 1,25 dihydroxycholecalciferol | 21–45 pg/ml |
| Vitamin E | Serum tocopherol | >0.7 mg/100 dl |
| | RBC hemolysis in H ₂ O ₂ | <10% |
| | Serum tocopherol/triglyceride | 35–120 |
| Vitamin K | Abnormal prothrombin antigen assay | <20 ng/ml |

Pyridoxine

Several procedures are available for assessing vitamin B₆ status. Unfortunately, substantial agreement on the best methodology has not been established as variations in phenotypes significantly alter the results of functional and loading tests.

Riboflavin

The most common measure of riboflavin is RBC glutathione reductase activity. The enzyme is stimulated in vitro by adding flavin adenine dinucleotide. Elevation of activity greater than 20% is suggestive of a functional deficiency.

Thiamine

The most common measure of thiamin is RBC transketolase activity. The enzyme is stimulated in vitro by adding thiamine pyrophosphate. Elevation in activity of greater than 15% indicates a functional deficiency. The test is not reliable in patients with

diabetes mellitus, pernicious anemia or a significant negative nitrogen balance.

Vitamin A

While liver biopsy is the most accurate method of assessment, other less invasive and less expensive methodologies are more appropriate. As with most other nutrients, serum levels only fall significantly after tissue reserves have been depleted. Fortunately, the dark adaptation test will detect early deficiency (see [Ch. 26](#) for a discussion of this useful, easily performed, office procedure).

Vitamin B₁₂

Serum levels are not very useful as they do not track cerebral spinal levels very well. Erythrocyte cell size is also not reliable, as neurological signs and symptoms

can precede macrocytosis by 6–12 months. Measurement of urinary methylmalonic acid is sensitive and accurate, especially when expressed as a ratio to urinary creatinine.

Vitamin D

Serum levels of vitamin D, especially its activated dihydroxy form, are clinically accurate and useful.

Vitamin E

Platelet vitamin E levels appear to be the most accurate measure of intake. However, a more clinically relevant measure appears to be the ratio of this important antioxidant to the one key molecule it protects: triglycerides.

Vitamin K

The various prothrombin and clotting time assays appear to be useful ways to assess vitamin K status.

CONCLUSION

As described above, many procedures are now available for the assessment of functional vitamin status. While research continues in this important area, the reader is advised to study carefully [Chapter 29](#) on urinary organic acids profiling. Utilizing metabolic products excreted in the urine is now allowing the clinician far greater specificity in recognizing dysfunctional enzyme systems, whether due to genetic

deviations or nutritional deficiencies.

Chapter 23 - Lactose intolerance breath test

Stephen Barrie ND

INTRODUCTION

More than 50 million Americans can't digest lactose (milk sugar) or other sugars because they lack the appropriate enzyme in their digestive systems. They may suffer from bloating, diarrhea, flatulence, abdominal cramps and discomfort and may never realize the cause of their symptoms.

The digestive system uses specific enzymes, such as disaccharidases, to break down sugars into smaller components. Disaccharidases hydrolyze disaccharides into monosaccharides, smaller molecules that the body absorbs more easily.^[1]

When an individual doesn't produce enough of a particular enzyme to break down a carbohydrate into simpler sugars, the carbohydrate passes into the colon. There, the bacteria ferment the carbohydrate, a side-effect of which is gas. Osmotic imbalances create diarrhea, and the gases cause the bloating seen in individuals with carbohydrate intolerances. Over time, the intestinal mucosal lining becomes irritated.

There are degrees of carbohydrate intolerance. Some individuals manufacture a small amount of the enzyme, while others lack the enzyme completely. Any degree of deficiency will result in malabsorption.^[2]

Unfortunately, many people never relate their symptoms to their diet and continue to eat foods they cannot digest properly. Studies indicate that 70% of lactoseintolerant patients do not relate their symptoms to lactose ingestion. At times, individuals may even mislead their physicians by denying a connection to their symptoms and their diet.^{[3] [4]} [Table 23.1](#) provides a list of lactase deficiency in various ethnic groups.

Ongoing carbohydrate malabsorption constantly damages the digestive system, leading to systemic disorders. The body cannot obtain needed nutrients when intestinal dysfunction disrupts absorption. The weakened digestive system is also more

susceptible to attack by parasites, yeast and bacterial overgrowth, which further tip the scales of healthy intestinal balance.

TABLE 23-1 -- Incidence of lactase deficiency by ethnic group

| Ethnic group | Incidence |
|---------------------------|------------------|
| African Blacks | 97–100% |
| Asians | 90–100% |
| N. American Blacks | 70–75% |
| Mexicans | 70–80% |
| Mediterraneans | 60–90% |
| Jewish descent | 60–80% |
| Middle Europeans | 10–20% |
| North American Caucasians | 7–15% |
| Northern Europeans | 1–5% |

Imbalanced gut flora, irritated mucosa, leaky gut, altered permeability, food allergies and chronic illness can result from these intestinal irritations. Therefore, suspected sugar malabsorption should be investigated and treated to ward off further damage to the body's digestive system.

TYPES OF SUGAR INTOLERANCE

Lactose

Lactose intolerance is the most common type of malabsorption because milk sugar is common in a typical diet. Without the lactase enzyme, the intestine cannot break down lactose into glucose and galactose ([Fig. 23.1](#)). Lactase retention is genetically determined as a dominant trait. Lactase reaches its maximum levels in the human intestine shortly after birth and declines after the age of 3½ years.^[1]

Lactose malabsorption often is recognized for the first time in older patients, possibly because they are more sensitive to intestinal problems. They may have endured gas and other symptoms for years without connecting the symptoms to their diet.^[5]

Conditions that damage the intestinal lining can create lactose malabsorption, such as infectious diarrhea, intestinal parasites or inflammatory bowel disease. Alcoholism,

malnutrition, pelvic radiation therapy and drugs such as antibiotics can also trigger lactose malabsorption.^[6]

Lactose intolerance is very different from milk allergy, and individuals who don't produce sufficient quantities of the lactase enzyme aren't necessarily allergic to milk proteins.

A reliable test for lactose intolerance can differentiate this disorder from other digestive problems such as milk allergy and irritable bowel syndrome. An accurate diagnosis is important because:

- Many patients don't relate intestinal troubles to what they eat. A lactose intolerance test can dramatically
-

207

demonstrate to patients the connection between symptoms and diet and the importance of following diet restrictions.^[3] Studies show that some patients with lactose intolerance are not observant about food-related symptoms. In one study, 42% of lactose intolerant patients did not associate their symptoms with any food.^[4]

- Patients may be unnecessarily avoiding dairy products. Since milk and dairy products can be important sources of nutrients for children, pregnant women, nursing mothers and older adults, they should not be eliminated from the diet without good reason.^[7] ^[8]

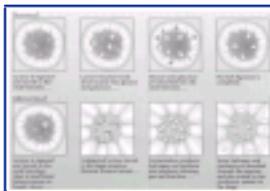

Figure 23-1

Treatment options, such as enzyme replacement therapy, can help individuals with lactose intolerance enjoy milk products. Lactase enzyme replacements will not benefit those people who are allergic to milk proteins or who cannot tolerate some other type of sugar.

Fructose

Fructose is used as a sweetener in many soft drinks and is present in a number of fruits. Individuals may be fructose malabsorbers and suffer symptoms similar to lactose intolerance.

Sucrose

Sucrose is common table sugar. The sucrase enzyme is needed to break down sucrose into glucose and fructose. If malabsorption symptoms exist but the lactose test is

negative, sucrose intolerance should be considered.

Maltose

Maltose is also produced by some foods. The maltase enzyme is needed to break down maltose into two molecules of glucose. If malabsorption symptoms exist but the lactose test is negative, maltose intolerance should be considered.

LACTOSE INTOLERANCE TESTS

Eliminating milk from the diet

Excluding milk products from the diet is not a conclusive test because many patients don't follow the diet completely. Furthermore, many unsuspected foods and drugs use lactose as a filler, making it difficult to totally remove milk products from the diet (see [Table 23.2](#)). Patients who continue eating these foods may experience ongoing symptoms, leading to a false-negative diagnosis.^[7]

Other common disaccharides and sweeteners can cause digestive disorders and symptoms, and removing milk from the diet does not resolve the underlying problem.

TABLE 23-2 -- Sources of lactose

| |
|---|
| <i>Obvious sources</i> |
| • All cheeses |
| • Butter |
| • Goat's milk |
| • Half-and-half cream |
| • Ice-cream and many sherbets |
| • Milk (whole, skim, dry powdered, evaporated) |
| • Yogurt |
| <i>Hidden sources</i> |
| • Artificial sweeteners containing lactose |
| • Breads, biscuits and crackers, doughnuts made with milk |
| • Breading on fried foods |
| • Breakfast and baby cereals containing milk solids |
| • Buttered or creamed foods (soups and vegetables) |
| • Cake and pudding mixes, many frostings |
| • Candies with milk chocolate |

- Cookies made with milk

- Hot dogs, luncheon meats, sausage, hash, processed and canned meats

- Many margarines

- Mayonnaise and salad dressings made with milk

- Non-dairy creamers (except for Coffee Rich)

- Pancakes, waffles, toaster tarts

- Pizza

- Weight-reduction formulas

- Many prescription drugs
 - birth control pills

 - thyroid medication

 - medications for gastrointestinal disorders (such as Reglan and Xanax)

- Many types of vitamins

- Foods containing whey, casein, caseinate, sodium caseinate and lactose

Histology

This test, while very accurate, is rarely used for disaccharide intolerance due to its expense and unpleasantness for patients. It requires an endoscopic biopsy of the small intestine, which is tested for its ability to generate glucose and galactose from lactose applied in vitro.

Blood and urine tests

After ingestion of large amounts of lactose (about 2 g/kg body weight), serial blood samples are drawn or serial urine samples collected to measure galactose change. If no change occurs over time, the test suggests lactose malabsorption. Because glucose is rapidly metabolized, a large dose of lactose is necessary, and this typically produces symptoms in lactase-deficient individuals.

The galactose serum and urine tests require prior oral ingestion of alcohol to suppress rapid galactose turnover by the liver, in addition to the large amount of lactose needed to produce measurable results. The alcohol can impair patients physically and mentally, making it impractical.^[9]

Breath hydrogen/methane test

The breath hydrogen/methane test is the clinical standard

for testing lactose intolerance because of its many benefits:

- Breath sampling is simple, non-invasive, inexpensive and well tolerated by patients. It can be done at home by the patient or in the physician's office.^{[7] [10]}
- A breath test is highly sensitive and specific for lactose malabsorption. It is able to quantify incomplete absorption of even small amounts of lactose, leading to a more precise estimate as to the degree of malabsorption compared with other methods. This enables patients to moderate their diets and enjoy more foods.^{[4] [5] [11] [12] [13] [14]}
- The lower challenge dose of lactose causes significantly fewer side-effects than the dose used in blood tests and does not require blood samples.^[15]
- False-positive results are rare and almost always due to improperly taking the test.^{[1] [16]}
- False-negative results are fewer than with the blood test, typically only 5%. These results can be reduced by testing suspected false-negative patients with another disaccharide carried to the colon.^{[4] [11] [12] [17]}
- The breath hydrogen/methane test is the standard in pediatric cases where other tests would be difficult to perform.^{[1] [18] [19] [20] [21]}
- Testing for both breath hydrogen and methane provides a more comprehensive picture than testing for hydrogen alone because a minority of individuals do not produce hydrogen in response to some carbohydrate challenges.

PROCEDURE

In the breath hydrogen/methane test, a patient fasts overnight and then collects a breath sample. The patient then ingests a challenge dose of lactose (up to a maximum of 25 g) and collects breath samples at 1, 2 and 3 hour intervals.^{[16] [22] [23] [24]} Longer sample collection periods are optional.

INTERPRETATION

When lactose is not broken down by lactase enzyme in the small intestine, it travels to the colon and undergoes bacterial fermentation. Fermentation causes hydrogen and/or methane levels in breath to rise within 1–2 hours. As little as 2 g of carbohydrate reaching the colon will produce a detectable increase in breath hydrogen.^[25] Using the total hydrogen and methane gas response increases the test's accuracy by reducing the number of false-negative responses.

Breath hydrogen

The normal breath hydrogen level in a healthy, fasting patient is less than 10 ppm.^[26] Lactose malabsorbers will show an increase in breath hydrogen concentration of 20 ppm or more during the test period.^{[1] [14] [27]} Lactose absorbers may show a small

variation in breath hydrogen of a few ppm during the test period.

Breath methane

The normal breath methane level in a fasting patient is 0–7 ppm. An increase of at least 12 ppm of methane alone during test is considered positive for lactose malabsorption, regardless of the hydrogen response.^{[1] [28] [29]}

Breath hydrogen plus methane

If both breath hydrogen and methane rise after a lactose challenge, the two responses are added to estimate the degree of malabsorption. An increase in methane will decrease the hydrogen response because methane is generated from the same substrate hydrolyzed by hydrogen-producing bacteria or produced by converting hydrogen to methane.

When breath hydrogen and methane are summed, the test interpretation requires a rise of 20 ppm or more to suggest lactose malabsorption:^[1]

- rise of 20–40 ppm – mild malabsorption
- rise of 40–80 ppm – moderate malabsorption
- rise of 80+ ppm – severe malabsorption.

False-positive results

False-positive results are infrequent compared with other types of lactose intolerance testing. The majority of false positives reported in the breath hydrogen/methane test can be eliminated if patients follow proper procedures and preparation instructions.

Typical causes of interference include:

- taking fiber supplements or eating high-fiber foods prior to the test, as fiber increases hydrogen production
- smoking in the area of the test, which produces high hydrogen levels and unstable baseline results; breath samples should not be collected where patients are exposed to tobacco smoke
- sleeping during the test, which increases both hydrogen and methane levels.

False-negative results

Approximately 5% of patients tested for lactose intolerance with the breath hydrogen/methane test produce a false-negative result, compared with 8–12% if only hydrogen is measured. The majority of malabsorbers who do not produce hydrogen after ingesting lactose will generate methane instead. Therefore, the combined breath hydrogen/methane test identifies most malabsorbers.

Typical causes of interference include:

- the use of lactase enzyme supplements, which should be discontinued 24 hours prior to the test
- taking antibiotics prior to the test^[9] ^[30]
- the use of laxatives or enemas, which decrease hydrogen and methane response in malabsorbers and create reduced fermentation in the colon^[31]
- severe diarrhea of hyperacidic colon contents. Hyperacidity inhibits the generation of hydrogen and causes generation of methane in addition to, or instead of, hydrogen by colonic bacteria.^[32] ^[33]

To reduce false-negative results, patients should wait at least 1 week after antibiotic treatment or recovery from severe diarrhea to reestablish colonic flora.

Suspected false-negative patients can also be tested with lactulose, another disaccharide carried to the colon and used to test for bacterial overgrowth. Lactulose determines whether patients produce hydrogen or do not react to lactose. A re-test on another day with a 10 g dose of lactulose as the challenge dose will produce positive breath hydrogen tests in patients capable of producing hydrogen.^[34] ^[35] ^[36]

High baseline levels

A baseline level of hydrogen above 10 ppm indicates that the patient may have fasted improperly, eaten high fiber foods the day before the breath test, or performed the test immediately after awakening.^[1] A baseline level above 20 ppm suggests patients have bacterial overgrowth of the small intestine. Levels typically rise during the first hour after lactose is ingested and fall to near-control levels during the test. Elevated methane levels are also seen with bacterial overgrowth.^[1] ^[37] ^[38]

CONCLUSION

One advantage of the lactose intolerance breath test is its greater specificity compared to other tests. By determining a patient's degree of malabsorption, physicians can tailor therapeutic recommendations more accurately than simply removing all milk products from the diet.

Patients may be able to limit their avoidance of dairy products, depending upon the severity of their malabsorption. For a mild to moderate malabsorber, it may be enough to limit the intake of dairy products at any one time to avoid symptoms. Studies also indicate that milk is tolerated better if accompanied by food.^[1] Decreasing the rate of gastric emptying by increasing the fat content and/or total caloric density of the lactose-containing meal may reduce symptoms, e.g. drinking whole rather than skim

milk.^[7]

For severe malabsorbers, lactase enzyme preparations that are added to milk and other products commercially available may provide relief from symptoms. These preparations can hydrolyze 70–99% of the lactose after 24 hours of refrigeration.^{[7] [39] [40]}

Chapter 24 - Mineral status evaluation

Stephen Markus MD

INTRODUCTION

The importance of trace mineral metabolism has only become appreciated in the past 30 years. Minerals play as important a role in the subtle biochemistry of the body as do vitamins. Virtually all reactions in the body require minerals as cofactors. With some trace elements, infinitesimally small amounts may be necessary, while others, such as calcium, make up a quarter of our body weight.

Assessment of body status for a particular trace element is extremely difficult (see [Table 24.1](#) for recommended methods for the different elements).^[1] For years there has been considerable controversy over hair mineral analysis. Although hair is the most convenient tissue for analyzing minerals, only a limited number of elements in the hair accurately reflect the true body content (see [Ch. 17](#)). Others are better measured intracellularly or extracellularly (depending on their state of equilibrium) or in specific cells, such as leukocytes. Many factors, such as specific protein carriers, the ionic charge of the element, or its capacity to be in equilibrium in the blood, affect the usefulness and reproducibility of a specific assay method and the appropriateness of a chosen tissue.

TABLE 24-1 -- Recommended methods for assessing essential mineral status

| Mineral | Method | Normal range |
|----------|---------------|--------------|
| Calcium | Hair analysis | 340–850 |
| Chromium | Hair analysis | 0.5–1.5 ppm |
| Copper | Serum copper | 0.8–1.5 ppm |
| | Hair analysis | 8–22 ppm |

| | | |
|-----------|-------------------|-----------------|
| Iron | Serum iron | 0.65–1.75 ppm |
| | Serum ferritin | Male, 27–329 |
| | | Female, 12–120 |
| Magnesium | Mg retention test | <25%, normal |
| | Leukocyte Mg | 0.98–2.82 ug/L |
| Manganese | Whole blood Mn | 0.005–0.02 ppm |
| Potassium | Whole blood K | 3741–4045 ppm |
| Selenium | Hair analysis | 1.0–3.0 ppm |
| Zinc | Leukocyte zinc | 0.082–0.57 ug/L |

Over the last century, with increasing industrialization of our society, our exposure to toxic metals has increased enormously. Hair serves as an excellent source for measurement of continuous cumulative exposure more typical of environmental sources. Hair is also biologically stable and can be stored for analysis over a long period without degradation. Hair also concentrates toxic minerals several hundred times higher than blood, allowing for analytical determinations of ultra trace quantities. The fact that toxic minerals can have deleterious effects on multiple enzyme systems, neuro-nal structures, and organs, including the brain, heart, thyroid, liver, kidneys, and skin, at extraordinarily low levels suggests that hair mineral analysis should be an important screening test for many patients. [\[2\]](#) [\[3\]](#) [\[4\]](#) [\[5\]](#)

ESSENTIAL MINERALS

Calcium

Despite detailed calcium balance studies measuring both intake and excretion with radiolabeled isotopes, determining calcium balance in an outpatient setting is extremely difficult. [\[6\]](#) Assessment of dietary intake of calcium is confounded by multiple factors which affect absorption, such as:

- the quantity of fiber and other natural chelators in the diet
- gastric acidity
- the ratio of dietary calcium to phosphorus (and dietary magnesium)
- gut transit time, etc.

When all of these are considered, multivariate analysis is currently very difficult with so many uncontrolled and difficult to measure variables.

Serum calcium, like other electrolytes, is so closely regulated (by the parathyroid gland)

that its use as a measurement of calcium balance is rarely of value. Ionized calcium is currently being examined in more detail and may play a partial role in evaluation of calcium status in the future. Urinary calcium is of value in a patient with a known low total calcium intake and persistent calciuria.

At present, perhaps the most useful screening test for calcium balance is hair analysis. However, hair calcium levels are subject to considerable variability and should not be taken as a quantitative determination of calcium status. A few studies evaluating calcium content in hair have shown promising correlations. Two studies in particular were able to find a relationship between hair calcium and coronary disease.^{[7] [8]} Future studies need to be conducted for further verification. One team of researchers conducted careful studies of a group of patients and showed that calcium intake, and the ratio of calcium to phosphorus intake, significantly altered hair calcium. Those patients with high phosphorus/low calcium consistently showed hair calcium as much as three times higher than normal. Hair calcium returned to normal with proper supplementation and dietary changes.^[9]

Chromium

Establishment of reliable laboratory assays for the assessment of chromium status has been a subject of considerable research. Only recently has analytical instrumentation of sufficient sensitivity been developed to allow accurate quantitative analysis of this ultra trace mineral. Plasma chromium is probably not a valid indicator of body status since it is not in equilibrium with tissue chromium, and plasma levels may be less than 1 ng/ml making measurement very difficult.

Since 80% of chromium is excreted in the urine, urinary chromium may be the most valid indicator of chromium status. Glucose consumption has been shown to increase plasma and, subsequently, urinary chromium. Pre- and post-glucose-load urinary chromium have been measured, but results have shown unacceptable variability.

Substantial GTF (glucose tolerance factor) activity has been found in hair follicles suggesting that hair chromium may be a useful indicator of body status.^{[10] [11] [12]} This mineral is found in the hair at concentrations over 100 times that found in the blood, making measurement more technically feasible.

Copper

Under normal conditions, far more copper is absorbed than is needed by the body. Nearly all dietary copper is initially stored in the liver, leaving only a small percentage in the blood. Ninety-five per cent of plasma copper is bound to the protein ceruloplasmin, with almost no ionic copper; thus urinary output is nil. The principal homeostatic mechanism for controlling copper is by excretion through the biliary system.

As one might expect with such a large turnover of absorbed copper, assessing copper status is not easy. At present, serum copper may be the best indicator, if the clinical conditions which are known to cause abnormalities in copper metabolism (e.g.

Wilson's disease and cirrhosis of the liver) are first ruled out.^[13]

Measurement of superoxide dismutase function has been used in the assessment of copper status, but since this enzyme also requires zinc and manganese, it is not adequately specific.

The usefulness of hair analysis as an indicator of chronic copper toxicity is well documented, although external contamination must be considered, and it is not reliable in Wilson's disease. Some studies have shown

hair copper to be an acceptable method of assessment of copper status.^[14] ^[15] More studies are needed in this area.

Iron

Serum iron has a long history of use as an indicator of iron deficiency. It is not of much value by itself, however, since there is considerable variation in serum iron, even when samples are taken from the same person at the same time each day, and there is a considerable diurnal variation. The test is much more reliable when combined with measurement of serum transferrin or ferritin.

Ferritin is an iron storage protein accounting for 20% of the total body iron in normal adults. It is principally found in the cytoplasm of reticuloendothelial cells and liver cells, and, to some degree, in developing red cell precursors in bone marrow. It is involved in both iron absorption and recycling.

During the early stages of iron deficiency, a decreased serum ferritin level is the first sign that body stores are decreased. As iron deficiency progresses, anemia, decreased serum iron and elevated iron binding capacity become apparent.^[16] ^[17] The patient is done a disservice if the physician waits for hypochromia and microcytosis to appear before making a diagnosis of iron deficiency.^[18] [Table 24.2](#) compares the various methods of determining iron deficiency.

Serum ferritin levels are, however, not totally reliable since they are inappropriately elevated in several common medical conditions, including cancer, infections, inflammation, and acute and chronic liver disease. When iron overload is associated with hemochromatosis, hemosiderosis, or thalassemia, serum ferritin is also elevated. Overall serum ferritin is a convenient and usually reliable measurement of total body iron storage.

Magnesium

Measurement of magnesium status, like other minerals, has many problems. The

magnesium retention test is probably the most accurate method of assessment currently available.^[19] The test procedure is as follows:

1. The patient is injected with 2 ml of a 50% MgSO₄ solution.
2. 24 hour pre- and post-injection urine samples are collected and measured for magnesium and creatinine.
3. Retention of greater than 25% indicates magnesium deficiency.

Needless to say, this is a cumbersome procedure.

Serum magnesium is of little value since it is influenced by many factors. The degree of binding, complexing or chelating of magnesium to serum proteins and other fractions is subject to many uncontrollable variables. Values as low as 1.2 mEq/L have been measured in patients with normal total body magnesium.^[19]

Although there has been interest in RBC magnesium, it has been shown that its value may vary by a factor of five depending on the age of the red blood cell, making this technique somewhat unreliable.^[19] Early research is indicating that WBC magnesium is far easier to measure and may be nearly as accurate as the magnesium retention test. Its clinical usefulness awaits further studies.^[20]

Manganese

Assessment of body status for manganese is difficult due to its low levels (1% of the level of copper or zinc in blood). Whole blood manganese is a valid indicator of body manganese and soft tissue levels.^[21] Proper technique is essential in the collection procedure as well as the actual analysis. Hair manganese may be a rough indicator, especially in chronic toxicity, but is not as reliable as whole blood.

Potassium

Since potassium is primarily an intracellular ion, serum measurements do not accurately reflect body stores. A low serum potassium usually indicates an advanced intracellular deficit. However, an intracellular deficit may also occur with normal or high serum potassium. Several researchers have been studying red blood cell potassium which has been shown to reflect the potassium content of other tissue cells.^{[22] [23]} Although red blood cells do not have nuclei, the sodium–potassium membrane pump is intact, maintaining the proper influx and efflux of these ions. Whole blood potassium is almost as

TABLE 24-2 -- Comparison of various methods of determining iron status

| | Normal | Iron deficiency | | Severe iron deficiency |
|--|--------|-----------------|----------------|------------------------|
| | | With anemia | Without anemia | |
| | | | | |

| | | | | |
|---------------------------------|-------------------|--------------------|--------------------|----------------|
| Plasma iron level | 75–150 ug/100 ml | Normal or reduced | Normal or reduced | <40 ug/100 ml |
| Iron-binding capacity | 300–400 ug/100 ml | Normal or elevated | Normal or elevated | >400 ug/100 ml |
| Hemoglobin level | 13–15 g/100 ml | 13–15 g/100 ml | 9–12 g/100 ml | 6–7 g/100 ml |
| Hypochromia and microcytosis | Not present | Not present | SI or not present | Profound |
| Ferritin level | 12–300 ng/ml | <12 ng/ml | <12 ng/ml | <6 ng/ml |
| Free erythrocyte protoporphyrin | 30–70 ug/100 ml | Normal or elevated | >100 ug/100ml | >100 ug/100 ml |

accurate as RBC potassium since 98% of the potassium is intracellular.

An example of the validity of measuring intracellular potassium was demonstrated in a study which measured electrocardiographically the repolarization phase in the elderly. Alterations of repolarization correlated well with intracellular potassium levels but showed no correlation occurred with serum levels.^[24]

Selenium

After absorption, selenium is distributed throughout the tissues but does not seem to be in equilibrium with the blood. Research currently indicates that blood selenium levels do not correlate with selenium intake, except at extremes.^[25] Hair selenium does correlate well.^{[26] [27] [28] [29] [30]} As with chromium and manganese, special analytical techniques must be used to ensure accuracy of measurements with this element.

Zinc

Since zinc is an intracellular ion, plasma and serum zinc are not sensitive indicators of depletion.^[31] Erythrocyte zinc is an even less sensitive indicator of zinc status than plasma. Urine zinc is also not a good indicator. Low hair zinc levels indicate depletion, but normal values do not rule out low body stores.^{[15] [32] [33]} Leukocyte zinc has been investigated and found to be an accurate index of body stores.^[34]

CONCLUSION

No analysis is better than the laboratory performing it. Proper analytical procedures must be used and each step in the collection and preparation of a sample must be carefully monitored. For example, in hair analysis, proper washing of hair, and use of

ultra-high pure digesting acid and distilled water are important. In blood analysis, collection tubes specially designed for the specific mineral being collected must be used.

Ultimately, it is the physician's responsibility to verify the validity of an analytical procedure. When in doubt, obtain a copy of the actual procedure for review and compare it with the limits of detection for the particular instrument being used.

Many of the reference articles listed here are reviews, and thus can serve as sources of additional information.

Chapter 25 - Oral manifestations of nutritional status

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

The structures and lining of the oral cavity offer valuable, and easily accessible, information on the nutritional status of an individual. The lesions may indicate a nutrient deficiency or may be manifestations of gastrointestinal or other disease. Due to the very rapid cell turnover of the oral mucosa, these lesions often may precede other manifestations of nutrient deficiency or systemic disease. Some typical lesions are mucosal ulceration, cheilosis, gingivitis, and glossitis. Since between 5 and 10% of the people in the United States are deficient in one or more nutrients, signs of nutritional deficiency are common.

The healthy mouth

The ventral surface of the healthy tongue is covered with smooth, pink, mucous membrane and lymphoid follicles. On the dorsal surface, the filiform, fungiform, and circumvallate papillae (which contain the organs of taste) produce a rough, grayish-red appearance. The thick epithelial tufts of the filiform papillae give the tongue its characteristic grayish-white coating, whereas the globular, pale red fungiform papillae give it a speckled pink appearance. Furrows are not a characteristic of the healthy tongue.

The buccal mucosa has a grayish-red color and may be crossed by fine grayish ridges where it touches the closed teeth.

The healthy gums have a light reddish appearance and cover the roots of the teeth completely.^[1]

ABNORMALITIES OF THE ORAL MEMBRANES

[Table 25.1](#) summarizes the typical oral manifestations associated with a particular nutrient deficiency, while [Table 25.2](#) summarizes common disorders associated with oral manifestations.

TABLE 25-1 -- Oral signs of nutrient deficiency^{[2] [3] [4] [5] [6] [7]}

| Nutrient | Oral deficiency signs |
|-------------------------|---|
| Biotin | Geographic tongue, atrophy of lingual papillae |
| Folic acid | Gingivitis, glossitis with atrophy or hypertrophy of filiform papillae, cheilosis |
| Niacin | Intraoral burning, glossitis, tongue swollen with red tip and sides, swollen red fungiform papillae, filiform papillae become inflamed and lose their epithelial tufts (giving the characteristic slick red appearance) |
| Pyridoxine | Intraoral burning, glossitis, mucosal ulcerations and erosions, cheilosis |
| Vitamin B ₁₂ | Intraoral burning, mucosal ulcerations and erosions, painful glossitis with a beefy red or fiery appearance eventually resulting in an atrophic (smooth and shiny) tongue |
| Riboflavin | Soreness and intraoral burning, cheilosis, angular stomatitis, glossitis with a magenta tongue |
| Vitamin C | Sore and bleeding gums, gums deep blue-red color, loose teeth, follicular hyperkeratosis |
| Vitamin D | Intraoral burning |
| Vitamin E | Glossitis |
| Calcium | Periodontal disease, tooth decay |
| Iron | Cheilosis, atrophic glossitis, gingivitis, candidiasis, intraoral burning or pain, mucosal ulcerations and erosions, pallor |
| Zinc | Marked halitosis, cheilosis, stomatitis, discrete red, scaly plaques from short-lived vesicles, white coating on tongue and mucosa, intraoral burning |

In general, *ulceration* should be considered a non-specific expression of a disease state. A search for the etiology will usually result in a specific therapy. Aphthous stomatitis is a common example of a mucosal ulceration and is discussed in detail in [Chapter 130](#) .

Similarly, *cheilosis* is a common expression for acquired nutrient deficiency. *Gingivitis* is associated with the classical signs of scurvy, but more recently other nutrients have been shown to play a role in gingival health. This subject is discussed in [Chapter 181](#) .

Glossitis is associated with numerous vitamin deficiency states, each with a characteristic appearance.

Like glossitis, *intraoral burning* represents a non-specific expression of a possible nutrient deficiency or systemic disease. Besides those listed in [Table 25.2](#) , other possible causes include:

TABLE 25-2 -- Common disorders associated with oral manifestations^{[2] [3] [4] [5] [6] [7]}

| Oral manifestation | Disorder |
|-----------------------|---|
| Cheilosis | Crohn's disease, acrodermatitis enteropathica, alcoholism, celiac disease, malabsorption syndrome |
| Gingivitis | Crohn's disease, anorexia nervosa, celiac disease, scurvy |
| Erythroplakia | Dysplasia or carcinoma |
| Glossitis | Crohn's disease, diabetes, alcoholism, celiac disease, malabsorption syndrome, pernicious anemia, iron-deficiency anemia, amyloidosis, carcinoid syndrome, cigarette smoking, anemia |
| Intraoral burning | Menopause, diabetes mellitus, esophageal reflux, Sjögren's syndrome |
| Leukoplakia | Chronic irritation, dysplasia, early invasive squamous cell carcinoma |
| Ulcerations, erosions | Crohn's disease, ulcerative colitis, celiac disease, corticosteroid use, acrodermatitis enteropathica, anorexia nervosa, pernicious anemia, iron-deficient anemia, mercury poisoning, nicotine withdrawal |

- xerostomia
- dentures
- deficiency states of iron, B₁₂ , folic acid, B₆ , and protein
- steatorrhea
- antibiotic use
- changes in mucosal innervation
- anxiety states.

In non-denture wearers, nutritional disorders are the most common causative factors.^[8]

Leukoplakia is any white lesion of the oral cavity that cannot be removed by rubbing the mucosal surface. While they are usually only a sign of chronic irritation, 2–6% represent either dysplasia or early invasive squamous cell carcinoma.^[4]

Erythroplakia is similar to leukoplakia, except that it has a definite erythematous component. This is a far more serious sign, with 90% representing dysplasia or carcinoma.

Chapter 26 - Rapid dark adaptation test

Dirk Wm Powell ND

INTRODUCTION

The earliest sign of vitamin A deficiency is a decrease in dark adaptation, or night vision. Serum retinol levels are not predictive of subclinical deficiency states. However, classical dark adaptation testing is a cumbersome and time-consuming process (usually taking 45 minutes).

A rapid test (6 minutes) was described by Thornton^[1] and evaluated by Vinton & Russell.^[2] This rapid dark adaptation test (RDAT) has significant clinical utility. The basis for the test is the measurement of the time of the so-called Purkinje shift. This refers to the shifting of peak retinal wavelength sensitivity from the red toward the blue end of the visual spectrum during the transition from day (cone-mediated) vision to night (rod-mediated) vision. When color vision is non-functional, this shift causes the intensity, not the color, of blue to appear brighter than red under dim lighting.

CLINICAL APPLICATION

While the various dark adaptation tests have the advantage of being *in vivo* tests, and therefore directly relevant to function, they are also somewhat less specific. [Table 26.1](#) lists conditions which may give abnormal dark adaptation results despite normal serum levels of vitamin A.

PROCEDURE

Method

1. The procedure is explained to the subject.
-

2. The subject is light-adapted by fixation on a standard X-ray viewer for 1 minute at a distance of 0.5 m. The X-ray viewer is then turned off (the darkroom light is, of course, on).
3. The subject is given a pile containing all 18 discs mixed in random order and the stopwatch is started.
4. The subject separates the white and then the blue discs as fast as possible. Under these controlled lighting conditions, the subject will not be able to recognize the colors, since the cones cannot distinguish color with the limited light available. The ability to separate the discs by brightness is therefore dependent upon the rods. Any disc mistakenly separated by the subject is returned to the original pile until 100% accuracy of sorting is achieved.
5. The first test performed by a subject should be redone to allow for learning and standardization.

TABLE 26-1 -- Conditions causing abnormal DAT results with normal levels of vitamin A

- Zinc deficiency
- Cataract
- Retinitis pigmentosa
- Diabetic retinopathy
- Severe errors of refraction
- Miosis caused by pharmaceutical agents
- Tinted corrective lenses

Equipment and supplies

- Light-proof room.
- A standard darkroom light fixture fitted with a 7.5 W bulb and a neutral density filter (allowing 1% transmittance). Alternately, an exposed X-ray film may serve as filter. The bottom of the fixture is suspended 1.2 m above the work surface, so that the target brightness on the work area is approximately 0.0068 candela/m².
- Munsell color discs with matte finish – five white discs (N9.5/-), six blue discs (5PB5/10), and seven red discs (5R5/10). Available from Munsell Color and Macbeth Division (Baltimore, MD).
- A non-reflective work surface.
- A stopwatch.
- A standard X-ray viewbox.

Results

- Normals
 - 20–39 years old: 3.03 ± 1.00 min
 - 40–60 years old: 4.41 ± 0.83 min
- Vitamin A-deficient
 - 7.63 ± 1.79 min.

INTERPRETATION

The RDAT time will depend largely upon the individual setting. However, the difference in the RDAT time between normal and vitamin A-deficient individuals is significant, and therefore standardization is easily achieved. The normal values are dependent on the age of the subject, with older subjects having an increased RDAT time. Vinton & Russell's average RDAT time for normal subjects between the ages of 20 and 39 was 3.03 ± 1.00 minutes, while for the 40–60 years age group it was 4.41 ± 0.83 minutes. In vitamin A-deficient patients, the value was 7.63 ± 1.79 minutes. An increased RDAT time may also be indicative of a zinc deficiency.

Chapter 27 - Serum bile acids assay

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

The standard serum enzyme studies (SGPT, GGTP, SGOT, LDH, alkaline phosphatase, etc.), which have traditionally been used for detecting hepatic damage, have been shown to be unreliable in identifying the early phases or progression of liver disease and the liver damage caused by a variety of toxic chemicals.^{[1] [2] [3] [4] [5] [6]} These enzyme studies are often of limited value because they measure acute disruption of cell membrane integrity (liver cell “leakage”) rather than functional activity of the liver, i.e. uptake, metabolism, storage, and excretion. In subacute, chronic, and end-stage liver disease, the enzymes often return to normal levels after initial elevation and fail to reflect the decreased metabolic capacity of the remaining parenchyma.

Currently, measuring clearance rates of substances primarily removed from circulation by the liver provides the most sensitive and specific indicator of liver function. Such substances include exogenous anionic dyes (e.g. bromsulphalein (BSP) or indocyanine green) and endogenous metabolites (e.g. serum bile acids). The use of the anionic dyes does, however, carry with it significant risk of adverse reaction. In contrast, the measurement of serum bile acids represents a safe approach to measuring the functional capacity of the liver.

The usefulness of measuring serum bile acid concentrations for the detection of liver disease has been extensively studied in numerous clinical studies.^{[2] [3] [4] [5] [6] [7] [8] [9] [10] [11] [12] [13] [14] [15] [16] [17]} However, until recently, the use of this extremely sensitive liver function test has not been widely used in clinical practice, due to complex methodology and inadequate precision and standardization between laboratories. Now, several commercial assays are available.

The radioimmunoassay and bioluminescent enzymatic assay methodologies are sensitive, precise, and relatively inexpensive.^{[6] [8]} In contrast, enzymatic measurement based on bacterial dehydrogenases appears to be much less sensitive than the RIA and

bioluminescent methods, especially when the elevation is only marginal. Accurate

interpretation requires that the method being used by the laboratory be known.

There has been considerable disagreement as to whether fasting or postprandial serum bile acid measurement is the better determinant of abnormal liver function. As a postprandial rise is governed largely by non-hepatic factors, fasting levels are probably more reproducible. In addition, many studies have demonstrated fasting levels to be a more sensitive indicator than postprandial levels.^{[6] [7] [8] [9] [10] [11]}

DETERMINANTS OF SERUM BILE ACID LEVELS

In healthy subjects, the bile acid pool consists of primary, secondary, and tertiary bile acids. The two primary bile acids in humans, cholic acid and chenodeoxycholic acid (which are formed from cholesterol), are converted by intestinal bacteria (through deconjugation and 7- α -hydroxylation) to the secondary bile acids, deoxycholic acid and lithocholic acid. A fraction of chenodeoxycholic acid is transformed, via 7-ketolithocholic acid, into the tertiary bile acid, ursodeoxycholic acid.^{[6] [8]} All bile acids secreted by the liver are conjugated with either glycine or taurine, and about two-thirds of lithocholic acids are in addition sulphated. In health, only a small fraction of bile acids is glucuronidated.

The bile acid pool cycles five to 10 times daily through the enterohepatic circulation, where it is almost completely confined. The liver normally clears 20 g of bile salt from the blood each day.^[12] Less than 1% of the total bile acid pool is present in the peripheral blood due to high efficiency of the hepatic transport mechanism for the bile acids.^[8]

Serum bile acid levels at any moment are determined by the balance between intestinal absorption and hepatic elimination of bile acids. Input of bile acids from the intestine into the systemic circulation may occur via two pathways: portal-systemic shunts and the hepatic circulation.

Hepatic elimination of bile acids occurs as first-pass elimination from the portal blood and as systemic clearance from peripheral blood. Systemic clearance of bile acids depends on the intrinsic ability of the liver to remove bile acids and on hepatic blood flow. In patients with liver disease, diminished hepatic elimination of bile acids can be caused by reduced hepatic extraction, portosystemic shunting, or by a combination of both.

CLINICAL INDICATIONS FOR SERUM BILE ACID DETERMINATION

Fasting serum bile acid (SBA) determination can be used clinically in the diagnosis and

prognosis of liver disease in conjunction with standard liver function tests. Because of the increased sensitivity of SBA determination as compared with standard liver function tests, SBA offers significant additional diagnostic information concerning liver function, especially in minor hepatic derangements. It is of particular benefit in the determination of hepatic dysfunction as a result of chemical and environmental injury.^{[2] [3] [4] [5] [6] [7] [8] [9] [10] [11] [12] [13] [14] [15] [16] [17]}

Liver injury as a result of occupational or environmental exposure to a wide variety of chemical substances can be determined to a much finer degree by SBA than by standard liver enzymes, especially when the liver has been only slightly damaged. In one study of individuals exposed to organic solvents, 73% of the exposed cases had elevated SBA levels, whereas increased levels of SGGT, alanine aminotransferase (ALT), aspartate aminotransferase (AST) and bilirubin were observed respectively in 8, 3, 2, and 1% of exposed workers.^[2] These results and others support the hypothesis that standard liver function tests are not sensitive enough to determine hepatic dysfunction caused by such organic solvents as toluene, xylene, acetone, styrene, *n*-butylacetate, *n*-butanol, ethylacetate, and other aromatic hydrocarbons and ketones.

Other indications for SBA determination include patients presenting with generalized pruritus^[14] and pregnant women experiencing nausea and vomiting of pregnancy.^[16] Both of these conditions can be a result of impaired hepatic function, yet standard liver function tests are usually not sensitive enough to be of value. In contrast, SBA determination has shown a significant correlation between hepatic dysfunction and both nausea and vomiting of pregnancy^[16] and generalized pruritus.^[14]

SBA determination also offers useful prognostic information in cases of cirrhosis. In one large study,^[15] the SBA concentration correlated more closely with mortality than did the commonly used clinical and laboratory parameters such as the “number connection test”, ascites, albumin, pseudocholinesterase, bilirubin, prothrombin time, and nutritional state. SBA levels below 20 $\mu\text{mol/L}$ indicated a good prognosis, while those individuals with SBA levels exceeding 50 $\mu\text{mol/L}$ had a very poor prognosis.

PROCEDURE

Method

1. Have the patient fast overnight.
2. Take 10 ml (in a red-top tube) from the antecubital vein.
3. Allow to clot, and separate within 20 minutes.
4. Freeze until delivered to laboratory.
5. Use only laboratories which use the radioimmunoassay and bioluminescent enzymatic assay methodologies.

Results

These values are for the radioimmunoassay technique:

- Normal: 1.3 ± 0.2 $\mu\text{mol/L}$
- Solvent exposure: 3.7 ± 2.8
- Mild liver dz: $5.5 \pm .3$
- Moderate liver dz: 12.5 ± 1.8
- Cirrhosis: 20.4 ± 3.2
- Cirrhosis (dying < 1 year): 79.6 ± 28.0 .

INTERPRETATION

Bile sequestering agents, such as cholestyramine and cholestipol, will interfere with the test by decreasing reabsorption of bile acids from the intestine. Decreasing the total level of bile acids in the enterohepatic circulation may result in lower serum values, thus masking decreased liver function. The typical causes of elevated levels are listed in [Table 27.1](#). Serum bile acid levels are normal in Gilbert's disease and are generally not useful in differentiating between the various types of liver disease.^[6]

SUMMARY

Fasting serum bile acid determination by radioimmunoassay

TABLE 27-1 -- Conditions with elevated fasting serum bile acids levels^[18]

-
- Anicteric liver disease

 - Viral hepatitis
-
-

or bioluminescent enzymatic assay provides valuable information concerning the functional activity of the liver. SBA determination has a much greater specificity and sensitivity than standard liver function tests in the diagnosis of liver disease induced by chemical and environmental exposure and in diagnosing low levels of hepatic dysfunction.

Chapter 28 - Tryptophan load test

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

The use of an oral loading dose of L-tryptophan to detect abnormalities in tryptophan and vitamin B₆ status is an under-utilized laboratory procedure. If used only to measure B₆ status, it may be less indicative than other indices, such as the methionine load test (urinary cystathionine), serum pyridoxal-5-phosphate, urinary vitamin B₆, or 4-pyridoxic acid. It may, however, be more accurate than erythrocyte aminotransaminases. The real value of the test is in the evaluation of tryptophan metabolism. Aberrations in tryptophan metabolism have been implicated in a wide range of diseases, including depression, autism, hypertension, and asthma. Correction of these aberrations is sometimes possible with supplementation of B₆ and magnesium, as these two nutrients play a major role in tryptophan metabolism. Even marginal B₆ or magnesium deficiencies cause significant alterations. A simplified schematic representation of tryptophan metabolism is shown in [Figure 28.1](#).

PROCEDURE

The procedure is straightforward: tryptophan breakdown products are measured in the urine after a loading dose is orally administered.^[2]

Method

1. Two grams of L-tryptophan are administered orally.
2. Urine is collected for the next 24 hours.
3. The urinary levels of 3-hydroxykynurenine, kynurenine, and xanthurenic acid are determined (xanthurenic acid is the easiest to measure and may be the only metabolite measured by some laboratories).

Results are interpreted as shown in [Table 28.1](#) .

INTERPRETATION

Kynurenine aminotransferase is apparently less sensitive

226

Figure 28-1 Tryptophan metabolism.^[1]

227

TABLE 28-1 -- Vitamin B₆ and tryptophan metabolism status according to 24 hour urinary excretion of tryptophan metabolites

| Metabolite | Abnormal (mg/24 h) | Normal (mg/24 h) |
|---------------------|--------------------|------------------|
| Xanthurenic acid | >50 | <25 |
| 3-Hydroxykynurenine | >50 | <25 |
| Kynurenine | >50 | <10 |

to a vitamin B₆ deficiency than kynureninase, resulting in a shunting to xanthurenic acid and, as the deficiency worsens, 3-hydroxykynurenine and kynurenine. The first two metabolites may also be increased in response to increased activity of tryptophan pyrrolase. This enzyme is stimulated by glucocorticoids, glucagon, and oral contraceptives, and inhibited by insulin. The tryptophan load test can be used to evaluate the therapeutic effect of vitamin B₆ supplementation.

Chapter 29 - Urinary organic acids profiling for assessment of functional nutrient deficiencies, gut dysbiosis, and toxicity

J. Alexander Bralley PhD
Richard S. Lord PhD

INTRODUCTION

Urinary organic acid analysis for metabolic profiling has traditionally only been used to assess and define inborn errors of metabolism that cause death within the first year of life or severe mental retardation. Profiling of organics in urine is a relatively recent addition to routine laboratory evaluation of chronic diseases. The identification of isovaleric acidemia in 1966 was soon followed by numerous additional acidurias as the severe enzyme impairments found in genetic diseases were found to result in greatly elevated amounts of organic compounds excreted in urine.^[1]

The availability of instrumentation with improved reliability, sensitivity and reduced cost is now allowing greatly expanded clinical application. This valuable technique can be used for the detection of subtle functional nutritional deficiencies, identification of genetic variants and the source of toxicants from the environment and the gut.^{[2] [3] [4]} For example, elevated methylmalonic acid in urine is a well-established and sensitive indicator of functional vitamin B₁₂ deficiency.^[5] This method of assessment of nutritional status is of far greater clinical applicability than serum levels of specific nutrients, as it allows a functional evaluation of nutritional status, thus incorporating the wide variability of biochemical individuality.

Organic acids

The term “organic acids” refers to a broad class of compounds used in fundamental metabolic processes of the body. Derived from dietary protein, fat and carbohydrate, they are used by the body to generate cellular energy and provide the building blocks necessary for cell function. Chemically they share the common features of water

solubility, acidity, and ninhydrin-negativity which means that amino acids are usually excluded from this group. The term is generally considered to include all carboxylic acids, with or without keto, hydroxyl or

other non-amino functional groups. Some nitrogen containing compounds are included such as pyroglutamate or amino conjugates like hippurate (benzoylglycine). Short chain fatty acids are also contained in this group. With the inclusion of neutral compounds of fungal origin such as arabinose and arabinitol in the metabolic profile, the name organic acid analysis is more correctly termed organics profiling.

URINARY ORGANICS PROFILING

The measurement of organic acids and neutrals in urine allows the simultaneous assessment of mitochondrial energy production efficiency, functional vitamin, mineral and certain amino acid deficiencies, neurotransmitter metabolism, clinically significant microflora imbalances in the gut, and metabolic toxicity problems.

The test is performed on an overnight urine sample from which the organic compounds are extracted and analyzed by gas chromatography with mass spectrometric detection. The basic methodologies are well known, but improvements are regularly reported.^[6] ^[7]

The information content of the profile is high, but the interpretation is simplified by keeping in mind that the data supply answers to four basic questions of clinical relevance:

- Is mitochondrial energy production adversely affected?
- Are functional nutrient deficiencies present?
- Are symptoms related to excessive growth of bacteria and fungi in the gut?
- Is there an undue toxic load and is this adversely affecting detoxification capacity?

Each of several compounds reported in the typical profiling of organics in urine is discussed briefly, with key references cited, to indicate why they are related to these clinical questions.

[Figure 29.1](#) provides a graphic overview of the nutrient requirements for the citric acid cycle, while [Table 29.1](#) shows various nutrient-related abnormalities that might appear on a typical quantitative report of organics in urine. The supplementary nutrient amounts are given as guides to starting points that might improve clinical outcomes for adults. For more information on how well the associations are established, see the discussions below.

Central energy pathway intermediates

Citrate, isocitrate, a-ketoglutarate (aKG), cis-aconitate, succinate, fumarate

These components are intermediates in the core metabolic pathway which generates cellular energy. The Krebs or citric acid cycle (CAC) is not only the final common pathway of food components, but also the source of basic structural or anabolic molecules that feed and support organ maintenance and neurological function. Therefore, the CAC serves both anabolic and catabolic functions of the body, representing the “crossroads” of food conversion and utilization.

Conversions of the CAC intermediates are under the control of enzymes that often require vitamin-derived cofactors and minerals for their function. Abnormal spilling of CAC intermediates indicates mitochondrial inefficiencies at specific steps in energy production. This fundamental pathway of energy flow is critical for all organ systems. The measurement of the intermediates listed above provides a unique perspective to energy metabolism, along with clues on how to improve energy production by supplying B complex vitamins to assure adequate coenzyme concentrations. In cytochrome C oxidase deficiency, for example, there is inefficient removal of the primary product of the CAC (NADH), and citrate, malate, fumarate, and aKG are all increased.^[8] Coenzyme Q₁₀ deficiency can also result in elevated CAC intermediates (see “Hydroxymethylglutarate” below).

Mild inborn errors of energy metabolism which may be compatible with survival at least into young adulthood, but not with normal development of mental and neurological functions, have been associated with the excretion of elevated aKG.^[9] The clinical heterogeneity of neurometabolic disorders and the importance of organic acid analysis in the diagnosis of static encephalopathy were underscored by the finding of excretion of excess fumaric acid in a 5-year-old girl with a previous diagnosis of cerebral palsy.^[10]

Intermediates of the cycle can also be derived from amino acids. This would explain the energy-boosting effect people often report when they take free form amino acid supplements. The effect is due to the conversion of specific amino acids directly into depleted CAC intermediates needed for the energy-producing cycle. The fatigue-reducing effect of supplementation of aspartate salts and a-ketoglutaric acid has been attributed to such a mechanism.^{[11] [12]} Supplementation of the precursors serves to drive the cycle and generate reducing equivalents used in the electron transport chain where ATP is produced via oxidative phosphorylation. Low levels of a specific metabolite may be indicative of suboptimal amino acid availability and need for supplemental amounts of these specific amino acids for improved function.

Lactate and pyruvate

These two compounds provide useful insight into basic metabolic factors due to their position in the energy production process. Pyruvate is the anaerobic breakdown product of glucose. Its further conversion to acetyl-CoA requires the pyruvate dehydrogenase enzyme complex.

Figure 29-1 Vitamin and mineral cofactor requirements for the extraction of energy from food.

Pyruvate dehydrogenase requires cofactors derived from thiamin, riboflavin, niacin, lipoic acid, and pantothenic acid for optimal function. Elevated levels of pyruvate may reflect failure of the enzyme due to a functional need for increased B vitamins, particularly thiamin and pantothenic acid.

Levels of pyruvate in the tissues are further controlled by the biotin-containing protein, pyruvate carboxylase, which controls the first step in the reformation of glucose from pyruvate. Multiple forms of pyruvate carboxylase deficiency, some of which are biotin-responsive, have been reported.^[13]

Lactate accumulates when there is a block in the final oxidative phosphorylation (ox/phos) stage of energy production. Such a block results in inactivation of the CAC. Coenzyme Q₁₀ has been used in cases of lactic

TABLE 29-1 -- Quick reference to clinical significance of abnormal levels of organics in urine

| Name | Abnormality | Potential intervention | Metabolic pathway |
|--------------------------|-------------|---|-------------------|
| <i>Energy production</i> | | | |
| Citrate | L | Aspartic acid, 500 mg | |
| <i>Cis</i> -aconitate | H | Iron, 18 mg; cysteine, 1000 mg b.i.d. | |
| Isocitrate | H | aKG, 300mg t.i.d.; B ₃ , 100mg | |

| | | | |
|-----------------|---|---|--|
| | | Magnesium, 400 mg; manganese, 20 mg | |
| a-Ketoglutarate | L | aKG, 300 mg; arginine, 1000 mg; glutamine, 1–5g | Citric acid cycle intermediates |
| | H | B-complex, 1 t.i.d.; lipoic acid 100 mg | |
| Succinate | L | Isoleucine, 1000 mg t.i.d.; valine, 1000 mg t.i.d. | |
| | H | Magnesium, 500 mg | |
| Fumarate | L | Tyrosine, 1000 mg b.i.d.; phenylalanine, 500 mg b.i.d. | |
| Malate | H | B ₃ , 100 mg t.i.d. | |
| Lactate | H | Coenzyme Q ₁₀ , 50 mg t.i.d. | |
| Pyruvate | H | B-complex, 1 capsule t.i.d.; | Aerobic/anaerobic energy production |
| | | B ₁ , 100 mg t.i.d.; lipoic acid, 100 mg t.i.d. | |

Specific vitamin indicators

| | | | |
|-------------------------|-----|---|---|
| a-Ketoisovalerate | H | B-complex, 1 capsule t.i.d.; B ₁ , 100 mg t.i.d.; | Amino acid catabolism utilizing |
| | | lipoic acid, 100 mg t.i.d. | B-complex vitamins |
| a-Ketoisocaproate | H | | |
| a-Keto-β-methylvalerate | H | | |
| Methylmalonate | H | B ₁₂ , 1000 mcg t.i.d. | BCAA input to Krebs cycle |
| β-Hydroxyisovalerate | H | Biotin, 5 mg b.i.d.; magnesium, 100 mg b.i.d. | Dicarboxylic acid metabolism requiring biotin |
| Hydroxymethylglutarate | H/L | Coenzyme Q ₁₀ , 50 mg t.i.d. | Co-Q ₁₀ synthesis |

Carbohydrate metabolism

| | | | |
|---------------------------|---|--|--------------------------------------|
| β -Hydroxybutyrate | H | Chromium picolinate, 200 mcg b.i.d. | Balance of fat and CHO metabolism |
| α -Hydroxybutyrate | H | | |

Detoxication indicators

| | | | |
|--------------------------------|-----|--|--|
| Glucarate | H | Glycine, GSH, NAC, 500–5000 mg/day | Detox. liver enzyme induction |
| Orotate | H | aKG, 300 mg t.i.d.; arginine, 1–3 g/day; aspartic acid, 500 mg b.i.d.; magnesium, 300 mg | Ammonia clearance, pyrimidine synthesis |
| <i>p</i> -Hydroxyphenyllactate | H | Vitamin C up to 100 mg/kg | Prooxidant and carcinogen |
| 2-Methylhippurate | H | Avoidance of xylene | Hepatic conjugation |
| Pyroglutamate | L/H | NAC, 1000 mg; glutathione, 300 mg | Renal amino acid recovery |
| Sulfate | L | Taurine, 500 mg b.i.d.; glutathione, 300 mg | Detox. and antioxidant functions |

Fatty acid oxidation

| | | | |
|---------------|---|--|-------------------------|
| Adipate | H | L-carnitine, 250 mg t.i.d.; B ₂ , 100 mg b.i.d.; | |
| Suberate | H | B ₅ , 500 mg b.i.d.; choline, 100 mg t.i.d.; | Fatty acid oxidation |
| Ethylmalonate | H | vitamin C, 1000 mg t.i.d.; CoQ ₁₀ , 150 mg | |

Neurotransmitter metabolism

| | | | |
|-----------------------|-----|--|---|
| Vanilmandelate | L/H | Tyrosine, 1000 mg b.i.d.-t.i.d., between meals; contraindicated for patients taking MAO inhibitors | Catecholamine catabolism, neurotransmitter metabolites |
| Homovanillate | L/H | | |
| 5-Hydroxyindolacetate | L | 5-Hydroxytryptophan, 100 mg t.i.d. | |
| Quinolinatate | H | Magnesium, 300 mg | Serotonin catabolism |

Dysbiosis markers (products of abnormal gut microflora)

| | | | |
|--------------------------------|---|--|---|
| <i>p</i> -Hydroxybenzoate | H | If any of these compounds is high, the possibility of dysbiosis is reinforced. Glutamine, 10–30 g daily and free form amino acids normalize gut permeability. Take appropriate steps to ensure favorable gut microflora population | Numerous interferences in pathways and cellular energy control mechanisms |
| <i>p</i> -Hydroxyphenylacetate | H | | |
| β -ketoglutarate | H | | |
| Hydrocaffeate | H | | |
| Tartarate | H | | |
| Citramalate | H | | |
| Arabinose | H | | |
| Arabinitol | H | | |
| Tricarballylate | H | | |

acidosis associated with ox/phos impairments.^{[14] [15]} Increased lactate is a common acidotic condition that can be caused by a variety of metabolic problems. Decreased lactate is seen in people with very little physical activity. Highly trained athletes have such efficient conversion of lactate to glucose that they also demonstrate lower lactate levels.

Carbohydrate metabolism

***a*-Hydroxybutyrate, β -hydroxybutyrate**

These two compounds are also called ketone bodies. Ketone body production occurs in conditions where glucose oxidation is impaired and free fatty acids are utilized as the predominant energy source. Ketone bodies

can be thought of as a transportable form of acetate resulting from oxidation of fatty acids. β -Hydroxybutyrate is normally produced in much larger amounts than the *a*-isomer, but both compounds can serve the energy needs of most tissues. Elevations seen in an overnight urine collection may indicate inefficient utilization or mobilization of carbohydrate stores. Excessive fatigue on exertion is the most common symptom associated with ketosis. Chromium and vanadium supplementation may support the carbohydrate utilization by improving the action of insulin.

Indicators of a specific vitamin deficiency

β -Hydroxyisovalerate

This compound is elevated in multiple carboxylase insufficiency. This occurs due to

genetic abnormalities and/or a biotin deficiency (biotin is the cofactor for three mitochondrial carboxylase enzymes). Symptoms of multiple carboxylase deficiencies include alopecia, skin rash, *Candida* dermatitis, unusual odor to the urine, immune deficiencies and muscle weakness. Biotin deficiencies of various degrees develop in a substantial minority of normal pregnancies and in patients on long-term therapy with anticonvulsants.^[17] ^[18] Other possible indications of biotin deficiency are elevations of lactate and alanine in urine, and accumulations of odd-chain fatty acids in plasma or red cell membranes.^[19] Supplementation of biotin may improve these conditions.

Hydroxymethylglutarate (HMG)

HMG is the metabolic precursor of cholesterol and coenzyme Q₁₀ (CoQ₁₀). Low levels may reflect inadequate synthesis and possible deficiency of the coenzyme Q₁₀.

Cholesterol-lowering drugs that block utilization of HMG for cholesterol synthesis also lower coenzyme Q₁₀ levels.^[20] CoQ₁₀ is utilized in the mitochondrial oxidative phosphorylation pathway for ATP synthesis and is a potent antioxidant. It has been used extensively as a cardiovascular protective agent.^[21]

Coenzyme Q₁₀ has been used successfully to improve mitochondrial function in clinical situations of cardiac and skeletal muscle weakness and cramping and, in the extreme, mitochondrial encephalomyopathy.^[22] ^[23] The coenzyme has been found useful in the treatment of fatigue, particularly when both lactate and pyruvate are elevated. Such responses reflect the inability of mitochondrial oxidative phosphorylation to proceed efficiently, possibly due to CoQ₁₀ deficiency (see [Ch. 76](#) for a full discussion of this useful nutrient).

α -Ketoisovalerate, α -ketoisocaproate, α -keto- β -methylvalerate

These compounds are the ketoacids of the branched chain amino acids, isoleucine, leucine and valine, respectively. They are formed by the removal of the amine group in the first step of their catabolism and are excreted in large amounts along with their amino acid precursors in the inherited disorder known as maple syrup urine disease. There are 10 known metabolic disorders in the pathways of catabolism of the ketoacids. The reactions require enzymes similar to pyruvate dehydrogenase that use the B-complex cofactors, B₁, B₂, B₃, B₅ and lipoic acid. Elevations of the branched chain ketoacids provide a functional assessment of the sufficiency of these vitamins, especially thiamin.^[24]

Methylmalonate

This compound is converted into succinic acid using a vitamin B₁₂-dependent enzyme, methylmalonyl CoA mutase (see [Fig. 29.2](#)). The lack of vitamin B₁₂ impairs this conversion, as well as the one in which methionine is recovered from homocysteine, leading to accumulation of homocysteine. As discussed above, high levels indicate a functional deficiency of vitamin B₁₂. A differential diagnosis can be made when

considering both methylmalonate and the amino acid homocysteine. If homocysteine is also elevated, both B₁₂ and folate functional deficiencies are indicated. If only homocysteine is high, folate and B₆ supplementation are suggested. If methylmalonate only is elevated, only B₁₂ supplementation is needed.^[25]

Fatty acid oxidation

Adipate and suberate, ethylmalonate

Adipate and suberate are short-chain dicarboxylic fatty acids. They are produced by an alternate oxidation pathway called omega-oxidation. Their production is normally very low because the predominant pathway is beta oxidation in the mitochondria. Transport of fatty acids into the mitochondria, however, requires carnitine as a carrier. Suboptimal levels of carnitine result in inadequate transfer of fatty acids into the mitochondria and subsequent compensation via omega oxidation, producing excess amounts of adipate and suberate. The same metabolic impairment leads to production of ethylmalonate. All three of these compounds will be elevated in overt enzyme failure, but the patterns of elevations in milder carnitine deficiencies will vary.

Symptoms include periodic mild weakness, nausea, fatigue, hypoglycemia, “sweaty feet” odor, recurrent infections, and increased free fatty acids. Patients may also exhibit a Reye’s-like syndrome with dicarboxylic aciduria, which has been associated with various metabolic toxins generated from viral infections that affect mitochondrial function. Mild, heterozygotic forms of dicarboxylic aciduria may be more commonly seen clinically and go unrecognized. The enzymes involved also respond to

234

Figure 29-2 Methylmalonate is converted into succinic acid using a vitamin B₁₂-dependent enzyme, methylmalonyl CoA mutase.

environmental toxin exposure with altered lipid metabolism, which can lead to impaired immune responsiveness.^{[26] [27]} Supplementation of carnitine and other supportive nutrients is indicated when adipate, suberate or ethylmalonate are elevated.

Neurotransmitter metabolism

Vanilmandelate (VMA), homovanillate (HVA)

These two compounds are metabolites of the catecholamines, epinephrine and

norepinephrine. Low urinary levels have been associated with low CNS levels of these neurotransmitters. Symptoms associated with this condition are depression, sleep disturbances, inability to deal with stress, and fatigue. Treatments aimed at improving protein digestion and supplementation of the amino acid precursors can normalize neurotransmitter levels in the CNS.^[28] A further indication of need for these precursors is low fumarate, a metabolic intermediate that can also be derived from tyrosine and phenylalanine.

5-Hydroxyindolacetate (5-HIA)

Catabolic breakdown of serotonin leads to excretion of 5-hydroxyindoleacetate. Abnormal high levels of this metabolite result from increased release of serotonin from any of three primary sites: CNS, Argentaffin cells in the gut, or platelets. Carcinoid tumors composed of chromaffin tissue can also release large amounts of serotonin.

Serotonin is required for control of gut motility as it activates smooth muscle activity. Inadequate production of serotonin leads to constipation. Low levels have also been associated with depression, fatigue, insomnia, suicide, attention deficit and behavioral disorders. When HIA levels are low, dietary therapy should focus on improving protein digestion (see [Ch. 19](#) for a discussion of hypochlorhydria and [Ch. 101](#) for a discussion of pancreatic insufficiency) and increasing consumption of foods high in tryptophan, including turkey, bananas, low fat milk, lentils, and eggs. These actions minimize the need for oral tryptophan or 5-hydroxytryptophan use.

Products of gut microflora

Several studies have used the unique products of microbial metabolism as indicators of the abnormal overgrowth of unfavorable intestinal microflora, a condition sometimes referred to as “gut dysbiosis”. Such a condition has been related to a wide variety of symptoms due to pathogenic toxins produced by these populations of microflora. No false-negative results and only 2% false-positive results for small bowel disease and bacterial overgrowth syndrome were found in a study of *p*-hydroxy-phenylacetate in 360 acutely ill babies and children.^[29] Some compounds are absorbed and enter the detoxification pathways of the liver to be excreted as products that can serve as sensitive indicators of changes in gastrointestinal flora.^[30] One product of anaerobic bacteria, 3-phenylpropionic acid, is normally converted to common hippuric acid, but is excreted as 3-phenylpropionylglycine in individuals with a relatively common inborn error of fatty acid oxidation.^[31] In people of north-western European origin, the incidence of this disorder may be 1 in 10,000.

***p*-Hydroxybenzoate, *p*-hydroxyphenylacetate, tricarballic acid**

For individuals with normal, healthy intestinal function, these compounds should not appear at more than background concentrations in urine, due to the efficient metabolic

conservation or recycling of phenyl group compounds of which they are composed. They are produced by microbial action on tyrosine and phenylalanine and are markers of bacterial growth in the gut. *p*-Hydroxy-phenylacetic aciduria has been found useful in detecting small bowel disease associated with *Giardia lamblia* infestation, ileal resection with blind loop, and other diseases of the small intestine associated with anaerobic bacterial overgrowth.^[32] Use of antibiotics such as neomycin, which act primarily against aerobic bacteria, can encourage the growth of *Giardia* and anaerobic bacteria that then produce greater amounts of these compounds.^[33]

Other GI disorders, including cystic fibrosis of the pancreas, celiac disease, and unclassified enteritis, have been associated with increased excretion of *p*-hydroxybenzoate, phenylacetate, and *p*-hydroxyphenylacetate. The patients with cystic fibrosis had elevated *p*-hydroxy-phenylacetate even while on pancreatine therapy. Because of variations in the relative amounts of these compounds observed with this type of GI disturbance, the patterns of excretion are apparently determined by the microbial flora present in the patient's intestinal lumen.^[34] Tricarballylate is produced by aerobic bacteria that quickly repopulate in the gut of germ-free animals.^[35]

Arabinose, and arabinitol

Arabinose is a carbohydrate and arabinitol is the related sugar-alcohol which is a product specifically of anaerobic fungal growth in the gut. The D isomer of arabinitol is produced by fungal metabolism, and urinary excretion is elevated in patients with invasive candidiasis.^[36] ^[37]

Tartarate, citramalate, hydrocaffeate, β -ketoglutarate

The structures of these compounds are closely related to those of intermediates of normal human metabolism. They have accordingly been called anti-metabolites. The pathways that they impact upon are those of central energy production. They have been reported along with arabinose to be elevated in children who began to display autistic traits after repeated treatment with broad-spectrum antibiotics.^[38] Patterns of elevations of any of the compounds in this category suggest treatments with bowel detoxification regimens to normalize the microbial flora of the gut.

Indicators of detoxification function

Glucarate

Glucaric acid (glucarate) is the oxidation product of glucuronic acid. It is a by-product of the predominant liver phase II detoxification reactions involving glucuronic acid conjugation. A great variety of drugs, environmental toxins, food components and products of gut microbial metabolism are prepared for excretion by glucuronidation. Decreased glucarate is an indicator of reduced overall hepatic function, while elevation is an indication of enzyme induction due to such potentially toxic exposures.^[39] ^[40]

The excretion of D-glucaric acid is considered a marker of the viability of hepatocytes

and is a useful clinical prognostic predictor in biliary atresia.^[41] Most exposures that result in stimulation of hepatic P-450 activity will result in increased excretion of glucarate. For example, urinary D-glucaric acid is elevated in pesticide-exposed groups.^[42] Patients with clinically quiescent chronic pancreatitis also show elevated glucarate, indicating a relationship of toxic metabolite stress to heightened free radical activity and hence to the genesis of chronic pancreatitis.^[43] The evidence of increased utilization of phase II conjugation pathways of xenobiotic disposal is in keeping with ongoing toxic metabolite stress from heightened phase I oxidative metabolism. Glucarate measurements have been advanced as useful biomarkers to xenobiotic exposure, being particularly useful as a screening tool in reproductive epidemiology.^[44]

Orotate

Orotic acid accumulation is a sensitive marker of ammonia build-up. Ammonia (via glutamine) is normally disposed of by forming carbamoyl phosphate which enters the urea cycle. When there is insufficient capacity for detoxifying the load of ammonia, carbamoyl phosphate leaves the mitochondria and stimulates the synthesis of orotic acid.^[45] Increased orotic acid production is a sensitive indicator of arginine availability. Most of the symptoms that develop following arginine deprivation can largely be accounted for by a decreased efficiency of ammonia detoxification. Increased orotic biosynthesis is observed with increasing ammonia concentrations in rat, mouse and human liver and is reduced by in vitro arginine supplementation.^[46]

Medium-chain acyl coenzyme A dehydrogenase deficiency and other disorders of fatty acid oxidation may present long after infancy in patients such as those with a clinical diagnosis of Reye's syndrome. They may mimic the symptoms of defects in the urea cycle such as that reported for a 13-year-old girl with hyperammonemic encephalopathy and orotic aciduria due to ornithine trans-carbamylase deficiency.^[47] Responses should include steps to stimulate ureogenesis, including alpha-ketoglutarate, magnesium, aspartic and glutamic acids.

In addition, orotate requires magnesium for its metabolism. While a normal level in a urinary organic acid

panel may not necessarily indicate magnesium sufficiency, high levels should alert one to a significant possibility of intracellular magnesium insufficiency. Red cell magnesium levels can confirm a deficiency condition. Symptoms of magnesium insufficiency include irritability, muscle cramping and twitching, irregular heart rhythm and fatigue.

p-Hydroxyphenyllactate (HPLA)

p-Hydroxyphenyllactate is a carcinogenic metabolite of tyrosine that increases lipid peroxidation in the liver.^[48] Methyl p-hydroxyphenyllactate (MeHPLA) is an important cell growth-regulating agent, and tumor cells contain esterase enzymes that hydrolyse the

compound to the free acid, HPLA.^[49] HPLA is an important regulator of normal and malignant cell growth and it appears to mediate the cancer-promoting effects of estrogen. MeHPLA blocks uterine growth in vivo and inhibits MCF-7 human breast cancer cell growth in vitro.^[50] High doses of ascorbic acid (100 mg/kg body weight daily) were shown to arrest or significantly inhibit the excretion of HPLA in patients with hemoblastoses and nephroblastoma.^[51] HPLA is also produced by some microbes that could inhabit the gut, but the recently discovered cell proliferative and pro-oxidant functions are of far greater clinical relevance.^[52]

2-Methylhippurate

This compound is a metabolite of the detoxification of the common solvent, xylene. Elevations indicate an exposure to this potentially toxic compound.^[53] ^[54] Methylhippurate, the product of hepatic oxidation and conjugation of xylene, is used to monitor xylene exposure.^[55] A wide range of compounds which may be abused by inhalation can be detected by measuring the excretion of this compound or one of its metabolic products.^[56] Spray-painting workers showed elevated methylhippurate, indicating recent exposure to xylene.^[57] Patient counseling in avoidance of these compounds is indicated.

Pyroglutamate

Pyroglutamate is a cyclic form of glutamic acid. Small amounts are always present in overnight urine because it is produced as an intermediate in a cycle thought to be used in the active transport of amino acids.^[58] This process utilizes glutathione as a carrier. With each molecule of amino acid resorbed, glutathione is split and then reformed by an ATP-requiring enzymatic step. When the energy-requiring step is impaired, the glutamic acid portion of glutathione is converted to pyroglutamate which is excreted. This shunt pathway conserves amino acids at the expense of glutathione. Glutamic acid, αKG, methionine and glutathione can replenish the intermediates in the amino acid recovery cycle and help rebuild total body glutathione.

Sulfate

Urinary sulfate is the only inorganic compound reported with the profiling of organics. It is measured in a separate assay and is included because of the added value in assessing the functioning of the detoxification pathways. Sulfation pathways are used in phase II liver detoxification for the important biotransformation of many drugs, steroid hormones, and phenolic compounds, among others. The ratio of sulfate to creatinine has been used to assess the body's reserve of sulfur-containing compounds (especially glutathione) used in phase II pathways. When the ratio of sulfate to creatinine is low, these stores need replenishment. Glutathione administration, in combination with oral cysteine and taurine and salts of sulfate, is used to replenish sulfur pathways and restore the hepatic supply of inorganic sulfate.^[59] ^[60] Glutathione levels in the liver can be increased 35% in normals by supplementation with *Silybum marianum* (see [Ch. 111](#)).

SUMMARY

Measurement of organics in the urine is rapidly becoming an indispensable tool for clinicians interested in deeply understanding the metabolic status of their patients. Through appropriate interpretation, energy production, carbohydrate metabolism, functional nutritional status, fatty acid metabolism, detoxification, gut biosis and neurotransmitter metabolism can all be assessed. Many of the detected abnormalities can then be corrected through the appropriate use of dietary changes, lifestyle improvements and nutritional and botanical supplements.

Chapter 30 - Urinary porphyrins for the detection of heavy metal and toxic chemical exposure

Carl P. Verdon PhD
Terry A. Pollock MS
J. Alexander Bralley PhD

INTRODUCTION

Toxic chemicals, at any level of chronic exposure, affect human biochemistry. Fortunately, the body has mechanisms for transforming, eliminating or compartmentalizing the many toxic chemicals encountered over a lifetime. Nonetheless, these “safety” mechanisms may be inadequate or even inappropriate in our modern industrialized society, especially for susceptible people such as the elderly, individuals with poor nutritional habits, and others who are physiologically stressed.^{[1] [2]}

Recognizing and identifying offending chemical(s) can present a difficult challenge for the clinician. Many chemicals exert their effect at such low concentrations that they escape detection except by very sophisticated laboratory methods. While measuring *effects* of toxicity by observing symptoms is a time-honored procedure, determination of the actual toxicant often requires the use of laboratory methods that measure *biomarkers*, which are specific indicators of the toxicant’s action.

Porphyrins measured in urine serve as such a biomarker. The presence or elevation of various urinary porphyrin species can flag a potentially toxic condition. Metals and other toxic chemicals with pro-oxidant reactivity can inactivate porphyrinogenic enzymes, deplete glutathione and other antioxidants and increase oxidant stress, all of which lead to damaged membranes, enzymes and other proteins in cells.^{[3] [4]} In addition, porphyrinogens (precursors to porphyrins in the reduced state) themselves are easily non-enzymatically oxidized to porphyrins by toxic metals such as mercury ([Fig. 30.1](#)). Thus, the distribution pattern of porphyrins in the urine serves as a functional fingerprint of toxicity.^[5]

The utility of urinary porphyrins as a diagnostic tool is not new – its use has been

documented in the literature since 1934. Specific diseases collectively known as the *porphyrias*, which can be inherited or acquired (e.g. acute intermittent porphyria, porphyria cutanea tarda, variegate porphyria), are often diagnosed with the aid of

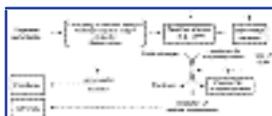

Figure 30-1 Toxic metal induction of porphyria and cell injury occurs as follows: (1) metals promote an increase in reactive prooxidants; (2) metals complex with glutathione compromising antioxidant and thiol status; (3) metals impair enzymes and other proteins via SH-complexation; (4) oxidant stress induced by metals causes cell injury and oxidation of porphyrinogens to porphyrins which are excreted in the urine (porphyrinuria).^[7]

information regarding the distribution profile of individual porphyrin species in human urine.

Definitions

Porphyrins are oxidized by-products that have escaped from the heme biosynthetic pathway, an essential pathway occurring in all nucleated mammalian cells. Heme is the all-important iron-binding molecule essential for the proper function of many proteins, including hemoglobin (oxygen transport), cytochrome c (energy production) and cytochrome P-450 (detoxification). Biosynthesis of heme involves eight enzymes ([Fig. 30.2](#)), five of which produce intermediate molecules that are collectively called *porphyrinogens*. Some porphyrinogens escape the intracellular pathway to become oxidized by other cellular processes to porphyrins. Some porphyrins, in turn, are excreted in urine and feces.

The different molecular species of porphyrins that occur in the urine of healthy individuals form a predictable, characteristic pattern. Elevated levels of one or more porphyrins is designated *porphyrinuria*. The term *porphyria* is reserved for primary conditions exhibiting specific clinical symptoms caused by an inherited defect in one or more of the heme biosynthetic enzymes. *Porphyriopathy* is an umbrella term for any disorder in porphyrin metabolism.

PORPHYRIAS

The porphyrias have been classified in the literature in several different ways. Most commonly, porphyrias are presented in textbooks with specific biochemical reference to the principal enzyme deficiency (e.g. ALA dehydratase deficiency, etc.) and the site of the deficiency (i.e. hepatic, erythropoietic, or both). Furthermore, the temporal pattern of appearance of overt clinical signs (acute vs. chronic) and the primary presentation of symptoms (neuropathic, dermatopathic, or mixed) are valid classifications that arrange porphyrias according to symptomatology. It is also useful to organize porphyrias

according to etiology (hereditary vs. acquired or toxicant-induced).

PORPHYRINOPATHIES

Inhibition of an enzyme for heme biosynthesis can result in the inappropriate accumulation of that enzyme's substrate. The more severe the enzyme's inhibition, the greater the tissue accumulation of porphyrins, sometimes becoming severe enough to cause clinical porphyria.

One class of toxic chemicals capable of subtle yet insidious health effects that may mimic other disorders, especially in children, is the heavy metals. Lead, mercury, arsenic, aluminum, and cadmium are well-documented examples. Chronic exposure to these metals often results in organ-specific accumulation which compromises the physiology of that organ. Heavy metals damage many aspects of metabolism, as shown in [Figure 30.1](#). Similarly, chronic exposure to organic chemicals such as herbicides, pesticides, and industrial and manufacturing by-products can have deleterious impact on the body's biochemistry which results in the decline of cellular function ([Table 30.1](#)).^[3]

241

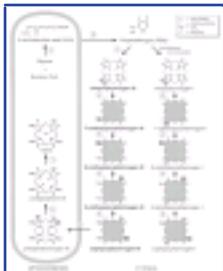

Figure 30-2 Biosynthesis of heme. The enzymes that drive the heme pathway are: (1) d-aminolevulinic acid (ALA) synthetase, (2) ALA dehydratase, (3) uroporphyrinogen III synthetase (PBG deaminase) and uroporphyrinogen III cosynthetase, two enzymes that work in concert, (4) uroporphyrinogen decarboxylase, (5) coproporphyrinogen oxidase, (6) protoporphyrinogen oxidase, and (7) ferrochelatase (heme synthetase). Spilled porphyrins derived from porphyrinogens with 8-, 7-, 6-, 5-, and 4-carboxyl groups are largely excreted in the urine, while the less polar 2-carboxyporphyrin (protoporphyrin) is excreted exclusively in the feces. The physiologically relevant pathway leading to heme is via uroporphyrinogen III in which the propionyl and acetyl groups are “reversed” compared with the type I pathway, which “dead ends” with coproporphyrinogen I. The physiological significance of the type I pathway remains unclear; however, coproporphyrin I is elevated in hepatobiliary diseases.

242

TABLE 30-1 -- Symptomatology of the porphyrinopathies

| Primary complaints | Associated symptoms | Condition exacerbated by |
|--|--|--|
| <i>Neurologic presentations</i> | | |
| Abdominal pain; nausea; vomiting; constipation; seizures | Headaches; difficulty in concentration; personality changes; weakness; muscle and joint aches; unsteady gait, poor coordination; numbness, tingling of arms and legs; fluid retention; rapid heart rate; high blood pressure; increased sweating; intermittent fever | Low carbohydrate diets (skipped meals); intake of alcoholic beverages; medications, including sulfa-drug antibiotics, barbiturates, estrogen, birth control pills; exposure to toxic chemicals |
| <i>Cutaneous presentations</i> | | |
| Changes in skin pigmentation; changes in facial hair; fragile skin; rashes; blistering | Dark-colored urine (especially after its exposure to sunlight), and above symptoms may be present | Above factors, and skin symptoms made worse by exposure to sunlight. Copper or brass jewelry exacerbates reaction |

PROCEDURE

The clinical utility of urinary porphyrins is maximized when urine samples are taken when the patient is experiencing symptoms (see [Table 30.4](#) below). Urine is best collected over a 24-hour period with 7 g of sodium carbonate added as a preservative. It may be useful with some patients to provoke their porphyria (e.g. a low carbohydrate diet for 2 days can be effective).

CLINICAL APPLICATIONS

Changes in the urinary porphyrins (i.e. porphyrinuria) coincident with provocation (e.g. fasting) or therapeutic intervention (e.g. medications, chelation therapy) are suggestive of some type of porphyriopathy. If the patient's response upon provocation can be duplicated then the possibility of a diagnosis of porphyria should be investigated. Twenty-four hour output of any urinary porphyrin that is three or more times the upper limit of the reference range may indicate that organ accumulation of porphyrins is reaching pathological levels. In such cases, a comprehensive porphyria work-up is warranted. For out-of-range results that are lower than three times the upper limit, the rationale for further porphyria testing is predicated upon the availability of corroborating clinical and/or biochemical data such as complaints, family and patient medical history.

Elevations of the individual porphyrin species above the normal range have a number of causes, both inherited

TABLE 30-2 -- Enzymatic defects of the common porphyrias

| Enzymatic defect | Porphyria |
|--|--|
| d-Aminolevulinic acid (ALA) synthetase | |
| ALA dehydratase | Plumboporphyria |
| Porphobilinogen deaminase | Acute intermittent porphyria |
| Uroporphyrinogen cosynthetase | Congenital erythropoietic porphyria |
| Uroporphyrinogen decarboxylase | Porphyria cutanea tarda and hepatoerythropoietic porphyria |
| Coproporphyrinogen | Hereditary coproporphyria |
| Prototporphyrinogen | Variegate porphyria |
| Ferrochelataase | Protoporphuria |

and environmental (see [Tables 30.2](#) and [30.3](#)).^[6] The effect of chemicals on the porphyrin pathway has been the subject of many scientific reports. Lead, mercury or arsenic toxicity induces porphyrinuria,^[7] as well as polychlorinated phenyls (e.g. dioxin, PCBs),^[8] and many drugs (see [Table 30.4](#)).^[9] A study of practicing dentists reported correlations between elevated urinary 5-carboxyporphyrin, pre-coproporphyrin, coproporphyrin and behavioral changes that were related to urinary excretion of mercury.^[10]^[11] Together, elevations of these porphyrins served as biomarkers of mercury toxicity.

Upregulation of the heme biosynthetic pathway, with the concomitant increase in delta-aminolevulinic acid (ALA), is another mechanism by which porphyria can be precipitated. Increased ALA production is usually a normal physiological response to provide enough of this pre-porphyrin precursor to meet the body's demand for heme. However, overproduction of ALA can overwhelm even a normally functioning heme biosynthetic pathway, resulting in the inappropriate accumulation of ALA and/or the porphyrins.^[6] Commonly, active porphyria occurs when ALA overproduction coincides with inhibition of one or more of the porphyrinogenic enzymes. Very often, porphyria is the result of a chemical insult to a porphyrinogenic enzyme combined with an external stressor that provokes dysregulation of the heme biosynthetic pathway. It is estimated that among cases of a porphyrinogenic enzyme deficiency, as many as 90% are healthy throughout adulthood until their porphyria is triggered mid-life by toxic chemicals or drugs, an acute illness or worsening chronic condition, or a major dietary change ([Table 30.5](#)).^[12]

TABLE 30-4 -- Drugs known to cause or exacerbate porphyria^a

- Trimethadone
- Valproic acid

^a Although this list includes many of the better known drugs that can exacerbate porphyria, it should not be considered complete.

TABLE 30-5 -- Interpretation of abnormal urinary porphyrin test results: relationship to heme pathway defects and possible causes (with emphasis on toxic metals)

| Abnormal test result ^a | Heme pathway defect ^b | Possible environmental cause ^c |
|---|---|---|
| Uroporphyrin and 7-carboxyporphyrin (sometimes) | Uroporphyrinogen decarboxylase | Arsenic [2] |
| | | Certain organic chemicals |
| 5-Carboxyporphyrin and coproporphyrin, | Uroporphyrinogen decarboxylase | Mercury [5] |
| 6-Carboxyporphyrin (sometimes) | Coproporphyrinogen oxidase | Certain organic chemicals |
| Precoproporphyrin ^d (almost always accompanied by elevated coproporphyrin III) | Uroporphyrinogen decarboxylase (possibly) | Mercury [5] |
| Coproporphyrin III, coproporphyrin I (sometimes) | Coproporphyrinogen oxidase | Lead or mercury [2] |
| | | Certain organic chemicals |
| Coproporphyrin I:coproporphyrin III ratio >1 | Hepatobiliary dysfunction [3] | Arsenic |
| | PBG deaminase | |

^a Reference ranges vary depending upon the laboratory doing the analysis. The following reference range (in units of nanomoles/24 h) was set to accentuate sensitivity (i.e. more patients with true porphyrinuria being detected at the risk of an increased false-positive rate). Multiplication factors to convert values to micrograms/24 h are shown in parentheses: uroporphyrin, 41 (0.830); 7-carboxyporphyrin, 14 (0.787); 6-carboxyporphyrin, 6 (0.743); 5-carboxyporphyrin, 5 (0.699); coproporphyrin I, 40 (0.654); coproporphyrin III, 79 (0.654). The reference range for the particular laboratory conducting the analysis should be used.

^b Inherited disorders in the enzymes of heme biosynthesis are relatively rare, but such a possibility should be considered if urinary porphyrins are greatly elevated. Please consult a specialist in inherited disorders if such a disorder is suspected.

^c When evaluating urinary porphyrin results to arrive at a diagnosis of metal or chemical toxicity, the following should be ruled out: use of ethanol, estrogens, oral contraceptives, antibiotics, sedatives, analgesics, dietary brewer's yeast; also rule out pregnancy, liver disease, malignancies, hematologic diseases such as pernicious or iron deficiency anemias. See [Table 30.5](#) for a more complete list.

^d The detection of precoproporphyrin is specifically diagnostic for mercury toxicity (see Woods et al [5]).

CONCLUSION

Use of porphyrin tests as biomarkers of chemical toxicity is reasonable in combination with other laboratory tests (e.g. hair analysis in cases of suspected metal toxicity). The clinician should realize that there are many conditions unrelated to primary or toxicant-induced porphyria that can cause porphyrinuria.^[12] When considering a urinary porphyrin result, the clinician should be mindful that the distribution of normal urinary porphyrin values, representing healthy individuals, overlaps significantly with values representing those who have suffered from porphyria at one time or another.

Any patients testing positive on the urinary porphyrins test should be followed up with more specific testing for a differential diagnosis. Tests that assay toxic metals directly in biological samples (i.e. blood, urine and hair) are essential for confirming whether the toxicity symptoms are caused by a metal. Identification of toxic organic chemicals by laboratory methods is also possible. Ruling out porphyria as the primary cause of porphyria-like symptoms requires tests for porphyrinogenic enzyme activities (e.g. uroporphyrinogen decarboxylase), as well as tests for blood, fecal and urine porphobilinogen (PBG) and delta-aminolevulinic acid (ALA).

Chapter 31 - Urine indican test (Obermeyer test)

Dirk Wm Powell ND

INTRODUCTION

The essential amino acid tryptophan is converted to indole by intestinal bacterial cleavage of the tryptophan side chain. Following absorption, indole is converted to 3-hydroxy indole (indoxyl or indican) in the liver, where it is then conjugated with potassium sulfate or glucuronic acid. It is then transported through the blood to the kidneys for excretion.

CLINICAL APPLICATION

As most of the endogenous indoles have a side chain which prevents cleavage and are instead metabolized to skatole, the production of indicans (indoxyl potassium sulfate and indoxyl glucuronate) reflects bacterial activity in the small and large intestines. [Table 31.1](#) lists conditions in which increased levels are found. Elevated levels are considered by natural health care doctors as an indicator of intestinal toxemia and overgrowth of anaerobic bacteria.

PROCEDURE

Detection of indicans depends upon its decomposition to indoxyl and subsequent oxidation to indigo blue. It is then concentrated into a layer of chloroform for easier measurement.

TABLE 31-1 -- Conditions with elevated levels of urinary indican^[1] ^[2] ^[3] ^[4]

- Inflammatory bowel disease
- Celiac disease
- Hypochlorhydria
- Gastric ulcer

- Biliary and intestinal obstruction

- Jejunal diverticulosis

- Scleroderma

- Postgastrectomy

- Hartnup's disease

- Pancreatic insufficiency

- Diminished peristalsis

- Blue diaper syndrome

246

Method

1. Put 5 ml of fresh urine in a test tube.
2. Add 5 ml of Obermeyer reagent.
3. Mix.
4. Add 2 ml of chloroform and invert several times.
5. Allow the chloroform to settle and observe.
6. The results are then rated by the color present in the chloroform layer.

Reagents

- Obermeyer reagent – dissolve 0.8 g ferric chloride in 100 ml concentrated HCl (*caution: caustic*)
- Chloroform (*caution: volatile, keep tightly capped*).

Results

- Urine color: 0 (normal)
- Light blue: +1
- Blue: +2
- Violet: +3
- Jet black: +4

INTERPRETATION

A positive test may indicate one of the diseases listed in [Table 31.1](#) , hypochlorhydria, bacterial overgrowth in the small intestine, malabsorption of protein, or simply a high protein intake. The latter indication could be eliminated by the institution of a consistent dietary regime (moderate protein intake) for 2 days prior to testing.

False-negatives occur when formalin, methamine, or azulfidine are present.^[2] Indigo red may form occasionally from slow oxidation. The presence of iodine, salicylic acid, methylene blue or thymol will cause a violet color, which can be removed by the addition of a crystal of sodium thiosulfate. Bile pigments interfere with the reaction, but can be removed by shaking the urine with barium chloride and filtering.

Chapter 32 - Zinc status assessment

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

Zinc serves as the mineral cofactor in over 70 metalloenzymes. Severe zinc deficiency is manifested by bullous-pustular dermatitis, diarrhea, alopecia, mental disturbances, and recurrent infections as a result of cell-mediated disorders, while chronic zinc toxicity is characterized by copper deficiency.^[1] Acute toxicity is quite rare, as the ingestion of amounts large enough to cause toxicity symptoms (2 g/kg body weight) will usually provoke vomiting. The area between severe deficiency and toxicity is termed the gray area of nutrition; somewhere between these two states lies a point of optimum zinc nutriture. In the USA, marginal zinc deficiency is widespread, particularly in the elderly.^[2] [Table 32.1](#) lists, alphabetically, clinical indications for zinc assessment, while [Table 32.2](#) lists conditions predisposing to zinc deficiency.

ASSESSMENT OF ZINC STATUS

No “gold standard” yet exists for the assessment of zinc status. The following are functional and laboratory methodologies, each with strengths and weaknesses.

Functional tests of zinc status

Physical signs of zinc deficiency

Some physical findings that appear to correlate with low zinc status include poor wound healing, alopecia, skin disorders (e.g. acne, atopic dermatitis, and psoriasis), hypogeusia, hyposmia, poor dark adaptation, growth retardation, hypogonadism, stomatitis, a white coating on the tongue and buccal mucosa, and marked halitosis.^[1] ^[4]

It has also been reported that white spots on the fingernails reflect zinc status.^[5] This may have some significance, as poor wound healing due to a zinc deficiency secondary

to trauma to the nail bed may be responsible for the lesions in some subjects. Clinical judgment is

TABLE 32-1 -- Clinical indications for zinc assessment

-
- Acne

 - Alcohol abuse

 - Alopecia

 - Amenorrhea

 - Amnesia

 - Anorexia

 - Apathy

 - Brittle nails

 - Chronic fatigue

 - Chronic and/or severe infections

 - Connective tissue disease

 - Dandruff and alopecia

 - Delayed sexual maturation

 - Delayed wound healing

- Rheumatoid arthritis

- Sleep and behavioral disturbances

- White spots on nails

- Wound healing impairment

required to ascertain the significance of these lesions in a particular patient, i.e. do the lesions correspond to the level of trauma to the nail beds?

Two in-office tests that may indicate functional zinc deficiency are the zinc taste test (described below) and the dark adaptation response (described in [Ch. 26](#)).

Zinc taste test

Since loss of taste acuity is a well-documented sign of zinc deficiency, measurement of taste acuity is a useful functional test of zinc status. The taste solution is made by dissolving 1 g zinc sulfate heptahydrate ($\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$) in 1 L of distilled water. Responses to tasting 5 ml of this solution normally fall into one of the following four categories:

1. No specific taste or other sensation is noticed after the solution has been kept in the mouth for 10 seconds.
2. No immediate taste is noticed, but after a few seconds a slight taste variously described as “dry”, “mineral”, “furry”, or “sweet” develops.
3. A definite, though not strongly unpleasant, taste is noted almost immediately and tends to intensify with time.
4. A strong and unpleasant taste is noted almost immediately.

TABLE 32-2 -- Conditions predisposing to zinc deficiency, decreased intake, and/or decreased utilization

Decreased intake

- Anorexia nervosa

- Fad diets

- Protein deficiency

- Vegetarianism

- Alcoholic cirrhosis
- Old age
- Acute infections/inflammation
- Low socioeconomic status

- Alcoholism

Increased body losses

- Starvation
- Burns
- Post-trauma

Decreased absorption

- Diabetes mellitus
- High phytate diet
- Alcoholism
- High dietary iron:zinc ratio
- Chelating agents
- Acrodermatitis enteropathica
- Dialysis
- Achlorhydria/hypochlorhydria
- Hepatic disease
- Celiac disease
- Inflammatory bowel disease
- Diarrhea
- Intestinal resection
- Chronic blood loss
- Short bowel syndrome
- Pancreatic insufficiency

Increased requirement

- Old age
- Pregnancy and lactation
- Oral contraceptive use
- Growth spurts and puberty

A reaction falling into categories 1 or 2 suggests a zinc deficiency and a favorable response to zinc supplementation.^[6]

Laboratory determination of zinc status

A large number of laboratory analyses for determining zinc status have been developed, as listed in [Table 32.3](#). Unfortunately, none has been determined to be the definitive methodology. A few of the procedures are discussed in detail below.

Plasma and serum zinc

Although these are perhaps the most widely used methods of zinc assessment, they are a poor measure of total body zinc status.^[1] ^[7] As zinc is bound primarily to albumin, changes in albumin concentrations will have a significant impact on zinc levels.^[7] Total circulating zinc concentration reflects both serum albumin concentrations and the affinity of albumin for zinc, rather than zinc status.^[7] Zinc's main functions are intracellular; therefore, like other minerals, serum and plasma levels do not reflect total body stores.

TABLE 32-3 -- Laboratory methods used in assessing zinc status

-
- Dark adaptation test

 - Erythrocyte carbonic anhydrase

 - Fingernail zinc content

 - Hair zinc content

 - Lymphoblast transformation

 - Macrophage chemotaxis

 - Neutrophil chemotaxis

 - Plasma zinc concentration

 - Radioisotope zinc turnover

 - RBC zinc concentration

 - Salivary zinc concentration

 - Serum alkaline phosphatase

 - Serum retinol binding protein concentration

 - Serum ribonuclease activity

 - Serum zinc concentration

- Sperm count

- Sweat zinc concentration and pool size

- WBC zinc concentration

- Zinc balance

- Zinc repletion test

- Zinc tolerance test

Plasma copper:zinc ratios have been used by some investigators as a clinical assessment aid in a variety of conditions.^[4] This appears to be a more promising diagnostic aid, as it reflects the level of metallothionein uptake of zinc.^[8] This protein is responsible for maintaining copper and zinc homeostasis. In inflammation or infection, macrophages release leukocyte endogenous mediator (LEM), which stimulates hepatic zinc uptake by metallothionein and ceruloplasmin.^[9] Therefore, a high copper:zinc ratio – greater than 2 – is likely to be a result of an inflammatory process, either acute or chronic. Normal serum and plasma levels for zinc are 80–120 µg/dl. This ratio is commonly found in patients with psychiatric problems, which may suggest that a chronic inflammatory condition is taking place, rather than an overload of dietary copper or decreased intake of zinc.

Hair zinc

Hair mineral analysis has been a popular screening method for mineral deficiencies.^[10] It has some procedural problems, and reference ranges are still being developed for all ages and hair colors (for further discussion, see [Ch. 17](#)). Low hair zinc content has been shown to be a good indicator of mild to moderate zinc deficiency.^{[1] [7] [10] [11]} However, in severe zinc deficiency, hair levels will be elevated as a result of concentration due to impaired hair growth.^{[7] [10]} A normal hair zinc level does not necessarily assure adequate tissue stores.^[10] In addition, standard washing procedures are unable to remove exogenous zinc without removing endogenous zinc, making analysis unreliable where external contamination may have occurred. In summary, while low hair zinc levels may be indicative of low zinc status, further testing is required to confirm a clinical diagnosis.^{[7] [10]}

Serum alkaline phosphatase

The enzyme alkaline phosphatase (AP) is a zinc-dependent enzyme that is sensitive to dietary levels.^[1] Although neutrophil AP is more reflective of zinc status, serum levels of AP are frequently assayed on routine chemistry screens.^{[1] [12]} Individuals with zinc deficiency will have low circulating levels of AP.^{[1] [7] [12]} In one study, the ratio of maximal post-treatment to pretreatment serum activity (AP ratio) correlated inversely with pretreatment serum zinc level in subjects who received a zinc-restricted diet initially, and who were later supplemented with zinc.^[12] It was suggested that a serial determination of serum AP and calculation of the AP ratio during a trial of zinc therapy may provide biochemical confirmation of the adequacy of zinc replacement and may be useful in

detection of mild zinc deficiency.^[12] It should be kept in mind that AP levels will be increased in liver and bone disease and by many drugs, and decreased in hypothyroidism, pernicious anemia, and vitamin D excess.^[13]

Zinc tolerance test (ZTT)

An oral loading dose of 220 mg zinc sulfate is used to determine zinc absorption. The normal patient usually shows a two- to threefold increase in plasma zinc concentrations 2 hours after supplementation.^[7] ^[14] This does not reflect zinc status as much as it determines the integrity of the small intestine mucosa and pancreatic sufficiency.^[7] ^[14] ^[15]

The zinc tolerance test has been used to assess intestinal absorption of zinc in patients treated for obesity by jejunal bypass, hepatic cirrhosis, Crohn's disease, pancreatic insufficiency, celiac disease, and dermatitis herpetiformis.^[14] The procedure for the test is as follows:

1. A gelatin capsule containing 110 mg zinc sulfate heptahydrate (25 mg elemental zinc) is given to the subject following an overnight fast.
2. Samples are taken by venipuncture into trace metal-free heparinized tubes before administration of the zinc and at half-hour intervals for 3 hours.
3. The plasma is separated and stored until analysis.
4. Values are plotted as an increase above baseline, i.e. the initial reading is 0. The maximum reading is usually at 2 hours.

Normal readings for the test at various times are as follows:

- 0.5 hour – 40 ug/dl
- 1.0 hour – 65 ug/dl
- 1.5 hours – 80 ug/dl
- 2.0 hours – 90 ug/dl
- 2.5 hours – 70 ug/dl
- 3.0 hours – 65 ug/dl.

Patients with pancreatic insufficiency display an abnormal ZTT when zinc sulfate is used, but when zinc picolenate is used zinc absorption normalizes.^[15] Picolinic acid is a metabolite of tryptophan and is believed to be the zinc-binding ligand secreted by the pancreas that facilitates transportation of zinc into the intestinal mucosa. If there is an abnormal ZTT using zinc sulfate, the test should be repeated using zinc picolenate to determine if pancreatic insufficiency contributes to the impaired ZTT.^[15]

White and red cell zinc

The use of leukocytes, in particular the neutrophil, for assessing mineral status is gaining increasing support in the literature. The leukocyte zinc level appears to be the most reliable and reflective way of determining zinc status.^[11] ^[7] This test, however, is

currently not widely available. Lymphocyte zinc also appears to be a more reliable assessment methodology than plasma, urine, or hair.^[16]

Red cell zinc, while sometimes low in zinc deficiency, is unreliable, as RBC zinc levels are greatly altered by factors which affect zinc partitioning across cell membranes.^[7] A more promising, newly defined erythrocyte ⁶⁵Zn uptake test will soon be clinically available. This methodology shows a much lower variance and is able to detect zinc deficiency more accurately in children suffering from such disorders as acrodermatitis enteropathica, diarrhea, chronic infections and growth retardation.^[17] Reference standards for various population groups are now being established.

Another promising assessment is the alkaline phosphatase activity in erythrocyte membrane. In a nicely designed, controlled zinc depletion study, 15 normal men were fed a low-Zn diet with high phytates for 7 weeks, followed by a 2 week repletion period with 30 mg/day of supplemental zinc. While zinc concentrations in neutrophils, platelets, erythrocytes and erythrocyte membranes, and activity of alkaline phosphatase did not respond to the changes in zinc status, erythrocyte alkaline phosphatase showed significant and consistent changes.^[18]

Sweat zinc

Sweat zinc appears to be a useful and sensitive index of zinc status. This simple, non-invasive test is more reliable than both hair and serum zinc, and may become clinically available.^[7] ^[19]

SUMMARY

Several methods of assessing zinc status have been presented. Each has some strong points and also some limitations. At this time the authors recommend the plasma copper:zinc ratio and neutrophil zinc test as the most accurate of those available. Serum zinc concentration is not considered useful, and hair zinc is useful only if the levels are low.

Chapter 33 - Acupuncture

M. Harrison Nolting ND LAc

INTRODUCTION

Around 210 AD, Zhang Ji, a highly revered Chinese doctor referred to as the “sage of medicine” in China’s long history,^[1] might have been found teaching students in the grottos of legendary Qing Chang Mountain outside of Chengdu, Sichuan Province, China. The philosophy was largely Taoist and Naturalist as well as quite practical, with roots probably linked to India. Out of these beginnings a distinctively Chinese system would arise that is referred to as traditional Chinese medicine and Oriental medicine. The science of classical China is an ancient science filled with myth, superstition, and unlimited wisdom – a wisdom that provided many medical “discoveries” such as the circulation of blood, circadian rhythms, thyroid hormone use, deficiency diseases, and a multitude of others long before their “rediscovery” in the West.^[2] The basic question – How does acupuncture work? – awaits the scrutiny of the West. For thousands of Western-trained acupuncturists, acupuncture is a comprehensive system of medicine based in classical Chinese philosophy. Yin, Yang, Qi, Wu Hsing, Zang Fu – this is the language of traditional Chinese Medicine. While acupuncture is defined in many arenas as a comprehensive system of medicine, in others it is a modality, a treatment used alongside other practices. The needle defines acupuncture visually. For many acupuncturists, their practice is far more than needles, including moxibustion, cupping, shu sha (also called gua sha), herbs, tuina, and qigong. In order to properly respect and understand the field of acupuncture, a broad look is necessary.

HISTORY

The principles and theory underlying the techniques of acupuncture, so-called acuology, date to the ancient times of the great Yellow Emperor, Huangdi (~2698–2598 BC).^[3] ^[4] Huangdi has held a place of great legend and esteem in Chinese history. The question of whether

this ruler actually authored the great medical work entitled *Huangdi Nei Jing* (*The Yellow Emperor's Inner Cannon*) will perhaps always remain a mystery.^[5] Nevertheless it is attributed to the reign of Huangdi and is said to highlight questions and answers between the emperor and his ministers, chief among them a physician named Qi Bo. Huangdi discoursed on medicine, health, lifestyle, nutrition, and religious tenets of the times. He is ascribed such a high place in Chinese history that many Chinese consider themselves descendants. Huangdi is viewed as the “symbol of vital spirit of Chinese civilization”.^[6] Probably the most important text in the history of Chinese medicine, often “overshadowed” by the “reputation and authority of the original classic”, the *Huangdi Nei Jing*, was the *Nan Jing* (*The Classic of Difficult Issues*), thought to have been compiled around the first or second century AD. According to Unschuld,^[7] the *Nan Jing* was “a significant and innovative work that was the apex and conclusion of the developmental phase of the conceptual system unknown as the medicine of systematic correspondence”. He goes on to describe the importance of the *Nan Jing* saying “the Nan-ching (jing in pinyin romanization) is comprehensive ... discusses the origins and the nature of illness; outlines a system of therapeutic needling; and develops – in great detail – an innovative approach to diagnosis”. The *Nei Jing* predates the historically available writings of ancient China, it delves strongly into “demonological medicine and religious healing”, while the *Nan Jing* is homogeneous and highly systemized, basically intact and well focused.^[7]

In terms of acupuncture specifically, Unschuld^[8] cites no reliable references prior to 90 BC appearing in Chinese literature. Ancient works as a whole were written on bamboo strips and silk. These went through countless hands and copies, creating a body of written work that contained numerous errors and omissions. It was not until 26 BC that the Chinese government organized medical officials to collate and revise the royal collection of medical works preserved at the Mifu Natnal Royal Library.^[9] The earliest recorded physician reputed to be versed in pulse-taking and acupuncture was Bian Que (~500 BC). Several medical works ascribed to him have all been lost.^[4] Su Ma Qian, historian of the Han dynasty (206 BC–220 AD), writing in the Historical Note about 100 BC, wrote a chapter on the biography of Bian Que. This was the first reliable reference documenting acupuncture and moxibustion in Chinese.^[10] He told many stories of Que's ability to treat with acupuncture.^[11] Zhang Ji (AD 150–219) referred to as the sage of Chinese medicine authored the classic work *Shanghanlun*.^[12] Statues of the legendary Zhong Ji are common on many of the TCM college campuses in mainland China today. Another of the famous ancient masters of Chinese medicine was Hua Tuo (?–208 AD), a surgeon and practitioner of an eclectic range of therapies including acupuncture and hydrotherapy, and originator of the therapeutice exercises called the “five animals”.^[4]

Huangfu Mi (214–282 AD), a famous acupuncturist, compiled *Zhen Jiu Jia Yi Jing* (*A Classic of Acupuncture and Moxibustion*), first monograph on acupuncture in history, around 282 AD. These 12 volumes covered all aspects of acupuncture practice and theory and are considered a monumental work.^[13]

The first usage of the English term, acupuncture, meaning needle puncture, is attributed to a Dutch physician, Rhyne, who visited Japan sometime in early 17th century.^[14] A Dr Berlioz in Paris, at the Paris Medical School, was attributed the first recorded use of acupuncture in the West. John Churchill, in 1821, was the first British acupuncturist publishing works highlighting treatment of tympany and rheumatism. Acupuncture is also mentioned in the *Lancet's* first edition in 1823. Dr Elliotson published results of 42 cases of acupuncture treatment of rheumatism, concluding that acupuncture was effective as a treatment.^[14]

In 1849, the Gold Rush in California brought about a large immigration of Chinese into the western America. Heading for “Gold Mountain”, they brought all elements of their culture including their traditional medicine with its acupuncture and Chinese herbs. Writing in his book, *Chinese Medicine on the Golden Mountain*, Paul Buell states:^[15]

... [there] was an acute shortage of any form of medical care in Western America where most Chinese settled. ... Well practiced Chinese medicine was often superior to contemporary Western practice. ... Western medicine did not gain any real advantage over well practiced Chinese medicine until the coming of any ‘wonder drugs’ in the 1930s, and in some respects, as in many chronic ailments, (traditional) Chinese medicine is still superior.

In 1892, William Osler wrote, in his *Principles and Practice of Medicine*, about the use of acupuncture in the treatment of sciatica.^[16]

FUNDAMENTALS OF ACUPUNCTURE

Acupuncture is a technique involving the insertion of fine needles into the skin at select points or points of tenderness. As discussed earlier, the theory, or acuology that surrounds the practice dates back as much as 4,000–5,000 years. For many contemporary practitioners, their practices are defined by the theory of the fundamental principles: five elements, Yin, Yang, Qi, and Zang Fu. For still others these ancient theories remain just that – ancient and removed from modern science – and they practice acupuncture based on recent theories of mechanism and anecdotal evidence.^[17]

Yin and Yang, the base upon which all diagnosis and treatment in TCM arises

In perfect balance, in optimal health, Yin and Yang are

harmonious, the ebb and flow of the tides, day and night. The theory when translated can be set in quite poetic terms. A deficiency of liver and kidney Yin, for example, might result in clinical symptoms such as dizziness, vertigo, insomnia, dry throat, and lumbago, whereas a deficiency of spleen and kidney Yang may manifest clinically as cold limbs, lumbago, diarrhea, and scanty urine. Excess is usually seen as a relative state due to the deficiency of the other, as in deficient Yin resulting in an apparent excess of Yang.

Qi

Qi is the energy and potential energy that courses throughout the organism and defines what we call life. The lack of proper Qi flow in the system results in numerous maladies. Qi stagnation is often manifested as pain. Rebellious Qi manifests as belching, burping, and vomiting, a reversal of the normal downward movement of Qi digestively. There is also the potential energy, the Qi that occupies the rock, the board, this desk, that potential energy that lies in the way of being expressed. And then there is the Qi that waves through space connecting us to the web of the universe – a concept that begins to sound like theories in quantum physics.

Zang Fu

The Zang Fu are the Chinese organs, five solid Yin, and six hollow Yang. In the West, we use the English names for the organs – liver, heart, spleen, kidneys, and lungs – but depending solely on the Western name without a thorough understanding of the traditional Chinese meaning will lead to much confusion clinically. A complete and clinically sound synthesis of the Western biomedical understanding with the traditional Chinese understanding has not occurred to date. For example, the liver as we know it in the West is defined according to its anatomical structure and function, i.e. it is a large glandular organ that secretes bile and metabolizes blood-borne compounds. The Chinese gan stores blood and Qi and is responsible for the smooth transmission of Qi and blood throughout the body. Moreover, it has a chief role in emotions; an unbalanced gan (liver) results in anger, high blood pressure, and a general state of agitation. The liver in the Chinese sense is much more a functional system with many body-wide interactions. The hollow organs are the gall bladder, large and small intestines, triple burner, urinary bladder, and stomach. The triple burner is a good example of how different the Western and Chinese views are, since this has no meaning in the West. In the Zang Fu system, the triple burner corresponds to the thoracic and abdominal regions including all of the organs within. It has a specific function that distinguishes it as a fu organ, namely to transport water.

The five elements

The five elements (also called the five phases or in Chinese wu xing) are fire, metal, wood, earth, and water. The correspondences between these elements have become a

method of diagnosing and treating patients. In the West, a school of thought following the teachings of Dr Worsley in England has evolved which has grown into a worldwide system of schools and practitioners associated with the so-called “law of five elements”. There is a stark contrast between this system of acupuncture practice and the TCM systems.

Points and meridians

The other key aspect of the fundamentals of acupuncture is, of course, the theory of the channels. There are the basic 365 mapped acupuncture points along the 12 major and eight extra channels as well as over 1,000 extra points and special use points, including the microsystems such as the hand, ear, and scalp, all with very specialized functions. The so-called ashi points, or pain points, can literally be located anywhere on the body where there is a pain locus. Qi and blood flow throughout the channels and this is where the proper manipulation of the needle is critical in properly moving this flow.

RESEARCH

Western medical practice has grown within a system of great scrutiny and self-analysis. A massive research culture spins off studies by the thousands. The double-blinded, placebo-controlled trial has become the hallmark of the “appropriately conducted research trial”. Acupuncture evolved in a completely different culture, that of China, where, ironically, as we were “discovering” the Chinese traditional system of acupuncture, not so many years previously the Chinese began a wholesale discovery of traditional Western medicine. Acupuncture, and indeed all that is traditional Chinese medicine, has been extensively researched in China.

Large research academies, the largest being the China Academy of Traditional Chinese Medicine in Beijing, and various universities and schools of TCM, have created a huge research culture in China. While there is considerable emphasis on herbal research, there is still quite a lot of research examining the other areas of TCM. But what does this Chinese research culture mean for Western medicine? This is a big question that is being sorted out in a number of ways today. The issues at hand are:

- poor translations
 - a lack of studies utilizing “approved” Western research standards
-

- terminology problems
- major design problems
- cultural assumptions coloring the studies
- Western research arrogance.

To date, very few cross-cultural studies have been undertaken and we are really just

making headway into reproducing studies with a Western perspective.

Acupuncture research is now occurring in many countries outside of China. Most notable since 1991 are the efforts by the Office of Alternative Medicine (OAM) at the National Institutes of Health (NIH) to generate research. Calls for research are increasing and a growing number of institutions are receiving grants. A positive sign of progress in this arena was the 1997 Consensus Conference on Acupuncture at the NIH.

China is the country where, since 1950, much of the research has been performed, from basic research to clinical trials, animal studies, and others, and this continues to be the case. In America, clinical research, outcome studies, are increasing but still are relatively few. Basic research is all but non-existent. An important step forward in documentation of the body of clinical outcomes-based research that exists in English can be found in a book titled *Acupuncture Efficacy*. ^[18]

The basic question posed in the West remains unanswered from a Western perspective: “How does acupuncture work?”

Chapter 34 - Ayurveda: the science of life and mother of the healing arts

Virender Sodhi MD(Ayurveda) ND

INTRODUCTION

Ayurveda is one of the most ancient systems of medicine known today. The origins of this science of life (*Ayu* – life, and *Veda* – knowledge), though difficult to pinpoint, have been placed by scholars of ancient Indian Ayurvedic literature at somewhere around 6000 BC.^[1]

Ayurveda is a holistic science of balance and health. Disease is seen as an imbalance, and its treatment involves diverse strategies to restore optimal function and balance. Using dietary alterations, yoga, exercise, complex, integrated herbal formulas, and elaborate surgical techniques, the Ayurvedic physician treats the whole person, removing disease completely by ending the imbalance that created it.

HISTORY

In ancient India, it was the custom for a teacher's instruction to be recorded by his students, who would then repeat the information orally to their own disciples. Thus, according to the different interpretations given by the various disciples of Ayurveda, a number of treatises came to be written. Although specific instructions differed, the basic principles remained similar.

Ayurvedic teachings were orally transmitted for thousands of years, and then written down in melodious Sanskrit poetry. The contents of a number of Sanskrit verses, or *shlokas*, though written many centuries ago, still sound a note of familiarity in today's scientific environment. Ayurveda, in its first recorded form (in *vedas*, the world's oldest literature), is specifically called *Atharveda*.

The development of Ayurvedic medicine

Hindu legend holds that, seeing the suffering of human beings, Lord Brahma, the god of creation, elaborated ways to ease that suffering to Daksha, who, in turn, taught them to the Ashwin twins. [Figure 34.1](#) presents the chronology of Ayurveda's development.

258

Figure 34-1 The chronology of Ayurveda.

Dhanvantari and Bhardwaj separately developed the surgical and medical aspects of Ayurveda around the 9th century BC. Their students recorded these principles in great detail in compendia which are called *Samhitas*.

The *Sushruta Samhita*, one of the most widely accepted Ayurvedic texts, emphasizes the surgical aspects of therapy. Its author, Sushruta, is considered the father of surgery (particularly of plastic and reconstructive surgery). The medical teachings of Charak were a synthesis of earlier work. His material has become a classic text of the non-surgical medical wisdom of Ayurveda. Successive generations have modified his work, the *Samhita*.

THE MAJOR SCHOOLS AND SPECIALTIES

School of physicians (Atreya sampradaya)

Charak wrote a complete text on Ayurvedic medicine in which he revised the work of Agnivesh. Charak's text described *Tridosh* physiology (*Vat*, *Pit*, and *Kaph*), seven *Dhatu*s (tissues), and three *Malas* (excretions). Charak also presented in his text the pathophysiology and treatment of diseases, human constitution (*Pakriti*), classifications and preparations of drugs, diet, "right conduct", medical ethics, and many other aspects of medicine.

School of surgeons (Dhanvantri sampradaya)

Sushruta wrote the first comprehensive works on surgery. These were later revised by

Nagarjuna in the 2nd century AD. Major subjects in his texts were:

- injections
- pre-operative care
- postoperative care
- suturing
- asepsis
- sterilization
- operation theaters
- hospitals.

He described 141 types of instruments and listed 40 types of surgeries, and surgical techniques for treating cataracts, hemorrhoids, hernias, and bone problems, for cosmetic and plastic purposes, and for the removal of renal and gallstones.

Branches of Ayurveda

There are eight specialties or branches in Ayurveda. They comprise a system developed to prevent and cure disease, as well as achieving and maintaining excellent health. The branches are listed in [Table 34.1](#) .

PHILOSOPHY

Ayurvedic philosophy is based on the *Samkhya* philosophy of creation. It has influenced major strains of philosophy in both the East and the West. The word *Samkhya* is derived from the Sanskrit *Sat* (truth) and *Khya* (to know). The Rishi Kapila (*Rishi* means realized beings or seers of truth) realized the *Samkhya* philosophy of creation. They perceived:

- the close relationship between humans and the universe (that humans are a microcosm, a universe)

259

within themselves, while the external environment is the macrocosm)

- that cosmic energy is manifest in all living and non-living things
- the 24 elements of the universe
- that the source of all existence is cosmic consciousness, manifest as male (*Shiva*, *Purusha*) and female (*Shakti*, *Prakriti*) energy.

TABLE 34-1 -- Specialties in Ayurveda

| | |
|---------------|--------------------------------------|
| Shalya Tantra | General surgery |
| Shalkya | Ophthalmology and otorhiolaryngology |

| | |
|---------------|------------------------------------|
| Kaya Chikitsa | Medicine |
| Bhutvidya | Psychiatry |
| Kumar-Bhritya | Pediatrics, obstetrics, gynecology |
| Agada Tantra | Toxicology and jurisprudence |
| Rasayana | Geriatrics |
| Vajikaran | Fertility and sterility |

Purusha is formless, colorless, and beyond attribute. It is choiceless, does not take an active part in the manifestation of the universe, and has passive awareness. *Prakriti* has form, color, awareness and choice. *Prakriti* creates all the forms of the universe and has three attributes (*Gunas*): *Satva* (essence), *Rajas* (movement), and *Tamas* (inertia). It is also represented by Brahma (the god of creation), Vishnu (god of protection), and Mahesh (god of destruction), which together comprise a cycle active in this universe.

In *Pakriti*, the three attributes are in balance. Whenever this balance is disturbed, they interact to bring about the evolution of the universe, yielding the cosmic vibration of *Aum*.

The cosmic intellect (the *Mahad*) manifests itself as ego (*Ahamkar*) which, through the help of *Satva*, manifests the five senses and five motor organs which together constitute the “organic universe”. Ego further manifests into the five basic elements (space, air, fire, water, and earth) which, under the influence of *Tamas*, create the “inorganic universe”.

Rajas is the active vital force which moves both the organic and inorganic universes to *Satva* and *Tamas*, respectively. *Satva* and *Tamas* are inactive, potential energies which need the active kinetic protective force of *Rajas*. *Satva* is a creative potential (*Brahma*), *Rajas* is a kinetic protective force (*Vishnu*), and *Tamas* is a potentially destructive force (*Mahesh*). These three – *rahma*, *Vishnu*, and *Mahesh* – are constantly operating in the universe.

Five basic elements and the universe (Panchbhuta philosophy)

Ayurvedic knowledge is based on the concept of the five basic elements: ether (space), air, fire, water, and earth. The Rishis perceived that consciousness consists of these five basic elements or principles. At the beginning of the world, consciousness was without form, existing as the subtle vibration of the cosmic “soundless” sound *Aum*.

Within these vibrations appeared the element ether. Ether started to move, creating air. The movement of ether also produced friction and through friction, generated heat, then fire. From the heat of the fire, ethereal elements dissolved and liquified into water. Water then solidified to form molecules of earth. Thus was all matter born from the five

elements. These five elements exist in subatomic forms.

Humans are a microcosm of nature and, as such, themselves comprise the five basic elements:

- Ether is represented in the hollow spaces of the mouth, nose, gastrointestinal tract, abdomen, thorax, respiratory apparatus, capillaries, lymphatics, tissues, and cells.
- Air exists as movement – as pulsation, expansion, or contraction of the various organs. Bodily movement is controlled by the central nervous system, itself governed by air.
- Fire is the source of heat and light somatically present as metabolism, gray matter, vision, temperature, digestion, and intelligence.
- Water exists as secretions of the salivary and digestive glands and the mucous membranes, and within plasma and cytoplasm.
- Earth is the solid structures, i.e. the bones, cartilage, nails, muscles, tendons, skin, and hair.

Five elements and the senses

The five elements also connect with the five senses – ether-hearing, air-touch, fire-vision, water-taste, and earth-smell – and they are present in certain physiological functions. Expressing the functions of the sensory organs are five actions (see [Table 34.2](#)). In this manner, the elements are directly related to humans' abilities both to perceive the external environment in which they live and to respond to it:

- Ether is the medium through which sound travels. The ear is the organ of hearing, expressing its action through the organ of speech, which creates meaningful sound.
- Air is related to skin and the sense of touch. Its organ of action is the hand, which is especially sensitive, and is the organ of the actions of holding, giving, and receiving.
- Fire produces light, heat, and color, and is thus related to vision and direction. Its organ is the eye.
- Water relates to the organ of taste. The tongue is also related to the action of the genitals, the penis, and clitoris. In Ayurveda, the penis and clitoris are called the lower tongues. By controlling the upper tongue, one naturally controls the lower tongue.
- The earth element relates to the sense of smell, and the nose is its organ.

TABLE 34-2 -- The five elements and the senses

| Element | Sense | Organ | Action | Vehicle of action |
|---------|---------|--------|----------------------------|-------------------|
| Ether | Hearing | Ear | Speech | Mouth |
| Air | Touch | Skin | Holding, giving, receiving | Hand |
| Fire | Vision | Eye | Walking | Feet |
| Water | Taste | Tongue | Procreation | Genitals |

PHYSIOLOGY

The five elements manifest within the body as the *Tridosha* (*Dosha* means protective or, when out of balance, disease-producing). The *Tridosha* are the three humors, or basic principles, known as *Vat*, *Pit*, and *Kaph*.

From the bodily combination of ether and air comes the bodily air principle, *Vat Dosha*. Likewise, fire and water combine as *Pit Dosha*, or fire principle; and earth and water produce the *Kaph Dosha*, or water principle.

These three control all biological, psychological, and physiopathological functions of the body, mind, and consciousness. They produce natural urges and individual tastes in food, flavor, and temperature. They govern the maintenance and destruction of bodily tissue and the elimination of waste products. They also are responsible for psychological phenomena, including the emotions of fear, anger, and greed, as well as the highest order of emotions: understanding, compassion, and love.

Properties of *Dosha*

Vat, *Pit* and *Kaph* control all human biological, psychological and physiopathological functions, and have subtle properties, as shown in [Table 34.3](#).

The *Doshas* increase by similar properties and are diminished by opposite properties. For example, *Vat* is dry, light and cold, so any food, medicine, lifestyle, or behavior which increases these qualities will increase *Vat* within the body. Conversely, oily, heavy, or hot factors will decrease *Vat*.

Functions of *Tridosha*

Each of the three humors has a specific action. *Vat* is the principle of movement, and may be called the bodily air principle, as opposed to the environmental air principle. *Vat* is a subtle energy governing all biological movement – breathing, blinking, muscle and joint movement, heartbeat, and all nerve and membrane contractions and expansions. In addition, it controls the psychological functions governing the emotions of fear and anxiety. *Vat* also controls pain, tremors, and spasms. Broadly

TABLE 34-3 -- Properties of *Dosha*

| <i>Vat</i> | <i>Pit</i> | <i>Kaph</i> |
|------------|------------|-------------|
| Dry | Oily | Oily |

| | | |
|------------|-------------|--------|
| Light | Light | Heavy |
| Cold | Hot | Cold |
| Rough | Liquid | Slimy |
| Subtle | Penetrating | Soft |
| Mobile | Mobile | Static |
| Clear | | Dense |
| Dispersing | | Slow |
| | Smells sour | |

speaking, the whole nervous system can be labeled as *Vat* function. The large intestine, pelvic cavity, bones, skin, ears, and thighs are the places of *Vat*. Any excess of *Vat* will accumulate in these areas.

Pit, or bodily fire, governs digestion, absorption, assimilation, nutrition, temperature, skin color, luster of the eye, intelligence, and understanding. It arouses anger, hate, and jealousy. The small intestine, stomach, blood, sweat glands, fat, eyes, and skin are the places of *Pit*; in fact all metabolism is governed by *Pit*.

Kaph, biological water, is the cement of the body, providing for physical structure. It is responsible for body resistance and biological strength. It lubricates the joints, provides moisture to skin, and promotes wound healing, strength, vigor, and stability. It supports memory, gives energy to the heart and lungs, and maintains immunity. *Kaph* is present within the throat, chest, head, sinuses, nose, mouth, stomach, joints, the cytoplasm, plasma, and liquid secretions. Psychologically, *Kaph* governs attachment, greed, long-standing envy, calmness, forgiveness, and love.

A balance of the *Dosha* is necessary for optimal health. Together, they govern all metabolic activities: anabolism (*Kaph*), catabolism (*Vat*), and metabolism (*Pit*). An excess of *Vat* results in an excess of catabolism, creating emaciation. When anabolism outstrips catabolism, there is an increase of growth and repair in the organs and tissues. Excessive *Pit* disturbs metabolism.

In childhood, *Kaph* elements, associated with growth, predominate. In adulthood, *Pit* is more apparent. As the body deteriorates in old age, *Vat* is most prominent.

Individual psychosomatic constitutions – *Prakriti*

Prakriti, a Sanskrit word composed of *pra* (before) and *akriti* (creativity), denotes the constitution of each individual as determined at conception. At the time of fertilization permutations of *Vat*, *Pit*, and *Kaph* determine the constitution of the new individual, with maleness or femaleness dominating other traits. These basic traits will also be shaped by other important factors, such as diet, lifestyle, behavior, emotions, seasons, etc.

As illustrated in [Table 34.4](#) , there can be up to seven different constitutions depending upon the permutation and combination of *Vat*, *Pit*, and *Kaph*. *Pakriti* is genetically

TABLE 34-4 -- The seven types of constitution

| |
|-----------------------|
| • <i>Vat</i> |
| • <i>Pit</i> |
| • <i>Kaph</i> |
| • <i>Vat-Pit</i> |
| • <i>Pit-Kaph</i> |
| • <i>Kaph-Vat</i> |
| • <i>Vat-Pit-Kaph</i> |

determined; the basic constitution, the combination of the three humors, remains unchanged throughout an individual's lifetime. The combination can, however, respond to environmental changes.

Life is considered a sacred path in Ayurveda, a ceaseless interaction between the internal (*Tridosha*) environment and the external environment, or the sum of cosmic forces. To counteract external change, an individual may create a balance in the internal forces by altering diet, lifestyle, and behavior. The characteristics of the corresponding psychosomatic constitutions are listed in [Table 34.5](#) .

TABLE 34-5 -- Psychosomatic constitutions (*Prakriti*)

| Characteristic | <i>Vat</i> | <i>Pit</i> | <i>Kaph</i> |
|-----------------------|---|---|--|
| Body frame | Tall or small, thin, ill-nourished, hard, dry, cold | Medium, many moles, well nourished, pimples patches of pigment, tender appearance | Stout, well-nourished big, oily, greasy, cold, beautiful |
| Skin | Dry, cracked, tough, broken, brownish, black | Soft, thin, yellow, red, pink | Greasy, soft, yellow, white |
| Body hair | Scanty, coarse, dry, brown | Moderate, soft, pink | Plentiful, smooth, greasy, black |

| | | | |
|----------------|--|---|--|
| Hair on head | Brown, scanty, coarse, curved, wavy, wrinkled | Pinkish, yellow, moderate, soft, baldness, premature greyness | Black, plentiful, firm, wavy, curved |
| Head | Small size | Moderate in size | Big and steady |
| Forehead | Small | Moderate with many folds | Big, broad |
| Eyebrows | Small, thin, unsteady | Moderate | Thick, plentiful |
| Eyelashes | Small, dry, firm | Small, thin | Big, greasy, firm |
| Eyes | Small, dry, thin, muddy brown, unsteady gaze, not pleasant-looking | Thin, yellow, pink coppery, quickly become inflamed, pleasant-looking | Big, white, pink, pleasant-looking, thick, fixed, greasy |
| Nose | Small, dry, firm | Medium | Thick, big, greasy |
| Mustaches | Small, coarse, dry, blackish | Soft, pink, moderate | Heavy, thick, shining, black |
| Lips | Thin, small, blackish, brownish, dry, unsteady | Moderate, red, pink | Thick, big, smooth, firm, greasy |
| Teeth and gums | Dry, small, rough | Moderate | Thick, greasy, moist, soft, pink |
| Tongue | Thin, dry, fissured, unsteady | Moderate, pink, reddish | Thick, big, smooth, moist |
| Palate | Dry, blue, black | Pink | Moist, white |
| Lower jaw | Thin, small, dry | Moderate | Thick, big |
| Shoulders | Thin, small, unsteady, dry | Moderate | Thick, big, firm |
| Chest | Thin, small, not well-built | Moderate | Thick, big, well-developed |
| Arm | Thin, small, poorly built | Moderate | Thick, big, well-built |
| Hands | Thin, dry, small rough, fissured, unsteady | Moderate, pink | Thick, oily, big, hard |
| Calves | Small, hard | Loose soft | Shaped firmly, hard |
| Feet | Thin, small, coarse, dry, cracked, fissured, unsteady | Medium, soft, pink | Big, hard, steady |

| | | | |
|------------------------|--|--|---|
| Joints | Thin, small, dry, unsteady, produce sound | Medium, soft, loose | Thick, big, well-built |
| Nails | Thin, small, dry, rough, black | Medium, soft, pink | Thick, big, greasy, smooth, white, firm |
| Body weight | Less | Moderate | Heavy |
| Action of body | Quick unsteady walk, quick actions and movements | Moderate, intelligent actions | Steady walk: slow and dignified |
| Eliminations | Less, constipated | Copious, watery | Moderate, solid |
| Strength | Less, tires quickly | Moderate | Strong, hard worker, can withstand strains |
| Body odor | No smell, less sweating | Heavy sweating, bad smell | Less sweating, pleasant smell |
| Voice | Feeble, broken, hidden, hoarse, unpleasant | High pitch | Pleasant, deep bass voice, good tone |
| Speech | Quick, very talkative | Moderate | Slow, definite |
| Likes and dislikes | Poor quality things, irregular eating habits, likes roaming, journeys, dance, hunting, quarrels, stories, music, painting, artistic pursuits | Moderate, eats more, drinks more, likes sweet, bitter and astringent tastes, cold food, hates hot, eats very often, likes flowers, scents, music | Poor appetite, thirstless, likes sweet, pungent, hot, bitter, astringent and fat tastes, likes flowers and cosmetics |
| Mental and temperament | Poor memory, quick forgetting, quick mind; unsteady courage, quick passion and attachment, cowardice, sorrowful, steals, jealous, ungrateful; no control over senses, Atheist, impoverished, less resourceful, few friends | Loves opposite sex, intelligent, scholar, genius, quick to anger and cool off, brave, adventurous, active, alert, secretive, politician, cruel in punishing disobedience, speaks well of obedient subordinates, invincible in assemblies, moderate wealth, resourceful | Good insight and forethought; slow to grasp, scholar, courageous; firm belief in religion, science, faithful, intelligent, little anger or desire, calm, civilized, grateful, truthful, shy, obedient, wealthy, does not waste money, resourceful, many friends |
| Sleep | Less sleep, wakeful at night | Moderate | Sleeps a good deal |

| | | | |
|---------------------|--|---|--|
| Dreams | Moving in sky, action | Cold, flowers, sun, fire, lightening, red, frightful dreams | Ponds, lakes, flowers, swans, beautiful sights |
| Sex | Less sex capacity, less semen/menses, few children | Less sex capacity, few children | Great sex capacity |
| Life expectancy | Short | Moderate | Long-lived |
| Reaction to disease | Quick to get diseases, usually nervous disorders | Moderate, usually inflammations | Good resistance, usually cold and phlegm type |
| Reaction to drugs | Minimum dosages required | Intolerance to drugs | Slow, tolerates at high dose |

Mental constitutions

On the mental and astral planes, three *Gunas* (attributes of female energy or *Pakriti*) correspond to the three *humors* that make up the physical constitution. In the Ayurvedic system, the *Gunas* are *Satva*, *Rajas*, and *Tamas*. They provide the basis for the distinctions in human temperament and individual differences in psychological and moral dispositions. These attributes are further subdivided, but that is beyond the scope of this chapter.

Satva

This type of mind expresses essence, understanding, purity, clarity, compassion, and love. People of Satvic psyche (*Satva* temperament) have healthy bodies and very pure behavior and consciousness. They believe in the existence of God and are religious, often very holy, persons.

Rajas

This type of mind operates on the sensual level. Such persons are interested in business, prosperity, power, prestige, and position. They enjoy wealth, are generally extroverted, and are politically minded.

Tamas

This type is distinguished by its ignorance, inertia, heaviness, and dullness. Tamasic people are lazy, selfish, destructive by nature, and show very little respect to others. All their activities are egocentric.

The Satvic person attains self-realization without much effort, while those of Rajasic or

Tamasic mind have difficulty. These three subtle mental energies are responsible for behavior patterns which may be altered and improved through practice and spiritual discipline, such as yoga and meditation.

HEALTH AND DISEASE

Health is defined in Ayurveda as soundness of body (*Shrira*), mind (*Manas*), and soul (*Atma*). Each part of this tripod of life should receive equal attention, to ensure that the individual achieves sound health. Ayurvedic medicine stresses that psychic influences strongly affect the body in health as well as disease, a fact which must also be taken into account in modern therapeutics.

Modern science takes pride in its understanding of physiology, but in so doing has emphasized fragmentation, isolation, and disunity. Instead of wholeness and interaction, this modern view accepts only physical objects as causes of disease, whereas these objects are merely the agents of disease, able to cause specific symptoms, but only in a susceptible host. Disease is the result of a disruption of the spontaneous flow of nature's intelligence within our physiology. When we violate nature's law and cannot adequately rid ourselves of the results of this action, then we have disease.

Ayurveda is based on certain fundamental doctrines (see [Table 34.6](#)) known as the *Darshnas*. It conceives of the body as being composed of three principal divisions: three *Dosha* (humors), seven *Dhatu*s (tissues), and three *Malas* (excretions).

TABLE 34-6 -- *Doshas, Dhatus, and Malas*

| |
|---------------------------------------|
| <i>Doshas (humors)</i> |
| • Vat |
| • Pit |
| • Kaph |
| <i>Dhatus (tissues)</i> |
| • Ras (secretion) |
| • Rakata (blood) |
| • Mamsa (muscles) |
| • Meda (fat) |
| • Asthi (bone and cartilage) |
| • Majja (bone marrow) |
| • Shaukra (sex hormones and immunity) |

Malas (excretions)

- Svet (sweat)
 - Poorish (feces)
 - Mutra (urine)
-

The three *Doshas* regulate cell functions. *Pit* gives energy and is responsible for cellular, enzymatic, and metabolic functions; *Kaph* helps in synthesizing blocks of cells; and *Vat* controls the other two. A balance of these *Doshas*, good quality tissues (the seven *Dhatus*), and a certain character of excretions are essential for maintaining health. All are, however, subject to qualitative and quantitative alterations.

As has been explained, an individual is born with a particular *Dosha* predominating in his or her constitution (*Pakriti*). This predominant *Dosha*, quite apart from genetic, age, environment, and dietary factors, may make an individual susceptible to a certain disease. For example, *Pit Pakriti* individuals are more prone to develop a disease syndrome with symptoms similar to a peptic ulcer. This is due to hyperactivity of the *Pit Dosha*, which regulates enzymatic activity. Now we know that hyperpepsinogenic individuals are more susceptible to duodenal ulcer formation.^[2]

Ayurveda teaches that the origin of most diseases is found either in an exogenous or endogenous *Dosha* imbalance, or in an inherent or acquired weakness of the tissues. Therefore, the successful treatment or prevention of disease will consist of normalizing cellular functions through correcting any *Dosha* imbalance or improving inherent tissue vitality. For example, in the treatment of cancer, the use of agents cytotoxic to the cancer cells is important. However, equally important is potentiation of the immune system and stimulation of the body's own healing mechanisms.

MODES OF THERAPY

Once a diagnosis is made, Ayurveda offers various modes of therapy. The treatment is chosen according to patient constitution as well as disease process. Modalities include dietary alterations, botanical medicines, minerals, animal products, exercise, yoga, meditation, counseling, and surgery.

Diet

Ayurveda places great emphasis on diet, for both its direct effect on the individual's physiological state and its influence upon the action of medicines. Proper assimilation of dietary constituents is essential for the maintenance of good health. Improper assimilation results in the formation of intermediary products of digestion which have toxic properties and are therefore treated as foreign by the body. Such toxic products are called *Ama* (this leads to the concepts of immune and autoimmune disorders).

Arthritic diseases, such as rheumatoid arthritis, are considered to originate due to an

accumulation of *Ama*. Could these toxic intermediates – macromolecules absorbed transmucosally from the intestine (in nutritionally insignificant amounts) – provoke strong immune reactions? It is known that the human gut has a complex system to control the continuous onslaught of antigenic substances derived from food, microorganisms, and toxins.^[3] It has been suggested that absorption of such compounds could underlie the pathogenesis of disease in the gut as well as in distant sites, such as the liver and spleen.^[4]

Ayurveda stresses prevention of the formation and accumulation of *Ama* through appropriate diet and the use of therapies to improve digestion. It also considers various dietary factors which trigger or eliminate certain diseases.^[5] That is why Ayurveda places emphasis on diet according to the patient's psychosomatic constitution (*Prakriti*), time of day (*Dincharya*), and season (*Ritucharya*). For example, a person with the *Pit* psychosomatic constitution should not eat foods which are very hot, pungent, or spicy at noon in the summer time, as this tends to increase diseases of inflammation.

Ayurveda prescribes specific diets for several psychiatric disorders. Recent research supports this approach. Brain levels of the neurotransmitters 5HT, catecholamine, and acetylcholine have been found to be influenced by dietary constituents. Consequently, it has been suggested that normal brain functions and mental disease can be altered by diet.^[6] Recent exciting developments include the successful treatment of mental depression with neurotransmitter precursors.^{[7] [8]}

Ayurveda also prescribes certain diets (*Pathya*) during drug therapies, as dietary constituents are believed to influence drug action.

Individualization of medicinal therapy

Medicinal therapy is highly individualized in Ayurveda.^[9] The choice and dose of medicine are influenced not only

by disease, but by the individual's constitution and the environmental conditions likely to affect that individual's *Doshas*.

For example, *Piper rotundum* (black pepper) and *Zingiber officinale* (ginger), which increase *Pit* (increasing stomach acid and pepsin secretion), are used cautiously in individuals with a *Pit* constitution. Another example is in the treatment of the patient with hypertension. Ayurveda prescribes *Terminalia chebuli* for the treatment of hypertensive patients who have *Vat Pakriti*, while for the patient with *Pit Pakriti*, one uses *Terminalia arjuna*.

A parallel to this approach can be found in modern medicine. For example, it is well-known that hypertensive patients with normal renal status respond better to beta blockers or angiotensin-converting enzyme inhibitors than do those with a poor renal

status.^[10]

In the *Vimanastrana*, Charak presents a very interesting discussion of host- and drug-related factors which help in the determination of the drug and the dosage (see [Table 34.7](#)).

Ayurveda also emphasizes proper timing for the administration of medicines. Considering that chronopharmacology (the study of the timing of drug administration in relation to physiological function) has only recently been developed as a branch of modern therapeutics, it seems remarkable that such astute observations about the timing of medicaments were made so many centuries ago.

Pharmacy in Ayurveda

In Ayurveda, pharmacy is highly developed. There are almost 70 books containing more than 8,000 recipes for the preparation of different medicines, most of which are

TABLE 34-7 -- Host- and drug-related factors

| <i>Drug factors</i> | |
|---------------------|---------------------------------|
| Pakiriti | Constitution of the drug |
| Guna | Properties |
| Prabhava | Activity (potency) |
| Desh | Place |
| Ritu | Season |
| Grahan | Storage |
| Nihit | Transport |
| Sanskar | Refinement |
| Matra | Dose |
| Sanyog | Combination |
| Adhishthan | Ability to reach site of action |
| <i>Host factors</i> | |
| Pakriti | Constitution of host |
| Vayam | Age |
| Vikriti | Pathological condition |
| Sar | System strength |
| Satamya | Tolerability |
| Satva | Psychological state |

| | |
|---------------|--------------------|
| Ahar Shakti | Digestive capacity |
| Vyayam Shakti | Exercise tolerance |
| Balam | Strength of host |

derived from minerals and plants. Many formulations, including simple distillates (*Arka*), decoctions (*Kwatha*), tinctures (*Avleha*), powders (*Churna*), pills (*Vati*, *Goti*, and *Modak*), fermented products (*Asva*), and medicated oils (*Taila* and *Ghrita*), are available. The oil preparations are particularly useful as they help to target the sites of actions.

There are also detailed descriptions of the methods recommended to ensure a medicine is suitable for human use.^[11] One pharmaceutical technique, *Samskara* (refinement), is known as *Shudhi* (purification), a process which eliminates the toxicity of some minerals and plants. Another practice is the administration of drugs in combination (*Samyoga*) in order to reduce toxicity and increase efficacy.

At the beginning of the 20th century, Paul Ehrlich introduced the Western world to the concept of targeting drugs to the site of action, a concept that was used in the East since the teachings of Charak, who wrote, among other texts, the *Adhithana* in the 1st century AD, in which he described using drugs that have an affinity for specific tissues.

RESEARCH

Considerable modern research has proven the efficacy of Ayurvedic herbal preparations, and research has now moved to elucidating their mechanisms and sites of action.^[12] Reserpine, an antihypertensive drug, was isolated from *Rauwolfia serpentina* (*Sarpagandha*, used for hypertension). *Curcumin*, the active principle of *Curcuma longa*, has been found to exert an anti-inflammatory effect by inhibiting prostaglandin synthesis. Further, it has been shown to selectively inhibit platelet prostaglandin production, while sparing vascular endothelial prostaglandin synthesis.

Many plant preparations have been used to strengthen general host resistance. These are called *Rasayna*, *Jeevaniya*, or *Balya* and they increase tissue resistance to disease, a concept similar to “prohost therapy” as put forward by Hadden.^[13] Prohost therapy is claimed to augment cellular responses and, consequently, ameliorate disease states.^[14]

Perhaps most exciting, however, is the current research demonstrating efficacy of Ayurvedic herbal preparations in conditions for which modern medicine has limited or no success. For example, animal studies have shown that *Winthania somnifera* (Ashwagandha) is able to reverse the immunosuppression cyclophosphamide, azathioprin, and prednisolone and a 50% alcoholic extract of *Phyllanthus emblica* protects the liver from paracetamol.^{[15] [16]} Recent human studies found that patients with acne vulgaris demonstrated substantial improvement, with no significant side-effects, of Sunder Vati when compared with placebo (interestingly, the study found three other Ayur-vedic formulas ineffective) and patients with osteoarthritis

experienced substantial, highly significant improvement in pain and disability with no significant side-effects (however, the radiological findings did not improve).^[17]

AYURVEDIC AND MODERN MEDICINE

In evaluating Ayurvedic medicine by modern standards, one encounters a number of difficulties. First, there is in nature a wide variation in the quantity of pharmacologically active substances in plants. In addition, many findings are more subjective than objective. The modern scientist has difficulty recognizing subjective experiences because no reliable methodology has been developed to measure and reproduce such experiences. Yet we know that totally objective experience, which completely disregards the subjective, may be wrong and even dangerous.

In fact, there is no such thing as complete objectivity. What we claim as such is merely agreement among many minds. Subjective experience is limited. Our senses vary in ability, and reality for one is unreality for another. When using the tools of quantitative, technical science to describe biological and living systems phenomena, we soon encounter limits. We must impose artificial distinctions to reduce variables and interpret non-linear events intelligibly.

Science has often confused the map for the actual reality. Take the example of color vision in bees. The eye of a bee is more sensitive to blue, violet, and ultraviolet light, while receptors in the human eye more readily detect red, green, and blue wavelengths. Thus bees are nearly blind to red light, and humans are quite blind to ultraviolet light. These differing characteristics result in members of each species forming a completely different perception of the same object. Color, rather than being a part of the “reality” of a perceived object, is an expression of sensory apparatus, determined by each species’ or individual’s unique pattern of interneural connections. Even more interesting is the fact that, within the same species, perception may vary considerably.

Ayurvedic philosophy may strike the contemporary reader as unnecessarily complex for the conceptual territory it addresses. However, it is actually quite succinct and very relevant to modern life. Its precepts have influenced many systems of healing, including naturopathic medicine, through the several paths of its root traditions. It emerged alongside systems known to early Persians and Greeks, as well as the Chinese. Modern medicine is itself a distillation of these same rich traditions. Compare Ayurvedic concepts with those of pre-industrial Europe and much similarity becomes apparent.

SUMMARY

Only some glimpses of Ayurveda are presented here. This ancient system of medicine, developed over centuries, has a consistent and logical framework and gives detailed

instructions for the preservation of health and the treatment of disease. Ayurveda faced a setback when modern medicine subjected all knowledge to experimental and statistical verification which, although useful, is limited by the tools available and the perceptions underlying the questions asked. Now that we have accumulated considerable knowledge of cellular physiology and have much more sensitive modern biomedical research tools, we may be able to evaluate the concepts of Ayurveda more effectively.

Chapter 35 - Botanical medicine – a modern perspective

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

The term “herb” refers to a plant used for medicinal purposes. Are herbs effective medicinal agents or is their use merely a reflection of folklore, outdated theories, and myth? To the uninformed, herbs are generally thought of as ineffective medicines used prior to the advent of more effective synthetic drugs. To others, herbs are simply sources of compounds to isolate and then market as drugs. But to some, herbs and crude plant extracts are effective medicines to be respected and appreciated.

For many of the people of the world, herbal medicines are the only therapeutic agents available. In 1985, the World Health Organization estimated that about 80% of the world’s population rely on herbs for their primary health care needs.^[1] This widespread use of herbal medicines is not restricted to developing countries, as it has been estimated that 70% of all medical doctors in France and Germany regularly prescribe herbal preparations.

Although herbal medicine has existed since the dawn of time, our knowledge of how plants actually affect human physiology remains largely unexplored. Many individuals formulate their view of herbal medicine based on opinion, philosophy, and ideology. This chapter seeks to facilitate an informed view of herbal medicine. The past as well as the future of herbal medicines are discussed. The authors believe that the continued evolution of the tradition of herbal medicine can only be accomplished within the context of continued scientific investigation.

THE REBIRTH OF HERBAL MEDICINE

Throughout the world, but especially in Europe and Asia, there has been a tremendous renaissance in the use and appreciation of herbal medicine. In Germany, estimates

show that over \$4 billion are spent on herbal products each year. In Japan, the figure is thought to be even higher. Herbal products are a major business

in the US as well, with an estimated annual sales of \$4 billion for 1996. Annual sales have been increasing for several years. However, it is interesting to note that while annual sales of ginseng products in the US in 1992 was roughly \$10 million, over 3 million pounds (roughly \$100 million) of American ginseng were exported.^[2] ^[3]

The rebirth of herbal medicine, especially in developed countries, is largely based on a renewed interest by the public and scientific researchers. During the last 10–20 years, there has been an explosion of scientific information concerning plants, crude plant extracts, and various substances from plants as medicinal agents. Plants still play a major role in modern pharmacy.

The role of herbs in modern pharmacy

For the past 25 years, about 25% of all prescription drugs in the US have contained active constituents obtained from plants. Digoxin, codeine, colchicine, morphine, vincristine, and yohimbine are some popular examples. Many over-the-counter (OTC) preparations are also composed of plant compounds. Current estimates show that more than \$11 billion of plant-based medicines are purchased each year in the US alone and \$43 billion worldwide.^[4]

Pharmacognosy, the study of natural drugs and their constituents, plays a major role in current drug development. Unfortunately, the standard path of the approval of a drug is a process that typically takes 10–18 years at a total cost of roughly \$230 million.

Because a plant cannot be patented, plants are screened for biological activity and then the so-called “active” constituents (compounds) are isolated and, typically, chemically modified to produce unique substances. If the compound is powerful enough, the drug company will begin the process to procure Food and Drug Administration (FDA) approval. Because of the expense and lack of patent protection, very little research has been done during this century on whole plants or crude plant extracts as medicinal agents, per se, by the large American pharmaceutical firms.

In contrast, European regulatory policies and practices have made it economically feasible for companies to research and develop herbs as medicines. For example, in Germany, herbal products can be marketed with drug claims if they have been proven to be safe and effective.^[5] Whether the herbal product is available by prescription or OTC is based upon its application and safety of use. Herbal products sold in pharmacies are reimbursed by insurance if they are prescribed by a physician.

The proof required by a manufacturer in Germany to illustrate safety and effectiveness for an herbal product is less (and more appropriate) than the proof required by the FDA

for drugs in the US. In Germany, a special commission (Commission E) developed a series of 400 monographs on herbal products similar to the OTC monographs in the US.^[6] An herbal product is viewed as safe and effective if a manufacturer meets the quality requirements of the monograph or produces additional evidence of safety and effectiveness that can include data from existing literature, anecdotal information from practicing physicians, as well as limited clinical studies.

The best single illustration of the difference in the regulatory issues of herbal products in the US compared to Germany is *Ginkgo biloba*. In Germany, as well as France, extracts of *Ginkgo biloba* leaves are registered for the treatment of cerebral and peripheral vascular insufficiency.^[7] *Ginkgo* products are available by prescription and OTC purchase. *Ginkgo* extracts are among the top three most widely prescribed drugs in both Germany and France, with a combined annual sales of more than \$500 million. In contrast, in the US, extracts, which are identical to those approved in Germany and France, are available as “food supplements”.

No medicinal claims are allowed for most herbal products, because the FDA requires the same standard of absolute proof as is required for new synthetic drugs. Thus far, the FDA has rejected the idea of establishing an independent “expert advisory panel” for the development of monographs similar to Germany’s Commission E monographs, as well as other ideas to create a suitable framework for the marketing of herbal products in the US. Currently, herbal products continue to be sold as “food supplements” and manufacturers are prohibited from making any therapeutic claims for their products.

The German experience: St John’s wort extract as an example

Over 25 double-blind controlled trials (15 vs. placebo, 10 vs. standard anti-depressant drugs) have shown St John’s wort (*Hypericum perforatum*) extracts standardized for hypericin content to yield excellent results in the treatment in depression with virtually no side-effects.^[8] Yet, most American physicians have never heard of St John’s wort extract and go on to erroneously state that there is no research to support its use when patients or the media ask them about them.

In contrast, a total of 66 million daily doses of St John’s wort preparations were prescribed by German physicians in 1994.^[9] The obvious question is: “Why do so many German MDs know about St John’s wort, *Ginkgo*, and other herbal medicines while conventional medical doctors in the US remain ignorant?” The answer: Germany addressed the issue of rational claims for herbal products by developing the Commission E series of monographs (now totaling over 400).

The monograph system allowed companies to market their products according to the guidelines of the Commission E. With the ability to make appropriate claims,

many companies achieved success with their products and were then able to then fund

the necessary research to gain greater acceptance within mainstream, conventional medicine. The use of St John's wort extract in the treatment of depression is a perfect case in point to illustrate how the Commission E monographs have led to significant documentation of the efficacy of plants with a long history of folk use for depression.

When the Commission E monograph for St John's wort came out in 1984, it identified the constituent hypericin as the active constituent and permitted the medicinal use of the herb (in average doses of 2–4 g of herb, or 0.2–1.0 mg total hypericin) for depression, anxiety, or nervous excitement.

Originally it was thought that hypericin acted as an inhibitor of the enzyme monoamine oxidase, thereby resulting in the increase of CNS monoamines such as serotonin and dopamine. However, newer information indicates that St John's wort does not inhibit MAO in vivo.^[9] The anti-depressant activities appear to be related more to inhibiting serotonin reuptake, similar to the SRI drugs like Prozac, Paxil, and Zoloft.^[9] ^[10] In addition, it appears that while hypericin is an important marker, there are other compounds such as flavonoids which are thought to play a major role in the pharmacology of St John's wort.

The great fallacy

One of the great fallacies promoted by the US's medical establishment has been that there is no firm scientific evidence for the use of many natural therapies, including herbal medicine. This assertion is simply not true. In fact, during the last 10–20 years there has been an explosion of information concerning plants, crude plant extracts, and nutritional substances as medicinal agents.

Science and medicine now have available the technology and understanding necessary to evaluate herbal medicines properly. Thirty years ago it was impossible to determine exactly how herbs promote their healing effects because analytical science had not advanced to a sufficient level of sophistication. This point is well illustrated by the fact that the main mechanism of action responsible for aspirin's anti-inflammatory effect was not understood until the early 1970s, and its mechanism of action for pain relief has yet to be fully understood.

Since the mechanism of therapeutic action of a particular herb could not be fully elicited, many effective plant medicines were erroneously labeled as possessing no pharmacological activity. Now, researchers equipped with greater understanding and more sophisticated technology are rediscovering the wonder of plants as medicinal agents. Much of the increased understanding is, interestingly, a result of synthetic drug research.

For example, one of the latest classes of so-called "wonder drugs" are the calcium-channel blockers. These agents block the entry of calcium into smooth muscle cells, thereby inhibiting contraction and promoting muscular relaxation. Calcium-channel blocking drugs are currently being used in the treatment of high blood pressure, angina, asthma, and other conditions associated with smooth muscle contraction. They, in many ways, represent the most highly evolved stage of modern drug pharmacy. After calcium

channel drugs became better understood, it was discovered that many herbs contain components which possess calcium-channel blocking activity. In most cases, the historical use of these herbs correspond to their calcium-channel blocking activity.

In addition to possessing currently understood pharmacological activity, many herbs possess pharmacological actions that are not consistent with modern pharmacological understanding. For example, many herbs appear to impact on homeostatic control mechanisms to aid normalization of many of the body's processes. When there is a hyper-state the herb will have a lowering effect, and when there is a hypo-state it will have a heightening effect. This action is totally baffling to orthodox pharmacologists, but not to experienced herbalists who have used terms such as alterative, amphiteric, adaptogen, or tonic to describe this effect.

The advantages of herbal medicines

In general, herbal preparations are thought to have three major advantages: lower cost, fewer side-effects and medicinal effects which tend to normalize physiological function. When used most effectively, the mechanism of action of an herb will often correct the underlying cause of a disorder. In contrast, a synthetic drug is often designed to alleviate the symptom or effect without addressing the underlying cause. Interestingly, research has often shown for many plants that the whole plant or crude extract is much more effective than isolated constituents.

Herbal medicine will certainly play a major role in the medicine of the future. As modern medicine gains more knowledge and understanding about health and disease, it is adopting therapies that are more natural and less toxic. Lifestyle modification, stress reduction, exercise, meditation, dietary changes and many other traditional naturopathic therapies are becoming much more popular in standard medical circles. This illustrates the paradigm shift that is occurring in medicine. What was once scoffed at is now becoming generally accepted as an effective alternative. In fact, in most instances these natural alternatives offer significant benefit over standard medical practices.

The difference is due to the growing sophistication of herbal medicine. With the continuing advancement in science and technology, there has been a great improvement

in the quality of herbal medicines available and in the understanding of their optimal clinical utilization. Improvements in cultivation techniques coupled with improvements in quality control and standardization of potency will continue to increase the effectiveness of herbal medicines.

The study of herbal medicine

The study of herbal medicine spans the breadth of pharmacology, the study of the

history, source, physical and chemical properties, mechanisms of action, absorption, distribution, biotransformation, excretion, and therapeutic uses of “drugs”. In many respects, the pharmacological investigation of herbal medicine is just beginning. This textbook is replete with examples of herbs whose historical use is being justified by new investigations into its pharmacology.

THE HISTORY OF HERBAL MEDICINE

The history of the use of plants as medicines is full of interesting stories and fascinating facts. The evolution that has occurred in herbal medicine over the centuries is only beginning to be recognized as more natural medicines gain acceptance. Interestingly, this acceptance is largely a result of increased scientific investigation.

There is a trend towards using substances found in nature, including compounds which are found in the human body such as interferon, interleukin, insulin, and human growth hormone, as well as foods, food components, herbs, and herbal compounds. More and more researchers are discovering the tremendous healing properties of these natural compounds and their advantages over synthetic medicines and surgery in the treatment of many health conditions. Through these scientific investigations, a trend towards natural medicine is emerging. To better appreciate this evolutionary trend, this section presents some of the historical aspects of herbal medicine. Much of the following is derived from Barbara Griggs' *Green Pharmacy: a History of Herbal Medicine*. [\[11\]](#)

In the beginning

Plants have been used as medicines since the dawn of animal life. The initial use of plants as medicines by humans is thought to have been a result of “instinctive” dowsing. Animals in the wild still provide evidence that this phenomena occurs. Animals will, with a few notable exceptions, eat those plants that will heal them and avoid those plants which will do them harm. Presumably humans also possessed this instinct at one time.

As civilizations developed, medicine men and women were responsible for transmitting the information on herbs to their successors. Before the advent of written language, this information was handed down by verbal and experiential means.

Besides instinctive dowsing, it was commonly believed that plants had been signed by the “creator” with some visible or other clue that would indicate its therapeutic use. This concept is commonly referred to as “the doctrine of signatures”. Common examples of this doctrine are:

- *Panax ginseng* (ginseng), whose root bears strong resemblance to a human figure and whose general use is as a tonic
- *Caulophyllum thalictroides* blue (cohosh), whose branches are arranged like limbs in spasm indicating its usefulness in the treatment of muscular spasm
- *Sanguinaria canadensis* (bloodroot), whose roots and sap are a beautiful blood color corresponding to its traditional use as a “blood purifier”

- *Lobelia inflata* (lobelia), whose flowers are shaped like a stomach corresponding to its emetic qualities
- *Hydrastis canadensis* (goldenseal), whose yellow-green root signifies its use in jaundice as well as infectious processes.

All of these uses have been confirmed by recent research.

Materia medicas

With the development of written language, materia medicas (books containing prescribing information on herbs) became the vehicle of passing information about the medicinal use of herbs to future herbalists. Materia medicas were recorded in ancient China, Babylon, Egypt, India, Greece, and other parts of the world. From these materia medicas, it is quite obvious that herbal medicines were highly respected therapies in ancient times.

Galen's influence

There was no system, rules, or classification to Western herbal materia medicas until the 1st century AD when Galen, the Greek physician who founded experimental physiology, established his system of rules and classification. Galen's classification was based on Hippocratic medicine, i.e. balance of the four humors – blood, bile, phlegm, and choler – and a profound belief in a beneficent nature. Although his system is considered seriously flawed in the light of modern medical knowledge, Galen is historically considered to be the founder of scientific herbalism.

Galen evaluated and classified each plant according to its relation to Hippocratic medical theory. Although based initially in Hippocratic principles, Galen constructed his own elaborate, and rigid, system of medicine. Galen's work also signified the beginning of a clear division

between the professional physician and the traditional healer. As only the well educated could understand Galen's system, and even with the best schooling it remained a mystery to many, all challenges to the professional physician were effectively squelched by dogma.

Galen's system dominated European medical thinking for 1,500 years. Perhaps if the Roman Empire had continued to flourish others would have surfaced to develop alternative theories. Instead, Galenical medicine reigned unchallenged throughout the middle ages. By the 19th century, the "professional" physician, confident in his supposedly superior knowledge, took Galenical philosophy to an extreme probably never imagined by Galen by the adoption of bloodletting, purging, and administering exotic medicines. This was in direct contrast to the traditional healer's patient use of

traditional herbs and tremendous faith in the healing power of nature.

The Black Plague and syphilis

Although Galenical medicine dominated the Middle Ages, herbal medicine was still deeply entrenched in Europe culture. The Black Plague of 1348 may have been the beginning of change in medical thought, as conventional medicine was totally useless. As nearly one-third of Europe died as a result of this plague, the public began to lose faith in Galenical medicine. Nearly 150 years later another blow was dealt to Galenical medicine when syphilis became the major medical problem. Unlike the Black Death, patients with syphilis tended to survive longer, giving physicians more time to experiment with treatments. At this time, perhaps the greatest hoax in the history of medicine began. Mercury became the standard medical treatment for syphilis despite the fact that even Galen thought mercury too poisonous to use.

Syphilis did, however, open the door for the use of some new herbs from the Americas. A French physician, Nicholas Monardes, published a comprehensive account of sarsaparilla and several other “new” drugs in the treatment of syphilis in 1574. Many Europeans at the time believed that syphilis had come to Europe from the West Indies with Columbus’ sailors, and since there was a general belief that whatever disease was native to a country might be cured by the medicinal herbs growing in that region, it was only natural for sarsaparilla to become a very popular remedy. Since at that time the standard treatment of syphilis was the use of mercury, which often resulted in greater morbidity than did syphilis, sarsaparilla was a welcome alternative. Despite initial excitement, Monardes’ sarsaparilla cure eventually lost favor, probably due to other components in the cure; specifically, patients were confined to a warm room for 30 days, and for the following 40 days were required to abstain from both wine and sexual intercourse.

Although the public popularity of sarsaparilla waned, it continued to be used in the treatment of syphilis. During military operations in Portugal in 1812, a British Inspector General of Hospitals noted that the Portuguese soldiers suffering from syphilis who used sarsaparilla recovered much faster and more completely than their British counterparts who were treated with mercury.

Sarsaparilla was also used by the Chinese in the treatment of syphilis. Later clinical observations in China would demonstrate, through the use of blood tests, that sarsaparilla is effective in about 90% of cases of acute syphilis and 50% of cases of chronic syphilis.^[11]

Although sarsaparilla was clearly more beneficial than mercury in the treatment of syphilis, mercury was the standard medical treatment of choice for over four and a half centuries. Some historians have stated that “the use of mercury in the treatment of syphilis may have been the most colossal hoax ever perpetrated” in the history of medicine.^[11] Mercury represented a new kind of medicine, one formulated and prepared in a laboratory using the new techniques of chemistry. It helped to prepare the way for future synthetic and mineral drugs at the expense of herbal medicines.

Challenges to Galenical medicine

The 1500s also saw a strong challenge to Galenical medicine from within the traditional circles. Specifically, Paracelsus, an alchemist who believed strongly in the doctrine of signatures, was responsible for founding modern pharmaceutical medicine. Paracelsus is probably most remembered for the development of laudanum (tincture of opium). After Paracelsus, Galenical preparations and treatments fell greatly out of favor.

In public circles, herbal medicine was regaining some respect as well. In the early 1600s, Culpepper, an English pharmacist, published his book entitled, *The English Physician*. Instead of requiring patients to purchase expensive exotic or imported drugs, Culpepper recommended the herbs his clients and readers had growing in their own back yards. Although Culpepper's herbal is based on astrological rationalizations, it reinforced a strong English tradition of domestic herbal medicine. This came at a time when professional physicians were beginning to become contemptuous of herbal medicine.

Meanwhile, in the Americas during the 1600 and 1700s, herbs used traditionally by the Native Americans were becoming quite popular, especially in the treatment of malaria and scurvy. Herbal medicine continued to gain even greater respect in the late 1700s, as exemplified by English physician Withering's classic description of digitalis. However, mercury, bleeding, and purging were still the "standard" medical treatments epitomized by George Washington's death from complications incurred during treatment of a sore throat (i.e. he was bled to death).

The Thomsonian and Eclectic movements

During the early 1800s, standard medicine may have been ready to reconsider traditional herbal remedies, but then came the Thomsonian movement. Samuel Thomson (1769–1843) patented a system of herbal medicine that, in 1839, claimed over 3,000,000 faithful followers. Although Thomson brought back to medicine the vitalistic Hippocratic idea of *vis medicatrix naturae* and gained widespread public support for the use of herbal medicine, the Thomsonian movement was probably detrimental to medical reform.

Thomsonians became locked in prejudice and dogma and insisted that all medical knowledge was complete and could be found in Samuel Thomson's works. These and other claims roused scorn, indignation, rage, and resentment in the average North American doctor. Frequently based on purging through the use of herbal emetics, Thomson's treatments often were as harsh as the standard treatments of the times (for further discussion, see [Ch. 2](#)).

During the 1800s, the Eclectic movement attempted to bridge the gaps between

standard medical thought, Thomsonianism, and traditional herbal medicines. Rather than attack the existing medical system, the Eclectic movement sought to bring about reform by educating physicians about the use of herbal medicines. Several Eclectic medical colleges were established and, for a while, it appeared that the Eclectic movement was making headway in its attempt to reform the medical system from within.

The movement, however, eventually failed. Several factors were probably responsible for the failure of the Eclectic movement: a split in the ranks which diluted the movement; harsh measures like mercury, calomel, and bloodletting were finally discarded by the conventional professional physician due to a decrease in infectious disease as a result of improved sanitation and hygiene; and, perhaps most important, the failure to establish and sustain quality medical schools.

The Flexner report on medical education in 1910 spelled doom for the eclectics: by 1920, seven of the eight that existed prior to the report had closed with the last school closing in 1938. Meanwhile, the standard medical schools, aided by the Rockefeller Foundation, flourished, promoting the growth of the modern pharmaceutical industry and the current near-monopoly of the medical profession.

The growth of the pharmaceutical industry

Since a plant cannot be patented, very little research has been done this century on plants as medicinal agents, per se, by the large American pharmaceutical firms. Instead, plants have been screened for biological activity and then the so-called “active” constituents have been isolated and chemically modified to produce unique, patentable compounds. Much to the dismay of the researchers was the discovery that in many instances the isolated constituents were less biologically active than the crude herb. Since the crude herb provided no economical reward to the American pharmaceutical firm, the crude herb or extract never reached the marketplace. In contrast, European policies on herbal medicines made it economically feasible for companies to research and develop phytopharmaceuticals.

Another of the problems of herbal medicine in the US has been the lack of standardization. The herb which best exemplifies this dilemma is digitalis. One batch of crude digitalis might have a very low level of active constituents, making the crude herb ineffective, while the next batch might be unusually high in active constituents, resulting in toxicity or even death, when standard amounts were used. The lack of standardization made it easier for US pharmaceutical firms to rationalize their economic need to isolate, purify, and chemically modify the active constituents of digitalis so they could market these compounds as drugs. The problem with using the pure active constituent is that the safe dosage range is smaller: digitalis toxicity and death have increased dramatically as a result of purification. Toxicity was less of a factor when using the crude herb because overconsumption of potentially toxic doses resulted in vomiting or diarrhea, thus avoiding the severe heart disturbance and death which now occur with pure digitalis cardiac glycoside drugs.

Fortunately, several European and Asian pharmaceutical firms began specializing in phytopharmaceuticals in the early part of the 20th century. These companies have

played a prominent role in researching, developing, and promoting herbal medicines.

Research is demonstrating that crude extracts often have greater therapeutic benefit than the isolated “active” constituent. This has been known for quite some time in other parts of the world, but in this country isolated plant drugs are still thought of as having the greatest therapeutic effect. This myth is gradually being eroded as our knowledge of herbal medicines increases.

If current standardization techniques had been available earlier in this century, it is possible that the majority of our current prescription drugs would be herbal extracts instead of isolated and modified active constituents or synthetic chemicals.

THE FUTURE OF HERBAL MEDICINE

Currently, there is a renaissance occurring in herbal medicine. It is ironic that this renewal is coming not from traditional herbalists but rather from public demand for alternatives to the monopolistic conventional medicine

273

and renewed scientific investigation into the use of plant medicines. It seems that science and medicine have finally advanced to a level where nature can be appreciated rather than discounted. The scientific investigation of plant medicines is replacing some of the mystery and romance of herbalism with a greater understanding of the ways in which herbs work. Those herbal traditions willing to learn are being improved by modern scientific research and technology.

Improvements in plant cultivation techniques and the quality of herbal extracts (quality control and standardization) have led to the development of some very effective plant medicines. It is quite apparent that many of the “wonder drugs” of the future will be derived from plants or plant cell cultures and from compounds naturally occurring in the human body produced by cell cultures (e.g. interferon, interleukin-II, various hormones, etc.). Several herbal medicines described in this textbook may in fact already fulfill the role of wonder drug, e.g. *Ginkgo biloba*, *Hypericum perforatum*, *Silybum marianum*, *Panax ginseng*, and *Vaccinium myrtillus*.

The future of herbal medicine looks extremely positive. Many of the previous shortcomings of herbal medicine have been overcome (e.g. lack of scientific support, standardization, quality control, etc.). The future of herbal medicine is dependent on several factors:

- continued research into herbal medicine
- adoption by manufacturers of recognized standards of quality
- continued existence of the naturopathic medical schools teaching herbal medicine at a high level of sophistication

- increased public awareness of the tremendous therapeutic value of herbs.

Herbal medicine will undoubtedly play a major role in the medicine of the 21st century.

HERBAL PREPARATIONS

The clinical application of botanical medicine involves the use of a variety of herbal preparations. That being the case, it is imperative that practitioners and physicians using herbal medicines understand the differences among the various forms. Commercial herbal preparations are as bulk dried herbs, teas, tinctures, fluid extracts, and tablets or capsules. Each of these forms has advantages and disadvantages and varying ways of expressing their medicinal strength. This section reviews the major extraction forms, discusses the benefits of standardized botanical extracts and emphasizes the importance of delivering a clinically effective level of active compounds regardless of the form of the herbal preparation.

Extracts

Extracts defined

An extract is defined as a concentrated form of the herb obtained by mixing the crude herb with an appropriate solvent (such as alcohol and/or water). One of the major advances in the herb industry has been the improvement in extraction and concentration processes.^[12]

When an herbal tea bag is steeped in hot water, it is actually a type of herbal extract known as an infusion. The water is serving as a solvent in removing some of the medicinal properties from the herb. Teas often are better sources of bioavailable compounds than the powdered herb, but are relatively weak in action compared to tinctures, fluid extracts, and solid extracts. These forms are commonly used by the lay public and herbal practitioners for medicinal effects.

Tinctures are typically made using an alcohol and water mixture as the solvent. The herb is soaked in the solvent for a specified amount of time, depending on the herb. This soaking is usually from several hours to days; however, some herbs may be soaked for much longer periods of time. The solution is then pressed out, yielding the tincture.

Fluid extracts are similar to, but more concentrated than, tinctures. Although they are most often made from hydroalcoholic mixtures, other solvents may be used (vinegar, glycerin, propylene glycol, etc.). Commercial fluid extracts are usually made by distilling off some of the alcohol, typically by using methods that do not require elevated temperatures, such as vacuum distillation and counter-current filtration. However, some small manufacturers produce fluid extracts in a similar manner to tinctures via a percolation at room temperature.

A solid extract is produced by further concentration of the extract by the mechanisms

described above for fluid extracts, as well as by other techniques such as thin layer evaporation. The solvent is completely removed, leaving a viscous extract (soft solid extract) or a dry solid extract depending upon the plant, portion of the plant, solvent and drying process (if any) used. The dry solid extract, if not already in powdered form, can be ground into coarse granules or a fine powder. A solid extract also can be diluted with alcohol and water to form a fluid extract or tincture.

Strengths of extracts

The potencies or strengths of herbal extracts are generally expressed in two ways. If they contain known active principles, their strengths are commonly expressed in terms of the content of these active principles. Otherwise, the strength is expressed in terms of their concentration. For example, tinctures are typically made at a 1:5 (to 1:10) concentration. This means one part of the herb (in grams)

274

is soaked in five parts solvent (in ml of volume). This means that there is five times the amount of solvent (alcohol/water) in a tincture as there is herbal material. Fluid extracts are typically 1:1.

A 4:1 concentration means that one part of the extract is equivalent to, or derived from, four parts of the crude herb. This is the typical concentration of a solid extract. A quantity of 1 g of a 4:1 extract is concentrated from 4 g of crude herb.

Typically, 1 g of a 4:1 solid extract is equivalent to 4 ml of a fluid extract and 20–40 ml of a tincture. Some solid extracts are concentrated as high as 100:1, meaning it would take nearly 100 g of crude herb, or 100 ml of a fluid extract, or 1 L of a tincture to provide an equal amount of herbal material in 1 g of a 100:1 extract.

Determining quality

In the past, the quality of the extract produced often was difficult to determine as many of the active principles of the herbs were unknown. However, recent advances in extraction processes, coupled with improved analytical methods, have reduced this problem of quality control.^[12] ^[13] ^[14] The concentration method of expressing the strength of an extract does not accurately measure potency since there may be great variation among manufacturing techniques and raw materials. By using a high quality herb (i.e. rich in active compounds), it is possible to have a more potent dried herb, tincture, or fluid extract compared to the solid extract that was made from a lower quality herb. Standardization is the solution to this problem.^[14]

Standardized extracts: the best solution

Standardized extracts (also referred to as guaranteed potency extracts) refer to an

extract guaranteed to contain a “standardized” level of active compounds or key chemical marker. Stating the content of active compounds or key chemical marker rather than the concentration ratio allows for more accurate dosages to be made.

The best scenario for determining the quality of an herb is the level of active components or key biological markers. Regardless of the form the herb is in, it should be analyzed to ensure that it contains these components at an acceptable standardized level. More accurate dosages can then be given. This form of standardization is generally accepted in Europe and is beginning to be used in the US as well.

This form of standardization, i.e. stating the content of active constituents versus drug concentration ratio, allows for dosage to be based on active constituents.^[3] For example, in Europe *Vaccinium myrtillus*, *Silybum marianum*, and *Centella asiatica* extracts dosage levels are based on their active constituent levels rather than drug ratio or total extract weight, e.g. 40 mg anthocyanosides for *Vaccinium myrtillus*, 70 mg silymarin for *Silybum marianum*, and 30 mg triterpenic acids for *Centella asiatica*. This type of dosage recommendation provides the greatest degree of consistency and assurance of quality.

Although referred to in terms of active constituents, it must be kept in mind that these are still whole extracts and not isolated constituents. For example, an *Uva ursi* extract standardized for its arbutin content, say 10%, still contains all of the synergistic factors which enhance the active ingredient's (arbutin) function.

Techniques used in the production of herbal products

There is a tremendous range of sophistication in the processing of herbs – from crude herb to highly concentrated standardized extracts. Nonetheless, there are some common stages. The following describes some of the processes in the production of herbal products and the machines that perform the functions.^[15]

Collection/harvesting

When plants are collected from their natural habitat, they are said to be “wild-crafted”. When they are grown utilizing commercial farming techniques, they are said to be “cultivated”. Collection of plants from cultivated sources ensures that the plant collected is the one that is desired. When an herb is wild-crafted, there is a greater chance that the wrong herb will be picked and greater variation in potency. However, some herbal practitioners believe that wild-crafted herbs are inherently superior, since growth in their natural habitat produces an herb with constituents and properties more consistent with their traditional use. The use of analytical techniques can be employed to guarantee that the plant collected is the one desired and that its concentrations of medicinal constituents are within an acceptable range.

In the US marketplace, herbs from all over the world are marketed. The collectors of the herbs vary from uneducated natives to self-proclaimed “herbalists” to trained botanists.

The mode of harvesting varies from hand labor to very sophisticated equipment. The mode is not as important as the time of year. A plant should be harvested when the part of the plant being used contains the highest possible level of active compounds. Again, this is ensured by the use of analytical techniques.

Drying

After harvesting, most herbs have a moisture content of 60–80% and cannot be stored without drying. Otherwise, important compounds would break down and/or

275

microorganisms would contaminate the material. As many of the desired compounds are heat labile, the majority of herbs require relatively mild conditions for drying. Commercially, most plants are dried within a temperature range of 100–140°F. During drying, the plant constituents must not be damaged or suffer losses that would prevent it from conforming to accepted standards. With proper drying, the herb's moisture content is reduced to less than 14%.

Garbling

Garbling refers to the separation of the portion of the plant to be used from other parts of the plant, dirt, and other extraneous matter. This step is often done during collection. Although there are machines that perform garbling, garbling is usually performed by hand.

Grinding

Grinding or mincing an herb means mechanically breaking down either leaves, roots, seeds, or other parts of a plant into very small pieces ranging from larger course fragments to fine powder. Grinding is employed in the production of crude herbal products as well as in the initial phases of extracts.

Often the material has to be pre-chopped or minced before feeding it into a grinder. In the process of grinding, a number of machines can be used, but the most widely used is the hammer mill. These machines are simple in design. The hammers, arranged radially, follow the rotation of the shaft to which they are attached, breaking up the material that is fed into the machine from above. On the walls of the chamber is a grid, which determines the size of the material that is passed through it. Other types of grinders include knife mills and teeth mills.

Extraction

The process of extraction is used in making tinctures, fluid extracts, and solid extracts.

Extraction in the context of this textbook refers to separating by physical or chemical means the desired material from a plant with the aid of a solvent. In the US health food industry, most extracts utilize alcohol and water mixtures as solvents to remove soluble compounds from the herb. The exceptions are liposterolic extracts, which are produced either through the use of lipophilic solvents or with the aid of hypercritical carbon dioxide (CO₂ gas compressed to a liquid by high pressures).

Most extracts that are produced by small manufacturers use maceration procedures. The simplest process consists of soaking the herb in the alcohol/water solution for a period of time and then filtering. For many botanicals this process will yield a lower quantity of active constituents at a higher price because of the cost of the solvent. Since tinctures are 1:5 concentrates, this means that 80% of the bottle is alcohol and water and only 20% is herbal material. In essence, the cost of the alcohol is a major portion of the retail price of tinctures.

Larger manufacturers utilize more elaborate techniques to ensure that the herb is fully extracted and the solvent is reused. For example, counter-current extraction is often used. In this process, the herb enters into a column of a large percolator composed of several columns. The material to be extracted is pumped through the different columns at a specific temperature and flow speed where it continuously mixes with solvent. The extract-rich solvent then passes into another column, while fresh solvent once again comes into contact with herbal material as it is passed into a new chamber. In this process, complete extraction of health-promoting compounds can be performed. The extract-rich solvent is then concentrated by techniques described below.

Concentration

After extraction of the herb, the resulting solutions can be concentrated into fluid extracts or solid extracts. In large manufacturing operations, techniques and machines, such as thin layer evaporators, are utilized to ensure that the extracted plant components are not damaged. These machines work by evaporating the solvent and leaving the plant compounds. The solvent vapors pass into a condenser whereby they return to a liquid and for reuse. The result is separation of the extracted materials from the solvent so that the final product is a pure extract and the solvent can be used again and again.

Drying of extracts

Many practitioners prefer the extract dried to a solid form, since it is more chemically stable and lower in cost (alcohol is often more expensive than the herb). In addition, tinctures and fluid and soft extracts can more easily be contaminated by bacteria and other microorganisms. Liquid forms of extracts also promote reactions which eventually break down some active constituents. A number of drying techniques are employed including freeze-drying and spray-drying (atomization). The result is a dried powdered extract that can then be put into capsules or tablets.

Excipients

The same excipients used in the manufacture of drug preparations and vitamin and mineral supplements are often used in the production of tablets and capsules containing herbs or herbal extracts. Many manufacturers

276

will provide a list of excipients contained in their products.

Analytical methods

Improvements in analytical methods have definitely led to improvements in harvesting schedules, cultivation techniques, storage, stability and concentration of active compounds, and product purity. All of these gains have resulted in tremendous improvements in the quality of herbal preparations now available.

Methods currently utilized in evaluating herbs and their extracts include:

- organoleptic
- microscopic
- physical
- chemical/physical
- biological.

Organoleptic

Organoleptic means the “impression of the organs”. Organoleptic analysis involves the application of sight, smell, taste, touch, and occasionally even sound, to identify the plant. Typically, the initial sight of the plant or extract is so specific it is easily recognized. If this is not enough, perhaps the plant or extract has a characteristic odor or taste. Organoleptic analysis represents the simplest, yet the most human, form of analysis.

Microscopic evaluation

Microscopic evaluation is indispensable in the initial identification of herbs, as well as in identifying small fragments of crude or powdered herbs. It is also important in the detection of contaminants and adulterants (e.g. insects, animal feces, mold, fungi, etc.). Every plant possesses a characteristic tissue structure, which can be demonstrated through study of tissue arrangement, cell walls, and configuration when properly mounted in stains reagents and media.

Physical/chemical analysis

In crude plant evaluation, physical methods often are used to determine the solubility, specific gravity, melting point, water content, degree of fiber elasticity, and other physical characteristics. Various chemical/physical methods also are used to determine the percentage of active principles, alkaloids, flavonoids, enzymes, vitamins, essential oils, fats, carbohydrates, protein, ash, acid-insoluble ash, or crude fiber present.

Chromatography

The most sophisticated analytical processes involve more highly technological assays to determine quality. Advanced techniques, such as thin layer chromatography, high-pressure liquid chromatography (HPLC), capillary electrophoresis and nuclear magnetic resonance (NMR), are used to precisely separate, identify and quantify molecules. The readings from these machines provide a chemical “fingerprint” as to the nature of chemicals contained in the plant or extract. These techniques are invaluable in the effort to identify herbs, as well as standardize extracts.

Biological analysis

The plant or extract can also be evaluated by various biological methods, mostly animal tests, to determine pharmacological activity, potency, and toxicity.

Quality control in herbal products

Quality control is a term that refers to processes involved in maintaining the quality or validity of a product. Regardless of the form of herbal preparation, some degree of quality control should exist. Currently, there is no organization or government body that certifies an herb as labeled correctly.

Without quality control, there is no assurance that the herb contained in the bottle is the same as what is stated on the outside. The widespread disregard for quality control in the health food industry has tarnished the reputation of many important medicinal herbs. For example, it has been estimated that because of supplier errors in collection, more than 50% of the Echinacea sold in the US from 1908 through 1991 was actually *Parthenium integrifolium*.^[16] This highlights the importance of using the Latin scientific name, since both of the above-mentioned herbs are referred to as “Missouri snakeroot”, as well as the need for proper plant identification based upon organoleptic, microscopic, and technological analysis.

Recent chemical analysis of commercially available *Tanacetum parthenium* (feverfew) and *Tabebuia avellanedae* (taheebo) for active components parthenolide and lapachol, respectively, has also shown need for concern. Analysis of over 35 different commercial preparations of feverfew found that the majority of products contained no parthenolide or only traces.^[17] Analysis of 12 commercial sources of taheebo could identify lapachol (in trace amounts) in only one product.^[18] Perhaps the best example of problems that

can result when there is lack of quality control is *Panax ginseng*.

Panax ginseng and quality control

Panax ginseng (Korean ginseng) contains at least 13 different steroid-like compounds, collectively known

as ginsenosides, which are believed to be its most important active ingredients. The usual concentration of ginsenosides in mature ginseng roots is between 1 and 3%. Ginsenoside Rg1 is present in significant concentrations in *Panax ginseng*. In contrast, American ginseng (*Panax quinquefolius*) contains primarily ginsenosides Rb1 and very little, if any, Rg1. This difference is extremely important since Rb1 and Rg1 have different effects. In general, Rb1 possesses a sedative effect while Rg1 possesses a stimulatory effect. Since American ginseng is much higher in Rb1 than Rg1, its action is much different than that of Korean ginseng.

Independent research and published studies have clearly documented a tremendous variation in the ginsenoside content of commercial preparations.^{[19] [20]} In fact, the majority of products on the market contain only trace amounts of ginsenosides, and many formulations contain no ginseng at all. The lack of quality control has led to several problems, ranging from toxic reactions (discussed below) to absence of medicinal effect. The widespread disregard for quality control in the herbal industry has done much to tarnish the reputation of ginseng, as well as other important botanicals.

The problem of quality control is exemplified by a 1979 article entitled “Ginseng abuse syndrome” which appeared in the *Journal of the American Medical Association*.^[21] In this article, a number of side-effects are reported, including hypertension, euphoria, nervousness, insomnia, skin eruptions, and morning diarrhea. Given the extreme variation in quality of ginseng in the American marketplace and the use both of non-official parts of the plant and of adulterants, it is not surprising that side-effects were noted. None of the commercial preparations used in the trial had been subjected to controlled analysis. Furthermore, the species of ginseng used included *Panax ginseng*, *Panax quinquefolius*, *Eleutherococcus senticosus*, and *Rumex hymenosepalus* in a variety of different forms, i.e. roots, capsules, tablets, teas, extracts, cigarettes, chewing gum, and candies.

It is virtually impossible to derive any firm conclusions from the data presented in the *JAMA* article, especially in light of the fact that studies performed on standardized extracts of *Panax ginseng* have demonstrated the absence of side-effects, as well as no mutagenic or teratogenic effects.^{[22] [23]} These findings further support the superiority of using herbal products that were produced using quality control measures.

The “hairy baby” story

To further illustrate problems that can occur without proper plant identification and standardization, let's examine the case of the "hairy baby". In another *JAMA* article,^[24] it was reported that a 30-year-old woman took "Siberian ginseng" (mistakenly identified in the article as *Panax ginseng*) at a dose of two 650 mg tablets twice daily during her 9 months of pregnancy and 2 weeks of breast feeding. She had experienced repeated premature uterine contractions during late pregnancy and had noted increased and thicker hair growth on her head, face, and pubic area. The woman gave birth to a full-term baby boy who was noted to have thick black pubic hair over his entire forehead along with other signs suggestive of androgenization. The authors of the report used this anecdotal evidence to warn physicians of the dangers of ginseng.

At first glance, this case report appears to be quite alarming. However, when examining the scenario more closely, a different picture is presented. First of all, controlled animal and human studies with *Eleutherococcus senticosus* have shown it to be extremely safe. In fact, in the animal studies, eleutherococcus extract actually prevented the teratogenic effects of xenobiotics, and in a human study of 1,770 pregnant women it was shown that eleutherococcus improved pregnancy outcome. There were no signs of androgenic effects in either the animal or human studies.^[25]

The *JAMA* article caught the attention of Dr Dennis Awang (then head of the Natural Products Bureau of Drug Research, Health Protection Branch Health and Welfare Canada). Upon examination of the product the woman had taken, Dr Awang discovered that the product did not contain Siberian ginseng, but was a totally different herb, *Periploca sepium*.^[26]

Does this mean the woman's reaction was due to *Periploca sepium*? Studies in animals have determined that *Periploca sepium*, like Siberian ginseng, does not produce an androgenic response.^[27] The most likely explanation for the "hairy baby" was that it had nothing to do with the herbal product being used.

Addressing the quality control problem

The solution to the quality control problem that exists in the US is for manufacturers and suppliers of herbal products to adhere to quality control standards and good manufacturing practices. With improvements in the identification of plants by laboratory analysis, consumers should at least be guaranteed that the right plant is being used. Consumers, health food stores, pharmacists, herbalists and physicians who use or sell herbal products should ask for information from the suppliers of herbal products on their quality control process. What do they do to guarantee the validity of their product? As more consumers, retailers, and professionals begin demanding quality control from the suppliers, more quality control processes will be utilized by manufacturers.

Currently, only a few manufacturers adhere to complete quality control and good manufacturing procedures.

Companies supplying standardized extracts currently offer the greatest degree of quality control, hence these products typically offer the highest quality.

Most standardized extracts are currently made in Europe under strict guidelines set forth by individual members of the European Economic Council (EEC) as well as those proposed by the EEC.^{[12] [13] [14] [15]} Also included are guidelines for acceptable levels of impurities, such as parasites (bacterial counts), pesticides, residual solvents, heavy metals, and product stability.

The production of standardized extracts serves as a model for quality control processes for all forms of herbal preparations. In general, it is believed that if the active components of a particular herb are known, whatever the form of the herb product, the herb should be analyzed to ensure that it contains these components at a medicinally appropriate level. More accurate dosages can then be given. Products should also be subjected to bacteriological counts.

Currently, in many countries, numerous standardized extracts fulfill requirements for marketing as drugs. These extracts have typically gone through the quality control steps in [Table 35.1](#) .

Standardized extracts vs. tinctures

There are several misconceptions regarding standardized extracts that need to be addressed. One is that standardizing an extract results in the loss of important compounds. This is simply not true for the vast majority of standardized extracts. Chemical analysis of standardized extracts and tinctures, whether it be thin layer chromatography (TLC) or HPLC, have clearly demonstrated that standardized extracts are not only higher in active compounds but also have a broader range of chemical constituents due to more effective extraction.

Another common misconception is that they are more expensive than alcohol-based tinctures and fluid

TABLE 35-1 -- List of quality control steps necessary for the registration of plant-based drug formulation

14. Registration by National Drug Authorities

extracts. Calculations based on the cost of delivery of an effective dosage show that the standardized extract is significantly more cost-effective. This is because, as noted above, there is less of the herb in tinctures and fluid extracts, resulting in consumers paying extra for alcohol, bottle, and the cost of shipping.

The question of an effective dosage

The effectiveness of any herb or herbal product from a pharmacological perspective is dependent upon providing an effective dosage of active compounds. Regardless of the form of the herbal preparation, clinical effectiveness requires delivery of an active dosage. Standardization or accurate analysis of the content of active constituents or key biological markers is the only real assurance of the delivery of an effective dosage.

This view should not be controversial. Unfortunately, controversy arises from the fact that from a pharmacological perspective it is unlikely that the dosage schedules historically recommended for most herbal tinctures are sufficient to produce significant pharmacological effects. While tinctures of such potentially toxic herbs such as gelsemium, aconite, belladonna, and digitalis often produce a pharmacological effect when given at low dosages, for most common medicinal herbs it is very difficult to produce an adequate and cost-effective response when the herb is administered in tincture form.

The administration of small dosages of herbs in tincture form is an offshoot of the homeopathic and Eclectic use of “mother tinctures” and “specific medicines”. The effectiveness of these preparations and their ability to exert pharmacological effects have not been proved for all but a few botanicals.

The questioning of the clinical effectiveness of herbal tinctures by science-based or evidence-based naturopathic physicians is often viewed as heretical and sacrilegious by many professing to be “master herbalists”. The opinion of the editors of this textbook is that if a natural medicine, whether it is a tincture, standardized extract, or nutrient, is truly clinically effective it should be able to stand up to scientific scrutiny and rationale.

The systems of herbal medicine that have been proved to a very large extent are based upon delivering much higher levels of herbal compounds than those easily obtained via

the use of tinctures. Specifically, we are referring to the use of highly concentrated standardized extracts from Europe and the use of herbal preparations in Traditional Chinese Medicine and Ayurveda. In Traditional Chinese Medicine, the typical daily dosage of prescribed crude herbal material is approximately 20 g. This high level of dosage is in stark contrast to much smaller average amount of the herbal material recommended

in the *British Herbal Pharmacopoeia* of 2–4 ml of a 1:5 tincture, which provides less than 1 g of herbal material. This difference in dosage may explain the differences in popularity of herbal medicine in China, Japan, India, and Germany compared with its relative obscurity in England as well as in the US prior to the last decade. The key point is that herbal medicine is not going to be very popular if it is not very effective. The greater the effectiveness, the greater the popularity.

The tremendous growth noted in the US over the past decade is, in our opinion, the result of the influx of high quality standardized extracts into the marketplace. For years, herbal medicine in the US labored and struggled because of inadequate dosages. Now, better clinical results are being achieved with herbal medicines because they are using better products which are able to deliver an effective dosage of active constituents.

SUMMARY

One of the major developments in herbal medicine involves improvements in extraction and concentration processes. These improvements have led to several very effective, clinically proven herbal products. The best assurance of quality and results when using herbal products is to use those products from suppliers who employ quality control standards and good manufacturing practices. Standardized and accurately analyzed extracts which state the level of active compounds provide the greatest benefit due primarily to more accurate and reliable dosages.

While the future looks extremely promising for herbal medicine in the US, ultimately its success will determine by the degree to which reliable herbal products are used by health care providers and consumers.

Chapter 36 - Contemporary homeopathy

Allen M. Kratz PharmD

INTRODUCTION

Homeopathy is a therapeutic approach developed over 200 years ago by a German physician, Dr Samuel Hahnemann. A basic tenet is that symptoms of a “disease” are a natural part of the healing process. They are the body’s innate reaction to a challenge and, as such, should be respected and allowed to occur. In fact, the homeopathic practitioner actually seeks to express these symptoms through allopathic means. Assisting the body to heal is the focus of homeopathy.

Homeopathically prepared substances are chosen based on the “law of similarities”. Substances that, in large doses, induce similar symptoms in a well person, as determined by a homeopathic “proving”, are prescribed in homeopathic form to safely augment or express these same symptoms in an individual who is ill.

The appropriate homeopathic formulation is chosen based on a careful and thorough review and evaluation of symptoms, physical as well as mental. In classical homeopathy, a single, well chosen substance may be all that is needed, particularly in acute clinical conditions. However, in our modern day society, conditions or “diseases” have become more chronic, thus requiring more complex approaches.

One of the primary reasons for the revival of interest in homeopathy has been its contemporization. Since the late 1970s, homeotherapeutics has undergone a change. This change has been necessitated by the impact of modern day lifestyles – ingestion of devitalized, processed foods; higher levels of stress; and the reliance on symptom-suppressing drugs, all of which interfere with the body’s inherent ability to heal and self-repair. The accumulated effects of these damaging influences are the primary causes of the dramatic rise in the incidence of chronic, degenerative “disease”. The modern practice of homeopathy has contemporized to adapt to these new challenges.

HISTORY

Hippocrates taught “the same things which can cause disease can cure it” as well as “first, do no harm”, a definition of contemporary homeopathy from the father of medicine.

“The cause is the cure” is exemplified by the use of homeopathic mercury to treat iatrogenic mercury toxicity during the last century. Conventional physicians of that era were using mercury as a cure-all. It was the wonder drug of its time: a laxative, a diuretic, and an antisyphilitic. As with many wonder drugs, its toxicity caught up with it. In fact, the word “quack” comes from the German word for mercury, *quecksilber*, or our quicksilver, used as a pejorative term to describe those turn of the century conventional physicians who prescribed mercury so indiscriminately. It is interesting how the word “quack” is now being used to disparage the modern unconventional practitioner. In the current Homeopathic Pharmacopoeia of the US, there are 17 different monographs for mercury, all from an earlier time. This confirms the observation that, during the last century, conventionally prescribed mercury was being antidoted by homeopathically prepared mercury – “the cause is the cure”. Is history repeating itself with the use of dental amalgam/mercury?

CONTEMPORARY HOMEOTHERAPEUTICS

As mentioned, practitioners of contemporary homeopathy view all symptoms of a condition (“disease”) as positive events – signs of adaptation, detoxification and healing. To further assist the healing process, these symptoms are homeopathically expressed rather than suppressed. When symptoms are “relieved” by conventional medications, normal detoxification is suppressed, thereby creating a deeper retoxification of organs/systems. This retoxification can cause more severe conditions. Contemporary homeopathic practitioners recognize three basic types of conditions:

- acute
- chronic
- constitutional.

Acute

Many acute conditions are self-limiting and may be self-treated by informed consumers. Other acute conditions require a diagnosis from a physician and more skilled prescribing. These acute conditions respond to lower potencies (e.g. 3x, 6x) of single or complex homeopathic formulations.

Chronic

Chronic conditions, often associated with toxicity, require the counsel of a practitioner familiar with the effects of clearing, detoxification and support. These chronic conditions respond to middle range potencies (e.g. 9x to 200x) of complex homeopathic or homeovitic formulations.

Constitutional

Constitutional conditions, with both physical and emotional/mental components, require the supervision of a practitioner trained in classical homeopathy. These constitutional conditions respond to high potencies (e.g. above 200x) of single homeopathic formulations.

RECOGNITION OF CONTEMPORARY HOMEOPATHY

Over the years, homeopathy has proven to be very effective in both acute and constitutional conditions. Today's lifestyles and some conventional medical drug treatments have greatly increased the incidence of chronic conditions associated with toxicities. As a result, there has been a significant increase in the use of detoxifying homeopathic formulations. Homeopathy has contemporized to meet these new challenges.

The Homeopathic Pharmacopoeia of the United States (HPUS), the oldest official drug compendium in this country, has been in continuous publication since 1897. In 1982, a supplement to the HPUS was published to respond to changes that had occurred in the practice of homeopathy. The HPUS established two new classes of homeopathic formulations in its General Pharmacy section: allersodes and isodes.

The Homeopathic Pharmacopoeia Revision Service, initiated in 1988, has also embraced contemporary homeopathy by several inclusions in the General Pharmacy section:

- the recognition of the usefulness of complex/combination homeopathic formulations
- the acceptance of contemporary dosage forms, including oral liquids and compressed tablets
- the use of stabilizers other than alcohol in dosage forms
- the inclusion of newer sterilization techniques
- the inclusion of newer analytical procedures for quality control and stability assessment.

The General Pharmacy section of this Homeopathic Revision Service makes the following "statement regarding combinations of homeopathic drugs":

Whereas, combinations of homeopathic drugs are in general use by many homeopathic physicians of the United States and internationally, and,

Whereas, such combinations of homeopathic medicines are an essential

part of their armamentarium and,

283

Whereas, homeopathic physicians depend upon homeopathic pharmacists for manufacture and preparation of such homeopathic medicines and combinations of such homeopathic medicines and,

Whereas, the Pharmacopoeia Convention of the United States recognizes the necessity for the manufacture, preparation and distribution of combinations of homeopathic medicines to meet the needs of those homeopathic physicians using combination medicines.

Be it therefore resolved: That combination of homeopathic medicines are within the scope and tenants of Homeopathy, provided each component is listed in the Homeopathic Pharmacopoeia of the United States.

Approved this 11th day of February, 1981, by the Directors of the Homoeopathic Pharmacopoeia Convention of the United States.

Definitions

The following definitions of contemporary homeopathic terminology are presented.

Allersodes. Allersodes are homeopathic attenuations of antigens, i.e. substances which under suitable conditions can induce the formation of antibodies.

Isodes. Sometimes called “detoxodes”, isodes are homeopathic attenuations of botanical, biological, chemical or synthetic substances, or drugs, including excipients or binders, which have been ingested or otherwise absorbed by the body and are believed to have produced a disease or disorder which interferes with homeostasis.

Anthroposophic homeopathy. This is an etiological approach, utilizing specially prepared single ingredient and multiple ingredient remedies, based upon an understanding of the “essential nature” of a remedy and of its similarity to the “formative influences” ultimately responsible for conditions of illness or imbalance.

Biotherapy. This comprises a variety of therapeutic approaches, including nutritional, manipulative, mechanical and medicinal interventions, which act to stimulate or otherwise facilitate the living system to maintain or regain its healthy functions by means of its own internal health regulatory mechanisms. Homeopathy is one of these biotherapeutic approaches.

Classical homeopathy. This involves election of a single remedy, most similar to the “essence” of the case, based upon a hierarchical evaluation of the “totality of

symptoms”, with emphasis upon subjective sensations, “strange, rare and peculiar” symptoms, modalities, desires and aversions, and “mental generals”. In order for it to be possible to select a remedy in this manner, the remedy must present a delineated symptom “picture” complete with subjective sensations, mental and emotional symptoms, desires, aversions and reactional modalities. Since it is possible for only one remedy to be most similar to the “totality of symptoms,” only one remedy at a time is to be used; remedies are never to be alternated or mixed together. The selected single remedy is usually (but by no means always) administered in a medium or high attenuation.

Complexism or combination homeopathy. This is the practice of using two or more remedies at the same time or in combination with each other.

Gemmotherapy involves the use of glycerin/alcohol macerates (made in accordance with processes described in the French Pharmacopoeia) of fresh plant material taken from non-toxic plants during the budding, flowering or early growth cycle of the plant, and given upon organotropic indications in order to stimulate or facilitate the histological vitalization of the organ or tissue for which the plant has an elective affinity.

Homeovitics. This is a contemporary approach that focuses on the problem of cellular toxicity. Formulations are used to clear, destress, detoxify and support the body on a cellular level. This approach holds that toxicity, i.e. chemicals, metals, is a predisposing factor in all chronic conditions.

Isotherapy. As used in modern homeopathic literature, isotherapy refers to the therapeutic administration of isodes upon the basis of etiotropic similarity. The cause is the cure. It is also known as the homeovitic approach (*homeo*= same, *vitic* = energy). This practice is especially popular with many European homeopathic physicians (see also “tautopathy”).

Oligotherapy. This refers to trace elements as found in the human body under normal, healthy conditions and which play a role as catalysts in maintaining physiological life functions. Examples are tissue salts and other HPUS minerals or elements.

Organotropic. This pertains to substances which act on the organs of the body; having affinity for the tissues (Plakiston’s Medical Directory, 2nd edn); or, as would be said in homeopathy, remedies which have an elective affinity for particular organs or tissues of the body. Another phrase (with the same meaning) found in the older homeopathic literature is “seat of specificity of action”.

Potency accord, potency spectrum. This is the mixing of two or more attenuations of the same remedy in one preparation.

Single remedy therapy. This is the use of a single ingredient remedy based on the similarity of that single remedy to the characteristic indications found in a particular, individual case of illness or imbalance.

Tautopathy is the administration of a homeopharmaceutically attenuated preparation of the same substances which caused a state of ill health to develop. This is analogous to the homeovitic or isopathic approach.

Ultramolecular. This refers to the homeopharmaceutical preparation of a remedy which has been attenuated to the 12th centesimal or 24th decimal dilution, or beyond, and in which, therefore, no molecules of the original or base substance of the remedy can statistically be present.

Another term found in the literature which has the same meaning is “submolecular”.

Many of these definitions are included in pharmacist Jay Yasgur’s *A dictionary of homeopathic medical terminology*.^[1] This is a very useful reference text for all homeopathic practitioners, classical as well as contemporary.

RESEARCH

One of the seminal studies in contemporary homeopathy was published in *Human Toxicology* by Cazin et al.^[2] and was entitled “A study of the effect of decimal and centesimal dilutions of arsenic on the retention and mobilization of arsenic in the rat”. This study proved the effectiveness of homeopathic arsenic in helping laboratory rats to detoxify arsenic. Interestingly, the researchers found that middle range potencies (14x) had the strongest effects. They also concluded that decimal dilutions (1–10x) augmented the elimination of arsenic more than centesimals. This is an example of the isopathic or homeovitic approach. This study was cited as part of a comprehensive review of a significant number of studies on detoxification using homeopathically produced substances.^[3] After careful review of 105 studies, the authors concluded that this approach was scientifically valid.

Because of their greater popularity in Europe, most reports on clinical trials of these types of formulations have been published in France and Germany. Typical of these studies are two conducted in Germany. One was a randomized, placebo-controlled, double-blind study which demonstrated the efficacy of a combination formulations in the treatment of knee injuries.^[4] Another controlled trial demonstrated the clinical efficacy of a complex formulation homeopathic ointment in the treatment of athletic injuries.^[5]

Clinical research in contemporary homeopathy has also been conducted in the UK. In 1980, a double-blind clinical trial was conducted of 20 different homeopathic remedies employed in the treatment of rheumatoid arthritis. A significant positive clinical response was found over the placebo-controlled study group.^[6]

In 1985, Dr David T. Reilly, a noted Scottish homeopathic physician, and his colleagues

began the first of three landmark studies on the effectiveness of contemporary homeopathic therapies over placebo. The first study demonstrated efficacy using isopathic pollens in treating hay fever.^[7] Its positive results led to a second study which was published in *The Lancet*.^[8] Mixed pollens prepared homeopathically again showed very positive results in the treatment of hay fever as compared with placebo. The reporting of these two trials created quite a stir in conventional medical circles. The results were again replicated in a third trial. On December 10 1994, *The Lancet* published the results of this third positive trial under the title “Is evidence for homeopathy reproducible?”^[9] The introduction to this study is quoted below:

A pilot study specifically designed to answer the question “Is homeopathy a placebo response?” suggested that it was not, a result replicated in a larger trial. As these findings were controversial, the original investigators approached independent colleagues in the University of Glasgow to find out if the result could be replicated in a third trial. The three studies used homeopathic immunotherapy in inhalant allergy as a model, the first two in hay fever, the third in asthma with the same main outcome measure – a visual analogue source of overall symptom intensity. We report the results of this third study and a meta-analysis of all three.

As interest in contemporary homeopathy grows, one can expect more research to be published in medical journals. Clinical studies of combination or complex formulations are now being published in the US. The Office of Alternative Medicine of the National Institutes of Health is currently funding pilot studies on homeopathy.

HOMEOPATHIC ORGANIZATIONS

The Homeopathic Pharmacopoeial Convention of the United States (HPCUS) is responsible for the US Homeopathic Pharmacopoeia, now in its revised eighth edition. HPCUS is composed of representatives from all constituents of the profession: production, clinical practice, distribution and educational organizations.

The American Association of Homeopathic Pharmacists (AAHP) represents the majority of companies that produce homeopathic formulations. It is a trade organization that interacts with the US Food and Drug Administration to preserve the legal status of homeopathy. The American Homeopathic Pharmaceutical Association (AHPA) is a newly formed group representing pharmacists with a special interest in homeopathy.

The National Center for Homeopathy (NCH) is a non-profit public educational organization. It disseminates information to the public about homeopathy and sponsors educational programs on homeotherapeutics to health care providers. The NCH publishes a monthly newsletter, *Homeopathy Today* [(703)548-7790]. It also maintains a directory of practitioners. A similar organization is the International Foundation for Homeopathy (IFH), which publishes *Resonance* [(206)324-8230].

The American Institute of Homeopathy (AIH), founded in 1844, is the oldest medical society in the US. It represents physicians that specialize in homeopathy and publishes the *Journal of the AIH* [(303)898-5477]. The Homeopathic Academy of Naturopathic

Physicians (HANP) comprises a membership of naturopathic physicians with an interest in homeopathy. It publishes the journal *Simillimum*[(503)829-5477]. The Chiropractic Academy of Homeopathy (CAH) represents chiropractic physicians with interests in homeopathy. It publishes a journal, *The Prover* [(303)226-1719].

CONCLUSION

Contemporary homeopathy is being used by greater numbers of informed individuals who have become aware of the need to be more responsible for their own health. A person who uses a homeopathic formulation for acute first aid at home will welcome its use in more serious, chronic conditions under the care of a practitioner.

Physicians interested in treating chronic illness in a natural, drugless way will find the use of contemporary homeotherapeutics, particularly for clearing and detoxification, a logical prelude to rebuilding with clinical nutrition and/or botanical medicines.

Chapter 37 - Environmental medicine

Walter J. Crinnion ND

INTRODUCTION

The 20th century with its promise of “better living through chemistry” has also brought a host of chemical toxin-related illnesses (referred to here as “environmental illnesses”). Recent articles in the medical literature have shown that the rate of cancers not associated with smoking is higher for those born after 1940 than before, and that this increase of cancer is due to environmental factors not related to smoking.^[1] We are also experiencing the new medical diagnoses of sick (closed) building syndrome^{[2] [3]} and multiple chemical sensitivity (MCS),^{[4] [5] [6]} both of which are known to be related to overexposure to environmental contaminants. The environmental toxins which cause the most problems are pesticides, solvents and heavy metals. The primary damage caused by the solvents and major pesticide classes is to disrupt neurological function.^[7]^[8] In addition to being neurotoxic, these compounds are profoundly immunotoxic and are often toxic to the endocrine system as well.^{[9] [10] [11] [12]} The adverse health effects are not limited to those systems only, as these compounds can also cause a variety of dermatological, gastrointestinal, genitourinary, respiratory, musculoskeletal, and cardiological problems. Heavy metals poison a diverse range of enzyme function, affecting virtually every system of the body.^[6]

ENVIRONMENTAL TOXIC LOAD

Prevalence of environmental toxins in humans

Our environment is currently flooded with chemicals that contaminate our air, our water, our food and ourselves. Since 1976, the Environmental Protection Agency (EPA) has been engaged in the National Human Adipose Tissue Survey (NHATS).^[13] In this study, adipose samples are taken from cadavers and elective surgeries from all regions of the country and the levels of toxins are measured. In 1982, they expanded beyond their original list to look for the presence of 54 different environmental chemical

toxins. Their results are a cause for great concern. Five of the chemicals – OCDD (a dioxin), styrene, 1,4-dichlorobenzene, xylene, and ethylphenol – were found in 100% of all samples. Another nine chemicals – benzene, toluene, chlorobenzene, ethylbenzene, DDE, three dioxins and one furan – were found in 91–98% of all samples. In addition, PCBs were found in 83% of all samples and beta-BHC in 87%. A total of 20 toxic compounds were found in 76% or more of all samples! These ongoing assessments have shown quite clearly that it is not a question of *if* we are carrying a burden of toxic xenobiotic compounds, but one of *how much* and how do they affect our health.

Additional studies have shown the same alarming facts. A CDC study of 5,994 persons aged 12–74 found that 99.5% had *p,p*-DDE at levels in the range 1–379 ppb.^[14] A study of adipose levels of chemicals in persons from Texas showed the presence of *p,p*-DDE, dieldrin, oxychlorodane, heptachlor epoxide and *para*-BHC in 100% of all samples.^[15] That study was done on adipose samples taken from autopsies, and was from older subjects. A study of 4-year-olds in Michigan showed the presence of DDT in over 70%, PCB in 50% and PBB in 13–21%.^[16] Nursing was the primary source of exposure for these children.

Sources of environmental toxins

This multiple chemical load is due to several decades of chemical exposure from contaminated air, food and water. Both outdoor and indoor air are contaminated with chemicals. The EPA's TEAM study has documented the following chemicals as 'ubiquitous' in the air:

- *p*-xylene
- tetrachloroethylene
- ethylbenzene
- benzene
- 1,1,1-trichloroethane
- *o*-xylene.

Those listed as "often present" were:^[17]

- chloroform
- carbon tetrachloride
- styrene
- *p*-dichlorobenzene.

This study found that air samples taken with a personal monitor attached to the study individuals showed higher levels of chemicals in the "personal" air space over a 24-hour period than in outdoor air samples. These elevated personal levels and elevated breath levels were more directly attributable to indoor air pollution. However, they did note that persons who visited a service station or a dry cleaner had elevated personal breath

levels of the solvents, as well as those who smoked and drove a vehicle during the day. They also found that certain occupations, such as chemical manufacturing, painting and plastic manufacturing, caused higher levels of exposure.

Testing for chemical residues on food has been routinely employed throughout the world. None of the studies has found food sources free of contamination. On the contrary, multiple contaminants are usually found. The most comprehensive for the United States is the ongoing FDA Total Diet Survey.^[18] While the Total Diet Survey looked for the presence of many different chemicals, their findings for chlorinated pesticides, listed in [Table 37.1](#) , are alarming. For example, DDE was found in 63% or more of the 42 foods sampled.

The foods with the highest concentrations of DDE were:

- fresh or frozen spinach (mean concentration, 0.0234 ppm)
- butter (mean concentration, 0.0195 ppm)
- collards (0.0126 ppm)
- pork sausage (0.0124 ppm)
- lamb chops (0.0113 ppm)
- canned spinach (0.0109 ppm).

Since DDT and DDE have been banned from use in the US since 1972, it is likely that some of this contamination is from produce imported from other countries where it is still used.

Unfortunately, since toxic chemicals are ubiquitously used throughout the world, they move easily around the globe on the winds. Unless these pesticides are trapped in the soil, tree bark, or other stable materials, persistent volatile pesticides, including DDT and toxaphene, begin a wind-driven leapfrogging around the globe.

The more volatile the chemical, the faster it hops and the less readily it enters the fat of any plant or animal

TABLE 37-1 -- Presence of DDT in US food samples

| Food | Percentage of samples contaminated |
|---|---|
| Raisins, spinach (fresh and frozen), chili con carne (beef and bean), beef | 100 |
| American processed cheese, hamburger, hot dogs, bologna, collards, chicken, turkey, ice cream | 93 |
| Lamb chops, salami, canned spinach, meat loaf and butter | 87 |
| Cheddar cheese, pork sausage, quarter pounders, white sauce, creamed spinach | 81 |

* DDE is formed by a partial dechlorination of DDT. This can occur in the human body within 6 months of exposure to DDT. It also occurs in nature, but studies vary as to the half-life ($t_{1/2}$) of DDT in nature. Previously, the $t_{1/2}$ of DDT was thought to be 2 years, but recent findings in Yakima, Washington, indicate that it may be decades in certain circumstances. Upon degradation the DDT becomes DDE or DDD.

it contacts. Volatile chemicals applied in tropical regions evaporate into the atmosphere and then condense in cooler climates. As the ambient temperature falls, the compound becomes less volatile, so the periods between hopping of a compound from one place to another tend to lengthen. So, if two forests were exposed to identical amounts of a volatile pesticide, trees in the colder climate would become more heavily contaminated.

DDT and DDE are less volatile than solvents and do not leapfrog as well, and so tend to stay where they land and may be there for a year before jumping again. This global leapfrogging can account for one alarming study of the diet of Arctic indigenous women. The diet of two groups of women (from the eastern and western Canadian Arctic) were found to be very high in organochlorine compounds (OCC). The primary sources of these compounds were the meat and blubber of ringed seal, walrus, mattak and narwhal, as well as caribou, whitefish, inconnu, trout and duck.^[19] Since these OCCs were transported in the air, they landed in the Arctic, but due to the low temperature were unable to volatilize again and leapfrog away.

HEALTH EFFECTS OF ENVIRONMENTAL TOXINS

While there is virtually no debate left about whether our world is polluted or not, there is a considerable amount of debate as to whether or not these environmental toxins have adverse health effects on humans. This chapter provides information that supports the concept that accumulation of recurrent low-level exposures to environmental toxins is damaging to health. Enough evidence of a positive association between chemical exposure and disease exists to document that a serious problem exists and that caution is urged.

An article published in *JAMA* in 1994 by Devra Lee Davis et al,^[20] entitled “Decreasing cardiovascular disease and increasing cancer among whites in the United States from 1973 through 1987, good news and bad news”, showed that while heart disease was declining, cancer mortality for men and women born after 1940 was much higher than for previous generations. These cancers were not linked to smoking, but were relegated to other environmental factors. For men the rate of cancer was 200% of that of previous generations, and for women the rate was 50% higher. Not only are cancer rates rising, but there is currently an alarming rise in the incidence of asthma, especially among children throughout the world. These incidents appear to be associated with ambient pollution levels. Much has also been said about the estrogenic effect of certain environmental chemicals and the devastating effect upon wildlife, and possibly humans as well.

There is, therefore, much evidence to indicate that several chronic health problems

appear to be related to environmental chemicals. For the purpose of this chapter, the discussion is confined to the known immunotoxic, neurotoxic and endocrinotoxic effects of these environmental chemicals.

Immunotoxicity

Environmental chemicals have a wide range of damaging effects on the function of the immune system. These range from decreased cell-mediated immunity (with a decrease in infection and tumor fighting) to increased sensitivity (allergy) and increased autoimmunity.^[21] ^[22] ^[23]

Organochlorine compounds

Among the organochlorine compounds (OCCs), DDT has been found to have many damaging effects on the immune system:

- reduced killing capacity of PMNs
- reduced number of plasma responder cells
- increased degranulation of mast cells
- leukopenia
- decreased phagocytic ability
- changes in the spleen, thymus, and lymph glands
- variation in complement
- disturbances in fetal and perinatal immune regulation.

Similar effects have also been found after exposure to hexachlorobenzene (HCB) and the chlordanes (also OCCs).^[23] Hexachlorobenzene is a chlorinated pesticide used as a fungicide. It is also found to be present in chlorinated solvents such as perchloroethylene, which is used in dry cleaning and is very elevated in individuals from western Europe. Chlordanes were primarily used as termiticides in the US and Canada until 1978 when they were banned from use in the home. They are still used on certain crops and in some seed treatment.

Studies of thousands of patients at the Environmental Health Center-Dallas have shown that persons with two or more OCCs present in their serum have some form of immunotoxicity.^[24]

Polycyclic aromatic hydrocarbons

The chemicals produced by combustion, the polycyclic aromatic hydrocarbons (PAHs), have been shown to have similar inhibiting effects on the immune system, including:^[25]

- decreased T-cell-dependent antibody response
- decreased splenic activity
- diminished T-cell effector functions
- suppression of T-cytotoxic induction

- lower natural killer cell activity.

They are also highly carcinogenic.

Organophosphate pesticides

The organophosphate pesticides (OPs), which are not as biologically persistent as the OCCs, are also toxic to the immune system. They have been found to cause decreased percentages of CD₄ and CD₅ cells, increased number and percentages of CD₂₆ cells, increased incidence of atopy and antibiotic sensitivity, and high rates of autoimmunity. This elevation in autoimmunity is reflected by high levels of antibodies to smooth muscle, parietal cells, brush border, thyroid, myelin and elevated ANA.^[26] Similar immunosuppression is also found for the organotins and for the heavy metals.^[26]

The mode of exposure to the pesticide appears to have an effect on the persistence of immunotoxicity, as demonstrated by two polybrominated biphenyl (PBB) spills. One exposure took place in Taiwan when rice bran cooking oil was contaminated with PBBs. Those who used this oil for cooking were found to have immune abnormalities. One year after exposure, they were found to have decreased concentrations of IgM and IgA (with normal IgG), low T-suppressor cells, low B-cells and suppression of delayed hypersensitivity to recall antigens. When rechecked 2 years after exposure, the above indices had returned to normal. This was not the case in Michigan, where a massive PBB spill occurred in 1973/74. During that time, a PBB-containing flame retardant called "Firemaster" was inadvertently sold as an animal feed called "Nutrimaster". This mistake was devastating to both the livestock and those who raised them and consumed their products. Exposed individuals were found to have lower levels of circulating T-lymphocytes and reduced lymphoproliferation response, resulting in reduced cell-mediated immunity (CMI). They also had a high prevalence of persistent skin, neurological and musculoskeletal symptoms.^[27] These changes have persisted in all subsequent studies. This seems to indicate that when these toxins are concentrated in the food chain before reaching humans, their effect is longer lasting.

(For a good review of numerous studies of the immunotoxicity of pesticides the author recommends Repetto & Baliga^[28]).

Autoimmune disease

The development of autoimmunity has been linked with chemical exposure as well. The notion of chemically induced autoimmune states is, of course, not new since many chemicals are known to induce the onset of SLE. Some chemicals, like formaldehyde and other volatile organic compounds, are thought to induce tissue-specific autoimmune reactions by acting as haptens. These low-molecular-weight molecules will bind to various tissues in the body, making a new antigenic combination. The immune system

then makes an antibody to this new

TABLE 37-2 -- Abnormalities found in patients with exposure to industrial chemicals^[30]

-
- Either very low activity or very high activity when compared with controls
-
- Lymphocyte blastogenic response to T-cell mitogens (PHA, CONA) and B-cell mitogens were between 30 and 45% lower than controls
-
- Elevated IgG and IgM levels against formaldehyde, trimellitic anhydride, phthalic anhydride, and benzene ring. These rates were usually higher in persons with elevated T4/T8 ratio, which was found in almost 15% of the exposed patients
-
- Autoantibodies against their own tissue

combination which can attack the parent tissue with or without the chemicals being present. Chemically exposed individuals will often present with elevated antibodies to certain body tissues, including anti-myelin, anti-parietal, anti-brush border, and anti-smooth muscle.^[29] The abnormalities found in a study of 298 patients exposed to industrial chemicals are shown in [Table 37.2](#) .

Toxin-associated cancers

As mentioned earlier, the Davis et al^[20] study showed that men born in the 1940s had twice as many cancers as those born in 1888–1897, and more than twice as many cancers not linked to smoking. Women born in the 1940s had 50% more cancers, and 30% more cancers not linked to smoking (whites). In the following, we present a condensed version of the voluminous amount of information available in the literature associating cancers with environmental toxins.

Breast cancer

One of the cancers that has very clear association with environmental chemicals is breast cancer. Three studies have shown elevated levels of different OCCs in the adipose tissue of breast cancer patients as compared with controls. The chemicals found to be higher in the women with malignancies were DDT, DDE, PCBs and HCH (hexachlorocyclohexane; also known as Lindane or BHC, this is a chlorinated pesticide that is still commonly used to treat lice infestations (Kwell shampoo)).^{[31] [32] [32A] [33] [33A]} Not only are they higher in the adipose tissue of breast cancer patients, but they are actually found in higher concentrations in the malignant tissue than in adjacent healthy tissue.^[31]

Serum levels of OCCs have also been associated with an increased risk of breast cancer. Elevated levels of DDE and PCB in the serum can indicate a fourfold increased risk of breast cancer compared with normal risk (which is already too high).^{[32] [32A]} The author has found that individuals with breast cancer often have both higher levels and greater numbers of individual OCCs than other patients. If Wolff et al's information is correct,^{[32] [32A]} then serum testing of OCCs may provide an easily obtained

and reliable means of assessing breast cancer risk. The presumption may then be made that early detection of elevated levels of DDE and PCB, followed by prompt treatment, could conceivably drastically reduce the risk for developing breast cancer in certain individuals.

Childhood cancers

Childhood cancers have also been evaluated for epidemiological association with chemical exposure. In one study, 45 childhood brain cancer patients were compared with 85 friend controls. A significant positive association was found between brain cancer and exposure to no-pest strips, termite treatment, Kwell shampoo (Lindane), flea collars on pets, diazinon use in the garden or orchard, and the use of herbicides in yard (odds ratio [OR], 6.2). When compared with 108 controls, a significant positive association was found with pesticide bombs in the home, termite treatment, flea collars on pets, insecticide use in the garden, carbaryl in garden, and herbicide use in the garden.^[33] ^[33A]

Several other studies of childhood chemical exposures found the following associations:

- 2,4-D (a common weed killer) use around the home associated with soft tissue sarcomas (OR, 4.0)^[34]
- no-pest strips in the home associated with leukemia (OR, 3.0)
- insecticide use in the home associated with brain tumors for those aged <20 (OR, 2.3)
- household pesticide use associated with leukemia (OR, 4.0)
- garden pesticide use associated with leukemia (OR, 5.6)
- household insecticide use associated with non-lymphocytic leukemia (OR, 3.5).

2,4-D, a chlorophenoxy acid herbicide, gained notoriety from its combination with 2,4,5-T to form a mixture known as "Agent Orange". It is commonly used by municipalities and states to spray roadways and rights-of-way to keep the weeds down. It can be purchased at home stores for home lawn care and is often applied by chemical lawn care companies. It contains several dioxin contaminants and, in my opinion, is quite toxic to animals, children and adults.

For adults, the use of chlorophenoxy acid herbicides (2,4-D) has been strongly associated with an increased incidence of lung cancer, stomach cancer, leukemia, Hodgkin's lymphoma (two studies found a fivefold increased risk), non-Hodgkin's lymphomas (NHL, five- to sixfold increased risk), and soft tissue sarcomas (many studies have shown a five to sevenfold increased risk, with one review study finding a 40-fold increased risk).^[35] One study showed Kansas farmers having a sixfold increased risk of lymphomas and soft tissue sarcomas in persons using it 20+ days/year compared with non-exposed individuals. Those who mixed and applied herbicides and

were exposed 20+ days/year were eight times as likely to contract NHL.

Factors associated with increased risk of NHL from 2,4-D exposure are:

- increased period of time of exposure
- not using protective equipment
- using backpack or hand sprayers
- employing tractor-mounted or mist blower sprayer
- applying herbicides aerially.

Hematologic malignancies

Several studies have associated exposure to solvents with acute myelogenous leukemia (AML), multiple myeloma, and other forms of leukemia. A retrospective cohort study of 14,457 workers exposed to trichloroethylene between 1952 and 1953 showed that mortality was increased for multiple myeloma and NHL in white women.^[36] In a Finnish study, workers exposed to 1,1,1-trichloroethylene showed excess cancers of the cervix uteri and lymphohematopoietic tissues. After 10 years (from the first measurement), excess pancreatic cancer and NHL were seen. At a 20 year follow-up, excess multiple myeloma and cancer of the nervous system were found. Workers exposed to trichloroethylene showed (after a 20 year follow-up) an excess of cancers of the stomach, liver, prostate, and lymphohematopoietic tissues.^[37]

A review article revealed that there have been 280 cases of aplastic anemia associated with pesticide exposure reported in the literature. The majority of these cases were young (average age 34) with a short latency (mean, 5 months) and had a history of occupational exposure to pesticides.^[38] Another study which looked at the cancer risk for painters showed increased cancer rates for multiple myeloma (OR, 1.95), bladder tumors (OR, 1.52), as well as kidney and other urothelial tumors (OR, 1.45).^[39] A study in Sweden of 275 confirmed diagnoses of multiple myeloma showed a clear association between farming and multiple myeloma. This study revealed that exposures to chlorophenoxy acid herbicides (2,4-D) and DDT were prime risk factors.^[40]

Neurotoxicity

The nervous system is a particularly sensitive target for toxic agents for several reasons, as listed in [Table 37.3](#).

Besides the nervous system being such a good target, there are powerful neurotoxic agents available to attack it. Most of the major classes of pesticides kill pests by attacking their nervous system. They are neurotoxins by design. The OCCs affect the nerve by disrupting the ion flow along the axon. The OPs, which came out of nerve

TABLE 37-3 -- Reasons for the high sensitivity of the nervous system to toxins

-
- The adult neuron does not divide, and therefore replacement of lost neurons is not possible. Nerve cells killed by toxins cannot regenerate
-
- The blood–brain barrier does not block non-polar substances or items that are actively transported
-
- Since the normal function of the nervous system requires the action of a complex integrated network, damage to even a small portion of the nervous system can sometimes result in marked effects on function
-
- Neurons are dependent on glucose and oxygen, and some cell bodies exist at borderline levels of O₂. If high-energy demands are placed on the system, and delivery of O₂ is reduced, then cell death may occur
-
- Because of high lipid content (myelin) there is an accumulation and storage of lipophilic xenobiotics
-
- Neurons have high surface areas and therefore increased exposure to toxins

gas research, and carbamates affect acetylcholinesterase, resulting in excessive acetylcholine levels in the synapses. Solvents, some of which were originally used as anesthetics, dampen the propagation and transmission of electrical impulses along the nerve axons. All of these agents produce various forms of toxic encephalopathy (either acute or chronic, selective or diffuse toxic encephalopathies), as neuronopathies, axonopathies, myelinopathies or vasculopathies.

Neuronopathies

Neuronopathies can be diffuse or selective, depending on whether specific neurons are affected, or if the damage is more broadly spread throughout the nervous system. The target site of toxic agents producing neuronopathies is the nerve cell body, with the consequence of either axonal or dendritic breakdown.

An example of a neurotoxin causing diffuse neuronopathy is methylmercury which preferentially damages the granule cells of layer IV in the visual cortex, granule cells in the granular layer of the cerebellum, and the sensory neurons of the dorsal root ganglia.^[26] This brings about neuronal degeneration, progressing to necrosis with axonal dystrophy and demyelination. Another is aluminum which causes fatal dialysis encephalopathy following 3–7 years of intermittent dialysis. Although brain aluminum levels were elevated, there was no evidence of neurofibrillary tangles in these patients, indicating that the presence of aluminum alone is insufficient to lead to the senile dementia of the Alzheimer's type.

The neuronopathies can also be selective, affecting only certain neurons. Examples of agents causing selective neuronopathies would include adriamycin, which affects the dorsal root ganglia; cisplatin, which affects sensory neurons; and manganese (metal

fume fever), which produces a Parkinson-like syndrome.

Manganese-induced damage is found in the substantia nigra, globus pallidus, and caudate nucleus, with depletion of dopamine and serotonin levels. Symptoms begin with psychiatric changes followed by impaired motor activity with muscle rigidity and tremors. Parkinsonism is also caused by MPTP, a contaminant found in synthetic heroin.^[41] This compound has brought on sudden Parkinson-like symptoms rapidly after exposure to the heroin. MPTP is metabolized in monoamine-oxidase (MAO) containing tissues to MPP+, “the ultimate neurotoxin to MAO-containing tissues” which is selectively toxic to substantia nigra cells. It effectively blocks dopamine production.^[42]

Axonopathies

Axonopathies are differentiated by the area of the axon that is affected. The proximal axon is different in its ability to initiate action potentials and to synthesize protein. Damage to this part of the axon is referred to as proximal axonopathy. This is the type of damage seen in amyotrophic lateral sclerosis (ALS). Proximal axonopathies are often caused by volatile organic compounds – e.g. halomethane, methylene chloride, carbon tetrachloride, and butane – all of which decrease the excitability of the neuron by stabilizing membranes and decreasing ion flux. Distal axonopathies have been shown to be caused by a variety of compounds including Acrylamide (a polymerizing agent to strengthen paper) which primarily affects sensory fibers, and carbon disulfide (a solvent for fats and lacquers and for extraction of oil from olives, palmstones and other oil-bearing fruits) which produces distal axonopathy to both sensory and motor fibers. It also decreases norepinephrine levels. Hexacarbon solvents lead to multifocal distal progressive sensorimotor axonopathy with giant axonal swelling. Paranodal demyelination of swollen axons occurs frequently with exposure to these solvents.

The group of compounds that causes distal axonopathies also includes the OPs (Parathion, malathion, diazinon, etc.) and the carbamates. OPs cause acetylcholinesterase enzymes to be phosphorylated. Exposures may be additive and the effects may last until more acetylcholinesterase is synthesized. Carbamates (carbaryl, sevin, aldicarb) cause the acetylcholinesterase to be carbamylated. This is not a stable bond, and is hydrolyzed fairly easily.

Myelinopathies

Myelinopathies are caused by the organotin, which are used as stabilizers in plastic polymers and catalysts in silicon and epoxy curing. They are also used in wood and textile preservation as fungicides, bactericides and insecticides. Examples of the organotin are TET and TMT. Hexachlorophene (HCP) added to soaps for antimicrobial

action also causes damage to the myelin. It is readily absorbed through intact skin and mucous membranes. Like TET and TMT, it causes blurred vision and muscular

weakness progressing to paralysis. The optic nerve is particularly susceptible to HCP. The optic nerve is also sensitive to particular solvents, such as ingested methanol and ethanol, inhaled trichlorethylene, toluene, CS₂, and benzene. Other solvents can lead to specific myelinopathies, as the trigeminal nerve is especially sensitive to trichloroethylene (found in dry cleaning fluid). Hearing loss is commonly caused by toluene, styrene, xylene, and trichloroethylene, which causes myelin damage to the vestibulocochlear nerve. Other toxins, such as carbon monoxide and cuprisone (a copper chelating agent used in the treatment of Wilson's disease), are examples of toxins affecting the maintenance of myelin.

Lead, a well-known neurotoxin, brings about encephalopathy by causing vascular changes leading to neuronal degeneration and necrosis as well as by causing neuronal degeneration itself. Early stages of plumbism include headache and nausea. Demyelination of motor nerves is also seen with lead.

Endocrinotoxicity

With the exception of the rodenticide Vacor, agents that affect endocrine function, other than reproduction, tend to be compounds with extensive effects on other organs as well (heavy metals, pesticides, solvents). It would be very unusual to find an endocrine disorder as the sole or primary manifestation of an environmental toxicity.

The most common symptoms of toxic damage to the endocrine system are listed in [Table 37.4](#).

Adrenal gland

In addition to the well documented estrogenic effect of the OCCs, actual damage to the endocrine organs is also noticeable. Aliphatic compounds (3–6 carbons in length with electronegative groups on both ends) cause necrosis of zona fasciculata and zona reticularis of the adrenals, where the glucocorticoids are produced. OCCs and carbamates have caused histologic changes to these areas in animal models.^{[26] [43]} Cadmium and CCl₄ have both been shown to cause non-specific inhibition of steroidogenesis.

TABLE 37-4 -- Common symptoms of toxic damage to the endocrine system

-
- Sleep disturbances or changes in energy level or mood
-
- Alterations in weight, appetite and bowel function
-
- Sexual interest and function change; in females any menstrual change
-
- Changes in temperature perception, sweating, or flushing
-
- Alteration of hair growth and skin texture

Occupational lead workers showed decreased secretions of corticosteroids, both glucocorticoids (17-hydroxy) and androgenic steroids (17-keto). In these persons, the

lesion was apparently at the hypothalamus/ pituitary level because normal ACTH response was found with stimulation. Dioxins and mirex (used to treat fire ants) cause direct suppression of glucocorticoid synthesis, resulting in hypoglycemia.

Thyroid

The thyroid is not immune to environmental toxins, as many chemicals can cause a reduction of both T4 and T3. Thiocyanates, perchlorates and pertechnetates are all competitive inhibitors of iodine transport in the thyroid, causing decreases in T4 and T3 and an increase in TSH. Compounds which inhibit the thyroid peroxidase needed in the second step of thyroid hormone synthesis include:

- thiourea
- thiouracil
- PTU
- carbimazole
- aniline derivatives
- PABA
- substituted phenols like resorcinol
- phloroglucinol.

Iodide and lithium block thyroid hormone release from the gland itself. Depressed levels of thyroid function have been correlated with exposures to lead, carbon disulfide, and PBBs. Lead workers, a heavily studied population, appear to suffer from a decrease in thyroid secondary to problems with the hypothalamus (TRF). In Michigan, PBB-exposed persons showed non-goitrogenic thyroid dysfunction. Less well documented, but suggested to adversely affect the thyroid, are:

- organophosphates
- carbamates
- OCCs
- fungicides
- food coloring
- PCBs
- mercury (animal studies).

Inducers of hepatic cytochrome P450 like phenobarbital, benzodiazepines, calcium-channel blockers, steroids, retinoids, chlorinated hydrocarbons, and polyhalogenated biphenyls will (in addition to inducing P450) cause alteration in thyroid structure, leading to reduction in T4.^[25]

Besides causing reduced functioning, some compounds will also cause thyroid cancer. Polycyclic hydrocarbons, nitrosamines, and other compounds are initiators of thyroid carcinogenesis. A common component of permanent hair dye preparations, 2,4-diaminoanisole sulfate (2,4-DAAS), when fed at high doses, caused a 58%

incidence of thyroid neoplasms in male rats and 42% in females, compared with 7–8% in controls.^[25]

Reproductive

The effect of environmental chemicals, especially the estrogenic OCCs, are well documented. While many are estrogenic by themselves, when combined together their estrogenicity can increase by a factor of 1,600. Some combinations can also cause previously non-estrogenic compounds to become estrogenic.^[44] The facts about environmental estrogens have been cogently set forth in Theo Colborn et al's recent book *Our Stolen Future*, and the reader is directed to that excellent resource for a comprehensive discussion^[45]. However, there are also non-estrogenic toxic effects of the OCCs on both male and female reproduction. High levels of OCCs in the serum have been strongly linked to infertility, stillbirths and miscarriages.^[46] Urban air pollution has been associated with reduced male fertility.^[47] While there appears to be a worldwide decline in the sperm levels of males,^[48] males who are organic farmers have very high sperm density.^[49] This gives rise to the supposition that exposure to environmental chemicals lowers sperm levels, and that avoidance of such chemicals may help to bring the levels back up. There have been multiple studies on one OCC that is used agriculturally – dibromochloropropane (DBCP) – looking at its effect on sperm levels. These studies have demonstrated that exposure to DBCP leads to azospermia, and severe oligospermia.^[50] This may be only associated with DBCP or it may serve as a model of other OCC-induced spermatogenesis problems.

DIAGNOSIS

History

A comprehensive history is the cornerstone of detecting chemically induced health problems. When taking a history, special attention should be paid to both occupational and non-occupational chemical exposures. Occupational exposures are usually the easiest to document, and should always be followed up with a request for the material safety data sheet on each chemical from the employer. Non-occupational exposures are harder to document, but in a family practice are often found to be the main culprit. Specific questions should be asked about the history of residences:

- where the patient lived
- how new the structure is
- age of carpeting
- time of remodel
- type of heating
- use of indoor or outdoor pesticides
- attached garage, etc.

Once the history of residential exposure is garnered and compared with the chronological symptom history, the answer may become quite clear.

Laboratory

Given the ubiquitous nature of the chemicals in question, a history may not always provide a clear picture of exposure. Laboratory tests may be helpful in these cases. The standard CBC and general blood chemistry tests are usually non-remarkable in cases of chronic low-level exposures (although the author has often found leukopenia in his population of toxic patients). In addition, liver enzymes, even when solvents and pesticides are present in the serum, are rarely elevated.^[51] Serum tests for the presence of OCCs and solvents are invaluable in detecting such problems. When interpreting these tests, the clinician must keep in mind that the laboratory “normals” generally reflect the average level found in the blood of the most toxic population in the country (the population tested by the laboratory), not the average American. There is no “RDA” for pesticides or solvents, and the presence of any of these compounds should be cause for concern. It should also be kept in mind that serum levels of these compounds are generally lower than tissue levels. This has been demonstrated with DDE in which 1 ppb in the serum will indicate that 5–10 ppb would be found in the brain, 47 ppb in the liver, and 100–300 ppb in the adipose tissue.

If the patient has been exposed to OPs or carbamates, then plasma or RBC cholinesterase levels can be measured. Unfortunately, it is often difficult to assess an OP or carbamate pesticide exposure with this method unless a pre-exposure cholinesterase was obtained for use as a baseline. If that was not done, then a follow-up cholinesterase test may be done after 3 months, provided that the patient does not return to more exposures.

Carbon monoxide exposure can be easily checked with a carboxyhemoglobin level.

If the patient is poisoned by a chemical that cannot be tested for in the serum or urine, then other tests can be considered. Immune panels including T and B sub-sets, autoantibody panels, chemical antibodies, and NK activity will all indicate that toxin-induced damage to the immune system has occurred.^[23]

Neurotoxicity can be diagnosed by SPECT scans,^[52] evoked response audiometry,^[53] balance testing, and measurement with an iris corder. It can also be indicated when a positive Rombergism is present.^[25]

TREATMENT

The basics of effective treatment for chemically induced illnesses are:

- avoidance of further exposures
-

- supplementation to support chemical elimination and antioxidant protection mechanisms
- reduction of the body burden of xenobiotics.

Avoidance

Avoidance of further chemical exposure cannot be overlooked, although compliance is often very difficult to obtain. In cases of multiple chemical sensitivity, avoidance is indispensable. Compounds to be avoided include:

- solvents
- paints
- exhaust fumes
- perfumes
- hair sprays
- new furniture
- carpeting, and cabinetry
- plastics
- gas or oil heat, etc.

Since the home is the environment that is most in the patient's control, the home must be made a "safe oasis". If there are building materials that are off-gassing chemicals and these materials cannot be removed, they should be sealed. A number of good books are available to help with this process.^[54] ^[55] ^[56] If the living space has molds present, an ozone generator can be used to clear out the molds. It is very important that no one be present in the home when an ozone generator is being used, as ozone is a potent respiratory sensitizer.

In addition to avoiding environmental chemicals, any foods that cause adverse reactions should be avoided (see [Ch. 51](#)). Organically grown foods should be consumed wherever possible as well as purified water. Air purifiers can be used to help reduce the level of chemicals in the indoor air. Charcoal or Hepa filters do the best job of clearing toxins out of the air, but some plants do an admirable job as well. In a study from NASA, five plants were found to be the most effective in cleaning the air:^[57]

- Mass cane (*Dracaena massangeana*)
- Pot mum (*Chrysanthemum morifolium*)
- Gerbera daisy (*Gerbera jamesonii*)
- Warnecki (*Dracaena deremensis* "Warnecki")
- ficus (*Ficus benjamina*).

If plants are chosen as the preferred method for cleaning the air, then the specific room to be cleaned must have many plants put in it. A single plant in a normal-sized room will have no effect. The author generally tells his patients to "make your home a jungle".

Those that have complied with these instructions invariably report that their symptoms decreased after the plants were introduced.

Nutritional support

Nutritional support is aimed at two main areas: critical cofactors for enzymatic biotransformation of xenobiotic compounds, and antioxidants. Additional supplementation will undoubtedly be needed to address the organ systems and tissues that have been damaged by the xenobiotic compounds. However, that is not the focus of this chapter.

Protein

Metabolism of toxic chemicals and drugs has been shown to be impaired by protein deprivation (see [Table 37.5](#)). Increased toxicity of chemical compounds and drugs have been reported with protein deficiency. Protein deficiency decreases the activity of liver mixed function oxidase (MFO) systems, which results in an increase in the half-life of numerous toxic chemicals and drugs and potentiates drug action and toxicity. The quantity and quality of protein in the diet alter both phase I and phase II liver drug metabolism processes (a gelatin diet induces very low MFO activity). The toxicity of OCCs, acetylcholinesterase inhibitors, herbicides, and fungicides have all been shown to be increased several-fold by protein deficiency. Reduced clearance and increased half-life of antipyrine are found in Asian vegetarians eating a low-protein diet. This was not found in Caucasian vegetarians with adequate protein intake.

While protein deficiency clearly reduces the ability of the body to adequately metabolize chemicals, the oppo-site also appears to be true.^[58] Isocalorically increasing of the ratio of dietary protein to carbohydrate in well-nourished volunteers has been shown to enhance clearance of antipyrine and theophylline. While it is not clear if the effect of the protein is due to the amino acid content alone, it is known that methionine and cysteine deficiency leads to reduction of intestinal and hepatic MFO enzyme activity. Hepatic MFO activity can also be suppressed by folic and choline deficiency. Low methionine intake also impacts selenium metabolism by making less selenium available for GSH-peroxidase biosynthesis. High sugar intake is also known to reduce the clearance rate of certain chemicals from the liver.

Vitamin E

Vitamin E is a well known stabilizer of membranes and therefore facilitates a suitable environment for the

TABLE 37-5 -- Effects of a low-protein diet on detoxification

-
- Decreased cytochrome P450 content of liver, secondary to decreased quantity of microsomal protein
-
- Decreased NADPH-cytochrome P-450 (c) reductase
-
- Decreased cytochrome b5
-

- Decrease in hepatic GSH
 - Increased liver UDP-glucuronyltransferase (phase II)
-

296

synthesis and activity of membrane-associated enzymes that protect against toxin damage. In addition, it has antioxidant properties. Although CCl₄ does not cause liver damage via lipid peroxidation, vitamin E partially prevents CCl₄ hepatotoxicity.

Pretreatment of animals and humans with vitamin E prior to ozone and nitrous oxide exposure has been shown to provide partial protection against the toxicity of these agents.

Vitamin A and beta-carotene

Beta-carotene is required for epithelial cell differentiation and regulates the stability of biological membranes. It quenches singlet oxygen species non-chemically and is essential for a normal estrogen cycle. Beta-carotene also protects against singlet oxygen-induced damage.

Deficiency of vitamin A is associated with increased binding of benzo(a)pyrene to tracheal epithelia. Organophosphates, DDT and PCBs will decrease the vitamin A content in the liver which increases their toxic effect on the body. In another example of how veterinarian nutritional care is more advanced than human care, an intramuscular injection of 1,500,000 units of vitamin A is given yearly to cattle to treat organophosphate poisoning. OPs are applied directly to the animals once yearly to take care of insects that would otherwise cause problems with the cattle. The author has not yet heard of the farmers who apply these pesticides by hand to each of their cattle ever getting the vitamin A injection!

Other items that lower vitamin A levels are:

- alcohol
- coffee
- cold weather
- cortisone
- diabetes
- excessive iron
- infections
- laxatives
- liver disease
- mineral oil
- nitrates
- sugar
- tobacco
- vitamin D deficiency

- zinc deficiency.

Thiamin

Thiamin depletion occurs from excess formaldehyde exposure or any other items that increase aldehydes (alcohol, *Candida*, etc.), because the coenzyme of thiamin (TPP) is used to metabolize the aldehyde group. Magnesium is also used in this process. Thiamin also serves as a coenzyme (TPP) for pyruvate dehydrogenase and alpha-ketoglutarate dehydrogenase. Besides being used in the phase II pathways, thiamin is needed to restore oxidized GSH.

Thiamin deficiency increases the toxicity of PCBs, dieldrin, heptachlor and the aniline dyes. These compounds can also lead to thiamin deficiency, which enhances their toxicity.

Treatment of cattle with 100 mg/day of thiamin prevents clinical signs of lead poisoning and death.

Riboflavin

Riboflavin is a component of the coenzymes in various flavoprotein enzymes required for oxidation/reduction reactions. Liver microsomal flavoprotein NADPHcytochrome reductase supplies reducing equivalents to cytochrome P450. These are essential for proper functioning of the phase I biotransformation pathways. Riboflavin facilitates the destruction of azo dyes in the liver by MFO, thereby protecting against azo dye-induced cancer. Riboflavin is also used in the glutathione reductase pathways, which work with SOD to block free radical damage.

Niacin

Nicotinamide is a component of two related coenzymes NAD and NADP which are oxidized to NAD^+ and NADP^+ , and are reduced to NADH and NADPH. These are needed for the proper functioning of phase I. This vitamin is used in the deamination of amino acids, fatty acid synthesis, and beta-oxidation of fatty acids. It also participates in steroid formation and drug metabolism.

Pyridoxine

Exposure to carbon disulfide (CS_2), PCBs and penicillamine has been shown to disrupt the normal function of vitamin B_6 . Chronic exposure to these compounds can cause B_6 deficiency. Dr Rea has stated that 60% of the chemically sensitive patients at EHC-Dallas are deficient in this nutrient, whether or not they are taking oral supplements.^[6]

Low B_6 can lead to low taurine levels. When taurine is low, extreme sensitivities to chlorine, chlorite (bleach), aldehydes, alcohols, solvents, and ammonia can develop.

Vitamin B₆ deficiency also results in a poor ability to conjugate epinephrine and serotonin.

Vitamin C

A cellular antioxidant, ascorbic acid scavenges free radical superoxides and hydroxyl radicals. It protects against phenol, phenylquimolin, carboxylic acid and barbiturate toxicity. It protects against ozone-induced pulmonary edema, O₂ toxicity and CCl₄ toxicity. It reduces

297

the toxicity of pesticides, heavy metals, hydrocarbons, PCB, and acetaminophen. It enhances MFO activity (there is decreased cytochrome P450 activity in vitamin C deficiency) and enhances the incorporation of iron into heme. Vitamin C prevents nitrosamine formation from nitrites in the gastrointestinal tract, and protects against lead and cadmium toxicity.

Elevated levels of dietary vitamin C may facilitate metabolic degradation of xenobiotics by liver MFO. Conversely xenobiotics will increase vitamin C excretion in the urine.

Iron

Iron plays a central role in the heme-containing molecules of cytochrome P450 and hemoglobin. However, there is no apparent increase in phase I levels with supplementation of iron. Aniline metabolism is most sensitive to iron deficiency, and increases susceptibility to lead toxicity, yet there is a decrease in MFO activity in iron-overloading states.

Magnesium

A deficiency of magnesium was found in 40% of the chemically sensitive patients at EHC-Dallas.^[6] Deficiency of magnesium leads to decreased amounts of cytochrome P450 and NADPH cytochrome reductase, both of which are essential to the proper functioning of phase I. Decreased hydroxylation of aniline, and demethylation of aminopyrene are seen in cases of magnesium deficiency. Fortunately, magnesium supplementation reverses both of these effects.

Selenium

Selenium is a required component of glutathione peroxidase (GSH-PX) which maintains integrity of cellular and subcellular membranes, as well as being one of the main molecules for phase II xenobiotic conjugation. Fortunately selenium supplementation increases GSH-PX levels, something that reduced glutathione supplementation does not appear to do. This feat is also accomplished by supplementation with *N*-acetyl

cysteine and L-cysteine. This provides us with a low-cost, reliable method to increase GSH levels. Selenium reduces the toxicity of lead, and increases biliary excretion of cadmium and mercury. It also prevents the typical cadmium-induced decrease of Cyto-P450.

Selenium deficiency increases the toxicity of numerous xenobiotic compounds.

Zinc

Both deficient and excess zinc can influence the metabolism and detoxification of xenobiotics. Zinc deficiency decreases enzyme function, but excess zinc decreases cytochrome P450 levels! Zinc deficiency also causes a reduction of GSH levels.

Glutathione (GSH)

Not only is glutathione crucial to the glutathione conjugation pathway, one of the phase II pathways, but it is also one of the main molecules that quenches the peroxide molecules in the body, especially in the liver. While many naturally minded physicians give reduced glutathione to their patients in the hope of helping to increase their levels, there is insufficient evidence to support this practice at the present time. There is only one human study on oral glutathione absorption, and the subjects showed no increase in their glutathione levels with oral supplementation.^[59] All of the other studies reported the use of injectable or food source GSH rather than oral doses. On the other hand, there have been many studies showing that supplementation with selenium, N-acetyl cysteine, cysteine, vitamin A and vitamin E can increase GSH levels.^[60] Other compounds such as the botanical medicine *Silybum marianum* have also been shown to increase the GSH level. Vitamins E and C, as well as cysteine have all been shown to inhibit GSH depletion and lipid peroxidation after endrin exposure.

Botanical medicines

The two major botanical medicines useful in treating chemical toxicity are *Silybum marianum* (milk thistle) and *Curcuma longa* (turmeric). The reader is referred to the [Chapters 111](#) and [80](#) further information.

Depuration (cleansing)

The removal of impurities from the body is known as depuration. This is the preferred term for cleansing xenobiotics from the body. The commonly used term “detoxification” means to remove or alter the toxic quality of a compound. Since healing for the toxic person involves removal of the actual xenobiotic from the body, rather than mere alteration of the compound, the word depuration will be used.

There are only two methods of xenobiotic depuration discussed in the scientific literature. Most of the published literature is from one of the Health Med clinics, associated with the Church of Scientology, who are doing the “Hubbard purification rundown”. This protocol utilizes exercise, high temperature saunas, increasing doses of

niacin, and electrolyte replacement. They have published several studies showing the benefit of this protocol for reducing levels of PCBs, PBBs, and HCBs.^[61] ^[62] ^[63] Their studies, along with unpublished data from William Rea MD at the Environmental Health Center-Dallas have

shown that sauna therapy will bring about a reduction of the xenobiotic levels in treated individuals.

The only published treatment besides sauna therapy that has shown benefit in treating poisoned individuals is fasting (see [Ch. 47](#)). This has been documented in a study which looked at individuals poisoned by PBB-contaminated rice bran cooking oil in Taiwan.^[64] While fasting reduced their symptoms, it increased the level of circulating xenobiotics in their serum. Presumably the elevation of circulating toxins is due to the increased rate of lipolysis in fasting individuals. Thus the fat-soluble PBBs were released from storage into the bloodstream at higher than normal rates. At that point, it would be up to the liver to clear these out of the serum or they would be redeposited into the adipose tissue. More research is obviously needed on the role of fasting in the treatment of environmental overload.

A comprehensive naturopathic protocol for treating environmentally poisoned individuals was developed by the author and has been used for over 10 years. An outcome study on patients who underwent this protocol for a variety of chemically induced ills showed it to be surprisingly effective. Of the subjects (with various problems) treated with the depuration protocol, 83% rated their results as good or great. The two conditions in which 100% of the participants reported great results were asthma ($n = 3$), and addiction recovery ($n = 1$). The problem (chief complaint) categories in which 100% of the participants rated their results as moderate, good or great were autoimmune, dermatological, and GI/liver. The categories with the next highest ratings of moderate, good or great were fatigue, with 92% improvement; allergies, with 85% improvement; and chemical sensitivities, with 84% improvement.^[65]

The Crinnion depuration protocol

The Crinnion depuration protocol consists of the following components:

- *Exercise*— daily exercise usually consisting of using an exercycle, rebounder or brisk walking to begin lipolysis and diaphoresis.
- *Thermal chambers*. Up to three 60 minute “sauna” sessions are done with temperatures at a range of 120–135°F with cool-down periods in between. Glass bottled spring water is given along with electrolyte replacement. While the Hubbard clinics use higher temperatures, we find that individuals will put out more toxins (as evidenced by stronger chemical odors) and will experience less adverse symptoms when the lower temperatures are used. The thermal chambers will increase the rate of lipolysis in the adipose tissue throughout the body. When this occurs the lipophilic

xenobiotics will be released into the bloodstream. The compounds in the subcutaneous fat pads will be mobilized through sweat as well as into the blood.

- *Constitutional hydrotherapy*– the use of alternating hot and cold towels with sine wave stimulation as done by pioneering naturopaths Drs O. G. Carrol and Harold Dick. This therapy has been used for decades to stimulate the body’s own self-healing activity. We have found that it also increased the amount of toxin-laden bile dumped from the liver into the intestines. Also assisting the cholerectic and cholegogue action on the liver is a herbal capsule taken daily consisting of *Chelidonium*, *Chionanthus*, *Taraxacum*, *Arctium lappa*, *Silybum marianum* and *Urtica dioica*.

- *Colonic irrigation*. Gravity-fed machines are used to gently introduce triple-filtered water into the large intestines, providing an avenue for the toxic bile to rapidly leave the body. Individuals will routinely have “liver dumps” of bile that ranges in color from yellow to red, with occasional gray or brown. The color of bile normally ranges from green to yellow to orange to red depending upon the amount of time of exposure to bacterial action in the bowel. However, in this situation we believe that it is dumped from the liver and rapidly passed through the small intestines, similar to what is seen in “gastric dumping” syndrome. We are therefore unable to account for the differences in color of this effluent. In some patients with heavy agricultural exposure, we have seen higher amounts of fluorescent yellow bile. Hence, the color of the bile may be more attributable to the chemical compounds in the bile than the bacterial action upon the bile. We have documented that chlorinated pesticides are present in this effluent that we refer to as “bile dumps”.

- *Constitutional homeopathy*. This has been used primarily as a stand-alone treatment with the use of any other supplements or treatments prohibited. However, we have found it to be a valuable component of this protocol and completely compatible with all the other treatment methods involved. It appears most beneficial in those individuals who need a boost for their vital force to facilitate their moving toward healing, and for those who are stuck in emotional issues that they haven’t been willing to look at.

- *Body therapies (massage, shiatsu, craniosacral, visceral, spinal and joint adjustment)*. These are done as needed for the individual to treat specific musculoskeletal problems and to assist in mobilizing toxins that were stored in the tissues.

- *Counseling*. Mental and emotional toxins are as big a problem as physical/chemical toxins. When people are exposed to powerful emotional toxins (abuse, etc.) that they have no outlet for handling, they end up “stuffing” the emotional toxins. When this “emotional stuffing” occurs, any physical toxins that they were exposed to at that time are also “stuffed” (stored) rather than being eliminated. Because of this, when they start to mobilize the physical toxins, the old emotional issues will come

back into consciousness. When this occurs and individuals choose once again to suppress the emotional issues (rather than facing them), their physical cleansing will also stop. This is evidenced by the observations that they will stop sweating in the thermal chambers, stop heating the cold towels in the hydrotherapy and stop having good liver releases during the colonic therapy. When the emotional “toxins” are

faced and released, these cleansing parameters are returned to former levels. Assisting all of the individuals going through this depuration protocol with their emotional issues helps them to cleanse physically. (See [Ch. 4](#), especially the section "Utilize altered states of consciousness", for a more complete discussion of the role of past emotional states and associations in the development and maintenance of disease.)

This protocol is utilized on a daily basis that usually lasts between 4 and 8 weeks (five sessions weekly). The protocol begins the depuration process which must then be continued once the individual returns home. Most individuals will need to continue regular cleansing (use of home saunas, hydrotherapy and colon therapy) for at least 12 months after completing their intensive in-office cleansing. When testing for serum levels of OCCs and solvents is repeated along with immune parameters after 12 months, improvements are routinely seen. In addition to symptomatic relief, improvements in the laboratory reports (decrease in serum xenobiotics and reduction in autoantibodies, etc.) is clearly evident.

Treatment overview

- Avoidance of further chemical exposure through air, food and water
- Nutrient support for transformation, elimination, and antioxidant pathways
 - vitamin C: 6,000–12,000 mg/day
 - vitamin E: 400–1,200 units of D-alpha-tocopherol daily
 - B-complex: once daily
 - vitamin A: 25,000–50,000 units/day (unless the person is a menstruating female who is at risk for pregnancy)
 - N-acetyl cysteine: up to 1000 mg t.i.d.
 - selenium: 300–600 mcg/day
 - Silybum marianum* (standardized): 100 mg two to three times/day
 - adequate protein in diet with each meal
 - magnesium: 300–600 mg/day
 - psyllium husks powder: begin with 0.5 tsp in water nightly (to bind bile in the intestines)
- Depuration protocol
 - daily exercise
 - thermal chambers (low temperature saunas)
 - constitutional hydrotherapy

- colonic irrigations
- constitutional homeopathy
- body work
- counseling

SUMMARY

Environmental chemicals are ubiquitous in our environment. Once they enter the body they bioaccumulate and are stored in adipose tissue throughout the body. They alter the functioning of the immune system, nervous system and endocrine system, leading to a host of chronic problems. The diagnosis of xenobiotic-induced damage can be elucidated by a comprehensive history along with evidence of serum toxin levels and toxin-induced immune system damage.

Chapter 38 - The exercise prescription

Bobbi Lutack MS ND

INTRODUCTION

The publication of Dr Kenneth Cooper's book, *Aerobics*, in 1968, had a profound influence on the exercise habits of Americans. Sedentary men and women all across the country were prompted by the book's message to take up aerobic training programs. Aerobics became the exercise catchword, and the fitness boom had begun. Running was the primary aerobic exercise, and beginning in the mid-1970s, marathon running became popular. More than 20,000 runners now annually participate in the New York, London, and Glasgow marathons.

In 1984, however, running took a giant step backward with the death of Jim Fixx, an internationally known runner and author who died of a massive myocardial infarction while running in Vermont. With him died an exercise myth: marathoner immunity to heart disease.

While a complete description of the physiologic changes induced by exercise is beyond the scope of this chapter, the following review will help provide a basis for understanding the exercise prescription. The basics of exercise physiology will be reviewed, considering the benefits and adverse effects of exercise with regard to the primary and secondary prevention of chronic lifestyle diseases, and the potential contraindications to exercise will be discussed. Special topics are also discussed. The reader is encouraged to peruse the position papers listed in [Appendix 1](#) for additional resources.

EXERCISE PHYSIOLOGY

Exercise places significant metabolic and cardiorespiratory stress on the body. At maximal exertion, skeletal muscle increases its metabolic rate 50-fold, the overall metabolic rate 10-fold, and cardiac output from fourfold to as much as sixfold in the physically fit (due primarily to a threefold increase in heart rate).^{[1] [2]} In healthy

individuals at submaximal workloads, the relationship between heart rate and oxygen uptake is essentially linear.

The physiological effects of exercise depend on the

302

intensity, duration and frequency, as well as the type of exercise. Isometric exercise (increase in muscle tension without a shortening in muscle length) increases peripheral vascular resistance without a significant change in cardiac output. Isotonic exercise (shortening of muscle with little increase in tension) increases cardiac output and decreases peripheral vascular resistance. Isometric exercise increases muscle strength and bulk, but has little effect on cardiorespiratory conditioning, while isotonic exercise increases endurance and cardiorespiratory conditioning, the goal of most exercise programs.

Well-conditioned individuals typically have lower heart rates than those who are sedentary. This is thought to be due to increased vagal tone, decreased sympathetic activity (probably due to the drop in beta-adrenergic receptor density), and increased stroke volume.^[2] The best overall measurement of physical fitness is $\dot{V}O_{2\max}$, which decreases with age; for example, a 60-year-old has only two-thirds the $\dot{V}O_{2\max}$ of a 20-year-old. This trend is, however, much less apparent in those who exercise regularly. Three weeks of bed rest will cause a 20–25% decline in $\dot{V}O_{2\max}$, while sedentary individuals can increase their $\dot{V}O_{2\max}$ by 30–40% by engaging in a program of moderate exercise.^[2]

MUSCLE PHYSIOLOGY

Skeletal muscle is composed of two types of fiber: red fibers (type I) and white fibers (type II). The red fibers are high in myoglobin content, mitochondria, and oxidative capacity but are low in glycolytic enzymes and slow in contraction time. White fibers are lower in myoglobin content, mitochondria, and oxidative capacity, and high in glycolytic enzymes and myosin ATPase activity, and fast in reaction time.^[2] Sprinters have high proportions of white fibers for high-intensity exercise, while long-distance runners have a preponderance of red fibers. It is unclear, however, if training can alter the phenotype of muscle fibers.^[3]

As skeletal muscle contains only limited amounts of high-energy phosphate compounds – preformed adenosine triphosphate (ATP) and creatine phosphate (CP) muscle stores are inadequate for a 100 yard dash – energy must be generated during exercise. Three sources of fuel are available to skeletal muscle:

- endogenous muscle glycogen
- blood glucose

- free fatty acids (FFA) derived from muscle triglycerides stores or adipose tissue.

[Table 38.1](#) lists the body's relative proportions of each of these energy stores.

The intensity of exercise determines the substrate utilized. Low-intensity exercise and exercise well within the aerobic limits preferentially utilize free fatty acids

TABLE 38-1 -- Energy stores available to skeletal muscle

| Body store | Size of store (kcal) | Running distance (miles) |
|-------------------|-----------------------------|---------------------------------|
| Blood glucose | 40 | 0.5 |
| Liver glycogen | 220 | 2.2 |
| Muscle glycogen | 380 | 3.8 |
| Adipose tissue | 100,000 | 1,000 |

(FFAs) first, and muscle glycogen second. Catecholamines, released early in exercise, stimulate adipose lipase, which cleaves triglyceride into glycerol and three FFAs. Serum FFA levels of six times the normal level are rapidly induced during exercise. In muscle, FFAs are metabolized to acetyl CoA, which undergoes oxidative metabolism in the citric acid cycle to produce ATP production during exercise; (see [Fig. 38.1](#) and [Fig. 47.2](#) in [Ch. 47](#)).^{[2] [4]}

As the exercise intensity increases, glycogen becomes more important than FFAs, contributing twice the energy at 80% maximal work capacity and virtually all at 100%. While within the aerobic limit, glycogen is metabolized in the cytoplasm to pyruvate, which then enters the citric acid cycle. When sufficient oxygen is not available, in anaerobic metabolism, energy is produced by glycolysis (only 5% as efficient), and pyruvate is reduced to lactate instead of entering the citric acid cycle. The resulting acidosis limits muscular performance, and buffering by bicarbonate generates CO₂, causing tachypnea.^{[2] [4]}

THE COMPONENTS OF PHYSICAL FITNESS

There are five components of physical fitness:

- cardiovascular endurance
- muscular strength
- muscular endurance
- flexibility
- body composition.

Cardiovascular endurance

Cardiovascular endurance refers to the ability of the heart, lungs, and blood vessels to function optimally both at rest and during exercise. From the exercise specialist's point

of view, it is the most important component. This variable is addressed through the aerobic portion of an exercise program. Aerobic is defined as the ability to process and deliver enough oxygen to meet tissue energy needs. At work loads above 80% of maximum, skeletal muscle demands more oxygen than can be delivered, thus exceeding the aerobic limit.^[2] As muscle metabolism becomes anaerobic, energy is produced by glycolysis rather than glucose oxidation. This results in the build-up of lactic acid, requiring the buffering of bicarbonate.

303

Figure 38-1 Muscle energy metabolism.

The subsequent CO₂ release results in increased respiratory rate, a sensation of dyspnea, and progressively decreased work capacity. (Although some athletes inhale 100% of oxygen after intense activity to hasten recovery and improve subsequent performance, this has proven to be ineffective.^[5])

To qualify as an aerobic activity, the exercise must be continuous, rhythmical, use large muscle groups, and be performed at an intensity that significantly increases cardiovascular output. Examples of aerobic exercise include running, cross-country skiing, cycling, swimming, skating, hiking, etc. The aerobic concept, applied to physical fitness, requires following specific training guide-lines. If pursued regularly and with proper intensity and duration, this training:^[6]

- strengthens the respiratory muscles
- increases breathing efficiency
- stabilizes or lowers blood pressure
- improves tissue capacity to utilize oxygen and dispose of waste products
- increases muscular endurance
- increases heart function and circulation
- controls body weight
- provides increased energy
- promotes psychological well-being.

Cardiovascular endurance can be measured in the physician's office with a graded exercise test on a treadmill or bike, or in the field with, for example, the popular 12-minute walk-run (see Cooper^[7] for a detailed description) on a measured course. The distance covered correlates well with maximum oxygen consumption.^[7]

Muscular strength

Muscular strength refers to the ability of a muscle to exert force against resistance. Typically, strength is defined relative to maximum force-producing capabilities. A simple, but accurate, estimate of strength, referred to as the “one repetition maximum”, is to have an individual lift as much as he or she can lift just one time. Upper and lower body strength can be assessed using exercises like the bench press and the leg press.^[8] As a rule of thumb, the ability to bench press one’s own body weight indicates good upper body strength.

Muscular endurance

Muscular endurance is the ability of a muscle or muscle group to sustain repeated contractions of a given force over time. This ability is highly correlated with strength.

304

Push-up and sit-up tests have traditionally been used to determine muscular endurance, although abdominal “crunches” or half sit-ups are actually a better measure of abdominal endurance/strength. An example of good muscular endurance for a 30-year-old male is the ability to perform 35–39 timed (60 second) sit-ups. For a 30-year-old female, 25–39 modified push-ups and 31–35 timed (60 second) sit-ups would indicate good muscular endurance.^[8]

Flexibility

Flexibility is the ability to move a muscle through its full range of motion, which involves the interrelationships between muscles, ligaments, tendons, and joints. Range of motion is restricted by a lack of flexibility and the performance of routine movement is hindered. It is difficult to test flexibility as it is joint-specific, but one test that is frequently used to test low back, hamstring, and hip flexibility is the “sit and reach test”. This test is described in detail in [Appendix 1](#) . A good score is 19–21 inches.^[8] An exercise program which incorporates stretching and yoga exercises can increase flexibility.

Body composition

Body composition is the interrelationship between lean body mass (muscle, bones, and connective tissues) and body fat. For optimal fitness, high levels of lean tissue and relatively low levels of body fat (about 20% for women and 15% for men) are desirable. The percentage of body fat can be measured quickly, accurately, and relatively inexpensively in a physician’s office through the use of skinfold calipers (we recommend high-quality calipers such as Lange or Harpenden). Several skinfold sites must be measured to maximize accuracy. One set of recommended measurement sites for women comprises the thigh, triceps, and suprailium, and for men the thigh, chest, and

abdomen. These measurements are then used in a regression equation or a table (such as the one found in Pollack et al,^[8] p. 220) to estimate body fat. The body fat percentages are based on Siri's underwater equation, where percentage fat = $[(4.95/Db) - 4.5] \times 100$, where Db is the body density. (See [Chapter 175](#) for a discussion of one- and four-site skinfold measurement techniques and interpretive tables.)

THE EXERCISE PRESCRIPTION: BASIC GUIDELINES

Many people are confused about the type and amount of exercise necessary to become fit. Knowledgeable and accurate instructions are important to help prepare an exercise program that meets the specific needs of each individual. The American College of Sports Medicine (ACSM), an internationally recognized expert organization in the field of exercise science, has published a position paper (see [Appendix 1](#)) on the proper exercise prescription for healthy adults. This paper, based on existing documentation from throughout the world, summarizes the most widely accepted guidelines for developing and maintaining cardiovascular fitness and optimal body composition. The following is a summary of its content.

Cardiorespiratory conditioning

The essential components of cardiorespiratory exercise

There are four essential components of a sound cardiorespiratory exercise program:

Type of activity. Aerobic (defined previously).

Intensity. The exercise has to be strenuous enough to place an “overload” on the cardiorespiratory system. This corresponds to 60–90% of maximum heart rate. To calculate maximum heart rate (MHR), subtract the individual's age from 220. Multiplying this figure by 0.60 and 0.90 yields the target heart rate (THR), i.e. the range of sufficient intensity to overload the cardiorespiratory system. For example, for a 40-year-old:

- MHR = $220 - 40 = 180$ bpm
- $180 \text{ bpm} \times 60\% = 108$ bpm
- $180 \text{ bpm} \times 90\% = 162$ bpm
- THR = 108 –162 bpm.

Although the MHR covers a wide range, it is useful as a ball park measure of how to determine the intensity of exercise.

To further increase the accuracy of intensity evaluation, a rating scale of perceived exertion (RPE) can be used. The Borg scale of perceived exertion is a good example.^[9] The Borg scale is numerical, ranging from 6 to 20, with corresponding verbal descriptions provided at odd numbers of how hard the exercise feels. For example, a rating of 6–7 corresponds to “very, very easy”, while a rating of 19–20 corresponds to “very, very hard”. The RPE response to graded exercise correlates closely with cardiorespiratory and metabolic variables such as heart rate. As a valid and reliable

indicator of the level of exertion of a given exercise, it can be used to prescribe intensity. A rating of 12–13 (described as “comfortable” to “somewhat hard”) corresponds to about 60% of MHR and a rating of 15–16 (expressed as “hard”) corresponds to about 90% of MHR.^[10] When prescribing an exercise program, a perceived exertion range of “comfortable” to “hard” is the recommended intensity level. When used in conjunction with the THR at the beginning of an exercise program, it helps participants to develop a physical and cognitive “feel” for how hard exercise should be. Once this knowledge is obtained, RPE can be used as the primary indicator of intensity.

Duration. This is inversely related to intensity. Duration of aerobic exercise, exclusive of warm-up and cooldown, typically varies in length from 15 to 60 minutes. A common conditioning phase is 30 minutes. High-intensity exercise requires a shorter duration for the same cardiovascular effect, and vice versa. High-intensity, short-duration exercise is not recommended until good cardiovascular conditioning has been achieved. A good rule of thumb to gauge a proper intensity/duration ratio is the degree of fatigue experienced 1 hour after exercising.

Frequency. Three to five exercise sessions per week are recommended, with no more than 48 hours between workouts. Depending on the level of fitness, intensity, duration, and motivation, sessions can be daily. With less than three sessions per week, improvement in cardiorespiratory endurance is minimal and there is no loss in body fat.^[11]

When instructing previously sedentary individuals on how to exercise properly and become conditioned, emphasis should be placed on making progression slowly. People who have been sedentary for years will require time to rebuild their bodies. It is better to do too little than too much. All too often, people who are motivated to “get back in shape” will over-exert themselves their first time out (e.g. by jogging 2 miles instead of combining walking and jogging). When they wake up the next day with sore muscles and unaccustomed pain, they give up on the exercise program. The old adage “no pain, no gain” is an exercise myth (except in strength building, as noted below). The aerobic exercise component of a physical fitness program should feel fairly comfortable. Being able to talk with an exercise partner while working out suggests an appropriate level of exercise, while breathlessness and inability to carry on a conversation indicates excessive intensity. Being able to sing suggests too little intensity.

The three phases of cardiorespiratory exercise

In addition to the components of mode, frequency, intensity and duration, the effective exercise session is divided into three phases:

- warm-up
- cardiorespiratory conditioning

- cool-down.

The warm-up phase should be of 5–10 minutes' duration and should prepare the body for the conditioning activity. Light calisthenics, stretching and/or the conditioning activity performed at a light intensity (approximately 50% of the intensity of the conditioning phase) are suitable warm-up activities. Breaking into “a light sweat” is a sign that the body is warming up. Proper warm-up may also help to prevent exercise-induced muscle pulls, strains and soreness.^[12]

The conditioning phase is the 15–60 minutes of aerobic activity described earlier. Vigorous participation in sports is recommended as an enjoyable alternative but only after an adequate level of fitness is achieved. The adage “don't play sports to get in shape, get in shape to play sports” is sound advice.

The recommended cool-down is 5–10 minutes of tapering-off activity, such as slowing the intensity of the exercise performed in the conditioning phase, stretching, and then relaxing for a short period. For most people, the heart rate should be under 100 bpm at the end of the cool-down period.^[12] The major purpose of this phase is to keep the primary muscle groups involved in the conditioning phase moving, to prevent peripheral pooling of blood, which can cause a vaso-vagal response. Cooling down can also help to prevent muscle soreness.^[8]

Muscular conditioning

Most of the attention for exercise program prescriptions has focused on the cardiovascular component, probably due to the belief of exercise authorities that cardiovascular fitness is the most important component. However, flexibility, strength and muscular endurance also form an important part of any physical fitness program. Sound musculoskeletal function is necessary throughout life to make daily living activities easier to perform, to help prevent low back problems, and to help prevent the inevitable loss of lean body tissue as one ages. As lean body mass is lost, a concomitant decrease in basal metabolic rate and strength occurs.

Individual exercise prescriptions for developing muscular endurance and strength should be tailored to the sport being played or to the individual's goals. Weight loss (fat loss), for example, would necessitate a different prescription from power lifting. For a general overall strength/endurance-building program, the following guidelines may be used:

- *Mode* – free weights, universal, Nautilus, Cybex, calisthenics, etc.
- *Duration* – one to three sets of five to 15 repetitions (optimal strength gains appear to be achieved with five to seven repetitions if the muscle is maximally fatigued). Allow about 1 minute's rest between sets.
- *Intensity* – the intensity (weight lifted) should be such that only five to 15 repetitions can be performed. The adage, “no burn, no gain” has much validity.
- *Frequency* – 3–5 days per week (5 days only after preconditioning). Allow at least a 24 hour rest period between workouts of the same muscle group (i.e. a complete day of rest between workouts).^[8]

- Example:
 - Monday: upper body workout
 - Tuesday: lower body workout
 - Thursday: upper body workout
 - Friday: lower body workout.

Proper and safe strength training requires emphasis on form, technique and execution. The following guidelines will help to maximize the effects and minimize the risks of exercise programs:^[10]

- *Warm-up.* To prepare the muscles for the intense effort that lies ahead, stretch and perform a few repetitions with about 50% of the weight to be used during the training sets.
- *Controlled movement.* Control all movements to achieve steadiness. Do not “throw” the weight. For maximum strengthening benefits, at the height of the lift or at its fullest extension or flexion, pause briefly before lowering the weight. A good routine is to lift for 2 seconds, pause and then lower for 4 seconds.
- *Muscle group isolation.* Concentrate on isolating the muscle(s) being exercised and moving them through their full range of motion.
- *Fatigue avoidance.* Proceed from major muscle groups to minor muscle groups to minimize fatigue.
- *Proper breathing.* Do not hold the breath or perform the Valsalva maneuver. Exhale as the weight is lifted and inhale as it is lowered.

For additional information, please refer to [Appendix 1](#) .

Flexibility conditioning

Flexibility is necessary to ensure maintenance of adequate range of motion of all joints. Decreased flexibility can lead to the common complaint of low back pain (discussed further below).^[8] Stretching should be done at least three times per week (ideally before and after each workout) and can be part of the warm-up and cool-down phases of the cardiovascular portion of the fitness program. Stretching should be preceded by a mild warm-up (e.g. light calisthenics), and the exercises tailored to the muscles being worked. Stretches should be performed slowly and progressively, using a dynamic movement followed by a static stretch held for 30–60 seconds. The stretch should cause a feeling of tightness but no pain.^[13]

At this point, a note of caution is necessary. The above recommendations and guidelines are designed for apparently healthy, asymptomatic adults. According to the

ACSM, apparently healthy individuals under the age of 45 can begin and participate in exercise programs without prior stress testing; however, some screening prior to participation is recommended.^[10] The age, health status and type of exercise program the participant will be engaging in determines the degree of evaluation required. Individuals with known cardiac, pulmonary or metabolic disease or who have symptoms suggesting coronary artery disease and/or at least one major coronary risk factor should undergo a maximal exercise tolerance test prior to beginning a vigorous exercise program. The ACSM also recommends such a test for anyone who is 45 or older prior to participation in an exercise program.

EXERCISE AND SPECIFIC DISEASES

(Additional discussion of the current research into the benefit of exercise can be found in the chapters covering most of the following conditions.)

Coronary heart disease

Running was the popular aerobic exercise in the 1970s and was touted to have many beneficial side-effects. During its heyday, Dr Tom Bassler even proposed that marathoners were immune to heart disease.^[14] ^[15] The death of Jim Fixx in 1984 laid that theory permanently to rest.

The concept that regular aerobic exercise will provide some protection against the clinical manifestation of coronary heart disease (CHD) is generally accepted today by both the public and health professionals. Regular exercise, in conjunction with other risk-reducing behaviors, is believed to help protect against an initial cardiac event (primary prevention), aid in the recovery following a cardiac event (e.g. myocardial infarction, coronary artery bypass graft surgery, etc.), and help to reduce the risk of recurrent cardiac events (secondary prevention). The exercise conditioning effects that help to prevent CHD are listed in [Table 38.2](#) .

Although the etiology and pathogenesis of CHD and atherosclerosis are still not completely understood, multiple research approaches have identified several factors which play causative roles. Although a cause and effect relationship has yet to be definitively demonstrated, there are strong indications that regular exercise leads to reduced risk for CHD and its clinical manifestations of myocardial ischemia, myocardial infarction, and cardiac arrest.

Pioneering observational studies by Morris et al,^[18] Paffenbarger et al,^[19] and Taylor et al^[20] of London bus drivers and postal workers, longshoremen, and US railroad workers, respectively, were among the first to report an inverse correlation between CHD risk and physical activity. Another landmark investigation, the Framingham study, also indicated that moderate exercise was associated with decreased CHD risk.^[21]

TABLE 38-2 -- Exercise conditioning effects are potentially beneficial for the prevention of CHD^[16] ^[17]

| |
|--|
| <i>Serum lipid effects</i> |
| • Reduction of serum cholesterol and triglycerides |
| • Increase of serum high-density lipoproteins (HDL ₂) |
| <i>Metabolic effects</i> |
| • Lowering of circulating catecholamines – lowering of circulating by exercise |
| • Reduction of blood clotting – reduction by exercise; tendencies |
| • Increased fibrinolysis |
| • Increase of insulin sensitivity – increased by exercise |
| <i>Cardiac effects</i> |
| • Augmentation of coronary arterial bed |
| • Decrease of myocardial work and oxygen demand |
| • Increase of myocardial function (increased stroke volume) |
| • Reduction of systolic and diastolic blood pressure – reduction by exercise |
| <i>Miscellaneous effects</i> |
| • Improvement of psychological outlook – improvement by exercise |
| • Reduction of adiposity |

More recently, an observational study by Leon found physical inactivity to increase risk of heart attack, and the 7 year MRFIT study showed that moderate exercise reduced both fatal and non-fatal CHD events.^[22] ^[23]

Research has shown that higher levels of leisure-time physical activity are associated with increased longevity in college alumni, while Paffenbarger et al^[24] ^[25] have shown that it was physical activity as an adult, not college athleticism, that is associated with a decreased risk of death.

In a study conducted at the Cooper clinic in Dallas, Texas, the physical fitness and risk of all-cause and cause-specific mortality were followed in 10,000 men and 3,000 women for an average of 8+ years.^[26] The study concluded that poor physical fitness was an important risk factor in both men and women. Higher levels of physical fitness appeared to delay all-cause mortality, primarily due to lowered rates of CHD and cancer. This study is particularly important as it is the first large-scale study to include extensive

follow-up, maximal exercise tests, a wide range of physical fitness evaluations, an objective end-point (mortality), and a large enough sample of women to permit meaningful comparative gender analyses. The results of the study are useful from both a clinical and a public health standpoint.

In addition to lowering risk for developing CHD, aerobic exercise training has been shown to help in recovery from cardiac events (cardiac rehabilitation). ^[27] ^[28] ^[29]

One additional note of interest: until recently, most exercise scientists believed that only aerobic exercise training was beneficial in reducing CHD risk. Research now shows that weight resistance training also has a beneficial effect on CHD risk by favorably affecting lipoprotein-lipid profiles, insulin response to glucose ingestion, and blood pressure. ^[30] ^[31] ^[32] ^[33]

Hypertension

Exercise training clearly decreases the risk of hypertension. One study of 6,000 healthy adults found a 52% increased risk for hypertension in sedentary individuals compared with those who were fit, while another found a 35% increase. ^[34] ^[35] Regular exercise produces a sustained decrease in systolic and diastolic blood pressure and catecholamine levels in hypertensive patients. ^[36] One study of patients with mild hypertension found that half could discontinue their antihypertensive drugs after engaging in a regular aerobic program. ^[37] A note of caution: as isometric exercises cause an acute increase in blood pressure, static exercise by patients with significant hypertension should be supervised.

Cancer

Lack of regular physical activity has been linked to colon cancer, breast cancer, and lung cancer, with most of the research focusing on the link between fitness and colon cancer. ^[38] ^[39] ^[40] ^[41] Physical activity may reduce the incidence of colon cancer because it reduces intestinal transit time. ^[42] In the Cooper clinic study, higher levels of physical fitness were associated with delayed mortality partly due to lowered rates of cancer. ^[26]

Obesity

Physical inactivity may be a major cause of obesity in the US. Indeed, childhood obesity seems to be associated more with inactivity than overeating, and strong evidence suggests that 80–86% of adult obesity begins in childhood. In the adult population, Brownell and Stunkard found that obese adults were less active than their normal-weighted counterparts. ^[8] However, it is still unclear whether inactivity is a cause of obesity or a result of it. Despite the lack of definitive evidence, regular exercise should be prescribed for the obese due to the following factors:

- When weight loss is achieved by dieting without exercise, a substantial portion of the total weight loss comes from the lean tissue primarily as water loss. ^[43]
- When exercise is included in a weight-loss program, there is usually an

improvement in body composition due to a gain in lean body weight because of an increase in muscle mass and a concomitant decrease in body fat.^[44]

- Exercise helps to counter the reduction in basal metabolic rate (BMR) that usually accompanies calorie restriction alone.^[45]
 - Exercise increases the BMR for an extended period of time following the exercise session.^[10]
 - Moderate to intense exercise may have an appetite suppressant effect.^[10]
 - Those subjects who exercise during and after weight
-

reduction are better able to maintain the weight loss than those who do not exercise.^[46]

The concept of “spot reduction” is a myth.^[47] Exercise draws from all of the fat stores of the body, not just from local deposits. While aerobic exercise generally enhances weight loss programs, weight training programs can also substantially alter body composition, by increasing lean body weight and decreasing body fat.^[48] ^[49] ^[50] Research into the use of resistance training during energy restriction is limited, but preliminary evidence suggests that calorie restriction does not affect the strengthening or hypertrophic response of muscle.^[50] Thus, weight training may be just as, or more, effective than aerobic exercise in maintaining or increasing lean body weight and, therefore, the metabolic rate of individuals undergoing weight reduction.

Generally, aerobic exercise prescriptions for weight loss should emphasize long duration, low intensity, and a frequency of at least 3–4 days/week since, as the discussion of muscle metabolism above indicates, this type of exercise preferentially utilizes fatty acids from adipose stores. Swimming appears less effective than walking or cycling for reducing body fat.^[51] It takes 35 miles of walking or jogging to metabolize the calories contained in 1 pound of fat. [Table 38.3](#) lists the metabolic costs of various activities.

Weight loss (combined diet and exercise) should not exceed 2–3 pounds/week.^[10] For additional information, refer to the ACSM position statement in [Appendix 1](#).

Diabetes

The current treatment for type II diabetes is exercise, oral hypoglycemics, and dietary modification.^[10] Exercise is beneficial to diabetics as it increases insulin sensitivity and enhances the biological effects of endogenous insulin.^[52] As mentioned previously, exercise can also help by combating obesity and improving lipoprotein profiles.

Special precautions need to be taken when prescribing exercise for those with insulin-dependent diabetes, as exercise may induce hypoglycemia through its insulin-like effect. An exercising insulin-dependent diabetic needs to reduce insulin intake or increase carbohydrate intake. The following regime is recommended for

insulin-dependent diabetics who exercise to maintain blood glucose control:

1. Monitor blood glucose more frequently.
2. Decrease insulin dose (1–2 units or as needed) or increase carbohydrate intake (10–15 g per 0.5 hour of exercise) prior to an exercise session.
3. Inject insulin into a site that will not be active during exercise (e.g. runners might inject into the abdomen).
4. Avoid exercise during peak insulin periods.
5. Eat carbohydrate snacks before and during prolonged exercise sessions.
6. Exercise with a partner (in case of a hypoglycemic reaction).
7. Avoid late evening exercise.^{[10] [53]}
8. Wear a medical-alert bracelet.

The exercise prescription needs to be individualized, and in some cases exercise is not advisable due to poor metabolic control and/or frequent hypoglycemic reactions.^[53]

For type I diabetics, exercise consistency is most important.^[54] Daily exercise helps to maintain a regular pattern of diet and insulin dosage. Intensity can be prescribed in the normal range (i.e. 60–90% of MHR) and duration need only be 20–30 minutes per session, due to the high frequency.

Prescribing exercise for type II diabetics is not as complicated. As obesity is a key contributing factor to this type of diabetes, emphasis should be placed on high frequency (5–7 days/week), long duration (45–60 minutes per session), and low intensity (about 60% of MHR) for maximizing caloric expenditure from fat stores.^{[10] [52]}

Diabetic patients with advanced retinopathy should not participate in activities that jar or those that cause marked fluctuations in blood pressure. A non-jarring exercise like swimming is recommended.^[10]

TABLE 38-3 -- Metabolic costs* of various activities^[2]

| Occupational | Recreational | Energy used (kcal/min) |
|------------------------|--------------------------------|------------------------|
| Desk work, driving | Standing, walking | 2–2.5 kcal/min |
| Janitor, typing | Level bicycling | 2.5–4 |
| Cleaning windows | Cycling, 6 mph; walking, 3 mph | 4–5 |
| Painting, paperhanging | Dancing, table tennis | 5–6 |
| Digging in garden | Walking, 4 mph; skating | 6–7 |
| Shoveling, 10# 10x/min | Cycling, 11 mph; tennis | 7–8 |
| Sawing hardwood | Jogging, 5 mph; basketball | 8–10 |
| Shoveling, 14# 10x/min | Running, 5.5 mph; handball | 10–11 |
| Shoveling, 16# 10x/min | Running, >6 mph | >10 |

* Includes resting metabolic needs.

Pulmonary disease

In patients with advanced chronic obstructive pulmonary disease (COPD), dyspnea at progressively lower levels of exertion often results in deconditioning, which can lead to further disability. Although aerobic exercise will not improve indices of pulmonary function,^{[55] [56]} it may improve endurance and exercise tolerance.^{[56] [57] [58] [59]} In patients with mild to moderate asthma, 3 months of controlled, submaximal exercise can produce significant improvements in fitness and cardiorespiratory performance.^[60]

The effects of exercise are tempered by the severity of airway obstruction, which may vary from mild to severe. Individuals with mild COPD will respond to exercise in a similar way to patients with CHD, so the intensity can also be prescribed by the heart rate method. The recommended duration, frequency, and mode are also the same as for CHD patients.^[10]

Individuals suffering from more severe COPD who experience dyspnea with mild exercise will be limited by their dysfunctional respiratory systems. Supplemental oxygen may be used during exercise if a trial shows objective improvement in exercise capacity as a result of oxygen use; however, modifications to the exercise prescription will be required.^[10] Duration should be “as tolerated”, with perhaps two 10-minute or four 5-minute sessions/day to build up tolerance. As tolerance increases, sessions can gradually be reduced to 3–5 days/ week for 20–30 minutes. Intensity should be determined by signs of breathlessness. Lower body aerobic exercise, such as walking or cycling, is preferable to upper body exercise due to the higher ventilation requirement of upper body exercise.

Additional benefits of exercise therapy for pulmonary patients include improved mechanical skills in the trained muscles, particularly in the respiratory muscles, and improved psychological state.^{[61] [62]}

End-stage renal disease

Many patients with end-stage renal disease (ESRD) suffer from muscle weakness, fatigue, bone disease, CHD, and multiple psychosocial problems. Attention has recently been directed at rehabilitation of this patient group. Exercise training has been found to be especially beneficial for selected patients undergoing hemodialysis.

The incidence of ESRD in the United States is approximately 1 in 10,000 per annum, and the average age of patients on dialysis is 48.^[63] The most common treatment for

ESRD patients is hemodialysis.

A major study conducted at the Washington University School of Medicine and the Chrolalloy American Kidney Center using an aerobic exercise program on non-dialysis days found:^[63]

- a 19% increase in the duration of exercise tolerance
- a 21% increase in $VO_{2\text{ max}}$
- improvements in blood pressure and lipoprotein profiles
- lowered fasting plasma insulin
- a 27% increase in hematocrit
- a reduction of depression.

There were no changes in these parameters in the control group. Positive results were also reported by Squires et al^[64] with exercise training following renal transplantation.

Exercise training (specifically cycling) has also been performed during hemodialysis.^[65] The benefits are similar to those found with training on non-dialysis days. Because typical hemodialysis patients utilize an artificial kidney machine three times a week for 4–5 hours/ session, exercise training could help to alleviate the tediousness of the sessions and provide a supervised setting for exercise in this high-risk group of patients.

The exercise prescription for ESRD patients has to be a low-intensity (use the RPE method to designate intensity), non-weight-bearing (e.g. stationary cycling), interval (i.e. exercise period followed by a rest period) activity. Frequency should be at least 3 days/week and duration should be about 30–45 minutes. Exercise sessions should be monitored and adjustments made to accommodate any complications, e.g. an increase in serum potassium.^{[63] [66]}

Chronic pain

Pain is the leading symptom that prompts patients to see physicians. Today, virtually all pain management programs include some type of aerobic and/or weight training exercise program.^[67] Pain specialists attribute the positive effects of decreased sensitivity to pain and significant psychological benefit to exercise-induced elevation of endorphins.^{[68] [69]} A recent study proposed that prolonged rhythmic exercise activates central opiod systems by triggering increased discharge from mechano-sensitive afferent nerve fibers in contracting skeletal muscle and that many of the cardiovascular, analgesic, and behavioral effects of exercise are mediated by this mechanism. The authors also proposed that the same or similar mechanisms are responsible for the central and peripheral effects of acupuncture.^[69] Aerobic exercise may also help to reduce pain through promotion of delta sleep, the deepest stage of sleep, during which musculoskeletal renewal takes place.^[67] The two most common pain complaints are low back pain (LBP), affecting about 15% of Americans, and headaches.^[67]

Low back pain

While 90% of patients with back injuries return to work within 2 months, the remaining 10% account for billions of dollars in medical expenses, lost income and productivity, workers' compensation benefits, and litigation

fees.^[67] ^[70] It has been postulated that post-injury deconditioning, not the original injury, is the primary cause of the chronic pain condition and is frequently the major impediment to functional restoration.^[68] Reversal of post-injury deconditioning through a progressive, active physical exercise program can restore function and decrease pain. While healing may restore structural integrity, it does not restore flexibility, strength, endurance, or coordination. Unrecognized or untreated deconditioning can lead to the recurrence of pain on return to work or resumption of normal activities. It is theorized that high-resistance exercise training helps minimize pain by breaking down existing muscle fiber and stimulating its replacement with stronger and more flexible replacement fiber.^[67]

Arthritis

With arthritis, slight pain may have to be tolerated during exercise sessions in order to achieve the pain-alleviating effects of conditioning. Exercise producing excessive stress on osteoarthritic joints should be avoided, but a program designed to improve range of motion and muscle strength should be performed daily to combat the effects of disuse and decrease pain. Exercises of short duration and high frequency help to limit stress on the joints. Weight-bearing activities may have to be limited due to inflammation, but cycling, rowing, swimming, etc. are all acceptable modes of exercise.^[10] ^[71] There is no evidence to support the assertion that running causes degenerative joint disease. Since synovial fluid enters cartilage to provide nutrition through exercise-induced compression, it is possible that long-term repetitive exercise is actually beneficial for joints as well as bones.^[2] Excessive trauma is, however, associated with joint degeneration (see [Ch. 176](#)).

Peripheral vascular disease

Individuals with peripheral vascular disease (PVD) suffer claudication discomfort ranging from excruciating and unbearable pain to definite discomfort. Exercise can help to alleviate the pain. Frequency should be 7 days/ week, preferably with two periods of exercise per day. The duration should be at least 20 minutes (exercise might have to be intermittent), and the type of exercise should be aerobic (walking, stationary cycling, warm water exercise, etc.). The intensity will be determined by the level of pain (moderate discomfort or pain from which the patient can be distracted by conversation or other stimuli may have to be tolerated).^[10]

Mental health

A considerable body of knowledge attests to the mental health benefits associated with long-term aerobic exercise.^{[72] [73] [74] [75]} Improved mood has been observed in both non-hospitalized outpatients and normal individuals, as well as those suffering from psychopathology.^[76] Exercise may also help normal individuals as it decreases stress, and emotions such as anxiety, and decreases the sympathoadrenal response to stress found in men with a type A personality.^{[77] [78] [79] [80]} An “improved sense of well-being” has been reported by many people following exercise. In general, this has been attributed to a decrease in anxiety and depression.^[79] Exercise is almost as effective as antidepressant drug therapy in selected types of anxiety and depression.^[69]

Although studies are controversial, the endorphin hypothesis has become widely accepted as a mechanism by which exercise improves mood.^[81] The controversy is largely due to the inability of some investigators to block exercise-induced mood elevation with naloxone.^[69] Perhaps the dosages were insufficient or other mechanisms are in action. Evidence also indicates that aerobic exercise produces an effect in depressed persons that is similar to the effect caused by tricyclic antidepressants, i.e. it increases the production of the neurotransmitter norepinephrine. This exercise effect is not found in those who are not depressed.^[82]

Whatever the relationship, cause and effect, or association, there is sufficient evidence to support regular, vigorous exercise to promote psychological well-being. In general, the principles of exercise prescription described for healthy adults are also appropriate for those who suffer from mental illness.

EXERCISE IN SPECIAL CONDITIONS

Pregnancy

Many physically active women want to continue exercising during pregnancy. The currently accepted view is that this is satisfactory if they take some precautions. In addition to benefits cited earlier, exercising during pregnancy can:^{[83] [84] [85]}

- enhance self-esteem
- increase energy
- improve sleep
- decrease backache
- decrease problems with varicose veins
- decrease water retention
- improve posture and appearance
- possibly decrease labor complications
- shorten labor and postpartum recovery.

For trained women, exercise therapists typically recommend continuing the prepregnancy exercise program at the same “perceived level of exertion” (use RPE) during pregnancy. Women who previously have been

sedentary and want to exercise while pregnant should begin at a very low intensity and increase gradually.^[86]

General and relative contraindications include: hemodynamically significant CHD, toxemia, eclampsia, uncontrolled diabetes mellitus, uncontrolled hypertension, and obesity.^[10]^[87] Pregnant women should avoid participating in sporting activities that involve physical contact or that might induce a fall, e.g. downhill skiing for the inexperienced. As body weight increases, a non-weight-bearing activity might be more suitable, e.g. swimming instead of jogging, and intensity should be decreased to minimize oxygen debt and lactate production. Intensity and duration should also be modified to limit core temperature increases.^[87]

Some concerns regarding fetal heart rate during maternal exertion have been raised. Signs of fetal distress include prolonged fetal bradycardia and tachycardia. Several studies have shown no effect on fetal heart rate with maternal exertion at 70–80% of their MHR.^[88]^[89]^[90]

With some modifications, continuing a regular exercise program during pregnancy can be both a safe and enjoyable experience for the expectant mother.

Children

The leading causes of mortality in the United States are lifestyle-induced diseases, typically originating in childhood. Risk factors such as smoking, hypertension, obesity, diabetes mellitus, hyperlipidemia and stress are seen in children and youth aged 7–17 years. Studies have also reported high-risk profiles in preschool-age children.^[91] According to current statistics, an American child has a one in five chance of developing clinical symptoms of CHD before the age of 16.^[91]

Although studies in adults have linked regular exercise to decreased overall risk for mortality, the few studies of children have been equivocal, except those conducted on obesity which confirm that increased daily activity and exercise help to control weight in obese children.^[91] As mentioned earlier in the section on obesity, studies suggest that childhood obesity is associated more with inactivity than with overeating.

Encouraging exercise habits at an early age is especially important in light of research indicating that advancing age and elapsed time after initial adaptation of an activity routine are among the most consistent predictors of inactivity.^[91] The ACSM currently recommends 20–30 minutes of vigorous exercise every day (see [Appendix 1](#)).^[92]

As can be seen in [Table 38.4](#), strength training with weights shows differing results in pre- (Tanner stage II) and postpubescent boys and girls.

A special concern that needs to be addressed in exercising children is the still common

practice of “making weight” by wrestlers (i.e. losing weight to be certified

TABLE 38-4 -- Effects of weight training on boys and girls^[93] ^[94] ^[95]

| Group | Strength | Muscle mass |
|---------------|--------------------------------------|--|
| Prepubescent | | |
| Boys | SI increase in only abdomen and back | No change |
| Girls | No data | No data |
| Postpubescent | | |
| Boys | Increases | Increases |
| Girls | Increases | No change, unless anabolic steroids are used |

for a weight class lower than their pre-season weight). Wrestlers typically make weight by a combination of food restriction, fluid deprivation, and sweating induced by thermal or exercise procedures.^[96] Dehydration through sweating appears to be the most commonly used method.^[96] Misuse of rubber suits, saunas, laxatives, steam rooms, and diuretics, singly or in combination, have all been employed in the practice of making weight.^[96] Not only are these practices dangerous, but a recent study looking at repeated weight loss and gain, or weight cycling, in adolescent wrestlers also indicated decreased resting metabolic rate which may result in an increase in body fat.^[97] The possibility of future problems with obesity is suggested. Physicians can help to prevent such problems by educating coaches, wrestlers and others, in the same manner as was suggested in the section on steroids.

The elderly

From peak function at the age of 30, the functional capacity of most organ systems decreases at a rate of about 0.75–1.0% per year. Physical work capacity, muscle strength and mass, flexibility, cardiac output, maximum heart rate, vital capacity, and renal and liver function all decline approximately 30% between the ages of 30 and 70.^[98] Moreover, by the age of 70, women lose 30%, and men about 15%, of their bone mass. Approximately 50% of this decrease in function can be attributed to decreased physical activity.^[98]

Exercise training can help to offset the decline in physiological function associated with aging. Elderly males and females can help to maintain bone mass and increase their physical work capacity through improving their cardiorespiratory endurance, strength, flexibility, and body composition.^[99] These positive changes are demonstrated regardless of previous exercise patterns and current fitness status. The degree of improvement (expressed in relative terms) is comparable to that demonstrated by younger individuals, although the mechanism for the improvement may differ (i.e. strength may increase through improved recruitment of motor units rather than muscle

hypertrophy).^[99]

The older individual may need to begin exercising at a lower intensity, and progress more slowly than a

younger subject, but with time the benefits will be the same.

Exercise and the immune system

Recently, attention has been focused on the possible effects of exercise on immune function. Early research with experimental animals found that it may enhance resistance to the growth of experimentally induced tumors, suggesting that exercise may stimulate the immunosurveillance function of natural immunity.^[100] A recent study in humans indicated that frequent *tai chi quan* induced increases in T-lymphocyte count; exercise increased T-lymphocytes in the body.^[101] The research thus far suggests that moderate exercise stimulates the immune system,^[102] while intense exercise (e.g. training for the Olympics) can have the opposite effect.^[102] The combination of increased stress and intense training that competitive athletics require may explain this phenomenon. The mechanism responsible for exercise-induced suppression or enhancement of immune function may be increased cortisol, catecholamines and/or endorphins, singly or in combination.

ENVIRONMENTAL CONSIDERATIONS

For outdoor exercisers, uncontrolled factors such as heat, cold, air pollution, and altitude will affect the exercise prescription.

Heat and humidity

During exercise, 75% of the metabolic energy of muscle action is converted to heat. Elite marathoners generate heat at 15–18 times the basal rate, which, if no heat were dissipated externally, would result in a 1°C increase in core temperature every 5 minutes.^[103]

It is not surprising, then, that a number of deaths have been attributed to exercising in heat coupled with high relative humidity.^[104] ^[105] When exercising in hot weather, the body relies on the sweating mechanism for cooling, but in high humidity, evaporation cooling is limited. The amount of sun exposure is also critical as direct radiation is a major source of heat gain. Evaporation is also reduced when air movement is low.

There are a number of ways by which an exercising individual can decrease his/her risk of suffering heat-caused illness (heat cramps, heat exhaustion, heat stroke, or heat

syncope) or death while exercising in hot weather.

Adequate hydration is a primary concern, particularly as strenuous exercise in a warm environment can result in water loss of up to 2 L/hour. The thirst mechanism is not a reliable indicator of the need to drink as dehydration will have already begun.^[106] Water should be consumed prior (6–8 ounces), regularly during, and after strenuous exercise. Water and a diluted electrolyte solution appear to be the best fluids for quick rehydration.^[8] Fluids high in glucose content slow gastric emptying and are not recommended.^[106] Salt tablets are also not recommended as they draw water from the cells back into the gastrointestinal system. If necessary, extra salt added to food is more appropriate.^[8] ^[105]

Exercising during the cooler part of the day (i.e. early morning or early evening) and avoiding the sun's direct radiation is recommended. Wearing light-colored and minimal clothing (to expose the skin to air) is also recommended, as well as decreasing the intensity and duration of exercise during high-temperature and/or high-humidity days.

Exercisers should be able to recognize the early symptoms of heat injury, which include excessive sweating, headache, nausea, dizziness, and any impairment of consciousness.^[105] They should also be aware that some populations are more susceptible than others – the very young and very old, the obese, the unconditioned, the unacclimatized, etc. – and that heat injury can occur under varied conditions: high temperature and low humidity, high humidity and low temperature, high solar radiation, little wind, on a relatively warm day following a bout of cooler weather and, of course, the lethal combination of high temperature and high humidity.^[105]

Individuals respond differently to heat, and for those who cannot or do not want to change their routines, acclimatization helps the body to tolerate heat much more effectively. Fourteen days of training in the heat is necessary to become 90% acclimatized.^[8] For additional information, refer to [Appendix 1](#). The ACSM recommends against distance races when the wet bulb temperature exceeds 28¹/₄C.

Cold

Cold weather exercising presents far fewer problems than exercising in the heat. Temperatures (including wind chill factor) as low as –20¹/₄F can be tolerated if an individual is dressed appropriately.^[8] Clothing should be worn in layers to allow flexibility in achieving the desired level of heat retention. The inner layer – cotton or silk – should absorb sweat to keep the outermost layer dry. A middle layer of wool will absorb excess sweat and allow evaporation, and an outermost layer of Goretex or polypropylene will protect against wind, rain and snow, yet let the body “breathe”. A hat that covers the ears is very important, as 50% of body heat is lost or gained via the head. (On extremely cold days, goggles, a mask and/or petroleum jelly on the face might be necessary.) Gloves or mittens are particularly critical as circulation to the extremities is decreased due

to their distance from the heart and limited musculature. Socks should be a wool/cotton mix or a ribbed, woven synthetic material.^[8] Overdressing should be avoided; when appropriately dressed, the exerciser should feel slightly chilly at the start of exercise and begin to warm shortly after.

The clinical manifestations of cold injury include chilblains, muscle cramps, frostbite, and/or whole-body hypothermia, i.e. a rectal temperature of less than 35°C.^[107] Conditions that increase the risk of cold stress include wet clothing, wind chill, remaining outside while sweating after cessation of the exercise session, and becoming lost while exercising in the cold.

Wind-chill factor, the combined effects of absolute temperature and wind velocity, should be a matter of great concern to the outdoor exerciser. Wind chill can dramatically affect absolute temperature, e.g. a 15 mph wind at 0°F would reduce effective temperature to -32°F.^[8] Severe cold such as this can freeze exposed skin within minutes. As the exerciser tires, the metabolic heat production from exercise may decrease (if energy substrates are no longer available) to a point where heat loss to the environment exceeds heat production. After 1–2 hours of exposure, there are potentially fatal consequences.^[8]

Some people are uncomfortable breathing cold air (especially cardiac patients susceptible to angina). A scarf draped around the face or a knitted ski mask worn to warm the inhaled air will help to prevent discomfort.^[8]

The aforementioned guidelines are for outdoor exercise in cold air. Rapid heat loss is also a serious situation when swimming in a non-heated water environment. Extreme caution is advised.^[107]

Air pollution

Recently, air pollution has become another factor to be concerned about when exercising outdoors, particularly in large metropolitan areas.

Carbon monoxide, due to its great affinity for binding with hemoglobin, impedes oxygen transport. High concentrations of carbon monoxide greatly decrease physical work capacity. Ozone has also been shown to have a negative effect on exercise performance.^[8] Although only one pollutant in a given area may be identified as having reached an “alert” level, typically other pollutants will also be present, with cumulative detrimental effects on exercising individuals.

Exercisers can decrease air pollution exposure by exercising during the early morning hours before pollution accumulates, during periods of increased air movement (i.e. windy days), in less traveled areas, or indoors when pollution levels are high. The author has found value in wearing a surgical mask while exercising in major

metropolitan areas, but has been unable to find any studies that have evaluated the efficacy of this or other more extreme precautionary measures, such as gas masks.

Altitude

As altitude increases, the partial pressure of oxygen is proportionately lower than at sea level. This makes it more difficult to deliver oxygen to the exercising muscles, and so performance is decreased in direct proportion to altitude.^[8] As elevation increases, ambient temperature decreases, adding the stressor of cold to the equation.

As a result of this additional stress, exercise intensity should be decreased. If the RPE method for determining exercise intensity is used regularly, exercisers can adjust to maintain a level of exertion at high altitudes comparable to that they experience at sea level. After several weeks at a particular altitude, the body partially acclimatizes, but performance is still compromised. Caution must be exercised by individuals with CHD or abnormal lung function (i.e. emphysema and chronic bronchitis).^[8]

SIDE-EFFECTS AND CONTRAINDICATIONS OF EXERCISE

Athlete's heart

While originally a pathologic diagnosis, athlete's heart, or increased heart size, is now known as a normal physiological response to training. Increased heart size may manifest as:^[2]

- bradycardia
- a more prominent sinus arrhythmia
- a forceful apical impulse
- third and fourth heart sounds
- systolic flow murmurs.

ECG changes consistent with increased vagal tone (sinus bradycardia and arrhythmia, PR prolongation, and Wenckebach second-degree heart block) and ventricular hypertrophy may also be present.

Sports anemia

A mild decrease in hemoglobin or hematocrit, the so-called sports anemia, is commonly seen in endurance athletes. This, however, is not a true anemia, as red cell mass is normal. Rather, plasma volume is disproportionately increased.^[2] Although only a small amount of iron is lost through perspiration, menstruating women who consume a low-iron diet may be at risk.

Exercise-induced hemolysis or gastrointestinal bleeding (occurring in 8–22% of marathon runners) may, however, exist and should be considered. While footstrike can produce intravascular hemolysis in runners, intravascular hemolysis has also been

reported in swimmers,

suggesting that trauma alone does not explain the phenomenon.^[2] Contact activities such as karate, marching and football may produce enough trauma to capillaries to damage normal red blood cells. The effects are typically short-term and chronic anemia is rare. Sick cell trait may increase risk, but the research is mixed.^[2]

Athlete's hematuria and albuminuria

Exercise-induced hematuria and albuminuria are benign, self-limiting conditions occurring in many athletes. Microscopic or gross hematuria and mild albuminuria are most likely in the first urine voided after exercise and should resolve within 48 hours.^[2] Severe or slowly resolving hematuria or albuminuria indicate the need for careful urinary tract evaluation.

Exercise-induced asthma

The association between vigorous exercise and asthma has long been recognized. Exercise-induced asthma (EIA) is not a variant form of asthma but rather a non-specific response occurring in approximately 12% of the population. During or immediately after exercise, symptoms and signs of EIA or bronchospasm are recognizable as dyspnea, choking, increased mucous production, fatigue, chest pain, and/or wheezing. The mechanism by which EIA is triggered is still unknown. It has been suggested that the increased loss of heat and/or water from the respiratory tract that results from exercise-induced hyperpnea, may be a trigger.^[108] It has also been suggested that exercise intensity is the triggering factor, and that climatic conditions modify the severity of the EIA. In the study by Noriski et al,^[109] it was found that the higher the intensity, the more severe the EIA.

Exercise therapy for asthma was not generally accepted as a treatment 10–15 years ago, due to the 40–95% rate of exercise-induced bronchospasm in asthmatic children exercising at school or on a playground.^[110] Today, it is recognized that although exercise doesn't change the basic asthmatic condition as objectively measured by spirometry, it does improve physical fitness, develop skills, and help affected individuals to cope with the disease and its emotional component.^[111]

EIA is frequently defined as 5–15 minutes of respiratory difficulty following 5–8 minutes of sustained exercise.^[111] Running appears to be the most attack-provoking exercise and swimming the least.^{[111] [112]} Swimming the backstroke may help to alleviate breathing problems encountered in the water.^[110]

The exercise prescription should initially be limited to 5 minute intervals to avoid triggering an attack. Short bursts of activity are tolerated well. The mode of exercise tolerated best appears to be those performed indoors in a controlled environment such

as swimming, wrestling or stationary bicycling. Intensity can be high if intervals are short, 2–3 minutes. However, moderate exercises build endurance more effectively.^[111] Frequency is the same as recommended for those without EIA. After training regularly for a year, other modes of exercise, even running, may be substituted.^[110]

Exercise-induced urticaria and anaphylaxis

Exercise, fever, or a warm bath may induce a hypersensitivity reaction characterized by tiny urticarial lesions surrounded by large areas of erythema. Serum histamine levels are elevated and wheezing may occur^[2] (see [Ch. 191](#) for further discussion and therapeutic approach).

Occasionally, exercise may produce a syndrome virtually identical to allergen-induced anaphylaxis. The syndrome begins with a prodrome fatigue, warmth and pruritis, progressing to generalized urticaria and possibly to angioedema. Full-blown attacks result in choking, respiratory distress, abdominal colic, nausea, and syncope.^[2] While the cause is unknown, the mechanism includes mast cell activation and elevated levels of histamine. There is a possible link to specific foods,^[113] and familial cases have been reported.

Menstrual dysfunction and changes in sex hormones

Delayed menarche has been reported in girls who train heavily before puberty and amenorrhea or oligomenorrhea in highly trained adult female athletes. Nineteen per cent of Olympic marathon runners are amenorrheic. The pathogenesis is unknown, but is most likely multifactorial. Many factors have been associated with athletic menstrual dysfunction (AMD) including:

- weight loss
- intensity of exercise
- energy drain
- quantity and quality of diet
- aberrant nutritional patterns
- chronological age
- gynecological age
- competition stress-induced hypothalamic dysfunction (elevated serum cortisol and catecholamines appear to suppress LH release and possibly FSH, prolactin, and estradiol).

No long-term effects on reproductive function have been noted.^[2]

A frequently cited cause is low body fat based on the work of Frisch and McArthur. They suggested that 22% body fat is necessary for onset and maintenance of menstrual function and hypothesized that this amount of body fat is necessary as adipose tissue converts androgens to estrogen. The major criticism of their research is that they used an indirect method, i.e. equations

and height/weight tables, to estimate body fat. Other researchers using more direct body fat measurement, i.e. hydrostatic weighing, found no significant association between percentage body fat and AMD.^[114] The body fat connection to athletic amenorrhea is controversial. While some studies have found a correlation,^[115] several others have not,^{[114] [116] [117] [118]} suggesting that other factors are involved.

Endurance athletes, especially those who are amenorrheic, may be taking in too few calories to compensate for their energy output. Yet these athletes appear to maintain a stable weight, suggesting that there may be conservation of energy in other areas. As a lower resting metabolic rate has been associated with calorie restriction, it has been proposed that amenorrhea may be an energy-conserving response to a hypocaloric diet. Eating disorders have been found to be prevalent amongst endurance athletes, ballet dancers, and recreational and competitive body builders.^{[114] [119]} Research attention is now being focused on the association between diet and athletic activity as the cause of AMD. One recent study found that amenorrheic high-mileage runners seem to have a less adequate diet than eumenorrheic runners, although they appear to maintain an adequate energy balance and stable weight through a reduction in resting metabolic rate.^[114]

In men, acute exercise increases, while chronic exercise and weight loss decrease, testosterone. A small number of highly trained marathon runners are also found to have oligospermia.^[2]

Osteoporosis

Amenorrheic athletes may be at risk of osteoporosis. Vertebral (but not radius) bone density is reduced in these women, and an increased incidence of fractures has been found.^[2] Young ballet dancers with delayed menarche and secondary amenorrhea have an increased risk of scoliosis and stress fractures.^[120] Slightly decreasing exercise or increasing body weight usually re-establishes their menstrual cycle. Both menstruating and menopausal physically fit women have higher bone density than sedentary women.

Incontinence

A common, although little known, problem for women is incontinence during exercise. While considerable research has studied the effects of exercise on most of the body's organs and structures, little attention has been paid to the lower urogenital tract until recently. A 1990 study by Nygaard et al^[121] found that 47% of participants had some degree of incontinence. This figure correlated with the number of vaginal deliveries. Of these, 30% noted incontinence during at least one type of exercise. Exercises involving repetitive bouncing (i.e. running, high-impact aerobics, tennis, low-impact aerobics, and walking) were associated with the highest incidence of incontinence. Incontinence caused 20% of exercisers to stop an exercise, 18% to change the way a specific exercise was performed, and 55% to wear a pad during exercise. With one in three

women experiencing the problem, this study clearly demonstrated that incontinence during exercise is not unusual. Exercise per se is not the cause of incontinence (only one woman was incontinent solely during exercise), but could prove to be a possible obstacle for some women. In this study, women appeared to be very adaptive. Some non-surgical options to ameliorate incontinence include Kegel exercises, weighted vaginal cones, and interferential therapy.^[122]

Acute muscle injury

Elevated levels of muscle enzymes usually accompany exercise. Creatine kinase is the most sensitive, rising within minutes of even mild exercise and lasting for days after strenuous exercise. Delayed onset muscle soreness after exercise correlates with CK levels. Strenuous exercise produces mild elevations in serum AST (formerly SGOT) and myoglobin, while high levels of the latter may indicate potentially serious rhabdomyolysis.

Heat stroke

Heat stroke, representing a serious failure of thermoregulation, is a medical emergency. A diminution of sweating is commonly observed prior to the onset of symptoms, which are, typically:

- the abrupt onset of altered consciousness
- prostration
- flushed, dry skin
- tachycardia
- dehydration.

Body temperatures in excess of 41.1°C are common, although some victims have lower temperatures. The primary treatment is intravenous fluids and active cooling, involving the application of ice packs or ice-water baths until core temperature reaches 39°C. Adjunct therapy includes fluids, electrolytes as needed, correction of acidosis, treatment of arrhythmias, and circulatory and respiratory support.^[2]

Sudden death

The 1984 death of author and marathon runner, Jim Fixx, raised questions about the safety of vigorous exercise. As exercising increased in popularity in the 1970s and 1980s, several studies were published reporting cardiovascular complications and sudden deaths during or

following vigorous exercise.^{[123] [124] [125] [126] [127] [128]} However, a report by Koplan^[129] estimated that, statistically, 100 deaths per year would occur during jogging, simply by

chance.

The cause of death in both young (under 30 years) and old (over 30 years) conditioned subjects who die suddenly during or immediately following vigorous exercise is congenital or acquired CHD in 90% of cases.^[130] In those over the age of 30, atherosclerotic heart disease is the primary killer, while in those under 30, congenital coronary artery anomalies and hypertrophic cardiomyopathy are the primary causes.^[130]^[131]^[132] Sudden death in young men is often predated by such symptoms as syncope and chest pain.

The data suggests that exercise contributes to sudden death in susceptible persons. This implies that those over the age of 30 who participate in vigorous exercise without also modifying other high-risk factors for CHD (e.g. hypercholesterolemia, smoking, etc.), increase their risk of sudden death during vigorous exercise.^[133]^[134] This is, however, offset by the decreased risk of cardiac mortality induced by fitness.

Steroid use

Anabolic-androgenic steroid use is currently viewed as a serious health problem. At one time, weight lifters were the primary consumers of these drugs, but recently both male and female power athletes, endurance athletes, and even non-athletes are consuming steroids.

While the use of steroids may be accompanied by gains in lean body mass, body weight, and strength, it has also been associated with adverse effects. These include liver, cardiovascular, reproductive, and psychological abnormalities, as well as lowered HDL levels.^[2]^[135]^[136] Other risks include diseases associated with shared needles, such as hepatitis and AIDS.^[137]

Despite the growing awareness of the potential side-effects of steroid use, its popularity is increasing and the consumers are getting younger. A recent study by Windsor & Dumitru^[138] found a significant percentage of male and female high school students (particularly male athletes from upper socioeconomic levels) using anabolic steroids obtained illicitly (group I male athletes reported a 10.2% prevalence).

Athletes use steroids in an attempt to improve performance in a variety of sports, most commonly those requiring considerable strength such as football, wrestling, weight lifting, sprinting, shot put, etc. They are also used by swimmers, cyclists, and male and female bodybuilders. One recent study found users among high school students who did not even participate in organized sports.^[139]

The use of androgenic steroids began in the 1950s and has increased in the decades since, despite warnings of potential harmful side-effects and their banning by the International Olympic Committee.^[135] Education is of vital importance to curb the abuse of steroids. Physicians can contribute to the education effort by providing athletes and other users with timely and accurate information on the health risks and performance enhancement effects of steroid use. For additional information, please refer to the

ACSM position statement in [Appendix 1](#) .

CONCLUSION

Although many unanswered questions still remain, a sufficient body of data is available to conclude that regular physical activity promotes good health. This may seem an obvious statement to those who believe in the value of exercise, but due to the multifactorial nature of disease, it is a difficult hypothesis to prove. The probable benefits of exercise are many, including prevention of the leading causes of morbidity and mortality in the United States. Exercise therapy plays a major role in naturopathic medicine, which advances the concept that a healthy and fit body promotes a healthy and fit mind.

Chapter 39 - Faith: a powerful force for healing

Lara E. Pizzorno MA (Divinity)

INTRODUCTION

Faith and medical science are not mutually exclusive. In fact, faith's efficacy as a powerful healing force has been scientifically validated by hundreds of experiments exhibiting all the criteria of good science.^[1] Research into the healing power of participation in religious activities such as prayer has demonstrated that faith in a supreme being – whether God, Allah, Brahman, the Tao, the Absolute, the Universal Mind – produces significant, beneficial effects on health, including lowering blood pressure, protecting against heart disease, improving surgical outcomes and lessening recovery time, increasing feelings of well-being, ameliorating depression, and improving the ability to cope with stress while lessening its adverse physiological effects. Religious commitment has been shown to help protect children from drug abuse, alcohol abuse, and suicide. Among the elderly, those who live in faith tend to live longer.^[2]

In the current medical model, most physicians are led to believe that any consideration of religious commitment is beyond the interest and scope of medical care. The dogma is that faith is not amenable to serious scientific scrutiny, and is merely a relic from earlier less enlightened ages, a crutch for the scientifically disinclined. Medical students and residents get the subliminal message that to personally pursue an active religious faith is to court schizophrenia, traveling simultaneously down the right-brain path of faith, religion, and prayer (read: irrationality and superstition), and the left-brain arterial of logic, analytical diaphoresis, and rational thought (read: science). In modern medical education, devotions are to be paid only to "Science" with a capital "S", which leaves the whole realm of the numinous outside the Venn diagram locus of serious medicine. So, members of the health care professions tend to disassociate their spirituality from their science, both in their training and later in their clinical practice and academic endeavors. Recent scientific research itself, however, has made such an uncritical stance medically irresponsible.

Significant evidence exists that prayer functions at a distance to change physical processes in a variety of organisms, from bacteria to humans. In addition to humans, the subjects in studies have included water, enzymes, bacteria, fungi, yeast, red blood cells, cancer cells, pacemaker cells, seeds, plants, algae, moth larvae, mice and chicks. Processes influenced include the activity of enzymes, the growth rates of leukemic white blood cells, mutation rates of bacteria, germination and growth rates of various seeds, the firing rate of pacemaker cells, healing rates of wounds, the size of goiters and tumors, the time required to awaken from anesthesia, autonomic effects such as electrodermal activity of the skin, rates of hemolysis of red blood cells, and hemoglobin levels.^[3] Given the scientific support of prayer's beneficial effects, not praying for the best possible outcome for one's patients may be the equivalent of deliberately withholding an effective drug or surgical procedure.

PRAYER CONCEPTUALIZED

In *Healing Words: the Power of Prayer and the Practice of Medicine*,^[4] Larry Dossey MD provides a review of the scientific evidence plus the terminology and conceptual framework with which to discuss and evaluate new studies on prayer.

The word "prayer" is derived from the Latin *precarius* ("obtained by begging") and *precari* ("to entreat – to ask earnestly, beseech, implore"). This suggests the two most common forms of prayer: *petition*, asking something for one's self; and *intercession*, asking something for others. Other types of prayer include:

- *confession* – the repentance of wrongdoing and asking for forgiveness
- *lamentation* – crying in distress and asking for vindication
- *adoration* – giving honor and praise
- *invocation* – summoning the presence of the Almighty
- *thanksgiving* – offering gratitude.

Prayer, in which communication frequently surpasses the limits of language, is often wordless. Theologian Ann Ulanov and Professor Barry Ulanov have termed such prayer "primary speech...the most fundamental, primordial, and important 'language' humans speak".^[4] Prayer may be individual or communal, conscious or unconscious, emerging in dreams.

Perhaps most importantly, prayer is a *non-local* event – it is not confined to a specific place and time, but reaches outside the here and now, operating at a distance, and outside the present moment. Since prayer is initiated by a mental action, the implication is that some aspect of ourselves is also non-local. Because a limited non-locality is a contradiction in terms, the non-locality of prayer implies that something of ourselves is infinite in space and time, eternal, immortal. Empirical evidence for the power of prayer is indirect evidence for the soul, and for a relationship with the Divine whose locus is

within each of us.

RESEARCH

Despite growing practitioner and patient acceptance of the important role of faith and prayer in health and healing, this area has received relatively little research attention, and health care professionals receive minimal or no formal training. A systematic analysis of 4,306,906 studies indexed on Medline from 1980 to 1996 revealed only 364 abstracts considering faith, religion or prayer. Although all of these case reports involved religious and spiritual issues, only 45 (12%) explicitly mentioned a religious professional. Of these, only eight (2%) indicated any collaboration between health care and religious professionals.^[5]

Another study looked at all quantitative studies in the *Journal of Family Practice* published from 1976 to 1986, to determine how often religious variables were included.^[6] A total of 1,086 studies were reviewed. More than half measured at least one quantified variable. However, only 21 (3.5%) of those quantified studies measured at least one religious variable. Measures of religious commitment, such as frequency of church attendance, social support, prayer and relationship with God, were found to be beneficial to health 83% of the time, neutral 17% of the time and harmful at no time at all.

A systematic review of major psychiatric journals from 1978 through 1989 found 2,348 studies that included quantified data. Among the quantitative studies, 59 (2.5%) included one or more religious measures. In only three of the studies was a religious measure a central variable.^[7] During 12 years, religious commitment measures of ceremony, social support, prayer and relationship with God showed benefit 92% of the time, were neutral 4% of the time, and negative 4% of the time.

Larson et al^[8] have identified several factors impeding clinical research in this area:

- conceptual barriers – lack of consensus regarding what constitutes religion and spirituality
- methodological barriers – difficulty in establishing appropriate control groups, and difficulty in controlling for factors which might not be measured
- structural barriers – long history of conflict between science and religion
- professional disincentive – publication bias, possible inhibition of tenure and limited funding.

One interesting investigation found that studies on

alternative approaches are likely to be discriminated against by journals. Using a randomized, double-blind protocol, one researcher submitted a fictional study on obesity treatment to 398 expert peer reviewers. The articles were identical, except for the

therapy – one used a conventional drug, the other a homeopathic remedy. The reviewers were three times more likely to recommend publication of the drug study over the homeopathic study.^[9]

The paucity of published studies (0.008% of the Medline records) and appalling lack of collaboration between health care and religious professionals demonstrate a serious gap between the public, the health care system and the medical research establishment. This gap must be bridged for the benefit of our patients.

Religious activity is prevalent in society

Religion plays an important role in the lives of the vast majority of patients, especially the elderly. This is well demonstrated in a study that examined the prevalence of religious beliefs and practices among medically ill hospitalized older adults and related them to social, psychological and health characteristics. Consecutive patients age 60 or over admitted to the general medicine cardiology and neurology services of Duke University Medical Center were evaluated for participation in a depression study. As part of the evaluation, information on religious affiliation, religious attendance, private religious activities, intrinsic religiosity and religious coping was collected from 455 cognitively unimpaired patients. Demographic, social, psychological and physical health characteristics were also assessed. Over one-half (53.4%) of the sample reported attending religious services once per week or more often; 58.7% prayed or studied the Bible daily or more often; over 85% of patients held intrinsic religious attitudes; and over 40% spontaneously reported that their religious faith was the most important factor that enabled them to cope. Bivariate and multivariate analysis showed that religious belief and activity were consistently and independently related to race (black), lower education, higher social support and greater life stressors, and religious attendance was associated with a lower medical illness burden. Religious attendance was also related to fewer depressive symptoms, although the association weakened when other covariates were controlled.^[10]

Religious commitment and engaging in prayer improve health

The positive benefit of religious commitment is documented by a growing number of studies in the medical literature. Looking at the single religious commitment measure of frequency of attendance at religious services, one review of studies found that those attending services weekly or more had significantly better health across a vast array of illnesses. Attending religious services benefited health 81% of the time, showed no effect 15% of the time, and had a 4% rate of harm. Researchers concluded that given this strikingly positive association, infrequent church attendance could be regarded as a risk factor for greater incidence of disease.^[11]

An intriguing large randomized, controlled, double-blind study utilized 90 volunteers (agents) to pray for 406 subjects. The subjects were randomly assigned to three groups: controls, prayed for directly and prayed for indirectly. Agents were randomly assigned to either the directed or non-directed prayer group. In the directed prayer group, prayers had a specific goal, image or outcome in mind; in the non-directed group, no specific outcome was requested. Photographs and names of subjects were used as foci. Prayer

was offered for 15 minutes daily for 12 weeks. Three agents prayed for each subject. Five pre-test and post-test objective measures and six post-test subjective measures were taken. Subjects improved significantly on all 11 measures, and the agents themselves improved significantly on 10 measures. A significant positive correlation was found between the amount of prayer the agents did and their scores on the five objective tests. Agents had significantly better scores than did subjects on all objective measures. Subjects' views of the locus of God's action showed significance in three objective measures. Improvement on four objective measures was significantly related to subjects' belief in the power of prayer for others. Improvement on all 11 measures was significantly related to subjects' conviction concerning whether they had been assigned to a control or an experimental group.^[12]

However, no differences in outcome were found between the control and experimental conditions, and no differences were found between the directed and non-directed prayer groups. While agents experienced a highly significant relationship between the amount of prayer and health benefits, there was no such correlation with the subjects. Possible explanations suggested by the researchers included:

- Prayer does not work.
- Simply enrolling in the project was a commitment to improvement that overwhelmed the experimental effect.
- The subjects may all have had a specific expectation of improvement causing significant differences.
- All subjects were told that if prayer proved effective, those in the control group would be prayed for at the completion of the study. This could have caused a time-displaced effect.
- Outside prayer "contaminated" the results.

Specific areas in which prayer and religious activity have been shown to be effective

Blood pressure

One study found that people who were both frequent church attendees and rated their religion as very important had lower diastolic blood pressures, an association that held true even for smokers.^[13] The analyses were adjusted for other blood pressure risk factors, such as age, socioeconomic status, and weight. Those who rated religion as highly important to them and attended church weekly or more had mean diastolic pressures almost 5 mm lower than those who rated religion as unimportant and infrequently or never attended church.

Smokers who rated religion as very important were 7.1 times less likely to have to have an abnormal diastolic pressure than those smokers who gave a low rating for the personal importance of religion. Furthermore, smokers who attended church weekly or

more frequently were four times less likely to have abnormal diastolic pressure than were less frequent attendees or non-attendees. These beneficial findings among smokers who attend church frequently contradict the thesis that religion is clinically beneficial only because it helps people to avoid risk-producing behaviors.

A systematic review of 20 studies published over 30 years on blood pressure and religious activity found an inverse correlation between strong religious commitment and blood pressure.^[14] The authors concluded: "Hypertension is a common and serious problem which appears to be mitigated by religion...."

Another study found an inverse association between frequency of religious attendance and rates of arteriosclerotic disease in both men and women.^[6] Even after allowing for the effects of smoking, socioeconomic status and water hardness, the risk for the frequent church attendees was only 60% of the risk for men who attended church infrequently. The risk of dying from heart disease among women was about twice as high among infrequent church attendees than among those who attended church weekly or more regularly.

A recent study examined the association between blood pressure, selected health behaviors, and religious activity. Data were obtained on 112 women who were at least 35 years of age and of the Judeo-Christian faith. Resting blood pressure measures were taken with an automated sphygmomanometer; height and weight were measured to determine body mass index (BMI), and intermediate health variables (e.g. physical activity, smoking, diet, and alcohol consumption) were measured by questionnaire. A multifactorial questionnaire was used to assess various dimensions of religious activity. Multiple regression analysis found a direct inverse effect between both systolic and diastolic blood pressure and the level of religious activity, not mediated by changes in health behaviors.

Alcohol and drug abuse

A review of the literature found 20 studies that examined the relationship between religion and drug use.^[15] One study found that religious commitment was a protector against drug abuse.^[16]

Whenever religion is used in an analysis, it predicts those who have not used an illicit drug regardless of whether the religious variable is defined in terms of membership, active participation, religious upbringing, or the meaningfulness of religion as viewed by the person himself.

In a more recent review of the literature, 11 of 12 studies found that drug abuse is correlated with the absence of religious commitment in a person's life.^[16] In 10 of 11 studies of alcohol abuse, religious commitment protected against such abuse.^{[16] [17] [18] [19]}

Suicide

One community study found that persons who did not attend church were four times more likely to commit suicide than were frequent church attendees. In a review of studies on suicide, 12 out of 12 studies showed that persons with a strong religious commitment were substantially less likely to commit suicide. The religiously committed had fewer suicidal thoughts and more negative attitudes towards taking their own lives.^[20]

Delinquency

Twelve of 13 studies summarized in two reviews found that religious commitment – particularly church attendance – played a protective role against delinquency.^{[20] [21]} An additional, particularly revealing, study by Freeman^[22] showed that those black males who are able to leave the ghetto and avoid falling prey to delinquency or drug abuse are those who attend church on a regular basis.

Surgical outcome

Elderly women recovering from hip surgery who regarded God as a source of strength and comfort and who attended religious services frequently were less depressed and could walk a greater distance at discharge than others. The authors suggested that the ability to walk farther was possibly explained by the lower amount of depression, as the more religious patients were less depressed and thus responded better to physical therapy.^[23]

An interesting double-blind intervention study measured the effect of prayer on cardiac surgery outcome. Patients in a care unit in a large general hospital who consented to participate were randomly assigned to

receive or not to receive regular intercessory prayers by an interdenominational group of committed Christians unknown to them. The patients themselves, staff, and doctors were unaware as to which patients were assigned to which group. Each intercessor was asked to pray on a daily basis for each of the following clinical issues: rapid recovery, prevention of complications and death, and any other areas they believed would be beneficial to the patient. The patients who received daily intercessory prayer had fewer life-threatening events and complications (congestive heart failure, cardiopulmonary arrests, intubations, and pneumonia) during their stay in the hospital coronary care unit than did those patients who did not receive the prayer.^[24]

Length and quality of life

Five community-based studies have shown that the religiously committed person, particularly the church attendee, has a greater chance of living longer than do persons

lacking such a commitment.^[7] Not only do the religiously committed have a greater chance of living longer, but they are more satisfied with their lives. Another study showed that those who frequently pray and who have a close relationship with God have high levels of life satisfaction, existential well-being, and overall happiness.^[21]

EFFECTIVE PRAYER

After spending more than a decade performing simple laboratory experiments that showed that prayer works, the Spindrift organization in Salem, Oregon, investigated which type of prayer strategy works best. Distinguishing essentially two types of prayer – “directed” prayer in which prayers have a specific goal, image or outcome in mind, and “undirected” prayer, in which no specific outcome is requested – researchers found that while both types of prayer produced results, the undirected approach was quantitatively more effective, frequently yielding results twice as great, or more, compared with the directed approach.^[25]

Undirected prayer, a letting go and affirmation of trust in the Absolute, is at once a source of release, peace and hope. “Thy will be done” confers its own immediate blessing, regardless of physiological outcome.

Side-effects and contraindications

As with any intervention, misuse or inappropriate usage can cause problems. While the explicit inclusion of faith and prayer in health care can have a significant positive impact on clinical outcomes, this does not mean that these approaches can take the place of effective treatment. Unfortunately, some religious beliefs can be interpreted to prohibit many types of conventional medical interventions. One disconcerting study evaluated the deaths of children from families whose beliefs prohibited certain types of medical intervention. The researchers evaluated the records of 172 of these children who died in the US between 1975 and 1995 and for whom there was sufficient documentation to determine the cause of death. Of these, medical intervention would have resulted in a typical survival rate of 90% in 140, >50% in 18, and all but three of the remainder would likely have had some benefit.^[26] While the research was flawed by the design bias, i.e. researchers did not look for positive results, only negative ones, the study gives cause for grave concern.

While it is easy for the clinician and social worker to condemn the belief systems of these children’s families, how much does the well-documented unwillingness of most practitioners to consider faith and religious practice as factors in the therapeutic process contribute to these families’ extreme position?

ILLNESS, THE GIFT OF SPIRITUAL HEALING

We have typecast illness as our enemy, when, in fact, it is our teacher. In the words of Germany’s great poet, Rainer Maria Rilke:^[27]

So you must not be frightened... You must think that... life has not forgotten

you, that it holds you in its hand; it will not let you fall. Why do you want to shut out of your life any agitation, any pain, any melancholy, since you really do not know what these states are working upon you? Why do you want to persecute yourself with the question when all this may be coming and whither it is bound? ...just remember that sickness is the means by which an organism frees itself of foreign matter; so one must just help it to be sick, to have its whole sickness and break out with it, for that is its progress...you must be patient as a sick man...there are in every illness many days when the doctor can do nothing but wait. And this it is that you, insofar as you are your own doctor, must now above all do.

Although physicians are taught to banish pain at all costs, and allopathic doctors are trained to eliminate symptoms as quickly as possible with drugs and surgery, failure to effect an immediate physiological cure does not necessarily mean failure to assist in a patient's healing process. Particularly during times of serious illness, we are forced to be quiet, to tune in to our true center. When our stillness is grounded in faith, what we recognize when we search within is God. Prayer at this intersection of quiet and acceptance, where we become truly aware that we are not our disease, but essentially something inviolate, is the type of prayer most frequently associated with miracle cures, radical spontaneous remissions and healings.

On a spiritual level, simply to recognize this dimension of the spiritual, the numinous, is to be healed. As Jung put it: "The approach to the numinous is the real therapy

326

and inasmuch as you attain to the numinous experiences you are released from the curse of pathology. Even the very disease takes on a numinous character."^[28]

SUMMARY

Religious faith, as primarily measured by regular attendance at religious services and a personal belief in God, is remarkably effective in the promotion of health. A substantial body of research published in diverse journals documents the efficacy of faith and prayer, for both the person praying and those prayed for, in longevity, recovery from surgery, prevention of disease, and improvement in lifestyle and behaviors. Every practitioner committed to providing the best possible care needs to be aware of, and use, this powerful healing factor.

Chapter 40 - Glandular therapy

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

For almost as long as historic records have been kept, glandular therapy has been an important form of medicine. The basic concept underlying the medicinal use of glandular substances from animals is that “like heals like”. For example, if the liver needs support or a patient is suffering from liver disease then they may benefit from eating beef liver. Modern glandular therapy, however, primarily involves the use of concentrated glandular extracts.

What is a gland?

A gland is defined as a secretory organ. The internal secretory organs of the body are called endocrine glands. These ductless glands secrete hormones directly into the bloodstream. The glands which are known to have endocrine function include the pineal, pituitary, thyroid, parathyroid, thymus, adrenal, pancreas, and gonads (testes or ovaries). Although not technically glands, it is common to refer to other organs of the body as glandulars when they are used in glandular therapy. For example, tissue extracts of heart, spleen, prostate, uterus, brain, and other tissues are often used in glandular or organotherapy.

SCIENTIFIC VALIDATION OF GLANDULAR THERAPY

Science has, without question, confirmed that certain glandular preparations and hormones are quite effective when taken orally. It is well established that a number of glandular preparations are effective orally because of active hormone or enzyme content, e.g. thyroid, adrenal cortex, and pancreatin preparations. There is also a good deal of literature support for pharmaceutical grade liver, aorta, and thymus extracts, and some support for pituitary, spleen, orchic (testes), and ovarian extracts as well.

However, despite this scientific support, many

people still question the effectiveness of glandular products on human health.

The true question should not be “Are glandulars effective?”, but rather “Are the glandulars currently available in the United States effective?”. Manufacturers of glandular products will claim their method of production of a glandular extract is the most ideal. However, the majority of their contentions are based on theoretical or philosophical grounds, not on firm scientific evidence or clinical results. There are no quality control procedures or standards enforced in the glandular industry. It is left up to the individual company to adopt quality control and good manufacturing procedures. Nonetheless, many glandular preparations available in the US marketplace appear to be effective.

METHODS OF MANUFACTURE OF GLANDULAR PREPARATIONS

It is critical that properly processed glandular material be used, as the biologically active material such as enzymes, soluble proteins, natural lipid factors, vitamins, minerals and hormone precursors are destroyed or eliminated if the product is not prepared properly.

Most glandular products are derived from beef (bovine) sources, the exception being pancreatic extracts which are most often derived from pork (porcine). The four most widely-known methods of processing are the azeotropic method, salt precipitation, freeze-drying, and predigesting.

The azeotropic method

The azeotropic method begins by quick freezing the material at well below 0°F, and then washing the material with a powerful solvent (ethylene dichloride) to remove the fatty tissue. The solvent is then distilled off and the material is dried and ground into a powder so that it can be placed in tablets or capsules. Although the azeotropic method eliminates the problem of fat-stored toxins like pesticides and heavy metals, unfortunately it also removes fat-soluble hormones, enzymes, essential fatty acids, and other potentially beneficial materials and there are still traces of the solvent that remain.

The salt precipitation method

This method involves the maceration of fresh glandular material in a salt and water. Because the salt increases the density of the water soluble material, when the mixture is centrifuged the lighter fat-soluble material can be separated out. The material is then dried and powdered. The benefit with the salt precipitation method is that no toxic solvents are used to separate the fatty material. The down side is that most people

could do without the remaining salt in the product.

Freeze-drying

The freeze-drying process involves quickly freezing the glandular material at temperatures 40–60° below 0°F and then placing the material into a vacuum chamber which removes the water by direct vaporization from its frozen state – hence the term freeze-drying. The benefit of freeze-drying is that it contains a higher concentration of unaltered protein and enzymes as well as all of the fat-soluble components. Since the fat is not removed, it is critical that the glands are derived from livestock that have grazed on open ranges not sprayed with pesticides or herbicides. The animals must also be free from antibiotics, synthetic hormones, and infection.

Predigestion

The final process to discuss is the predigestion method. This method employs the aid of plant and animal enzymes or some other method to partially digest or hydrolyze the glandular material. The partially digested material is then passed through a series of filtrations to separate out fat-soluble and large molecules. The purified material is then freeze-dried. This method of extraction is ideal for glandulars (such as the liver and thymus) where the polypeptide (small proteins) and other water-soluble fractions are desired.

EVIDENCE FOR INTACT PROTEIN ABSORPTION

Contrary to long-held theories that the healthy intestinal mucosa is an essentially impermeable barrier to proteins and large polypeptides, there is now irrefutable evidence that large macromolecules can and do pass intact from the human gut into the bloodstream under normal conditions. In some instances, the body appears to recognize which molecules it needs to absorb intact and which molecules it needs to break down into smaller units. This phenomenon may help to explain the effectiveness of glandular therapy.

Numerous whole proteins have been shown in human and animal studies to be absorbed intact into the bloodstream following oral administration.^{[1] [2] [3] [4] [5] [6] [7]} These include human albumin and lactalbumin, bovine albumin, ovalbumin, lactoglobulin, ferritin (molecular weight, 500,000), chymotrypsinogen, elastase, and other large molecules.

Furthermore, proteins and polypeptides, as well as various hormones that are absorbed intact from the gut, have been shown to exert effects in target tissues. For example, in addition to thyroxine or thyroid hormone and cortisone, several peptide hormones are known to be biologically active when administered orally, including luteinizing hormone-releasing factor and thyrotropin-releasing hormone.^{[8] [9]} Even insulin has been shown to be absorbed orally under certain circumstances (e.g. in the

presence of protease inhibitors or hypertonic solutions in the intestines).^{[10] [11]}

All of this data indicates that at least some of the larger molecules in glandular products are absorbed intact to induce physiological effects, particularly polypeptides which exert hormone or hormone-like action. Detractors of glandular therapy often claim that when a glandular is consumed, it is immediately digested into smaller building blocks like amino acids. However, these detractors are not up to date with current understanding of normal physiology.

CLINICAL APPLICATIONS

An adequate body of research now exists to support the use of orally administered glandular extracts. The following is a brief discussion of several glandular preparations and their use. [Table 40.1](#) lists the primary conditions responding to glandular therapy.

Adrenal extracts

Oral adrenal extracts have been used in medicine since at least 1931.^[12] Adrenal extracts may be made from the whole adrenal or just from the adrenal cortex. Whole adrenal extracts (usually in combination with essential nutrients for the adrenal gland) are most often used in cases of low adrenal function, presenting as fatigue, inability to cope with stress, and reduced resistance. Because extracts made from the adrenal cortex contain small amounts of corticosteroids, they are typically used as a “natural” cortisone in severe cases of allergy and inflammation (asthma, eczema, psoriasis, rheumatoid arthritis, etc.).

Dosage

The dosage of adrenal extract depends upon the quality and potency of the product. The best measure of an

TABLE 40-1 -- Therapeutic uses of glandular extracts

| Extract | Clinical applications |
|------------------|-----------------------|
| Adrenal extracts | Chronic fatigue |
| | Asthma |
| | Eczema |
| | Psoriasis |
| | Rheumatoid arthritis |

| | |
|---------------------------|---|
| Aortic glycosaminoglycans | Cerebral and peripheral arterial insufficiency |
| | Venous insufficiency and varicose veins |
| | Hemorrhoids |
| | Vascular retinopathies, including macular degeneration |
| | Post-surgical edema |
| Liver extracts | Chronic hepatitis |
| | Chronic liver disease |
| Pancreatic extracts | Pancreatic insufficiency |
| | Cystic fibrosis |
| | Inflammatory and autoimmune diseases such as rheumatoid arthritis, scleroderma, athletic injuries, and tendinitis |
| | Cancer |
| | Infections |
| Spleen extracts | After splenectomy |
| | Immune potentiation |
| | Infection |
| | Cancer |
| | Hyposplenism |
| | Celiac disease |
| | Dermatitis herpetiformis |
| | Ulcerative colitis |
| | Rheumatoid arthritis |
| | Glomerulonephritis |
| | Systemic lupus erythematosus |
| | Vasculitis |
| | Low white cell counts |
| Thrombocytopenia | |

| | |
|------------------|---|
| Thymus extracts | Recurrent and chronic viral infections, such as chronic fatigue syndrome, respiratory infections, AIDS, acute hepatitis B infection |
| | Cancer patients with immune depression from chemotherapy or radiation |
| | Allergies such as asthma, hayfever, eczema, and food allergies |
| | Autoimmune disorders, such as rheumatoid arthritis, lupus erythematosus, and scleroderma |
| Thyroid extracts | Hypothyroidism |

effective dose for a preparation may be the level of stimulation (irritability, restlessness, and insomnia) the patient experiences. When prescribing adrenal extracts, start at one-third the recommended dosage on the label and slowly increase the dosage every 2 days until a stimulatory effect is noted. Once this effect is noticed, reduce the dosage to a level just below the level that will produce stimulation.

Aortic glycosaminoglycans

A mixture of highly purified bovine-derived glycosaminoglycans naturally present in the aorta, including dermatan sulfate, heparan sulfate, hyaluronic acid, chondroitin sulfate, and related hexosaminoglycans, has been shown to protect and promote normal artery and vein function. Over 50 clinical studies have shown an orally administered complex of aortic GAGs to be effective in a number of vascular disorders, including:

- cerebral and peripheral arterial insufficiency
- venous insufficiency and varicose veins
- hemorrhoids
- vascular retinopathies, including macular degeneration post-surgical edema.^{[13] [14] [15] [16] [17] [18] [19] [20] [21] [22]}

Significant improvements in both symptoms and blood flow have been noted.

In addition, aortic GAGs have many important effects which interfere with the progression of atherosclerosis, including preventing damage to the surface of the artery, formation of damaging blood clots, migration of smooth muscle cells into the intima, and formation of fat and cholesterol deposits, as well as lowering total cholesterol levels while raising HDL-cholesterol.^{[23] [24] [25] [26] [27] [28]}

Dosage

The dosage of the mixture of highly purified bovine-derived glycosaminoglycans naturally present in the aorta is 100 mg daily. Similar, but not nearly as impressive, results in the treatment of atherosclerosis have been noted with chondroitin sulfate at a daily dose of 3 g (1 g with meals, three times daily).^[29]

Liver extracts

Hydrolyzed liver extracts have been used to treat chronic liver diseases since 1896. Numerous scientific investigations into the therapeutic efficacy of liver extracts have demonstrated that these extracts improve fat utilization, promote tissue regeneration, and prevent damage to the liver.^{[30] [31] [32] [33]} In short, clinical studies have demonstrated that oral administration of hydrolyzed liver extracts can be quite effective in improving liver function.

For example, in one double-blind study, 556 patients with chronic hepatitis were given either 70 mg of liver hydrosylate or a placebo three times daily.^[33] At the end of 3 months of treatment, the group receiving the liver extract was shown to have far lower serum liver enzyme levels. Since the level of liver enzymes in the blood reflect damage to the liver, it can be concluded that the liver extract is effective in chronic hepatitis via an ability to improve the function of damaged liver cells as well as prevent further damage to the liver.

Dosage

The dosage is entirely dependent upon the concentration, method of preparation, and quality of the liver extract. The highest quality products are aqueous hydrolyzed extracts because they have had the fat-soluble components removed and typically contain more than 20 times the nutritional content of raw liver, including 3–4 mg of heme-iron per gram.

Liver extracts should not be used in patients suffering from an iron-storage disorder such as hemochromatosis.

Pancreatic extracts

Pancreatic enzymes are most often employed in the treatment of pancreatic insufficiency. Pancreatic insufficiency is characterized by impaired digestion, malabsorption, nutrient deficiencies, and abdominal discomfort. Pancreatic enzymes are also used by physicians in the treatment of:

- cystic fibrosis
- inflammatory and autoimmune diseases like rheumatoid arthritis, scleroderma, athletic injuries, tendinitis, etc.
- cancer
- infections.

For a full discussion of pancreatic enzymes see [Chapter 101](#) .

Dosage

Full-strength products are preferred to lower potency pancreatin products because lower potency products are often diluted with salt, lactose, or galactose to achieve desired strength (e.g. 4x or 1x). The dosage recommendation for a 10x USP pancreatic enzyme product is 500–1,000 mg three times a day immediately before meals when used as a digestive aid and at least 20 minutes before meals or on an empty stomach when antiinflammatory effects are desired.

Pancreatic extracts are generally well tolerated and are not associated with any significant side-effects.

Spleen extracts

As early as the 1930s, orally administered bovine spleen extracts were shown to possess some physiological action in increasing white blood cell counts in patients with extreme deficiencies of white blood cells, as well as being of some benefit in patients with malaria and typhoid fever.^{[34] [35] [36]}

Like thymus extracts, pharmaceutical grade bovine spleen extracts are currently quite popular in Germany for the treatment of infectious conditions and as an immune-enhancing agent in cancer. Spleen tissue extracts may be of benefit in enhancing general immune function, as many potent immune system enhancing compounds secreted by the spleen are small molecular weight peptides. For example, the potent immunostimulants tuftsin and splenopentin are composed of only four and five amino acids, respectively.

Both tuftsin and splenopentin have been shown to exert profound immune enhancing activity. Tuftsin stimulates macrophages that have taken up residence in specific tissues like the liver, spleen, and lymph nodes. These large cells engulf and destroy foreign particles, including bacteria, cancer cells, and cellular debris. Macrophages are essential in protecting against invasion by microorganisms as well as cancer. Tuftsin also helps to mobilize other white blood cells to fight against infection and cancer. A deficiency of tuftsin is associated with signs and symptoms of frequent infections.^[37]

Splenopentin, like tuftsin, has also demonstrated significant immune-enhancing effects. Its effects are primarily directed towards enhancing the immune system's response to regulating compounds such as colony-stimulating factors.^[38] Colony-stimulating factors, such as interleukin-3, and granulocyte/macrophage colony-stimulating factors stimulate the production of white blood cells. Splenopentin is probably the factor responsible for

the results noted in those clinical studies during the 1930s with spleen extracts in the treatment of depressed white blood cell counts.

Splenopentin has also been shown to enhance natural killer cell activity.^[39] Natural killer cells destroy cells that have become cancerous or infected with viruses and are the body's first line of defense against cancer.

In addition to tuftsins and splenopentin, hydrolyzed (predigested) spleen extracts concentrated for peptides have demonstrated impressive immune restorative properties in mice.^[40] In one study, mice were exposed to radiation to significantly damage the immune system. Mice treated with the spleen extract recovered within 6–8 weeks. In contrast, those treated with a placebo recovered after 10 weeks at the earliest.

The primary clinical uses of spleen extracts are after removal of the spleen and conditions associated with low spleen function (hyposplenism) such as:

- celiac disease
- dermatitis herpetiformis
- ulcerative colitis
- rheumatoid arthritis
- glomerulonephritis
- systemic lupus erythematosus
- vasculitis
- thrombocytopenia.

Spleen extracts may also be useful in the treatment of low white blood cell counts, bacterial infections, and as an adjunct in cancer therapy. Individuals who have had splenectomies, who have low tuftsins levels, or autoimmune conditions linked to low RES activity should use spleen extracts.

Since the spleen is difficult to repair, severe spleen trauma usually requires splenectomy to stop the severe hemorrhage. The spleen is also removed in the medical treatment of certain diseases such as idiopathic thrombocytopenic purpura (ITP) and to determine the extent of Hodgkin's disease.

The removal of the spleen is associated with an increased risk for infection. In children and adults this increased risk of infection makes them particularly susceptible to pneumococcal pneumonia. About 2.5% of patients having their spleen removed will die from pneumococcal pneumonia within 5 years of splenectomy. It is often recommended that a child who has undergone a splenectomy receive a pneumococcal vaccine and receive long-term antibiotic treatment. Use of spleen extracts, especially those rich in tuftsins, may be a natural alternative.

Spleen extracts should probably be viewed as a necessary medicine for people who have had their spleen removed. If the thyroid, adrenals, or ovaries are removed, most patients would be prescribed the corresponding hormone. It only makes sense that if the spleen is removed, the body should be supplied with necessary spleen substances like

tuftsin and splenopentin.

The increased risk of infection is attributed primarily to a deficiency of tuftsin.^[41] ^[42] Tuftsin is produced only in the spleen; without the spleen there simply is no tuftsin in the circulation. Without tuftsin, the body is without one of its key stimulators of the immune system. Individuals without spleens need an outside source of tuftsin like spleen extracts.

Dosage

Clinically, hydrolyzed (predigested) products concentrated for tuftsin and splenopentin content are preferable to crude preparations. The daily dose should provide 50 mg tuftsin and splenopentin or roughly 1.5 g of total spleen peptides.

No side-effects or adverse effects have been reported with the use of oral spleen preparations.

Thymus extracts

There is a substantial amount of clinical research to support the effectiveness of orally administered thymus extracts. Specifically, numerous clinical trials have shown that oral administration of predigested calf thymus extract rich in thymus-derived polypeptides is effective in:

- preventing recurrent respiratory infections in children
- correcting the T-cell defects in human immunodeficiency virus infections (AIDS)
- treating acute hepatitis B infections
- restoring the number of peripheral leukocytes in cancer patients with chemotherapy-induced depression of WBC counts
- allergies including asthma, hayfever, and food allergies in children.^[43] ^[44]

The effectiveness of the thymus extract in these conditions is reflective of broad-spectrum immune system enhancement presumably mediated by improved thymus gland activity. This effect fits in nicely with one of the basic concepts of glandular therapy, i.e. that the oral ingestion of glandular material of a certain animal gland will strengthen the corresponding human gland. The result is a broad general effect indicative of improved glandular function. It is interesting that thymus extracts have been shown to normalize the ratio of T-helper cells to suppressor cells whether the ratio is low, as in AIDS, chronic infections, and cancer, or high, as in allergies, migraine headaches, and autoimmune diseases like rheumatoid arthritis.

Chronic viral infections. Recurrent or chronic infections, including the so-called *chronic fatigue syndrome* and *chronic post-viral syndrome*, are characterized by a

depressed immune system. This is a difficult condition to treat due to the repetitive cycle of a compromised immune system leading to infection, which leads to damage to the immune system, further weakening resistance to viral infection. Thymus extracts may provide the answer to chronic infections by restoring healthy immune function.

The ability of thymus extracts to treat and then reduce the number of recurrent infections was studied in groups of children with a history of recurrent respiratory tract infections. Double-blind studies revealed not only that orally administered thymus extracts were able to effectively eliminate infection, but also that treatment over the course of a year significantly reduced the number of respiratory infections and significantly improved numerous immune parameters.^[45]

One of the most difficult viral infections for the body to throw off is type B viral hepatitis. Thymus extracts have been shown to be effective in several double-blind studies in both acute and chronic cases. In these studies, therapeutic effect was noted by accelerated decreases of liver enzymes (transaminases), elimination of the virus, and a higher rate of seroconversion to anti-HBe, signifying clinical remission.^{[46] [47]}

The most extreme example of a chronic viral infection is AIDS. Although thymus extracts have not been shown to reverse this difficult disease, studies have shown an ability to improve several immune parameters including an ability to raise the T-helper cells, a critical goal in AIDS treatment.^[48]

Cancer. The primary application of thymus extracts in cancer has been to counteract the immune-suppressing effects of radiation and chemotherapy. The net effect of thymus extract administration is to prevent the tremendous depression of white blood cell levels and activity that result from chemotherapy or radiation.^{[44] [49]}

Allergies. People with allergies typically have derangements in the immune system. Levels of the allergic IgE antibody and eosinophils are typically elevated, while levels of suppressor T-cells are typically depressed. These abnormalities are clear indications of altered immune function.

The oral administration of thymus extracts has been shown in double-blind clinical studies to improve the symptoms and course of hayfever, allergic rhinitis, asthma, eczema, and food allergies.^{[44] [50] [51] [52]} Presumably this clinical improvement is the result of restoration of proper immune function, as levels of IgE and eosinophils have been reduced while the ratio of helper to suppressor T-cells have improved.

It is interesting to note that, in several double-blind studies, children receiving thymus extracts during food allergy elimination diets are often able to tolerate foods that had previously been allergenic and symptom-producing.^{[51] [52]}

Autoimmune disorders. Autoimmune disorders, such as rheumatoid arthritis, are characterized by the body's own antibodies attacking body tissues. Central to this autoimmunity is a high T-helper to suppressor cell ratio. A high T-helper to suppressor cell ratio results in increased antibody formation. The higher the ratio, the higher the

number of antibodies being produced to damage body structures. In one clinical study, rheumatoid arthritis patients with a helper to suppressor ratio of 3.3 achieved normal ratios (1.02–2.46) after 3 months of therapy with a thymus extract.^[44]

Although use of a thymus extract may not result in substantial clinical improvement, it appears to be useful in restoring proper immune function in autoimmune diseases including rheumatoid arthritis, lupus, and scleroderma.

Dosage

From a practical view, products concentrated and standardized for polypeptide content are preferable to

333

crude preparations. The daily dose should be equivalent to 120 mg pure polypeptides with molecular weights less than 10,000 or roughly 750 mg of the crude polypeptide fraction.

No side-effects or adverse effects have been reported with the use of thymus preparations.

Thyroid extracts

Desiccated natural thyroid is available by prescription according to United States Pharmacopoeia (USP) guidelines. Preparations are derived from porcine thyroid glands. Many naturopathic physicians prefer natural thyroid to isolated synthetic T_4 , as it contains both thyroxine (T_4) and tri-iodothyronine (T_3). Typical levels of thyroid hormone contained per grain in USP thyroid are 38 mcg for T_4 and 9 mcg for T_3 .

The thyroid extracts sold as “nutritional supplements” are required by the Food and Drug Administration (FDA) to be thyroxine-free. However, it is nearly impossible to remove all the hormone from the gland. In other words, think of these nutritional thyroid preparations as milder forms of desiccated natural thyroid.

The primary use of thyroid preparations is in the medical treatment of hypothyroidism. In all but its most mildest forms, treatment involves the use of desiccated thyroid or synthetic thyroid hormone. For more discussion, see [Chapter 162](#).

Dosage

Dosage is determined by basal body temperature (see [Ch. 162](#) for directions).

SUMMARY

From the scientific data that currently exists, there is enough evidence to support the use of orally administered glandular extracts. For best results, physicians should choose glandular products made by reputable companies that employ established methods of manufacture to produce extracts of known concentration.

Chapter 41 - Homeopathy

Andrew Lange ND

INTRODUCTION

Homeopathy is a highly systematized method of medical therapeutics and clinical evaluation. The term “homeopathy” is derived from the Greek words *homeos*, meaning similar, and *pathos*, meaning suffering. The medicines used in this system of therapeutics are chosen according to the “law of similars” (the concept of like curing like), a fundamental homeopathic principle based upon the observed relationship between a medicine’s ability to produce a specific constellation of signs and symptoms in a healthy individual and the same medicine’s ability to cure a sick patient with similar signs and symptoms. This principle was first recognized by Hippocrates, who noticed that herbs given in low doses tended to cure the same symptoms they produced when given in toxic doses.

Homeopathic medicines are derived from a wide variety of plant, mineral, and chemical substances. They are prepared according to the standards of the *United States Homeopathic Pharmacopoeia*, a recently revised version of which has been approved by the Food and Drug Administration, and Congress.

HISTORY

The homeopathic school of medicine was founded by a German physician, Samuel Hahnemann. He had already gained a reputation in chemistry and medicine, having formulated a soluble form of mercury and developed a safer method for its use, and having written a number of works on pharmacology, hygiene and public health, industrial toxicology, and psychiatry. His treatise on arsenic poisoning (1786) is still considered authoritative. A prolific writer, Hahnemann collected, compiled, revised, and edited the existing pharmacological knowledge. The work was well received by the medical profession of the time. In fact, Hahnemann was one of the most learned men of his generation in medicine, chemistry, and pharmacology, making his later criticisms of

medicine all the more significant.^[1]

Disillusioned with the theories and practice of 18th century medicine, Hahnemann retired from practice in 1782 and spent the next 14 years earning a meager living doing chemical research, writing, and translating English, French, Italian, and Latin works. He wrote of his time of practice:^[2]

It was painful for me to grope in the dark, guided only by books in the treatment of the sick. To prescribe according to this or that (fanciful) view of the nature of diseases, substances that only owed to mere opinion their place in the materia medica; I had conscientious scruples about treating unknown morbid states in my suffering fellow creatures with these unknown medicines which, being powerful substances, may, if they were not exactly suitable (and how could the physician know whether they were suitable or not, seeing that their peculiar special actions were not yet elucidated) easily change life into death, or produce new affections and chronic ailments, which are often more difficult to remove than the original disease.

In his struggle to determine a reliable basis for therapeutics, he was distressed by his inability to provide medical care for the acute illnesses of his own growing family. In 1790, during his translation of William Cullen's (a Scottish physician) *Materia Medica*, he added a footnote disagreeing with Cullen's conclusions that the basis of cinchona bark's effectiveness was its bitter and astringent qualities. *Cinchona officinalis* (Peruvian bark), from which the drug quinine is derived, was known to be clinically effective in malaria and intermittent fevers (then called ague). He argued that there were several drugs in common usage that, in smaller doses, had greater bitter and astringent qualities, yet had no specific action upon fevers. As an experiment, Hahnemann took four drachms of cinchona twice daily, and soon developed the paroxysmal symptoms characteristic of intermittent fevers.

This duplication of symptoms was a revelation to him and ultimately resulted in his formulation of the concept of determining the properties of a medicine by studying its effects on healthy humans.

While homeopathy offers a profoundly deep and unified evaluation in the treatment of chronic diseases (see "Evaluating the case" below), it had gained most of its early reputation in the treatment of acute and epidemic diseases. An uproar was caused in Cincinnati in 1849, when two immigrant German homeopaths, treating cholera with camphor and other homeopathically prescribed remedies, published in the newspapers statistics indicating that only 35 of their 1,116 treated cases had died. During the 19th century, 33–50% of patients with cholera who were given standard medical care, died. In the 1879 epidemic of yellow fever, New Orleans homeopaths treated 1,945 cases with a mortality rate of 5.6%, while the standard medical doctors were losing 16%.

These and similar statistics had a profound effect on Congress and public opinion.^[3]

Over time, the homeopaths established their own network of treatment facilities. By 1892, they controlled about 110 hospitals, 145 dispensaries, 62 orphan asylums and retirement homes, over 30 nursing homes and sanatoria, and 16 insane asylums.

Constantine Hering established the first homeopathic medical school in the United States in 1835. It later moved from its original site in Allentown, Pennsylvania to Philadelphia, where it remains today as an orthodox medical school: the Hahnemann Medical College and Hospital. Hering's promotion of homeopathy and development of the materia medica was equaled only by Hahnemann himself. His 10 volume work, *The Guiding Symptoms of Our Materia Medica*, remains the definitive work on the clinical verifications of the homeopathic approach. It is unfortunate that, of the many medicines introduced by Hering, only nitroglycerine remains in medical practice as a tribute to his medical genius.

Throughout the world, homeopathy has maintained a consistent tradition. Frederick Harvey Foster Quinn introduced it to England in the 1840s. It has since become a postgraduate medical specialty, recognized by the Department of Health by virtue of an Act of Parliament. Homeopathic hospitals and outpatient clinics are part of the National Health System. Homeopaths have been engaged as personal physicians to the royal family for the past four generations.

Homeopathy is widely practiced in Europe, India, Argentina, and Mexico, and is experiencing a renaissance in the United States.

PHILOSOPHY

Provings

Hahnemann defined his method of testing medicines on healthy people as "provings". He expanded his investigations to include a wide range of substances, using his family, friends, and associates as experimental subjects.

Historically, Hahnemann was not the first to utilize this methodology: in 1760, Anton Stoerck reported testing *stramonium* (*datura*) by rubbing it on the skin, inhaling the vapors of the freshly crushed leaves, and, finally, ingesting the fresh extract. He theorized that if *stramonium* disturbs the senses and produces mental derangements in healthy people, it might be administered to maniacs for the purpose of restoring the senses by effecting a change of ideas. The recent medical literature has contained examples of inadvertent provings: in 1983, a study in the *New England Journal of Medicine* reported that pyridoxine (vitamin B₆), which is used in the treatment of some types of peripheral neuropathy, was also capable of producing neuropathies when given in very large doses.^[4] In 1796, Hahnemann published, in *Hufeland's Journal*, the fruit of his investigations in an article, "Essay on a new principle for ascertaining the curative power of drugs, with a few glances at those hitherto employed".

Like treating like

Hahnemann also recognized the tendency of a natural disease to have a “homeopathic effect”, i.e. a preventive or therapeutic effect, on other diseases with similar symptomatology. Although he ascribed this to the stimulation of the organism to eradicate the disease, he felt the deliberate induction of a disease to be difficult, uncertain, and dangerous.^[5] This concept has many parallels in modern medical science. Descriptions of viral interference under natural conditions were described in 1937 by G. Findley and F. MacCallum, who found that monkeys infected with the Raft Valley fever virus were protected from the more fatal yellow fever virus. They adopted the term “virus interference” and believed that when one virus infects a group of cells, a second virus is somehow excluded.^[6] This eventually led to the discovery of interferon in 1957 by Alick Isaacs and Jean Lindenmann.

In 1799, Hahnemann gained increased professional acceptance of his ideas by the successful application of *Atropa belladonna* (deadly nightshade) in the prevention and treatment of scarlet fever (which had at that time reached epidemic proportions). In 1860, it was recommended as the treatment of choice in the National Dispensatory, which stated: “as long as persons are under the influence of belladonna ... the liability to contract scarlatina is very much diminished.”^[7]

The organon of medicine

In 1810, Hahnemann published his *Organon of Medicine*, a book which, through six editions, formed the foundation and definition of the homeopathic practice of medicine. It contains the philosophy, observations, and clinical applications of homeopathy, and citations from the historical and current literature of the time. Hahnemann challenged the reductionistic and mechanistic practices of his time, stating that the nature of disease is dynamic and could not be defined by isolating process, grasping for an explanation. He further asserted that the cause of disease could not be known, and that the categorization of disease states and attempts to manipulate physiology were insufficient, since they did not address the integrity and complexity of organization of the organism as a whole.

He described this organization as spiritual, meaning in accordance with the animating principle of life which is the underlying energetic pattern to which matter conforms.

Disease is therefore addressed descriptively in the context of the whole patient, with the patient’s unique symptoms being indicative of that individual’s vital response to the condition. For any given disease there may be a long list of remedies which have been clinically effective, but it is the individualization and differentiation between medicines, based on the patient’s unique indications, that leads to a successful homeopathic prescription.

Vitalism

Disease, in the homeopathic model, is thought to arise from inherent or developed weaknesses in the patient's defense mechanisms, creating a susceptibility to "morbid influences" (toxic factors in the environment, bacteria, psychological stresses, etc.). This viewpoint is considered "vitalistic" (see [Ch. 3](#) for a more detailed discussion) and, while not denying a corporeal reality, considers pathology to be but a singular focus in a complex net of interactions.

William Boyd, in his *A Textbook of Pathology*, discusses the limitations of the causal approach to disease, currently in vogue in medicine, when he states:^[8]

We must admit, however unwillingly, that we seldom or never really know the cause of anything. Many a beautiful idea has been slain by ugly fact. We merely note a constant association with one thing always following another. We say that the tubercle bacillus is the cause of tuberculosis. That is merely another way of saying that the bacillus is associated with a constant type of lesion; it is no explanation of how the lesions are produced by the bacillus. Nor does it explain why some persons and animals are susceptible to the infection while others are immune.

Vitalism can be better understood in the context of Hahnemann's time, when theories of the causation of disease and its treatment abounded, such as:

- Galen's doctrine that the secondary quality of a medicine, i.e. its action on the disease, can be determined from its primary qualities, such as, its taste or smell
- the evaluation of medicines by the study of their interactions when mixed with human blood in a jar^[1]
- iatrochemistry, which had been reduced from the Paracelcean application of spagyric tinctures or oils of metals to dangerous toxic doses
- the classification of drugs according to the Dioscoridian approach, which was based on the physiological action (i.e. diuresis, diaphoresis, etc.) and chemical composition
- the "doctrine of signatures," which held that the outer form and color of a plant revealed its inner archetypal action.

Although some studies of the effects of medicinal agents were done with animals, Hahnemann observed that they had different effects on humans: pigs could safely eat *Nux vomica* in quantities that would immediately kill humans; dogs could eat *Aconitum napellus*, a deadly poison to humans, without injury. He also rejected the method of testing drugs by studying their

effects on the sick as haphazard and unreliable, particularly since the results being sought were often only symptomatic relief rather than eradication of the disease state.

Hahnemann defined the application of medicines whose purpose was to alter physiology or act as an antagonist to disease as the practice of “allopathy” (*allo*-meaning “contrary” in Greek). The current dominant medical system is heavily influenced by the causalistic and allopathic paradigms. This results in the diagnosis being the focal point of practice, without which appropriate therapy cannot be instituted. This pharmacological approach is limited to the end results of disease rather than the origins of pathogenesis. This causes problems, since only the primary action of the pharmaceutical agent is utilized for treating a specific disease state, while the remaining range of physiological, as well as psychological, effects are ignored or unwanted and therefore classified as side-effects. In the homeopathic model, the side-effects are an important part of the agent’s action and the body’s response to them, and by ignoring them, a drug’s usefulness is greatly limited, while its toxicity is increased.

Hahnemann’s empirical investigations led not only to new applications of medicines, but provided a method for integrating the physical, mental, and emotional effects of a drug. This allowed the treatment of the totality of a patient’s symptoms as a dynamic pattern of interaction. Vitalists stress the teleological behavior of organisms, i.e. the goal-directedness and design in biological phenomena. Disease is therefore regarded as a positive expression of the organism’s self-regulatory process in response to an environmental, or other, stress. This response is not accidental or caused by the stressor, but is rather the effort of the organism to ward off deeper or more internal disorganization. It is the natural wisdom of the body, the *vis medicatrix naturae*, or, using current scientific terminology, the tendency of the body to maintain homeostasis. Medical intervention often acts in conflict with these vital intra- and extracellular regulatory functions.

Karl Menninger, in 1948, commented on this medical dilemma:^[9]

I believe that clinicians have come to think more and more in terms of a disturbance in the total economics of the personality, a temporary overwhelming of the efforts of the organism to maintain a continuous internal and external adaptation to continuously changing relationships, threats, pressures, instinctive needs and reality demands. ... It is the imbalance, the organismic disequilibrium, which is the real pathology, and when that imbalance reaches a degree or duration that threatens the comfort or survival of the individual, it may correctly be denoted disease.

Homeopathy is a method of specific induction of non-specific resistance, which stimulates the body’s inherent defense and self-regulatory mechanisms, rather than, by taking over a function of the body, initiating dependency on the medicine itself.

THE CLINICAL APPLICATION OF HOMEOPATHIC PRINCIPLES

The homeopathic clinical, or therapeutic, process consists of three interrelated processes: case-taking, evaluation, and prescribing. The process is comprehensive and engages the observations of the patient as well as those of the doctor. Hahnemann describes the process in paragraphs 84–103 of the *Organon* and stresses the

importance of distinguishing between chronic and acute, or self-limiting disease.

The homeopathic interview

The initial history of complaints is elicited from the patient with as little interruption as possible (as long as the patient does not digress unduly) so that the patient's train of thought is not disrupted or directed along lines imposed by the physician's biases. According to Hahnemann:

The physician elicits further particulars about each of the patient's statements without ever putting words in his mouth, or asking a question that can be answered only by yes or no, which induces the patient to affirm something untrue or half true or else deny something really there to avoid discomfort or out of desire to please, thereby giving a wrong picture of the disease, which would lead to the wrong treatment.

An entire review of symptoms is recorded in descriptive detail, taking into consideration all modalities which affect a symptom. Hahnemann emphasized the general symptoms, i.e. those affecting the entire organism, as the leading indications for the remedy. These key symptoms include mental and emotional affects, the metabolism and its reactions to environmental stimuli, sleep positions, food cravings and aversions, thirst, body type, and all manifestations of unconscious and autonomic regulation.

Unique characteristic symptoms, particularly those regarded as "strange, rare, and peculiar", are important considerations in the selection of the remedy. These might be the expression of a paradoxical or unusual relationship, such as pain ameliorated by pressure or the sensation of the legs being made of wood or glass. The association of the start of a disease or symptom complex with an environmental or emotional event can be very important and emphasizes the importance of an accurate and extensive interview.

Hahnemann emphasizes the importance of taking a comprehensive case, particularly in chronic disease:^[5]

In chronic diseases in women one should pay particular attention to such things as pregnancy, infertility, sexual

desire, confinement, miscarriages, nursing, vaginal discharges, and the condition of the monthly flow, especially noting whether it recurs at intervals that are too short or too long, how many days it lasts, whether or not it is interrupted, the quantity, how dark with color, any leukorrhea before or after the flow. If there is leukorrhea, what it is like, what symptoms accompany it, what is its quantity, under what conditions does it appear, what brings it on?

Since the patient's symptoms are the expressions of the body's attempts to heal itself, symptomatic treatment, i.e. most allopathic therapies, impairs the physician's ability to obtain vital information and complicates the taking of the case. This problem has also been recognized by some medical authors, such as Boyd, who states: "We recognize that the pattern of disease has changed out of recognition during the last thirty to forty years owing to modern drugs, particularly the antibiotics."^[8]

Case evaluation

Considering the vitalistic and holistic perspective of the homeopathic approach, a clear definition of cure is necessary in order to establish the treatment goal. Mere palliation or suppression of symptoms at the cost of the overall vitality and function of the individual is considered negligent by the homeopathic practitioner. For example, if a patient's skin disease is treated and appears to resolve, but is followed by asthma, fatigue, and confusion, the treatment is evaluated as having been suppressive. If, upon proper treatment, the more serious lung and systemic disruptions are alleviated and the prior skin lesions return, the patient is considered as progressing towards a cure. When further appropriate therapy results in final alleviation of the skin disease, without any undue stress to the patient, it is then considered a true cure.

This evaluative procedure is part of what is known as "Hering's law of cure", an observation of the principles of curative responses which can be applied to any healing process, regardless of the school of thought. In true healing, according to this set of observations, symptoms follow these patterns:

- from above, down the body to the extremities
- from within to without (often in the form of discharges and other eliminative processes)
- from the most important organs (e.g. the CNS) to the least important organs (typically the skin)
- in reverse order of their appearance, i.e. the chronologically most recent being replaced by those of the earlier stages of the disease, and, in some instances, earlier in the patient's life.

Homeopathy holds that the disease first affects the vital force, and is manifested first by a change in the patient's well-being, long before any objective changes can be observed. Illness is usually first recognized when the patient becomes aware of the early manifestations of the disease.

Disease and cure must also be considered in the context of the belief system and culture of the patient. Much of what we call disease arises from the individual's inability to find meaning and purpose. Many forms of healing are capable of enabling the person to integrate into the fabric of daily life and of providing ways to help the person address personal needs for fulfillment.

In his study of disease, Hahnemann noted that there were inherited predispositions to

disease, which he related to the improper treatment, and therefore suppression, of skin eruptions and venereal disease. He called these predispositions miasmas, and in 1828, published his findings in *Chronic Diseases: Their Nature and Homeopathic Cure*. He observed that many people, despite apparently healthy lifestyles, develop degenerative diseases. These often become established in childhood, and continue to plague the person throughout life, despite medical treatment.

More recently, George Vithoulkas, a contemporary homeopathic author and teacher, has defined health on three levels: mental, emotional, and physical. The mind should be capable of functioning with clarity, rationality, coherence, and logical sequence. It should be capable of engaging in creative service for the good of others, as well as for the good of oneself, demonstrating a freedom from selfishness and possessiveness. On the emotional level, there should be a state of serenity free from excessive passion, a state which should not be confused with lack of emotional response generated as a protection against emotional vulnerability. Finally, on the physical level, there should be freedom from pain. The healing person should experience a subjective sense of well-being and a progressive increase in vitality.^[10]

Prescription

Since homeopathy is oriented towards the administration of a single medicine at a time (probably due to the fact that there have been few provings of combination remedies, whose interactions can therefore only be assumed, but not known), careful prescribing is important. It is through the application of single medicines that physicians have been able to record clinical verification of the provings and amass an impressive body of literature.

The process of selecting the correct remedy is called “repertorization”, and involves both careful study of the patient’s symptomatology and medical history, and matching these with the appropriate remedy. This requires a sound understanding of the homeopathic materia medica (see below).

Homeopathic pharmacy and potency selection

This leads to a discussion of what has remained the greatest mystery of homeopathic medicine (and the source of the considerable ridicule and misunderstanding) – the use of “potentized” substances.

As Hahnemann began his research, he found that when treating patients according to the law of similars there was an initial aggravation of the symptoms, the “healing crisis,” when using the high dosages typical of that era. He empirically tried using progressive dilutions of the medicines, beginning with tinctures from plants and titrations with milk sugar for metals and salts. He made the dilutions serially by mixing one drop of the tincture to 100 drops of alcohol which were then succussed (shaken by pounding

against a resilient surface) vigorously. He found that, with increasing dilution, the severity of the aggravation lessened while the patient continued to improve, often with deeper and more enduring results. He called these diluted remedies “potentized”. As an analytical chemist, he was aware of Avogadro’s theories (they were contemporaries), but he persisted in evaluating dilutions beyond the point where chemical activity could be detected.

Various techniques have been used to determine if there is a physical difference between the potentized dilution and the unmodified vehicle. These studies have used UV spectroscopy, conductivity measurements, IR spectroscopy, surface tension measurements, Raman-laser spectroscopy, NMR, and other methods. Much of this work has shown regular peaks and troughs in activity with progressive dilutions, and Heintz has claimed that the peaks correspond to the maximum effects found in the biological studies he has reported.^[11]

The most cogent demonstration of the physical properties of homeopathic preparations has been the work of Shui-Yin Lo PhD. Dr Lo, a particle physicist, has demonstrated that stable rigid structures, which he calls IE structures, can be formed in water molecules by the electric dipole moment, which can conform to solutes present in the water.^{[12] [13]} IE structures stand for ice formed under electric fields. Although most of Dr Lo’s work has been concerned with applications of IE crystals in engine combustion efficiency, when he tested homeopathic preparations by fluorescence spectrophotometry and transmission electron microscopy, he was able to demonstrate unique structures of IE crystals, which were stable at room temperatures and heat-resistant.

Further studies are necessary to confirm and develop the understanding of the mechanisms and validity of homeopathic medicines.

In terms of clinical practice, there have evolved general guidelines for the determination of potency. In the sixth edition of the *Organon*, Hahnemann recommends ascending the scale of potencies gradually. In paragraph 248, he suggests that the medicinal solution be succussed anew with use. In chronic cases, the patient is directed to take 1 teaspoonful daily or every other day, and in acute diseases, as frequently as needed. If the solution is used up before the problem alleviates, the next higher dilution is used (if still indicated by the symptom pattern).^[5]

The higher potencies, whose use largely developed in the United States, are given much less frequently, and are generally reserved for the experienced practitioner. The more potentized the remedy, the closer it must meet the law of similars, i.e. the accuracy of the prescription must be high, for a curative effect.

It is important to note however, that the sixth edition was unavailable until 1924, 76 years after Hahnemann’s death. The predominant clinical application of homeopathic potencies had developed using an ascending scale. A single dose was used until its action had ceased, when the same potency would be repeated. When that potency seemed to no longer demonstrate an enduring effect, a higher potency was used. The general range of potencies used included 6C, 12C, 30C, 200C, 1M, 10M, and CM (“C”

denotes the centesimal scale utilized by Hahnemann).

The study of the materia medica

Constantine Hering once stated:

A mere acquaintance with the principle symptoms cannot be called studying the materia medica, although we make it the basis of our study. The study of materia medica must be regarded and dealt with in exactly the same manner as that of other natural sciences.

To give a perspective on the way in which homeopathic physicians organize the proving symptoms into clinical pictures, we will draw from an essay on *Sepia* by E. B. Nash:^[14]

This is another of our wonderful remedies of which the dominant school knows nothing, except what they have learned from us. Its chief sphere of action seems to be in the abdomen and pelvis, especially in women. No remedy produces stronger symptoms here. We quote from different but equally good observers.

Sensation of bearing down in the pelvic region, with dragging pains from the sacrum; or feeling of bearing down of all pelvic organs. (Hahnemann)

Labor-like pains accompanied with the feeling as though she must cross her legs and "sit close" to keep something from coming out through the vagina. (Guernsey)

Pain in uterus, bearing down, comes from back to abdomen, causing oppression of breathing; crosses limbs to prevent protrusion of parts. (Hering)

Prolapse of the uterus, of the vagina, with pressure as if everything would protrude. (Lippe)

Experience has shown its value in cases of ulceration and congestion of the os and cervix uteri. Its use supersedes all local applications. (Dunham)

No higher authority than the united testimony of these five of our best observers could be brought to show the action of *Sepia* upon the pelvic organs.

Now when we come to examine the provings in Allen's *Encyclopedia*, we find that these symptoms were mainly produced by Hahnemann and his

provers, and Hahnemann advocated proving remedies in the 30th, and some of them were produced by the 200th, especially those most strongly verified by black-faced type.

We confess that we cannot understand how so many question the value of potencies for proving or curing...

Sepia, like *Sulphur*, affects the general circulation in a very marked manner. **Flashes of heat with perspiration and faintness** is almost as characteristic of this remedy as of *Sulphur*. But there are, with *Sepia*, more apt to be associated with them the pelvic symptoms already given, and they are also more apt to occur in conjunction with the **climacteric**. Indeed, these flashes often seem with *Sepia* to start in the pelvic organs and from thence to spread over the body.

But this irregularity of circulation extends as far as that of *Sulphur*. The hands and feet are hot alternately, that is, if the feet are hot, the hands are cold, and *vice versa*. There is not so much **sensation** of burning with *Sepia* as with *Sulphur*, but there is actual heat, and the venous congestion, which seems to be the real state of the organs where the pressive bearing down et cetera is felt, is also accompanied with much throbbing and beating.

This local congestion to the pelvic organs is not simply sensational. There are actual displacements in consequence of it, and the long continued congestion results in inflammations, ulcerations, leukorrhoeas and even malignancies or cancerous organizations. Induration with a painful **sense** of stiffness in the uterine region is characteristic.

This pelvic congestion also affects the rectum in a marked degree. The rectum prolapses, there is a sensation of fullness, or of a foreign substance as of a **ball or weight**, and oozing of moisture from the rectum. Indeed, the rectal and anal symptoms are almost as strong as the uterine and vaginal. It is impossible to enumerate all the symptoms connected with the circulatory disturbances of *Sepia* is such a work as this, only a general study of the *Materia Medica* can do it.

The urinary organs come in for their share of symptoms. The same pressure and fullness consequent upon the portal congestion reaches here. We will now proceed to give what we have found to be particularly valuable symptoms under the various organs in this region. "Pressure on bladder and frequent micturation with tension in lower abdomen." "Sediment in the urine like clay; as if clay burnt on the bottom of the vessel; urine **very offensive** (*Indium*), can't endure to have it in the room, it is reddish or may be bloody." This is found mostly in women. With children there is one peculiar symptom which has often been verified. "The child always wets the bed during its **first sleep**."

Upon the male organs I have found it particularly useful in chronic gleet. There is not much discharge, but a few drops, perhaps, which glue up the orifice of the urethra in the morning; but it is so persistent and the usual remedies will not “dry it up.” In my early practice I used to use a weak injection of *Sulphate of Zinc*, but it used to annoy me that I could not use it without resorting to local measures. *Sepia* does it in the majority of cases and *Kali iodatum* will do it in the rest. I have, where there was a thick discharge of long standing and the smarting and burning on urination continued, several times finished the case with *Capsicum*.

As a rule, this long continued slight, passive gleety discharge is a result of weakness of the male genitals, *as is shown by a flaccidity of the organs and frequent seminal emissions. The emissions are thin and watery. Sepia* covers all of this and often sets all to rights in a short time.

The mind symptoms of *Sepia* are like *Pulsatilla*, in that she is sad and cries frequently without knowing the reason why. So if in a tearful mind with uterine disturbances *Pulsatilla* should fail you, the next remedy to be studied is *Sepia*. But there is another condition of mind not found under *Pulsatilla* or any other remedy in the same degree, and that is, that, notwithstanding there is no sign of dementia from actual brain lesion, the patient, contrary to her usual habit, **becomes indifferent to her occupation**, her house work, her family or their comfort, **even to those whom she loves the best**. This is a very peculiar symptom and a genuine keynote for the exhibition of *Sepia*...

I once cured a very obstinate case of entero-colitis (so-called cholera infantum), after the complete failure of two eminent allopaths, with *Sepia*, the leading symptom being, **always worse after taking milk**. Oozing of moisture from the anus finds its remedy here sometimes, but oftener in *Antimonium crudum*. The *Sepia* patient is very weak. A short walk fatigues her very much. She **faints** easily from extremes of cold and heat, after getting wet, from riding in a carriage, while kneeling at church, and on other trifling occasions. This fainting, or sense of sinking faintness, may be found in pregnancy, child bed, or during lactation; or, again, it may come on after hard work, such as “laundry work;” so it has come to be called the “washer woman’s” remedy. *Phosphorus* has washer woman’s toothache.”

As can be seen by this excerpt, the indications for a remedy are complex, requiring study and understanding.

RESEARCH IN HOMEOPATHY

Since homeopathy arose from empirical observations, and operates from phenomenologically descriptive fields rather than causal relationships, its evaluation by the scientific method, as described by Karl Popper, poses unique problems. A recent critical review appeared in *The British Homeopathic Journal* describing the methods

utilized in various attempts to verify this school of medicine.^[11] The following briefly discusses some of the studies which have been done.

Human studies

Science is based on the premise of non-biased inquiry. Despite antagonism towards homeopathy, researchers have persisted in producing clinical trials, most of which have demonstrated its efficacy. The method of individualization in homeopathic prescribing has challenged study designs, and required several studies to be questioned. However a recent meta-analysis of 119 placebo-controlled trials showed that for every negative study, an average of 2.45 studies were published which demonstrated the efficacy of homeopathy.^[15] The *British Journal of Homeopathy* and *The Lancet* remain useful resources for homeopathic research published in English. References for homeopathic research may be found on the internet

342

at www.healthy.net/homeopathicresearch. A few interesting studies follow.

During World War II, isopathic preparations were given prophylactically, and homeopathic therapies were used in mustard gas burns. A statistical analysis shows that these treatments yielded significant results when compared with placebos. The remedies used were mustard gas, *Rhus toxicodendron*, and *Kali bichromium*.^[11]

Gibson et al^[16] published a double-blind clinical trial of homeopathic treatment in rheumatoid arthritis.^[20] The 3-month study was elegantly designed, in that the prescribing was individualized to the patient's symptoms and was controlled, on a double-blind basis, by giving half the patients the correct remedy and the rest a placebo. All patients continued to use conventional, non-steroidal, anti-inflammatory drugs, and the treated group showed significant improvement in subjective pain, articular index, stiffness, and grip strength.

In another study, Shipley et al^[17] compared *Rhus toxicodendron* and fenoprofen in the treatment of osteoarthritis. The study demonstrated no effects from the *Rhus toxicodendron*, but it has been deservedly criticized since it lasted only 2 weeks (hardly enough time for the remedy to work since, in chronic diseases, homeopaths typically wait 4–6 weeks before attempting to evaluate the efficacy of the remedy) and the remedy was not individualized for the patient.

Animal studies

Caulophyllum (in the 30th centesimal potency) was given to 10 sows to test its efficacy in the control of stillbirths. The results showed a statistically significant drop in the number of stillbirths and led to a larger, uncontrolled study in a whole herd. After 4

months of therapy, piglet mortality dropped from 20 to 2.6%.^[18]

Cloudhury^[19] obtained dramatic results from injecting mice intraperitoneally with *Kali phosphoricum*, *Calcarea phosphorica*, or *Ferrum phosphorica* (in the 30th decimal potency) 12 days after implantation of fibrosarcoma. Of the 77 treated mice, 52% were cured and survived more than 1 year, whereas all of the 77 controls died within 10–15 days.

Scofield,^[20] in his review article, discusses numerous experiments with humans, animals, and plants using isopathic treatment for poisoning and experimental liver damage, and various in vitro studies. According to his exhaustive evaluations, although many of the studies demonstrated that homeopathic preparations have effects, even when not applied according to the homeopathic method, most lacked statistical analysis or were poorly designed, making a definitive statement of efficacy impossible at this time.

CONCLUSION

Homeopathy represents an integrated holistic system of natural therapeutics. Its capacity for addressing psychosomatic disease and acute pathology as a dynamic process is unique. It has remained a coherent system, with extensive clinical verification, for over two centuries. Homeopathy is an economical and effective method which has been established as an integral part of the medical system in several countries. With the resurgence of interest in natural medicine, this discipline will undoubtedly be more widely utilized.

Unfortunately, however, homeopathy is also an extremely difficult system to master, requiring both considerable understanding of case-taking and materia medica as well as extensive consultation time with the patient. It has, therefore, often been discarded, even by those aware of its efficacy. Although attempts have been made to reduce it to simpler systems (allergy desensitizations, vaccination, Schuessler's cell salts, and isopathic preparations from diseased tissues and heavy metals, etc.), they are not considered homeopathic unless prescribed according to their effects upon healthy people or the confirmed observations of cured symptoms.

In the context of modern naturopathic medicine, it is important to recognize that Hahnemann did not ignore the importance of lifestyle in the treatment of the patient:

While taking a case of chronic disease one should examine and weigh the particular conditions of the patient's day to day activities, living habits, diet, domestic situation, and so on. One should ascertain whether there is anything in them which may cause or sustain the disease and remove it to help the cure.

Chapter 42 - Hydrotherapy

Robert Barry ND

INTRODUCTION

Hydrotherapy may be defined as the use of water, in any of its forms, for the maintenance of health or the treatment of disease. Although one of the oldest known therapies, it has received little attention from the research community, particularly recently. Much of the information presented here is compiled from older works which, although they lack the quantification available with current technology, show a remarkable attention to clinical effects and patient response.

HISTORY

As one of the ancient methods of treatment, hydrotherapy has been used to treat disease and injury by many different peoples, including the Egyptians, Assyrians, Persians, Greeks, Hebrews, Hindus, and Chinese. In the *Rig Veda*, written about 1500 BC, we read that “water cures the fever’s glow”.

Hippocrates used hydrotherapy extensively around 400 BC. In his writings concerning baths are some of the earliest dictums on the therapeutic uses of water:^[1]

Much will depend on whether the patient, when in good health, was very fond of the bath, and in the custom of taking it: for such persons, especially feel the want of it, and are benefited if they are bathed, and injured if they are not. In general it suits better with cases of pneumonia than in ardent fevers; for the bath soothes the pain in the side, chest and back; cuts the sputum, promotes expectoration, improves the respiration, and allays lassitude; for it soothes the joints and outer skin, and is diuretic, removes heaviness of the head, and moistens the nose. Such are the benefits to be derived from the bath, if all the proper requisites be present; but if one or more be wanting, the bath, instead of doing good, may rather prove injurious; for every one of them may do harm if not prepared by the

attendants in the proper manner.

He writes further to explain the specific contraindications to the use of the bath.

As these early writings show, the uses of water had been explored extensively at very early times, with many of the principal effects having been observed and utilized.

The modern history of hydrotherapy begins in the 17th century with the publication, in 1697, of *The history of cold bathing* by Sir John Floyer. Following Floyer were several works which attempted to provide a scientific foundation for the uses of water in medicine. Probably the strongest impetus for its use came from central Europe, where it was advocated by such well known hydropaths as Priessnitz, Rausse, and Father Kneipp. They were able to popularize specific water treatments which quickly became the vogue in Europe during the 19th century. By the end of the 19th century, there were many individuals, both in the US and in Europe, who were actively engaged in practicing hydrotherapy.

Probably the best known American was J. H. Kellogg, a medical doctor who approached hydrotherapy scientifically, performing many and varied experiments on its use and effects. In 1900, he published what may still be considered a definitive treatise on hydrotherapy, entitled *Rational hydrotherapy*,^[2] in which he considers the physiological and therapeutic effects of water, along with an extensive discussion of hydrotherapeutic techniques.

The scientific and lay literature of this period shows a wide disparity of thought as to the validity and efficacy of hydrotherapeutic treatments. In Germany the uses of hydrotherapy were openly embraced, whereas in nearby France hydrotherapy was seriously questioned, never becoming as popular or widely used.

During the 20th century, the popularity of hydrotherapy treatments declined, along with the numbers of practitioners and institutions providing treatments. One of the few physicians to maintain an active practice in hydrotherapy was Dr O. G. Carroll, a naturopath practicing for many years in Spokane, Washington. He developed a specific constitutional hydrotherapy treatment which is currently receiving an increased amount of interest from the naturopathic profession.

Although hydrotherapy declined in use for many years, it is rightfully being revived at the present time. It is a highly effective, non-invasive means of treating the sick, which may be used both in the office and in the home, is economical, and involves patients directly in their care. As such, it is an ideal naturopathic treatment modality.

RECENT RESEARCH

The scientific medical literature, although not replete with research concerning hydrotherapy, continues to have occasional articles or books devoted to the subject.

Two articles that clearly demonstrate the disparity of current thought have appeared. The first, an extensive review article from Belgium, states:^[3]

Hydrotherapy is based on the physical properties of water, acting from outside the body mainly during the time of its application. The underlying cause of the disease being treated is not affected, so hydrotherapy must be considered as an adjunct, as a palliative measure facilitating the activity of other remedies or spontaneous healing.

The second article, appearing in 1977 in a German medical journal, would seem to be in counterpoint to the Belgian premise. It states:

Immunological tests were performed on 34 patients undergoing hydrotherapy according to Kneipp. IgM, alpha-2-macroglobulin and complement factor C₃ concentrations were increased after this treatment but not in 10 health volunteers (controls).

These two articles exemplify the nature of the continuing debate concerning the uses of hydrotherapy. German healers continue to be the most active proponents of hydrotherapy as a significant means of treating disease.

In a review article in *Scientific American*, Edelson & Fink^[4] discussed the significant role of the skin in immune function. Although they make no references to topical applications of water having an effect on this mechanism, it certainly provides an impetus for further work in this area and may, at some point, provide the rationale for many of the effects which have been ascribed to hydrotherapeutic procedures.

Two recent studies provide additional documentation of the physiological effects of hydrotherapy. In the first study, 10 healthy subjects who swim regularly in ice cold water during the winter were evaluated before and after their short-term whole body exposure. The researchers found a drastic decrease in uric acid concentration seen during and following the exposure to cold stimulus and an increase in the level of oxidized glutathione and the ratio of oxidized glutathione/total glutathione. Baseline concentration of reduced glutathione was increased and the concentration of oxidized glutathione was decreased in the erythrocytes of winter swimmers as compared with those of non-winter swimmers. These changes were interpreted by the researchers as an adaptation to repeated oxidative stress. This research supports the hydrotherapy concept of "hardening", i.e. the exposure to a natural stimulus, in this case thermal, which results in an increased tolerance to stress and disease.^[5]

The other study evaluated the impact of a cold-wet sheet pack on the trunk in patients suffering from chronic cardiac, rheumatic, and metabolic diseases, as well as functional disorders. The control group received a dry sheet pack, but without the stimulus of

hydrotherapy. The study showed a significant difference in the outcome of both applications. The mental well-being was affected positively in 18 patients during their real treatment, compared with nine in the control group.^[6]

PROPERTIES OF WATER

Water has several unique properties which contribute to its effectiveness as a therapeutic agent. It has an ability

347

to store and transmit heat, which renders it most appropriate for treatment purposes. Water absorbs more heat for a given weight than any other substance – almost twice as much as alcohol or paraffin, 10 times more than copper or iron, and 30 times more than lead or gold. Water is also a good conductor of heat.

The solvent properties of water account for its usefulness in the most common of all hydrotherapy procedures, baths and showers. Water is commonly considered the universal solvent.

Water's non-toxicity allows for its use both internally and externally, even in individuals who are extremely sensitive to their surroundings.

Water also has the ability to change states within a narrow, easily obtainable temperature range. As ice, it is an effective cooling agent. In the liquid state, water may be applied as packs, baths, sprays, compresses, and douches at any desired pressure and temperature. As a vapor, it may be employed in vapor or steam baths or by inhalation.

Since the density of water is near that of the human body, it can be used as an exercise medium for patients with paralysis, inflammations, or atrophy.^[7] Upon immersion of the body in water, hydrostatic pressure is exerted upon the body surface, which has the effect of increasing venous and lymph flow from the periphery and increasing urine output.

Water is also unique in that it is universally available, readily accessible, and applied with relatively simple and inexpensive equipment.

Physiological effects

The physiological effects of hydrotherapy may be classified as thermal, mechanical, and chemical. Thermal effects are produced by the application of water at temperatures above or below that of the body. The greater the variation from body temperature, the greater the effect produced, other factors being equal. The mechanical effects are produced by the impact of water upon the surface of the body in the form of sprays,

douches, frictions, whirlpools, etc. The chemical effects are produced when it is taken by mouth or used to irrigate a body cavity, such as the large colon. The most commonly utilized effect, therapeutically, is the thermal one. It is the only one which will be dealt with in this section.

Heat may be transferred from one object to another in several different ways, including conduction, convection or conversion. In hydrotherapy, the heating and cooling effects are produced by conduction of heat from the water to the body. The contact of water with the body is accomplished by means of baths, showers, sprays, packs, compresses, etc.

The primary variable of concern is temperature, both of the water and of the patient. The temperature of the human body in a state of health is considered to be normal at 98.6°F orally, although it varies throughout the day from a low of near 97°F between 3 and 6 a.m. to a high of over 99°F around 6 p.m. These variations are important to consider when evaluating an individual prior to a hydrotherapy application. There is also a wide range of temperature variation within the healthy human body, as can be seen in [Table 42.1](#). ^[2]

Body temperature is also a reflection of other factors, such as exercise, fasting, ovulation, etc. In an infant, the temperature may be elevated by 1–3°F during a prolonged crying spell.

During a fever, the temperature is elevated due to any of several factors, including:

- infection
- tissue destruction
- malignancy
- foreign proteins in the blood
- dehydration
- hormonal imbalances
- muscular or chemical activity.

Proper evaluation of the degree and cause of a fever is necessary prior to hydrotherapy treatments.

When we consider water temperature, the terms “hot” and “cold” are related to body temperature. The range of temperatures useful in hydrotherapy applications varies from very cold to very hot. [Table 42.2](#) provides general terminology.

Deep well water is near 53°F. Cold tap water in Seattle varies in temperature throughout the year depending on the depth of the pipes and other exposures to the environment. During the winter it may be as low as 40°F, and in the summer as high as 60°F. This temperature

TABLE 42-1 -- Temperature of various tissues

| Tissue | Temperature (°F) |
|--------|------------------|
|--------|------------------|

| | |
|-----------------------------|-----|
| Average temp of the skin | 93 |
| Average temp of the blood | 102 |
| Brain | 104 |
| Liver | 106 |
| Left ventricle of the heart | 107 |

TABLE 42-2 -- Sensations when the forearm is immersed in water of various temperatures

| Temperature (°F) | Description | Sensation |
|------------------|-------------|--------------------------------------|
| >104 | Very hot | Can tolerate for only a short period |
| 98–104 | Hot | Skin redness if prolonged |
| 95–98 | Warm | Comfortably warm |
| 92–95 | Neutral | No sensation |
| 80–92 | Tepid | Slightly cooling |
| 65–80 | Cool | Cool |
| 55–65 | Cold | Sensation of coldness |
| 32–55 | Very cold | Pain and numbness |

variation may be a significant factor in hydrotherapy treatments; therefore, it is advisable to be aware of your water temperature when using hydrotherapy techniques.

Effects of cold applications

Cold applications may be made by means of ice, cold water, or cold air, or by the evaporation of water or other liquids from the surface of the body. Although the applications may vary, the principles and effects remain consistent.

The primary or direct effect of cold applications is depressant in nature, leading to a decrease in function, either locally or systemically, depending on the application. The longer and colder the application, the longer and more intense will be the depressant effect. However, as the body responds to the cold application, there is a return to normal function which may lead to a state of increased activity. This is known as the secondary, or indirect, effect of cold, also termed the “reaction”. If the cold application is a short one, the reaction follows quickly, its intensity reflecting the intensity (i.e. coldness) of the application. The secondary effect, or reaction, occurs only when the body has the vitality to respond to the cold, either following its removal from the body, in such applications as

showers, sprays, baths, etc., or after the body has warmed the application, in such cases as cold compresses or packs. In general, the colder the application the greater the reaction.

Many hydrotherapy techniques are directed at producing the reaction to the cold application.

Effects of hot applications

Heat may be applied to the body in a variety of ways, including hot packs, fomentations, steam, hot air, baths, showers, etc. All hot applications produce definite physiological responses which are attempts to eliminate heat in order to prevent a rise in local and systemic temperatures. The effects produced by hot applications depend on the mode, temperature, and duration of the application and the condition of the patient.

Water at 98°F or above is generally perceived as hot, and over 104°F it is considered to be very hot. At 120°F, an immersion bath becomes unendurable, although small areas of the body, such as the hand, may be conditioned to endure a temperature 10–15° higher for short periods. The mucous membranes, unlike the skin, may endure temperatures as high as 135°F, which accounts for our ability to drink very hot liquids, such as tea or coffee. Hot air may be tolerated by many individuals for fairly long periods, such as in a sauna, in which the temperature may reach as high as 200°F. Although exposure to the high temperatures of hot tubs and saunas has become quite popular in recent years, repeated and prolonged use may act to weaken the individual, unless counteracted by frequent cold applications, such as showers or ablutions.^[2]

A comparison of the effects of hot and cold on several body systems is given in [Table 42.3](#).

PRINCIPLES OF BLOOD MOVEMENT WITH HYDROTHERAPY

In order to promote healing, either locally or systemically, it is important to maximize circulation of well-oxygenated, nutrient-rich, toxin-low blood. Hydrotherapy techniques are one of the most effective means of accomplishing this, if used in conjunction with proper levels of activity, optimal nutritional intake, and adequate detoxification.

There are four basic modifications of blood movement within the body:

- increased rate of blood flow through an organ or area of the body
- decreased rate of blood flow through an organ or area of the body
- increased volume of blood in an anemic area
- decreased volume of blood in a congested area.

TABLE 42-3 -- Comparison of the effects of hot and cold on several body systems^[2]

| System/Organ | Cold | Hot |
|--------------|------|-----|
|--------------|------|-----|

| | Primary | Secondary | |
|----------------|----------------------------|----------------|------------------------------------|
| Skin | | | |
| —blood vessels | Constriction | Dilation | Dilation |
| —respiration | Decreased | Increased | Increased |
| —heat loss | Decreased | Increased | Increased |
| Blood vessels | Constriction | Dilation | Dilation (constriction if intense) |
| Heart | Rate increased | Rate decreased | First decreased, then increased |
| Nerves | Numbed | | Excited |
| Muscles | Volume decreased | | Volume increased |
| Respiration | Slowed and deepened | | Rate increased |
| Stomach | Motility and HCl increased | | Motility and HCl decreased |

In order to accomplish these modifications there are five relevant physiological principles:

- revulsive effect
- derivative effect
- spinal cord reflex
- collateral circulation
- arterial trunk reflex.

Revulsive effect

The revulsive effect provides a means of increasing the rate of blood flow through an organ or other body part, such as an extremity. The most effective means of accomplishing this is by using alternating hot/cold either as compresses, baths, showers, sprays, etc.

Local, alternating, hot and cold applications produce marked stimulation of local circulation. It has been shown that a 30 minute contrast bath produces a 95% increase in local blood flow when the lower extremities alone are immersed. When all four extremities are immersed at the same time, there is a 100% increase in blood flow in the upper extremities and a 70% increase in the lower extremities.^[8]

Several studies have researched the optimal treatment times for revulsive effects.

Woodmansey et al^[9] found 6 minutes of hot application and 4 of cold to be optimal for the British subjects he studied. Krussen^[10] found 4 minutes hot and 1 minute cold to be the best treatment protocol. Moor^[11] states that 3 minutes hot, followed by 30–60 seconds of cold, provides satisfactory clinical results. From these variations, we may infer that, due to the variations in procedures and locales, it is best for practitioners to determine their own ideals, based on their observations of clinical results. Basically, the cold application need only be long enough to produce vasoconstriction, and this can be shown to occur in as short a period as 20 seconds.

Repetition of applications is another important variable to be considered when applying revulsive treatments. A series of three hot/cold applications seems to be practical. Most individuals show a decreasing secondary reaction to repeated applications of cold.

Due to the increased blood flow within an area, the revulsive effect is ideal for treating situations presenting primarily as congestion. An example of this effect is the use of alternating hot/cold compresses over the face for sinus congestion. As a powerful decongestant, the revulsive effect also acts as an analgesic for pain resulting from congestion. Because of its marked stimulation of local circulation, the revulsive treatment is an exceptionally effective hydrotherapeutic procedure.

Derivative effect

The derivative effect may be considered the opposite of the revulsive effect. Its primary intent is to alter the volume of blood in an organ or area of the body. This effect is best obtained by the prolonged use of either cold or heat depending on whether one wants to draw blood into an area (hot application) or to drive blood out of an area (cold application). An example of the derivative effect would be the prolonged application of heat to the feet, as with a hot foot bath, in order to decrease congestion in the head. This form of treatment may be quite successful for certain forms of congestive headaches. In general, the greater the area of the body exposed to the application, the more extreme the temperature, and the longer the application, the greater will be the effect.

Spinal reflex effect

The spinal reflex effect provides a means of affecting a distant area of the body through a local application. A sufficiently intense local application of hot or cold not only affects the immediate skin area, but also causes remote physiological changes, mediated through spinal reflex arcs. These effects have been carefully observed over many years, and have led to a mapping which correlates each surface area with its corresponding internal area and/or organ. Most texts on hydrotherapy contain such a diagram (see Kellogg,^[2] pp. 721–722).

Some examples of studies dealing with specific reflex effects follow. Hewlett,^[12] Stewart^[13] and Briscoe^[14] all noted changes in blood flow in the opposite arm and hand when one arm and hand were placed in hot or cold water. Ruhmann^[15] observed that when cold was applied to the epigastrium, there was a decrease in tone of the stomach, with a quieting of the pylorus. Heat at 50°C applied to the epigastrium produced

increased tone in a relaxed stomach and decreased tone in a contracted stomach. Poulton^[16] demonstrated that esophageal function could be influenced by irritation of the skin over the sternum. Bing & Tobiassen^[17] were able to show reflex relationships between the skin of the abdominal wall and the colon. Bing & Tobiassen also demonstrated a reflex relationship between the lungs and the skin of the chest wall. Kuntz^[18] stated that:

In view of the facility with which cutaneous stimulation elicits reflex visceral reactions, particularly vasomotor changes and changes in the tonic state of the visceral musculature, it must be apparent that many visceral disorders, particularly disorders of the gastrointestinal canal, may be influenced beneficially by appropriate stimulation of the corresponding cutaneous area.

Fisher & Solomon^[19] stated: “externally applied heat not only decreased intestinal blood flow, but also diminishes intestinal motility and decreases acid secretion in the stomach, while cold has the opposite effect”. This is an example of a contrary effect in which the reflex effect is not the same as that observed in the local reflex

TABLE 42-4 -- Reflex effects of prolonged heat

| Application location | Effect |
|-----------------------------|---|
| One extremity | Vasodilation in contralateral extremity |
| Abdominal wall | Decreased intestinal blood flow, intestinal motility and acid secretion |
| Pelvis | Relaxes pelvic muscles, dilates blood vessels, increases menstrual flow |
| Precordium | Increases heart rate, decreases its force and lowers blood pressure |
| Chest | Promotes ease of respiration and expectoration |
| Trunk | Relaxes ureters or bile ducts, relieves renal or gall bladder colic |
| Over kidney | Increases production of urine |

TABLE 42-5 -- Reflex effects of prolonged cold

| Application location | Effect |
|------------------------------|--|
| Trunk of an artery | Contraction of the artery and its branches |
| Nose, back of neck and hands | Contraction of the blood vessels of the nasal mucosa |

| | |
|-----------------------------------|---|
| Precordium (ice bag) | Slows the heart rate and increases its stroke volume |
| Abdomen | Increases intestinal blood flow, intestinal motility and acid secretion |
| Pelvic area | Stimulates muscles of the pelvic organs |
| Thyroid gland | Contracts its blood vessels and decreases its function |
| Hands and scalp | Contraction of brain blood vessels |
| Acutely inflamed joints or bursae | Vasoconstriction and relief of pain |

TABLE 42-6 -- Reflex effects of short cold

| Application location | Effect |
|--|---|
| Local application of intense cold as brief as 30 seconds | General peripheral vasoconstriction |
| Face, hands and head | Increase in mental alertness and activity |
| Precordial area | Increase in heart rate and stroke volume |
| Chest, with friction or percussion | Initial increase in respiratory rate, then slower, deeper respiration |

skin area, i.e. local heat decreases, rather than increases, intestinal blood flow as one might expect. Prolonged cold has the opposite effect.

[Tables 42.4](#) , [42.5](#) , [42.6](#) show some of the observed reflex effects of hydrotherapeutic procedures.^[11]

Collateral circulation effect

The collateral circulation effect may be considered as a special case of the derivative effect.^[2] In general use, the derivative effect involves blood volume changes from one area of the body to another, as previously discussed. The collateral circulation effect, on the other hand, more specifically considers the local circulatory effects on deep (rather than superficial) collateral branches of the same artery.

If we consider the circulatory patterns of a large body part, such as the thigh, we see that both superficial and deep areas are supplied by the same artery. A hot application to this area will dilate the surface vessels, drawing blood to the superficial areas and concurrently decreasing the blood flow to the deep areas. A cold application will cause the opposite effect. Local compresses and fomentations are the most commonly used techniques to affect collateral circulatory changes.

Arterial trunk reflex

The arterial trunk reflex effect is a special case of general reflex effects.^[2] It has been observed that prolonged cold applied over the trunk of an artery produces contraction of the artery and its branches distal to the application. Prolonged hot applications have the opposite effect of producing dilatation in the distal arterial bed.

An example of this effect would be the application of prolonged cold to the area of the femoral artery in the groin in order to decrease blood flow in a foot or ankle that had sustained an acute injury which resulted in either internal or external hemorrhage. Following the acute phase, prolonged hot applications might be used in like manner in order to increase circulation and speed healing of the injured part.

GENERAL RULES OF HYDROTHERAPY

1. The first rule of hydrotherapy is the same as for any therapy: treat the whole person. This involves considering all aspects, including medical history, current condition, current medications and any other relevant information.
 2. Use hydrotherapy treatments in a coordinated and integrated manner with any treatments or medications the individual is receiving.
 3. Always measure the person's temperature before beginning a treatment. If their temperature is below normal, apply more heat or leave the hot applications on for a longer time. If body temperature is above normal, use less heat and more intense cold during the treatment.
 4. Explain the treatment procedure before beginning, including the technique to be used, the duration, frequency, and any other relevant factors. Try to ensure that the patient feels comfortable with the procedure before beginning.
 5. In order to provide as precise a treatment as possible, grade the patient in terms of age, severity of problems, vitality, emotional state, circulatory condition, etc. Be especially careful with young or elderly persons, individuals who are chilly, have cardiac problems, are
-

weak or debilitated, are obese, or have other severe physical compromises. For individuals with insulin-dependent diabetes, the application of heat to the extremities is never indicated. Diabetics frequently have arterial disease, which may reduce blood flow to an extremity. The application of heat increases the metabolism of the tissues. Due to impaired circulation, the metabolic needs can very quickly overuse the nutrients and oxygen available from the blood, and cells may die from oxygen depletion simply as the result of hot applications.^[20]

Therefore, hot foot baths are contraindicated in diabetics.

For diabetics with conditions in which a hot application to the feet would normally be the treatment of choice, you may use instead a large hot compress to the lower abdomen, groin, and thighs in order to get a reflex reaction in the lower extremities.

Diabetics may also display peripheral neuropathies which decrease their ability to sense heat, thereby increasing the possibility of causing a burn with hot

applications. Other individuals with neurological injury or disease should also be treated with extreme caution during hot applications.

6. The environment in which the treatments are given should enhance and stimulate the healing forces as much as possible. This may include such considerations as color of the room, light intensity, music, plants, etc.
7. If a patient becomes chilled during a treatment, it may be necessary to stop the treatment and warm the person. Sometimes it may suffice to warm the person (by such means as hot drinks, friction rubs, additional blankets, or a hot water bottle to the feet) while continuing the treatment. If the person fails to warm following these attempts, then stop the treatments and warm them. Never allow a patient to become chilled to the point of shivering.
8. Following a hydrotherapy treatment, avoid excessive heat in the form of overly warm clothing, overly warm rooms, sun exposure, or exercise. Excessive heat may slow or prevent the body reaction to the treatment and negate the benefit of the treatment.
9. It is best to do the treatment at an optimal time of day for that patient. It is best to do treatments before meals, or at least 1 hour after a meal. From Chinese medicine, we learn the relationships between disease and time of day. For those who have this knowledge, it is well to use it when deciding at what time to do hydrotherapy treatments.

As with any therapy, it is important to practice hydrotherapy with a research orientation, noting unusual reactions and physiological effects. Many physiological parameters, such as urine chemistries and microscopic components, specific gravity, body temperature, and blood sugar levels, may be easily monitored and recorded during treatment. This information helps to optimize the treatment protocols, stimulates further research, and validates hydrotherapy as an effective and useful therapeutic modality.

POSSIBLE SIDE-EFFECTS OF HYDROTHERAPY

Although hydrotherapeutic procedures are generally mild, they may in some situations produce unexpected or undesired effects. These effects may be the result of improperly applied treatments, but they may, in some cases, result simply from the individual's reaction to the treatment. They may, in the long term, be beneficial. Any time an individual experiences an undesired effect following a treatment, the therapist should review the treatment's length, intensity, and appropriateness for the individual at this time. If more treatments are considered, they may need to be modified in order to lessen the undesired effects.

Some of the possible side-effects of hydrotherapy treatments are:

- headache (resulting from too long or intense a treatment, or from the release of toxic products in the body)
- vertigo
- nervousness
- aches and pains
- insomnia
- nausea

- palpitations
- faintness
- chilliness.

Following an unpleasant reaction to a hydrotherapy treatment, discontinue the treatment and wait at least 2–3 hours before attempting another treatment. Calming teas, such as catnip or chamomile, may be helpful. In cases of chilliness, always act quickly to warm the person. Coaching the person in deep, slow breathing exercises for several minutes often relaxes the person and decreases the reaction.^[20] If you are providing the treatment in your office, reassure yourself that the patient has fully regained his/her balance before allowing him/her to leave.

Although these effects may occur during, or immediately following, treatments, they may also occur as long as 24 hours later. Therefore, it is important for practitioners to be available to patients during off-duty hours.

HYDROTHERAPY TECHNIQUES

The variety of ways in which water may be applied to the human body therapeutically is only limited by the

imagination of the practitioner. J. H. Kellogg, in his seemingly exhaustive treatise on hydrotherapy, devotes 541 pages to describing the techniques of hydrotherapy. There are also several other books available which describe in detail specific procedures and techniques.^{[11] [20] [21] [22] [23] [24] [25]} Those desiring to use these techniques in practice are encouraged to obtain one or several of these reference works.

To successfully use hydrotherapy, one must be familiar enough with the procedure to use it in an efficient and competent manner. Although the equipment required for these techniques is quite simple, it is important that it be clean, easily available, and maintained properly. Care for the comfort and confidence of the patient will greatly increase the effectiveness of the treatments.

Compresses

There are three basic types of compresses: hot, cold, and alternating hot and cold. They are each applied using cloth, or other compress material, which is wrung out to the desired amount of moisture, and then applied to any surface of the body.

A single compress consists only of layers of the wet material, whereas a double compress is one in which the wet cloth is completely covered by dry material, usually wool, which acts to prevent cooling by evaporation or heat loss. This allows the body, in the case of a cold double compress, to warm the area, thereby producing a secondary

reaction to the cold.

Compresses are commonly referred to by the area of the body they are applied to, such as the throat, head, joint, trunk, or limb.

Cold compress

A cold compress consists of a cloth wrung from cold or ice water and then applied to the body. The water may contain solutes such as NaCl, baking soda, Epsom salts, boric acid, or cider vinegar. Herbs may also be used to create a more specific effect from the compress. Some commonly used herbs are hayflower, oatstraw, and fenugreek, made as teas into which the compress cloths are dipped.

The *cold single compress* has primarily a vasoconstrictive effect, both locally and distally. Due to this effect, it may be used to prevent or relieve congestion, reduce blood flow to an area, prevent edema following injury, inhibit inflammation, and relieve pain due to congestion. It may also be used to reduce body temperature when applied over a large area of the body.

These compresses are renewed frequently (every 1–5 minutes) in order to maintain the primary cold effect. The temperature of a cold compress will depend on the specific problem being treated, as well as the state of health of the patient. In general, the colder the application, the briefer the period of application.

Cold compresses should not be used locally in a person who is chilly or who has pleurisy, sinusitis, or acute asthma, as these conditions may be seriously aggravated.

The *cold double compress*, also known as the heating compress, consists of a cold compress covered completely by several layers of dry material such as flannel or wool. It is allowed to remain on until warmed by the body. The layers of dry material prevent heat loss by evaporation, thereby permitting accumulation of heat and creating a general heating effect. Cold double compresses are used most commonly in upper respiratory infections, such as sore throats, bronchitis, influenza, pneumonia, and swollen lymph glands in the neck. They may also be applied over the trunk or abdomen, genital area, joints, limbs or feet.

The primary effect of cold double compresses is to increase the local circulation, thereby providing for increased nutrition and oxygenation of the tissues, and increased elimination of metabolic waste from the area. As with cold single compresses, the temperature of the initial application depends on the state of the patient and the condition being treated. In general, the colder the application, the stronger will be the secondary reaction to the cold. As weak and debilitated patients are unable to generate a strong secondary reaction, cool rather than cold application may be indicated. The same general precautions as for a cold single compress should be followed.

Hot compress

The hot compress is a prolonged application of moist heat, generally to a local area of the body. The fomentation is a special case of a hot compress, which provides prolonged exposure at a higher temperature.

Hot compresses and fomentations have several therapeutic effects. In many situations they may create an analgesic effect, thereby decreasing pain. They are generally more effective locally for pain resulting from spasm than for pain due to congestion. They also create a derivative effect, which may be used to increase blood flow to the periphery, thereby decreasing internal congestion. By applying short, intensely hot compresses, a stimulation effect may be obtained. This may be used to increase blood flow to a part, to stimulate certain organ functions, to decrease others, and to produce tissue warming and relaxation. Mildly hot compresses may be beneficial for their sedative effects in treating insomnia, nervous tension, and mild muscular spasms.

Fairly hot compresses may be applied directly to the skin surface, with care taken to not burn or startle the patient. As stated previously, hot applications are contraindicated on the extremities of diabetic individuals.

When treating the elderly, or those with impaired neurological function, edema, or decreased circulation, special caution must also be taken. Fomentations are commonly applied at temperatures which are not tolerated directly on the skin, and therefore must be applied over a bath towel placed on the area.

Baths

Baths are full or partial immersions of the body into water of various temperatures. Bath waters may contain additional substances such as salts, minerals, herbs, or medications and may be in an agitated state, as with a whirlpool.

Hot full immersion baths

These are given within a temperature range of 100–106°F for up to 20 minutes. They are indicated as home treatment for rheumatoid arthritis, to aid in relief of muscular spasms, for cleansing the body, and to induce sweating. Given for brief periods, they may help to reduce fevers by creating peripheral vasodilation, thereby promoting an increased heat loss.

In most instances they are best followed by a brief cool bath, shower, or spray. Prolonged hot tub baths are never appropriate in the very old or very young, weak or anemic persons, individuals with severe organic disease, or in anyone with a tendency to hemorrhage.

Neutral bath

The neutral bath is a full immersion bath given at the average temperature of the skin, 92–95°F, in which the recipient has neither the sensation of being warmed nor that of being cooled. A minor variation in temperature of as little as 2°F may create a totally different therapeutic effect. As the ideal temperature is dependent on the patient's condition and reaction to the water, it is often better to use their sensation, rather than a thermometer, as a guide to adjusting the temperature. The duration of a neutral bath may vary from 15 minutes to 4 hours. If the bath lasts longer than 20 minutes, it will be necessary to add warm water to maintain the temperature.

The primary effect of a neutral bath is to create a state of decreased excitation. This sedative effect, similar to that produced in deprivation tanks, calms the nervous system.

A second effect is activation of the kidneys, creating increased urinary output due to the absorption of water into the body during periods of prolonged immersion.^[26] It is aided by the neutral temperature, which provides no stimulus for water loss through sweating. Nephrotic patients display increased phosphate excretion following prolonged immersion; therefore, they warrant special care when given prolonged immersion baths.^[27]

Lastly, the neutral bath causes a decrease in the surface temperature of the body due to the lack of the normal heat-producing stimulus of cool air on the skin. As a result, the surface may be cooled as much as 6°F, creating a tendency to chilling following the bath. This effect necessitates special care in keeping the patient warm. When prescribed for home treatment, a neutral bath is best taken just before getting into bed, in order to avoid chilling.

Therapeutically, neutral baths are most commonly used for their calmative effects in cases of insomnia, anxiety, nervous irritability, exhaustion, or chronic pain. By increasing kidney output, they may be appropriate in detoxification programs for substances such as alcohol, tobacco, or coffee, or as an adjunct treatment for peripheral edema. They also serve a valuable role in the control of fevers in individuals who would not be able to react to stronger measures, such as the Brand bath. These patients would include the very young, very old, feeble, or exhausted.

Start the baths at about 98°F and lower the temperature slowly over a period of 5–10 minutes to 92–93°F, until the desired body temperature is reached.^[21]

Sitz bath

The sitz bath is a partial immersion bath of the pelvic region. It is more easily given in a specially constructed tub but may also be effectively done in a regular bath tub. Often it is taken with the feet immersed in a separate tub of hot water before or during the bath. A sitz bath may be taken hot, neutral, cold, or contrast hot and cold.

The *hot sitz bath* is generally taken for 3–10 minutes at 105–115°F. The primary effect is analgesic. It may be helpful in cramps of the uterus or ureters, pain from hemorrhoids, ovaries or testicles, sciatica, urinary retention, and after cystoscopy or hemorrhoidectomy. It is followed by cool sponging or effusion of the area. Hot sitz baths are not indicated in cases of acute inflammation, but may be appropriate for chronic PID. Hot applications to the pelvis are also contraindicated during menses in most instances. The hot sitz bath is best taken with a hot foot bath at 110–115°F.

Neutral sitz baths are more appropriate for situations of acute inflammation, such as cystitis and acute PID. They are given at 92–95°F for between 15 minutes and 2 hours. It is necessary to provide adequate coverings during this period to avoid chilling. Neutral sitz baths may also be very effective for pruritis of the anus or vulva. Appropriate herbs, salts or other medications may be added to the water to optimize the treatment.

The *cold sitz bath* is given immediately following a warm-to-hot sitz bath of 1–3 minutes, and lasts (at a temperature of 55–75°F) from 30 seconds to 8 minutes. It is important to ensure that the water level of the hot

bath on the body is at least 1 inch above the level of the cold water. This insures adequate warming of the area, thereby preventing chilling. Friction rubs to the hips during the cold sitz bath promote an increased reaction.

The cold sitz bath is used mainly for its tonifying effects. It may be used for subinvolution of the uterus, metrorrhagia, atonic constipation, enuresis, atony of the bladder, and chronic prostatic congestion. Since it increases the tone of the smooth muscles of the uterus, bladder, and colon, it lessens the tendency to bleed from the uterus, the lower bowel and rectum.

Contrast sitz baths are given in groups of three, i.e. three alterations of hot to cold. Two separate tubs are necessary to facilitate this process. The hot is at 105–115°F, the cold at 55–85°F, with the temperatures again dependent on the condition being treated and the strength of the patient. A standard treatment would be 3 minutes hot and 30 seconds cold. The water level in the hot tub is set 1 inch higher than in the cold. Adequate draping is necessary to prevent chilling. As with all hydrotherapy treatments, one always finishes with the cold.

The contrast sitz bath increases pelvic circulation and tone of the smooth muscles of the region. It is indicated in chronic PID, chronic prostatitis, atonic constipation, and other atonic conditions of the pelvis. The strong revulsive effect created increases the blood flow in the pelvic region dramatically.

Cold friction rubs and ablutions

Cold friction rubs, or ablutions, consist of frictioning the body in a predetermined sequence with cold water. They differ from spongings in that they are more tonifying and are done more vigorously with rougher materials. A woolen bath mitt works well, but if this is not available, a coarse washcloth or loofa may also be used.

A *whole body ablution* is carried out with the patient lying supine, covered completely and not chilly. Using cool to cold water the therapist dips the mitt into the water and vigorously frictions a portion of the body. Depending on the cooling effect desired, the mitt may either be saturated or wrung dry prior to the frictioning. The body part is frictioned until reddening occurs. If the patient is weak, it is best to dry the areas as you proceed using a coarse dry towel. If the patient is strong and vigorous, one can wait and dry them at the end of the treatment.

One sequence for an ablution treatment would be, with the patient supine, to proceed from the chest to the arms, and then the legs, then, turning the patient over, to do the back of the legs and feet, the buttocks, and finally the back. Only that part being frictioned is exposed at any time.

The primary effect of a cold ablution is tonic. Therefore, it may be used for any condition in which you desire a tonifying treatment, such as fatigue following illness or surgery or after hot applications, such as saunas, whirlpools, or hot baths. It is an excellent prophylactic hydrotherapy technique when used regularly along with saunas, hot tubs, and massage.

Wet sheet pack

The wet sheet pack is one of the most useful of all hydrotherapy procedures. It may be done either in the office or as a home treatment, if adequate direction is provided. It requires from 1–3 hours, depending on the condition of the patient. The technique is common to most schools of hydrotherapy. It is important to understand the process completely before using this treatment:

1. Using either a bed or treatment table, place two wool blankets lengthwise on the table with a small pillow at the head. The blankets must be large enough to cover the person being treated. If wool is not available, acrylic is the next best choice.
2. The patient must be warm before the pack is applied. If not, they may be warmed by a hot bath or shower, dry blanket pack, diathermy over the back, or any other appropriate technique.
3. Once the patient is ready, a clean white cotton sheet (equal in length to the height of the patient) is wrung as dry as possible after being soaked in cold water. It is much easier if two people are available to wring out the sheet. The sheet is opened and placed lengthwise along the table with equal amounts draped over each side of the table. The sheet should be 1–2 inches below the height of the blankets.

4. The patient now removes all clothing and lies on the wet sheet with shoulders 4 inches below the top of the sheet. Both arms are raised while the attendants quickly wrap one side of the sheet around the body, tucking it in on the opposite side, and carefully molding it to the body. Below the hips, the sheet is wrapped around the leg on the same side.
5. The arms are now lowered and the opposite side of the sheet is drawn over the body, covering both arms. It also wraps the opposite leg. The wet sheet is quickly smoothed over the body to ensure complete contact and is tucked in around the feet. As this is a shocking experience, it should be performed quickly and efficiently.
6. At this point, the blankets are quickly pulled over the body and tucked in firmly, ensuring there are no drafts around the neck or the feet. Additional blanket(s) may be laid over the patient and tucked in as appropriate. A stocking cap may be pulled over the head to increase the heating effect.

While the patient is in the pack, it is necessary to have someone nearby at all times. Sudden attacks of claustrophobia in some individuals can create extreme

355

anxiety. Should this occur, first remove the sheet from the feet, as this may allow enough movement to allay the attack. If this is unsuccessful, it may be necessary to stop the treatment.

Providing hot teas is very helpful throughout the treatment. If the patient complains of chilliness, add blankets, place a hot water bottle to the feet, or provide warm drinks.

The wet sheet pack proceeds through four stages: tonic or cooling, neutral, heating, and eliminative. Depending on the desired effect, the therapist may wish to prolong any one specific stage:

- *Tonic stage.* This stage may last from 2 to 15 minutes and is finished when the patient no longer perceives the sheet as being cold. This phase is intensely alterative to the body, due to the intense thermic reaction induced. The length of this stage is directly dependent on the amount of water left in the sheet. For weak or exhausted patients, the sheet should be wrung out as completely as possible. For young, strong individuals for whom a more tonifying treatment is desired, more water may be left in the sheet.
- *Neutral stage.* Once the sheet reaches body temperature, the person no longer feels cold. At this time, the neutral phase begins. It may last from 15 minutes to an hour or longer, depending on the vitality of the patient. During this phase, there is a sense of calm which is similar to that experienced during a neutral bath. Very often the patient will fall asleep during this phase. This stage is indicated in cases of insomnia, anxiety, and delirium. In order to prolong the neutral phase, provide only adequate covering to prevent the patient feeling cool. Greater amounts of blankets will trap more heat and the neutral phase will finish sooner.

- *Heating stage.* As heat accumulates beneath the blankets, the patient will gradually sense the warming, and eventually begin to show light perspiration on the forehead. The time between the patient feeling warm and the beginning of perspiration is known as the heating phase. This may last from 15 minutes to 1 hour.
- *Elimination stage.* The final stage begins when the body begins to perspire. In a febrile patient this stage will be reached sooner. This stage is especially beneficial for those patients in a detoxification process such as from alcohol, tobacco, coffee, or other toxins. It may also be used with acute infections, such as colds, flu or bronchitis. Certain skin conditions, such as jaundice, may also benefit from this stage, as well as acute inflammatory conditions, such as arthritis.

During the elimination phase, it is important to provide adequate fluid to the patient. Herb teas, used for either their diaphoretic or therapeutic effects, are most appropriate.

This phase may last up to 1 hour. The treatment should be ended quickly if the patient begins to feel chilled or becomes uncomfortable.

The treatment is ended by quickly removing the patient from the pack, frictioning the skin briskly with a dry towel, and having the patient dress. As this is often an intensive treatment, it should be followed with rest or appropriate activity. Lying in a warm room for an hour is an ideal follow-up to this treatment. If done at home, it is best done in the evening just prior to retiring.

CONCLUSION

Hydrotherapy provides the naturopathic physician with an effective form of treatment for many conditions. In this chapter we have touched on only a few of the many techniques which have been developed over the years. References 2, 11, 20 and 21 provide those who are interested in further study in this area with appropriate information.

Chapter 43 - Manipulation

Robert M. Martinez DC ND

THERAPEUTIC KEYS

- Manipulation is a passive manual maneuver that is performed in such a way that the patient is unable to prevent it and that introduces movement beyond the passive range of motion's elastic barrier but does not exceed the anatomical barrier.^[1] Mobilizations are passive stretches with or without oscillations over which the patient can exert control.^[2] Spinal adjustments are chiropractic techniques that range in force from a near imperceptible force to high-velocity thrust with joint cavitation (popping noise).
- Initial evaluation of patients for “red flags” of fracture, infection, neoplasm, progressive neurologic deficit, cord pressure or cauda equina syndrome is the prudent starting point.^{[3] [4]}
- A correct differential diagnosis is key to the selection of patients, and the functional assessment is key to the selection of appropriate manual medicine techniques.^[5]
- If gross signs of inflammation are present in a joint (heat, swelling, redness, and pain), manipulation of that joint most likely will aggravate the condition.
- When a motion causes pain, forcing the motion can result in injury.
- If applying heat for 10 minutes, followed by active and passive motion of the joint, improves the condition, manipulation will usually help. When this causes aggravation, manipulation will usually make the condition worse.
- Relaxation techniques (heat, muscle work, calming environment) prior to a manipulation are very helpful in achieving best results. They are especially indicated in patients complaining of aching and stiffness prior to manipulation.^[6]
- If pain is the chief complaint, icing the area for 5 minutes will cause surface anesthesia, and 20 minutes will cause sedation of the actions of the muscle spindle cells. Sedation of a muscle reflex arc prior to manipulation of a fixated painful joint will facilitate the treatment.^[2]

-
- If the patient reports an increase in pain or stiffness after a manipulation, ice the

area of treatment for 10–30 minutes after manipulation to reduce spasm and pain.^[7]
^[8]

- “The goal of manipulation is to restore maximal pain-free movement of the musculoskeletal system in postural balance.”^[9]
- Don’t treat muscle spasm as a primary condition. Muscle spasm is almost always a response of the body to a noxious stimulus. Find the cause and treat it.^[10]
- Trigger points (TPs) are myofascial irritations which are frequently caused by underlying joint fixations. If one manipulates over a TP, it will frequently precipitate a muscle spasm later that day or the next morning.^[11]

HISTORICAL PERSPECTIVE

The popularity of manipulation could be likened to the course of a roller coaster – diving up and down and taking many unexpected turns. The literature is replete with references to the use of manipulation. Manipulations are depicted in prehistoric cave drawings and Chinese statues, circa 2700 BC.^[12] The early history of manipulation has been researched by Lomax and presented in two papers. She credits Hippocrates with the earliest recorded written physician’s prescription of manipulative treatment methods. Worthington notes that Hippocrates in *On Joints* clearly states method and motive for the application of manipulative therapy.^[13] Hippocrates advocated many of the premises in use today: judicious use of force, direction of thrust, and proper levering of the joints. Even at this early date, mention is made of the abuse of manipulative therapy.^[13]

Until the sixth century, manipulative treatment saw little change. At that time, treatment with open wounds was used by Arab physicians, based on the humoral theory of disease.^[13] During the Dark Ages, priests provided medical treatment at their monasteries. Kessler states: “Friar Moulton, of the order of St. Augustine, wrote *The Complete Bonesetter*. The text, which was revised by John Turner in 1656, suggests that manipulation was practiced in medical settings throughout the Middle Ages and Renaissance.”^[14]

The course of the history of manipulation in the late 1700s and afterward is colorful and flamboyant. Three main concepts developed during this time still have a major influence on our thoughts regarding manipulation. The first held that vertebral luxation was responsible for spinal deformity. The second was held by the largest group which followed the writings of Percival Pott and maintained that caries of the spine were more common than previously thought. This idea caught hold and was taken to an extreme. This faction of physicians treated spinal deformity by blood-letting and rest, while condemning extension and manipulation as both useless and dangerous. A third group held that muscles were the main cause of problems, and treatment should be complete rest or active exercise, as the case warranted.^[13]

Central to the early issues, aside from the political and economic waves the irregulars were creating for the allopaths, were concerns about the potentially disastrous effects of manipulating tuberculous, neoplastic, rheumatic, or fractured joints. More recently, questions of vertebral disc herniation, precipitation of CVAs (cerebral vascular accidents), and the lack of a differential diagnosis by many non-allopathic manipulators has caused concern. To this, add the controversial issues of cost-effectiveness and

efficacy of treatment, and one can begin to understand the apprehension with which allopathic practitioners approach manipulative therapy.

It is interesting to note that:

- Hippocrates railed against the abuse of manipulative therapy by physicians and others of his time.
- Physicians of the late 1700s assailed one another's methods of treatment (an example can be found in *The Lancet* December 16, 1826, p. 347, the page banner appropriately reading "THE YELLOW JOURNAL").
- Surgeons held "bonesetters" in great contempt "when they condescend[ed] to speak at all of bonesetters and their works".^[12]
- Bonesetters held their secrets and passed them from father to son.
- Financial competition was noted early in the literature. "It is known to most practitioners of surgery, and has been made known to many to their great cost and loss, that a large portion of the cases of impaired mobility or usefulness of limbs after injury fall into the hands of a class of men called 'bonesetters'".^[15]
- Although there is a great deal of animosity, and claims of superiority are made by the various practitioners of manipulative treatment even today, "specific conclusions cannot be derived from the scientific literature for or against either the efficacy of spinal manipulative therapy or the pathophysiologic foundations from which it is derived".^[16]

There appears to be nothing new in the controversies except the names of the groups and the coined terms they use.

The allopathic group claims the right to control over all the healing arts, and the sole privilege of using the generic terms "physician", "medicine", and "medical treatment".^[17] The "unorthodox" groups buck this authority. They seek a physician's position, while not always being willing to accept the accompanying responsibility of adequate differential diagnosis and critical assessment and validation (other than empirical and anecdotal reporting) of their therapeutic regimens. Each group maneuvers politically, judicially, and economically to gain advantage over the other.^[18]

SCHOOLS OF THOUGHT IN MANIPULATION

Early history (Oriental, Egyptian, Greek, Indian)

Knowledge of exactly which techniques were used, and with what success, is limited or speculative. It is known that many cultures have used manipulative techniques.^[12]

Bone setters of England

They generally held that a bone was out of place and had a “feel” for what was wrong. Hutton described the information gained from a bonesetter as “bring[ing] some spoils out of the camp of the Philistines”.^[15]

Chiropractic

D. D. Palmer, “the founder”, and his son B. J. Palmer, “the developer”, of chiropractic added one of the most colorful pages to the history of manipulative treatment. D. D., who “rediscovered” the principle of “lost nerve tone” in a revelation from a deceased friend, Dr Atkinson, re-established this method of healing.

The first chiropractic manipulation was given to a deaf janitor. D.D. learned that the janitor’s hearing had been lost when he stooped over and felt something give in his back. D.D. reasoned that if the deafness occurred from something slipping out, restoring the vertebra to its correct position should cure the condition: “With this new objective in view, a half-hour’s talk persuaded Mr. Lillard to allow me to replace it.”^[19]

The stormy history of chiropractic was led by a son who hated his father (and was actually accused of running him down in a parade, causing injuries that lead to his death), who drove chiropractic to a zenith, and who later nearly destroyed the profession. The evolution of chiropractic is well documented by Gibbons. It is worth noting that many early developments in chiropractic were years ahead of their time. B. J. developed the prototype of today’s EEG, he started a radiology laboratory only 13 years after Roentgen discovered X-radiation, and he had one of the finest diagnostic centers in the midwest at his school (complete with MDs and PhDs).^[20]

A new focus in chiropractic is rehabilitation and incorporation of manual medicine techniques. *Rehabilitation of the Spine, A Practitioner’s Manual*, edited by Craig Liebenson,^[4] is considered by many in the field a landmark publication. It emphasizes the need for rehabilitation and puts manipulation as a component of the process.

Naturopathic

All naturopathic techniques result from the blending of the thoughts of the other schools of medicine. This is appropriate when one realizes there is little new in manipulation, only refining and relabelling. It is also appropriate that naturopathy doesn’t lay claim to originating a school of thought on manipulation, but uses this method of treatment when indicated, not exclusively, but as part of a therapeutic regime.

Several naturopathic schools in the past were associated with chiropractic and eclectic schools of medicine. The genesis of the naturopathic profession is well documented in [Chapter 2](#) .

Osteopathic

Andrew Still, three of whose children died from meningitis, in the tradition of Hanneman

left the practice of medicine and started the school of osteopathy in Kirksville, Missouri. It is highly probable that D. D. Palmer went to this school and learned some of the techniques, but it is not well documented. The famed “equal but separate” movement of the osteopaths led to a 1921 resolution, submitted at the AOA convention, that allowed entrance of chiropractors with advanced standing into their schools. Still, before his death, saw the defection of his osteopathic profession into the ranks of medical orthodoxy.^[20] ^[21] ^[22] It is interesting to note that manipulation is now only an elective segment in some American osteopathic schools, while in England it is still the mainstay of osteopathic practice.

The resurgence of interest in manual medicine has been brought to the forefront by the Osteopathic College at Michigan State University. Greenman's^[4] *Principles of Manual Medicine* adds a useful text to the field of manual medicine. This school has been teaching manual medicine to physical therapists, MDs and DOs.

Allopathic

In the 20th century, the numbers of allopathic practitioners who promote manipulative treatment are growing daily. The individuals mainly responsible for major contributions are James Cyriax, James Mennell, and John Mennell. These brilliant physicians have written valuable texts on manipulative therapy, although they do not agree totally on the effects they achieve with manipulation. Mennell holds to the correction of lost joint play and denies effect on the intervertebral disc,^[23] while Cyriax claims reduction of a protruding disc.^[10]

Bourdillion, Calliet, McNabb, Maigne, Maitland, Kaltenborn, and Williams are popularizing the treatment modality. Their works are too exhaustive to mention in this brief chapter.

“Controversy and contention” best describe the higher levels of the respective schools of medical thought. The impression one gets in reading through the literature is intolerance of others’ ideas expressed in *ad hominem* attacks. The mistake “lay” manipulators and “non-physicians” make is not ineffectiveness but their willingness to

seek training outside the fraternal order of the “medical” brotherhood; to address the public directly rather than communicating exclusively within the order; and, worst of all, to openly compete, economically and politically, against the fraternal order (Star, Lomax, Hood).

Donald B. Tower, in the chairman’s summary at the NINCDS conference in 1975, noted a physician who has received little credit for his early contribution to the field: J. Evans Riadore, a London physician who wrote a treatise on “Irritation of the spinal nerves” in 1843. He attributed many diseases to this condition, stating: “If any organ is deficiently supplied with nervous energy of blood, its functions immediately, and sooner or later its

structure, become deranged.” This was a viewpoint subsequently echoed by osteopaths and chiropractors.^[24]

Spinal Manipulation (5th edn) by Bourdillion et al,^[25] the first author of which was a medical manipulator, has been largely reworked from previous editions and heavily influenced by osteopathic methods.

Over the past 15 years, American awareness of contributions in manual medicine from other countries has been growing. Jirout, Lewit, Janda, Bogduk and many others have been teaching and publishing in the US.

DIFFERENTIAL DIAGNOSIS

The methodology for performing the differential diagnosis of musculoskeletal pain can follow many diverse patterns depending on the approach taken, but the multiple branching pathway^[3] ^[26] for patient selection is a very good start. Four basic categories of pathology are described to begin the sorting process: neoplasm, infection, neurologic, and mechanical disorder. The following presents a brief overview in differentiating between these, and is organized to aid the generalist in selecting a starting point for making the final diagnosis. Refer to the texts and articles noted for detailed information.

Four primary categories of spinal disorders

Neoplasm

The patient history or family history may reveal neoplasm. The character of the pain is often described as deep, boring, and usually worse at night. The pain is progressive – sometimes better, sometimes worse – but is usually always present to some degree. Laboratory tests will possibly reveal an elevated sedimentation rate. Most mechanical conditions will show a 50% improvement in 2–4 weeks with appropriate care or the patient should be carefully re-evaluated or referred for a second opinion.

Infection

There will be signs of acute or chronic illness. Laboratory tests will reveal a shift to the left in the WBC count and possibly an elevated sedimentation rate. There will be local joint inflammation.

Neurologic

A routine office neurologic screening examination will often reveal the presence of a lesion. Specific neurologic tests help to determine if a lesion is present and, if so, its location; whether the lesion is life-threatening; and whether the patient will respond to conservative care.

The search pattern for neurologic lesions breaks the system into the following:

Cerebrum. Lesions are discovered during the consultation by the patient's affected cognition, interaction, mannerisms or loss of orientation in time, space, or body part awareness, etc. Nausea, vomiting, seizure, loss of consciousness, visual disturbances and headache are warning signs.

Cerebellar vs. posterior column lesions. Test coordination of movements, with basic differentiation done by repeating acts with the eyes open and eyes closed.

Cerebellar. Actions are jerky with the eyes open or closed; dysarthria, ataxic (drunken) gait, and dysdiadochokinesia may be present.

Posterior columns. The actions are smooth with the eyes open, but cannot be repeated as well with the eyes closed, due to the loss of proprioception. A broad-based, stomping gait may be present.

Brain stem. This area is evaluated by testing the cranial nerves.

Spinal cord lesions and peripheral nerve lesions (differentiation between upper and lower motor neuron lesions). Think of the abnormal reactions by focusing on the words "spastic" and "flaccid". If the superficial reflexes are absent, continue with tests to rule out upper motor neuron lesions (UMNs) and lower motor neuron lesions (LMNs). [Table 43.1](#) lists the key differential considerations.

Muscle stretch reflexes (MSRs). These are often incorrectly called deep tendon reflexes.^[27] Communication of results can be confusing, since various practitioners use different notations, e.g. a grade 3 may be listed 3, +3, 3+, +++ or just 3, and do not have a consistent definition. [Table 43.2](#) lists a grading scale that is commonly used.

The main objective is to compare the reflexes side to

TABLE 43-1 -- Comparison of neurological signs of upper vs. lower motor neuron disease^[28]

| Sign/symptom | UMN (spastic) | LMN (flaccid) |
|----------------------|----------------------|----------------------|
| Paralysis | Spastic | Flaccid |
| Deep tendon reflexes | Clonic | Diminished/absent |
| Muscle tone | Increased | Decreased |
| Pathologic reflexes | Present | Absent |
| Superficial reflexes | Absent | Absent |
| Fasciculations | Absent | Present |

Reaction of degeneration

Absent

Present

TABLE 43-2 -- Grading of reflexes

| Grade | Reflex |
|--------|---|
| 0 | Absent with reinforcement |
| 1 | Hypoactive – less than the expected response |
| 2 | Normal – you may note brisk or sluggish |
| 3 | Hyperactive – more than the expected response |
| 4 | Hyperactive with transient clonus |
| 5 | Hyperactive with sustained clonus |
| Clonus | More than one muscle jerk when the tendon is tapped |

TABLE 43-3 -- Grading of muscle strength

| Grade | Muscle strength |
|------------|---|
| 0 (zero) | No trace of muscle contraction |
| 1 (trace) | Evidence of slight contractility, no joint motion |
| 2 (poor) | Complete range of motion with gravity eliminated |
| 3 (fair) | Complete range of motion against gravity |
| 4 (good) | Complete range of motion against gravity with some resistance |
| 5 (normal) | Complete range of motion against full resistance |

side and in comparison to [Table 43.2](#) . If the reactions are not equal, note according to the scale.

Pathologic reflexes. Toe sign (Babinski), Hoffman’s, glabellar (indicating upper motor neuron lesions). Practice on an infant to elicit these abnormal signs.

Painless loss of strength. This is usually neurologic. Use numbers 0–5 to rate muscle strength, according to the scale shown in [Table 43.3](#) .

Loss of sensation. If it follows a dermatome, the problem is usually a nerve root; if it follows a named nerve pattern, a peripheral mixed nerve is involved.

Nerve root tension signs. Patients may be bracing themselves when they present (in an effort to decompress the nerve root) and may complain of pain radiating into an extremity. Movement may cause pains shooting into the extremity. Loss of sensation follows the dermatome distribution, MSR's are diminished or lost, and muscle strength in muscles innervated by the affected nerve is lost or diminished.

If neurologic findings are present, other than minor changes in sensation, keep the patient under close observation. Direct nerve root pressure can cause permanent muscle weakness with resultant permanent impairment. Appropriate conservative care is effective.^[29] Progressive neurologic deficit is an indication for referral to a neurosurgeon or physiatrist.

Mechanical

A fracture is usually traumatic when presenting in young and middle-aged patients. In older patients, pathologic fractures are a concern. Presentation may be delayed in motor vehicle accidents or athletic injuries, or non-traumatic fractures in the elderly. The cardinal signs of fracture are:

- pinpoint pain over the site
- deformity of the part
- crepitus
- loss of function of the part, usually proportional to the severity of the injury
- abnormal mobility at the site of pain.

Always check for nerve lesions and soft tissue injuries that would complicate the injury before beginning treatment.

Also check for multiple injuries (ring fracture in two places). In particular, look above and below the site of injury, as the force of trauma may be transmitted and cause a fracture some distance from the site of impact.^[26]

Note. Don't be deceived by the absence of obvious signs of fracture.

Orthopedic tests

Orthopedic tests are designed to stress the damaged tissue and reproduce the pain of the primary complaint. The examiner is not looking merely for pain to be reported as a result of the maneuver, but rather pain that is specific for the test *and* reproduces the pain of the primary complaint. Therefore:

- The examiner can make the patient worse by forcing tests or performing them incorrectly.
- Do the least stressful tests first. If the first test causes severe pain, most of the other motions will be painful afterward and confuse your findings.
- The test *by definition* has a positive response, that correlates to a *specific*

condition, that must be produced when the test is performed for the test to be positive; e.g. Lindner's test and Soto Hall test are performed in the same way, but the findings to report a positive test are different.

- The test must reproduce the pain of the primary complaint and be positive by the test's definition.
- The tests are centered in allopathic medicine to diagnose pathology, fracture, moderate to severe sprain/ strain and dislocation and will often be negative in the ambulatory, chronic patient.

When used without an understanding of the mechanism of action of the stress and the tissues the stress will act on, the plethora of tests and maneuvers available usually serve to confuse the practitioner and aggravate the patient's condition. A detailed text that covers this area in detail, such as Magee^[30] or Evans^[31], is helpful and should be referred to for additional information.

Lumbar spine

The following summarizes the key mechanisms utilized by orthopedic tests of the spine.

362

Lumbar spine nerve root entrapment. The patient presents with pain radiating into the gluteal muscle, hip, thigh, or possibly to the foot. Flexion and lateral bending with extension will aggravate the pain and reproduce or exacerbate the radiation of pain.

Disc lesion. The position of the patient, leaning towards the side of the leg pain (posteromedial – 60% require surgery), away from the side of leg pain (posterolateral), or forward (central) gives an indication of the direction of the disc lesion.

Straight leg raising (SLR). When the thigh is flexed on the abdomen in the SLR, the initial 30° of motion is primarily in the ipsilateral hip and sacroiliac joint. The 30–60° range stresses the ipsilateral nerve roots and lumbar spine, while the 60–90° range stresses the contralateral sacroiliac and lumbosacral joints.

In the SLR maneuver with a disc protrusion, the nerve root is being stretched over the bulge and causes pain. This effect can be accentuated by internal rotation and dorsiflexion of the foot. Additionally, the Valsalva maneuver may be added at the same time to increase the intrathecal pressure, thus causing swelling of the meninges by decreasing venous drainage. By putting all the stresses on at the same time, the amount of irritation present in the area can be discovered.

Methods of accentuating the signs and symptoms of space-occupying lesions of the spine

Following the principle of “do no harm”, test reflexes and sensation first. Then proceed to active tests such as the Valsalva maneuver to test if there is increased intrathecal

pressure. If radiating pain results, it is a sign of a space-occupying lesion. Next do light stretch/distraction tests (SLR and add dorsiflexion of the foot with extension of the great toe) and finally compression tests (Milgram's bilateral leg raising and Lindner's test (forcefully flexing the trunk while the patient is supine): this forces the disc posteriorly (if herniated) and causes increased intraabdominal pressure, resulting in increased intrathecal pressure (Valsalva effect).

Some additional ideas to finding the area of lesion in the lumbar spine are:

- Support Adams (the belt test) – With the patient standing, have him/her bend forward and note the level of pain. The doctor then secures the patient's pelvis by hugging the anterior superior iliac spines with the arms, pressing the patient's sacrum into the doctor's hip. If the patient's pain is decreased, it indicates the lesion is in the pelvis (probably the sacroiliac joint); if pain increases, it is in the lumbar spine (probably the lumbosacral joint).
- Patrick's FABER – flexion, **ab**duction and **ex**ternal rotation of the hip are blocked; this causes pain over the inguinal fossa and into the thigh when a hip lesion is present.

This is only an introduction to one common problem that may present with many variations. Careful study of the mechanism of action of the tests used will add confirmation, rather than confusion, to a diagnostic impression.

Cervical spine

The cervical spine presents another diagnostic challenge. Although the mechanism of the tests in the lumbar spine are similar, the area is much more delicate and thus requires more careful application. If there is compression of the nerve root or cervical instability, the patient may present holding the head, lifting it cephalically to decompress the root. If there is traction on the brachial plexus, the patient may support the arm in abduction and flexion. Any such presentation is best handled by a neurosurgeon because even passive ranges of motion assessment may cause permanent injury.

If overt signs of nerve root compression are present, mobilization and manipulation must be performed with skill and caution.

Cervical distraction. If distraction of the head from the shoulders causes aggravation of the patient's complaints at 12 pounds of traction (the average weight of the head), stabilization and relaxation techniques are indicated. If distraction of the head from the shoulders causes relief of the radiating pain at 12 pounds of traction, slowly increase the traction to 25 pounds. If this relieves the complaint of neck pain, it is an indication that mobilization and traction are indicated therapies. If it aggravates the complaint, it is an indication of inflammation or instability and suggests caution in using mobilization or traction.

Cervical compression that causes radiating pain to the arms is a sign that stabilization

and relaxation techniques are indicated.

MCRC. If rotation, lateral bending and compression (MCRC) cause radiating arm pain, it is a sign of nerve root compression and you should avoid mobilizing in that direction.

Spurling's maneuver. When combined cervical rotation, lateral bending and extension with overpressure (Spurling's maneuver) aggravates or reproduces the complaint or radiating pain to the midback or arm, it indicates nerve root irritation, and manipulation in that direction places the patient at risk for aggravation of their condition. If the pain is local it is a sign of facet irritation that often responds well to manipulation.

After determining that the lesion is not a "hard" orthopedic or neurologic lesion, differential tissue tension tests are used to determine the involved tissue.

THE DIFFERENTIAL DIAGNOSIS OF SOFT TISSUE INJURIES BY MEANS OF ACTIVE AND PASSIVE MOVEMENTS

This is based on the work of James Cryiack,^[10] but recent texts give a much improved presentation of the material.^[14]^[30] The process is to assess strain and sprain injuries, and is most appropriate in the early stages of a complaint, but monitoring the capsular patterns of joints will help to guide the rehabilitation process. This brief overview is only intended to give an introduction to the material.

Active movements

First, active ROMs are performed to determine voluntary ROM and patient status. Measuring active ROMs cannot differentiate whether the loss of function is due to pain, weakness or stiffness/lesion, but are helpful to determine patient tolerance to motion and how guarded they are when moving.

Resisted isometric tests

Next, isometric muscle tests are performed to test the contractile tissue (muscle and tendons) with the joint in neutral to avoid involving the non-contractile tissues. The following results may be noted:

- normal – painless and full strength
- minor tear – pain with full strength
- moderate tear – pain with little strength
- neurologic deficit – no pain and little strength.

Passive movements

When the joint is put through passive motion, it reaches an end-point, which has an “end-feel” that helps to determine the status of the soft tissue around the joint. The end-feel of a joint may be:

- normal – the amount of motion and feel of the tissues are appropriate for age
- abnormal – normal end-feels that are not normal for the joint and ROM that are being tested, e.g. the feeling of bone on bone is the normal end-feel at the elbow when extended, but is abnormal when it occurs at the end range of knee extension.
- pathologic – these end-feels are only present in joints that have undergone pathologic changes.

Normal end-feels

Capsular end-feel. This is a firm, “leathery” feeling, felt, for example, when the normal shoulder is at full external rotation. When felt in conjunction with a capsular pattern of restriction, and in the absence of significant inflammation or effusion, it indicates capsular fibrosis.

Bony end-feel. This feels abrupt as when moving the normal elbow into full extension. When accompanying a restriction of movement, it may suggest hypertrophic bony changes, such as those that occur with degenerative joint disease, or possible malunion of bony segments following healing of a fracture.

Soft tissue approximation end-feel. This is a soft end-feel, as when fully flexing the normal elbow or knee. It may accompany joint restriction in the presence of significant muscular hypertrophy.

Muscular end-feel. This more rubbery feel resembles what is felt at the extremes of straight-leg raising from tension on the hamstrings. It is less abrupt than a capsular end-feel.

Pathologic joint end-feels indicate disease; they are limited and are never normal:

- empty – bursitis, space-occupying lesion, neoplasm
- boggy – joint effusion
- spasm – guarding from inflammation
- internal derangement – loose body/torn meniscus.

The tissue involved is determined by the response to the passive ROMs and by moving the joint into closed pack position.

Muscle or tendon. Active and passive movements are limited and/or painful when the

muscle is contracting *and* the muscle is being stretched at the same time.

Ligaments. Both active and passive movements are limited and/or painful in the same direction.

Capsular pattern. Only joints that are controlled by muscles will have a capsular pattern. Pain will be caused on both active and passive motions and the limitation of motion is in a specific proportion that is listed in tables in the texts referenced.

Barrier concepts^[1]

Joint motion is described from neutral to an end range that is ultimately limited by the anatomical barrier of the surrounding tissues, which if exceeded causes tissue trauma. The extent of the active range of motion can be increased by passive motion to a point at which all of the tissues around the joint have been brought to tension, called by some the elastic barrier. Beyond the elastic barrier is a very small range of motion referred to as the parapsychologic space.^[32] It is within the parapsychologic space that joint cavitation, the “popping” sound, occurs. It is important to remember that when joints and soft tissues are dysfunctional, alterations of ranges of motion may occur both within the range of motion and at the end of the range of motion. If one focuses only on working in the parapsychologic space, one severely limits the effects we can have on dysfunction.

TREATMENT CONCEPTS

In the case of injury, treatment with passive therapies is indicated to control pain and inflammation until the tissues heal. Use of passive therapies in chronic conditions is falling into disfavor due to the issues of cost-effectiveness and managed care protocols. Determine the stage of inflammation by comparing the cardinal signs of inflammation (heat, swelling, pain, redness, and loss of function) with the suspected stage of the acute inflammatory process. In reality, the stages overlap and it is a continuum:^[33]

1. vasoconstriction – inconsistent, lasting only 3–5 seconds in minor injuries
2. active congestion – caused by vasodilation and increased vessel permeability
3. passive congestion – the venous return is partially dammed by clotting
4. consolidation – fibrinous coagulation at the site of the injury
5. fibrosis – resulting from the formation of scar tissue.

By knowing time frame and pathophysiology of the affected tissues, one can select an appropriate therapy. Manipulation is contraindicated in the first two phases and may be contraindicated in the third. Direct treatment of the tissues according to the level of inflammation. Observe the post-treatment results to see if the signs of inflammation worsen, indicating incorrect application or inappropriate therapy.

During treatment, the patient should be in a position that relieves symptoms. If the patient can't get into such a position, it is probable that the severity of the lesion is such that it won't respond to conservative therapy alone, or that the patient's condition is misdiagnosed or misunderstood.

Use the differential tissue tension tests and joint function tests to determine joint lesions, and functional assessment to determine the therapeutic regimen.

Before using manipulation, think about the joint end-feel (the way the joint feels at the end of its range of motion) and determine which pattern is present:

- Edematous and boggy end-feel – indicates joint effusion and possibly inflammation. Remember not to treat muscle spasm as a primary condition, it is almost always a response of the body to a noxious stimulus or pathophysiologic fault. Cryotherapy, positive galvanism, and pulsed ultrasound are indicated in acute conditions.
- Springy and taut end-feel – ligamentous fixations (as felt in the normal knee in lateral bending stress tests and drawer tests). Manipulation will work well on these types of fixations. Surging sinusoidal and interferential current, ultrasound, and moist hot packs will facilitate the treatment. Follow with cryotherapy in the subacute stages.
- Bone on bone end-feel – usually indicative of degenerative joint disease (as felt in the normal elbow in extension). If there is fine crepitus, mild degenerative joint disease (DJD) may be present; coarse crepitus indicates moderate DJD; and joint creaking may be advanced DJD. Diathermy, contrast baths, and other naturopathic therapies indicated in osteoarthritis are helpful.

Develop the habit of looking at the sedimentation rate and WBC differential count to avoid missing a concurrent condition or a difficult diagnosis.

By always starting high on the differential list, one misses few diagnoses. Exhaustive work-ups are infrequently warranted, but if treatment is directed to mechanical relief and the patient can't find a comfortable position which relieves the pain, it is doubtful that satisfactory results will be achieved using a mechanical approach.

General guides for manipulative technique

Texts on manipulative techniques by Liebenson, Lewit, Greenman, McKenzie, Bourdillion, and Maitland are good sources for learning the basics of the art. (Refer to the annotated further reading list for recommendations.)

Personal instruction is invaluable, but unless the rationales of joint mechanics, pathomechanics and pathophysiology are the basis of the teacher's approach it can be confusing and lead to cookbook approaches.

Functional assessment

Often the focus is on injury, pathology and disease, but the majority of musculoskeletal pain is from pathomechanics due to repetitive strain, deconditioning, fatigue and nutritional factors that must be addressed if treatment is to be successful. Once the portion of the patient's condition that is a musculoskeletal problem has been established, the mechanical fault should be determined. Manipulative treatment without correction of the mechanical fault will result in prolonged treatment and recurrence. Detecting this is sometimes easy, while at other times it is a mystery that takes careful investigation, as discussed in Greenman,^[4] Lewit,^[5] and Liebenson.^[4]

Preparation for the manipulation

The patient should be comfortable and relaxed and on a firm but well-padded table. The room should be at a comfortable ambient temperature, and the physician should wear no watches or jewelry that might catch the patient's hair or skin.

The physician must be comfortable and relaxed. Manipulation is an individual art, but in general side posture manipulation of the pelvis and lumbar spine is easiest

on a table that is at knee height; prone and supine thoracic manipulation is easiest at mid-thigh height; and cervical manipulation is easiest when seated, kneeling, or on a table at waist height. One may either change the height of the table or simply bend at the knees. Manipulation of the joints of the extremities can be performed in any position that allows the physician control over the joint and body parts.

Notes on the art

Manipulation is an art. Assuming a proper differential diagnosis, one acquires a "feel" that allows recognition of the difference between the three basic types of fixations and knowledge of when to manipulate.

If a movement causes pain, do not perform the movement, unless the diagnosis of the patient's condition is sure and the motion will cause no harm. Frequently, motion in the direction that is free and painless will free other ranges of motion.^[34]

Joint motion

Joint motion descriptions can become elaborate, or one may simply say that there are six degrees of freedom of motion (plus long axis extension): flexion, extension, left and right rotation, left and right lateral bending. Not all joints have all six degrees of motion. The normal degrees and range of motion of joints are listed in anatomy and kinesiology texts. If a degree of motion is lost or blocked, determine the type of fixation and which

form of manual medicine is indicated.

The fixation

Manipulation of a joint is performed to correct joint fixation, therefore one must:

1. Determine if mobilization or manipulation is the appropriate technique.
2. Identify the location and direction of the fixation.
3. Bring the joint to tension removing the periarticular tissue slack. Mobilization with tissue slack not taken up is safe, but manipulation when tissue slack is present invites injury.
4. Thrust only when the patient is relaxed and the fixation is felt.
5. After the elastic barrier has been stretched, repeated manipulation in the same direction is complicated because the end-feel tension normally felt prior to a manipulation is reduced or absent for at least 20 minutes. The same phenomenon occurs when one “pops” their knuckles. The risk of injury is much greater and changing to mobilization or active muscular relaxation techniques is recommended rather than repeated manipulation.

Stabilization

A point of stabilization is created by one hand and the physician's body weight, while the other hand performs the manipulation. Minor corrections of the position of the stabilized part and/or hand are frequently interpreted by an observer as twisting or wrenching motions. Twisting and wrenching are difficult to control and may cause injury to the patient.

Thrust

The manipulative thrust can be described according to:

- Direction of line of thrust – through the joint space, parallel to joint surfaces or tangential to the point of fixation.
- Velocity – slow for mobilizations. High velocity can correct joint fixations and the speed must be faster than the patient's reaction time, or a strain injury will result if the patient's muscular resistance occurs at the time of the manipulative thrust.
- Amplitude – governed by the quality of the health of the tissue, the quality of the fixation, and the location of the condition on the spectrum of the inflammation response.

Reassess

The condition of the joint fixation should be reassessed after every treatment to determine if the therapy has been successful.

A single manipulation will rarely correct a problem completely. Learning a joint-scanning technique will show one where the problems are that need further evaluation. The goal

is to alleviate acute conditions or, if unsuccessful, to turn them into subacute conditions and resolve subacute and chronic conditions before they cause a chronic fatigue response, joint fixation and degeneration, and/or chronic myositis.

Troubleshooting your technique

Common problems blocking successful manipulation can be overcome by:

- learning joint play analysis on the peripheral joints and practicing manipulations of those joints before attempting to manipulate the spinal joints
 - practicing the manipulative procedure with repeated light oscillatory movements while modifying the direction to feel the changes in joint tension, thus gaining experience, confidence, and knowledge without inflicting injury
 - being sure of the procedure, otherwise the patient may sense the physician's hesitation and guard,
-

366

preventing the manipulation and increasing the risk of a poor outcome

- feeling the fixation of the joint as it is brought to tension, otherwise the manipulation will traumatize the tissues unnecessarily or will not gain the desired result
- learning the arthrology of the joint to be manipulated so as not to put the joint in a "locked" or jammed position that will cause the force of the manipulation to be dispersed to the surrounding tissues and joints.

Motion palpation

The following is a short lesson in motion palpation to determine the presence of sacroiliac joint fixation.

Review of anatomy and motion mechanism

Anatomy of the SI joint. The joint is L- or ear-shaped, with the apex of the L facing anteriorly. There can be fixation of the upper fibrous or lower synovial sacroiliac joint, thus altering the normal axis of rotation of the pelvis and causing excess wear on the lumbar spine, hip, knee, and ankle joints.

Sacroiliac gait mechanism. The sacrum and both iliums must be free to move in relation to each other. The sacrum flexes, extends, and nutates (nutations means nodding) in a gyrating figure-of-eight motion.

Effect of position on sacroiliac joint angles. As one sits, there is usually a decreased sacral base angle (slight flexion of the pelvis), and as one stands, the sacral base slightly increases (the pelvis slightly extends).

Mechanism of gait. Analysis of the normal right forward step:

1. The left leg is weight-bearing.
2. The right leg is in swing phase just prior to heel strike.
3. The left gluteus medius contracts to tilt the pelvis right superior, and the right sacrospinalis contracts and is counteracted by contraction of the left psoas muscle.
4. The right knee bends, allowing for foot-drop.
5. The hip rotates internally on the weight-bearing side (left) and rotates externally on the non-weight bearing side (right).

This motion results in right ilium flexion, left ilium extension and a *relative* flexion of the sacrum in relation to the ilium on the left.

In normal gait, the lumbar spine will not deviate to either side. The sacrospinalis will exert a pull on the weight-bearing side, and the psoas group will counter the movement by contracting on the non-weight-bearing side, so the lumbar spine remains in the midline.

Method of motion palpation of the sacroiliac joints

1. Contact the PSIS on the right with the right thumb.
2. Contact the second sacral tubercle with your left thumb.
3. Now ask the patient to flex their right thigh slowly three times up and down to below 90°. This causes flexion of the right innominate, while the sacral prominence will remain relatively stationary. The motion of the PSIS will normally be posterior, toward the floor, and slightly toward the midline. If no motion occurs between the PSIS and second sacral tubercle, there is a fixation of the right upper joint in flexion. Remember, it is the motion *between* the PSIS and second sacral tubercle, not the motion of the joint relative to the floor, that is important.
4. Next, ask the patient to flex their left thigh slowly three times above 90°. The right leg is now weight-bearing and fixed and we are causing the sacrum to flex, which causes a relative extension of the right ilium. If the sacral prominence does not swing medially away from the PSIS as the left thigh flexes above 90°, then the right upper joint is fixed in extension.
5. Now, shift your right thumb to the PIIS and have the patient slowly flex their right thigh three times to below 90° again. The PIIS should move laterally away from the sacral prominence, or there is a flexion fixation of the right lower SI joint.
6. Again, the left thigh is flexed slowly three time above 90° and the sacral prominence should swing medially away from the PIIS, unless there is an extension fixation of the right ilium in the lower joint (after Gillete and Gittleman).

Techniques for correction of these fixations are described in many manipulative texts. I recommend Maigne (pp. 390–395), Bourdillion (pp. 146–173), and Maitland (pp. 314–317).

Psychology

Management of chronic pain and assistance for the patient in dealing with stress are of major importance in the treatment of all conditions, especially NMS injuries. The psychosomatic component of myofascial pain syndromes, and the unique combination of therapies the naturopathic physician can offer, necessitate a thorough understanding of the relaxation response, hypnosis, biofeedback, guided imagery, and personal motivation.

If this area is not developed, some patients seeking help will not find their treatment results satisfactory.

Chapter 44 - Nutritional medicine

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

Let your food be your medicine and let your medicine be your food. (*Hippocrates*)

INTRODUCTION

Nutritional medicine, as described in this textbook, consists of the use of diet and nutritional supplementation as therapeutic modalities. The foundation of nutritional medicine is a health-promoting diet which focuses on the consumption of whole, natural foods. Nutritional supplements are used in the overall context of nutritional medicine as complementary agents, not as sole primary medicines. Diet is always primary, and supplementation secondary.

DIETARY GUIDELINES

There is an ever-growing appreciation of the major role diet plays in determining the level of health. It is now well-established that certain dietary practices cause, as well as prevent, a wide range of diseases. In addition, more and more research is accumulating which indicates that certain diets and foods offer immediate therapeutic benefit. The purpose of this chapter is to initiate the reader into the growing field of nutritional medicine by focusing on 10 key dietary recommendations for a health-promoting diet. These 10 principles are utilized by most naturopathic physicians in their goal of educating and inspiring their patients to attain a higher level of wellness and are as follows:

1. Eat a plant-based, predominantly vegetarian diet
2. Reduce the intake of fat
3. Eliminate refined sugar
4. Reduce exposure to pesticides and herbicides
5. Eliminate the intake of food additives and coloring agents

6. Keep salt intake low, potassium intake high
 7. Drink 32–48 ounces of water daily
 8. Identify and address food allergies
-

370

9. Determine caloric needs to achieve or maintain ideal body weight
10. Use the Healthy Exchange System to construct a health-promoting diet.

A discussion of these 10 recommendations will be followed by a concise description of the role of nutritional supplementation in nutritional medicine.

Eat a plant-based, predominantly vegetarian diet

Based on detailed anatomical and historical evidence, it is thought that humans evolved as “hunter-gatherers”, i.e. humans appear to be omnivores capable of surviving on both gathered (plant) and hunted (animal) foods.^[1] However, while the human gastrointestinal tract is capable of digesting both animal and plant foods, there are indications that it can accommodate plant foods much easier than animal foods.^[2] Specifically, human teeth are composed of 20 molars which are optimal for crushing and grinding plant foods along with eight front incisors which are well-suited for biting into fruits and vegetables. Only the front four canine teeth are designed for meat eating. Human jaws swing both vertically to tear and laterally to crush, while carnivores’ jaws only swing vertically. Additional evidence to support the preference for plant foods is the long length of the human intestinal tract. Carnivores typically have a short bowel while herbivores have a bowel length proportionally comparable to humans.

To further examine what humans should eat, many researchers look to other primates, such as chimpanzees, monkeys, and gorillas. Non-human primates are also omnivores – or, as often described, herbivores and opportunistic carnivores. They eat mainly fruits and vegetables but may also eat small animals, lizards, and eggs if given the opportunity. In primates, animal food consumption is inversely related to body weight. The smaller primates eat more animal foods while the larger primates eat much less animal foods. As a percentage of total calories, the gorilla and the orangutan eat only 1 and 2% animal foods, respectively,. The remainder of their diet is from plant foods. Since humans are between the weight of the gorilla and the orangutan, it has been suggested that humans have evolved to eat around 1.5% of their diet as animal foods.^[2] Most Americans currently derive well over 50% of their calories from animal foods.^[3]

It should also be pointed out that the meat that our ancestors consumed was much different than the meat of modern commerce. Domesticated animals have always had higher fat levels than their wild counterpart, but the desire for tender meat has led to the breeding of cattle which produce meat with a fat content of 25–30% or higher compared with a fat content of lower than 4% for free-living animals or wild game. In addition, the type of fat is considerably different. Domestic beef contains primarily saturated fats and virtually undetectable amounts of omega-3 fatty acids. In contrast, the fat of wild animals contains over five times more polyunsaturated fat per gram and has high levels of the

essential omega-3 fatty acids (approximately 4%).^[1]

A tremendous amount of evidence now shows that deviating from a predominantly plant-based to a domesticated animal-based diet is a major factor in the development of heart disease, cancer, strokes, arthritis, and many other chronic degenerative disease. It is now the recommendation of many health and medical organizations that the human diet should focus primarily on plant-based foods – vegetables, fruits, grains, legumes, nuts, seeds, etc. Such a diet is thought to offer significant protection against the development of chronic degenerative disease.^{[3] [4] [5]}

The health-promoting components of a plant-based diet

One of the key aspects of a predominantly plant-based diet is its high content of dietary fiber. This aspect is thoroughly discussed in [Chapter 57](#) . In addition, a predominantly plant-based diet is low in saturated fat, high in essential fatty acids, and high in antioxidant nutrients and phytochemicals.

Many medical experts and departments of the US Government, including the US National Academy of Science, the US Department of Agriculture, the US Department of Health and Human Services, the National Research Council, and the National Cancer Institute, are recommending that Americans consume two to three servings of fruit and three to five servings of vegetables per day in an attempt to reduce the risk of developing heart disease, cancer, and other chronic degenerative diseases. Unfortunately, less than 10% of population are meeting even the lowest recommendation of five servings of a combination of fruits and vegetables.

Numerous population studies have repeatedly demonstrated that a high intake of carotene-rich and flavonoid-rich fruits and vegetables reduces the risk of cancer, heart disease and strokes (see [Ch. 67](#) for a full discussion).^{[3] [5]} Carotenes represent the most widespread group of naturally occurring pigments in nature. They are a highly colored (red and yellow) group of fat-soluble compounds. Over 600 carotenoids have been characterized, including 30–50 that the body can transform into vitamin A. Beta-carotene has been termed the most active of the carotenoids, due to its higher provitamin A activity, but several other carotenes exert greater antioxidant effects.

The best dietary sources of carotenes are green leafy vegetables and yellow-orange colored fruits and vegetables, e.g. carrots, apricots, mangoes, yams, and squash.

Red and purple vegetables and fruits – such as tomatoes, red cabbage, berries, and plums – contain a large portion of non-vitamin-A active pigments, including flavonoids. Legumes, grains, and seeds are also significant sources of carotenoids.

The flavonoids are another group of plant pigments providing remarkable protection against cancer, heart disease and strokes. These compounds are largely responsible

for the colors of fruits and flowers. Flavonoids act as powerful antioxidants in providing protection against oxidative and free radical damage. Good dietary sources of flavonoids include citrus fruits, berries, onions, parsley, legumes, green tea, and red wine. The average daily intake of flavonoids in the United States is estimated to be somewhere between 150 and 200 mg.

Reduce the intake of fat

There is a great deal of research linking a diet high in fat, particularly a diet high in saturated fat and cholesterol, to numerous cancers, heart disease, and strokes. Both the American Cancer Society and the American Heart Association have recommended a diet containing less than 30% of calories as fat.^[3] The easiest way for most people to achieve this goal is to eat less animal products and more plant foods. With the exception of nuts and seeds, most plant foods are very low in fat. With regard to nuts and seeds, while they do contain high levels of fat calories, the calories are derived largely from polyunsaturated essential fatty acids.

In addition to providing the body with energy, the essential fatty acids, linoleic and linolenic acid provided by plant foods function as components of nerve cells, cellular membranes, and prostaglandins. In addition, these polyunsaturated fats, are being shown to be protective and therapeutic against heart disease, cancer, autoimmune diseases like multiple sclerosis and rheumatoid arthritis, many skin diseases, and many others.

Much of the therapeutic benefits in these conditions is related to altering prostaglandin metabolism (see [Ch. 85](#) for a complete discussion of fatty acid metabolism). Prostaglandins and related compounds (e.g. thromboxanes and leukotrienes) are hormone-like molecules derived from 20 carbon chain fatty acids that contain three, four, or five double bonds. Linoleic and linolenic can be converted to prostaglandins through adding two carbon molecules and removing hydrogen molecules (if necessary). The number and position of double bonds in the fatty acid determine the classification of the prostaglandin.

Series 1 and 2 prostaglandins come from the omega-6 fatty acids, with the linoleic acid serving as the starting point. Linoleic acid is changed to gamma-linolenic acid and then dihomo-gamma-linolenic acid, which contains three double bonds and is the precursor to prostaglandin of the 1 series. Dihomo-gamma-linolenic acid (DHGLA) can also be converted to arachidonic acid, which contains four double bonds and is a precursor to the series 2 prostaglandins. However, because the enzyme (delta-5-desaturase) responsible for the conversion of DHGLA to arachidonic acid prefers the omega-3 oils, in humans the greatest source of arachidonic acid is from the diet. Arachidonic acid is found almost entirely in domesticated animal foods along with saturated fats.

Particularly beneficial are the series 3 prostaglandins produced from the omega-3 prostaglandin pathway. This pathway can begin with linolenic acid which can eventually be converted to eicosapentaenoic acid or EPA which is the precursor to the 3 series prostaglandins. Although EPA is found pre-formed in cold-water fish such as salmon, mackerel and herring, certain vegetable oils, such as flaxseed and canola, can, by

providing linolenic acid, increase body EPA and 3-series prostaglandin levels.

Prostaglandins of the 1 and 3 series are generally viewed as “good” prostaglandins while prostaglandins of the 2 series are viewed as bad. This is most evident by looking at their effects on platelets. Prostaglandins of the 2 series promote platelet adhesiveness which leads to hardening of the arteries, heart disease, and strokes. In contrast, the 1 and 3 series prostaglandins prevent platelet adhesiveness, improve blood flow, and reduce inflammation. Although the precursor to 2 series prostaglandins can be derived from linoleic acid, in humans the greatest source is directly from the diet. Arachidonic acid is found almost entirely in animal foods along with saturated fats. Prostaglandin metabolism can be manipulated through restricting saturated fat and arachidonic acid intake along with increasing the intake of the other precursors like linolenic, gamma-linolenic, and EPA. Conditions improved through this manipulation include atherosclerosis, multiple sclerosis, psoriasis, eczema, menstrual cramps, rheumatoid arthritis, and many other allergic or inflammatory conditions.

It is important to note that *trans*-fatty acids, which are found primarily in margarines and shortenings, along with alcohol, saturated fats, deficiencies of vitamin C, niacin, B₆, zinc, and magnesium can greatly interfere with prostaglandin metabolism.

Avoid *trans* fatty acids

For optimal health it appears to be very important to eliminate the intake of margarine and foods containing *trans*-fatty acids and partially hydrogenated oils. The manufacture of margarine and shortening entails the hydrogenation of vegetable oils. This means that a hydrogen molecule is added to the natural unsaturated fatty acid molecules of the vegetable oil to make it more saturated. Hydrogenation results in changing the structure

of the natural fatty acid which exists in the *cis*- configuration to the *trans*- configuration. *Trans*-fatty acids interfere with the body’s ability to utilize essential fatty acids.

Many researchers and nutritionists have been concerned about the health effects of margarines since they were first introduced. Although many Americans assume they are promoting their health by consuming margarine rather than butter and saturated fats, the reverse appears to be the case. Margarine and other hydrogenated vegetable oils not only raise LDL cholesterol, they also lower the protective HDL cholesterol level, interfere with essential fatty acid metabolism, and are suspected of being causes of certain cancers, such as breast cancer.^{[6] [7] [8] [9]}

At the very least, patients should be encouraged to eat less saturated fat and cholesterol, by reducing or eliminating the amounts of animal products in the diet, and to increase the consumption of fiber-rich plant foods (fruits, vegetables, grains, and legumes). Limit the intake of animal protein sources to no more than 4–6 ounces/day and recommend patients choose fish, skinless poultry, and lean cuts rather than

fat-laden choices. Finally, synthetically hydrogenated fats should be eliminated from the diet.

Eliminate refined sugar

Refined sugar and simple sugars in general stress blood sugar control and other homeostatic mechanisms. When high sugar foods are eaten alone, blood sugar levels rise quickly, producing a heightened release of insulin. Eating foods high in simple sugars is usually harmful to blood sugar control – especially in hypoglycemics and diabetics. Sugar, especially when combined with caffeine, also has a detrimental effect on mood, premenstrual syndrome, and many other health conditions.

Currently, more than half of the carbohydrates being consumed by most Americans are in the form of sugars being added to foods as sweetening agents.^[9] Encourage patients to read food labels carefully for clues on sugar content. If the words sucrose, glucose, maltose, lactose, fructose, corn syrup, or white grape juice concentrate appear on the label, extra sugar has been added.

Reduce exposure to pesticides and herbicides

In the US each year over 1.2 billion pounds of pesticides and herbicides are sprayed or added to food crops. That is roughly 10 pounds of pesticides for each man, woman, and child. Although the pesticides are designed to act against insects and other organisms, experts estimate that only 2% of the pesticide actually serves its purpose, while over 98% of the pesticide is absorbed into the air, water, soil, or food supply. Most pesticides in use are synthetic chemicals of questionable safety. The major long-term health risks include increased risk of cancer, birth defects and many chronic diseases, while the major health risks of acute intoxication include vomiting, diarrhea, blurred vision, tremors, convulsions, and nerve damage.^{[10] [11] [12]}

The health problems of the farmer provide an illustrative example of the problem with agricultural chemicals. The lifestyle of a farmer is generally a healthy one, in that a farmer eats fresh food, breathes clean air, works hard, and doesn't have as high a level of such unhealthy habits as cigarette smoking and alcohol use as city dwellers. Despite this lifestyle, it has been shown in several studies that farmers are at greater risk for several cancers including lymphomas, leukemias, and cancers of the stomach, prostate, brain, and skin.^[13]

Large studies of farmers in Canada, Australia, Europe, New Zealand, and the United States have demonstrated that the greater the exposure to agricultural chemicals, the greater is the risk for non-Hodgkin's lymphoma.^{[11] [12]} However, because the evidence for the cancer-causing capabilities of pesticides in animals is inadequate, the formal opinion of many "experts" is that they pose no significant risk for the public or the farmer, an apparently untenable position.

The history of pesticide use in the US is riddled with pesticides that were once widely used and then later banned due to health risks. Perhaps the best known example is

DDT. Widely used from the early 1940s to 1973, DDT was largely responsible for increasing farm productivity in this country. In 1962, Rachel Carson's classic *Silent Spring* detailed the full range of DDT's hazards, including its persistence in the food chain and its deadly effects, but it was 10 years later before the Federal Government banned the use of this deadly compound. Unfortunately, although DDT has been banned for nearly 20 years, it is still found in the soil and root vegetables such as carrots and potatoes. According to studies performed by the National Resources Defense Council, a public interest environmental group, 17% of the carrots they analyzed still contained detectable levels of DDT.^[14]

Widespread environmental contamination has occurred with the halogenated hydrocarbons, DDT, DDE, PCB, PCP, dieldrin, and chlordane. These molecules persist for long periods in the environment, are hard to detoxify and accumulate in fat cells. Many of these chemicals mimic estrogen in the body and are thought to be a major factor in the growing epidemics of estrogen-related health problems such as PMS, breast cancer, and low sperm counts^{[15] [16]} (see [Ch. 37](#) for an in-depth discussion of this important topic).

Pesticides in use today

The majority of pesticides currently used in the US are

373

probably less toxic than DDT and other banned pesticides including aldrin, dieldrin, endrin, and heptachlor. However, many pesticides banned from use in the US are shipped to other countries such as Mexico which then in turn sends contaminated food back to the US. Although over 600 pesticides are currently used in the US, most experts are most concerned about relatively few of these. The Environmental Protection Agency has identified 64 pesticides as potential cancer-causing compounds, while the National Research Council found that 80% of US cancer risk from pesticides is due to 13 pesticides used widely on 15 important food crops.^{[11] [14]} The pesticides are: linuron, permethrin, chlordimeform, zineb, captafol, captan, maneb, mancozeb, folpet, chlorothalonil, metiram, benomyl, and O-phenylphenol. They are found in many crops, but of greatest concern are the following (in order of decreasing importance):

- tomatoes
- beef
- potatoes
- oranges
- lettuce
- apples
- peaches
- pork
- wheat
- soybeans

- beans
- carrots
- chicken
- corn
- grapes.

Pesticide residue levels in food are monitored by both state and federal regulatory agencies. Such monitoring is used to enforce legal tolerance levels. However, there has been increasing public and governmental concern about the adequacy of the residue monitoring programs. The monitoring system is composed of three collaboration components: the EPA, FDA and a variety of individual state agricultural agencies. The EPA establishes a tolerance level for pesticides in raw or unprocessed foods utilizing key data. The Food and Drug Agency (FDA) is then responsible for enforcing the EPA limits. Individual state organizations, such as the departments of health and agriculture, may also be involved in the monitoring of food safety. Where this system falls short is not simply in the determination of the tolerance level, but in other critical ways:

- less than 1% of the domestic food supply is screened by the FDA
- the FDA does not test for all pesticides
- the FDA does not prevent the marketing of the foods that it finds to contain illegal residues.

A number of pesticide poisoning epidemics have been reported. The largest to date occurred in 1985. It involved aldicarb, an extremely toxic pesticide, and its illegal use on watermelons. Aldicarb is a systemic pesticide, which means it permeates the entire fruit. Over 1,000 people in the western US and Canada were affected. Illness ranged from mild gastrointestinal upset to severe poisoning (vomiting, diarrhea, blurred vision, tremors, convulsions, and nerve damage).^[11]

While the EPA and FDA estimate that excessive pesticide residues are found on about 3% of domestic and 6% of foreign produce, and acceptable levels are found in 13% of domestic produce, other organizations report much higher estimates. For example, the National Resources Defense Council conducted a survey of fresh produce sold in San Francisco markets for pesticide residues and found that 44% of 71 fruit and vegetables had detectable levels of 19 different pesticides, with 42% of produce with detectable pesticide residues containing more than one pesticide.^[14] The sheer number and amount of pesticides applied to certain foods is alarming. For example, over 50 different pesticides are used on broccoli, 110 on apples, and 70 on bell peppers.^[10] As many of the pesticides penetrate the entire fruit or vegetable and cannot be washed off, it is obviously best to buy organic.

Many supermarket chains and produce suppliers are employing their own testing measures for determining the pesticide content of produce and are refusing to stock foods that have been treated with some of the more toxic pesticides such as alachlor, captan, or EBDCs (ethylene bisdithiocarbamates). In addition, many stores are asking growers to disclose all pesticides used on the foods and to phase out the use of the 64 pesticides suspected of being capable of causing cancers. Ultimately it will be pressure from consumers which will influence food suppliers the greatest. Crop yield studies

support the use of organic farming if the risk of human health is added to the equation.

Waxes

In addition to pesticides, waxes are applied to many fruits and vegetables to seal in the water contained in the produce, thereby keeping the produce looking fresh. According to FDA law, grocery stores must display a sign noting that waxes or post-harvest pesticides have been applied. Unfortunately, most stores do not comply with the law and the FDA lacks the manpower to enforce it. Currently, the FDA has approved six different waxes for use on produce. Approved compounds include shellac, paraffin, palm oil derivatives, and synthetic resins. These same items are used in furniture, floor, and car waxes. Foods to which these compounds can be applied include apples, avocados, bell peppers,

374

cantaloupes, cucumbers, eggplants, grapefruits, lemons, limes, melons, oranges, parsnips, passion fruits, peaches, pineapples, pumpkins, rutabagas, squashes, sweet potatoes, tomatoes, and turnips.^[10]

One of the main reasons the waxes are added is to keep the produce from spoiling during the (often long) period of time from harvest to the grocery store shelves. If grocery store chains bought more local produce, it would not require the chemicals to keep it looking fresh. Instead the large chains sign contracts with large produce suppliers regardless of their location. This is why, for example, a grocery store in New York is stocked with Washington State apples and California broccoli.

The waxes themselves probably pose little health risk. However, most waxes have powerful pesticides or fungicides added to them. Since the waxes cannot be washed off with water, the fungicide or pesticide literally becomes cemented to the produce.

Pesticides exposure can be reduced by:

- Avoiding foods which concentrate pesticides, e.g. animal fat, meat, eggs, cheese, and milk – it makes good sense to avoid these foods
- Buying organic produce. In the context of food and farming, the term organic is used to imply that the produce was grown without the aid of synthetic chemicals including pesticides and fertilizers. In 1973, Oregon became the first state to pass laws that define labeling laws for organic produce. By 1989, 16 other states (California, Colorado, Iowa, Maine, Massachusetts, Minnesota, Montana, Nebraska, New Hampshire, North Dakota, Ohio, South Dakota, Texas, Vermont, Washington, and Wisconsin) had also adopted state laws governing organic agriculture. Highly reputable certification organizations include:
 - California Certified Organic Farmers
 - Demeter

- Farm Verified Organic
- Natural Organic Farmers Association
- the Organic Crop Improvement Association.

Although under 3% of the total produce grown in the US is grown without the aid of pesticides, organic produce is widely available.

- Encouraging patients, where organic produce is not readily available, to develop a good relationship with the local grocery store produce manager. Have them explain to him or her their desire to reduce the exposure to pesticides and waxes. Ask what measures the store takes to assure pesticide residues are within the tolerance limits. Ask where they get their produce as foreign produce is much more likely to contain excessive levels of pesticides as well as pesticides that have been banned in the US due to suspected toxicity. Try and buy local produce that is in season.
- Removing surface pesticide residues, waxes, fungicides, and fertilizers. This can be done by soaking in a mild solution of additive-free soap like Ivory or pure castille soap from the health food store. There are also all-natural, biodegradable cleansers available at most health food stores. The produce can be sprayed with the cleanser, gently scrubbed, and then rinsed.
- Simply peeling off the skin or removing the outer layer of leaves. This will reduce pesticide levels. The down-side of this is that many of the nutritional benefits are concentrated in the skin and outer layers.

The presence of pesticides in fruits and vegetables should not deter patients from eating a diet high in these foods. The concentrations in fruits and vegetables are much lower than the levels found in animal fats, meat, cheese, whole milk, and eggs. Furthermore, the various antioxidant components in fruits and vegetables help the body to deal with the pesticides.

Eliminate the intake of food additives and coloring agents

Food additives are used to prevent spoiling or enhance flavor and include such substances as preservatives, artificial colors, artificial flavorings, and acidifiers. Although the government has banned many synthetic food additives, it should not be assumed that all the additives currently used in the food supply are safe. There are still a great number of synthetic food additives still in use that are being linked to such diseases as depression, asthma or other allergy, hyperactivity or learning disabilities in children, and migraine headaches.

The FDA has approved the use of over 2,800 different food additives. In 1985, the per capita daily consumption of these food additives was approximately 13–15 g.^[17] While an extremist might argue that no food additive is safe, many food additives fulfill important functions in the modern day food supply. Some compounds approved as additives are natural in origin and possess health-promoting properties, while others are

synthetic compounds with known cancer-causing effects. Obviously, the most sensible approach is to focus on whole, natural foods and avoid foods which are highly processed.

Coloring agents

The total annual consumption of food colors in the US is approximately 100 million pounds for the entire population. Food color additives are officially designated as either certified or exempt from certification.^[18] The

food color additives which are exempt from certification are primarily natural in origin. This reflects the popular belief that natural compounds are safer. This contention appears to hold up to scientific scrutiny.

One of the most widely used food colors is FD&C yellow dye #5 or tartrazine. Tartrazine is added to almost every packaged food as well as many drugs, including some antihistamines, antibiotics, steroids, and sedatives.^[19] In the United States, the average daily per capita consumption of certified dyes is 15 mg, of which 85% is tartrazine. Among children, consumption is usually much higher.

Although the overall rate of allergic reactions to tartrazine is quite low in the general population, allergic reactions due to tartrazine are extremely common (20–50%) in allergic individuals, especially those sensitive to aspirin.^[20] ^[21] Like aspirin, tartrazine is a known inducer of asthma, hives, and other allergic conditions, particularly in children.^[21] In addition, tartrazine, as well as benzoate and aspirin, increases the production of the number of mast cells.^[1] As mast cells are involved in producing histamine and other allergic compounds, those with increased levels are more prone to allergies. For example, examination of patients with hives shows that greater than 95% have an increase in mast cells.^[23]

In studies using provocation tests to determine sensitivity to tartrazine and other food additives in patients with hives, results have ranged from 5 to 46%.^[24] ^[25] ^[26] ^[27] ^[28] ^[29] ^[30] ^[31] ^[32] ^[33] ^[34] ^[35] ^[36] ^[37] Diets eliminating tartrazine as well as other food additives in sensitive individuals have in many cases been shown to be of great benefit in patients with hives and other allergic conditions like asthma and eczema.^[24] ^[25] ^[26] ^[27] ^[28] ^[29] ^[30] ^[31] ^[32] Obviously, patients suffering from allergic conditions should eliminate artificial food colors from their diets.

Antioxidants

The two most widely used antioxidants are butylated hydroxyanisole (BHA) and butylated hydroxytoluene (BHT). These food additives cause cancers in rats. However, there are other studies showing that these antioxidants actually protect against the development of cancers. In fact, many so-called “experts” in life extension have

recommended that these substances be taken as food supplements at very high doses (i.e. 2 g/day). Based on extensive research this recommendation is extremely unwise as it is 100 times the estimated acceptable intake of BHA, BHT, or the sum of both as set by the Joint Food and Agriculture Organization of the United Nations/World Health Organization Expert Committee on Food Additives.^[38] It is also over 100 times the estimated inhibitory activity and may actually promote cancer. While BHA and BHT may be safe at low levels in foods, in the future they will most likely be replaced by naturally occurring antioxidants.

Preservatives

Preservatives like sodium benzoate, nitrates, nitrites, and sulfites work primarily to prevent spoilage by checking the growth of microorganisms. All of these preservatives have come under attack recently. In the case of nitrates and nitrites, these compounds are known carcinogens. Sulfites and benzoates, on the other hand, are capable of producing allergic reactions.^{[17] [39]}

Benzoic acid and benzoates are the most commonly used food preservatives.^[17] Although for the general population the rate of allergic response is thought to be less than 1%, the frequency of positive challenges in patients with chronic hives or asthma varies from 4 to 44%.^{[24] [25] [26] [27] [28] [29] [30] [31] [32]} Even more of a problem are sulfites, which were once widely used on produce at restaurant salad bars. Since most people were not aware that sulfites were being added, and because most people were unaware they had a sensitivity to sulfites, many unsuspecting people experienced severe allergic or asthmatic reactions. For years the FDA refused to even consider a ban on sulfites, even while admitting these agents provoked attacks in an unknown number of people and in 5–10% of asthma victims. It was not until 1985, when sulfite sensitivity was linked to 15 deaths between 1983 and 1985, that the FDA agreed to review the matter. In 1986, the FDA finally banned sulfite use on produce and required labeling of other foods, such as wine, beer, and dried fruit, that have added sulfites. The average person consumes an average of 2–3 mg/day of sulfites, while wine and beer drinkers typically consume up to 10 mg/day.^[39]

The Feingold hypothesis

The hypothesis that food additives can cause hyperactivity in children stemmed from the research of Benjamin Feingold MD and is commonly referred to as the “Feingold hypothesis”. According to Feingold, many hyperactive children, perhaps 40–50%, are sensitive to artificial food colors, flavors, and preservatives as well as to naturally occurring salicylates and phenolic compounds.^[40] Further discussion on the Feingold hypothesis is given in [Chapter 135](#).

Keep salt intake low, potassium intake high

Excessive sodium chloride consumption, coupled with diminished dietary potassium, greatly stresses the kidney’s ability to maintain proper fluid volume. As a result some people are “salt-sensitive”, in that high salt intake causes high blood pressure or, in other cases, water retention. However, it is not simply a matter of reducing salt intake,

as patients should be encouraged

to simultaneously increase the intake of potassium. This is easily done by increasing the intake of high-potassium foods and avoiding high-sodium foods (most processed foods). Instruct patients to read labels carefully in order to keep their total daily sodium intake below 1,800 mg.

Most Americans have a potassium-to-sodium (K:Na) ratio of less than 1:2. This 1:2 ratio means that most people ingest twice as much sodium as potassium. Researchers recommend a dietary potassium-to-sodium ratio of greater than 5:1 to maintain health. This is 10 times higher than the average intake. However, even this may not be optimal. A natural diet rich in fruits and vegetables can produce a K:Na ratio greater than 100:1, as most fruits and vegetables have a K:Na ratio of at least 50:1.

If patients really must have the taste of salt, encourage them to try the so-called salt substitutes such as the popular brands “NoSalt” and “Nu-Salt”. These products are composed of potassium chloride which tastes very similar to sodium chloride. Patient compliance can be monitored with the Fantus test (see [Ch. 12](#)).

Drink 32–48 ounces of water daily

Adequate water consumption is vital to optimal health. Inadequate water consumption impairs kidney function, increases the concentration of toxins in the urinary tract, increases the risk of gallstones and kidney stones, and impairs immune function.

Unfortunately, there are problems with the water supply. Most of the water supply is full of chemicals, including not only chlorine and fluoride which are intentionally added, but a wide range of toxic organic compounds and chemicals such as PCBs, pesticide residues, nitrates, and heavy metals like lead, mercury, and cadmium.^[41] It is estimated that lead alone may contaminate the water of more than 40 million Americans. In an effort to reduce the exposure to these toxic compounds, roughly 2 million home water filtration units are purchased annually.

Identify and address food allergies

The importance of identifying and addressing food allergies and sensitivities is fully discussed in [Chapters 15](#) and [51](#).

Determine caloric needs to achieve or maintain ideal body weight

In determining calorie needs, it is necessary to first determine ideal body weight. The most popular height and weight charts are the tables of “desirable weight” provided by the Metropolitan Life Insurance Company. The most recent edition of these tables,

published in 1983, gives weight ranges for men and women at 1 inch

TABLE 44-1 -- 1983 Metropolitan height and weight table

| Height | Small frame | Medium frame | Large frame |
|---------------|--------------------|---------------------|--------------------|
| <i>Men</i> | | | |
| 5'2? | 128–134 | 131–141 | 138–150 |
| 5'3? | 130–136 | 133–143 | 140–153 |
| 5'4? | 132–138 | 135–145 | 142–156 |
| 5'5? | 134–140 | 137–148 | 144–160 |
| 5'6? | 136–142 | 139–151 | 146–164 |
| 5'7? | 138–145 | 142–154 | 149–168 |
| 5'8? | 140–148 | 145–157 | 152–172 |
| 5'9? | 142–151 | 148–160 | 155–176 |
| 5'10? | 144–154 | 151–163 | 158–180 |
| 5'11? | 146–157 | 154–166 | 161–184 |
| 6'0? | 149–160 | 157–170 | 164–188 |
| 6'1? | 152–164 | 160–174 | 168–192 |
| 6'2? | 155–168 | 164–178 | 172–197 |
| 6'3? | 158–172 | 167–182 | 176–202 |
| 6'4? | 162–176 | 171–187 | 181–207 |
| <i>Women</i> | | | |
| 4'10? | 102–111 | 109–121 | 118–131 |
| 4'11? | 103–113 | 111–123 | 120–134 |
| 5'0? | 104–115 | 113–126 | 122–137 |
| 5'1? | 106–118 | 115–129 | 125–140 |
| 5'2? | 108–121 | 118–132 | 128–143 |
| 5'3? | 111–124 | 121–135 | 131–147 |
| 5'4? | 114–127 | 124–138 | 134–151 |
| 5'5? | 117–130 | 127–141 | 137–155 |
| 5'6? | 120–133 | 130–144 | 140–159 |
| 5'7? | 123–136 | 133–147 | 143–163 |

| | | | |
|-------|---------|---------|---------|
| 5'8? | 126–139 | 136–150 | 146–167 |
| 5'9? | 129–142 | 139–153 | 149–170 |
| 5'10? | 132–145 | 142–156 | 152–173 |
| 5'11? | 135–148 | 145–159 | 155–176 |
| 6'0? | 138–151 | 148–162 | 158–179 |

* Weights for adults aged 25–59 years based on lowest mortality. Weight are in pounds according to frame size and include indoor clothing (5 pounds for men and 3 pounds for women) and shoes with 1 inch heels.

increments of height for three body frame sizes (see [Table 44.1](#)).

Determining frame size

Frame size is determined by measuring elbow breadth. Elbow breadth is determined by having the patient bend his or her elbow at a 90° angle and then measuring, with a caliper, the distance between the medial and lateral epicondyles. [Table 44.2](#) lists the elbow breadths of a medium frame size in men and women. A lower reading indicates a small frame, while higher readings indicate a large frame.

Determining appropriate calorie consumption

After the desirable weight has been determined in pounds, convert it to kilograms by dividing it by 2.2. This number is then multiplied by the following calories, depending upon activity level:

- Little physical activity: 30 calories
- Light physical activity: 35 calories
- Moderate physical activity: 40 calories

377

- Heavy physical activity: 45 calories.

TABLE 44-2 -- Elbow breadth of a medium frame size in men and women

| Height in 1? heels | Elbow breadth |
|--------------------|---------------|
| <i>Men</i> | |
| 5'2?–5'3? | 2½?–2?? |
| 5'4?–5'7? | 2??–2?? |
| 5'8?–5'11? | 2¾?–3? |

| | |
|--------------|---------|
| 6'0?–6'3? | 2¾?–3?? |
| 6'4? | 2??–3¼? |
| <i>Women</i> | |
| 4'10?–5'3? | 2¼?–2½? |
| 5'4?–5'11? | 2??–2?? |
| 6'0? | 2½?–2¾? |

Use the Healthy Exchange System to construct a health-promoting diet

The American Dietetic Association (ADA), in conjunction with the American Diabetes Association and other groups, have developed the Exchange System, a convenient tool for the rapid estimation of the calorie, protein, fat, and carbohydrate content of a diet. Originally designed for use in designing dietary recommendations for diabetics, the exchange method is now used in the calculation and design of virtually all therapeutic diets. Unfortunately, the ADA exchange plan does not place a strong enough emphasis on the quality of food choices.

The Healthy Exchange System presented here is a healthier version because it emphasizes better food choices and focuses on unprocessed, whole foods. The diet is prescribed by allotting the number of exchanges allowed per list for 1 day. There are seven exchange lists, although the milk and meat lists should be considered optional:

- List 1: vegetables
- List 2: fruits
- List 3: breads, cereals, and starchy vegetables
- List 4: legumes
- List 5: fats
- List 6: milk
- List 7: meats, fish, cheese, and eggs.

The healthy exchange lists in [Appendix 6](#) can be provided to your patients to facilitate their understanding and adoption of a healthy diet.

Because all food portions within each exchange list provide approximately the same calories, proteins, fats, and carbohydrates per serving, it is easy to construct a diet consisting of the recommended percentages of:

- carbohydrates: 60–70% of total calories
- fats: 15–25% of total calories
- protein: 15–20% of total calories
- dietary fiber: at least 50 g.

Of the carbohydrates ingested, 90% should be complex carbohydrates or naturally

occurring sugars. Intake of refined carbohydrate and concentrated sugars (including honey, pasteurized fruit juices, and dried fruit, as well as sugar and white flour) should be limited to less than 10% of the total calorie intake.

Constructing a diet which meets these recommendations is simple using the exchange lists. In addition, the recommendations ensure a high intake of vital whole foods, particularly vegetables, rich in nutritional value. Following are examples of exchange recommendations.

1,500 calorie vegan diet

- List 1 – vegetables: 5 servings
- List 2 – fruits: 2 servings
- List 3 – breads, cereals, and starchy vegetables: 9 servings
- List 4 – beans: 2.5 servings
- List 5 – fats: 4 servings.

This recommendation would result in an intake of approximately 1,500 calories, of which 67% are derived from complex carbohydrates and naturally occurring sugars, 18% from fat, and 15% from protein. The protein intake is entirely from plant sources, but still provides approximately 55 g; this number is well above the recommended daily allowance of protein intake for someone requiring 1,500 calories. At least one-half of the fat servings should be from nuts, seeds, and other whole foods from the Fat Exchange List. The dietary fiber intake would be approximately 31–74.5 g:

- percentage of calories as carbohydrates: 67%
- percentage of calories as fats: 18%
- percentage of calories as protein: 15%
- protein content: 55 g
- dietary fiber content: 31–74.5 g.

1,500 calorie omnivore diet

- List 1 – vegetables: 5 servings
- List 2 – fruits: 2.5 servings
- List 3 – breads, cereals, and starchy vegetables: 6 servings
- List 4 – beans: 1 serving
- List 5 – fats: 5 servings
- List 6 – milk: 1 serving
- List 7 – meats, fish, cheese, and eggs: 2 servings.

- Percentage of calories as carbohydrates: 67%
 - Percentage of calories as fats: 18%
 - Percentage of calories as protein: 15%
-

- Protein content: 61 g (75% from plant sources)
- Dietary fiber content: 19.5–53.5 g.

2,000 calorie vegan diet

- List 1 – vegetables: 5.5 servings
 - List 2 – fruits: 2 servings
 - List 3 – breads, cereals, and starchy vegetables: 11 servings
 - List 4 – beans: 5 servings
 - List 5 – fats: 8 servings.
-
- Percentage of calories as carbohydrates: 67%
 - Percentage of calories as fats: 18%
 - Percentage of calories as protein: 15%
 - Protein content: 79 g
 - Dietary fiber content: 48.5–101.5 g.

2,000 calorie omnivore diet

- List 1 – vegetables: 5 servings
 - List 2 – fruits: 2.5 servings
 - List 3 – breads, cereals, and starchy vegetables: 13 servings
 - List 4 – beans: 2 servings
 - List 5 – fats: 7 servings
 - List 6 – milk: 1 serving
 - List 7 – meats, fish, cheese, and eggs: 2 servings.
-
- Percentage of calories as carbohydrates: 66%
 - Percentage of calories as fats: 19%
 - Percentage of calories as protein: 15%
 - Protein content: 78 g (72% from plant sources)
 - Dietary fiber content: 32.5–88.5 g.

2,500 calorie vegan diet

- List 1 – vegetables: 8 servings
 - List 2 – fruits: 3 servings
 - List 3 – breads, cereals, and starchy vegetables: 17 servings
 - List 4 – beans: 5 servings
 - List 5 – fats: 8 servings.
-
- Percentage of calories as carbohydrates: 69%
 - Percentage of calories as fats: 15%

- Percentage of calories as protein: 16%
- Protein content: 101 g
- Dietary fiber content: 33–121 g.

2,500 calorie omnivore diet

- List 1 – vegetables: 8 servings
 - List 2 – fruits: 3.5 servings
 - List 3 – breads, cereals, and starchy vegetables: 17 servings
 - List 4 – beans: 2 servings
 - List 5 – fats: 8 servings
 - List 6 – milk: 1 serving
 - List 7 – meats, fish, cheese, and eggs: 3 servings.
-
- Percentage of calories as carbohydrates: 66%
 - Percentage of calories as fats: 18%
 - Percentage of calories as protein: 16%
 - Protein content: 102 g (80% from plant sources)
 - Dietary fiber content: 40.5–116.5 g.

3,000 calorie vegan diet

- List 1 – vegetables: 10 servings
 - List 2 – fruits: 4 servings
 - List 3 – breads, cereals, and starchy vegetables: 17 servings
 - List 4 – beans: 6 servings
 - List 5 – fats: 10 servings.
-
- Percentage of calories as carbohydrates: 70%
 - Percentage of calories as fats: 16%
 - Percentage of calories as protein: 14%
 - Protein content: 116 g
 - Dietary fiber content: 50–84 g.

3,000 calorie omnivore diet

- List 1 – vegetables: 10 servings
 - List 2 – fruits: 3 servings
 - List 3 – breads, cereals, and starchy vegetables: 20 servings
 - List 4 – beans: 2 servings
 - List 5 – fats: 10 servings
 - List 6 – milk: 1 serving
 - List 7 – meats, fish, cheese, and eggs: 3 servings.
-
- Percentage of calories as carbohydrates: 67%
 - Percentage of calories as fats: 18%
 - Percentage of calories as protein: 15%

- Protein content: 116 g (81% from plant sources)
- Dietary fiber content: 45–133 g.

(Note: Use these recommendations as the basis for calculating other calorie diets. For example, for a 4,000 calorie diet add the 2,500 to the 1,500. For a 1,000 calorie diet divide the 2,000 calorie diet by 2.)

NUTRITIONAL SUPPLEMENTATION

The term nutritional supplementation includes the use of vitamins, minerals, and other food factors to support good health as well as preventing or treating illness. The key functions of nutrients like vitamins and minerals in the human body revolve around their role as essential

379

components in enzymes and coenzymes. One of the key concepts in nutritional medicine is to supply the necessary support or nutrients to allow the enzymes of a particular tissue to work at their optimum levels. The concept of “biochemical individuality” was coined by nutritional biochemist Roger Williams in the 1970s to recognize the wide range in enzymatic activity and nutritional needs of humans. These observations also provided the basis for “orthomolecular medicine” as envisioned by two time Nobel laureate Linus Pauling.

Pharmacological aspects

In addition to serving as necessary components in enzymes and coenzymes, many nutrients appear to exert pharmacological effects. Most of these effects appear to be the result of enzyme induction. In other words, when used at supraphysiological levels nutrients can induce the manufacture of enzymes, induce enzymes to become more active, or even inhibit enzyme action. For example, the B vitamin niacin (nicotinic acid) is well known as a lipid-lowering agent when given at high dosages (2–6 g/day in divided dosages). Its mechanism of action is quite diverse, but appears to be via inhibiting enzymes which manufacture of VLDL while simultaneously stimulating the production or activity of enzymes which take up LDL in the liver. The advantage of using nutrients at pharmacological dosages is that they are more recognizable and better metabolized by the body as evident by a broader therapeutic index. Even so, the use of nutrients as pharmacological agents is closely akin to drug therapy. That being the case, it is imperative that they be used and monitored appropriately.

The growing popularity of nutritional supplementation

Growing numbers of Americans are taking nutritional supplements, with one industry source estimating a growth rate of 25% per annum for the past 5 years. Over 100 million Americans now take dietary supplements on a regular basis. Despite the tremendous

body of research supporting the use of nutritional supplementation, most medical experts and researchers have still not publicly endorsed nutritional supplementation even though 98% of them take supplements themselves.

Numerous studies have demonstrated that most Americans consume a diet inadequate in nutritional value. Comprehensive studies sponsored by the US government (HANES I and II, Ten State Nutrition Survey, USDA nationwide food consumption studies, etc.) have revealed that marginal nutrient deficiencies exist in a substantial portion of the US population (approximately 50%) and that for some selected nutrients in certain age groups more than 80% of the group consumed less than the RDA.⁴³

While most Americans are deficient in many vitamins and minerals, the level of deficiency is usually not severe enough to result in obvious signs and symptoms of nutrient deficiency. A severe deficiency disease like scurvy (lack of vitamin C) is extremely rare, but marginal vitamin C deficiency is thought to be relatively common. The term “subclinical” deficiency is often used to describe marginal nutrient deficiencies. A subclinical or marginal deficiency indicates a deficiency of a particular vitamin or mineral that is not severe enough to produce a classic deficiency sign or symptom. In many instances the only clue of a subclinical nutrient deficiency may be fatigue, lethargy, difficulty in concentration, a lack of well-being, or some other vague symptom. Diagnosis of subclinical deficiencies is an extremely difficult process that involves detailed dietary or laboratory analysis. In most cases it is not worth the cost to perform these tests because they are usually more expensive than a year-long trial of the vitamin thought to be needed.

The RDA is inadequate

Recommended Dietary Allowances (RDAs) for vitamins and minerals have been prepared by the Food and Nutrition Board of the National Research Council since 1941. These guidelines were originally developed to reduce the rates of severe nutritional deficiency diseases such as scurvy (deficiency of vitamin C), pellagra (deficiency of niacin) and beri-beri (deficiency of vitamin B₁), not to promote optimal health. Another problem is that the RDAs were designed to serve as the basis for evaluating the adequacy of diets of groups of people, not individuals. As stated by the Food and Nutrition Board: “Individuals with special nutritional needs are not covered by the RDAs.”⁴³ Finally, the RDAs were designed for normal, “healthy” people experiencing no unusual stressors.

A tremendous amount of scientific research indicates that the “optimal” level for many nutrients, especially the so-called antioxidant nutrients such as vitamins C and E, beta-carotene, and selenium, may be much higher than their current RDA. The RDAs focus only on the prevention of nutritional deficiencies in population groups; they do not define “optimal” intake for an individual.

Other factors the RDAs do not adequately take into consideration are environmental and lifestyle factors which can destroy vitamins and bind minerals. For example, even the Food and Nutrition Board acknowledges that smokers require at least twice as much vitamin C as non-smokers. But, the effect of smoking on other nutrients and the effects

of alcohol consumption, food additives, heavy metals (lead, mercury, etc.), carbon monoxide, and other chemicals associated with our modern society are not considered (for a

comprehensive discussion of this important topic, see [Ch. 108](#)).

Accessory nutrients

In addition to essential nutrients, there are a number of food components and natural physiological agents which have demonstrated impressive health-promoting effects. Many examples are contained in Section V: Pharmacology of Natural Medicines, such as carotenoids, flavonoids, probiotics, carnitine, and coenzyme Q₁₀ . These compounds exert significant therapeutic effects with little, if any, toxicity. More and more research indicates that these accessory nutrients, although not considered “essential” in the classical sense, play a major role in preventing illness.

SUMMARY

Nutritional medicine involves the use of dietary therapies and supplementation with naturally occurring compounds to provide an optimal nutritional state for the cellular environment. Nutritional medicine is one of the key foundations of naturopathic medicine and involves adherence to some basic concepts, yet must be tailored for the individual to account for biochemical individuality.

Chapter 45 - Peat therapeutics and balneotherapy

Mark D. Groven ND

INTRODUCTION

Balneology refers to the art and science of bathing. Balneotherapy is the use of baths, peloids and other natural substances as well as various climatic elements singly or in combination with each other for the prevention and treatment of disease. The term peloid refers to the pulp of a substance which is applied to the body. Common peloids include peat pulp, lake or sea muds and plant substances to name a few.

For many conditions balneotherapy is a preferable treatment to the pharmacological approach due to the side-effects of synthetic drugs. The combination of balneotherapy and peloid therapy and the percutaneous absorption of their constituents along with the physiological and psychological effects provide an excellent therapy for those who can no longer tolerate oral or injectable pharmaceuticals and are suffering from chronic degenerative diseases. Life is stressful and our society is aging. We would be wise to utilize the positive benefits of balneotherapy in the conventional treatment of illness along with maintenance and prevention of disease.^{[1] [2] [3] [4]} The purpose of this chapter is to describe the general concept of balneotherapy with emphasis on the medicinal application of peat.

BALNEOLOGY

History

Therapeutic bathing is an ancient art and probably the oldest of medical procedures. It enjoyed tremendous popularity until about 75 years ago when, along with other natural techniques, it fell out of favor as conventional medicine produced its modern successes. Since then, the large corpus of empirical wisdom has been expanded upon and much scientific evidence has contributed to the advancement of balneology as a science. Many of balneotherapies' modern day roots lie predominantly in European spas which

have some of the longest continuous running histories of any medical institution.

Millions of patients flock to clinics throughout Europe and the world each year for treatment in hydrology departments under the supervision of physicians and their staffs. They provide a variety of balneotherapeutic techniques.^{[1] [2] [3] [4] [5] [6] [7] [8] [9] [10] [11] [12] [13] [14] [15] [16] [17] [18] [19] [20] [21] [22] [23] [31]}

Regular research continues in this emerging field. Every 4 years a conference of the International Society of Medical Hydrology and Climatology presents new scientific research and validates its findings.

Physiological effects

Balneotherapeutics consider direct and indirect actions on the body. The *direct actions* of balneotherapy take into consideration the physical actions of water on the body such as hydrostatic pressure, buoyancy, viscosity and frictional resistance, as well as thermal effects and the chemical and pharmacological effects of the percutaneous absorption of the substance being used. These substances include hot spring waters of various types such as carbon dioxide, hydrogen sulfide, chloride, sulfate, iron, acid, or radon. Peat muds, plant preparations and mineral-containing muds are also used. In Europe, peat bath and peloids are traditional. These applications are used in combination with exercise, aquatics, steam bath, sauna therapy, climatotherapy, physical therapy and pharmacotherapy, among others, with important consideration during treatment being given to the chronobiological and circadian rhythmic phases of the body.^{[1] [2] [3] [4] [22] [25]}

The *indirect actions* of balneotherapy arise from the repeated application of therapeutic stimulation such as climatic exposure to the elements, training effects of exercises and social and psychological effects arising from changes in environment. These elements act as a complex stimulation in a *non-specific* manner of the physiological function of the organism's central nervous system, autonomic nervous system, endocrine system, immune system, etc. The result of these stimulations is a reactive response by the body leading to activation and improvement of capacity, adaptation, and self-healing potential. In other words balneotherapy has a normalizing effect on the body's systems and rhythms.^{[2] [4] [7] [11] [10] [15]}

Skin response

The skin is a reflex, metabolic and immune organ. It affects the autonomic, immune and circulatory systems and participates in the biosynthesis of not only vitamin D, but acetylcholine, histamine, and serotonin as well.^{[2] [4] [10] [15]} With baths, significantly higher concentrations of minerals and medicaments can be reached in the epidermis than with systemic flooding via the vascular system.

The primary effects of bath components take place within the skin. For instance

hydrogen sulfide acts as a radical trap for oxygen radicals. This functions to reduce inflammation. It is thought that the action comes from the effect of sulfur on the Langerhans cells which play a role in immune presentation and inflammation modulation. In this way, skin responses can act as transmitter activating helping functions. Sulfur-containing peat baths show a pain-reducing and healing effect on rheumatic and degenerative disease. One reason may be because of the reduction in Langerhans cell activity which results from the combination of the components within peat and thermal radiation.^{[7] [15] [20] [24]}

PEAT THERAPEUTICS

History

Peat is a substance that has been used as a medicinal preparation in baths and peloid packs extensively in Europe for the past 200 years. This unique substance contains many chemical constituents which can interact with organic and inorganic compounds. The scientific basis for the physical, chemical and pharmacological effects of peat baths has been long known and used extensively in balneotherapeutic applications in Europe and other parts of the world to treat rheumatic diseases, gynecological disorders, osteoarthritis, lumbago, sciatica, skin diseases, trauma and its sequelae and many other ailments and afflictions. The many substances in peat offer a vast possibility of medicinal cure applications.^{[6] [8] [9] [10] [11] [17] [18] [20] [23] [24] [25] [26] [29] [31] [32] [33] [34] [35]}

It is important to consider the region and origin of the peat being used for medicinal purposes. Low moor peat has been shown to contain higher concentrations of nitrous substances, which are thought to contain a higher content of biologically active substances than the high moor peats or peats taken from a shallower depth. It is not just high nitrous content that makes a certain peat more medically useful, but the quality, type and amount of the biologically active substances it contains that is the determining factor on medicinal effect. In Germany these types of peats are now a national resource.^{[15] [16]}

Physiological effects

Peat has a structure containing micropores, which accounts for its sponge-like water carrying capacity and its ability to maintain either hot or cold temperatures. When applied, peat produces a gradient rise or fall in temperature which is especially desirable in a therapeutic bath. A peat bath influences the neuromuscular, endocrinological, blood in pulmonary and kidney hemodynamics depending on the consistency volume, partial or full bath.^{[4] [10]}

Peat has well documented effects such as tissue dilation, increase in stroke volume and metabolism and immunological stimulation. Peat bath may be preferable to water bath if one considers the gradient rise and fall of temperature, increased buoyancy and

prevention of heat loss during a bath and the possible positive chemical and pharmacological effects of the constituents of peat.^{[1] [2] [3] [4] [6] [8] [15] [19] [21] [25] [26] [32] [33]}

Peat substances are able to permeate the skin. Their absorption and action has been documented by the comparison of placebo, water, and peat bath using Doppler ultrasound measurement. One study which measured circulation in the uterine artery after bath therapy showed that only the peat bath achieves the physiological effect of prolonged vasodilation and circulation. This effect lasts for several hours after the treatment and is only achieved with the peat bath. It is thought that absorption of peat substances takes place through the hair follicles and apocrine glands by diffusion and partial pinocytosis.^[10]

The functions of peat in medicinal applications are antimicrobial, antiviral, anti-inflammatory, and antineoplastic, to name a few.^{[6] [9] [10] [11] [21]} Many biochemical effects have been demonstrated in humans and animals. These include elevation of protein synthesis, estrogen stimulation, reduction of arachidonic acid, and inhibition of inflammatory mediators such as leukotrienes, prostaglandins, and thromboxane. Biological activity is ascribed to peat ingredients such as sulfur compounds, magnesium, manganese, iron and humic acids.^{[6] [7] [10] [11] [16] [20] [26] [33]}

CLINICAL APPLICATIONS

Peat has many beneficial applications.

Human papilloma virus

Antiviral effects of peat have been demonstrated on several viruses, including the human papilloma virus. Remission and prevention of implantation of the virus has been described. This is a measure which prevents cancer. The antiviral and antineoplastic effects are thought to be associated with the ability of peat constituents such as humate to bind on lectin binding junctions blocking viral entry into cells.^{[9] [10]}

Infertility

A study on infertility due to immature follicle maturation syndrome demonstrated good results with peat therapy in comparison to the group receiving pharmacotherapy. In the peat therapy group, the rate of pregnancy was very good, along with a practically non-existent spontaneous abortion rate, while in the pharmaceutical group the rate of spontaneous abortions was very high.^[36]

Ankylosing spondylitis

In the treatment of ankylosing spondylitis, peat therapy has shown a decrease in the level of C-reactive protein and an elevation of hemoglobin with a series of treatments. This coincided with a significant decrease in pain and an increase in function.^{[26] [28]}

Hematoma

Organic peat with its intense vasodilating and anti-inflammatory effects, and interactions of its ions and mineral properties, including free iron not transported by macrophages, is an efficient therapy for the treatment of hematomas. Hematomas treated with thermal peat application were resolved 50% faster, with no hemosiderin residue, as compared with treatment with only heat applications which often left residues.^[23]

Immune stimulation

Peat bath in combination with hyperthermia shows leukocyte elevation. The immune-stimulating effects of peat bath seen clinically correspond to hematological changes after baths.^[33]

PROCEDURE

The following procedures should be applied with care and forethought as to diagnosis and the skillful administration of the treatment. These procedures are stimulations to the body and the thermal effects should not be taken lightly. Patients must be thoroughly screened for contraindications to treatment before doing full-body immersion hyperthermia.

Hyperthermic medicinal peat bath

The indications and contraindications of this procedure are given in [Table 45.1](#) .

Materials

- Peat bath material – the author uses Dr Schirmer's formula
 - Tub with water thermometer and safety features like handrails and non-slip floor mats
 - Room with table for perspiration time
 - Gown or loose-fitting bathing suit
 - Two sheets
 - Three wool blankets
 - Two large towels (one for patient to dry off after treatment and one for head wrap)
 - Basin with ice water and a face cloth
 - Digital thermometer or othothermometer for patient monitoring (no glass mercury thermometers)
-

- Exhaust fan or room air filter

- Foot stool for entering and leaving tub.

TABLE 45-1 -- Indications and contraindications for hyperthermic medicinal peat bath

| Indications | Contraindications |
|------------------------------|---------------------------|
| Acne | Pre-existing high fever |
| Arthritis pain | Open wounds |
| Back pain | Cardiac deficiency |
| Benign prostatic hypertrophy | Pulmonary deficiency |
| Bursitis | Respiratory insufficiency |
| Carpal tunnel syndrome | Lupus |
| Fibromyalgia | Acute hypertension |
| Flu | Diabetes |
| Fractures | Pregnancy |
| Acute gouty toe | Breast feeding |
| Chronic gout | Multiple sclerosis |
| Gynecological disorders | |
| Headaches | |
| Hematomas | |
| Hives | |
| Insomnia | |
| Lumbalgia | |
| Metabolic disorders | |
| Muscle tension | |
| Neurological disorders | |
| Obesity | |
| Orthopedic disorders | |
| Osteoarthritis | |
| Postoperative rehabilitation | |
| Premenstrual syndrome | |
| Prostatitis | |
| Psoriasis | |

| | |
|----------------------|--|
| Rashes | |
| Rheumatoid arthritis | |
| Sciatica | |
| Skin care | |
| Sprains | |
| Strains | |
| Stress relief | |
| Trauma | |
| Viral infections | |

The design of the bath area should take into consideration getting patients in and out of the tub and then as directly as possible to a treatment table.

Procedure

1. Patients should be ruled out for cardiovascular risk or any other conditions which do not respond to or are aggravated by thermal therapy before treatments begin.
2. Make sure the tank is clean without a ring. Check log book on last treatment and cleaning. If any evidence of an unclean tank is seen, it must be cleaned and disinfected before use. This is done by using rubber gloves with a scouring sponge and scrubbing tank with disinfectant soap followed by a rinse of first hot and then cold water. Follow this by spraying the surface with 10% bleach solution and wait 10 minutes before rinsing with very hot water.
3. Fill the tank 10 inches from the top with water at a temperature of 105–113°F (41–45°C).
4. The starting temperature and possible duration of treatment are determined by the condition.
5. Straight water bath should not exceed 110°F. With peat additive do not exceed 113°F.
6. Add peat to the bath.
7. Close monitoring during treatment by periodic recording of the patient's pulse, oral temperature, duration of treatment and tank temperature is necessary. A quick spike in pulse above initial pulse within the first minute or minutes is a contraindication to treatment. Any adverse reaction such as fingers and toes tingling, nausea, headache, light-headedness or dizziness should be evaluated closely and treatment terminated. For some patients they may only be able to tolerate a low temperature and short duration for the first treatment. When doing a series of treatments, the first treatment is of shorter duration and lower temperature to see how the patient responds. The ability to tolerate treatments should improve as patients acclimatize through their series of treatments.
8. The patient should enter extremely still water slowly. It will not feel as hot if the water is still.
9. Have them remain still as they become fully immersed to help decrease the

- sensation of intense heat.
10. To treat the pelvis utilize a sitz bath rather than a full bath to concentrate the effects of the treatment.
 11. The water will cool as time passes, although the peat material will help maintain the temperature. If the starting temperature was 105°F, hot water may need to be added.
 12. Bath duration is 8–20 minutes and should not exceed 20 minutes.
 13. If the patient becomes fatigued or distressed, they should exit the bath to awaiting sheet and wool blankets. Do not wait.
 14. As the patient exits the tub, they must have help from two people who provide lifting support from under the arms bilaterally. This is a time to be very careful.
 15. Encourage the patient to concentrate on walking on their own.
 16. Have them lie down on a fresh sheet and wrap them in both sheets and two or three wool blankets. Cover the head with a towel.
 17. Continue to monitor pulse and oral temperature for the duration of the 20 minute perspiration time.
 18. Rinse a face cloth in cold water and wipe perspiration from patients face frequently during both bath and perspiration time. This is done every 1 or 2 minutes and is extremely important.
 19. Encourage the patient to relax and help them keep their mind on pleasant matters during the bath.
 20. After the patient has been wrapped from head to foot in sheet and wool blankets, allow them to go through
-

385

hydrotherapy reaction of rise and fall in temperature, pulse and diaphoresis three times before they are removed from sheet and allowed to return to normal activities.

21. Have the patient rest and replace electrolytes after treatment.
22. During the perspiration time, manual traction can be applied to the spine. This is done by grasping the patient's ankles when they are supine and pulling for 30–45 seconds with enough traction that they almost slide on the table. Indications for manual traction are disc problems, scoliosis, impingement.
23. Advise the patient not to shower with soap for up to 12 hours after peat bath as absorption rates continue post-bath if peat additives have been used.
24. Patients should dry thoroughly and remain covered, warm and *out of draft* for 3 hours post-treatment.
25. Clean the tank and room thoroughly after use. Log out time of bath and tank cleaning.

Medicinal peat peloid

The indications and contraindications of this procedure are given in [Table 45.2](#) .

Materials

- Peat pulp
- Large towel
- Small towel
- Face cloth
- Small blanket to cover hydrocollator
- Two small stainless basins
- One small paper cup
- Hydrocollator (hot water bottle can alternately be used).

TABLE 45-2 -- Indications and contraindications for medicinal peat peloid

| Indications | Contraindications |
|------------------------------|--|
| Acne | Open wounds |
| Arthritis pain | Pregnancy |
| Back pain | Very thin fragile skin |
| Bursitis | Heat insensitive skin |
| Carpal tunnel syndrome | Allergies to any of the peloid materials |
| Fibromyalgia | |
| Fractures | |
| Acute gouty toe | |
| Chronic gout | |
| Headaches | |
| Hematomas | |
| Hives | |
| Lumbalgia | |
| Muscle tension | |
| Molluscum contagiosum | |
| Orthopedic disorders | |
| Osteoarthritis | |
| Postoperative rehabilitation | |
| Premenstrual syndrome | |
| Prostatitis | |
| Psoriasis | |
| Rashes | |
| Rheumatoid arthritis | |

| | |
|---------------|--|
| Sciatica | |
| Skin care | |
| Sprains | |
| Strains | |
| Stress relief | |
| Trauma | |

Procedure

This is a thermal peat pack and utilizes Dr Schirmer's technique and medicinal peat formula.

The procedure is as follows:

1. Make a square layer of peat material about 0.25 inches thick, 2 inches bilateral of the spine and 6–8 inches long over the spine. If you are not treating the spinal area, cover the area to be treated. Try to make the area of application flat and level.
2. Cover the peat directly with a warm wet face cloth. Remember borders of peloid exactly by ridging the facecloth around the margins of the peat.
3. Border the wet face cloth-covered peloid with a rolled bath towel, making a quarter turn while folding the towel to match the margin of the peat.
4. Apply one layer of towel over the face cloth and peat material.
5. Put a fresh hydrocollator pack directly over the towel. The hydrocollator should be heated at a gently boil for 1 hour prior to using. *Do not allow any exposed skin to come in contact with the hot pack.*
6. Cover the hydrocollator pack with a towel or small blanket to insulate and prevent heat loss.
7. Have a cup of cold water ready to pour on the wet face cloth-covered peloid if it gets too hot. In a good treatment the peloid pack should get hot enough to require two to three dowsings of water.
8. As soon as the patient tells you that the pack is getting too hot, lift up the hydrocollator pack and towel and pour the water directly over the face cloth-covered peloid until cool. Then replace the hydrocollator and coverings.
9. *Never leave the patient unattended!*
10. Treatment time is approximately 25 minutes.
11. To remove the peat from the skin after treatment, slide a small basin along the skin under the peat, scraping the peat into the bowl. Wipe with a full face cloth wetted with warm water in a gentle twisting motion back and forth to remove peat residue from the skin.
12. Cover the treated area after treatment to maintain warmth for 3 hours.

Partial immersion medicinal peat bath

The indications and contraindications of this procedure are given in [Table 45.3](#) .

TABLE 45-3 -- Indications and contraindications of partial immersion medicinal peat bath

| Indications | Contraindications |
|------------------------------|--------------------------|
| Arthritis pain | Open wounds |
| Bursitis | Pregnancy |
| Carpal tunnel syndrome | Heat-insensitive area |
| Eczema | |
| Fibromyalgia | |
| Fractures | |
| Acute gouty toe | |
| Chronic gout | |
| Hematomas | |
| Orthopedic disorders | |
| Osteoarthritis | |
| Plantar fasciitis | |
| Postoperative rehabilitation | |
| Psoriasis | |
| Rashes | |
| Rheumatoid arthritis | |
| Skin care | |
| Sprains | |
| Strains | |
| Tendinitis | |
| Tenosynovitis | |
| Trauma | |

Materials

- Deep well basin – the tall plastic waste basket size works well for the leg
- Medicinal peat bath
- Water thermometer
- Small towel.

Procedure

1. Fill basin to three-quarters full with 108–114°F water.
2. Add peat to the bath.
3. Have the patient immerse their wrist, ankle, or elbow slowly into the water. Try to immerse the forearm and leg if treating the hand or foot.
4. Keep the body part immersed for 25 minutes.
5. After the treatment, cover the area with a wool sock or clothing and keep covered for 3 hours post-treatment.
6. Often peat material will be sent home with the patient to do home treatments.
7. Clean up the basin by washing with antimicrobial soap. Then disinfect with 10% bleach solution and rinse after 10 minutes.

CONCLUSION

As a physician using Dr Shirmer's technique and peat formula, I have seen accelerated results that would not be achieved with any other method. I have seen excellent results for:

- arthritis
- tenosynovitis
- strains and sprains
- plantar fasciitis
- low back pain including sciatica
- scoliosis
- fractures
- gout
- muscle pain
- dermatologic conditions such as eczema.

The combination of medical sophistication in diagnosis and application of various balneological methods provides an excellent tool for the physician to treat in a natural way to the great benefit of their patients.

Chapter 46 - Soft tissue manipulation: diagnostic and therapeutic potential

Leon Chaitow ND DO

INTRODUCTION

Acupuncture, osteopathy, chiropractic, naturopathic medicine, orthopedic medicine, and physiotherapy all pay attention to the diagnostic and therapeutic potential of the soft tissues of the body. These and other similar therapeutic systems have developed methods of identifying those aspects of soft tissue dysfunction which indicate disease or injury or reflex activity of some type. Regardless of the terms used or the theories propounded, all the systems seem to refer to the same phenomenon: distinct, palpable, usually sensitive areas of soft tissue aberration which are either directly or reflexively related to local or organ dysfunction.^{[1] [2]}

The sustained or intermittent adaptive results to the influences listed in [Table 46.1](#) can result in progressive changes, summarized in [Table 46.2](#) . These adaptations are discussed fully on [p. 391](#) .

Soft tissue manipulation may be utilized to:

- normalize dysfunction preparatory to manipulation of osseous structures^[9]
- restore postural or functional integrity – achieving what osseous adjustments can seldom achieve: actual alterations in structural position of musculoskeletal segments^[10]
- function as part of a comprehensive approach to health care in which the reflex activity, as manifested in surface structures, is used diagnostically and therapeutically.^[11]

TABLE 46-1 -- Soft tissue stressors

- Congenital factors, such as short leg, small hemipelvis
-

- Birth trauma, such as cranial trauma from forceps delivery which distorts the internal cranial fascia – tentorium cerebelli and falx cerebri – which, because of body-wide fascial continuity, can cause distortions elsewhere
- Overuse, misuse or abuse of the musculoskeletal system in work or recreational settings
- Trauma – either repetitive minor forms or major incidents
- Reflexive factors, including myofascial trigger points
- Chronically held somatization influences generated by negative psychosomatic factors and emotional coping traits, including fear, anger, anxiety, depression, etc.
- Biochemical changes resulting from nutritional, toxic, endocrine, infectious and other influences

TABLE 46-2 -- Progressive adaptive changes to soft tissue stressors^[3] ^[4] ^[5] ^[6] ^[7]

- An initial “alarm” response will occur in which tissues become hypertonic
- If not short term, localized oxygen deficit is probable, together with retention of metabolic waste products, both of which result in discomfort or pain and the likelihood of an increased hypertonic response
- The constant activity of the neural reporting stations of these tissues leads to increased sensitization and the development of a tendency to hyperreactivity (known in osteopathic medicine as “facilitation”) ^[8]
- Macrophages become activated – along with increased vascularity, fibroblast action and connective tissue production – leading to cross-linkage and shortening of tissues
- Changes in the muscles as a result of hypertonicity which, if sustained, results in progressive fibrotic modification
- Sustained hypertonicity leads to drag on tendinous attachment to the periosteum, and the likelihood of pain and dysfunction in these tissues
- If such stressed tendons or muscles cross joints, they become crowded and their function is modified
- The antagonists of chronically hypertonic muscles will be reciprocally inhibited and, as a result, normal firing sequences of muscles may alter – e.g. where excessive activity of synergist muscles occur in order to take on the tasks of weakened (inhibited) primary movers
- Another possibility is that chronically shortened, hypertonic structures will have a sustained inhibitory effect on their antagonists – an example would be short, tight, erector spinae muscles and weakened (inhibited) abdominal muscles

- Chain reactions of such dysfunction can occur resulting from the shortening over time of postural muscles (type 1 fibers) and the inhibition and weakening (without shortening) of phasic muscles (type 2 fibers)
-
- Localized areas of hyperreactivity (facilitation) may evolve paraspinally or in particular stress-prone regions of any myofascial structures – trigger points and other reflexively related changes
-
- These triggers themselves become sources of further dysfunction
-
- Postural and functional changes will become apparent throughout the body, e.g. in relation to breathing function
-
- Therapeutic input at these stages involves a need to address the multiple changes which have occurred – reduce hypertonicity, resolve fibrotic changes, lengthen shortened structures, mobilize joints, deactivate trigger points – as well as removal of habitual patterns of use which have added to, or caused, the dysfunctional patterns, including postural and respiratory re-education
-
- The musculoskeletal changes described above may have components which include biomechanical, biochemical and psychological components, all of which need to be understood and, where possible, modified or removed

The distinguished Western acupuncture pioneer, Dr Felix Mann, has stated that, with the vast number of acupuncture and other reflexively active points now charted, there is little, if any, of the body surface left which has not been ascribed therapeutic potential.^[12] Thus he maintains that the traditional concept of points and meridians is no longer a valid hypothesis. He concludes that the whole body is, in fact, an acupuncture point. If other systems of identifying discreet areas of reflex potential in the soft tissue, such as Chapman's neurolymphatic reflexes^[13] and Bennett's neurovascular reflexes^[14] (see below), are examined alongside both traditional and more recently described acupuncture points, Mann's statement becomes readily acceptable.

SOFT TISSUE POINTS

A degree of reductionist thinking is necessary to understand the nature and value of the reflex areas, points, and zones that have been described by the many systems of soft tissue manipulation.

In general, these points can be divided into sensitive soft tissue alterations that result from physical strain or trauma (including the soft tissue effects of emotional stress) and alterations which are the result of reflex activity (e.g. viscerosomatic reflexes). These changes can be considered as adaptive responses to patterns of stress as outlined above.

Methods of identification

There are a variety of methods by which soft tissue changes may be located through

palpation. These include:

- traditional massage methods
- specific palpation techniques, such as those developed by osteopathic and other schools^[15]
- neuromuscular technique (a method of combined assessment and therapy developed in the 1930s by Stanley Lief, an American-trained naturopathic and chiropractic physician working in Europe)^[11]
- skin distraction techniques evolved by the German connective tissue massage (Bindesgewebssmassage) ^[16] practitioners (see “Hyperalgesic skin zones”, [p. 397](#)).

All of these, and other methods of palpation, may be utilized in order to identify areas of local soft tissue dysfunction which may be sources of, or results of, reflex activity or other local adaptive responses.^[17]

The analysis of the available information present in localized areas of the soft tissues requires consideration of a variety of classifications and systems.

It is necessary to examine some of the systems which have described the same tissue changes in different ways, in order to compare the similarities and differences in the descriptions of “points” (discrete, usually sensitive, areas

of altered structure and function in the soft tissue) and the diagnostic and therapeutic significance ascribed to them.

GENERAL SOFT TISSUE MANIPULATIVE TECHNIQUES

Therapeutic effort may be directed toward the diagnosis and correction of the mechanical aspects of dysfunction (trauma, strain, etc.) or toward the use of the available information from such reflex areas in a more wide-ranging, holistic approach to the health of the patient.

General, rhythmic techniques are often employed on the soft tissues to relieve local dysfunction and/or to prepare for subsequent adjustment of osseous structure. They may include all or some of the methods listed in [Table 46.3](#) .^[9]

In all of these variations, the objectives are the improvement of circulation and drainage, release of con-tracture, and increased range of movement. Inhibition implies a degree of pressure sufficient to achieve reduction in hepertonia or neurological activity. All of these may be applied in a stimulatory as well as a relaxing manner, but care should be taken to prevent stimulation from becoming irritation.

DISCRETE PALPABLE POINTS RELATED TO TRAUMA OR STRAIN

Researchers and clinicians have used differing terminology to describe similar phenomena, resulting in confusion of what is essentially an uncomplicated pattern.

In the musculature and connective tissues of the body, often in the regions of the origins and insertions of the muscles, there are palpable, sensitive areas of altered structure resulting from injury, irritation, stress, etc. These have been described as “tender” points,^[18] “trigger” points,^[19] “Ah Shi” points in traditional acupuncture (literally spontaneously tender points’),^[19] and “indurated” points,^[20] among other descriptions.

Common to these points is their size, which ranges from 0.5 to 1.0 cm across, and their feel, which is described as harder or firmer than surrounding normal tissue, or as having an edematous or stringy feel.^{[18] [19] [20] [21]}

It is often noted that these localized areas of altered structure and function occur in bands of stressed fibers, both fascial and muscular. In all cases, such localized areas are, to a greater or lesser degree, sensitive or tender out of proportion to the degree of pressure exerted.^[22] All these points are potential “trigger points”, but only those which, upon pressure, are noted to refer pain or other symptoms to a distant (target) area are thus classified.^[23]

Identification of these points as areas of localized dysfunction is dependent upon palpatory literacy – the ability of the examiner to readily distinguish between the texture and other characteristics of normal and abnormal tissues. Development of such a degree of sensitivity is a matter of practice and is readily acquired by any practitioner willing to spend but a little time touching, feeling, assessing, comparing, and judging what it is that is being felt.^[15] In most, but not all, cases, these altered areas of structure and function are found to lie in shortened muscle tissue or fascia.^{[21] [22]}

The morphology of acupuncture points has been analyzed and described by various workers. Bossy^[23] has noted that all of the maxima points described by Head,^[24] the motor points of medical electrotherapy,^[25] and fully 70% of Travell’s trigger points,^[26] are all acupuncture points described in Traditional Chinese Medicine.

As will be noted in the discussion below, there is also a large degree of overlap between these and points described in reflex systems, such as Chapman’s neurolymphatic reflexes^[13] (which include all the traditional acupuncture alarm points) and Bennett’s neurovascular reflexes^[14] (which includes all traditional acupuncture “associated” points).

Bossy notes that the common structures found under all acupuncture points include neurovascular structures,

TABLE 46-3 -- General soft tissues manipulative techniques

| Technique | Description |
|---------------------------------|---|
| Articulation | Repetitive passive movements employing leverage through variable ranges of the arc |
| Effleurage | Superficial drainage technique derived from massage therapy |
| Inhibition/Ischemic compression | Describes an objective rather than a method; consists of pressure applied for lengthy periods, slowly applied and slowly released, using thumb contact as a rule |
| Kneading | Deep or superficial rhythmical pressure, usually applied by the thenar or hypothenar eminence |
| Positional release methods | Approaches which instead of acting directly on restricted or shortened structures aim to position these in a state of “ease” by moving away from restriction barriers, allowing a spontaneous normalization to occur involving neural (muscle spindle) resetting and circulatory enhancement. These methods include what is known as strain/counterstrain |
| Rhythmic traction | Repetitive attempts to separate articulations in order to stretch inter- and periarticular structures |
| Springing | Repetitive, usually slowly applied, pressure of a gradual nature, often used diagnostically (see viscerosomatic reflex below) |
| Stretching | Short and long amplitude attempts at separation of muscular attachments, and stretch of ligaments, fascia, and membranes |
| Vibration | Rapid oscillatory pressure or movement |

connective tissues, and subcutaneous fatty tissues. The connective tissues are thought to be vital in producing the acupuncture sensation noted as being essential to effective therapy.^[27] These structures impart the “gripping” of the needle, and the manipulation of the needle affects, through localized tissue traction, minute neural reporting stations, such as Meissner corpuscles, muscle spindles, and Golgi tendon organs. Since many of the systems of reflex soft tissue manipulation (strain/counterstrain, etc.) maintain that it is just such neural structures which produce the reflex effects in their methodology,^[8] there appears to be common ground between acupuncture and these other systems. This similarity is found in both the identification of the reflex structure (acupuncture point, trigger point, tender point, etc. being the same phenomena in different systems of classification) and, at least in part, the element which acts to convey reflex benefits (e.g. Golgi tendon organs).

In an attempt to make sense of the vast amount of information available from soft tissue changes, a number of systems have been developed that classify variations in

significance, role, potential for therapy, etc. Some of these are described below.

All such points are sensitive to pressure, but some also refer symptoms to a distant site when stimulated. The latter are trigger points and the former are potential or latent trigger points. These may be classified in a variety of manners depending upon the system in question.^{[17] [28]}

Point classification

Tender points

In the system of soft tissue manipulation named strain/ counterstrain, described by Lawrence Jones,^{[18] [29]} the tender point lies in a particular area in relation to any strain of a given joint or area. This is often found, not in the area complained of by the patient, but in shortened tissues associated with the strain. Thus, in flexion strains of the low back (strains which occur in a forward bending position), the appropriate tender points will almost always be found on the anterior surface of the body, i.e. around the lateral abdominal region or anterior pelvis, despite the patient reporting back pain. On palpation, these anteriorly located points are reported to be extremely sensitive, although the patient is seldom aware of them prior to their being palpated. Jones's method is to maintain palpatory contact with the tender point while repositioning the patient's body in such a manner as to reduce the reported sensitivity from the point. This position of relative ease is then maintained for some 90 seconds while the neurological reporting stations in the injured tissues re-establish a balanced feedback to the CNS (central nervous system), with resulting release of spasm or contraction. No further therapy is required, since this will usually achieve release of soft tissue dysfunction resulting from strain, and a return to normality.

In many cases the position of ease mimics or exaggerates the position in which the original injury occurred, or the position into which the patient is distorted by the contraction or spasm. Thus, an individual unable to stand erect (due to low back strain, for example), may be placed in a position of increased flexion while the palpation of the tender point is used to "fine tune" the exact position of maximum ease of pain at that point. There is recent evidence confirming the value of these safe methods in bedridden, hospitalized patients.^[29]

The points described in this method are similar to those known as Ah Shi points in traditional acupuncture.^[19] Almost identical criteria are used to identify spontaneously sensitive Ah Shi points, which are then utilized for acupuncture or acupressure therapy (see below). It is reasonable, therefore, to suppose that the maintenance of inhibitory pressure on the tender point is itself of some therapeutic value, inducing a degree of local and reflex inhibition. Jones denies that this is the intention, stating that he considers the pressure used in his system to be purely diagnostic,^[18] but it must remain a strong probability that reflex inhibition of neural activity in the point is occurring as a result of this pressure, since evidence exists supporting the efficacy of pressure techniques in inducing pain relief in such conditions.^{[30] [31]}

Indeed, animal studies^[30] suggest that pressure techniques have a greater degree of

efficacy in promoting endorphin release and ultimate pain relief than does needling. Since Chinese texts describe pressure or needling of points as having the same pain-relieving effect, it is reasonable to assume that endorphin and/or enkephalin release is an important mediating element in such relief.^[32] In the experiments mentioned above, artificial CSF was perfused through the lateral ventricle of a donor rabbit while it was receiving finger pressure acupuncture. When this perfusate was injected into a recipient rabbit, a pain threshold increase of 82% was noted. When CSF from a non-treated rabbit was similarly injected, no change was noted in the pain threshold. Highly significant changes were thus noted involving what is assumed to be met-enkephalin. The research group at the Peking Medical College stated:

From the historical viewpoint, finger pressure was probably the most ancient methods of acupuncture. In our own experience the feeling of soreness and swelling stirred by finger acupuncture was sometimes even keener than that experienced in traditional needling, whereas the local tissue damage was much less with finger-acupuncture.

Trigger points

A trigger point is a localized palpable spot of deep hypersensitivity from which noxious impulses bombard the CNS to give rise to referred pain and other symptoms.

Trigger points as described by Travell and others are responsive to pressure techniques, to spray and stretch methods (see below), to injection with procaine and other anesthetics, and to acupuncture (dry needling).^[33] Whichever method is used to obliterate the local trigger point manifestation, several important additional measures are called for. One of these is identification of the cause, since, if it is not resolved, relief is often short-lived. Thus, factors such as posture, use of the body (ergonomics applied to sport or occupational habits, etc.), emotional stress, anatomical abnormalities (short leg, etc.), nutritional status, and inherited elements all require analysis, in this as in all areas of somatic dysfunction.^[28]

It is also necessary to normalize the ability of the muscle(s) in which the trigger(s) exists to subsequently reach its normal resting length.^{[21] [30] [34]} Trigger points are not found in muscles able to stretch to normal lengths. Trigger points are localized foci of neurological disorder. They continue to bombard the CNS and, in reflex, their target tissues until removed by therapy. Without therapy they are self-perpetuating.^[17] Once a trigger is dealt with, the muscle in which it lies should be examined for other trigger points, and target tissues should be searched for “satellite” triggers.^{[17] [21]}

Travell and others have reported a wide range of symptoms in target tissues associated with trigger point activity, including pain, local vasomotor disturbances (abnormality in pallor, coldness, cyanosis, flushing, etc.), increased or decreased sweat production, and pilomotor activity (all via autonomic nervous system involvement).^[35] Gutstein^[36] reports

trigger point involvement in production of a wide range of symptoms, such as menopausal hot flushes and other pre- and post-menopausal symptoms (triggers noted in occipital, cervical, interscapular, sternal, and abdominal structures) and gastrointestinal symptoms, including pylorospasm, halitosis, regurgitation, heartburn, nausea, distension, constipation, and diarrhea (triggers noted in the lower sternum, epigastrium and parasternal regions).

Direct local pressure starts the process of removing trigger points. It should involve enough pressure to produce the referred symptoms and then be maintained in a make-and-break pattern (5 seconds on and 2–3 seconds reduced by about a third) until symptoms noticeably lessen or tissue changes are palpated.^{[29] [37]} This is followed by chilling of both the trigger and target area with fluoromethane spray (or ice) together with simultaneous and subsequent stretching of the involved muscle in order to achieve a normal resting length.^{[17] [21] [34] [38]} Mennell^[22] advocates the spray and stretch methods, as does Travell, as part of the method used for obliteration of active trigger points. Many practitioners, such as Gutstein,^[36] advocate injection into trigger points of anesthetic substances (procaine, etc.) and some, such as Dittrich,^[39] advocate surgical excision. Another alternative, after identifying and ischemically compressing (inhibiting) the point described above, would be to place it into a position of ease (as in the strain/counterstrain methodology discussed earlier) prior to stretching the muscle housing the trigger points.^{[40] [41]}

Whichever method is used, stretching of the muscles involved to induce a return to normal resting length is necessary to ensure complete removal of the trigger. To achieve this, a number of methods, apart from standard active and passive stretching techniques, have been developed. Among these is the muscle energy technique.

Muscle energy technique

A potentially stressful physical therapy modality, known as proprioceptive neuromuscular facilitation (PNF), involving full-strength muscular contractions, has evolved into a gentler (very light contractions) method in osteopathic methodology, now called muscle energy technique or hold reflex technique.^{[42] [43]} It is aimed at restoring shortened, tight structures to a normal resting length.

A vast amount of research and clinical investigation into the value of this method has been conducted in Europe, mainly in Scandinavia and Czechoslovakia.^{[1] [43]} The muscles requiring muscle energy attention are identified by standard orthopedic tests for length and by palpation. Additionally, dysfunctional muscles can be identified by reading the firing sequence of muscles in particular movement patterns. For example, in the prone position, if the leg is elevated (hip extension) the firing sequence when normal is gluteus maximus, hamstrings, contralateral and ipsilateral erector spinae. If this is palpated as anything else, usually hamstring and erector contraction and subsequent gluteal firing, the implication is that there is overactivity in the erectors and hamstrings and inhibition of the gluteals, with a requirement for normalization of the overreactive muscles – using muscle energy procedures or other approaches.^[44]

Muscle energy technique involves the use of two physiological phenomena:

post-isometric relaxation and reciprocal inhibition. When a muscle is held in isometric contraction, its release is followed by a degree of relaxation not present prior to the contraction.^[28] Thus, when muscle fibers contract, but approximation of the origin and insertion is prevented by an exactly equal counterforce, usually provided by the operator (i.e. an isometric contraction), and this contraction is maintained for a specific length of time (typically 7–10 seconds) after which relaxation is allowed, there will occur a marked release of hypertonicity in the tissues. This allows a greater degree of pain-free stretch to take place in the shortened fibers.^[1]^[45] A new, but probably as yet still limited, resting length is then achieved, and this is used as the starting position of the next isometric contraction. This phenomenon of post-isometric relaxation (PIR) is used to sequentially stretch tight musculature in which triggers

are found.^[1]^[43] If the tight or shortened tissues are too sensitive to allow active isometric contraction, then their antagonists are contracted isometrically, producing the phenomenon of reciprocal inhibition which is similarly used to gradually increase normal resting length in the shortened structures.^[1]

There are a number of variations in muscle energy technique. It is extremely gentle, utilizing only a small percentage of available strength (unlike PNF), which makes it applicable to almost any condition of soft tissue dysfunction, either alone or in combination with pressure or other techniques.^[28]

Hartman^[1] describes the use of muscle energy techniques in the preparation of a joint for manipulation. The joint is placed in the appropriate position for adjustment, and the patient is then asked to push against the contacting hands of the operator, so that an isometric contraction develops in the tissues surrounding the joint or area being adjusted. After this contraction is released, the degree of “slack” available to the operator will be greater, and the joint will be more easily and effectively adjusted. Indeed, adjustment often occurs during the isometric contraction described (see [Table 46.4](#)).

Zones of irritation

Dvorak & Dvorak^[17] have described a system which identifies localized areas of spinal sensitivity. In this system, zones of irritation (ZI)^[46] are identified by palpation in the paraspinal tissues. These appear in most respects to correspond both with the paraspinal acupuncture points described in the 2nd century AD by Hua Tuo^[19]^[47] and with Jones’s tender points.^[18] In acupuncture, they are needled or pressed to produce appropriate local and distant effects.

In Dvorak’s method, the zones of irritation are used to identify the ideal manipulative direction for adjustment. They are contacted by a palpating thumb or finger (as in Jones’s method) and pressure is exerted against the spinous process adjacent to the ZI in such a manner as to reduce their sensitivity. This is considered to be the direction of

desirable adjustment. A marked similarity with the method described by Morrison (discussed below) and with strain/counterstrain techniques is recognizable.

Dvorak elaborates on the ZI phenomenon by describing what are termed spondylogenic reflex syndromes,^[48] in which ZI in specific paraspinal sites are noted to produce particular patterns of dysfunction in other spinal structures, including muscle groups and vertebral regions.

Induration technique

This method, which describes almost precisely the same technique as that advocated by Dvorak, was developed by Marsh Morrison DC in the 1940s.^[20] The sensitive paraspinal point is identified and a push (not an adjustment) is made on the adjacent spinous process until a direction is found in which sensitivity reduces, or tissue release is noted. The pressure is then held for a not less than 20 seconds and no other therapy used. Release of the contracted tissues and lessening of pain on palpation are noted. This is very similar to the Jones's method and is ideal for use by therapists not qualified or licensed to manipulate the osseous structures.^[28]

Nimmo's receptor tonus technique

Other workers, such as Raymond Nimmo DC, who developed the receptor/tonus technique, have described similar variations on the theme of identification and normalization of local areas of soft tissue dysfunction using pressure and stretching methods.^[49] Nimmo maintained that pressure on such points should last no more than 5–7 seconds and that further pressure was likely to injure tissue. Triggers thus treated would, he maintained, subsequently resolve. He also advocated stretching of the structures. His pressure was delivered by the use of a rubber-tipped wooden instrument, a T-bar, held in the palm of the hand in the interest of reducing stress on the operator's digits.

Different muscle types

In all of these systems, the tissues in which points are found are described as having a characteristic shortened or tight feel, and the work of Lewit^[11] and Janda^[50] helps to explain why these are found mostly in particular muscles. Janda states that there are two basic muscle activities and types: those which are predominantly postural and others which are mainly phasic in action.

Postural muscles include:

- tibialis posterior
- gastrocnemius-soleus
- rectus femoris
- iliopsoas
- tensor fascia lata
- hamstrings

- short thigh adductors
- quadratus lumborum
- piriformis
- some paravertebral muscles
- pectoralis major (and perhaps minor)
- sternocleidomastoid
- upper trapezius
- levator scapula
- flexors of the upper extremity.

These are all prone to shortening and hypertonia when stressed, abused, or under- or overused.

A number of conditions exist in which specific patterns

TABLE 46-4 -- Muscle energy technique: summary of variations

| Type of contraction | Indications | Modus operandi | Forces | Duration | Repetitions |
|----------------------------|--|---|--|--|--------------------|
| Isometric patient direct | Relaxing muscular spasm or contraction. Mobilizing restricted joints. Preparing joint for manipulation | Affected muscle not employed. Antagonists used, therefore shortened muscles relax via reciprocal inhibition. Patient is attempting to push through the barrier of restriction. After the isometric contraction, the tissues are taken to the new restriction barrier (in acute settings) or are stretched | Operator's and patient's forces are matched. Initial effort involves approximately 20% of patient's strength; slow increase to no more than 50% on subsequent contractions. Increase of duration often more effective than increase in force | 4–10 seconds initially, increasing to up to 30 seconds in subsequent contractions, in order to recruit additional fibers during the contraction effort | 3–5 times |

| | | | | | |
|---------------------------|--|--|--|---|-----------|
| | | are taken to the new restriction barrier (in acute settings) or are stretched through the barrier (in fibrotic settings) | | | |
| Isometric operator-direct | Relaxing muscular spasm or contraction. Mobilizing restricted joints. Preparing joint for manipulation | Affected muscles used, therefore shortened muscles relax via post-isometric relaxation. Operator is attempting to go through barrier of restriction. After the isometric contraction, the tissues are taken to the new restriction barrier (in acute settings) or are stretched through the barrier (in fibrotic settings) | Operator's and patient's forces are matched. Initial effort involves approximately 20% of patient's strength; slow increase to no more than 50% on subsequent contractions. Increase of duration often more effective than increase in force | 4–10 seconds initially, increasing to up to 30 seconds in subsequent contractions, if greater effort required | 3–5 times |
| Isotonic concentric | Toning weakened musculature | Contracting muscle is allowed to do so, with some resistance from operator | Patient's force is greater than operator resistance. Patient uses maximal effort available but force is built slowly, not via sudden effort | 3–4 seconds | 5–7 times |

| | | | | | |
|--|---|---|--|-------------|----------------------------------|
| Isotonic eccentric (isolytic) | Stretching tight fibrotic musculature | Contracted muscle is prevented from doing so via superior operator effort. Origin and insertion do not approximate. Muscle is taken to, or as close as possible to, full physiological resting length | Operator's force is greater than patient's. Less than maximal patient's force employed at first. Subsequent contractions build towards this, if pain not excessive | 2–4 seconds | 3–5 times, if pain not excessive |
| Isokinetic (isotonic and isometric contractions) | Toning weakened musculature. Building strength in all muscles involved in particular joint function. Training effect on muscle fibers | Patient resists with moderate effort at first, progressing to maximal effort subsequently, as operator puts joint through its full range of movements | Operator's force overcomes patient's effort to prevent movement. First mobilization involves moderate force, progressing to full force subsequently | | |

of dysfunction are associated with shortening of such muscles (e.g. iliopsoas, piriformis, tensor fascia lata, and iliotibial band), treatment of which is possible using variations of the techniques discussed here (neuromuscular technique, muscle energy technique, etc).^{[11] [28]}

The phasic muscles include:

- tibialis anterior
- the vasti
- the glutei
- abdominal muscles (mainly the recti)
- lower stabilizers of the scapula

- some deep neck flexors
- extensors of the upper extremity.

These all tend to hypotonia, weakening, and atrophy under conditions of under- or overuse, or abuse.

Janda asserts that before any attempt is made via exercise, etc. to strengthen weakened musculature, it is critical for the shortened antagonists to be stretched and relaxed. Commencing with exercising of the weakened structures is likely to further increase tone in the already tight musculature. Tight muscles act in an inhibitory way on their antagonists, creating hypotonia. This can be altered by normalization of the tight structures. Whether this stretching is achieved by muscle energy methods or active or passive stretching is a matter of choice.

Summary

In shortened fibers of the soft tissues can be found the palpable and sensitive points discussed above. They may be the result of a combination of structural anomalies, trauma, and/or physical or emotional stress and are always influenced by underlying nutritional and behavioral elements. Some of these may be the source of reflex symptoms and pain (active trigger points). All such soft tissue dysfunctions respond to manual pressure, needling, local anaesthesia, chilling, etc., as well as to release via positional alteration and/or resolution of identifiable underlying or causative factors.

REFLEXES RELATED TO ORGAN OR SYSTEM DYSFUNCTION

Connective tissue massage

The German system of connective tissue massage (CTM)^{[11] [16] [28] [51]} has identified a number of regions or zones which are associated with specific organ or functional problems (e.g. liver zone, constipation zone, arterial disturbance of the legs zone, etc.). Identification of such zones in a patient depends on a method of skin stretching by lifting which indicates the degree of adherence between overlying structures and underlying connective tissue. There is decreased elasticity in areas of dysfunction. Therapy involves a dry contact which lifts and stretches these tissues, producing powerful viscerocutaneous reflex effects. Clinical evidence shows this therapy to be of use in a wide range of problems, as it improves organ, circulatory, and neural dysfunction. A recent hospital study in Scotland indicated CTM to be effective in producing marked reduction in anxiety levels, with resolution of symptoms such as insomnia in patients resistant to drug therapy.^[52]

Chapman's neurolymphatic reflexes

Chapman's neurolymphatic reflexes are described in osteopathic literature and involve the use of pairs of reflex points located anteriorly and posteriorly on the body surface.^{[11] [13] [28] [53] [54]} The feel of such reflex points is described as similar to that of a nodule, an

edematous structure, or a fibrous shotty plaque, depending upon the location.

These reflexes are stated to be the somatic component of lymphatic stasis in associated structures, and treatment of these is felt to assist in resolution of such stasis. A reflex is said to be active if both points of a pair are found to be palpable and sensitive. Treatment is initiated by direct firm rotary pressure, via finger or thumb tip, on the anterior point for 20 seconds to 2 minutes or until decongestion (tissue change) is noted. The posterior point is then similarly treated. Subsequent re-examination of the anterior point of the pair is conducted to ascertain whether sensitivity is still present. If sensitivity is not present, then successful resolution of the associated lymphatic stasis is anticipated. If sensitivity is still noted, however, then it is considered that pathology is too great for this method to be effective and that other therapeutic input is required. This makes the method a useful prognostic indicator, whether or not the reflexes are used therapeutically in the manner described.

When methods such as hydrotherapy, botanical medicine, acupuncture, massage, or nutritional adjustment or supplementation are utilized to treat a particular condition, the activity and sensitivity of Chapman's neuro-lymphatic reflex points may be monitored in order to assess progress. Also, since these points become active long before symptoms are obvious in associated structures or organs, this method is of significant early diagnostic and prognostic value.

These reflex pairs have been studied in hospitals by the osteopathic profession and were found to be powerful reflex areas. Whether or not the influence is directly on the lymphatic structures is a matter for debate.^[55] Points are utilized therapeutically in groups associated with systems, such as the respiratory or gastrointestinal systems, rather than as individual pairs of points. There are some 50 pairs of points, many of which are identical to acupuncture points in location, if not in ascribed areas

of influence. Their location and corresponding organ, tissue, system, or symptom are clearly outlined and diagramed in Chaitow^[28] (pp. 163–172).

Bennett's neurovascular reflexes

This is a system which utilizes reflex areas, mainly on the abdomen and head.^{[14] [28]} It was developed by chiropractic practitioner, Terence Bennett, and involves identification of localized areas of dysfunction (points) which are contracted or indurated, and which display increased sensitivity. These are said to be related to vascular dysfunction. Therapy is via gentle skin distraction over the point, until a pulsation is noted under the palpating digit.^[56] Contact is made from a few seconds to several minutes in order to achieve this reflex effect. Many of the points are used purely diagnostically and others are used both diagnostically and therapeutically.

Cross-fertilization of systems

Systems such as applied kinesiology,^[57] touch for health,^[56] and sacro-occipital technique (SOT)^[58] have incorporated into their therapeutic and diagnostic methodology the use of many of the reflex points described by Chapman and Bennett.

Alarm and associated points

In acupuncture there exists a series of specialized points in the meridian system, which are found to become sensitive to pressure when the meridian or organ to which they are reflexively connected is distressed.^[59] The points which are sensitive to deep pressure are thought to be involved in excessive energy problems, and those noted on light pressure are related to deficiency problems. Many of the neurolymphatic and neurovascular reflexes described above are found to correlate with these two sets of points in location, and sometimes in ascribed effect (alarm points are found ventrally and associated points dorsally). Treatment of these is by needling as appropriate, or by pressure and by attention to the needs of the system correlated to the dysfunction noted.

Tsubo, G-Jo, judo revival, and other point systems related to Oriental medicine

A number of systems (e.g. Tsubo,^[60] G-Jo,^[61] and judo revival^[62]) with common roots in acupuncture employ reflex points in a variety of ways. Some utilize strong stimulation imparted via the thumbnail to produce rapid reflex effects, while others use more gentle pressures. One recently described method indicates a point on the upper lip (Du26) as an ideal locality for strong stimulation in attempting revival of unconscious children suffering grand or petit mal seizures.^[63] It was noted in some hundreds of cases thus treated that termination of the convulsion and full revival of consciousness were achieved in an average of less than 20 seconds. The only failures were in children who were not fully unconscious, for whom the vigorous stimulation was too painful.

Viscerosomatic reflexes

The osteopathic literature describes viscerosomatic reflexes as being localized, sensitive, palpable areas, often found in paraspinal tissues and associated with visceral dysfunction.^[64] Beal^[65] notes that rigidity is the most common soft tissue manifestation of such a reflex. Initial changes include vasomotor alterations such as increased skin temperature and subtle changes such as increased thickness of the skin, increased subcutaneous fluid, and increased muscular contraction. In chronic conditions, all of these become more evident. There are usually two or more adjacent spinal segments involved in any viscerosomatic reflex, encompassing, as a rule, the costotransverse junction. Areas which are most frequently involved include T1–T5 (associated with viscerosomatic reflexes from the cardiac structures), T5–T10 (esophagus, stomach, small intestine, liver, gall bladder, spleen, and pancreas), and T10–L2 (large bowel, appendix, kidney, ureter, testes, ovaries, adrenal medulla, urinary bladder, and

prostate). There is usually some lateralization, e.g. the liver reflex is found on the right.

For assessment, a springing technique is used in which the palpating hand is slid under the supine patient in order to push upwards on the paraspinal regions. Neuromuscular technique is also an excellent method of assessment of such structures.^{[11] [28]} Beal suggests that digital pressure may be used to affect local changes and to reflexively influence the involved organs (somaticovisceral reflex). Since this would have only a moderate effect on advanced organic disease, these reflexes are of more diagnostic than therapeutic value. Also, since they are manifested long before other evidence of organ distress is available, they are useful early warnings of developing dysfunction.^[65] Regular assessment of the paraspinal tissues, therefore, acts as a monitor of the internal function. This concept is well documented medically and is of potential value in monitoring the efficacy of any type of therapy, since the reflex condition will show improvement in tandem with the organ state.^{[66] [67]} The overlap between these reflexes and the points and zones described above should be borne in mind (see [Table 46.5](#)).

Hyperalgesic skin zones

Overlying all points and zones involved in reflex activity will be noted skin changes characterized by what may be termed hyperalgesia.

TABLE 46-5 -- Summary of ascribed roles of reflexes described in different systems, as found at the 8–10th thoracic inter-spinal and inter-transverse spaces

| System | Points/reflexes | Location | Relationship |
|-------------------------|--------------------|-------------------------------|--|
| Hua Tuo | | Paravertebral | Diseases of the abdomen and local and lumbar dysfunction |
| Neurolymphatic reflexes | Posterior reflexes | | |
| | Reflex #12 | 8/9/10 insterspaces | Small intestine dysfunction (anterior in 8/9/10 intercostal space) |
| | Reflex #33 | 10th costotransverse junction | Pyloric stenosis (anterior reflex is on the sternum) |
| | Reflex #42 | 9–10 or 10–11 intertransverse | Ovaries (anterior point is on the round ligaments from the superior border of the pubic bone inferiorly) |

| | | | |
|-------------------------|------------------------------|--|--|
| Associated points | Bilaterally bladder point 18 | 9th–10th interspace | Liver meridian |
| | Bilaterally bladder point 19 | 10th–11th interspace | Gall bladder meridian |
| Tender points | | | Extension strain at this level |
| Connective tissue zone | | Left side | Stomach zone |
| | | Right side | Liver zone |
| | | Central area | Kidney and part of the head zone |
| Trigger points | | Lower trapezius, multifidus, iliocostalis, and longissimus muscles | Wide distribution of target areas |
| Zone of irritation | | Costotransverse junction | Spondylogenic reflex syndromes involving tissues connected to C2–7, T1–6, L1–5, S1,3,4 |
| Viscerosomatic reflexes | | T5–T10 | Esophagus, stomach, small intestine, liver, gall bladder, spleen, pancreas |

There will be a reduced degree of elasticity noted, and this is diagnostic. Lewit^[1] maintains that the introduction of a mild degree of stretch into these hyperalgesic skin areas has a powerful reflex effect on underlying dysfunction (i.e. the trigger or tender point, or zone). Assessment is by gentle distraction of the skin in order to compare it with the surrounding skin and the skin in the same region on the contralateral side of the body. Mapping and confirmation of underlying reflex areas are possible by the use of pressure to ascertain sensitivity and possible referred symptoms. Treatment is by maintaining the degree of distraction in the skin zone (fingers pulling gently apart, or, for larger areas, lateral aspects of the hands doing the same) until a degree of release is noted, as the skin relaxes and is stretched to its normal range. This is all the treatment required to normalize the tissues and to introduce reflex changes into the underlying structures.

The maintenance of the restored elasticity depends upon whether the causative factors have also been dealt with, and the degree of activity in associated reflexes.

A number of other methods of normalization can be utilized, including skin rolling, as described in Western and Oriental massage texts.^{[11] [28] [68]} Chinese massage techniques include pinch–pull techniques which can be used to tonify or sedate the patient and which have marked similarities with German CTM methods. CTM, as described above, involves far more powerful skin stretching methods than either the pinch–pull techniques

or Lewit's distraction and stretch techniques.^[16]

Neuromuscular technique

The methods of neuromuscular technique involve the systematic combing of the tissues for the soft tissue changes described above.^{[11] [28] [69] [70]} Its economy of effort and combining of diagnostic and therapeutic procedures have made it popular among practitioners in Europe, where it evolved as a combination of methods derived from Ayurvedic massage,^[71] traditional massage, and an American "bloodless surgery" (not to be confused with the Philippine faith-healers' "bloodless surgery") method.^[72]

Typically, the thumb tip is used to exert variable pressure on all the accessible origins and insertions and muscle masses in order to identify changes, and, by variations in that pressure, simultaneously treat the recognized abnormalities. This approach is seen as part of an overall assessment rather than as an end in itself. Other methods of traditional massage from both East and West are combined with NMT to normalize those aspects of soft tissue dysfunction which are manifestations of stress, strain, and trauma and to address reflex changes where applicable.

THERAPY AS A STRESS FACTOR

Stress is any added load imposed by forces brought to bear on an individual, organ, or tissue. It may be chemical, toxic, psychic, emotional, or physical.^[73] Adaptation denotes the ways in which the organism adjusts itself

to intrinsic disturbances or challenges. These responses may be short- or long-term in nature, representing the body's homeostatic mechanisms at work.

Selye, in his classic experiments, noted specific and general responses in disease, observing that "stress can either cure or aggravate a disease, depending upon whether the inflammatory response to a local irritant is necessary or superfluous."^[74]

Speransky, in his landmark research in the 1940s, stated:^[75]

It is obvious from this research that the irritation of any point of the complex network of the nervous system can evoke changes not only in adjacent parts but also in remote regions of the organism.

He continues by observing: "There is a rule that only weak degrees of irritation can have useful significance, strong ones inevitably do damage."

Many therapeutic measures involve a degree of stress, whether this be an acupuncture needle, surgery, or intake of toxic substances – even in homeopathic dilutions;

applications of heat or cold, or electrotherapy; or, indeed in this consideration, manual pressures and efforts. Attaining the desired response, therefore, will depend upon the therapeutic effort not overwhelming the homeostatic potential of the organism.^[20] Therapy may be considered to consist largely of the application of graduated degrees of stress, to which the organism responds according to its unique attributes and potentials. Benefit or harm depends upon the degree of that stimulus and, most importantly, upon the vitality of the patient.

The implications for manual therapists are obvious and call for thoughtful application of the varieties of techniques available.

THE POTENTIAL OF SOFT TISSUE MANIPULATION

The professions within medicine which utilize manual therapy, such as physiotherapy, have tended to discard the tradition of “hands on” treatment in favor of a more technological approach, leaving the soft tissues to massage therapists and sports therapists. Osteopathy (as practiced in Europe where it is not a part of a general medical practice, as it is in the US, but rather a system which addresses structural and functional dysfunction via manipulative methods^{[9] [76]}) and chiropractic, which are conceived as being largely concerned with the joints and osseous component of the musculoskeletal system, have in recent years come to recognize the vast importance of the soft tissues in both diagnostic and therapeutic roles. The musculoskeletal system is both the greatest energy consumer of the body and its largest organ of sensory input. While this primary machinery of life has long been unappreciated, in therapeutic terms, the development of methods such as strain/counterstrain, muscle energy technique, and neuromuscular technique and the vast amount of information derived from acupuncture tradition and research, and other reflex systems ensure that the diagnostic and therapeutic potential of the soft tissues are now being recognized and utilized.

Korr,^[77] the premier osteopathic researcher of the past three decades, summarizes another vital implication of soft tissue dysfunction – interference with axonal transport mechanisms – thus:

Any factor that causes derangement of transport mechanism in the axon or that chronically alters the quality or quantity of the axonally transported substances could cause the trophic influences to become detrimental. This alteration in turn would produce aberrations of structure, function and metabolism, thereby contributing to dysfunction and disease. Almost certainly to be included among these harmful factors are the deformation of nerves and roots, such as compression, stretching, angulation and torsion that are known to occur all too commonly in the human being and that are likely to disturb the interaxonal transport mechanisms, intraneural microcirculation and the blood–nerve barrier. Neural structures are especially vulnerable in their passage over highly mobile joints, through bony canals, intervertebral foramina, fascial layers and tonically contracted muscles. Many of these biomechanically induced deformations are of course subject to manipulative amelioration and correction.

This survey has touched on some of the many ways in which soft tissue dysfunction may impinge upon the economy of the body as a whole. Soft tissue manipulation is an important diagnostic and treatment modality and should be considered an integral part of the practice of any physician or practitioner whose intent is to care for the whole person. (Those interested in studying this topic in more depth will find reference 28 very helpful. It thoroughly covers the topics surveyed here and provides useful tables, charts and diagrams and pictures of the various techniques as they are applied to a patient.)

Chapter 47 - Therapeutic fasting

Trevor K. Salloum ND

INTRODUCTION

Fasting is defined as abstinence from all food and drink except water for a specific period of time, usually for a therapeutic or religious purpose.^[1] This process spares essential tissue (e.g. vital organs) while utilizing non-essential tissue (e.g. adipose tissue, digestive enzymes, muscle contractile fibers, and glycolytic enzymes) for fuel.

Some medical references use the terms *fasting* and *starvation* interchangeably. Unlike fasting, starvation is a process in which the body uses essential tissue for fuel. During starvation, the body relies on protein as a major fuel source, as most fat stores have been depleted. If an organism does not receive food at the end of the maximum fasting period (several weeks to months depending on fat stores, metabolism, stress, and activity), starvation follows and death will ensue.^[2]

Although the term fasting is used loosely in medical literature, the strictest definition (water only) is the focus of this chapter. Some medical studies recommend supplementation with vitamins, fruit and vegetable juices, acaloric fluids (coffee, tea, etc.), and drugs while the patient is “fasting”. These practices have not been shown to produce any advantage, and serious problems have sometimes occurred, especially when non-essential medication was permitted. (In special cases it may be necessary to maintain the patient on essential medication while fasting, e.g. thyroid, prednisone, and insulin.)

Although therapeutic fasting is probably one of the oldest known therapies, it has been the object of only limited study by the scientific community. The most recent development in the study and promotion of fasting has been the formation of the International Association of Hygienic Physicians (IAHP).^[3] This organization comprises doctors specializing in therapeutic fasting as an integral part of total health care. The section on clinical protocol below reflects the format practiced by the IAHP. Any doctor contemplating the use of therapeutic fasting should receive adequate training. The

IAHP provides guidelines for doctors interested in this training.^[3]

Another recent development has been the work of clinical ecologists who use short-term fasting as part of their diagnosis and treatment of food intolerance.^{[4] [5]}

HISTORY

Throughout history, people of various cultures and religions have recognized the value of fasting. Numerous references occur in the Bible, Koran, pagan writings, and writings of the ancient Greeks.^{[6] [7] [8]}

One of the earliest doctors to use therapeutic fasting in the United States was Isaac Jennings MD (1788–1874). In 1822, Jennings discarded the use of drugs and, through the influence of a Presbyterian preacher, Sylvester Graham (1794–1851), began advocating fasting and other aspects of hygienic treatment (vegetarian diet, pure water, sunshine, clean air, exercise, emotional poise, and rest). This later came to be known as the Natural Hygiene or Hygienic system.^{[9] [10] [11]}

Other doctors who followed in the hygienic tradition included: James C. Jackson (1811–1895), Russell T. Trall (1812–1877), William A. Alcott (1798–1859), Mary Grove Nichols (1810–1884), Thomas L. Nichols (1815–1901), Edward H. Dewey (1837–1904), George H. Taylor (1821–1896), Harriet Austin (1826–1891), Charles E. Page (1840–1925), Emmett Densmore (1837–1911), Helen Densmore (?–1904), Susanna W. Dodds (1830–1915), Felix Oswald (1845–1906), Robert Walter (1841–1921), John H. Tilden (1851–1940), and George S. Weger (1874–1935). Most of these physicians graduated as MDs from eclectic medical schools, and they published various works on hygiene.^{[9] [10] [11] [12] [13] [14] [15] [16]}

Herbert M. Shelton

The hygienic lineage continued into the mid-1900s, mainly due to Herbert M. Shelton (1895–1985), who developed a stricter protocol for fasting (water only; no enemas, exercise, or treatments; and complete rest) and other aspects of hygiene. Shelton began his study of fasting in 1911 by reading the popular writers of his day: Sinclair, Carrington, Hazzard, Haskell, Purinton, Tilden, and MacFadden. He studied under the fasting authorities of his time at MacFadden's College (Chicago, IL), Crane's Sanatorium (Elmhurst, IL), and Crandall's Health School (York, PA).^{[9] [10]} (Among the earliest fasting institutions of this time were MacFadden's Healthatorium, Tilden's Health School, Lindlahr's Nature Cure Sanatoriums, and Lust's Jungborn – operated by Benedict Lust, the founder of naturopathy in the United States.^[10]) In 1924, he completed doctorates from the American School of Chiropractic and the American School of Naturopathy in New York.

Shelton was a dynamic lecturer, prolific writer, and publisher. He founded (in 1928) a fasting institution and health school which provided services for over 40 years.^[9] In 1949, along with William Esser ND DC, Christopher Gian-Cursio ND DC, and Gerald Benesh ND DC, he formed the American Natural Hygiene Society,^[9] ^[16] a lay organization dedicated to preserving the tenets of hygiene. In 1978, a professional branch was formed, the aforementioned International Association of Hygienic Physicians.^[3] Today, the IAHP organizes annual meetings, a journal, research and certification for doctors specializing in therapeutic fasting.

CLINICAL RESEARCH

Research into fasting has been reported since 1880. Since then, medical journals have carried articles on the use of fasting in the treatment of:

- diabetes
- mental disease
- skin disease
- obesity
- cardiovascular disease
- gastrointestinal disease
- chemical poisoning
- arthritis
- allergies.

The earliest research was primarily observational; physiologic and metabolic changes were recorded while an individual fasted. These included: Tanner, 40 days (1880);^[17] Jacques, 30 days (1887) and 40 days (1888);^[18] Penny, 30 days (1905);^[19] and Levanzin, 31 days (1912).^[20] The earliest record of therapeutic fasting in the medical literature occurred in 1910.

Further investigation into the physiologic changes that accompany fasting was conducted in 1923 at the University of Nebraska by Morgulis. This classic study, *Fasting and undernutrition*, provides an in-depth analysis of animal and human reactions during fasting.^[21]

In 1950, Ancel Keys and colleagues at the University of Minnesota compiled two volumes entitled *The biology of human starvation*. Thirty-two volunteers fasted for up to 8 months while detailed observations were made. These findings were compared with food deprivation observations which were made during the Second World War. Through their studies, the researchers found that fasting did not cause vitamin or mineral deficiencies and that diabetes and skin diseases improved.^[22]

Diabetes

Guelpa recorded the benefits of fasting in diabetes and gout, as well as in inflammation and surgery.^[23] The treatment of diabetes with fasting was further explored by Allen in

1915. He noted that rest and fasting usually stopped glycosuria, and he also observed improvements in gangrene and carbuncles.^[24]

Epilepsy

The treatment of seizures through fasting was begun in the early 1900s in France by Guelpa & Marie (cited by Kernt).^[25] In 1924, Hoeffel & Moriarty described fasting's beneficial effects in epilepsy.^[26] In 1928, Lennox, concurring with other researchers, found that the induction of ketosis via fasting decreased the length, severity, and number of seizures.^[27]

Obesity

Fasting for obesity has probably received more attention in the scientific literature than any other aspect. The earliest studies were conducted by Folin & Denis^[28] who, in 1915, advocated short fasts as a safe and effective means to lose weight. Bloom,^[29] Duncan,^[30] ^[31] Drenick,^[32] ^[33] and Thompson^[34] have published numerous works on the use of short and long fasts in obesity. Perhaps the most famous study on obesity appeared in the *Postgraduate Medical Journal* of 1973, which reported the experience of a 27-year-old male who fasted without complications for 382 days and lost 276 pounds.^[35]

In general, weight loss during fasting is initially approximately 0.3% of body weight per day, with a gradual decrease to 0.10%/day after 30 days. The initial weight loss is primarily water and salt. For every pound lost, the body loses approximately 140 g of protein and 250 g of fat.^[36]

Although fasting is very effective for weight reduction, fasting alone, without counseling and other lifestyle modifications, does not insure long-term maintenance of the lower weight level. This is well documented in a study of 121 obese patients who were followed for 7.3 years after fasts which had averaged two months. After 2–3 years, 50% had reverted to their pre-fast weight, and by the end of the study 90% had reverted.^[102]

Heart disease

Studies of the effects of fasting on patients with heart disease began in the early 1960s. Duncan noted improvements in hypertension and chronic cardiac disease.^[28] Others have also found fasting to be beneficial in heart disease, including Gresham,^[33] Lawlor,^[34] Suzuki,^[35] Vessby,^[36] and Sorbris.^[37] Improvements noted include reduced triglycerides, blood pressure, atheromas, and total cholesterol; increased HDL/cholesterol ratio; and alleviation of congestive heart failure.^[28] ^[33] ^[34] ^[35] ^[36] ^[37]

Pancreatitis

In a random trial, in 1984, of 88 patients with acute pancreatitis, fasting was determined to be the treatment of choice. It was suggested that “fasting alone be initially used as the simpler and more economical therapy”. The finding was that “neither nasogastric suction nor cimetidine offer any advantage over fasting alone in the treatment of mild to moderate acute pancreatitis of any etiology.”^[38]

PCB and DDT contamination

A most encouraging use of fasting was published in the *American Journal of Industrial Medicine* in 1984. This study involved patients who had ingested rice oil contaminated with PCBs. All patients reported improvement in symptoms, and some observed “dramatic” relief, after undergoing 7–10 day fasts.^[43] This research supports past studies conducted by Inamura of PCB-poisoned patients and indicates the therapeutic effects of fasting. Caution must be used, however, when treating patients known to suffer significant contamination with fat-soluble toxins. DDT is mobilized during a fast and may reach blood levels toxic to the nervous system.^[44]

Autoimmune disease

The beneficial effect of fasting in certain autoimmune diseases was reported in *Lancet* in 1958. The researchers found that fasting shortened the early stages of acute glomerulonephritis (reduced glomerular filtration rate, high blood pressure, and edema), thus improving the prognosis. They concluded that “all patients with acute glomerulonephritis should fast”.^[45] Other autoimmune diseases that have responded to fasting include rosacea, lupus, and chronic urticaria.^{[46] [47]}

Arthritis

The subject of arthritis and fasting is receiving greater attention in the scientific literature, with most of the research coming from Scandinavia. Scientists have documented the anti-inflammatory effects of fasting with observations of decreased ESR, arthralgia, pain, stiffness, and need for medication.^{[48] [49] [50] [51] [52] [53] [54] [55]} A 1984 US study of 43 patients with definite or classical rheumatoid arthritis found significant improvement in grip strength, pain, PIP swelling, ESR, and functional activity after a fast of 7 days.^[52]

A strong link between arthritis and food intolerance has been revealed through fasting (see also [Ch. 51](#)). The decrease in symptoms of rheumatoid arthritis during fasting may be due to the decrease in gut permeability which accompanies fasting.^[51] This would reduce the absorption of antigenic molecules into the blood from the gastrointestinal tract. In the 1984 *Bulletin on Rheumatic Diseases*, Panush proposes two theories:^[56]

- nutritional modification might alter immune responsiveness and thereby affect manifestations of rheumatic diseases

- rheumatic disease may be a manifestation of a food allergy or hypersensitivity.
-

Food allergy

Fasting, in conjunction with food challenging, is now being used as a diagnostic test to determine food intolerances. Patients are fasted for a minimum of 4 days, and then individual foods are given to determine if a reaction occurs. This method correlates well with skin prick and RAST testing. A letter in the 1984 *Lancet* states: ^[57]

When food avoidances prevent headaches, IBS, arthralgia and depression, it is more effective and less costly than traditional treatment and the observation also throws light on the etiology of the disorder.

Other diseases

Other diseases in which the scientific literature indicates that fasting has led to improvement include:

- psychosomatic diseases ^[39]
- neurogenic bladder^[39]
- psoriasis ^[22] ^[30] ^[31]
- eczema ^[22] ^[48]
- thrombophlebitis ^[38]
- varicose ulcers^[58]
- neurocirculatory disease^[39]
- IBS^[39]
- dysorexia nervosa (impaired or deranged appetite)^[39]
- bronchial asthma^[39]
- lumbago^[39]
- depression ^[39]
- neurosis and schizophrenia ^[59]
- parasites^[60]
- duodenal ulcers^[61]
- uterine fibroids. ^[46]

These diseases are not a complete list of indications for fasting, but rather are those that have been studied in the scientific literature. There has been considerable empirical study of fasting in the treatment of a wide variety of diseases. Records of the results can be found in lay, hygienic, and medical literature published since the early 1900s. ^[62] ^[63] ^[64] ^[65] ^[66] ^[67] ^[68] ^[69] ^[70] The vast potential of therapeutic fasting is only beginning to be realized, as recent research reveals such pervasive and important effects as enhancement of immune system function. ^[53] ^[71] ^[72] ^[73] ^[74] ^[75]

PHYSIOLOGY

The study of the physiology of fasting reveals a highly ordered series of events (see [Fig. 47.1](#)) which conserve body energy reserves while maintaining the basal metabolic rate (the BMR decreases by about 1%/day during fasting, until it stabilizes at about 75% of normal^[36]). It has been suggested that humans, like other species, have evolved special biochemical pathways to subsist for long periods of time without food.^[76] During periods of food scarcity due to climate, injury, illness, etc., animals require adaptive mechanisms to survive. It is now apparent that, in addition to maintaining the BMR, fasting also enhances the healing process.

Research in the early 1990s using MRS indicated that gluconeogenesis may be responsible for 64% and hepatic glycogenolysis for 36% of fuel requirements in the first 22 hours of fasting. This is a radical departure from biochemistry of the past which suggested that hepatic glycogenolysis represented 65% of fuel requirements in the first 22 hours of fasting. Scientists agree that this preliminary research necessitates further studies before any strong conclusions can be reached.^{[77] [78] [79]}

The body's response to the lack of energy input can be divided into three stages: early fasting, fasting, and starvation. Maintaining adequate energy resources for metabolism during fasting involves several adaptations, which change as the body moves from one stage to the next. The following discussion, [Tables 47.1](#), [47.2](#), [47.3](#), [47.4](#), and

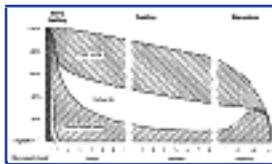

Figure 47-1 Energy reserve utilization during fasting.

TABLE 47-1 -- Mobilizable fuel reserves in a 70 kg man^[80]

| Tissue (weight, kg) | Glucose/glycogen | | Protein | | Triglyceride | |
|---------------------|------------------|-------|---------|--------|--------------|-------|
| | g | kcal | g | kcal | g | kcal |
| Blood (10) | 15 | 60 | 100 | 400 | 5 | 45 |
| Liver (1) | 100 | 400 | 100 | 400 | 50 | 450 |
| Intestines (1) | 0 | 0 | 100 | 400 | 0 | 0 |
| Brain (1.4) | 2 | 8 | 40 | 160 | 0 | 0 |
| Muscle (30) | 300 | 1,200 | 4,000 | 16,000 | 600 | 5,400 |

| | | | | | | |
|-----------------------|-----|-------|-------|--------|--------|---------|
| Adipose (15) | 20 | 80 | 300 | 1,200 | 12,000 | 108,000 |
| Skin, lung spleen (4) | 13 | 52 | 240 | 960 | 40 | 360 |
| Total | 450 | 1,800 | 4,880 | 19,520 | 12,695 | 114,255 |

TABLE 47-2 -- Energy reserve utilization^{[36] [81] [82] [83]}

| Energy source | Reserve* |
|---------------|--|
| Glucose | 1 hour |
| Digestion | 4–8 hours |
| Glycogen | 12 hours |
| Amino acids | 48 hours |
| Protein | 3 weeks (if protein were the only fuel used for gluconeogenesis) |
| | 24 weeks (obligatory loss only) |
| Triglycerides | 8 weeks |

* These estimates are based on 100% utilization of each fuel.

TABLE 47-3 -- Daily resource utilization of an average 70 kg man during fasting^[36]

| Resource | Early (g) | Late (g) |
|-----------|-----------|-----------|
| Protein | 60–84 | 18–24 |
| Fat | 100–140* | 160–200* |
| Glucose | 100–180 | 80 |
| Sodium | 3.5–5.8 | 0.02–0.35 |
| Potassium | 1.6–1.8 | 0.4–0.6 |

* These values are much higher in obese individuals.

TABLE 47-4 -- Summary of metabolic events in early versus late stages of fasting

| | Early | Late |
|----------------|-------------------------------|--|
| Brain | Uses glucose for fuel | Adapts to using ketones and some glucose |
| Liver glycogen | Breaks down to supply glucose | Slowly regenerates |

| | | |
|----------------|--|---|
| Amino acids | High demand for making glucose | Significantly reduced demand for making glucose |
| Glycerol | High demand for making glucose | Significantly reduced demand for making glucose |
| Fatty acids | Supply energy directly for most tissues | Major source of energy for most tissues, including ketones for brain |
| Metabolic rate | Slight reduction | Significant reduction |
| Net effect | High use of protein to supply glucose to the brain | Less need for glucose, conservation of protein, utilization of fat reserved |

Figures 47.1 and 47.2 describe these stages and their metabolic significance. First, however, a summary of energy production and utilization is useful.

Energy production and utilization

Glucose, fatty acids, and L-amino acids are the major fuels of the body. Although a complete description of their metabolism is beyond the scope of this chapter (a good resource is *Biochemistry: a case-oriented approach* ^[82]), their use for energy production can be simplified as follows:

1. Fatty acid catabolism occurs in the mitochondria of virtually all tissues except the brain and red blood cells. In the energy-producing process of beta-oxidation, two-carbon fragments are successively removed from

406

the fatty acid to form acetyl CoA and ATP. The acetyl CoA enters the Krebs cycle for conversion to more ATP.

2. Energy production from glucose metabolism is primarily through the formation of pyruvate (glycolysis), which is converted to acetyl CoA for entry into the Krebs cycle.
3. When used for energy production, the L-amino acids are, in general, converted to pyruvate, alpha-ketoglutarate, and oxaloacetate, again for entry into the Krebs cycle.

Figure 47-2 Mechanisms of glucose production during fasting.

The major form of utilizable energy in all cells is ATP, which is produced by oxidative catabolism of D-glucose, alpha-ketones, fatty acids, and/or L-amino acids.

The energy for resting heart and skeletal muscle is met primarily by oxidation of acetoacetate (produced by the liver from acetyl CoA) and fatty acids, and secondarily by glucose oxidation. Muscle contraction requires a continuous supply of ATP, large amounts of which may be almost instantaneously produced by massive conversion of glycogen to lactate (the primary purpose of muscle glycogen). During extreme muscle activity, other short-term energy sources, such as phosphocreatine, are also used. Neither of these is utilized, however, to maintain energy levels during fasting. Exercise also greatly increases glucose utilization by heart and skeletal muscle, which, as discussed below, is probably why resting is important in fasting, since the major source of glucose during fasting is protein catabolism.

Under the fed condition, the energy requirement of the mature brain is met almost entirely by glucose. Since the glycogen content of the brain is very low (0.1%), there is essentially no brain-glucose reserve. After a few days of fasting, the brain switches to oxidation of beta-hydroxybutyrate (produced by the liver from acetyl CoA) as its primary energy source.

Early fasting

The initial physiological response to the lack of food is the increased synthesis of the glucose by the liver for release into the bloodstream. Glucose is especially needed by the brain, which consumes about 65% of the total circulating glucose (400–600 kcal/day), and the red blood cells.^[36] ^[84] Together they consume 100–180 g of glucose per day. Early on in fasting, the liver is the sole source of glucose for the bloodstream. The liver initially synthesizes glucose from glycogen through glycogenolysis. However, liver glycogen stores can only supply enough glucose for a few hours (see [Tables 47.1](#) and [47.2](#)), and glucose production from gluconeogenesis soon becomes necessary. Although muscle actually contains more glycogen than liver, it lacks the enzyme D-glucose-6-phosphatase and therefore cannot convert glycogen to glucose for release into the bloodstream.^[85] Later in fasting, the glycogen reserves are restored.^[86]

Gluconeogenesis utilizes primarily L-amino acids for glucose synthesis, although glycerol from triglyceride catabolism is also used. Since liver glycogenic amino acid stores are quickly depleted, substrate from other tissues, primarily the muscles, is required. As the fast proceeds, the kidneys become progressively more important in the maintenance of blood glucose levels, and eventually the renal cortex synthesizes more glucose from amino acids than does the liver.^[76] If the body continued to require its normal 100–180 g/day of glucose, gluconeogenesis during fasting would quickly use up much body protein, and death would ensue within 3–4 weeks.^[81] Early on in fasting, the body catabolizes 60–84 g/day of protein.

Initially, sodium, potassium, and water diuresis occurs and hypovolemia develops. Calcium and magnesium are also lost. Plasma ketones rise, and ketones appear in the urine by the third day.^[36]

Fasting

Research using respiratory quotient and urinary nitrogen studies has repeatedly shown that triglycerides are the major fuel during fasting.^{[2] [20] [85] [87] [88] [89]} To leave the adipocyte, triglycerides must first be hydrolyzed (lypolsis) to fatty acids and glycerol. The fatty acids are transported in the blood, in a physical complex with albumin, to the liver, muscle, and other tissues.

Although the brain converts to oxidation of beta-hydroxybutyrate after 4–7 days, there is still an obligatory need for approximately 80 g/day of glucose for the brain, red cells, muscles, and other tissues.^[85] This requirement increases significantly during exercise. Although much of the lactate produced by anaerobic metabolism of glucose and glycogen is resynthesized to glucose by the liver via the Cori cycle, the need for glucose is increased, since there is a net loss due to urinary excretion of lactic acid and metabolic inefficiency. Approximately 16 g of glucose is synthesized from triglyceride glycerol, with the rest of the glucose requirement (and the other metabolic processes requiring amino acids, e.g. enzyme turnover) being met by the catabolism of 18–24 g/day of protein. In experimental animals, as much as 14% of the energy needed by muscle may come from the oxidation of branched-chain amino acids. Glucose is also recycled by the breakdown of blood cells in the liver.^{[85] [87] [88]} The mechanisms of glucose production during fasting are summarized in [Figure 47.2](#) .

Research has determined that an average 70 kg male has the fat stores to maintain basic caloric requirements for 2–3 months of fasting.^{[2] [20] [85] [87] [88]}

Starvation

Starvation occurs when the body's fat reserves are depleted and significant protein catabolism again becomes necessary for energy production.^[2] As noted above, unless fat reserves are being utilized for energy production and glucose sparing, the body protein stores are adequate

for only a few weeks of gluconeogenesis, after which essential proteins are utilized and death occurs.

Mechanism of ketosis

During fasting, when excessive amounts of fatty acids are being oxidized and inadequate glucose is available, large quantities of ketones are secreted into the bloodstream. Ketone bodies are made in the liver from acetyl CoA.

During adequate energy input, the conversion of fatty acids to acetyl CoA is regulated

by the availability of L-glycerol 3-phosphate (derived from glucose through the glycolytic pathway). As the concentration of acetyl CoA rises, it is resynthesized into triglycerides, with L-glycerol 3-phosphate serving as the acceptor to which three acyl CoA groups are attached (through esterification). During fasting, there is inadequate glucose to provide the needed glycerol for triglyceride synthesis, resulting in acetyl CoA levels in excess of the oxidative capacity of the Krebs cycle. The excess is then shunted into the synthesis of ketone bodies.^[82] These ketone bodies (acetoacetic acid, acetone, and beta-hydroxybutyric acid) are utilized by the heart, and, later in fasting, by the brain for energy production.

Mechanism of acidosis

Since the ketone bodies are acids, their entry into the plasma results in an increase in hydrogen ions. This is buffered by the conversion of bicarbonate into carbonic acid and then to CO₂, which is exhaled. Eventually the buffering capacity is exceeded, and the plasma pH decreases, resulting in mild metabolic acidosis. The body compensates for this by increasing the respiratory rate to promote further elimination of CO₂ and by excreting ketone bodies in the urine. These adaptations may result in some electrolyte imbalance.^[82]

Amino acid metabolism

With the exception of leucine, which appears to be a regulator of protein turnover in muscle,^[90] all amino acids are glucogenic. However, alanine plays a prominent role in a cycle analogous to the Cori cycle for lactate.^[91] ^[92] The alanine cycle provides the mechanism for the recycling of a fixed supply of glucose and the effective transportation to the liver of amino acid nitrogen derived from muscle breakdown. Because muscle, unlike liver, is incapable of synthesizing urea, most of the amino nitrogen from protein breakdown is transferred to pyruvate to form alanine. The alanine enters the blood and is taken up by the liver. The amino groups are removed to form urea, and the resulting pyruvate is converted to glucose. The newly synthesized glucose is secreted into the blood, taken up by the muscle, and catabolized to pyruvate to reseed the alanine cycle.^[82]

Electrolyte balance

Serum electrolyte levels usually do not change significantly during fasting and are not good indicators of tissue stores but are considered the most important blood values during fasting.^[93] During early fasting the body loses 150–250 mEq (3.5–5.8 g) of sodium and 40–45 mEq (1.6–1.8 g) of potassium a day. Later, these drop to 1–15 mEq (0.02–0.35 g) and 10–15 mEq (0.4–0.6 g), respectively. The total body stores of sodium are 83–97 g (of which 65% is exchangeable) and of potassium are 115–131 g (of which 98% is exchangeable). The typical daily dietary intake of sodium is 3–7 g and of potassium is 3–5 g.^[83] Serum potassium usually decreases but may be elevated. Results below 3 mEq/L or above 6 mEq/L may necessitate breaking the fast. Total calcium is usually stable, but ionic calcium often decreases, especially if vomiting is

present.^[93]

Physical changes during fasting

Physical changes during the fast generally include a decrease in weight, pulse,^{[20] [22] [95]} and blood pressure.^{[20] [21] [22] [96]} EKG changes may include sinus bradycardia, decreased QRS complex and T-wave amplitude, elongation of the QT interval, and shifts to the right of the QRS and T-wave axes. These changes return to normal after fasting.^{[22] [94] [95] [96]}

Laboratory changes during fasting

Most laboratory values of the body fluids during fasting do not follow specific patterns, but are unique to the individual and the disease process.^{[34] [94]} Assessment of a fasting patient's progress is not based on a sign or symptom, but on the total clinical picture. Although specific predictions of laboratory values during fasting are not possible, some general observations have been made. Some authorities indicate that triglycerides decline with fasting but find elevations if liver damage is present. Serum protein usually declines with fasting. Pancreatic lipase and amylase usually decline with fasting.^[93]

Liver enzymes may increase considerably if liver disease is present and may rise even when liver disease is not present. Triglyceride, cholesterol, and uric acid levels usually rise during fasting,^{[97] [98] [99]} indicating mobilization of tissue stores. Post-fast values often show a decrease from pre-fast values.^{[26] [40] [98]} A rise in BUN may occur, but some authors have observed a decrease.^{[22] [27] [38] [100]} Creatinine levels may be elevated^{[45] [97]} or may remain stable.^[101]

Blood glucose drops in most patients,^{[24] [26] [27] [48]} possibly below 30 mg/dl.^[97] If blood glucose is low prior to fasting, it may rise post-fasting.

Complete blood counts usually show no significant change,^[102] but decreases in hemoglobin and hematocrit have been observed.^{[38] [99] [103]} When this occurs, hemolysis

or hemorrhage must be ruled out.^[93] Hematocrit, hemoglobin, and RBC count may be increased, but this usually indicates inadequate hydration.^{[75] [97] [102]} Erythrocyte sedimentation rate usually decreases with fasting.^{[52] [53] [97]} White blood cells are usually unchanged or decrease slightly with fasting; however, infection may cause an increase. An increase may also be observed if levels are low prior to fasting.^[93]

Urinalyses may be difficult to interpret during fasting, since the body discards considerable waste via the kidneys.^[102] It is not uncommon to see various types of casts, RBCs, WBCs, bilirubin (+1 to +2), protein (trace, +2), and ketones (+4), and, if liver disease is present, urobilinogen elevation. Specific gravity is commonly elevated

(possibly to 1.035), which may reflect inadequate hydration.^[97]

Hormonal changes during fasting

Hormonal changes during fasting typically include decreases of insulin^{[76] [87] [89] [94] [104]} and thyroid hormones.^{[94] [95] [105]} Increased levels of growth hormone,^{[94] [95] [105]} cortisol,^[75] glucagon,^{[76] [87]} plasma norepinephrine,^[106] serum melatonin,^[106] and certain prostaglandins (in animals) usually occur.^[107] By contrast, a decrease in growth hormone is usually found in obese individuals.^[94]

In one study conducted on 10 postmenopausal women who underwent short-term fasts, no significant changes in adrenal hormones, androgens, serum and urinary estrogens, plasma epinephrine, or dopamine were recorded.^[106]

Effects of fasting on immune function

The immune system undergoes very important changes during the fast, and an increase in various aspects of immune function has been observed. The first evidence of this came from the study in 1923 which found increased resistance to infection during the post-fast period.^[21] Changes in the immune system during fasting include:^{[53] [71] [72] [73] [74] [75]}

- increased macrophage activity
- increased cell-mediated immunity (T-lymphocytes and lymphokines)
- decreased complement factors
- decreased antigen–antibody complexes
- increased immunoglobulin levels
- increased neutrophil bactericidal activity
- depressed lymphocyte blastogenesis
- heightened monocyte killing and bactericidal function
- enhanced natural killer cell activity in animals and humans.

CLINICAL PROTOCOL

Therapeutic fasting of more than 5 days' duration is probably best conducted under supervision at an in-patient facility. Several facilities now exist in the US, Canada, England, and Australia, and these centers follow the standards of care and principles of ethics established by the IAHP.^[3]

Consultation standards

- Appropriate case history
- Physical examination
- Evaluation or assessment of the chief complaints
- Explanation and recommendations.

Clinical standards

- Provide an environment conducive to rest and comfort
- Maintain a daily record of progress, including appropriate vital signs
- Supply adequate amounts of water
- Assure the availability of attendants
- Exercise care in terminating a fast and supervising post-fast recuperation, consistent with professional hygienic principles.

Water vs. juice

Only pure water (distilled, spring, reverse osmosis) is recommended while fasting.^[65] ^[69] Some authors have recommended juice, but this is considered a restricted diet, not a fast, since juice is a food, and the continued consumption of carbohydrates inhibits the body's conversion to ketotic metabolism. In most cases, the fast is superior to the restricted diet: hunger almost totally disappears;^[22] ^[30] ketosis occurs more quickly and efficiently;^[22] ^[30] famine edema does not occur;^[22] sodium diuresis is more pronounced;^[29] weight loss is more dramatic and is from fat rather than protein stores; healing time is shorter; and patient strength may be greater.^[69] It is interesting to note that people in developing world countries on protein-deficient diets die sooner than those who fast completely.^[76] Restricted diets, however, are often useful before and after fasting, and if a crisis develops or a fast is contraindicated.^[68]

Quantity of water

The optimal quantity of water to ingest during fasting is best determined by thirst, but patients should drink at least a few glasses a day. During fasting the need for water decreases, since obligatory water excretion is reduced (due to lower excretion of urea, the major osmotic solute) and water is released from catabolized fat.^[76] One cup of water each day is actually sufficient to maintain adequate hydration for most people,^[76] although researchers fasting obese individuals often recommend 3 L/day.^[36]

Supplements

Loss of minerals or vitamins is usually not a concern, and deficiencies while fasting are rare.^[22] ^[29] ^[65] ^[69] ^[108] ^[109] In fact, problems, such as nausea and indigestion, have been reported when these were supplemented during the fast.^[32] ^[101] For example, it is well known that nicotinic acid supplementation inhibits the release of free fatty acids from adipose tissue.^[36] In one patient in whom vitamin deficiency was reported in the medical literature, the actual fasting protocol was not described. In addition, activity was not restricted and oral medication for inter-current illness was maintained while fasting.^[32]

Vitamin and mineral excretion becomes very low after 10 days.

Exercise

Exercise is discouraged while fasting. Fuel conservation is necessary to allow maximal healign and the avoidance of unnecessary gluconeogenesis.^[65] ^[69] The body utilizes certain muscle proteins early in a fast, thus initiating the natural restriction of activity. Short walks or light stretching is permissible, but intense exercise will inhibit repair and elimination. In serious chronic disease, an excess of activity has been suspected as cause of death during fasting.^[110]

Sunlight

Sunlight is important for general health during fasting, and patients should try to obtain 10–20 minutes/day. An increase in heart rate of 10–15 beats/minute would indicate excessive exposure. Many fasting facilities have solariums in which patients may sunbathe.

Rest

Rest is a most important aspect of the fast, and patients may nap throughout the day. Less sleep is common at night, due possibly to the decreased daily activity and increase in daytime rest.

Laboratory tests

Laboratory tests such as a CBC and chem-screen are usually performed weekly, while others are performed as necessary. Daily urine tests are sometimes performed, and vital signs are checked daily.^[97] ^[102]

Enemas

Enemas are not usually necessary and may not offer any added benefit.^[49] Some authorities have found that they cause discomfort for the patients.^[69] To help prevent constipation, a pre-fast meal of fresh fruit or vegetables will assist in elimination.

Length of fast

The length of a fast is difficult to predict. Factors to consider include size of reserves (see [Tables 47.3](#) and [47.4](#)), individual metabolism, financial limitations, work schedules, degree of disease, age, and sex. This decision is based on all factors, especially the patient's mental state. "The doctor will look for good practical recovery where patient is symptom free and signs of regeneration are present."^[111] Although many old texts refer to fasting to completion (i.e. exhaustion of nutrient reserves), this is now uncommon and not usually necessary.^[111] Shelton states:^[69]

In most cases, except TB, there can be no sound objection to a fast to completion, although this will seldom be necessary and many patients will not want to fast so long, unless they must.

A positive mental outlook is important for any patient undergoing a fast. It should be emphasized that the benefits are broad and affect all bodily systems. Perhaps the greatest value for patients is the satisfaction of playing a major role in improvement of their own health.

SIDE-EFFECTS

Side-effects from fasting are rarely serious, but fasting may uncover pathology and reveal weaknesses that were previously subclinical.^[30] Discomfort during fasting may be due to withdrawal from stimulants, hypoglycemia, acidosis, elimination of wastes, and enhancement of repair. Patients may experience headaches, insomnia, skin irritations, dizziness, nausea, coated tongue, body odor, aching limbs, palpitations, mucous discharge, and visual and hearing disturbances. Hair growth is usually arrested, and dry, scaly skin may develop. Most signs and symptoms are usually brief as the body works to remove the disease.^[112]

In certain cases, complications occur which may necessitate breaking the fast early. Examples of such conditions include:

- a sudden drop in blood pressure (possibly due to peripheral circulatory collapse)
- delirium
- prolonged hypothermia
- rapid/slow/feeble/irregular pulse
- extreme weakness
- dyspnea
- vomiting and diarrhea leading to dehydration
- gastrointestinal bleeding
- hepatic decompensation
- renal insufficiency
- severe gout
- cardiac arrhythmias
- emotional distress.

Fasting elevates serum uric acid levels and uric acid

excretion, and if fluid intake is insufficient, gout or renal stones may be precipitated.^[36]
^[113]

A few studies have discussed the development of Wernicke's encephalopathy during

prolonged fasting, but since this rarely occurs during hygienic fasting, it is difficult to determine whether this is related to methodology. It is important, however, to acknowledge the importance of utilizing B vitamins, especially thiamine, when any fast is broken with i.v. glucose.^[114] ^[115]

The decision to terminate the fast should be based on the complete clinical picture and not on an isolated sign or symptom.

CONTRAINDICATIONS

Contraindications to fasting are few, and each case must be judged individually, since no two cases are alike. For example, an inexperienced practitioner may assume that emaciated patients should not fast, while Shelton states:^[69]

Extreme emaciation: In such cases a long fast is impossible. A short fast of 1–3 days may be found beneficial, or a series of such short fasts with longer periods of proper feeding intervening may be found advisable.

Contraindications include severe anemia, porphyria, and serious malnutrition. Individuals with a rare fatty acid deficiency of the enzyme medium-chain acyl-CoA dehydrogenase (MCAD) should also avoid fasting.^[46]

The fasting of children and pregnant women is controversial. While a short fast is appropriate for the sick child who does not want to eat, fasting a pregnant women may be seriously contraindicated: ketosis in pregnant diabetic women is known to cause fetal damage. Although this is commonly recognized, the fact that this information has come only from research of diabetic women is not as widely known. There appear to be no studies of the effects of non-diabetic ketosis on fetal development. Doctors (e.g. Shelton, Benesh, Sidwha, and Burton) with considerable experience of fasting pregnant women (during all three trimesters) have found no adverse effects with fasts of a few days to 2–3 weeks. Although the fasting of pregnant women appears, according to clinical observation, to be safe, definitive pronouncement cannot be made until careful research is performed (such as a controlled retrospective analysis of existing cases).^[116]

Fasts for children and pregnant women should be shorter and meticulously supervised by an experienced doctor. In *The science and fine art of fasting*, Shelton states: “Few infants require more than 2–3 days of fasting ... I have never hesitated to permit a sick infant to fast and I have yet to see one harmed by it.”^[69]

Regarding pregnancy he states: “The author would object to a long fast in chronic ‘disease’ during this period. There can, however, be no objection to a short fast ... ”

It is well recognized that fasting during lactation is not generally advised, since milk flow is halted and difficult to resume.^[69] Although fasting is considered inappropriate in renal insufficiency,^[36] the authors have seen patients with 65% renal function return to normal as a result of fasting and dietary management.

With regard to fasting contraindications in general, Burton stated:^[111]

I have found few health problems which are absolute contraindications to fasting. In my experience, if the need is evident, the only genuine contraindication is fear. ... As for the other conditions often mentioned, e.g. kidney disease, heart impairment, TB, etc., they merely require extreme caution, because of the limits imposed by pathology, but they are not inexorable contraindications.

Supervised fasting as a therapeutic procedure is generally safe and effective. The incidence of death at fasting institutions is low, which is promising, since many of the patients have serious chronic diseases and have exhausted other therapeutic options. Of the hundreds of cases of fasting described in the scientific literature, only seven cases of death have been reported prior to 1985.^{[58] [110] [117] [118] [119] [120]} In all cases, the patients had serious chronic disease prior to fasting, and in five of the seven cases drugs were given to the patients while fasting, while in the other two no description of protocol was provided.

There is no evidence in the scientific literature to suggest that fasting itself can be considered a cause of death. Death during fasting indicates that the remedial efforts of the body have been overpowered by the pathological process. This situation occurs in serious disease, whether eating or fasting. In examining the fallacy of attributing the cause of death to fasting, one researcher in the *Lancet* wrote:^[121]

Fasting short of emaciation is not hazardous, if death results, reasons other than those of the fast should be considered before concluding that all supervised fasts should be discouraged.

CONCLUSION

Therapeutic fasting is a useful protocol for any doctor interested in studying and promoting the inherent ability of the body to heal itself. This fine art and science is generally a safe, economical, and effective therapy for most patients in disease. Those interested in further study should initially direct their attention to the main historical texts and then to the recent hygienic and scientific literature. The references provide a greater depth of information for the topics discussed in this chapter. Internship with a doctor skilled in therapeutic fasting is strongly advised for those interested in providing safe and effective patient care.

Chapter 48 - Chronic candidiasis

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

An overgrowth in the gastrointestinal tract of the usually benign yeast *Candida albicans* is now becoming recognized as a complex medical syndrome known as chronic candidiasis or the yeast syndrome.^{[1] [2]} Specifically, the overgrowth of *Candida* is believed to cause a wide variety of symptoms in virtually every system of the body, with the gastrointestinal, genitourinary, endocrine, nervous, and immune systems being the most susceptible.^[3]

Although chronic candidiasis has been clinically defined for a long time, it was not until Orion Truss published *The Missing Diagnosis* and William Crook published *The Yeast Connection* that the public and many physicians became aware of the magnitude of the problem.^{[1] [2]}

GENERAL CONSIDERATIONS

Normally, *Candida albicans* lives harmoniously in the inner warm creases and crevices of the digestive tract (and vaginal tract in women). However, when this yeast overgrows, or immune system mechanisms are depleted, or the normal lining of the intestinal tract is damaged, the body can absorb yeast cells, particles of yeast cells, and various toxins.^[3] As a result, there may be significant disruption of body processes, resulting in

the development of the “yeast syndrome”.

This syndrome is generally characterized by patients saying they “feel sick all over”. Fatigue, allergies, immune system malfunction, depression, chemical sensitivities, and digestive disturbances are just some of the symptoms patients with the yeast syndrome may experience.^[3]

The typical patient with the yeast is female, as women are eight times more likely to experience the yeast syndrome compared with men due to the effects of estrogen, birth control pills, and the higher number of prescriptions for antibiotics (see [Table 48.1](#)).^[4]

TABLE 48-1 -- Typical chronic candidiasis patient profile

| |
|--|
| Sex: female |
| Age: 15–50 years |
| <i>General symptoms</i> |
| • Chronic fatigue |
| • Loss of energy |
| • General malaise |
| • Decreased libido |
| <i>Gastrointestinal symptoms</i> |
| • Thrush |
| • Bloating, gas |
| • Intestinal cramps |
| • Rectal itching |
| • Altered bowel function |
| <i>Genitourinary system complaints</i> |
| • Vaginal yeast infection |
| • Frequent bladder infections |

| • Primarily menstrual complaints |
| <i>Nervous system complaints</i> |
| • Depression |

- Irritability

- Inability to concentrate

Immune system complaints

- Allergies

- Chemical sensitivities

- Low immune function

Past history

- Chronic vaginal yeast infections

- Chronic antibiotic use for infections or acne

- Oral birth control usage

- Oral steroid hormone usage

Associated conditions

- Premenstrual syndrome

- Sensitivity to foods, chemicals, and other allergens

- Endocrine disturbances

- Eczema

- Psoriasis

- Irritable bowel syndrome

Other

- Craving for foods rich in carbohydrates or yeast

Causal factors

Chronic candidiasis is a classic example of a “multi-factorial” condition, as shown in [Table 48.2](#) . Therefore, the most effective treatment involves addressing and correcting the factors which predispose to *Candida* overgrowth and involves much more than killing the yeast with antifungal agents, whether synthetic or natural.

TABLE 48-2 -- Predisposing factors to *Candida* overgrowth

- Decreased digestive secretions

- Dietary factors

- Impaired immunity

- Nutrient deficiency

- Drugs (particularly antibiotics)

- Impaired liver function

- Underlying disease states

- Altered bowel flora

- Prolonged antibiotic use

Antibiotics

Prolonged antibiotic use is believed to be the most important factor in the development of chronic candidiasis in most cases. Antibiotics, through suppressing normal intestinal bacteria which prevent yeast overgrowth and suppression of the immune system, strongly promote the overgrowth of *Candida*.

There is little argument that, when used appropriately, antibiotics save lives. However, there is also little argument that antibiotics are seriously overused. While the appropriate use of antibiotics makes good medical sense, what does not make sense is the reliance on antibiotics for such conditions as acne, recurrent bladder infections, chronic ear infections, chronic sinusitis, chronic bronchitis, and non-bacterial sore throats. Relying on antibiotics in the treatment of these conditions does not make sense, as either the antibiotics rarely provide benefit or these conditions are effectively treated with natural measures.

The growing problem of antibiotic resistance. The widespread use and abuse of antibiotics is becoming increasingly alarming for many reasons besides the epidemic of chronic candidiasis, including the development of “superbugs” that are resistant to currently available antibiotics. According to many experts, as well as the World Health Organization, we are coming dangerously close to arriving at a “post-antibiotic era” where many infectious diseases will once again become almost impossible to treat.^[5] ^[6]
^[7]

Inappropriate use greatly increases the risk of developing complications such as overgrowth of *Candida albicans* and other organisms, as well as increasing the risk of developing a bacterial infection that is resistant to antibiotics.

Antibiotic resistance is probably an inevitable process, as bacteria transfer genetic material both within species and between species to help ensure survival of the organism. It has been well demonstrated that antibiotic resistance is much more common where antibiotics are used more often.^[6] This is particularly a problem in hospitals where infections caused by resistant strains of organisms such as *Staphylococcus aureus* and *Pseudomonas aeruginosa* often lead to fatal complications.

Since there is evidence that resistance to antibiotics is less of a problem when antibiotics are used sparingly, reduction in antibiotic prescriptions may be the only significant way to address the problem. According to several authorities, as well as the World Health Organization, antibiotic use must be restricted and the inappropriate use halted if the growing trend towards bacterial resistance to antibiotics is to be stopped or

reversed.^[5] ^[6] ^[7] However, prescriptions for antibiotics are not the only source of concern. Antibiotics have also been added to animal nutrition since the 1950s.

In addition to creating antibiotic-resistant microorganisms,

417

it may be several more decades before it is truly known what effects the widespread use of antibiotics is having in many different health conditions. For example, antibiotic exposure is now being linked to Crohn's disease.^[8] Prior to the 1950s, Crohn's disease was found in selected groups with a strong genetic component. Since this time, there has been a rapid increase in developed countries, particularly in the United States, and in countries that had previously had virtually no reported cases. In fact, since 1950, Crohn's disease has spread like an epidemic. The annual increase in prescriptions of antibiotics and the fact that there is a parallel increase in the annual incidence of Crohn's disease are causing great concern. Comparative statistics have shown that wherever antibiotics are used early and in large quantities, the incidence of Crohn's disease is now quite high.

Syndromes related to the yeast syndrome

Eventually the yeast syndrome will likely be replaced by a more comprehensive term to include small intestinal bacterial overgrowth and the leaky gut syndrome. Both of these conditions are often associated with *Candida albicans* overgrowth and may produce identical symptoms to the yeast syndrome. For further discussion of small intestinal bacterial overgrowth and leaky gut syndrome, see [Chapters 7](#) and [21](#) .

DIAGNOSIS

Questionnaire

One of the most useful screening methods for determining the likelihood of yeast-related illness is a comprehensive questionnaire (see [Appendix 2](#) : *Candida* questionnaire).

Although the *Candida* questionnaire can help, the best method for diagnosing chronic candidiasis is clinical evaluation by a physician knowledgeable about yeast-related illness. It is more than likely that the manner in which the doctor will diagnose the yeast syndrome will be based on clinical judgment from a detailed medical history and patient questionnaire. He or she may also employ laboratory techniques such as stool cultures for *Candida* and measurement of antibody levels to *Candida* or *Candida* antigens in the blood. However, while these laboratory exams are useful diagnostic aids, they should be used to confirm the diagnosis. In other words, the diagnosis is best made by evaluation of a patient's history and clinical picture.

The comprehensive stool and digestive analysis

Rather than simply culture a stool sample for the presence of *Candida albicans*, the comprehensive digestive stool analysis (CDSA) is more clinically useful (discussed in detail in [Ch. 9](#)). This battery of integrated diagnostic laboratory tests evaluates digestion, intestinal function, intestinal environment, and absorption by carefully examining the stool. It is a very useful tool in determining the digestive disturbance which is likely to be the underlying factor responsible for *Candida* overgrowth. In addition, the CDSA may determine that the symptoms are not related to *Candida* overgrowth but rather to conditions such as small intestinal bacterial overgrowth and the “leaky gut” syndrome.

Antibody and antigen levels

Another laboratory method to confirm the presence of *Candida* overgrowth is measuring the level of antibodies to *Candida* or the level of antigens in the blood.^{[3] [9]} However, rarely are these tests really needed, as the results typically only confirm what the patient history, physical examination, and CDSA reveal. Hence, the test does not change the course of action. Nonetheless, some patients and physicians may desire confirmation that *Candida albicans* is a responsible factor in the patient’s health equation. In that situation, these blood studies can be quite helpful and can also be used as a way of monitoring therapy.

THERAPEUTIC CONSIDERATIONS

A comprehensive approach is more effective in treating chronic candidiasis than simply trying to kill the *Candida* with a drug or natural anti-*Candida* agent. Drugs like nystatin, ketoconazol, and diflucan as well as various natural anti-*Candida* agents rarely produce significant long-term results because they fail to address the underlying factors which promote *Candida* overgrowth. It is a bit like trying to weed your garden by simply cutting the weed, instead of pulling it out by the roots. Nonetheless, in many cases it is very useful to try to eradicate *Candida albicans* from the system, preferably with the help of natural anti-*Candida* therapies such as timed-release caprylic acid preparations, enteric-coated volatile oil preparations, or fresh garlic preparations. A follow-up stool culture and *Candida* antigen determination will confirm if the *Candida* has been eliminated. If it has and symptoms are still apparent, it is likely that the symptoms they are experiencing are unrelated to an overgrowth of *Candida albicans*. Similar symptoms to those attributed to chronic candidiasis can be caused by small intestinal bacterial overgrowth. In this scenario, pancreatic enzymes and berberine-containing plants like goldenseal can be helpful.

In addition to using natural agents to eradicate *Candida albicans*, it is important to address predisposing factors, recommend a *Candida* control diet, and support various body systems according to the individual patient’s need.

Diet

A number of dietary factors appear to promote the overgrowth of *Candida*. The most important factors are a high intake of sugar, milk and other dairy products, foods containing a high content of yeast or mold, and food allergies.

Sugar

Sugar is the chief nutrient of *Candida albicans*. It is well accepted that restriction of sugar intake is an absolute necessity in the treatment of chronic candidiasis. Most patients do well by simply avoiding refined sugar and large amounts of honey, maple syrup, and fruit juice.^{[1] [2] [3] [4]}

Milk and dairy products

There are several reasons to restrict or eliminate the intake of milk in patients with chronic candidiasis:

- the high lactose content promotes the overgrowth of *Candida*
- milk is one of the most frequent food allergens
- milk may contain trace levels of antibiotics which can further disrupt the gastrointestinal bacterial flora and promote *Candida* overgrowth.^{[1] [2] [3] [4]}

Mold and yeast-containing foods

It is generally recommended by many experts that individuals with chronic candidiasis avoid foods with a high content of yeast or mold, including alcoholic beverages, cheeses, dried fruits and peanuts. Even though many patients with chronic candidiasis may be able to tolerate these foods, I think it is still a good idea to eliminate them from the diet. At the very least they should be avoided until the situation is under control.^{[1] [2] [3] [4]}

Food allergies

Food allergies are another common finding in patients with the yeast syndrome.^[3] ELISA tests, which determine both IgE- and IgG-mediated food allergies, are often very helpful in identifying food allergies.

Hypochlorhydria

An important step in treating chronic candidiasis in many cases is improving digestive secretions. Gastric hydrochloric acid, pancreatic enzymes, and bile all inhibit the overgrowth of *Candida* and prevent its penetration into the absorptive surfaces of the

small intestine. Decreased secretion of any of these important digestive components can lead to overgrowth of *Candida albicans* in the gastrointestinal tract. Therefore, restoration of normal digestive secretions through the use of supplemental hydrochloric acid, pancreatic enzymes, and substances which promote bile flow is critical in the treatment of chronic candidiasis. The comprehensive stool and digestive analysis can provide valuable information in identifying which factor is most important.

Patients on anti-ulcer drugs like Tagamet (cimetidine) and Zantac (ranitidine) actually develop *Candida* overgrowth in the stomach.^[10] This occurrence highlights the importance of hydrochloric acid in the prevention of *Candida* overgrowth. Restoring proper levels of gastric acid by supplemental hydrochloric acid is often quite useful in chronic candidiasis.

Pancreatic enzymes can also be quite useful in the treatment of chronic candidiasis. As well as being necessary for protein digestion, the proteases serve several other important functions. The proteases are largely responsible for keeping the small intestine free from parasites (including bacteria, yeast, protozoa, and intestinal worms).^{[11] [12]} A lack of proteases or other digestive secretions greatly increases an individual's risk of having an intestinal infection, including chronic *Candida* infections of the gastrointestinal tract.

Enhancing immunity

Recurrent or chronic infections, including chronic candidiasis, are characterized by a depressed immune system. What makes it difficult for these people to overcome chronic candidiasis is a repetitive cycle: a compromised immune system leads to infection, and infection leads to damage to the immune system, further weakening resistance.

The importance of a healthy immune function protecting against *Candida* overgrowth is well known by any physician who has seen a patient suffering from AIDS or taking drugs which suppress the immune system. In either case, severe overgrowth of *Candida albicans* is a hallmark feature. The occurrence of *Candida* overgrowth in these conditions provides considerable evidence that attaining better immune function is absolutely essential in the patient with chronic candidiasis.

In addition, patients with chronic candidiasis often suffer from other chronic infections, presumably due to a depressed immune system. Typically, this depression of immune function is related to decreased thymus function demonstrating primarily as depressed cell-mediated immunity. Although expensive laboratory tests can document this depression, it is better to rely on the history of repeated viral infections (including the common cold), outbreaks of cold sores or genital herpes, and prostatic (men) or vaginal (women) infections.

Causes of depressed immune function in candidiasis

The patient with chronic candidiasis is typically stuck in a vicious cycle ([Fig. 48.1](#)). With

regard to the immune

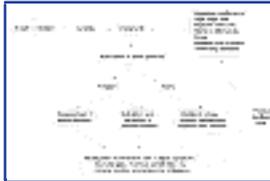

Figure 48-1 The vicious cycle of chronic candidiasis.

TABLE 48-3 -- Triggers to impaired immunity in candidiasis

system, a triggering event such as antibiotic use or nutrient deficiency (see [Table 48.3](#)) can lead to immune suppression allowing *Candida albicans* to overgrow and become more firmly entrenched in the lining of the gastrointestinal tract. Once the organism attaches itself to the intestinal cells, it competes with the cell and ultimately the entire body for nutrition – potentially robbing the body of vital nutrition. In addition, *Candida albicans* secretes a large number of mycotoxins and antigens.^{[13] [14]} *Candida albicans* is referred to as a “polyantigenic” organism because over 79 distinct antigens have been identified. Because of this tremendous number of antigens, an overgrowth of *Candida albicans* greatly taxes the immune system.

Restoring proper immune function

Restoring proper immune function is one of the key goals in the treatment of chronic candidiasis. There really isn't any single magic bullet which can immediately restore immune function in patients with chronic candidiasis. Instead, a comprehensive approach involving lifestyle, stress management, exercise, diet, nutritional supplementation, glandular therapy, and the use of plant-based medicines is used.

Perhaps the most effective intervention in re-establishing a healthy immune system is employing measures designed to improve thymus function. Promoting optimal thymus

gland activity involves:

- prevention of thymic involution or shrinkage by ensuring adequate dietary intake of antioxidant nutrients such as carotenes, vitamin C, vitamin E, zinc, and selenium
- use of nutrients that are required in the manufacture or action of thymic hormones
- using products containing concentrates of calf thymus tissue.

There is a substantial amount of clinical data to support the effectiveness of orally administered calf thymus extracts in restoring and enhancing immune function.^[15] ^[16] The effectiveness of thymus extract is reflective of broad-spectrum immune system enhancement presumably mediated by improved thymus gland activity.

The dosage will vary from one manufacturer to another as there are no quality control procedures or standards enforced in the glandular industry; it is left up to the individual company to adopt quality control and good manufacturing procedures.

From a practical view, products concentrated and standardized for polypeptide content are preferable to crude preparations. Based on current clinical research, the daily dose should be equivalent to 120 mg pure

polypeptides with molecular weights less than 10,000 or roughly 750 mg of the crude polypeptide fraction. No side-effects or adverse effects have been reported with the use of thymus preparations.

Promoting detoxification

Candida patients usually exhibit multiple chemical sensitivities and allergies, an indicator that detoxification reactions are stressed. Therefore, the liver function of the *Candida* patient needs to be supported. In fact, improving the health of the liver and promoting detoxification may comprise one of the most critical factors in the successful treatment of candidiasis.

Damage to the liver is often an underlying factor in chronic candidiasis as well as chronic fatigue. When the liver is even slightly damaged by chemical toxins, immune function is severely compromised.

The immune system suppressing effect of non-viral liver damage has been repeatedly demonstrated in experimental animal studies and human studies. For example, when the liver of a rat is damaged by a chemical toxin, immune function is severely hindered.^[17] Liver injury is also linked to *Candida* overgrowth, as evident in studies in mice demonstrating that when the liver is even slightly damaged, *Candida* runs rampant through the body.^[18]

A rational approach to aiding the body's detoxification involves:

- a diet which focuses on fresh fruits and vegetables, whole grains, legumes, nuts, and seeds
- a healthy lifestyle including avoiding alcohol and exercising regularly
- a high potency multiple vitamin and mineral supplement
- lipotropic formulas and silymarin to protect the liver and enhance liver function
- a 3 day fast at the change of each season.

If any of the factors in [Table 48.4](#) apply to the patient, enhancing detoxification is a major therapeutic goal.

Lipotropic factors

The nutrients choline, betaine, and methionine are often beneficial in enhancing liver function and detoxification reactions. These nutrients are referred to as “lipotropic agents” – compounds which promote the flow of fat and bile to and from the liver. In essence, they produce a “decongesting” effect on the liver and promote improved liver function and fat metabolism. Formulas containing lipotropic agents are very useful in enhancing detoxification reactions and other liver functions. Lipotropic formulas have been used for a wide variety of conditions by nutrition-oriented physicians, including a number of

TABLE 48-4 -- Indications of the need for detoxification

—thyroid hormone

- History of viral hepatitis

liver disorders such as hepatitis, cirrhosis, and chemical-induced liver disease. The dosage should provide a daily dose of 1,000 mg of choline and 1,000 mg of either methionine and/or cysteine.

Lipotropic formulas appear to increase the levels of two important liver substances: SAM (S-adenosylmethionine), the major lipotropic compound in the liver, and glutathione, one of the major detoxifying compounds in the liver.^{[19] [20]}

Silymarin

There are a long list of plants which exert beneficial effects on liver function. However, the most impressive research has been done on a special extract of milk thistle (*Silybum marianum*) known as silymarin. Silymarin refers to a group of flavonoid compounds. These compounds exert tremendous effect on protecting the liver from damage as well as enhancing detoxification processes. Silymarin has shown impressive results in doubleblind studies.^{[21] [22] [23]} The standard dosage for silymarin is 70–210 mg three times daily.

Promoting elimination

In addition to directly supporting liver function, proper detoxification also involves promoting proper elimination. A diet which focuses on high-fiber plant foods should be sufficient to promote proper elimination by supplying an ample amount of dietary fiber. If additional support is needed, fiber formulas can be prescribed. These formulas are composed of natural plant fibers derived from psyllium seed, kelp, agar, pectin, and plant gums like karaya and guar. Alternatively, they can be purified semi-synthetic polysaccharides like methyl-cellulose and carboxymethyl cellulose sodium. Psyllium-containing laxatives are the most popular and usually the most effective. Fiber formulas are the laxatives which

approximate most closely the natural mechanism that promotes a bowel movement. In the treatment of candidiasis, recommend 3–5 g of soluble fiber at bedtime – especially if anti-yeast therapies are employed to ensure that dead yeast cells are excreted and not absorbed.

Probiotics

The intestinal flora plays a major role in the health of the host.^[24] ^[25] The intestinal flora is intimately involved in the host's nutritional status and affects immune system function, cholesterol metabolism, carcinogenesis, and aging. Due to the importance of *L. acidophilus* and *B. bifidum* to human health, probiotic supplements can be used to promote overall good health. There are, however, several specific uses for probiotics. The four primary areas of uses related to chronic candidiasis are promotion of proper intestinal environment, post-antibiotic therapy, vaginal yeast infections, and urinary tract infections.

The dosage of a commercial probiotic supplement is based upon the number of live organisms. The ingestion of 1–10 billion viable *L. acidophilus* or *B. bifidum* cells daily is a sufficient dosage for most people. Amounts exceeding this may induce mild gastrointestinal disturbances, while smaller amounts may not be able to colonize the gastrointestinal tract.

Natural anti-yeast agents

There are a number of natural agents with proven activity against *Candida albicans*. Rather than relying on these agents as a primary therapy, however, it is still important to address the factors which predispose one to chronic candidiasis, especially lack of either hydrochloric acid or pancreatic enzymes. The four approaches we feel most comfortable in recommending as natural agents against *Candida albicans* are:

- caprylic acid
- berberine-containing plants
- garlic
- enteric-coated volatile oil preparations.

Most patients (but not all) can achieve benefits from the natural agents described here rather than the drug approach. Use of any effective anti-yeast therapy alone will likely result in the Herxheimer ("die-off") reaction due to the rapid killing of the organism and subsequent absorption of large quantities of yeast toxins, cell particles, and antigens. The Herxheimer reaction refers to a worsening of symptoms as a result of this dying off. The Herxheimer reaction can be minimized by:

- following the dietary recommendations for a minimum of 2 weeks before taking an anti-yeast agent
- supporting the liver by following the recommendations given above
- starting any of the above-described anti-yeast medications in low doses and gradually increasing dosages over 1 month to achieve full therapeutic dosage.

Caprylic acid

Caprylic acid is a naturally occurring fatty acid which has been reported to be an

effective antifungal compound in the treatment of candidiasis.^{[26] [27]} Since caprylic acid is readily absorbed in the intestines, it is necessary to take timed-release or enteric-coated caprylic acid formulas to allow for gradual release throughout the entire intestinal tract.^[28] The standard dosage for these delayed-release preparations is 1,000 to 2,000 mg with meals.

Berberine-containing plants

Berberine-containing plants include goldenseal (*Hydrastis canadensis*), barberry (*Berberis vulgaris*), Oregon grape (*Berberis aquifolium*), and goldthread (*Coptis chinensis*). Berberine, an alkaloid, has been extensively studied in both experimental and clinical settings for its antibiotic activity. Berberine exhibits a broad spectrum of antibiotic activity, having shown antibiotic activity against bacteria, protozoa, and fungi, including *Candida albicans*.^{[29] [30] [31] [32] [33] [34] [35]}

Berberine's antibiotic action against some of these pathogens is actually stronger than that of antibiotics commonly used for disease these pathogens cause. Berberine-containing plants should be considered in infectious processes involving the above-mentioned organisms. Berberine's action in inhibiting *Candida*, as well as pathogenic bacteria, prevents the overgrowth of yeast which is a common side-effect of antibiotic use.

Diarrhea is a common symptom in patients with chronic candidiasis. Berberine has shown remarkable anti-diarrheal activity in even the most severe cases. Positive clinical results have been shown with berberine in relieving diarrhea in cases of cholera, amebiasis, giardiasis, and other causes of acute gastrointestinal infection (e.g. *E. coli*, *Shigella*, *Salmonella*, and *Klebsiella*) and may also relieve the diarrhea seen in patients with chronic candidiasis.^{[36] [37] [38] [39] [40] [41] [42] [43] [44]}

The dosage of any berberine-containing plant should be based on berberine content. As there is a wide range of quality in goldenseal preparations, standardized extracts are preferred. Three times a day dosages are as follows:

- dried root or as infusion (tea), 2–4 g
- tincture (1:5), 6–12 ml (1.5–3 tsp)
- fluid extract (1:1), 2–4 ml (0.5–1 tsp)
- solid (powdered dry) extract (4:1 or 8–12% alkaloid content), 250–500 mg.

Note that the dosage recommendations for berberine would be 25–50 mg three times daily or a daily dosage of up to 150 mg. This dosage is consistent with the dosage range in the positive clinical studies in patients with gastrointestinal infections. For children, a dosage based on body weight is appropriate. The daily dosage would be the equivalent to 5–10 mg of berberine/kg (2.2 pounds) body weight.

Berberine and berberine-containing plants are generally non-toxic at the recommended dosages; however, berberine-containing plants are not recommended for use during pregnancy and higher dosages may interfere with B vitamin metabolism.^[45]

Allium sativum

Garlic has demonstrated significant antifungal activity. In fact, its inhibition of *Candida albicans* in both animal and test tube (in vitro) studies have shown it to be more potent than nystatin, gentian violet, and six other reputed antifungal agents.^[46] ^[47] ^[48] The active component is allicin – the pungent and odorous principle of garlic.

The modern clinical use of garlic features the use of commercial preparations designed to offer the benefits of garlic without the odor. These preparations are prepared in such a manner that the allicin is not formed until the enteric-coated tablet is delivered to the small and large intestine.

The treatment of chronic candidiasis requires a daily dose of at least 10 mg allicin or a total allicin potential of 4,000 mcg. This amount is equal to approximately one clove (4 g) of fresh garlic. Going beyond this dosage with these preparations usually results in the odor of garlic being detectable.

Enteric-coated volatile oils

The most recent “new wave” natural anti-*Candida* formulas are enteric-coated volatile oil preparations. Volatile oils from oregano, thyme, peppermint, and rosemary are all effective antifungal agents. A recent study compared the anti-*Candida* effect of oregano oil with that of caprylic acid.^[49] While the minimum inhibitory concentration of oregano oil was less than 0.1 mcg/ml and the 0.1% survival of *C. albicans* occurred at a concentration of 45 mcg/ml, the minimum inhibitory concentration of caprylic acid was less than 500 mcg/ml and 0.1% survival occurred at a concentration of 5,000 mcg/ml. These results indicate that the anti-*Candida* activity of oregano oil is greater than 100 times more potent than caprylic acid. Since the volatile oils are quickly absorbed, as well as being associated with inducing heartburn, an enteric coating is recommended to ensure delivery to the small and large intestine. An effective dosage for an enteric-coated volatile oil preparation is 0.2–0.4 ml twice daily between meals.

THERAPEUTIC APPROACH

The following is a comprehensive step by step approach to the successful elimination of chronic candidiasis.

Step 1. Identify and address predisposing factors:

- Eliminate the use of antibiotics, steroids, immune-suppressing drugs, and birth control pills (unless there is an absolute medical necessity)

- Perform a comprehensive stool and digestive analysis
- Follow the specific recommendations if the identifiable predisposing factor is dietary factors, impaired immunity, impaired liver function, or an underlying disease state.

Step 2. Recommend the *Candida* control diet:

- Eliminate refined and simple sugars
- Eliminate milk and other dairy products
- Eliminate foods with a high content of yeast or mold, including alcoholic beverages, cheeses, dried fruits, melons, and peanuts
- Eliminate all known or suspected food allergies.

Step 3. Provide nutritional support:

- A high potency multiple vitamin and mineral formula
- Additional antioxidants
- One tablespoon of flaxseed oil daily.

Step 4. Support immune function:

- Promote a positive mental attitude
- Help patients to deal with stress by teaching positive stress coping techniques
- Recommend avoiding factors like alcohol, sugar, smoking, and elevated cholesterol levels which can impair immune function
- Recommend plenty of rest and good sleep
- Support thymus gland function; prescribe 750 mg of crude polypeptide fractions daily.

Step 5. Promote detoxification and elimination:

- Recommend 3–5 g of a water-soluble fiber source such as guar gum, psyllium seed, or pectin at night
- If necessary, recommend lipotropic factors and silymarin to enhance liver function.

Step 6. Recommend probiotics:

- Dosage: 1–10 billion viable *L. acidophilus* and *B. bifidum* cells daily.

Step 7. Use appropriate anti-yeast therapy:

- Ideally, use the recommended nutritional and/or herbal supplements to help control against yeast overgrowth and promote a healthy bacterial flora
 - If necessary, use prescription anti-yeast drug appropriately.
-

These simple steps should take care of chronic candidiasis in most cases. If a patient follows these guidelines and fails to achieve significant improvement or complete resolution, further evaluation is necessary to determine if chronic candidiasis is the underlying factor. Repeat stool cultures and antigen levels are often helpful in this goal. If the organism has not been eradicated, stronger prescription antibiotics can be used along with the other general recommendations.

Chapter 49 - Chronic fatigue syndrome

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

DIAGNOSTIC SUMMARY

- Mild fever
- Recurrent sore throat
- Painful lymph nodes
- Muscle weakness
- Muscle pain
- Prolonged fatigue after exercise
- Recurrent headache
- Migratory joint pain
- Depression
- Sleep disturbance (hypersomnia or insomnia).

INTRODUCTION

The chronic fatigue syndrome (CFS) is a newly established syndrome that describes varying combinations of symptoms including recurrent fatigue, sore throats, low-grade fever, lymph node swelling, headache, muscle and joint pain, intestinal discomfort, emotional distress and/or depression, and loss of concentration.

Although newly defined and currently popular, CFS is not a new disease at all. References to a similar condition in the medical literature go back as far as the 1860s. In the past, chronic fatigue syndrome has been known by a variety of names including, among many others:

- chronic mononucleosis-like syndrome or chronic EBV syndrome
- Yuppie flu
- postviral fatigue syndrome
- post-infectious neuromyasthenia

- chronic fatigue and immune dysfunction syndrome (CFIDS)
- Iceland disease
- Royal Free Hospital disease.

In addition, symptoms of chronic fatigue syndrome mirror symptoms of neurasthenia, a condition first described in 1869.

Definition

In response to the growing interest, chronic fatigue syndrome was formally defined in 1988 by a consensus panel convened by the Centers for Disease Control (CDC) in an attempt to establish a guide for evaluating patients with chronic fatigue of unknown cause by clinical physicians and researchers.^[1]

A formal (and controversial) set of diagnostic criteria were established by the CDC (see [Table 49.1](#)). These criteria are controversial for many reasons including the fact that psychological symptoms are both a minor criterion and potential grounds for exclusion. One of the major complaints from physicians about the CDC definition is that it appears better suited for research than for clinical purposes. A major problem with the CDC criteria is that they ignore many of the common symptoms reported by patients with CFS (see [Table 49.2](#)).

The British and Australian criteria for the diagnosis of CFS are less strict than the CDC definition.^[2] In particular, the minor diagnostic criteria are not required and the major diagnostic criteria are not as strict. For example, in the Australian definition the major criterion is simply fatigue at a level which causes disruption of daily activities in the absence of other medical conditions associated with fatigue.

Using the CDC criteria, the prevalence of CFS in individuals suffering from chronic fatigue in the United States is thought to be about 11.5%, using British criteria

TABLE 49-1 -- CDC diagnostic criteria for chronic fatigue syndrome

| |
|---|
| <i>Major criteria</i> |
| <ul style="list-style-type: none"> • New onset of fatigue causing 50% reduction in activity for at least 6 months • Exclusion of other illnesses that can cause fatigue |
| <i>Minor criteria</i> |
| <ul style="list-style-type: none"> • Presence of eight of the 11 symptoms listed below, or six of the 11 symptoms and two of the three signs |
| Symptoms |
| 1. Mild fever |

2. Recurrent sore throat
3. Painful lymph nodes
4. Muscle weakness
5. Muscle pain
6. Prolonged fatigue after exercise
7. Recurrent headache
8. Migratory joint pain
9. Neurological or psychological complaints
 - sensitivity to bright light
 - forgetfulness
 - confusion
 - inability to concentrate
 - excessive irritability
 - depression
10. Sleep disturbance (hypersomnia or insomnia)
11. Sudden onset of symptom complex

Signs

1. Low-grade fever
2. Non-exudative pharyngitis
3. Palpable or tender lymph nodes

TABLE 49-2 -- Frequency of symptoms in CFS

| Symptom/sign | Frequency (%) |
|--------------------------|---------------|
| Fatigue | 100 |
| Low-grade fever | 60–95 |
| Muscle pain | 20–95 |
| Sleep disorder | 15–90 |
| Impaired mental function | 50–85 |
| Depression | 70–85 |
| Headache | 35–85 |
| Allergies | 55–80 |
| Sore throat | 50–75 |

| | |
|-------------------------------|-------|
| Anxiety | 50–70 |
| Muscle weakness | 40–70 |
| Post-exercise fatigue | 50–60 |
| Premenstrual syndrome (women) | 50–60 |
| Stiffness | 50–60 |
| Visual blurring | 50–60 |
| Nausea | 50–60 |
| Dizziness | 30–50 |
| Joint pain | 40–50 |
| Dry eyes and mouth | 30–40 |
| Diarrhea | 30–40 |
| Cough | 30–40 |
| Decreased appetite | 30–40 |
| Night sweats | 30–40 |
| Painful lymph nodes | 30–40 |

it is about 15%, and using the Australian criteria it is about 38%. [\[2\]](#)

ETIOLOGY

Epstein–Barr virus

Many research studies have focused on identifying an infectious agent as the cause of CFS. The Epstein–Barr virus (EBV) emerged as the leading, yet controversial, candidate. [\[3\]](#) [\[4\]](#) [\[5\]](#) [\[6\]](#) [\[7\]](#) EBV is a member of the herpes group of viruses, which includes herpes simplex types 1 and 2, varicella zoster virus, cytomegalovirus, and pseudorabies virus. A common aspect of these viruses is their ability to establish a life-long latent infection after the initial infection. This latent infection is kept in check by a normal immune system. When the immune system is compromised in any way, these viruses can become active as viral replication and spread is increased. This is commonly observed with herpes virus infections, especially in immunocompromised individuals such as those with AIDS, cancer, or drug-induced immunosuppression.

Infection with EBV is inevitable among humans. By the end of early adulthood, almost all individuals demonstrate detectable antibodies in their blood to the Epstein–Barr virus, indicating past infection. When the primary infection occurs in childhood, there are usually no symptoms, but when it occurs in adolescence or early adulthood, the clinical manifestations of infectious mononucleosis develop in approximately 50% of the cases.

Although reports of a prolonged or recurrent mononucleosis-like syndrome began appearing in the 1940s and 1950s, it wasn't until the 1980s that evidence had implicated EBV in this broad clinical spectrum of chronic fatigue and associated symptoms. Numerous studies have now demonstrated persistently elevated titers (levels) of serum antibodies against the Epstein–Barr virus (specifically, anti-EBV capsid antibody titers > 1:80) in a number of patients presenting with the symptom pattern of this syndrome.

A careful study of 134 patients who had undergone EBV antibody testing because of suspected chronic mononucleosis-like syndrome found mixed results about the importance of EBV infection.^[9] Fifteen patients identified as having severe, persistent fatigue of unknown origin were compared with the remaining 119 with less severe illness and with 30 age- and race-matched controls. The more seriously ill patients generally had higher levels of EBV antibodies than did the comparison groups, and, interestingly, they also demonstrated higher antibody titers to cytomegalovirus, herpes simplex viruses types 1 and 2, and measles. This led the researchers to conclude that “some patients with these illnesses (syndromes of chronic fatigue) may have an abnormality of infectious and/or immunologic origin”, and that there remain “questions concerning the relationship between CFS and EBV”.

Current knowledge about EBV infection can be summarized as follows:

- EBV and the herpes group of viruses produce latent life-long infections.
- The host's immune system (T-lymphocytes, interferon, and other lymphokines) normally holds the latent infection in check.
- Any compromise in the immune system can lead to the reactivation of the virus and recurrent infection.
- The infection itself can compromise and/or disrupt immunity, thereby leading to other diseases.
- Elevated EBV antibody levels are observed in a significant number of diseases characterized by immunological dysfunction.
- Elevated antibody titers to the herpes group viruses, measles, and other viruses have also been observed in patients with chronic fatigue syndrome.

EBV antibody testing (and antibody testing for other herpes group viruses and measles) may be useful as a measure of immune function and overall host resistance, but should not be relied upon for diagnosis of CFS.

Other infectious agents

In addition to EBV, a number of other viruses have been investigated as possible causes of EBV. This search

TABLE 49-3 -- Organisms proposed as causative agents in CFS

- Epstein–Barr virus

- Human herpes virus-6

- Inoue–Melnich virus

- *Brucella*

- *Borrelia burgdorferi*

- *Giardia lamblia*

- Cytomegalovirus

- Enterovirus

- Retrovirus

for a viral agent is consistent with the mainstream medical approach to focus on the infectious organism rather than on reducing susceptibility and supporting the individual's immune system to deal with the organism effectively.^{[3] [4] [5]} [Table 49.3](#) lists the organisms currently proposed as causative agents in CFS.

Immune system abnormalities

There is little argument that a disturbed immune system plays a central role in CFS. A variety of immune system abnormalities have been reported in CFS patients (see [Table 49.4](#)). While no specific immunological dysfunction pattern has been recognized, the most consistent abnormality is a decreased number or activity of natural killer (NK) cells.^{[3] [4] [9] [10]} NK cells received their name because of their ability to destroy cells that have become cancerous or infected with viruses. In fact, for a time, CFS was also referred to as low natural killer cell syndrome (LNKS).

Other consistent findings include a reduced ability of lymphocytes, key in the battle against viruses, to respond to stimuli.^[10] One of the reasons for this lack of response may be a reduced activity or decreased production of interferon. While both low and high levels of interferon have been reported in CFS, levels are depressed in most cases. When interferon levels are low, reactivation of latent viral infection is likely. Conversely, when interferon (as well as other chemical mediators like interleukin-1) levels are high, many of the symptoms may be related to the physiological effects of interferon. When interferon is used as a therapy in cancer and viral hepatitis, the side-effects produced are quite similar to the symptoms of CFS.

TABLE 49-4 -- Immunologic abnormalities reported for CFS

- Elevated levels of antibodies to viral proteins

- Decreased natural killer cell activity

- Low or elevated antibody levels

- Increased or decreased levels of circulating immune complexes

- Increased cytokine (e.g. interleukin-2) levels
- Increased or decreased interferon levels
- Altered helper/suppressor T-cell ratio

Chronic fatigue syndrome, fibromyalgia and multiple chemical sensitivities

Fibromyalgia (FM) and multiple chemical sensitivities (MCS), like CFS, are recently recognized disorders with a substantial overlap of symptomatology.^{[3] [4] [11] [12]} The only difference in diagnostic criteria for fibromyalgia and CFS is the requirement of musculoskeletal pain in fibromyalgia and fatigue in CFS. The likelihood of being diagnosed as having fibromyalgia or CFS is dependent upon the type of physician consulted. Specifically, if a rheumatologist or orthopedic specialist is consulted, the patient is much more likely to be diagnosed with fibromyalgia ([Table 49.5](#) presents the diagnostic criteria for fibromyalgia).

One group of researchers carefully compared the symptomatology of 90 patients who had been diagnosed as having CFS, MCS or FM (30 in each category).^[12] Utilizing the same questionnaire for all 90 patients, 70% of the patients diagnosed with FM and 30% with MCS met the Centers for Disease Control criteria for CFS. Particularly significant was the observation that 80% of both the FM and MCS patients met the CFS criteria of fatigue lasting more than 6 months with a 50% reduction in activity. More than 50% of the CFS and FM patients reported adverse reactions of various chemicals.

Other causes of chronic fatigue

Chronic fatigue can be caused by a variety of physical and psychological factors. [Table 49.6](#) lists the major causes of chronic fatigue in an order of importance that is representative of how common the cause is among sufferers of chronic fatigue in the general population. The list is based on the findings of several large studies as well as the authors' clinical experience (chronic fatigue syndrome is listed under a broader category of impaired immune function).

TABLE 49-5 -- Diagnostic criteria for fibromyalgia. Diagnosis requires fulfillment of all three major criteria and four or more minor criteria

Major criteria

- Generalized aches or stiffness of at least three anatomic sites for at least 3 months
- Six or more typical, reproducible tender points
- Exclusion of other disorders which can cause similar symptoms

Minor criteria

- Generalized fatigue
- Chronic headache
- Sleep disturbance
- Neurological and psychological complaints
- Joint swelling
- Numbing or tingling sensations
- Irritable bowel syndrome
- Variation of symptoms in relation to activity, stress, and weather changes

DIAGNOSIS

A great number of factors must be considered when evaluating a patient with chronic fatigue. A detailed medical history and review of body systems goes a long way to identifying important factors. The goal is to identify as many factors as possible which may be contributing to the patient's feeling of fatigue. For example, if a patient has heart disease, diabetes, or some other health condition, and the condition or the drug they are taking is clearly responsible for their fatigue, the treatment of their fatigue becomes secondary to the treatment of their underlying health condition.

In many cases of chronic fatigue, further evaluation is needed. The next steps can include a complete physical examination and laboratory studies. In the physical examination, look for any possible clues which may indicate the cause for the chronic fatigue. For example, swollen lymph nodes may indicate a chronic infection; and the presence of a diagonal crease on both ear lobes usually indicates impaired blood flow to the brain, a significant cause of fatigue in the elderly.

Avoid ordering expensive laboratory tests unless they are absolutely necessary. A complete blood count (CBC) and a chemistry panel (including serum ferritin in menstruating women) are useful as screening tools for other diseases. Avoid ordering laboratory tests to confirm a diagnosis that is not going to affect treatment. For example, if it is quite obvious that the patient has

impaired immunity, it does not make much sense to perform elaborate and expensive blood tests on immune function because the results of these tests are not likely to influence the method of treatment.

Of particular value are assessment of liver detoxification function, bowel dysbiosis and gastrointestinal permeability (see [Chs 9](#) , [16](#) and [21](#)).

THERAPEUTIC CONSIDERATIONS

Since chronic fatigue and the CFS are generally multifactorial conditions, the therapeutic approach typically involves multiple therapies which address different facets of the clinical picture.

A person's energy level, as well as their emotional state, is determined by an interplay between two primary factors – internal focus and physiology. Many people with chronic fatigue focus on how tired they are. They repeatedly reaffirm their fatigue to themselves and to anyone who will listen. Their physiology includes not only the chemicals and hormones floating around in the body, but also the way they hold their body (usually slouched) and the way they breathe (shallow). In most patients with chronic fatigue, both the mind and the body need to be addressed. The most effective treatment is a comprehensive program that is designed to help the use of their mind, attitude, and physiology to fuel higher energy levels.

Underlying health problems

Depression

The first factor to address is any underlying depression. Depression is one of the major causes of chronic fatigue and it is one of the common features of CFS. In the absence of a pre-existing physical condition, depression is generally regarded as the most common cause of chronic fatigue. However, it is often difficult to determine whether the depression preceded the fatigue or vice versa. Depression is fully discussed in [Chapter 126](#).

Stress

Stress is another factor to consider in the patient with chronic fatigue or CFS. Stress can be the underlying factor in the patient with depression, low immune function, or other cause of chronic fatigue (see [Ch. 60](#) for guidelines for assessing the role of stress in chronic fatigue and CFS).

One of the tools we recommend to rate stress levels is the “Social Readjustment Rating Scale” developed by Holmes & Rahe.^[13] The scale was originally designed to predict the likelihood of a person getting a serious disease due to stress. Various life-change events are numerically rated according to their potential for causing disease. Even events commonly viewed as positive, such as an outstanding personal achievement, carry with them stress.

Impaired liver function and/or environmental illness

Exposure to food additives, solvents (cleaning materials, formaldehyde, toluene, benzene, etc.), pesticides, herbicides, heavy metals (lead, mercury, cadmium, arsenic,

nickel, and aluminum), and other toxins can greatly stress liver and detoxification processes. This exposure can lead to a condition labeled by many naturopathic and nutrition-oriented physicians as the “congested liver” or “sluggish liver” or the more recently coined “impaired hepatic detoxification”. These terms signify a reduced ability of the liver to detoxify. The congested or sluggish liver is characterized by a diminished bile flow, a condition known in medical terms as cholestasis, while impaired hepatic detoxification refers to decreased phase I and/or phase II enzyme activity. Phase I detoxification rates in excess of phase II activity will also cause toxicity problems due to excessive accumulation of activated intermediates (see [Ch. 16](#)). In addition to exposure to toxic chemicals, impairment of bile flow within the liver can be caused by a variety of other agents and conditions, as listed in [Table 49.7](#).

Although many of the conditions listed in the table are typically associated with alterations in laboratory tests of liver function (serum bilirubin, AST, ALT, LDH, GGTP, etc.), relying on these tests alone to evaluate liver function may not be adequate, as these tests are elevated only when the liver has been significantly damaged and many of these conditions in the initial or “subclinical” stages may have normal laboratory values.

430

Although there are more sensitive tests to determine the functional activity of the liver, such as the serum bile acid assay and various clearance tests (see [Ch. 16](#)), clinical judgment based on medical history remains the major diagnostic tool for the “sluggish liver” or impaired hepatic detoxification enzymes, the presence of chronic fatigue being the hallmark symptom.

People with a sluggish liver may also complain of, among other things:

- depression
- general malaise
- headaches
- digestive disturbances
- allergies and chemical sensitivities
- premenstrual syndrome
- constipation.

Not surprisingly, these are the same types of symptoms that people exposed to toxic chemicals often complain of. Many toxic chemicals (especially solvents) and heavy metals (see [Ch. 18](#)) have an affinity to nervous tissue, giving rise to a variety of psychological and neurological symptoms, such as:^[14] ^[15]

- depression
- headaches
- mental confusion
- mental illness
- tingling in extremities
- abnormal nerve reflexes
- other signs of impaired nervous system function.

A hair mineral analysis is a good screening test for heavy metal toxicity. If the hair mineral analysis is inconclusive, a more sensitive indicator is the 8 hour lead mobilization test. This test employs the chelating agent EDTA (edetate calcium disodium) and measures the level of lead excreted in the urine for a period of 8 hours after the injection of EDTA.

An interesting multiclinic research study of chronically ill patients, many of whom were diagnosed as suffering from CFIDS, evaluated the efficacy of a comprehensive

detoxification program. Patients were placed on a hypoallergenic diet and provided a dietary food supplement rich in nutrients that facilitate liver detoxification. The patients reported a 52% reduction in symptoms after 10 weeks and symptom improvement was mirrored by normalization of hepatic phase I and phase II detoxification.^[16]

Excessive gastrointestinal permeability

Excessive gastrointestinal permeability, as measured by the lactulose/mannitol absorption test (see [Ch. 21](#)), is a common finding in CFS.^[17] A treatment program utilizing food allergy control, nutrients to stimulate gastrointestinal regeneration and to support hepatic phase I and II detoxification, and an oligoantigenic rice protein food replacement formula was provided to 22 patients who fulfilled the classic CDC/NIH criteria for CFS. The patients' average duration of CFS was 4.6 years. The treatment resulted in symptom reduction in 81.2% of the patients, with clinical improvement being paralleled by normalization of gastrointestinal permeability and hepatic detoxification function.^[18]

Impaired immune function and/or chronic infection

When the immune system is impaired, infections can linger and fatigue persist. There is a good reason for fatigue during an infection – fatigue is the body's response mechanism to infection because the immune system works best when the body is at rest.

In order to determine the role that the immune system is playing in patients with chronic fatigue, the series of questions listed in [Table 49.8](#) can be utilized during the patient interview to indicate an impaired immune system. [Chapter 20](#) describes in substantial detail the laboratory methodologies for assessing immune function.

Chronic Candida infection

One of the most common findings in individuals with impaired immune function is gastrointestinal overgrowth of *Candida albicans*. Candidal overgrowth is now becoming recognized as a complex medical syndrome also known as “the yeast syndrome” and “chronic candidiasis”. This overgrowth is believed to cause a wide variety of symptoms in virtually every system of the body, with the gastrointestinal, genitourinary, endocrine, nervous, and immune systems being the most susceptible. [Table 49.9](#) lists the typical chronic candidiasis patient profile (see [Ch. 48](#) for a comprehensive discussion).

The diagnosis of chronic candidiasis is often quite difficult as there is no single specific diagnostic test. Stool cultures and elevated antibody levels to *Candida* are useful diagnostic aids, but they should not be relied upon for diagnosis. The best method for diagnosing chronic candidiasis in most cases is a detailed medical history and patient questionnaire (see [Appendix 2](#)). [Table 49.10](#) lists the factors that typically predispose a patient to candidal overgrowth.

TABLE 49-8 -- Questionnaire for recognition of impaired immune function

-
- Do you get more than two colds per year?
 - When you catch a cold, does it take more than 5–7 days to get rid of the symptoms?
 - Have you ever had infectious mononucleosis?
 - Do you have herpes?
 - Do you suffer from chronic infections of any kind?
-

Immune system complaints

- Allergies
 - Chemical sensitivities
 - Low immune function
-

Past history

- Chronic vaginal yeast infections
 - Chronic antibiotic use for infections or acne
 - Oral birth control usage
 - Oral steroid hormone usage
-

Associated conditions

- Premenstrual syndrome
 - Sensitivity to foods, chemicals, and other allergens
 - Endocrine disturbances
 - Psoriasis
 - Irritable bowel syndrome
-

Other

- Craving for foods rich in carbohydrates or yeast
-

TABLE 49-10 -- Factors predisposing to *Candida* overgrowth

- Impaired immune function
- Anti-ulcer drugs
- Broad-spectrum antibiotics
- Cellular immunodeficiency
- Corticosteroids
- Diabetes mellitus
- Excessive sugar in the diet
- Intravascular catheters
- Intravenous drug use
- Lack of digestive secretions
- Oral contraceptive agents

Food allergies

As far back as 1930, chronic fatigue was recognized as a key feature of food allergies.^[19] Originally, Rowe & Rowe^[19] used the term “allergic toxemia” to describe a syndrome that included the symptoms of fatigue, muscle and joint aches, drowsiness, difficulty in concentration, nervousness, and depression. Around the 1950s, this syndrome began to be referred to as the “allergic tension-fatigue syndrome”.^[20] With the popularity of CFS, many physicians and others are forgetting that food allergies can lead to chronic fatigue. Furthermore, between 55 and 85% of individuals with CFS have allergies. For more information on food allergies, see [Chapter 15](#) .

Hypothyroidism

Hypothyroidism is a common cause of chronic fatigue. However, the condition is often overlooked. The reason for this may be the reliance on standard blood measurements of thyroid hormone levels as the method of diagnosis.^{[21] [22] [23]} Undiagnosed hypothyroidism is a serious concern as failure to treat such a critical and underlying problem will reduce the effectiveness of every other measure designed to increase energy levels. For more information, see [Chapter 162](#) .

Hypoglycemia

The association between hypoglycemia and fatigue is well known. What is not as well known is the role that hypoglycemia plays in contributing to depression. Numerous studies have shown that depressed individuals suffer from hypoglycemia.^{[24] [25] [26] [27]} Since depression is the most common cause of chronic fatigue, hypoglycemia must always be ruled out (see [Ch. 161](#)).

Hypoadrenalism

Adrenal exhaustion was first proposed as a cause of chronic fatigue over 50 years ago by Tintera.^[28] A small, but growing, body of evidence now supports the role of a disruption of the hypothalamic–pituitary–adrenal axis (HPA) in CFS.^[29]

One of the major symptoms of glucocorticoid deficiency is debilitating fatigue. Glucocorticoid insufficiency is also characterized by a stressing event followed by feverishness, arthralgias, myalgias, adenopathy, post-exertional fatigue, exacerbation of allergic responses and disturbances of mood and sleep, i.e. the typical presentation of CFS. These symptoms are seen in partial or subclinical adrenal insufficiency, which may only be detected by the ACTH stimulation test or other endocrine testing. Glucocorticoids have a very profound endogenous immunosuppressive effect. In subclinical adrenal insufficiency, this may allow for the symptoms of chronic fatigue, including exacerbation of allergic responses, enhanced antibody titers to a variety of viral antigens, and elevations in cytokine levels. A group of CFS researchers believe that these patients form a heterogenous group with a variety of infectious and

non-infectious antecedents.^[29] They feel that chronic fatigue syndrome

does not represent a discrete disease with a singular cause, but rather a clinical condition. Chronic fatigue syndrome is analogous to a number of complex medical conditions such as hypertension in which a variety of direct and indirect factors lead to the development of the clinical syndrome.

The researchers hypothesize that in chronic fatigue syndrome, specific pathophysiological antecedents, such as acute infection, stress, and pre-existing or concurrent psychiatric illness, may ultimately converge in a final common biological pathway resulting in the clinical syndrome of chronic fatigue syndrome. They believe that their data and others suggest that a reduction in adrenal cortical secretion is an important pathophysiological component in the development of many of the biological and behavioral features of the syndrome.

For example, in one of their studies, 30 patients with classically defined chronic fatigue syndrome were compared with 72 normal volunteers and patients.^[30] The CFS patients were found to have significantly reduced evening cortisol levels and low 24 hour urinary free cortisol excretion. The CFS patients also had elevated basal ACTH concentrations and increased adrenal cortical sensitivity to ACTH, but a reduced maximal response, and showed attenuated net integrated ACTH response to corticotrophin-releasing hormone. These results are most compatible with a mild, central, adrenal insufficiency, secondary to either a deficiency of CRH or some other central stimulus to the pituitary–adrenal axis. The authors feel that the hyperresponsiveness of the adrenal cortex to ACTH in patients with chronic fatigue syndrome may reflect a secondary adrenal insufficiency in which adrenal ACTH receptors have become hypersensitive due to inadequate exposure to ACTH. The reduction in response to large doses of ACTH might suggest overall adrenal atrophy. The evidence suggests that the mild hypocortisolism in these patients reflects a defect at or above the level of the hypothalamus, resulting in deficiency in the release of CRH and/or other secretagogues that serve to activate the pituitary–adrenal axis.

Mind and attitude

The mind and attitude play a critical role in determining the status of the immune system and energy levels. Many patients with chronic fatigue (including CFS) are either depressed or just seem to have lost a sense of real enthusiasm for life. Of course, it is not easy to have a lot of enthusiasm when you do not have much energy. But the two usually go hand in hand.

The first step is to convey to CFS patients that they can get better. Many patients with CFS are told it is “something they will have to live with” and “there is no cure”. Achieving or maintaining a positive mental attitude is critical to good health and high energy levels, especially in patients with CFS. In order to achieve a positive mind, a person needs to

exercise or condition the attitude, similar to the way in which one would condition the body. In order to help patients, prescribe mental exercises such as visualizations, goal setting, affirmations, and empowering questions as detailed in [Chapter 126](#) .

Diet

Energy level appears to be directly related to the quality of the foods routinely ingested. Have patients adhere to the dietary guidelines given in [Chapter 44](#) . It is especially important to eliminate or restrict caffeine and refined sugar.

Although acute caffeine consumption provides stimulation, regular caffeine intake may actually lead to chronic fatigue. While mice fed one dose of caffeine demonstrated significant increases in their swimming capacity, when the dose of caffeine was given for 6 weeks, a significant decrease in swimming capacity was observed.^[31]

It is also interesting to note that several studies have found caffeine intake to be extremely high in individuals with psychiatric disorders. Another interesting finding is that the degree of fatigue experienced is often related to the quantity of caffeine ingested. In one survey of hospitalized psychiatric patients, 61% of those ingesting at least 750 mg/day (at least five cups of coffee) complained of fatigue, compared with 54% of those ingesting 250–749 mg/day, and only 24% of those ingesting less than 250 mg/day.^[32]

Be aware that in patients who routinely drink coffee, abrupt cessation of coffee drinking will probably result in symptoms of caffeine withdrawal, including fatigue, headache, and an intense desire for coffee.^[33] ^[34] Fortunately, this withdrawal period does not last more than a few days.

Nutritional supplements

Nutritional supplementation is essential in the treatment of chronic fatigue. A deficiency of virtually any nutrient can produce the symptoms of fatigue as well as render the body more susceptible to infection. Individuals with chronic fatigue require, at the bare minimum, a high potency multiple vitamin–mineral formula, along with extra vitamin C (3,000 mg/day in divided doses) and magnesium (500–1,200 mg/day in divided doses).

Magnesium

An underlying magnesium deficiency, even if subclinical, can result in chronic fatigue and symptoms similar to CFS. In addition, low red blood cell magnesium levels, a more accurate measure of magnesium status than

routine blood analysis, have been found in many patients with chronic fatigue and CFS.

Several studies have shown good results with magnesium supplementation.

For example, in one double-blind, placebo-controlled trial, 32 CFS patients received an intramuscular injection of either magnesium sulfate (1 g in 2 ml injectable water) or a placebo (2 ml injectable water) for 6 weeks. At the end of the study, 12 of the 15 patients receiving magnesium reported, based on strict criteria, significantly improved energy levels, better emotional state, and less pain. In contrast, only three of the 17 placebo patients reported that they felt better and only one reported improved energy levels.^[35]

This study seems to confirm some impressive results obtained in clinical trials during the 1960s on patients suffering from chronic fatigue.^{[36] [37] [38] [39]} These studies utilized oral magnesium and potassium aspartate (1 g each) rather than injectable magnesium. Between 75 and 91% of the nearly 3,000 patients studied experienced relief of fatigue during treatment with the magnesium and potassium aspartate. In contrast, the number of patients responding to a placebo was between 9 and 26%. The beneficial effect was usually noted after only 4–5 days, but sometimes 10 days were required. Patients usually continued treatment for 4–6 weeks; afterwards fatigue frequently did not return.

Injectable magnesium is not necessary to restore magnesium status.^[40] Absorption studies indicate that magnesium is easily absorbed orally when it is bound to aspartate or citrate. In addition, both of these compounds may also help fight off fatigue. Aspartate feeds into the Krebs cycle, the final common pathway for the conversion of glucose, fatty acids, and amino acids to chemical energy (ATP), while citrate is itself a component of the Krebs cycle. Krebs cycle components including aspartate, citrate, fumarate, malate, and succinate usually provide a better mineral chelate, as evidence suggests that minerals chelated to the Krebs cycle intermediates are better absorbed, utilized, and tolerated compared with inorganic or relatively insoluble mineral salts, including magnesium chloride, oxide, or carbonate.^{[40] [41]}

Other therapies

Breathing, posture, and bodywork

Proper care of the body is critical to high energy levels. Breathing with the diaphragm, good posture, and bodywork (massage, spinal manipulation, etc.) are all important in helping to relieve the stress that is a common contributor to fatigue.

Exercise

Exercise alone has been demonstrated to have a tremendous impact on improving mood and the ability to handle stressful life situations.^[42] Regular exercise has also been shown to lead to improved immune status. For CFS patients, regular exercise has been shown to lead to a significant increase (up to 100%) in natural killer cell activity.^{[43] [44]} Although more strenuous exercise is required to benefit the cardiovascular system, light to moderate exercise may be best for the immune system. One study found that immune function was significantly increased by the practice of t'ai chi exercises.^[45] T'ai

chi is a martial art technique which features the movement from one posture to the next in a flowing motion that resembles dance. The research thus far suggests that light to moderate exercise stimulates the immune system, while intense exercise (e.g. training for the Olympics) can have the opposite effect.^[46]

Botanical medicine

Eleutherococcus senticosus

In addition to supporting adrenal function and acting as a non-specific adaptogen, Siberian ginseng has been shown to exert a number of beneficial effects on immune function that may be useful in the treatment of CFS. In one double-blind study, 36 healthy subjects received either 10 ml of a fluid extract of *Eleutherococcus senticosus* or placebo daily for 4 weeks.^[47] The group receiving the Siberian ginseng demonstrated significant improvements in a variety of immune system parameters. Most notable were a significant increase in T-helper cells and an increase in natural killer cell activity – both of which are of value in the treatment of CFS.

Glycyrrhiza glabra

Considering the possible roles of viral infection and hypoadrenalism in CFS, licorice root with its antiviral and glucocorticoid potentiating properties (see [Ch. 90](#) for documentation of these properties) would seem to be an ideal botanical for this condition.^[48] Unfortunately, this has not been rigorously evaluated, although an excellent response in a single patient has been reported.^[49] The whole root must be used as DGL has had the glucocorticoid potentiating glycyrrhizic and glycyrrhetic acids removed.

THERAPEUTIC APPROACH

Successful treatment of CFS requires a comprehensive diagnostic and therapeutic approach. Especially important is identifying underlying factors which may be impacting energy levels or the immune system. The strong correlation between chronic fatigue syndrome, fibromyalgia and multiple chemical sensitivities suggests that all may respond to hepatic detoxification, food allergy control, and a gut restoration diet.^{[16] [17] [18]}
^[50] Special

attention should be paid to the advice on immune support in [Chapter 53](#) .

Diet

Identify and control food allergies. Increase the consumption of water while eliminating consumption of caffeine-containing drinks and alcohol. Strongly suggest a diet of whole, organically grown foods. Control hypoglycemia through the elimination of sugar and

other refined foods and the regular consumption of small meals and snacks. To speed the detoxification process, consider prescribing a course lasting for several weeks of a medical food replacement such as one of the UltraClear products.

Lifestyle

Teach the patient diaphragmatic breathing and a proper posture. Prescribe a regular exercise program; low intensity activities may produce greatest benefits.

Supplementation

- High potency multiple vitamin and mineral formula according to guidelines given in [Chapter 44](#)
- Vitamin C: 500–1,000 mg three times/day
- Vitamin E: 200–400 IU/day
- Thymus extract: 750 mg of the crude polypeptide fraction once or twice daily
- Magnesium bound to citrate or Krebs cycle intermediates: 200–300 mg three times/day
- Pantothenic acid: 250 mg/day.

Botanical medicines

- *Eleutherococcus senticosus*
 - dried root: 2–4 g
 - tincture (1:5): 10–20 ml
 - fluid extract (1:1): 2.0–4.0 ml
 - solid (dry powdered) extract (20:1 or standardized to contain greater than 1% eleutheroside E): 100–200 mg
- *Glycyrrhiza glabra*
 - powdered root: 1–2 g
 - fluid extract (1:1): 2–4 ml
 - solid (dry powdered) extract (4:1): 250–500 mg

Counseling

Either counsel the patient directly or refer him or her to a professional counselor to establish a regular pattern of mental, emotional, and spiritual affirmations.

Chapter 50 - Detoxification

Michael T. Murray ND
Joseph E. Pizzorno Jr ND

INTRODUCTION

The concepts of internal cleansing and detoxifying have been integral to naturopathic philosophy since the profession's inception over a century ago. The problem of "toxicity" has grown as the number and quantity of poisonous compounds in the air, water, and food have increased. A substantial and growing body of research now supports the significant impact on health of acute and chronic exposure to endogenous and exogenous toxins and the efficacy of an individual's detoxification mechanisms (see [Ch. 37](#)).

Toxins damage the body in an insidious and cumulative way. Once the detoxification system becomes overloaded, toxic metabolites accumulate, and sensitivity to other chemicals, some of which are not normally toxic, becomes progressively greater. This accumulation of toxins can wreak havoc on normal metabolic processes.

This chapter identifies "toxins" and natural ways to support their detoxification and elimination, with particular focus on enhancing the function of the liver, the body's primary organ for neutralization of undesirable chemicals.

TOXINS

A toxin is defined as any compound that has a detrimental effect on cell function or structure. The discussion of toxins in this chapter is organized into the four areas:

- heavy metals
- chemical toxins
- microbial compounds
- breakdown products of protein metabolism.

Heavy metals

The heavy metals most commonly causing problems in humans are:

- lead
 - mercury
 - cadmium
-

438

- arsenic
- nickel
- aluminum.

These metals tend to accumulate within the brain, kidneys, and immune system where they can severely disrupt normal function.^{[1] [2] [3] [4] [5] [6]} It is conservatively estimated that up to 25% of the US population suffer to some extent from heavy metal poisoning. Hair mineral analysis is a good screening test for heavy metal toxicity (see [Ch. 18](#)).^[1]

Most of the heavy metals in the body are a result of environmental contamination due to industry. For example, in the United States alone, industrial sources contribute more than 600,000 tons/year of lead into the atmosphere to be inhaled or – after being deposited on food crops, in fresh water, and soil – to be ingested.^[1]

Common sources of heavy metals, in addition to industrial sources, include lead from the solder in tin cans and copper pipes, pesticide sprays, and cooking utensils; cadmium and lead from cigarette smoke; mercury from dental fillings, contaminated fish, latex paints and cosmetics; and aluminum from antacids and cookware.^[1] Some professions with extremely high exposure include battery makers, gasoline station attendants, printers, roofers, solderers, dentists, and jewelers.^[1] Unfortunately, arsenic and mercury have now also been found as contaminants or intentional additions to imported Chinese and Ayurvedic herbal medicines.

Early signs of heavy metal poisoning are vague or associated with other problems. Early symptoms can include:

- headache
- fatigue
- muscle pains
- indigestion
- tremors
- constipation
- anemia
- pallor
- dizziness

- poor coordination.

The person with even mild heavy metal toxicity will experience impaired ability to think or concentrate. As toxicity increases, so do the severity of signs and symptoms.^{[1] [2] [3] [4] [5] [6]}

Numerous studies have demonstrated a strong relationship between childhood learning disabilities (and other disorders including criminal behavior) and body stores of heavy metals, particularly lead^{[7] [8] [9] [10] [11] [12]} (see [Ch. 135](#)).

Chemical toxicants

This category of toxins, primarily dealt with by the liver, includes:

- toxic chemicals
- solvents, e.g. cleaning materials, formaldehyde, toluene, benzene, etc.
- drugs
- alcohol
- formaldehyde
- pesticides
- herbicides
- food additives.

Exposure or toxicity to toxic chemicals can give rise to a number of symptoms. Most common are psychological and neurological symptoms such as depression, headaches, mental confusion, mental illness, paresthesia, abnormal nerve reflexes, and other signs of impaired nervous system function. Respiratory tract allergies and increased rates for many cancers are also found in people chronically exposed to chemical toxins.^{[13] [14] [15] [16] [17] [18] [19]}

Microbial compounds

The waste products and cellular debris from bacteria and yeast in the gut can be absorbed, causing significant disruption of body functions. Examples include:

- endotoxins
- exotoxins
- toxic amines
- toxic derivatives of bile
- various carcinogenic substances.

Gut-derived microbial toxins have been implicated in a wide variety of diseases, including liver diseases, Crohn's disease, ulcerative colitis, thyroid disease, psoriasis, lupus erythematosus, pancreatitis, allergies, asthma, and immune disorders.

In addition to toxic substances being produced by microorganisms, antibodies formed against microbial antigens can cross-react with the body's own tissues, thereby causing

autoimmunity. The list of autoimmune diseases which have been linked to cross-reacting antibodies includes rheumatoid arthritis, myasthenia gravis, diabetes, pernicious anemia, and autoimmune thyroiditis.

The immune system and the liver are responsible for dealing with the toxic substances that are absorbed from the gut.

Breakdown products of protein metabolism

The end-products of protein metabolism – ammonia, urea, etc. – cause significant problems if allowed to accumulate. Most are eliminated by the kidneys.

DETOXIFICATION MECHANISMS

The body eliminates toxins either by directly neutralizing them or by excreting them in the urine or feces (and to

TABLE 50-1 -- Major detoxification systems

| Organ | Method | Typical toxin neutralized |
|--------------|-------------------------|---|
| Skin | Excretion through sweat | Fat-soluble toxins such as DDT and heavy metal such as lead and mercury |

| | | |
|------------|-------------------------|--|
| Liver | Filtering of the blood | Bacteria and bacterial products, immune complexes |
| | Bile secretion | Cholesterol, hemoglobin breakdown products, extra calcium |
| | Phase I detoxification | Many prescription drugs (e.g. amphetamine, digitalis, pentobarbital), many over-the-counter drugs (acetaminophen, ibuprofen), caffeine, histamine, hormones (both internally produced and externally supplied), benzopyrene (carcinogen from charcoal-broiled meat), aniline (the yellow dyes), carbon tetrachloride, insecticides (e.g. Aldrin, Heptachlor), arachidonic acid |
| | Phase II detoxification | |
| | Glutathione conjugation | Acetaminophen, nicotine from cigarette smoke, organophosphates (insecticides), epoxides (carcinogens) |
| | Amino acid conjugation | Benzoate (a common food preservative), aspirin |
| | Methylation | Dopamine (neurotransmitter), epinephrine (hormone from adrenal gland), histamine, thiouracil (cancer drug) |
| | Sulfation | Estrogen, aniline dyes, coumarin (blood thinner), acetaminophen, methyl-dopa (used for Parkinson's disease) |
| | Acetylation | Sulfonamides (antibiotics), mescaline |
| | Glucuronidation | Acetaminophen, morphine, diazepam (sedative, muscle relaxant), digitalis |
| | Sulfoxidation | Sulfites, garlic compounds |
| Intestines | Mucosal detoxification | Toxins from bowel bacteria |
| | Excretion through feces | Fat-soluble toxins excreted in the bile |
| Kidneys | Excretion through urine | Many toxins, after they are made water-soluble by the liver |

a lesser degree from the mucous membranes, lungs and skin). Toxins that the body is unable to eliminate build up in the tissues, typically in the fat stores and bone. The liver, intestines, and kidneys are the primary organs of detoxification (see [Table 50.1](#)).

EXPOSURE DIAGNOSIS

Both recognition of exposure and assessment of the efficacy of the detoxification mechanisms are essential for effective detoxification of the patient. Exposure

assessment is discussed here, while description of assessment of liver detoxification efficacy is integrated into the discussion of the liver's detoxification pathways.

While an accurate and exhaustive history and physical examination will probably always be the mainstay of diagnosis of toxin exposure and build-up, a number of useful laboratory techniques have been developed for detecting toxins in the body.

Heavy metal assessment

For heavy metals, the most reliable measure of chronic exposure is the hair mineral analysis. Reliable results of hair analysis is dependent upon (1) a properly collected, cleaned, and prepared sample of hair, and (2) the test being performed by experienced personnel using appropriate analytical methods in a qualified laboratory. This procedure is discussed thoroughly in [Chapter 18](#).

Chemical exposure

For determining exposure to toxic chemicals, a detailed medical history is essential. When appropriate, the laboratory analysis for this group of toxins can involve measuring blood and fatty tissue for suspected chemi-cals. [Table 50.2](#) lists common indications for suspecting chemical exposure.

Recently, innovative laboratory assessment methodologies for the assessment of chemical exposure have become commercially available. Perhaps the most promising is urinary organic acid analysis. Traditionally only used to assess and define inborn errors of metabolism that cause death within the first year of life or severe mental retardation, metabolic profiling has now become useful for identifying enzyme impairment due not only to genetic diseases but also to nutritional deficiencies and chemical poisoning (see [Ch. 29](#) for a full discussion of this useful methodology).

TABLE 50-2 -- Common indications for suspecting chemical exposure

| |
|---|
| • More than 20 pounds overweight |
| • Diabetes |
| • Presence of gallstones |
| • History of heavy alcohol use |
| • Psoriasis |
| • Natural and synthetic steroid hormone use |
| —anabolic steroids |
| —estrogens |
| —oral contraceptives |
| • High exposure to certain chemicals or drugs |
| —cleaning solvents |

—pesticides

—antibiotics

—diuretics

—non-steroidal anti-inflammatory drugs

—thyroid hormone

- History of viral hepatitis
-

Microbial compounds

A number of laboratory techniques are available to determine the presence of microbial compounds. Those most commonly used include tests for the presence of abnormal microbial concentrations and disease-causing organisms in the stool (see [Ch. 9](#)), microbial by-products (see [Ch. 31](#)), endotoxins (erythrocyte sedimentation rate is a rough estimator), and bacterial overgrowth in the small intestine (see [Ch. 7](#)).

Breakdown products of protein metabolism

The determination of the presence of high levels of breakdown products of protein metabolism and kidney function involves both blood and urine measurement of these compounds (see [Ch. 31](#)).

LIVER DETOXIFICATION

Overview

The liver is a complex organ that plays a key role in most metabolic processes, especially detoxification. The liver neutralizes a wide range of toxic chemicals, both those produced internally and those coming from the environment. The normal metabolic processes produce a wide range of chemicals and hormones for which the liver has evolved efficient neutralizing mechanisms. However, the level and type of internally produced toxins increases greatly when metabolic processes go awry, typically as a result of nutritional deficiencies. These non-end-product metabolites have become a significant problem in this age of conventionally grown foods and poor diets (see [Ch. 108](#)).

Many of the toxic chemicals the liver must detoxify come from the environment: the content of the bowels and the food, water, and air. The polycyclic hydrocarbons (e.g. DDT, dioxin, 2,4,5-T; 2,4-D, PCB, and PCP), which are components of various herbicides and pesticides, are one example of chemicals that are now found in virtually all adipose tissues measured. Even those eating unprocessed organic foods need an

effective detoxification system because all foods contain naturally occurring toxic constituents.

The liver plays several roles in detoxification: it filters the blood to remove large toxins, synthesizes and secretes bile full of cholesterol and other fat-soluble toxins, and enzymatically disassembles unwanted chemicals. This enzymatic process usually occurs in two steps referred to as phase I and phase II. Phase I either directly neutralizes a toxin, e.g. caffeine, or modifies the toxic chemical to form activated intermediates which are then neutralized by one or more of the several phase II enzyme systems. These processes are summarized in [Figure 50.1](#) .

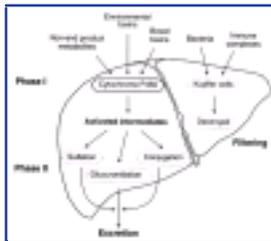

Figure 50-1 The liver's detoxification pathways.

Proper functioning of the liver's detoxification systems is especially important for the prevention of cancer. Up to 90% of all cancers are thought to be due to the effects of environmental carcinogens, such as those in cigarette smoke, food, water, and air, combined with deficiencies of the nutrients the body needs for proper functioning of the detoxification and immune systems. The level of exposure to environmental carcinogens varies widely, as does the efficiency of the detoxification enzymes, particularly phase II. High levels of exposure to carcinogens coupled with slow detoxification enzymes significantly increases susceptibility to cancer.

The link between the detoxification system's effectiveness and susceptibility to environmental toxins, such as carcinogens, is exemplified in a study in Italy of Turin chemical plant workers who had an unusually high rate of bladder cancer. When the liver detoxification enzyme activity of all the workers was tested, those with the most dysfunctional detoxification system were the ones who developed bladder cancer.^[20]

Filtering the blood

One of the liver's primary functions is filtering the blood. Almost 2 quarts of blood pass through the liver every minute for detoxification. Filtration of toxins is absolutely critical as the blood from the intestines contains high levels of bacteria, bacterial endotoxins, antigen-antibody complexes, and various other toxic substances. When working properly, the liver clears 99% of the bacteria and other toxins during the first pass. However, when the liver is damaged, such as in alcoholics, the passage of toxins increases by over a factor of 10.

Bile excretion

The liver's second detoxification process involves the synthesis and secretion of bile. Each day the liver manufactures approximately 1 quart of bile, which serves as a carrier in which many toxic substances are dumped into the intestines. In the intestines, the bile and its toxic load are absorbed by fiber and excreted. However, a diet low in fiber results in inadequate binding and reabsorption of the toxins. This problem is magnified when bacteria in the intestine modify these toxins to more damaging forms.

Phase I detoxification

The liver's third role in detoxification typically involves a two-step enzymatic process for the neutralization of unwanted chemical compounds ([Table 50.3](#)). These not only include drugs, pesticides, and toxins from the gut, but also normal body chemicals such as hormones and inflammatory chemicals (e.g. histamine) which become toxic if allowed to build up. Phase I enzymes directly neutralize some chemicals, but most are converted to intermediate forms that are then processed by phase II enzymes. These intermediate forms are much more chemically active and therefore more toxic. If the phase II detoxification systems are not working adequately, these intermediates can cause substantial damage, including the initiation of carcinogenic processes.

Phase I detoxification of most chemical toxins involves a group of enzymes which, collectively, have been named cytochrome P450. Some 50–100 enzymes make up the

cytochrome P450 system. Each enzyme works best in detoxifying certain types of chemicals, but with considerable overlap in activity among the enzymes.

The activity of the various cytochrome P450 enzymes varies significantly from one individual to another, based on genetics, the individual's level of exposure to chemical toxins, and his or her nutritional status. Since the activity of cytochrome P450 varies so much, so does an individual's risk for various diseases. For example, as highlighted in the study of chemical plant workers in Turin discussed above, those with underactive cytochrome P450 are more susceptible to cancer.^[21] This variability of cytochrome P450 enzymes is also seen in the variability of people's ability to detoxify the carcinogens found in cigarette smoke and helps to explain why some people can smoke with only modest damage to their lungs, while others develop lung cancer after only a few decades of smoking.

Patients with underactive phase I detoxification will experience caffeine intolerance, intolerance to perfumes and other environmental chemicals, and an increased risk for liver disease, while those with an overactive system will be relatively unaffected by caffeine drinks. One way of objectively determining the activity of phase I is to measure how efficiently a person detoxifies caffeine. Using this test, a surprising fivefold difference in the detoxification rates of apparently healthy adults has been discovered.^[22]

When cytochrome P450 metabolizes a toxin, it chemically transforms it to a less toxic form, makes it water-soluble, or converts it to a more chemically active form. Caffeine is an example of a chemical directly neutralized by phase I. Making a toxin water-soluble allows its ex-cretion by the kidneys. Transforming a toxin to a more chemically reactive form makes it more easily metabolized by the phase II enzymes.

A significant side-effect of phase I detoxification is the production of free radicals as the toxins are transformed – for each molecule of toxin metabolized by phase I, one

molecule of free radical is generated. Without adequate free radical defenses, every time the liver neutralizes a toxin exposure, it is damaged by the free radicals produced.

The most important antioxidant for neutralizing the free radicals produced in phase I is glutathione. In the process of neutralizing free radicals, however, glutathione (GSH) is oxidized to glutathione disulfide (GSSG). Glutathione is required for one of the key phase II detoxification processes. When high levels of toxin exposure produce so many free radicals from phase I detoxification that the glutathione is depleted, the phase II processes dependent upon glutathione stop.

Another potential problem occurs because the toxins transformed into activated intermediates by phase I are substantially more reactive. Unless quickly removed from the body by phase II detoxification mechanisms,

442

they can cause widespread problems, especially carcinogenesis. Therefore, the rate at which phase I produces activated intermediates must be balanced by the rate at which phase II finishes their processing. People with a very active phase I detoxification system coupled with slow or inactive phase II enzymes are termed “pathological detoxifiers”. These people suffer unusually severe toxic reactions to environmental poisons.

An imbalance between phase I and phase II can also occur when a person is exposed to large amounts of toxins or exposed to toxins for a long period of time. In these situations, the critical nutrients needed for phase II detoxification are depleted, which allows the highly toxic activated intermediates to build up.

Recent research shows that the cytochrome P450 enzyme systems are also found in other parts of the body, especially the brain cells. Inadequate antioxidants and nutrients in the brain result in an increased rate of neuron damage, such as seen in Alzheimer’s and Parkinson’s disease patients.

As with all enzymes, the cytochrome P450s require several nutrients, listed in [Table 50.4](#), in order to function.

A considerable amount of research has found that

TABLE 50-4 -- Nutrients needed by phase I detoxification

various substances activate cytochrome P450 (see [Table 50.5](#)) while other substances inhibit it (see [Table 50.6](#)).

Inducers of phase I detoxification

Cytochrome P450 is induced by some toxins and by some foods and nutrients. Obviously, it is beneficial to improve phase I detoxification in order to eliminate toxins as soon as possible. This is best accomplished by providing the needed nutrients and non-toxic stimulants while avoiding those substances that are toxic. However, stimulation of phase I is contraindicated if the patient's phase II systems are underactive.

All of the drugs and environmental toxins listed in [Table 50.5](#) activate P450 to combat their destructive effects, and in so doing, not only use up compounds needed for this detoxification system but contribute significantly to free radical formation and oxidative stress.

Among foods, the brassica family, i.e. cabbage, broccoli, and brussels sprouts, contains chemical constituents that stimulate both phase I and phase II detoxification enzymes. One such compound is indole-3-carbinol, which is also a powerful anti-cancer chemical. It is a very active stimulant of detoxifying enzymes in the gut as well as the liver.^[23] The net result is significant protection against several toxins, especially carcinogens. This helps to explain why consumption of cabbage family vegetables protects against

cancer.

Oranges and tangerines (as well as the seeds of caraway and dill) contain limonene, a phytochemical that has been found to prevent and even treat cancer in animal models.^[24] Limonene's protective effects are probably due to the fact that it is a strong inducer of both phase I and phase II detoxification enzymes that neutralize carcinogens.

Inhibitors of phase I detoxification

Many substances inhibit cytochrome P450. This situation can cause substantial problems as it makes toxins potentially more damaging because they remain in the body longer before detoxification. For example, grapefruit juice decreases the rate of elimination of drugs from the blood and has been found to substantially alter their clinical activity and toxicity.^[25] Eight ounces of grapefruit juice contains enough of the flavonoid naringenin to decrease cytochrome P450 activity by a remarkable 30%. The common inhibitors of phase I detoxification are listed in [Table 50.6](#).

Curcumin, the compound that gives turmeric its yellow color, is interesting because it inhibits phase I while stimulating phase II. This effect can be very useful in preventing certain types of cancer. Curcumin has been found to inhibit carcinogens, such as benzopyrene (the carcinogen found in charcoal-broiled meat), from inducing cancer in several animal models. It appears that the curcumin exerts its anti-carcinogenic activity by lowering the activation of carcinogens while increasing the detoxification of those that are activated. Curcumin has also been shown to directly inhibit the growth of cancer cells.^[26]

As most of the cancer-inducing chemicals in cigarette smoke are only carcinogenic during the period between activation by phase I and final detoxification by phase II, curcumin in the turmeric can help to prevent the cancer-causing effects of tobacco. In one human study, 16 chronic smokers were given 1.5 g/day of turmeric while six non-smokers served as a control group.^[27] At the end of the 30 day trial, the smokers receiving the turmeric demonstrated significant reduction in the level of mutagens excreted in the urine. These results are quite significant as the level of urinary mutagens is thought to correlate with the systemic load of carcinogens and the efficacy of detoxification mechanisms. Those exposed to smoke, aromatic hydrocarbons, and other environmental carcinogens will probably benefit from the frequent use of curry or turmeric.

The activity of phase I detoxification enzymes decreases in old age. Aging also decreases blood flow through the liver, further aggravating the problem. Lack of the physical activity necessary for good circulation combined with the poor nutrition commonly seen in the elderly add up to a significant impairment of detoxification capacity, which is typically found in aging individuals. This helps to explain why toxic

reactions to drugs are seen so commonly in the elderly.

Phase II detoxification

Phase II detoxification typically involves conjugation in which various enzymes in the liver attach small chemicals to the toxin. This conjugation reaction either neutralizes the toxin or makes the toxin more easily excreted through the urine or bile. Phase II enzymes act on some toxins directly, while others must first be activated by the phase I enzymes. There are essentially six phase II detoxification pathways:

- glutathione conjugation
- amino acid conjugation
- methylation
- sulfation
- acetylation
- glucuronidation.

[Table 50.1](#) provides examples of toxins neutralized by each of these pathways. Some toxins are neutralized through several pathways.

In order to work, these enzyme systems need nutrients both for their activation and to provide the small molecules they add to the toxins. In addition, they utilize metabolic energy to function and to synthesize some of the small conjugating molecules. Thus, mitochondrial dysfunction, such as found in chronic fatigue syndrome, a magnesium deficiency or physical inactivity, can cause phase II detoxification to slow down, allowing the build-up of toxic intermediates. [Table 50.7](#) lists the key nutrients needed by each of the six phase II detoxification systems. [Table 50.8](#) lists the activators and [Table 50.9](#) the inhibitors of phase II enzymes.

Glutathione conjugation

A primary phase II detoxification route is conjugation with glutathione (a tripeptide composed of three amino

TABLE 50-7 -- Nutrients needed by phase II detoxification enzymes

| Phase II system | Required nutrients |
|-------------------------|-------------------------------------|
| Glutathione conjugation | Glutathione, vitamin B ₆ |
| Amino acid conjugation | Glycine |

| Laboratory assessment | Acetaminophen clearance shows low urine acetaminophen mercaptates |

acids – cysteine, glutamic acid, and glycine) ([Table 50.10](#)). Glutathione conjugation produces water-soluble mercaptates which are excreted via the kidneys. The elimination of fat-soluble compounds, especially heavy metals like mercury and lead, is dependent upon adequate levels of glutathione, which in turn is dependent upon adequate levels of methionine and cysteine.

When increased levels of toxic compounds are present, more methionine is utilized for cysteine and glutathione synthesis. Methionine and cysteine have a protective effect on glutathione and prevent depletion during toxic overload. This, in turn, protects the liver from the damaging effects of toxic compounds and promotes their elimination.

Glutathione is also an important antioxidant. This combination of detoxification and free radical protection results in glutathione being one of the most important anticarcinogens and antioxidants in our cells, which means that a deficiency is cause of serious liver dysfunction and damage.^[28]

Exposure to high levels of toxins depletes glutathione faster than it can be produced or absorbed from the diet. This results in increased susceptibility to toxin-induced diseases, such as cancer, especially if phase I detoxification system is highly active.^[29]

Disease states due to glutathione deficiency are not uncommon. A deficiency can be induced either by diseases that increase the need for glutathione, deficiencies of the nutrients needed for synthesis, or diseases that inhibit its formation. For example, patients with idiopathic pulmonary fibrosis, adult respiratory distress syndrome, HIV infection, hepatic cirrhosis, cataract formation, and advanced AIDS have been found to have a deficiency of glutathione, probably due to their greatly increased need for glutathione, both as an antioxidant and for detoxification.^[30] Smoking increases the rate of utilization of glutathione, both in the detoxification of nicotine and in the neutralization of free radicals produced by the toxins in the smoke.

Glutathione is available through two routes: diet and synthesis. Dietary glutathione (found in fresh fruits and vegetables, cooked fish, and meat) is absorbed well by the intestines and does not appear to be affected by the digestive processes. Dietary glutathione in foods appears to be efficiently absorbed into the blood.^[31] However, the same may not be true for glutathione supplements.

In one study, seven healthy subjects were given a single dose of up to 3,000 mg of

glutathione. Blood values indicated that the concentration of glutathione did not increase significantly, suggesting the systemic availability of a single dose of up to 3,000 mg of glutathione is negligible.^[32] The authors of the study concluded: "It is not feasible to increase circulating glutathione to a clinically beneficial extent by the oral administration of a single dose of 3 g of glutathione."^[32]

In contrast, in healthy individuals, a daily dosage of 500 mg of vitamin C may be sufficient to elevate and maintain good tissue glutathione levels. In one double-blind study, the average red blood cell glutathione concentration rose nearly 50% with 500 mg/day of vitamin C.^[33] Increasing the dosage to 2,000 mg only raised RBC glutathione levels by another 5%.

Vitamin C raises glutathione by increasing its rate of synthesis. In addition, to vitamin C, other compounds which can help increase glutathione synthesis include *N*-acetylcysteine (NAC), glycine, and methionine.

In an effort to increase antioxidant status in individuals with impaired glutathione synthesis, a variety of antioxidants have been used. Of these agents, only vitamin C and NAC have been able to offer some possible benefit. To determine the relative effectiveness of vitamin C vs. NAC, a 45-month-old girl with an inherited deficiency of glutathione synthesis was followed before and during treatment with vitamin C or NAC. High doses of vitamin C (500 mg/day or 3 g/day) or NAC (800 mg/day) were given for 1–2 weeks. Measurements of glutathione (GSH) levels indicated that 3 g/day of vitamin C increased white blood cell GSH fourfold and plasma GSH levels eightfold. NAC also increased white blood cell (3.5-fold) and plasma (two- to fivefold) GSH. Based on these results, it was decided that vitamin C would be given for 1 year at the 3 g/day dosage. At the end of a year, glutathione levels remained elevated and the hematocrit increased from a baseline 25.4 to 32.6% and the reticulocyte

count decreased from 11 to 4%. These results indicate that vitamin C can decrease cellular damage in patients with hereditary glutathione deficiency and is more effective than the more expensive NAC.^[34]

Over the past 5–10 years the use of NAC and glutathione products as antioxidants has become increasingly popular among nutritionally oriented physicians and the public. While supplementing the diet with high doses of NAC may be beneficial in cases of extreme oxidative stress (e.g. AIDS, cancer patients going through chemotherapy, or drug overdose), it may be an unwise practice in healthy individuals. One study indicated that when NAC was given orally to six health volunteers at a dosage of 1.2 g/day for 4 weeks, followed by 2.4 g/day for an additional 2 weeks, it actually increased oxidative damage by acting as a pro-oxidant.^[35] Compared with controls, the concentration of glutathione in NAC-treated subjects was reduced by 48% and the concentration of oxidized glutathione was 80% higher. Oxidative stress increased by 83% in those

receiving NAC.

Amino acid conjugation

Several amino acids (glycine, taurine, glutamine, arginine, and ornithine) are used to combine with and neutralize toxins ([Table 50.11](#)). Of these, glycine is the most commonly utilized in phase II amino acid detoxification. Patients suffering from hepatitis, alcoholic liver disorders, carcinomas, chronic arthritis, hypothyroidism, toxemia of pregnancy, and excessive chemical exposure are commonly found to have a poorly functioning amino acid conjugation system. For example, using the benzoate clearance test (a measure of the rate at which the body detoxifies benzoate by conjugating it with glycine to form hippuric acid, which is excreted by the kidneys), the rate of clearance in those with liver disease is 50% of that in healthy adults.^[36]

Even in apparently normal adults, a wide variation exists in the activity of the glycine conjugation pathway. This is due not only to genetic variation, but also to the availability of glycine in the liver. Glycine and the other amino acids used for conjugation become deficient on a low-protein diet and when chronic exposure to toxins results in depletion.

TABLE 50-11 -- Phase II amino acid conjugation

| Inhibitors | Folic acid or vitamin B ₁₂ deficiency |
| Clinical indicators of dysfunction | Premenstrual syndrome, estrogen excess, cholestasis, OCA use |
| Laboratory assessment | |

Methylation

Methylation involves conjugating methyl groups to toxins ([Table 50.12](#)). Most of the methyl groups used for detoxification come from S-adenosylmethionine (SAM). SAM is synthesized from the amino acid methionine, a process which requires the nutrients choline, vitamin B₁₂ , and folic acid.

SAM is able to inactivate estrogens (through methylation), supporting the use of methionine in conditions of estrogen excess, such as PMS. Its effects in preventing estrogen-induced cholestasis (stagnation of bile in the gall bladder) have been demonstrated in pregnant women and those on oral contraceptives.^[37] In addition to its role in promoting estrogen excretion, methionine has been shown to increase the membrane fluidity that is typically decreased by estrogens, thereby restoring several factors that promote bile flow. Methionine also promotes the flow of lipids to and from the liver in humans. Methionine is a major source of numerous sulfur-containing compounds, including the amino acids cysteine and taurine.

Sulfation

Sulfation is the conjugation of toxins with sulfur-containing compounds ([Table 50.13](#)). The sulfation system is important for detoxifying several drugs, food additives, and, especially, toxins from intestinal bacteria and the environment.

In addition to environmental toxins, sulfation is also used to detoxify some normal body chemicals and is the main pathway for the elimination of steroid and thyroid

TABLE 50-13 -- Phase II sulfation

| | |
|------------------------------------|---|
| Detoxifies | Aniline dyes, coumarin, acetaminophen, methyl-dopa, estrogen, testosterone, thyroid |
| Nutrients needed | Cysteine, methionine, molybdenum |

| Laboratory assessment | Acetaminophen clearance shows low urine acetaminophen sulfates |

hormones. Since sulfation is also the primary route for the elimination of neurotransmitters, dysfunction in this system may contribute to the development of some nervous system disorders.

Many factors influence the activity of sulfate conjugation. For example, a diet low in methionine and cysteine has been shown to reduce sulfation.^[38] Sulfation is also reduced by excessive levels of molybdenum or vitamin B₆ (over about 100 mg/day).^[39] In some cases, sulfation can be increased by supplemental sulfate, extra amounts of sulfur-containing foods in the diet, and the amino acids taurine and glutathione.

Acetylation

Conjugation of toxins with acetyl-CoA is the primary method by which the body eliminates sulfa drugs ([Table 50.14](#)). This system appears to be especially sensitive to genetic variation, with those having a poor acetylation system being far more susceptible to sulfa drugs and other antibiotics. While not much is known about how to directly improve the activity of this system, it is known that acetylation is dependent on thiamin, pantothenic acid, and vitamin C.^[40]

Glucuronidation

Glucuronidation, the combining of glucuronic acid with toxins, requires the enzyme UDP-glucuronyl transferase (UDPGT) ([Table 50.15](#)). Many of the commonly prescribed drugs are detoxified through this pathway. It also helps to detoxify aspirin, menthol, vanillin (synthetic vanilla), food additives such as benzoates, and some hormones. Glucuronidation appears to work well, except for those with Gilbert's syndrome – a relatively common syndrome characterized by a chronically elevated serum

TABLE 50-14 -- Phase II acetylation

| Laboratory assessment | Acetaminophen clearance shows low urine acetaminophen glucuronide |

bilirubin level (1.2–3.0 mg/dl). Previously considered rare, this disorder is now known to affect as much as 5% of the general population. The condition is usually without serious symptoms, although some patients do complain about loss of appetite, malaise, and fatigue (typical symptoms of impaired liver function). The main way this condition is recognized is by a slight yellowish tinge to the skin and white of the eye due to inadequate metabolism of bilirubin, a breakdown product of hemoglobin.

The activity of UDPGT is increased by foods rich in the monoterpene limonene (citrus peel, dill weed oil, and caraway oil). Methionine administered as SAM has been shown to be quite beneficial in treating Gilbert's syndrome.^[41]

Sulfoxidation

Sulfoxidation is the process by which the sulfur-containing molecules in drugs (such as chlorpromazine) and foods (such as garlic) are metabolized ([Table 50.16](#)). It is also the process by which the body eliminates the sulfite food additives used to preserve many foods and drugs. Various sulfites are widely used in potato salad (as a preservative), salad bars (to keep the vegetable looking fresh), dried fruits (sulfites keep dried apricots orange), and some drugs (such as those used in the past for asthma). Normally, the enzyme sulfite oxidase metabolizes sulfites to safer sulfates, which are then excreted in the urine. Those with a poorly functioning sulfoxidation system, however, have an increased ratio of sulfite to sulfate in their urine.

The strong odor in the urine after eating asparagus is an interesting phenomenon because, while it is unheard of in China, 100% of the French have been estimated to experience such an odor (about 50% of adults in the US notice this effect). This situation is an excellent example of genetic variability in liver detoxification function.

Those with a poorly functioning sulfoxidation detoxification pathway are more sensitive to sulfur-containing drugs and foods containing sulfur or sulfite additives. This is especially important for asthmatics, who can react to these additives with life-threatening attacks. Dr Jonathan Wright discovered several years ago that providing molybdenum to asthmatics with an elevated

TABLE 50-16 -- Sulfoxidation

| | |
|------------------|--|
| Detoxifies | Sulfites, garlic compounds, chlorpromazine |
| Nutrients needed | Molybdenum |
| Activators | Molybdenum |

| | |
|------------------------------------|---|
| Clinical indicators of dysfunction | Adverse reactions to sulfite food additives, garlic; asthma reactions after eating at a restaurant; eating asparagus results in a strong urine odor |
| Laboratory assessment | Elevated urine sulfite/sulfate ratio |

ratio of sulfites to sulfates in their urine resulted in a significant improvement in their condition. Molybdenum helps because sulfite oxidase is dependent upon this trace mineral. Although most nutrition textbooks believe it to be an uncommon deficiency, an Austrian study of 1,750 patients found that 41.5% were molybdenum-deficient.^[42]

Bile excretion

One of the primary routes for the elimination of modified toxins is through the bile. However, when the excretion of bile is inhibited (i.e. cholestasis), toxins stay in the liver longer. Cholestasis has several causes, including obstruction of the bile ducts and impairment of bile flow within the liver. The most common cause of obstruction of the bile ducts is the presence of gallstones. Currently, it is conservatively estimated that 20 million people in the US have gallstones. Nearly 20% of the female and 8% of the male population over the age of 40 are found to have gallstones on biopsy and approximately 500,000 gall bladders are removed because of stones each year in the US. The prevalence of gallstones in this country has been linked to the high-fat, low-fiber diet consumed by the majority of Americans.

Impairment of bile flow within the liver can be caused by a variety of agents and conditions, as listed in [Table 50.17](#). These conditions are often associated with alterations of liver function in laboratory tests (serum bilirubin, alkaline phosphatase, SGOT, LDH, GGTP, etc.) signifying cellular damage. However, relying on these tests alone to evaluate liver function is not adequate, since, in the initial or subclinical stages of many problems with liver function, laboratory values remain normal. Among the symptoms people with enzymatic damage may complain of are:

- fatigue
- general malaise
- digestive disturbances
- allergies and chemical sensitivities
- premenstrual syndrome
- constipation.

TABLE 50-17 -- Causes of cholestasis

- Presence of gallstones

- Alcohol

- Endotoxins

- Hereditary disorders such as Gilbert's syndrome

- Hyperthyroidism or thyroxine supplementation

- Viral hepatitis

- Pregnancy

- Certain chemicals or drugs
 - natural and synthetic steroidal hormones: anabolic steroids, estrogens, oral contraceptives

 - aminosalicylic acid

 - chlorothiazide

 - erythromycin estolate

 - mepazine

 - phenylbutazone

 - sulphadiazine

 - thiouracil

Perhaps the most common cause of cholestasis and impaired liver function is alcohol ingestion. In some especially sensitive individuals, as little as 1 ounce of alcohol can produce damage to the liver, which results in fat being deposited within the liver. All active alcoholics demonstrate fatty infiltration of the liver.

Methionine administered as SAM has been shown to be quite beneficial in treating two common causes of stagnation of bile in the liver – estrogen excess (due to either oral contraceptive use or pregnancy) and Gilbert's syndrome.^{[41] [43]}

Liver detoxification support

Nutritional factors

Antioxidant vitamins like vitamin C, beta-carotene, and vitamin E are obviously quite important in protecting the liver from damage as well as helping in the detoxification mechanisms, but even simple nutrients like B vitamins, calcium, and trace minerals are critical in the elimination of heavy metals and other toxic compounds from the body.^{[44] [45] [46]}

The lipotropic agents, choline, betaine, methionine, vitamin B₆, folic acid, and vitamin B₁₂, are useful as they promote the flow of fat and bile to and from the liver. Lipotropic

formulas have been used for a wide variety of conditions by nutrition-oriented physicians including a number of liver disorders such as hepatitis, cirrhosis, and chemical-induced liver disease.

Lipotropic formulas appear to increase the levels of SAM and glutathione. Although SAM is not currently available in the United States, methionine, choline, and betaine have been shown to increase the levels of SAM.^[47] ^[48] ^[49]

Botanical medicines

There is a long list of plants which exert beneficial effects on liver function. However, the most impressive research has been done on silymarin, the flavonoids extracted from *Silybum marianum* (milk thistle). These compounds exert a substantial effect on protecting the liver from damage as well as enhancing detoxification processes. Silymarin prevents damage to the liver through several mechanisms: by acting as an antioxidant, by increasing the synthesis of glutathione and by increasing the rate of liver tissue regeneration.^[50] ^[51] ^[52]

Silymarin is many times more potent in antioxidant activity than vitamin E and vitamin C. The protective effect of silymarin against liver damage has been demonstrated in numerous experimental studies. For example,

448

silymarin has been shown to protect the liver from the damage produced by such liver-toxic chemicals as carbon tetrachloride, amanita toxin, galactosamine, and praseodymium nitrate.^[50] ^[51] ^[52]

One of the key mechanisms by which silymarin enhances detoxification is by preventing the depletion of glutathione. Silymarin not only prevents the depletion of glutathione induced by alcohol and other toxic chemicals, but has been shown to increase the level of glutathione of the liver by up to 35%, even in normals.^[53]

In human studies, silymarin has been shown to have positive effects in treating liver diseases of various kinds, including cirrhosis, chronic hepatitis, fatty infiltration of the liver (chemical- and alcohol-induced fatty liver), and inflammation of the bile duct.^[54] ^[55] ^[56] ^[57] ^[58] The standard dosage for silymarin is 70–210 mg three times/day.

HEAVY METAL DETOXIFICATION

Nutritional factors which combat heavy metal poisoning include:^[1] ^[59] ^[60] ^[61] ^[62] ^[63] ^[64] ^[65] ^[66] ^[67] ^[68] ^[69]

- a high potency multiple vitamin and mineral supplement
- minerals such as calcium, magnesium, zinc, iron, copper, and chromium

- vitamin C and B-complex vitamins
- sulfur-containing amino acids (methionine, cysteine, and taurine) and high sulfur-containing foods like garlic, onions, and eggs
- water-soluble fibers such as guar gum, oat bran, pectin, and psyllium seed.

Heavy metal toxicity and detoxification are discussed in detail in [Chapters 18](#) and [37](#) .

SYSTEMIC DETOXIFICATION

Over the millennia, several traditional systemic detoxification procedures have evolved: fasting, saunas, and hydrotherapy. Recent research has now not only documented their efficacy for many of the common toxins but also helped refine our understanding of how to better apply them.

Fasting

Fasting is often used as a detoxification method as it is one of the quickest ways to increase elimination of wastes and enhance the healing processes of the body. Fasting is defined as “abstinence from all food and drink except water for a specific period of time, usually for a therapeutic or religious purpose” (see [Ch. 47](#) for a full discussion of this useful therapy and specific instructions on its utilization).

Although therapeutic fasting is probably one of the oldest known therapies, it has been largely ignored by the medical community despite a substantial body of published research. Fasting has been studied in the treatment of:

- obesity
- chemical poisoning
- rheumatoid arthritis
- allergies
- psoriasis
- eczema
- thrombophlebitis
- leg ulcers
- the irritable bowel syndrome
- impaired or deranged appetite
- bronchial asthma
- depression
- neurosis
- schizophrenia.

One of the most significant studies regarding fasting and detoxification involved patients who had ingested rice oil contaminated with polychlorinated-biphenyls (PCBs). All patients reported improvement in symptoms, and some observed “dramatic” relief, after undergoing 7–10 day fasts.^[70] This documented efficacy with fat-soluble toxins also indicates the need for care when fasting patients with high levels of these toxins and impaired detoxification mechanisms. For example, the pesticide DDT has been shown

to be mobilized during a fast and may reach blood levels toxic to the nervous system.^[6]

Another challenge with fasting is the depletion of liver glutathione, which occurs after approximately 24 hours. This leads to impairment of free radical quenching from phase I and impaired glutathione conjugation. This has led to the development of “modified food fasts”.

Several products are now on the market to help aid the detoxification process. When used properly as part of a fast, these products initiate the same detoxification processes, albeit at a lower rate, while ensuring the availability of the critical nutrients needed to maintain energy and the liver’s detoxification processes. Especially important are glutathione, antioxidants, and botanicals like *Silybum marianum*.

Saunas

Saunas are an age-old detoxification therapy. They are based on the concept that as the body sweats, toxins are released through the skin. Prolonged saunas (over an hour at a lower temperature) are thought to increase the excretion of fatty acids through the skin and thus fat-soluble toxins. There is some research that documents this method of detoxification. One group of researchers studied 14 firemen who had been exposed to highly toxic polychlorinated biphenyls in a transformer fire and

TABLE 50-18 -- Effects of extended time, modest temperature saunas^{[72] [73] [74] [75]}

- Increases excretion of heavy metals (cadmium, lead)
 - Increases excretion of fat-soluble chemicals (PCBs, PBBs, and HCBs)
 - Increases excretion of trace minerals
 - Increases lipolysis, growth hormone
-

explosion and who subsequently developed neuropsychological problems 6 months after the fire. They underwent 2–3 weeks of experimental detoxification, which was a medically supervised diet, exercise, and sauna program. They were compared with firemen from the same department who did not participate in the detoxification program. Those who followed the detoxification program showed significant improvement in scores in three memory tests as compared with those who did not.^[71] Self-appraisal for depression, anger, and fatigue, however, did not improve. This was a very short period of time for eliminating such toxins, but the results do suggest potential benefit. [Table 50.18](#) lists the detoxification benefits of extended time, modest temperature saunas. Note, however, that this procedure also increases the secretion of essential trace minerals.^[72]

As valuable as saunas are, they must be used with care as greatly elevating body

temperature can cause problems in some situations. Specifically, they are contraindicated in pregnant women in their first trimester, young children, adults with heart disease or seizure disorders, immediately after intense exercise, and after drinking alcohol or ingesting cocaine.^[76]

Hydrotherapy

Hydrotherapy, the application of hot and/or cold water to the various surfaces of the body, has been used for health promotion and detoxification throughout recorded history (see [Ch. 42](#) for a full discussion). Some research is now documenting its efficacy in increasing the elimination of toxins, specifically lead.

A very interesting retrospective and experimental study evaluated the efficacy of the historic Bath General Hospital in treating lead poisoning. The hospital was established in 1741 to both treat patients suffering from lead poisoning (and other maladies) and objectively evaluate the efficacy of the therapies. Meticulous records were kept, and, considering the clear clinical picture of lead poisoning (*colica pictorum*), the diagnosis and evaluation, which were made by teams of doctors to limit bias, appear reliable. The researchers analyzed 120 years of documents which recorded the efficacy of the baths in 3,377 patients with lead poisoning. Their success was remarkable: 45.4% cured and 93% improved. As a control, they analyzed several other diseases for which the baths were used and found far lower success rates. The treatment protocol was composed of full-body (standing) immersion in 35°C water for at least 1.5 hours at least three times per week. In addition, the patients drank 1–1.5 pints of the Bath mineral waters a day. The average stay was 150 days.

The same researchers then conducted physiological experiments to determine if a rationale for this efficacy could be established. They found that full immersion increased cardiac output by 50% and increased urinary excretion of lead a remarkable 250%. The peak lead excretion was reached at 2.5 hours.^[77]

SUMMARY

Detoxification of harmful substances is a continual process in the body. The ability to detoxify and eliminate toxins largely determines an individual's health status. A number of toxins (heavy metals, solvents, pesticides, microbial toxins, etc.) are known to cause significant health problems and their concentration in the environment continues to increase. Optimal functioning of the detoxification systems combined with periodic systemic detoxification are important tools for the health promotion-oriented physician.

Chapter 51 - Food allergies

Stephen Barrie ND

INTRODUCTION

Food and environmental allergies have been implicated in a wide range of medical conditions affecting virtually every part of the body – from mildly uncomfortable symptoms such as indigestion and gastritis, to severe illnesses such as celiac disease, arthritis, and chronic infection. Allergies have also been linked to numerous disorders of the central nervous system, including depression, anxiety, and chronic fatigue.

Food allergy causes the immune system to synthesize and release reactive chemical agents, such as cytokines, lymphokines, and interferons. These hormone-like substances can dramatically influence cellular physiology, producing far-reaching effects on the immune, endocrine and nervous systems. Because toxins can initiate a very similar set of reactions, food allergy and toxicity are considered intimately connected in a clinical sense (see [Ch. 50](#)).

An allergic response to food or environmental inhalants may be the culprit lurking behind a “mysterious” set of symptoms which are not readily diagnosable using conventional methods of testing. Not being able to effectively pinpoint the cause of these symptoms can create profound frustration for the physician and the patient alike.

Testing for specific allergies (covered in [Ch. 15](#)) is one of the ways to uncover foundation causes of illness. Armed with the knowledge provided by approach, the physician can design a specific treatment program to reduce or eliminate exposure to antigenic substances, and thus effectively help to alleviate the patient’s symptoms.

Allergy testing is also valuable as a preventive measure for patients who are not currently experiencing overt symptoms related to allergic reactions. It can reveal unsuspected food sensitivities which, if ignored, could result in cumulative stress on the immune and other systems over time – a condition that may eventually lead to severe

illnesses.

History of food allergy

The recognition of food sensitivity was first recorded by Hippocrates, who observed that milk could cause gastric upset and urticaria. In 200AD, Galen described a case of allergy to goat's milk, and in 1679 Willis observed that the ingestion of wine could precipitate asthma.

Soon after the start of the 20th century, Shloss described several cases that established a strong correlation between food allergy and the pathogenesis of atopic dermatitis.^[1] Duke was one of the first to make extensive observations of foods causing allergic responses. In the early 1920s, he published several papers linking food ingestion to bladder pain, Ménière's syndrome, colitis, GI upset, and diarrhea.^{[2] [3]} Not long afterwards, Walzer and his colleagues^{[4] [5]} performed experiments clearly demonstrating that ingested food antigens could penetrate the GI barrier and be transported through the bloodstream to mast cells in the skin.

In the 1930s, Rinkel^[6] first described food sensitivities that differed from the classic immediate anaphylactic reactions. The symptoms he described occurred hours or even days subsequent to ingestion and could be masked or unmasked by the offending food. Rinkel's discovery has been borne out by recent research confirming that delayed-type food allergies play a primary role in the immune system's response to ingestants.^[7]

Allergies today

The incidence of food and environmental allergies and the number of atopic individuals have increased dramatically in recent times. Hypersensitivities involving bronchial symptoms and asthma, for example, have nearly doubled in the last decade.^[8] It is estimated that atopic dermatitis alone now affects between 10–15% of the population at some time during their lives, and that this condition is often directly provoked by food antigens.^{[9] [10]}

Adverse reactions to food are now reported in about 25% of younger children.^[11] Some physicians even claim that food allergies are a leading cause of most undiagnosed symptoms. As one investigator noted: "The management of allergic diseases involves considerable financial and other costs. In industrialized countries, atopic disease is the commonest cause of morbidity and a significant factor in mortality."^[8]

The primary causes for the increased incidence of allergy appears to be excessive, regular consumption of a limited number of foods (often hidden as ingredients in commercially prepared foods) and the high level of preservatives, stabilizers, artificial colorings and flavorings, as well as medicinal drugs such as penicillin, now added to foods.^[12] Some researchers and clinicians believe that the increased chemical pollution

in our air, water, and food is to blame. Foods can easily become contaminated following the use of insecticides in farming.

Other possible reasons for increased food hypersensitivity include:

- earlier weaning and earlier introduction of solid foods to infants
- genetic manipulation of plants, resulting in food components which cross-react with normal tissues
- impaired digestion (especially hypochlorhydria)
- less diversity in the average diet – leading to repeated exposure to food substances and the subsequent development of hypersensitivities.

Probably all of these and more have contributed to the increased frequency and severity of allergic symptoms.

Causes and development

It is well documented that food allergy is an expression of an inherited genetic predisposition.^[13] Hence allergic histories can often be found in both parents and siblings. One study discovered that when both parents are allergic, 67% of the children are also allergic. When only one parent is allergic, 33% are allergic.^[14]

Inadequate digestion of food products due to hypochlorhydria and/or pancreatic enzyme deficiency is also thought to be a significant cause of food allergies. When proteins are not digested to amino acids, dipeptides, or short-chain polypeptides, they retain their antigenic properties. These antigenic molecules are then exposed to the immune system, or absorbed through a “leaky gut”, creating a state of chronic immune hypersensitivity.

Signs and symptoms

Food and environmental allergies have been linked to a wide range of medical conditions affecting virtually every part of the body. They have been shown to cause migraine headache, eczema, thrombophlebitis, arthritis, colitis, enuresis, ear infections, gall bladder disease, childhood hyperactivity, hypotension, urticaria, asthma, glaucoma, and many other pathological conditions.^{[15] [16] [17] [18] [19] [20] [21] [22] [23] [24] [25]} [Table 51.1](#) lists symptoms and diseases that should make the clinician suspect possible food allergies. Gastrointestinal dysfunctions such as peptic ulcer, dyspepsia, gastroduodenitis, and hiatal hernia may promote some of these adverse reactions to food.^[26]

THE ROLE OF THE IMMUNE SYSTEM IN THE ALLERGIC RESPONSE

The immune system is a complex molecular network with specific functions that defend the human host against invading organisms and cancer cells. While the

TABLE 51-1 -- Symptoms and diseases commonly associated with food allergy

| System | Symptoms and diseases |
|------------------|--|
| Gastrointestinal | Canker sores, celiac disease, chronic diarrhea, duodenal ulcer, gastritis, irritable colon, malabsorption, ulcerative colitis |
| Genitourinary | Bed-wetting, chronic bladder infections, nephrosis |
| Immune | Chronic infections, frequent ear infections |
| Mental/emotional | Anxiety, depression, hyperactivity, inability to concentrate, insomnia, irritability, mental confusion, personality change, seizures |
| Musculoskeletal | Bursitis, joint pain, low back pain |

system normally performs well, indeed is essential to maintaining health, under certain circumstances it goes awry.

Overview of the immune system

There are two types of immunity the body develops to protect itself: innate immunity and acquired immunity.

Innate immunity

When functioning properly, the immune system has the ability to resist almost all types of organisms and toxins that damage human tissue. This system includes:

- phagocytosis of bacteria and other invaders by white blood cells and cells of the macrophage system
- destruction of organisms by the acid secretion of the stomach
- integumentary defense
- destruction of foreign organisms or toxins by chemical compounds in the bloodstream (lysozyme, complement complex, polypeptides, natural killer cells).

Acquired immunity

Acquired immunity is the human body's ability to develop extremely powerful specific immunity against individual invading agents such as lethal bacteria, viruses, toxins, etc.

There are two basic types of acquired immunity:

- humoral, or B-cell, immunity, which is the production of circulating antibodies
- cell-mediated, or T-cell, immunity, which is the formation of large numbers of activated lymphocytes specifically designed to destroy the foreign agent.

There are five major classes of immunoglobulins: IgE, IgD, IgG, IgM, and IgA. IgE defends against parasitic infection and is known as the reaginic antibody for its major role in instigating immediate allergic responses. The other immunoglobulins seem to be more involved in delayed reactions. Of these, IgG is the most abundant, comprising about 80% of all circulating antibodies.^[27]

Types of immune reactions

Although the function of the immune system is to protect the host from foreign antigens, abnormal immune responses can lead to tissue injury and disease. Food allergy reactions are just one expression of this type of immune-mediated damage. The mechanisms of immune tissue injury have been classified into four distinct types:^[28]

- *Type I – immediate hypersensitivity.* These reactions occur less than 2 hours after contact with allergens. Antigens bind to pre-formed IgE antibodies already attached to the surface of the mast cell or the basophil and cause the release of chemical mediators such as histamine and the eosinophilic chemotactic factor. A variety of allergic symptoms may result, depending on the location of the mast cell: in the nasal passages there may be sinus congestion; in the bronchioles, constriction (asthma); in the skin, hives and eczema; in the synovial cells, arthritis; in the intestinal mucosa, inflammation with resulting malabsorption; and in the brain, headaches, loss of memory and inability to concentrate.
 - *Type II – cytotoxic reactions.* These reactions involve the binding of either IgG or IgM antibodies to cell-bound antigen. The antigen–antibody binding activates the complement cascade, resulting in the destruction of the cell to which the antigen is bound.
 - *Type III – immune complex-mediated reactions.* Immune complexes are formed when antigens bind to antibodies. They are usually cleared from circulation by the phagocytic system. However, deposition of these complexes in tissues or in vascular endothelium can produce immune complex-mediated tissue injury. This tissue damage is further enhanced by the presence of vasoactive amines, which increase vascular permeability and promote the deposition of more immune complexes. Type III responses are usually delayed, occurring hours or even days after exposure. They have been shown to involve both IgG and IgG immune complexes.^{[29] [30]}
-

- *Type IV – T-cell-dependent.* This delayed-type reaction is mediated primarily by T-lymphocytes, after an allergen makes contact with a mucosal surface. By stimulating sensitized T-cells, inflammation may result within 36–72 hours of contact.

A type IV reaction does not involve antibodies.

The allergic reaction

Acquired immunity is extensively involved in allergic reactions. Substances that initiate immune response are known as antigens. Generally, antigens are proteins or large polysaccharides having a high molecular weight (8,000Da or greater).

Food represents the largest antigenic challenge confronting the human immune system.^[28] The surface area of the GI tract is greater than the area of a tennis court, making it the largest, most active immune-reacting surface in the body. Immunologically mediated food hypersensitivity is the result of interactions among ingested food antigens, the digestive tract, tissue mast cells and circulating basophils, and food antigen-specific immunoglobulins.

Role of IgE and IgG₄ in allergy

Repeated exposure to an antigen can eventually produce allergy-like responses, or hypersensitivities. IgE antibodies are believed to trigger allergic reactions when they cross-link on the surface of gastrointestinal mast cells, stimulating the release and production of chemical mediators such as histamine, proteoglycans, and leukotrienes. These potent reactors instigate a barrage of effects on surrounding intestinal tissue, such as increased intestinal permeability, which may allow passage of food antigens into the bloodstream. When this happens, other organs in the body can then also become involved in the allergic reaction. Involvement of other cell types in the body may result in the creation of a chronic, perpetual autoimmune response.

Since most severe, immediate allergy symptoms are IgE-mediated, many conventional practitioners have limited their testing to this class of immunoglobulins. Certainly, an abundance of medical literature supports using the IgE assay as a means of diagnosing type I allergic reactions.^{[31] [32] [33] [34] [35]} There is also considerable evidence, however, underscoring the significance of IgG as a marker in allergy testing as well. In fact, it is estimated that IgG and IgG complex mediators are involved in 80% of all food allergy reactions.^[36]

These reactions are usually delayed, with symptoms that may not surface until hours, or even days, after the initial exposure. One study found that nearly 60% of patients with food intolerance exhibited late (delayed), rather than immediate or early, reactions to provoking foods.^[37] Although IgE may be involved, it is theorized that the delayed reactions are primarily mediated by IgG. Specific IgE has a half-life in circulation of 1–2 days, and a half-life on the mast cell of about 14 days. IgG, on the other hand, appears to have a circulating half-life of 21 days with a residual time on the mast cells that can last as long as 2–3 months.^[38] Thus an IgG assay is an essential tool for diagnosing the possible causes of delayed, non-anaphylactic responses, the so-called “hidden” allergies, which cannot be detected with conventional IgE tests such as RAST or skin testing.

A greater clinical significance is attached to the IgG₄ subclass than to IgG alone. Several studies indicate a role for IgG₄ in non-IgE, mast-cell mediated diseases.^{[39] [40] [41] [42] [43]} IgG₄ is most commonly associated with high antigen levels, particularly food antigens. When antigen levels increase, more IgG₄ is produced by the body in response. After chronic antigenic exposure, IgG₄ concentrations reach much higher levels than do other IgG subclasses, particularly in atopic individuals.^{[35] [44] [45] [46]} Since antigen–antibody complexes trigger allergic responses, the measurement of IgG₄ is considered critical for a comprehensive assessment of antigen activity.

IgG₄ is also unique in that it is the only IgG subclass that induces basophil degranulation. This action triggers the release of histamine and other potent chemical mediators upon exposure to specific antigens – a common mechanism of allergic reactions.^{[39] [40] [41]}

IgE/IgG and physiological function

Besides providing a means for diagnosing suspected antigens, IgE and IgG can have crucial implications for gastrointestinal and immune function. In experimental models, IgG antibodies have been shown to increase intestinal permeability.^{[47] [48]} This increased permeability is believed to be caused by a selective transport mediated by Fc receptors on epithelial surfaces.^[49] By increasing intestinal permeability, elevated levels of IgG could result in increased exposure to antigens.

Production of IgG₄ and IgE is controlled by at least two cytokines, interleukin-4 (IL-4) and interferon-gamma (IFN-gamma). Since there is evidence that increased synthesis of IgG₄ and IgE is a result of decreased inhibitory effect of IFN-gamma,^{[50] [51]} it is postulated that defective immunoregulation involving IL-4 and IFN-gamma both sustains and increases the synthesis of IgG₄ and IgE antibodies.^[46]

FOOD ALLERGY TESTING

Skin testing, RAST and IgG₄

Although many food allergy experts believe that oral challenge testing provides the most accurate and reliable

results for diagnosing immediate food hypersensitivities, it can be costly, time-consuming, and potentially dangerous.^[52] Moreover, using an oral challenge test to diagnose delayed sensitivities can be an extremely difficult and complicated process. In patients with a defined history of allergic reaction to a particular food, measurement of

the combination of food-specific IgE and IgG₄ has been shown to correspond more closely with the history than the actual challenge itself.^[38]

Since RAST and skin testing only measure IgE-mediated reactions, they cannot guide physicians as to the potential for delayed, non-IgE-mediated reactions.^[38] In one study, researchers surmised that because IgG₄ was involved in late-onset reactions, patients exhibiting delayed bronchial allergic reactions failed to show positive skin test reactions or RAST results to a specific allergen.^[53] In addition, there are clinical situations where skin testing is unfeasible and may inadvertently trigger life-threatening symptoms.^[54] Food allergy testing is more completely discussed in [Chapter 15](#).

Follow-up testing

The immune system is a highly sensitive, reactive molecular network that is constantly changing and adapting in response to myriad stimuli. Because of this ongoing state of flux, food sensitivities in the same individual may vary over the course of time. In one study, 580 patients with pathological reactions to foods were examined after a period of 9 years. Researchers found a dramatic shift in the patients' antigenic responses to different food groups, with many individuals exhibiting sensitivities to foods they had not reacted to 9 years earlier, perhaps due to changes in food consumption patterns and preparation methods.^[12] This underscores the need for ongoing, consistent follow-up testing as time progresses, to carefully monitor the patient's immune response and to modify therapeutic interventions, as needed.

Related tests to consider

Intestinal permeability

A healthy intestinal tract provides an effective barrier against excessive absorption of food antigens. With increased gut permeability, greater quantities of antigens are allowed to penetrate the GI barrier, resulting in an overly sensitized, reactive immune system in some individuals. Increased permeability has been implicated in type I, type II, and type IV allergies.^[55] Contact between an allergen and the digestive tract significantly increases intestinal absorption of macromolecules, leading the researchers to conclude that: "evaluation of intestinal permeability ... provides an objective means of diagnosing food allergy and assessing the effectiveness of anti-allergic agents".^[56] ^[57] Intestinal permeability testing evaluates the small intestine's effectiveness as a macromolecule barrier, monitors changes in mucosal permeability, and determines underlying causes of systemic problems linked to GI function (see [Ch. 21](#) for a complete discussion of this important topic).

Comprehensive digestive stool analysis (CDSA)

Maldigestion of food products is considered a significant cause of food allergy. When proteins are not digested properly to amino acids, dipeptides, or short-chain polypeptides, they retain their antigenic properties. This can trigger repeated allergic responses by the immune system, possibly leading to a state of chronic hypersensitivity.

The comprehensive digestive stool analysis can provide clues about the possible cause of food allergies by closely examining the digestion and absorption status of the gastrointestinal tract.

Some researchers have suggested that food allergy is not an immunological disease but a disorder of bacterial fermentation in the colon. According to this theory, food intolerance is caused by a combination of factors, including reduced gut enzyme concentrations, imbalanced bacterial flora, and increased intestinal permeability (also known as “leaky gut syndrome”;^[58] see [Ch. 9](#) for a more complete discussion).

Fecal sIgA

Secretory IgA (sIgA) is the predominant immunoglobulin in intestinal secretions, the first-line defender against bacteria, parasites, fungi, toxins, and viruses. Found abundantly in saliva and other mucosal fluids, sIgA works by forming immune complexes with pathogenic microorganisms, allergenic food proteins, and carcinogens, preventing them from binding to the surface of absorptive cells. If sIgA response is impaired, mucosal tissue repair may be compromised, leading to reduced mucosal integrity and immunity against foreign invaders. Fecal sIgA testing uses sIgA as a clinical marker to evaluate the status of mucosal immunity. Low sIgA levels can signal the presence of a previously unsuspected allergy or other autoimmune disorder.

Adrenocortex stress and melatonin profiles

Since the etiology of food and environmental allergy involves interaction between numerous chemical mediators in the immune system, including serotonin, many sensitized individuals commonly exhibit various endocrine dysfunctions. Moreover, the severity of allergy symptoms often follow a chronobiotic pattern, highly influenced by circadian hormone rhythms.

THERAPEUTIC CONSIDERATIONS

Allergy testing reveals whether certain food and environmental substances may be antigenic, providing the clinician with clear, specific results to use in designing an effective therapeutic program. Treatment involves five essential components:

- avoidance of identified allergens
- rotation diet until sensitivity is decreased
- re-establishment of proper microbial milieu
- healing of the damaged intestinal mucosa
- correction of underlying causative factors, such as maldigestion.

Since the body’s immunological response involves a very complex series of molecular

relationships that are still not fully understood, it is important that each patient's case be carefully evaluated using a variety of criteria. Antibody test results, a detailed medical history, and a thorough physical examination are all important factors to consider when diagnosing a suspected adverse reaction to food or inhalants. Additional challenge tests may also be necessary, once certain antigen candidates have been ruled out as unlikely by preliminary diagnostic tests.

Diet

Oligoantigenic diet

An oligoantigenic diet has been proven, in a large number of studies, to be highly effective in treating many types of food allergies. Children with attention deficit disorder show a marked improvement in their hyperactive behavior following the removal of provoking foods from their diets.^[59] In another study, 93% of 88 children with severe frequent migraine recovered on an oligoantigenic diet, even in instances when the migraines were provoked by additional factors such as blows to the head, exercise, or flashing lights.^[60] A low-allergen diet also significantly reduced symptoms of colic in infants and chronic urticaria with arthralgia in adult patients.^[49] ^[61]

Rotation diet

Diversified rotation diets are often used to prevent new allergies from developing and to give the immune system a rest and the intestines a chance to heal (see [Ch. 58](#)). Once the intestines are damaged and a food allergy susceptibility established, virtually any food eaten regularly will eventually establish an antibody response.

This diet consists of eating tolerated foods at regularly spaced intervals of 4–7 days.^[62] This approach is based on the principle that infrequent consumption of tolerated foods is not likely to induce new sensitivities or increase any mild sensitivities, even in highly sensitized and immune-compromised individuals. As tolerance for eliminated foods returns, they may be added back into the rotation schedule without reactivation of the allergy. Professional nutritional counseling should be provided to a person attempting to design a rotation diet, in order to ensure proper nutritional intake and classification of foods by related taxonomical groupings. An excellent aid (*The rotation game* by Sally Rockwell, available at PO Box 31065, Seattle, WA, 98103) is available to assist patients in following such a diet.

Re-establishing a healthy bowel microflora

Fundamental to correction of gastrointestinal dysfunction is re-establishment of the appropriate microbial flora of the intestine. The health-inducing bacteria are especially important because they suppress the growth of toxic bacteria. Reseeding the intestines is done through the use of probiotics and prebiotics. Probiotics are the normal bacteria found in the healthy intestines. Prebiotics are indigestible substances that help the healthful bacteria grow. Prebiotics also help by increasing the production of secretory

IgA in the intestines, which also helps protect against bacteria and food allergens.^[63]

The primary beneficial organisms used to reseed the intestines are *Lactobacilli* and *Bifidobacteria*. They play many important roles, a crucial one of which is inhibiting the growth of toxic bacteria, viruses, fungi, yeasts, and parasites.^[64] An important part of reseeded the intestines is to ensure that the food the health-promoting bacteria need to live on is easily available. One of the best ways to do this is with oligosaccharides, especially fructooligosaccharides. Fructooligosaccharides are short-chain carbohydrates composed of three to 10 molecules of sugars, at least two of which are fructose. This molecule is essentially indigestible by humans. However, the *Bifidobacteria* and *Lactobacilli* preferentially utilize fructooligosaccharides to grow and multiply. In contrast, toxic bacteria are unable to use these short-chain carbohydrates.^[65] Foods rich in fructooligosaccharides include onions, asparagus, bananas, and maple syrup.

Healing the damaged gut

Re-establishing a healthy intestine is critical for the elimination of food allergies because a leaky gut will continue to expose food antigens to the immune system. Healing the damaged intestinal mucosa requires a comprehensive approach that includes eliminating all factors that injure the intestine (such as toxic bacteria), re-establishing the normal bowel flora, removing toxins from the intestines, improving digestion, decreasing inflammation, and promoting the metabolism and repair of the intestinal-lining cells.

Decreasing the gut inflammatory reaction

Several nutrients help decrease the local inflammatory reaction. Quercetin is a natural bioflavonoid that inhibits the release of inflammatory chemicals from sensitized mast cells, an especially useful effect for the sensitized gut. Quercetin and other bioflavonoids have been shown to inhibit the release of inflammatory chemicals from mast cells, scavenge free radicals, and inhibit irritability of the muscles of the intestines. It has been used in clinical trials to reduce the intestinal damage caused by ingestion of a food allergens.^[66] A typical dosage of quercetin is 250mg three times a day along with vitamin C.

Also of value are fish oils which have now been utilized for a wide variety of inflammatory and allergic diseases. Fish oil is rich in the polyunsaturated N-3 fatty acids, and eicosapentaenoic (EPA) and docosahexaenoic acids (DCHA). EPA competes with arachidonic acid (AA) for metabolism by the cyclooxygenase and lipoxygenase pathways. Metabolites derived from EPA have reduced inflammatory activities as compared with their AA-derived counterparts. Dietary supplementation with EPA leads to incorporation of EPA into membrane phospholipids, inhibition of 5-lipoxygenase pathway activity, and a reduction of the elaboration of platelet-activating factor. Neutrophil chemotaxis and the capacity of these cells to adhere to endothelial cells are also substantially attenuated. Clinical trials in rheumatoid arthritis, psoriasis, atopic

dermatitis, and bronchial asthma have shown beneficial effects.^[67] The typical dosage is 1–3 grams per day of EPA.

Stimulating regeneration of the gut mucosa

Several nutrients help heal the intestines. Of particular value is glutamine, the most abundant amino acid in the blood. As one of the principal fuels used by the intestinal lining cells, it accounts for 35% of their energy production. While readily available in the diet and synthesized in the body, supplementation improves the energy metabolism of the gastrointestinal mucosa, thus stimulating regeneration.^[68] Glutamine prevents intestinal mucosal damage and has been shown to decrease bacterial leakage across the intestines after they are damaged, presumably by stimulating repair.^[69] A typical dosage of glutamine is 100 mg three times a day (see [Ch. 54](#) for a more comprehensive discussion of intestinal repair).

Re-establishing normal digestion

The Heidelberg gastric analysis test should be performed if achlorhydria or hypochlorhydria is suspected (see [Ch. 19](#)). Hypochlorhydria can be treated with oral betaine HCl supplementation (see [Appendix 7](#)).

Pancreatic insufficiency can be treated with exogenous pork or beef pancreatin (see [Ch. 101](#)) or microbial-derived digestive enzymes such as those extracted from *Aspergillus oryzae* (see [Ch. 66](#)).

SUMMARY

Food allergies are a widespread, often unrecognized cause of chronic ill health and disease. Substantial experience has shown remarkable clinical response when the offending foods are recognized and eliminated from the diet. The primary challenge is the difficulty in making an accurate diagnosis.

Chapter 52 - Homocysteine metabolism: nutritional modulation and impact on health and disease*

Alan L. Miller ND
Gregory S. Kelly ND

INTRODUCTION

Homocysteinuria, an autosomal disease with considerable genetic heterogeneity, is the second most common inborn error of amino acid metabolism. While the full genetic disorder affects only 1:200,000 live births, abnormal homocysteine metabolism – due to enzyme dysfunction, lifestyle or nutritional deficiencies – appears to be surprisingly common.

Hyperhomocysteinemia has received increasing attention during the past decade and has joined smoking, dyslipidemia, hypertension, and obesity as a significant independent risk factor for cardiovascular disease. In addition to its possible role in cardiovascular disease, increased homocysteine levels have been implicated in several other clinical conditions, including neural tube defects, spontaneous abortion, placental abruption, renal failure, non-insulin-dependent diabetes and complications of diabetes, rheumatoid arthritis, alcoholism, osteoporosis, and neuropsychiatric disorders.

HOMOCYSTEINE METABOLISM

Homocysteine metabolism is greatly impacted by enzyme function, lifestyle choices, and nutritional status. Following is a discussion of the role of gender, genetics, lifestyle, and key nutrients in homocysteine metabolism.

Gender and genetics

Studies of healthy men and women indicate that certain acquired and genetic determinants may impact total plasma homocysteine. Women tend to have lower basal levels than men,^[1] and neither contraceptives nor hormone replacement therapy seem

to alter their levels significantly.^[2] However, in postmenopausal women, hormone replacement therapy might slightly decrease elevated homocysteine concentrations. No significant lowering effect was observed in women with low homocysteine

462

levels.^[3] Generally, homocysteine concentrations are significantly higher in postmenopausal women than in pre-menopausal women; however, the above-mentioned sex differences in homocysteine concentrations persist even in elderly populations.^[4] ^[5] ^[6] The anti-estrogen drug tamoxifen, used in the long-term treatment of breast cancer patients, is reported to decrease homocysteine levels in postmenopausal women with breast cancer.^[7]

Epidemiological evidence has shown homocysteine levels to be over 45% lower in Westernized adult black Africans than in age-matched white adults, revealing racial genetic differences in homocysteine metabolism.^[8]

Lifestyle

An association between coffee consumption and the concentration of total homocysteine in plasma has been reported. A marked positive dose–response relation between coffee consumption and plasma homocysteine levels was observed. The relationship was most marked in males and females consuming greater than eight cups of coffee per day. The combination of cigarette smoking and high coffee intake was associated with particularly high homocysteine concentrations.^[9] Chronic ingestion of alcohol has also been associated with increased homocysteine levels.^[10] ^[11]

Nutritional considerations

Nutrition impacts homocysteine concentrations in both men and women. For example, those individuals in the lowest quartiles for serum folate and vitamin B₁₂ (nutrients which significantly impact homocysteine metabolism) have significantly higher concentrations of homocysteine, and men in the lowest quartile of serum pyridoxal 5'-phosphate (P5P – the bioactive form of vitamin B₆) also have increased homocysteine concentrations.^[2]

Methionine

Metabolism of the amino acid methionine, a limiting amino acid in the synthesis of many proteins, affects several biochemical pathways involving the production of nutrients which are essential to the optimal functioning of the cardiovascular, skeletal, and nervous system.

Homocysteine is an intermediate product of methionine metabolism and is itself

metabolized by two pathways: the re-methylation pathway which regenerates methionine, and the trans-sulfuration pathway which degrades homocysteine into cysteine and then taurine. In essence, the intermediate metabolite homocysteine is located at a metabolic crossroads, so it directly and indirectly impacts all methyl and sulfur group metabolism occurring in the body. Experiments have demonstrated that high levels of L-homocysteine and adenosine in the cell inhibit all methylation reactions.^[12]

The re-methylation pathway (see [Fig. 52.1](#)) comprises two intersecting biochemical pathways and results in the transfer of a methyl group (CH_3) to homocysteine by either methylcobalamin or betaine (trimethylglycine). Methylcobalamin originally receives its methyl group from S-adenosylmethionine (SAM) or 5-methyltetrahydrofolate (5-methylTHF), an active form of folic acid. After re-methylation, methionine can be re-utilized to produce SAM, the body's "universal methyl donor", which participates in several key metabolic pathways, including methylation of DNA and myelin, synthesis of carnitine, coenzyme Q_{10} , creatine, epinephrine, melatonin, methylcobalamin, and phosphatidylcholine, as well as phase II methylation detoxification reactions.

The trans-sulfuration pathway of methionine/homocysteine degradation (see [Fig. 52.1](#)) produces the amino acids cysteine and taurine, which are important nutrients for cardiac health, hepatic detoxification, cholesterol excretion, bile salts formation, and glutathione production. This pathway is dependent on adequate dietary intake and hepatic conversion of vitamin B_6 into its active form, P5P. Also necessary is the amino acid serine, a down-line metabolite generated from betaine via the homocysteine-remethylation pathway.

In addition to 5-methylTHF, methylcobalamin, betaine, and P5P, *N*-acetylcysteine has been reported to significantly lower homocysteine levels.^[13]

Methyltetrahydrofolate

Folates function as carbon donors in the synthesis of serine from glycine, directly in the synthesis of purines and pyrimidine bases, indirectly in the synthesis of transfer RNA, and as a methyl donor to create methylcobalamin which is used for re-methylation of homocysteine to methionine. Dietary folic acid is a mixture of folates in the form of polyglutamates, which are readily destroyed by cooking.

Synthesis of the active forms of folic acid is a complex process requiring several enzymes as well as adequate supplies of niacin, P5P, and serine as cofactors (see [Fig. 52.2](#)). In plants, folic acid is formed from a hetero-bicyclic pteride ring, *para*-aminobenzoic acid (PABA), and glutamic acid. Folate is initially deconjugated in the cells of the intestinal wall to the monoglutamate form. This is then reduced to dihydrofolate and then to tetrahydrofolate (THF) via folate and dihydrofolate reductase. Both of these enzymes require NADPH (niacin-dependent) as a cofactor. Serine combines with P5P to transfer a hydroxymethyl group to THF. This results in the formation of 5,10-methylenetetrahydrofolate (5,10-methyleneTHF) and glycine. This molecule is of central importance, being the precursor of the metabolically active

5-methylTHF, which is involved in homocysteine metabolism, and methylidynetetrahydrofolate (involved

464

in purine synthesis), as well as functioning on its own in the generation of thymine side chains for incorporation into DNA.

The following may contribute to a deficiency of folic acid:

- a deficient food supply
- a defect in utilization, as in alcoholics
- malabsorption
- increased needs in pregnant women and in cancer patients
- metabolic interference by drugs
- folate losses in hemodialysis
- enzyme or cofactor deficiency needed for generation of active folic acid.

Individuals using supplements or consuming either breakfast cereals or green leafy vegetables have significantly greater plasma folate and lower homocysteine levels than non-users.^[4]

Folinic acid (5-formylTHF), available supplementally as calcium folinate (also known as

leucovorin calcium), is an immediate precursor to 5,10-methyleneTHF and 5-methylTHF. Folinic acid can correct deficiencies of the active forms of folic acid, is more stable than folic acid and has a longer half-life in the body. Folinic acid also readily crosses the blood–brain barrier and is slowly cleared, compared with folic acid, which is poorly transported into the brain, and once in the CNS is rapidly cleared.^[14]

Methylcobalamin

The coenzyme form of vitamin B₁₂ is a very complex molecule containing cobalt bound to five nitrogens and one carbon. The metal–carbon bond found on this coenzyme is the only known biological example of this type of linkage. Surrounding the cobalt is a corrin ring, which structurally resembles the porphyrin ring found in hemoglobin, the cytochromes and chlorophyll. The use of cobalt in the two biologically active forms of cobalamin, adenosyl- and methylcobalamin, is the only known function of this metal in biological systems.

In humans, the cobalt in cobalamin exists in a univalent oxidation state, designated as cob(I)alamin. The compound commonly referred to as vitamin B₁₂ has a cyanide molecule at the metal-carbon position and the oxidation state of the cobalt is +3 instead of the biologically active +1. In order to be utilized in the body, the cyanide molecule must be removed. It is thought that glutathione may be the compound that performs this function. Other available forms of vitamin B₁₂ include hydroxocobalamin, and the two active forms, adenosylcobalamin (cobamamide) and methylcobalamin.

The absorption of dietary cobalamin requires the formation of a complex between dietary B₁₂ and R-proteins and the secretion, by the stomach mucosa, of intrinsic factor. The B₁₂ complex is split by pancreatic proteases and the released B₁₂ attaches to intrinsic factor and is absorbed in the distal ileum. The amount of cobalamin required in the diet is very low and even people with pernicious anemia can generally absorb sufficient amounts if the coenzyme is supplemented at a high enough dosage.

Although the basic cobalamin molecule is only synthesized by microorganisms, all mammalian cells can convert this into the coenzymes adenosylcobalamin and methylcobalamin. Adenosylcobalamin is the major form in cellular tissues, where it is retained in the mitochondria. Methylcobalamin predominates in blood plasma and certain other body fluids, and in cells is found in the cytosol.

Adenosylcobalamin functions in reactions in which hydrogen groups and organic groups exchange places. In humans, adenosylcobalamin is required in only two reactions: the catabolic isomerization of methylmalonyl-CoA to succinyl-CoA, and interconversion of alpha- and beta-leucine. After its formation from methylmalonyl-CoA, succinyl-CoA is either involved in the synthesis of porphyrin molecules (along with glycine) or transfers its coenzyme A to form acetyl coenzyme A. The latter reaction is magnesium-dependent and the remaining succinate is fed into the citric acid cycle. Deficiencies in this coenzyme form of vitamin B₁₂ result in increased amounts of methylmalonyl-CoA and

generally an increase in glycine levels.

Methylcobalamin's only known biological function in humans is in the re-methylation of homocysteine to methionine via the enzyme methionine synthase, also known as 5-methyltetrahydrofolate-homocysteine methyltransferase. In order to originally form methylcobalamin from cyanocobalamin or other Cob(III)alamin or Cob(II)alamin precursors, SAM must be available to supply a methyl group. Once methylcobalamin is formed, it functions in the regeneration of methionine by transferring its methyl group to homocysteine. Methyl-cobalamin can then be regenerated by 5-methylTHF (see [Fig. 52.3](#)). The cell's ability to methylate important compounds such as proteins, lipids, and myelin will be compromised by a deficiency of either folate or vitamin B₁₂.^[15] Shortages of active folic acid, SAM, or a dietary deficiency of cobalamin will lead to a decrease in the generation of methylcobalamin and a subsequent impairment of homocysteine metabolism. Since lack of methylcobalamin leads to depressed DNA synthesis, rapidly dividing cells in the brain and elsewhere are affected.

At least 12 different inherited inborn errors of metabolism related to cobalamin are known. Abnormalities are detectable by urine and plasma assays of methylmalonic acid and homocysteine, and plasma and erythrocyte analysis of cobalamin coenzymes, which can reveal

465

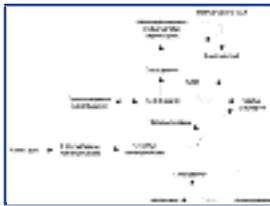

Figure 52-3 Cobalamin metabolism.

deficiencies of methylcobalamin or adenosylcobalamin^[16] (see [Ch. 29](#) for further discussion).

Betaine

The metabolic pathways of betaine, methionine, methylcobalamin and methylTHF are interrelated, intersecting at the regeneration of methionine from homocysteine. This regeneration is accomplished in one of two ways. One involves the generation in the cytosol of 5-methylTHF from methylene tetrahydrofolate and the transfer of its methyl group to regenerate methylcobalamin, which then acts as a coenzyme in the regeneration of methionine. Since tetrahydrofolate and its derivatives can only cross the mitochondrial membrane very slowly, inside the mitochondria regeneration of methionine relies on recovery of a methyl group from betaine.

Betaine donates one of its three methyl groups, via the enzyme betaine:homocysteine

methyltransferase, to homocysteine resulting in the regeneration of methionine. After the donation of the methyl group, one molecule of dimethylglycine (DMG) remains. This molecule is oxidized to glycine and to two molecules of formaldehyde, by riboflavin-dependent enzymes. The formaldehyde can combine with tetrahydrofolate within the mitochondria to generate one of the active forms of folic acid, methylenetetrahydrofolate, which can be converted to 5-methylTHF and subsequently used as a methyl donor (see [Fig. 52.4](#)).

In animal studies, a disturbance in the metabolism of either of the two methyl-donor pathways, due to limited availability of either betaine, or folates and vitamin B₁₂, has a direct impact on levels of nutrients in the coexisting pathway, since more of a drain will be placed on the other pathway as a source of methyl groups. Rats fed diets deficient in choline and methionine have hepatic folate concentrations half that of controls after 5 weeks.^[17] During choline deficiency, hepatic SAM concentrations have also been shown to decrease by as much as 50%.^[18] Similarly, THF deficiency results in decreased hepatic total choline levels.^[19]

Patients with a congenital deficiency of the enzyme methyltetrahydrofolate reductase (MTHFR), which is needed for the formation of 5-methylTHF, have reduced levels of both methionine and SAM in the cerebrospinal fluid and show demyelination in the brain and degeneration of the spinal cord. Methionine is effective in the treatment of some of these patients; however, betaine was shown to restore CSF SAM levels to normal and to prevent the progress of neurological symptoms in all patients in whom it was tried.^[20]

Betaine supplementation has been shown to reduce homocysteine levels while resulting in modest increases of plasma serine and cysteine levels.^[21] Stimulation of betaine-dependent homocysteine re-methylation causes a commensurate decrease in plasma homocysteine that can be maintained as long as supplemental betaine is taken.^[22]

Serine levels are depressed in some individuals with excess homocysteine who are treated with folic acid, cobalamin, and vitamin B₆.^[23] Because serine is required: (1) for the conversion of folic acid to its active form, (2) as a shuttle for methyl groups between the cytosol and

Figure 52-4 Phosphatidylcholine metabolism.

the mitochondria, and (3) as a cofactor in the transsulfuration pathway of methionine/homocysteine metabolism, supplementation with betaine should be included with folic acid, cobalamin, and P5P in order to optimize the interrelated pathways of homocysteine metabolism.

Pyridoxal 5'-phosphate

P5P is the active coenzyme form of vitamin B₆. This cofactor is involved in a myriad biological processes, including the trans-sulfuration pathway of homocysteine. This degradation pathway involves a two-step process, resulting in the formation of cystathionine and its subsequent cleavage to cysteine. Both of the enzymes involved, cystathionine synthase and cystathioninase, require P5P as a cofactor, and the committed first step in the degradation of homocysteine, cystathionine synthase, also requires serine, a downstream metabolite of betaine (see [Fig. 52.5](#)).

Once cysteine is generated, it can be directed into

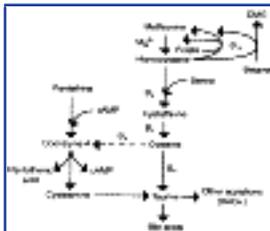

Figure 52-5 Synthesis of taurine.

several different pathways, including synthesis of glutathione, acetyl-CoA, and taurine. There are three known pathways from cysteine to taurine; all require P5P.

IMPACT OF HOMOCYSTEINE ON KEY NUTRIENTS

Because of its central role in sulfur and methyl group metabolism, elevated levels of homocysteine would be expected to negatively impact the biosynthesis of all of the following: SAM, carnitine, chondroitin sulfates, coenzyme A, coenzyme Q₁₀, creatine, cysteine, dimethylglycine, epinephrine, glucosamine sulfate, glutathione, glycine, melatonin, pantethine, phosphatidylcholine, phosphatidylserine, serine, and taurine.

S-Adenosylmethionine

Methionine is a component of many proteins and cannot be manufactured from other dietary amino acids. It serves as a source of available sulfur for the synthesis of both cysteine and taurine, and, as SAM, it is the most important methyl-group donor in cellular metabolism.

SAM is formed by the transfer of an adenosyl group from ATP to the sulfur atom of methionine. This reaction requires magnesium as a cofactor. When methyl groups are transferred from SAM, S-adenosylhomocysteine is formed. This is then hydrolyzed to release the adenosine, and results in the formation of homocysteine.

SAM is known to be utilized in the synthesis of the following compounds: carnitine, coenzyme Q₁₀, creatine, methylcobalamin from cob(III)alamin, 1-methylnicotinamide, *N*-methyltryptamine, phosphatidylcholine, and polyamines. It is also utilized in methylation reactions as part of hepatic phase II detoxification.

467

Carnitine

A trimethylated amino acid roughly similar in structure to choline, carnitine is a cofactor for transformation of free long-chain fatty acids into acyl-carnitines, and their transport into mitochondrial matrix, where they undergo beta-oxidation for cellular energy production. Mitochondrial fatty acid oxidation is the primary fuel source in heart and skeletal muscle. Synthesis of carnitine begins with the methylation of the amino acid L-lysine by SAM. Methionine, magnesium, vitamin C, iron, P5P, and niacin, along with the cofactors responsible for regenerating SAM from homocysteine (5-methylTHF, methylcobalamin, and betaine), are required for optimal carnitine synthesis (see [Fig. 52.6](#)).

A pivotal enzyme in carnitine synthesis, betaine aldehyde dehydrogenase, is the same enzyme responsible for synthesis of betaine from choline. Two recent studies suggest that this enzyme has a preference for the choline–betaine conversion, and that choline supplementation may decrease carnitine synthesis; therefore, it may be of greater benefit to supplement with betaine rather than its precursor. ^[24] ^[25]

Chondroitin sulfates, glucosamine sulfate and other sulfated proteoglycans

Proteoglycans are amino sugars found in all tissues, but which are highest in cartilage, tendons, ligaments, synovial fluid, skin, finger, and toenails, heart valves, and the basement membrane of all blood vessels. Perhaps

Figure 52-6 Synthesis of carnitine.

the most widely known of the amino sugars are the chondroitin sulfates and glucosamine sulfate (see [Ch. 89](#) for further discussion).

Chondroitin sulfates are primarily composed of alternating residues of *N*-acetyl-D-galactosamine and D-glucuronate. Sulfate residues are present on C-4 of the galactosamine residues in one type of chondroitin and on C-6 in another. Glucosamine sulfate is a simple molecule composed of glucose, the amino acid glutamine, and a sulfate group. Other sulfated proteoglycans include dermatan sulfates, keratan sulfates, and heparan sulfates.

High levels of homocysteine are likely to negatively impact the formation of the sulfated amino sugars because, although some sulfates are present in the diet, the sulfoxidation of cysteine is an important source of sulfate molecules. The sulfoxidation pathway proceeds through the toxic intermediate sulfite and requires molybdenum as a cofactor.

Coenzyme A

Coenzyme A consists of an adenine nucleotide and phosphopantetheine. Contained within the structure of this coenzyme is pantothenic acid; however, the reactive component of the molecule is a sulfhydryl group which is not contained within the vitamin. In order to form the sulfhydryl-containing molecule (pantotheine), pantothenic acid must combine with cysteamine. Cysteamine is formed through conjugation and decarboxylation reactions of cysteine. As was previously discussed, the metabolic stagnation implied with elevated homocysteine levels indicates that the body has suboptimal levels of cysteine. Because of this, even in the presence of adequate levels of pantothenic acid, it is possible to have inadequate biosynthesis of acetyl coenzyme A. The disulfate form of pantetheine, known as pantethine, as opposed to pantothenic acid, bypasses cysteine conjugation and decarboxylation. This might account for some of the clinical benefits seen with pantethine supplementation which have not been reproduced with the supplementation of pantothenic acid (see [Fig. 52.7A-D](#), for the chemical structures of pantotheine, pantethine, pantothenic acid, and cysteamine).
