CREDIMUS

We believe in the harmonic wholeness of the ecosphere. We believe that that harmonic wholeness is achievable through the application of positive cosmic energies.

Cosmic energy is available for use in attaining that harmonic wholeness. Cosmi-Culture is a system for gathering, amplifying, and redistributing that cosmic energy for the ultimate benefit of all mankind.

single entity, within this ecosphere, No can be singled out for emphasis, either to be reduced or enhanced at the expense of the whole. Disease, unwanted insects, undesirable plants (called weeds) are simply indications of conditions, in that environment, condusive to their existance particular time and place. Change at a those conditions by enhancing the environment for the desirable, and the reason for the undesirable ceases to exist. ReAgents are incorporated within the CosmiCulture system that will, at once, enhance the vitality of the desirable and reduce the vitality of the undesirable.

Our QUALITY of LIFE is dependent upon CLEAN thoughts, words, and deeds, as well as food and fiber, uncontaminated by poisons, excesses, and confusion. A high quality of life for all mankind is our goal.

🔘 Dr. T. Galen Hieronymus

TRANSMUTATION

1. ETHER ABSORPTION TEST IN SPROUTING The test procedure is simple enough. Take a clear test tube and insert a piece of sterilized cotton saturated with distilled water. (Put a bean or pea in the initial stage of germination inside the tube and seal it carefully with a glass stopper and wax, making it absolutely airtight and moistureproof. If we compare the weight in a few weeks hence. (after the seed inside has sprouted), we will find a considerable gain of weight which simply cannot be explained by contemporary physical laws theories. The gain can be demonstrated or with even a small letterscale, no laboratory precision scale is needed.

2. ETHER TRANSMUTATION TEST IN SPROUTS

But a follow-on test is even more revealing. A careful chemical analysis of the seed which has sprouted in the sterile environment of the sealed test tube as compared with an identical seed will prove the sudden appearance of new chemical elements in the sprout which also cannot be logically explained by contemporary textbook science. The mineral substances found in the sprouting seed will show a gain of 20 to 100% over the identical seed before the test. We know the tube was sterile, the water was distilled and contained no minerals, and no mineral substance can penetrate the glass wall of the testube.

The only logical explanation for these surprising results is of course the assumption of the existence of formative or "etheric forces" which are able to penetrate the molecular barrier of the material of the testube. We are again confronted with the "finer media" postulated by the esteemed Dr. Hieronymus. Around 1879, a German scientist named Von Herzeele had proved in more than 500 analysis

(c) Dr. T. Galen Hieronymus

that the mineral substances thus found in organic substances originate in a way comparable to alchemistic procedures. His published claims out-raged the scientific-materialistic so oligarchy of his day that his writings vanished from the libraries -- (shades of Dr. Wilhelm Reich!) it took a student of Dr. Rudolf Steiner, medical doctor named Dr. Rudolf Hauschka a many years of intensive efforts to locate the writings of Von Herzeele in an obscure small library in Berlin. Shortly after WW2, Hauchka proceeded to republish his own Dr. findings and he immediately received a joyous response in a letter from a Monsieur Spindler in France, reporting jubilantly that he too. had independently, come to identical experimental conclusions as Dr. Hauschka.

EXPERIMENTAL WORK FROM THE NOTES OF DR. T. GALEN HIERONYMUS, Ph.D.

I. Gather leaves from various plants. Put each leaf in a test tube. Make label for each. Label sheet.

Check 9-49 for each leaf. Record figures for each. Check and measure 23-25 (chlorophyll), record.

Sugar	5-70
Sodium	82-42
Iron	49-27
Nitrogen	12-19
Manganese	73-71
Calcium	24-4
Carbon Dioxide	47-67
Cobalt	7 2 - 8 4
Copper	73-28
Chlorine	37-93
Acidity	34-84
Alkalinity	26-41

II. Trees breathe. Check leaf for poisons that could have been absorbed from sprays, etc.

See list of poisons in book. Which poisons are commonly used in sprays for pesticides? Which poisons could have been absorbed by trees or bushes from run-off after spraying? Check leaves for these.

III. Gather specimens of water from well, neighbors water supply, lakes, streams and surrounding municipalities which have their own water supply.

MODERN FARMING PROBLEMS

Plant diseases and the elimination of plant pests are costing this country's farmers and ranchers around Six Billion Dollars a year. Think about that! Six Billion Dollars a year!

The cost is not only Six Billion Dollars a year, but the end results are Environmental Pollution, poisoning of fruit and vegetables designed for the market, and all the ensuing human poisoning and misery that results from these poisoned crops, and the cumulative achievements of poison sprays, powders, etc. used today to eliminate the bug population, and the plant disease infections.

The principle changes in the last thirty years have been that the infestations of insect pests have become more numerous, and the cost of chemical sprays and powders have shown a steady increase. Land, in its polluted state, becomes less fertile and useable as one of the great resources of the people in this (country. Acid rain has become a problem, stemming from industrial pollution of the atmosphere.

The massive pollution of the soil and air and water leads to smaller fruit, and less nutritional value of the fruit and vegetables.

The biological balance is constantly subjected to our practices of plowing, intense cultivation, clearing of new land, domesticating plants, close grazing practices, etc. It is time to approach the problems of this imbalance in a manner that recognizes man's relationship with Nature.

As for insect pests, there are over 30,000 insects which attack our plant crops grown for fiber crops or for food, to say nothing (of all the many insects and diseases that

DR. T. GALEN HIERONYMUS

attack our flowers, ornamental shrubs and lawns, and shade trees.

We use green plants so much that we are apt to take them for granted. There uses include food, clothing, and many other things. But that is not all the significance of plants. Green plants are living factories that manufacture the basic materials of life. They absorb carbon dioxide and give off oxygen. So we may acknowledge that human and animal life are both dependent on the survival and growth of green plants.

BOOSTING SEED ENERGY FOR BETTER GERMINATION

It has been proven in field and laboratory tests that the energy of wheat, cotton, soybean and other seed can be intensified as much as 30 times or more, so that seed will germinate faster, and plants will grow faster, and exhibit more stamina than untreated seed.

Tests may be made in a small way with wheat seed in test tubes. Put the test tube full of wheat seed on the plate of the Analyzer, and other test tube full of wheat seed in the Analyzer well. Set the dials on 0-0. Turn on the Power Switch. Count to ten. Turn off the Power Switch. Do this as many times as you wish to charge seed in test tube on plate.

If you are using the Beam Projector, put one test tube of wheat seed in each well with the Power Switch off. Now turn on the Power Switch. Count to ten. Turn the Power Switch off. Continue to turn on the power switch, count to ten, turn off the Power Switch, etc. as many times as you wish to charge the test tube of wheat seed in the right hand well.

When you have finished charging the seed, put the intensified seed test tube in the well of the Analyzer, and check the 9-49. Record the figure.

Don't forget to record the date, how you charged the testube of seed, and how many times you charged (intensified) it.

Plant some uncharged seed in a flat and some charged seed in another flat. Watch the growth carefully, measure at regular intervals of time and add this data to your written record of this experiment.

For practical charging of seed, a picture of seed in volume can be used on plate, with vial of seed in well as energy to charge with.

Rates for Cosmiculture Farming Continued

62

C Dr. T. Galen Hieronymus

METHODS OF WEED CONTROL

There are several methods Cosmiculture farmers may use to control weeds.

First, there are in this section, the burnt weed seed rates, (burnt weed (seed as recommended by Dr. Rudolph Steiner). If you use these rates:

I. Charge the rate for the type weed seed you wish to eliminate into a vial of distilled or neutralized water.

II. Put specimen into well of Beam Projector or Analyzer, place vial of water charged with burn of weed seed energy, and broadcast to field daily, until all weeds of such variety are dead.

You may, upon determining the species of weeds in your field, charge each vial of water with a different burnt weed seed rate, until you have a ReAgent of burnt weed seed energy suitable for treating each different species of weed growing in your field.

Put one vial in the well of the Analyzer. Measure the 9-49 and record the intensity. Put another vial of burnt weed seed energy into the well with the first vial. Measure the 9-49 and record.

Did the second vial of burnt weed seed energy raise or lower the 9-49 reading of the first vial of water? If not, these two are compatible. Leave them both in the well. Put another vial in the well with them and measure the 9-49. If compatible, these three may be combined by charging a neutralized vial of water by leaving all 3 charged vials in the well, with Power Switch OFF. Stand an uncharged, neutralized bottle of water on the plate, turn the Power Switch ON, count to 25, then turn the Power Switch OFF. Take the vials out of well, and away from the Analyzer. Put

C) Dr. T. Galen Hieronymus

the newly charged vial of water in the well. Meausre the 9-49 and record. If the 9-49 is low, turn off the switch, put the vials of burn weed seed energy back in the well, put the newly charged vial back on the plate, and charge several times with the combined weed seed energy, until the 9-49 intensity reading is at least 900.

Make other combinations of compatible burnt weed seed energy to use as Reagents.

The program of Treating with the burnt weed seed energies will last about three years if you treat a specimen of the field with weeds an hour or two every day.

Another procedure is to charge the rates of the specific weeds into vials of neutralized water. Measure the 9-49 and record. Number or letter vials of burntweed-seed energy. Put a vial of weed energy in the well of the Analyzer. Put vial of burnt weed seed energy into the well. Measure the 9-49 and Record. Has the energy of the weed in the vial of water decreased to a marked extent? To Zero? Treat on 0-0 until all weed energy is reduced to zero. This is the process of finding the efficiency of the burnt weed-seed energy for eliminating the weed.

When you have determined the rate of efficiency of the burnt weed-seed in eliminating the weed, you may increase the efficiency of the burnt weed seed energy by intensifying it by charging it several times into the vial of water to raise its intensity.

III. Another method of eliminating weeds is to place the leaf of a weed in a test tube, place in the well of your Analyzer with a picture of your field where the weeds grow, and treat the specimen with the weed leaf, on 0-0 with the Analyzer, or broadcast the energy of the leaf to (C) Dr. T. Galen Hieronymus the field, with a picture of the field in the well. The field should be treated with the weed specimen 30 minutes per day, until the field shows dying weeds.

IV. The simplist method, if you have a "Genuine Hieronymus" Cosmic Pipe on your land, is to place a leaf of each weed you wish to eliminate in the well of the Cosmic Pipe, along with the Reagents you put in the well, and leave the leaves in the well. You will notice discouraged and dying weeds in your fields as the growing season progresses.

V. Please observe your green and growing rye fields.

Are there any weeds growing there? Corn and Sunflowers drilled into small grain fields after gain has been harvested, do well and have very few weeds growing in these "after-crops".

Heavy straw mulch seems to harm soy bean germination.

(C) Dr. T. Galen Hieronymus

PROJECT WEATHER CHANGE

These rates are experimental in nature and we cannot guarantee that they will be effective in all cases.

Weather Project

Federal Law requires all experimenting with weather changes must register their names with the NOAA (Boulder, Colorado) and before beginning any project having to do with the weather or weather changes, advise the NOAA with the form filled in as they direct. They will provide the forms upon request.

It is well to study the weather reports and forecasts for several months, especially in the winter, so that you become familiar with the phenomena of weather changes.

LEY LINES AND VORTICES (Magnetic Fluxes)

32.5 -51.25

Left Line Vortex Left Hand

51.25-32.5

Right Line Vortex Right Hand

Energy grids over the earth consist of lines of energy something such as longitude and latitude type running east and west and the other north and south at regular distances. Where two of these cross, a definite amount of energy is released into the air. If a highway crosses such a vortex point, the energy influences traffic and most often more wrecks occur in such a location. In the fields or woods, such location can be identified by twisted o. а stunted growth of a tree which also displays a hollow trunk, black markings around such a hollow in the trunk. Bushes around such a spot will appear stunted in growth.

These rates are given so that such spots can be identified by analysis of leaves, stems, grass or soil.

Hay that has been damp and in the weather, often exhibits a small white mold, clinging to the stems and leaves, and a musty odor. { Hay such as this should not be fed to farm animals. In order to salvage hav in such condition you will need a picture of the pile of bundles of hay taken from the top the pile, and pictures of the buudles of of hay from each side. It is recommended that you use Polaroid or Automatic Kodak pictures, as specimens. Put pictures in well of Analyzer-Treatment Instrument. Check the 9-49 and record intensity Check 9-0 and record intensity Check 12.5-48 and record the intensity Check for poisons, such as Malathion, etc. in pesticides you know were used in fields, if any. (Treat all conditions found with picture in the well, with Reagents F-61 and F-62, and continue treating until all conditions read 0. Note the difference in odor and appearance of Hay. To treat out white mold in Hay: Check 9-49 and Record Mold Rate 5.5-0 Fungus 9-0; 12.5-48 Malathion 7.5-1.5 Parathion 8.5-48 Check for other poisons known to have been used as herbicides in hay field. Use Reagents #F-61 and #F-62 to treat mold . (rates. Treat all mold and poison rates to 0. When clean, hay will have a clean odor, as opposed to the odor of musty fungus it has when infected with white mold. © DR. T. GALEN HIERONYMUS

GARDEN PESTS

It is easier to eradicate garden pests when they are in the larval stage. Example: tomato hornworms, bagworms, tent catapillars, inch worms.

Neutralize the well of your instrument. Put the worm or bug in a test tube or small bottle. Put the test tube in the well. Measure 9-49 and record the amount of the 9-49.

With the specimen in the test tube, in the well, select various "wormers" and other substances. Put one at a time into the well with the specimen, and measure the 9-49. Whichever one lowers the 9-49 appreciably may be used. The one which will lower the 9-49 reading to 0, if you can find one which does this, should be used for future tests.

Neutralize the well. Put in a specimen of the plants attacked by the worms or bugs. Measure the 9-49 and record measurement.

Put the specimen of the reagent which lowers the 9-49 of the worm or bug into the well with the specimen of the plants (or you may use a picture of the garden for treating all plants). Measure the vitality, 9-49, of the plant or garden specimen with the reagent in the well. Again measure the 9-49. If the reagent does not affect the 9-49 of the plant or garden specimen, or if it raises the value of it, then the use of the reagent is indicated. <u>Never use poisons as reagents</u> or anything that lowers the vitality of the plants or garden specimen.

When you have found a suitable reagent, put the specimen of the plant or the picture of the garden area you wish to treat in the well with the reagent and treat for 20 minutes. Check. Continue treating until the bug is dead.. -37- \bigcirc Dr. T. Galen Hieronymu

General Vitality is the general well-being, or health, of an organism, be it soil, soil organisms, plants or animals (including man).

Humus (decayed organic matter). Five percent of the total organic matter is nitrogen in various compounds. A rule thumb--for each 1% of organic matter of soil's acre-furrow slice (6 of and а 2/3 inches of depth or approximately 2 million pounds of soil) equals 2,000 nounds of organic matter; therefore, if 5% of that organic matter is nitrogen, there is 1,000 pounds of nitrogen available for plant use. Approximately 3% of this nitrogen is available for plant use at any one time during the growing season. Humus also serves as а reservoir for phosphorus, sulfur, boron, zinc and all the cations, and is a major source of as well as food source for carbon, а all manner of soil organisms. High levels of magnesium and low calcium permit organic matter residue to decay into alcohols and aldehydes, sterilants to soil bacteria. Nearly 95% of the nutritional needs plant life depend on the "non-fertilizers" -carbon dioxide, sunlight and water.

Acidity can be reduced by any of several elements, thereby manufacturing the perfect pH with the wrong nutrient load. The acid condition of the soil means verv little if not related to the availability or absence of calcium, magnesium, potassium and sodium. Dr. W. A. Albrecht, as reported in An Acres USA Primer, demonstrated that "by bringing (these four elements) into equilibrium, we will automatically a soil system..." Calcium adjust pH in should occupy 60 to 70%% of the cation exchange capacity of the soil, together with magnesium totalling 80%, and potassium occupying 2 to 5%, with sodium maintaining -

(C) Dr. T. Galen Hieronymus

between .5 and 3%. Exchangeable hydrogen occupies the remaining 10 to 15%.

<u>Alkalinity</u> is directly coupled to acidity. It cannot be assumed that with a high pH soil reading, adequate calcium will be available. (For further explanation of the relationship of pH to soil fertility, refer to <u>An Acres USA Primer</u>, Lesson 9.)

Ĺ

The following list of elements are <u>anions</u> or negatively charged nutrients that cannot be complexed in the soil except through microbial action. Otherwise they are leached or simply "evaporate" from the surface layer of soil out of the reach of growing plants.

*Note: 95% of nutrients come from air and water.

<u>Nitrogen</u> (N) An excess, a most common condition with artificially produced fertilizers, causes a deficiency or an interference with the metabolism of potassium and magnesium. (1/168) A deficiency may be responsible for the presence of chlorosis. Apparently, there is a direct link between organic nitrogen (N₂) and (CO) Carbon

Monoxide as either one is transmutable into the other. You will find much exciting and useful information in a book written by Mr. Louis C. Kervran called Biological Transmutations, which documents the transmutations of one element to another explaining some of the observations that can and been made by laymen, but have gone have unexplained by scientists. A prime example: Where does the calcium come from that shell of chicken eggs? forms the Mr. Kervran explains this and many other, heretofore unexplained phenomenon, and will be quoted throughout this text.

Since Academia has chosen to exault the C Dr. T. Galen Hieronymus

-40-

artificial use of nitrogen over the remaining 89 naturally occurring elements, the use of nitrogen fertilizers over and above what occurs naturally, will not be itemized here, other than to say that; unless you are pushing for a record production at the expense of quality and/or profit, you probably will not need to add additional nitrogen once your soils have been brought back into harmonic balance.

Phosphorus (P) Many soils contain 40,000 to 80,000 pounds of P205 per acre in the top seven inches of soil. The quantity and quality of microbial activity in your soil will determine just how much of this storehouse of phosphate is available for your crops use during each growing season. An excess of available phosphate will cause a deficiency or an interference with magnesium, manganese, calcium, iron and zinc. It is most readily available in a slightly acid, nutritionally balanced, high organic-matter soil. Excesses mean poor yields, low vigor, low quality, and a micronutrient deficiency. (1/134, 199-206) For the effect of phosphorus in a feed ration, refer to An Acres USA Primer, page 365.

Sulfur (S) There are ten isotopes of sulfur with four occurring naturally. Sulfur, along with carbon, is one of the most chemically active nutrients a soil matrix. It readily combines in with many of the other elements to "release" them into forms useable by many soil microbes and plants. A deficiency in the soil first shows up in animals--sheep shed their wool, other animals shed their hair and have poor hair-coats, hoof and horn development is poor, and they have watery eyes and excess saliva. Excesses of sulfur cause an acid rumen and a copper C Dr. T. Galen Hieronymus deficiency. Manure, compost and green manures are good sources. Deficiency means sick crops, insect, bacterial and fungal attack. It is difficult to determine between sulfur and nitrogen deficiency, and it is usually associated with manganese shortages. Sulfur balance permits plants cold tolerance and insect resistance. (1/135, 207-210, 364) "Sulfur appears as a 'fritting' of two nuclei of oxygen. The most abundant form of sulfur is S_{32} , $(2-0_{16}^{--}S_{32})$." (4/65, 87-89).

ĺ

(

Ĺ

Carbon (C) 45 to 56% of a plants compounds are structured with carbon. We live on a carbon-based planet where carbon is the primary element used for the storage of sunlight energy. "A single human being gives off enough carbon dioxide in 24 hours to fill the photosynthesis requirement of a single tree. It has been computed that it takes 20 trees to handle the carbon dioxide given off by every five gallons of gasoline used by an internal combustion engine." (emphasis added) (1/133) One acre that produces 100 bushel of corn requires approximately four tons of carbon dioxide, some of which is derived directly out of the air, but the chief source of carbon remains the soil and its organic matter. Approximately 58% of soil organic matter exists as organic carbon (1/168) The symptom least likely to be observed is the decay system in the soil...As soils become infertile, the carbon dioxide level over them diminishes accordingly simply because the microbes of decay cannot function when the cycle is broken. In a living organism, it is the union of oxygen and carbon that generates energy. (1/69, 70) (Also see the Acres USA Primer for the importance of carbon in feed rations (page 362).

Oxygen (0) Oxygen is second only to carbon in its uses in the growth of plants and

C Dr. T. Galen Hieronymus

animals, with approximately 43% of all the compounds in a plant composed of it. Oxygen is derived from both air and water. Without oxygen, life on Earth (as we know it) could not exist. Within the cell structure, oxygen fuses with sodium to yield potassium. It also combines with magnesium to yield calcium. Oxygen can also be formed by the joining of sodium and lithium. (4/25, 33, 59, 65) Oxygen also reacts with carbon to yield silicon. (4/44)

The relationship of oxygen to other nutrients is explained in <u>An Acres USA Primer</u>, pages 362-363. The importance of oxygens role in humans is illustrated by the emphasis given the element by Adelle Davis in her book, <u>Let's Get Well</u>, pages 42, 56, 63-64, 68, 145, 279, 292, 335, 339 and 356.

Cations are positively charged nutrients that are complexed within the soil and organic matter structure and can be "released" for plant use either through the plants own chemical actions by the exchange of hydrogen ions, produced at the root surface and through microbial action. Plants absorb few nutrients simply because they are soluable. Therefore, soil tests for "water-soluable nutrients" are misleading and give a distorted picture of the fertility levels actually in the soils. We will concern ourselves with using the C.E.C. (Cation Exchange Capacity) of conventional soil tests and the N.E.L. (Nutrient Energy Levels) as recorded with the "Genuine Hieronymus" Analyzer and as produced and amplified by the "Genuine Hieronymus" Cosmic Pipeline.

A balanced soil should be saturated with useable cation nutrients up to 80 to 95% of the C.E.C. This leaves only 10 C Dr. T. Galen Hieronymus to 15% for hydrogen, a so-called non-nutrient. (1/126)

Hydrogen (H) Six percent of a plants compounds involve this element. It is exchanged at the root-hair surface for other cations complexed in the soil matrix. (1/133) Hydrogen is also important in feed rations where an excess of over 7.83% means that the feed energy level of the ration is in excess. Bloat is likely to result. A deficiency means nucosal disease, watery eyes, a hacking cough, undigested feed in droppings, unthriftiness. (1/363)

If potassium is too abundant in the presence of hydrogen, a transmutation will occur that yields calcium. Hydrogen is active in many other transmutations such as: phosphorus plus hydrogen will yield sulfur (reversible) and sodium plus hydrogen yields magnesium, among others. (4/23, 363)

<u>Calcium</u> (Ca) An excess of calcium causes a deficiency or interference with the metabolism of magnesium, phosphorus, manganese, zinc and other trace elements. Proper calcium levels help plants form better root systems, stems and leaves for more efficient use of sunlight energy, water, carbon dioxide, nitrogen and trace mineral nutrients. These levels (60 to 70% of C.E.C.) reduce the toxicity of several soil constituents and combinations.

Excessive calcium means plants with imbalanced hormone and enzyme systems, ergo, poor health--the magnet for bacterial, fungal and insect attack. (1/181, 191)

When calcium occupies between 65 to 70% of the positions on the soil colloidial C.E.C., it makes phosphorus and micronutrients available, then improves the environment for microorganisms and aids

-44-

(c) Dr. T. Galen Hieronymus

ť

ĺ

the growth of symbiotic and non-symbiotic nitrogen-fixing bacteria.

excess of hydrogen ions signifies An an acidity that might become dangerous for the cell. However, in that case potassium can join a hydrogen nucleus to produce calcium, thereby establishing alkalinity and an optimum calcium/potassium ration. (4/23) Magnesium can combine with oxygen to yield calcium. (4/25, 36-47, 56-64, 135-153) The plant needs calcium to make the magnesium of its chlorophyll, and the more calcium is given, the more the plant enriches itself in magnesium (up to a detrimental limit, of course). (4/129) See also Adelle Davis' book Let's Get Well for calcium's importance for humans.

Magnesium (Mg) Calcium, potassium, phosphorus, and nitrogen metabolism can be adversely affected by an excess of magnesium. A deficiency produces symptoms similar to manganese. High magnesium and low calcium permit organic residue to decay into alcohols and aldehydes, sterilants to bacteria. It may also prevent normal drydown and nutritional ripening of any growing crop.

Soils with this condition produce abundant weed crops that germinate best under anerobic conditions--foxtail, fall panicum and many others. Magnesium is essential to photosynthesis since a single atom serves as the inorganic core of chlorophyll. Magnesium should occupy 10 to 20% of the C.E.C., along with calcium, making up 80% of the C.E.C. (1/180-186)

The isotopes of magnesium plus the isotopes of oxygen can form four of the isotopes of calcium. Sodium plus hydrogen yields

C Dr. T. Galen Hieronymus

magnesium. Mr. Kervran, in <u>Biological</u> <u>Transmutations</u>, covers magnesium quite extensively (pages 25, 37, 48, 57-64 and 129) so we will only touch on the importance of this nutrient here.

Potassium (K) should occupy from 2 to 5% of the C.E.C. An excess will cause deficiency or interference with the а metabolism of calcium, magnesium, iron, sodium, manganese and zinc, however, the availability is usually deficient (in less than well-balanced soils) as it is seldom absorbed in excess. It acts as a catalyst in the soil matrix, along with the micronutrients. Potassium is of prime concern because it is required in the forming of chlorophyll, and it is required so plants can pull free nutrients out of the air--carbon, hydrogen and oxygen. Starches, sugars, proteins, vitamins, enzymes or cellulose cannot be made without potassium. It also aids plants in being drought resistant, disease resistant, and is essential to the size, color, and flavor of fruits and vegetables. (1/211-216) Also see the Acres Primer for the relationship to feedstuffs, page 364.

Potassium will neutralize the acidity caused by the micro-organisms (during metabolism they excrete hydrogen ions) by combining with the hydrogen to form calcium. The reaction is reversible. Sodium can also combine with oxygen to form potassium. (4/20-26, 128) Yeasts can produce potassium from sodium in the soil, and other microorganisms can produce it from calcium (4/131).

Sodium (Na) should occupy between .5 and 3% of the C.E.C., althouth it is seldom a problem. An excess, however, will cause a deficiency or interfere with the metabolism of calcium and potassium.

(C) Dr. T. Galen Hieronymus

- (

1

Sodium is very active chemically and is never found in its ionic state in nature. (1/126)

It has long been "known" that the presence of sodium makes potassium available. Mr. Kervran, in Biological Transmutations pages 27-35, demonstrates that sodium plus oxygen yields potassium and that this reaction is reversible. The presence of sodium also tends to conserve soil calcium and magnesium. "The optimum amount for a (feed) ration should be .27% of the dry matter. Possibly 90% of all rations...are low on sodium." Emphasis added. (1/364) Also see Kervran's Biological Transmutations pages 27-35 for additional information on sodium.

Iron (Fe) The manganese-iron link was verified long ago by agronomists. Plants require specific bacteria for absorption of manganese and iron. Curiously, a manganese excess produces the same effects as a lack of iron. In other words, an excess of manganese impedes the assimilation of iron, and vice versa. (Fe₅₆-H₁-Mn₅₅) (4/93-101) An excess of iron will also cause a deficiency or interference with copper, potassium, and phosphorus. Iron is a carrier of oxygen and "is essential" in the production of chlorophyll, however chlorosis is possible even in the presence of adequate iron. (An Acres USA Primer)

<u>Manganese</u> (Mn) An excess impedes the assimilation of iron and causes a deficiency or interference with phosphorus, potassium, and magnesium. Manganese aids the oxidase enzyme in carrying oxygen. Without the metal, the enzyme is ineffective. Manganese is also needed in carbohydrative metabolism and in seed formation. The deficiency pattern is the same as for iron. (1/136, 198)

(C) Dr. T. Galen Hieronymus

Doctors have found that a manganese deficiency in humans causes some types of allergies, but its biological role is best known in plants. The absence of manganese, however, does not indicate a deficiency of this element. (As shown under iron, manganese can be transmuted from iron by the removal of a hydrogen proton.)

Some plants are able to produce the missing manganese, while others are not (oats for example). The same is true of animals at certain periods. The human organism seems to contain enzymes which allow iron to change into manganese and vice versa. "...the enzymes called oxydases owe their property of fixing oxygen to their ever-present manganese." (G. Bertrand) The availability of manganese to plants is primarily subject to the presence in the soil of mangano-bacteria, Out of one gram of earth, and out of a total of 564.2 million total bacteria, 255.0 million mangano-bacteria were found in a soil sample. (4/93-101) This illustrates the importance of maintaining a soil environment which promotes active bacteria reproduction.

Zinc (Zn) aids in the formation of chlorophyll and stimulates plant growth. An excess adversely effects iron, copper, phosphorus and cadmium.

<u>Copper</u> (Cu) is vital to root metabolism and aids in the formation of proteins, amino acids, enzymes, and many organic compounds. An excess causes iron, zinc and phosphorus to be adversely affected.

Boron (B) Allows calcium to perform properly. Terminal bud death is a sign of deficiency. If the sugar level is low, check for a boron deficiency. It regulates flowering,

(c) Dr. T. Galen Hieronymus

(

(

-48-

fruiting, cell division, salt absorption, hormone movement and pollen germination. Carbohydrate metabolism, water usage, and nitrogen assimilation are also regulated. Without microflora and fauna, boron will be unavailable for plant use. Excesses will restrict plant growth with a pale green color that can be mistaken for a nitrogen deficiency. <u>Either</u> a shortage or an excess will invite insect and fungal attacks.

Molybdenum (Mo) This element is essential to the microbes that metabolize anions. These anions in turn become available for plant use upon the death and decay of those microbes. Molybdenum is only one of the micronutrients indispensible to the structuring of coenzymes. "If there is no metal in the coenzyme, the enzyme remains ineffective." (4/128) Apparently, molybdenum will attempt to compensate by increasing when potassium is deficient. However, an excess of potassium, even supplied by manure, will cause a deficiency of molybdenum.

Chlorine (C1) This element will stimulate plant growth. It is seldom deficient because plants seem to be able to produce it. The chlorine content of an organism seems to stay constant. It is of vital importance in its association with sodium. There could be no life without the proper proportions of these two elements. Chlorine is a regulator and is a reversible element. Nitrogen can combine with carbon to form chlorine. Chlorine can transmute into several other elements such as: carbon and sodium; carbon plus oxygen plus lithium; nitrogen plus lithium; as well as, silicon plus lithium; and each of these reactions is reversible.

It is easy to see that the balance of nature can be maintained by a constant (c) Dr. T. Galen Hieronymus -49-

balance of a few elements. (4/90)

Selenium (Se) White muscle disease, found in swine and sheep, is associated with a deficiency of selenium and Vitamin E. An excess of this element is toxic and can cause animals to lose hair, horns and even hooves in extreme cases.

Rhodium (Rh) Very little information is available as to soil, plant or animal response to this element. No toxic effects have been reported in either experimental animals or man. It appears to play some vital role in the scheme of nature.

Cadmium (Cd) Cadmium crosslinks in the human body to contribute to the hardening of arteries and to the loss of elasticity of skin and is apparently involved in the aging processes. (3/96) An excess causes a deficiency or interference with the metabolism of copper.

<u>Aluminum</u> (Al) At very low pH levels, it becomes soluable in toxic amounts. Excesses increase the need for phosphorus in animal health. Excesses of magnesium will combine with aluminum to form a toxic substance right in the soil itself. (1/182, 366) An excess of aluminum in humans is associated with Altzheimers Disease (a type of senility).

<u>Cobalt</u> (Co) An excess of cobalt causes a deficiency or effects the metabolism of iron. Both cobalt and iron are important for legume nodule formation and for nitrogen conversion to the organic form (N_2) .

Cobalt is the core of Vitamin B-12, which is essential for hemoglobin formation in the blood and to prevent degeneration of nerves. (1/196-197) In animals, it reduces the availability of copper, aluminum, iron, manganese, molybdenum and iodine. (1/368)

C Dr. T. Galen Hieronymus

1

<u>Nickel</u> (Ni) an excess in a feed ration makes it unpalatable. (1/368)

Berryllium (Be) Very little information is available concerning Berryllium as it relates to agriculture, except that it reacts chemically similar to aluminum. It is toxic to humans, but probably not in concentrations normally found in soils.

Iodine (I) No information is available as to the effect of iodine on plants. More study has been done on the effects on animals where an excess has been found to cause a secretion of mucous from the lungs and bronchial tubes, and cause a rapid pulse and nervous tremors. Also, young are born dead, or die soon after birth. Abortion of the fetus can occur at any state or reabsorption of the fetus. Excesses also cause irregular or suppressed heat periods, infertility and sterility, a reduced sex drive, and deterioration in semen. (1/368)

Silicon (Si) This element does not occur free in nature. It is found as silica (quartz, sand, sandstone) or as silicate (feldspar, etc.). It constitutes about 27.6% of the earth's crust, which makes it the second most abundant element on earth, second only to oxygen. (5/8233) Calcium is derived from the combination of silicon and carbon atoms. Proof of this can be seen in the development of the common chicken egg. The amount of calcium in the fertile egg is not enough to form the skeleton of the new born chick. The calcium of the shell of the egg is not diminished. However, the lining of the egg contains silica (Si 0_{2}) which transmutes with carbon to form sufficient calcium for the chick. (4/44-47)

Chlorophyll reflects the green color that we see in plants. Magnesium forms C Dr. T. Galen Hieronymus

-51-

the heart of the chlorophyll molecule, which in turn produces "food" for the plant in the presence of sunlight. There may be an association of chlorophyll with aluminum.

<u>Sugar</u> is the result of the action of chlorophyll with sunlight. This is the food for plant growth and is stored in the fruit as sugars and starches (a complex sugar). The level of sugar in plant tissue is a very good indication of the quality of production. The sugar level may play a key role in whether the plant attracts insects or not. Low levels seem to attract various insects, or at least plants with low levels of sugar seem more attractive to insects.

TOMATO MYSTERY DISEASE

Scientists at the University of California at Riverside have taken many soil samples in their efforts to test for viruses, molds, bacteria and other disease causing agents and have tested many plant samples for the same germs, molds, funguses and disease causing agents, all to no avail. So far they have found nothing that seems in any way to contribute to this Tomato Mystery Disease. Van Maren is experimenting with fumigation of affected areas with Methyl Bromide. This fumigation costs \$800.00 per acre. We note that the claim is made that the cost of growing tomatoes on unfumigated land is \$1,700.00 per acre.

Using the "Genuine Hieronymus" Analyzer and Treatment Instrument, our research analysis gives us a rate for Tomato Soil Rot 29-5.75, and Tomato Powdery Mildew 38.75-9. Analysis of specimen of the Mystery Tomato Disease gives us 6-0, 6-3.5, 21.75-24.5 and 49.75-0, all with high intensities.

So far the best treatment we have found is treatment on these rates until the rates are treated to zero and remain at zero. We recommend also our Energy Capsule Reagent F-54, if the soil seems overly alkaline.

(C) Dr. T. Galen Hieronymus

DISEASES OF FRUITS

These rates on the following pages are for diagnosing. Try treatment on rates with/without reagents. For a permanent cure, treat the soil with a combination of Bio-Dynamic Reagents and Reams color methods.

INSECT PESTS AFFECTING ROSES

Aphids

Tiny insects in clusters on new growth, buds or undersides of leaves, causing deformed and stunted foliage, creates sticky substance, attracting ants.

í

Causes stunted and deformed foilage. Insects are tiny, reddish or green or brown. They suck the juices out of the plant.

Rose Beetles

Chew, devour, cut holes in leaves. Larvae eat plant roots.

1.	Japanese Beetle	40.5-54.5
2.	Rose Chafer	21.25-8.25
3.	Rose Curculio	85.5-58.5
4.	Fuller Beetle	83.25-58.75

Rose Budworm Catapillar 19.25-12.5

Leaves rolled around larvae, flower buds eaten, mostly in late spring.

Bristly Rose Slugs 17.5-48

(Cane borers, or leaf worms)

Leaves skeletonized, eaten from underside, then large holes, and then veins devoured. These are larvae of the Saw Fly.

Rose Leaf Hoppers 12.5-27

Tiny, yellow-green, jumping insects found on underside of leaves. These are sucking insects, who suck out the juice in the leaf cells.

Rose Scales 37.5-43

Dirty gray, round, white or brown shell covered sucking insects. Their sucking activities cause wilting and darkening and premature death of foilage.

(c) Dr. T. Galen Hieronymus,

Virus Disease of Roses 83.5-59 Small colorless angular light spots on leaves. Mosaic, Oakleaf, or Riney patterns on leaves. Spread by propagation of infected plants.

Rust 95.5-9

Wilted leaves, dropped leaves, powdery rust colored spores, spread by wind. Winters in fallen leaves.

C Dr. T. Galen Hieronymus

DISEASES AFFECTING ROSES

Black Spot 10.5-68.5

A fungus disease, spreads by rain or use of hose. Lives through winter in small lesions on rose canes or in leaves on ground.

ĺ

Circular black spots with fringed margins on rose leaves. Leaves turn yellow and drop. Leaves may remain on fungus-resistant plants.

22.5-65.5 Rose Canker

Caused by fungus parasites entering plant through dying tissue or wounds.

Disease appears as lesions in woody stems, poor growth and/or death above infected area.

Rose Crown Gall 67.25-33.5

Rough, round shaped growths on crown or roots of plants. Plant's general vitality declines, flowers and foliage are abnormal, and plants soon die.

Bacterial Disease, carried in soil. It can live in soil after plant is removed and eventually affect other plants.

Rose Powdery Mildew 88-42.5

This disease is spread by wind, during warm days and cool nights. Lives during winter on fallen leaves and stems and bud scales. It shows as white powdery masses of spores on buds, shoots and young leaves, stunted foliage and distorted new growth.

Rose Gall

Rose Root Gall 92-54 Mossy Rose Gall 51-54

Large tough swellings on roots. Large (mossy swellings on stems. If cut open, Larvae will be found.

Caused by wasp type insects boring into stem or roots and depositing eggs.

> C Dr. T. Galen Hieronymus -60

Rose Pith Borers

- 1. Rose Stem Sawfly 17.5-48 2. Rose Stem Girdler 53.25-23.5
- 3. Small Carpenter Bees 16.5-4.5

Pests bore into cane and lay eggs. Larvae eat through canes. Causes plant shoot wilt, foliage wilt and wilting and death of canes, and sometimes canes becomes swollen.

Rose Midge 45-23

Rose Midges are yellowish, tiny flies which lay eggs in growing stem tips. Hatched larvae eat the tender plant tissue. Infested plants show deformed and blackened leaves and flower buds which die prematurely.

Rose Spider Mites 70.5-35.5

Minute, leaf-sucking spiders. Affected leaves look dry, turn red, yellow, brown or gray, curl up and drop off. Sometimes tiny webs can be seen on under side of leaves. These pests are abundant in hot dry weather.

Rose Thrips 43-12.75

Tiny, slender, brownish yellow flying insects, very active, hide in base of infected flowers. These cause flecked, and deformed flowers, especially on white roses.

These Rates are to be used for identifying Rose diseases and insect pests.

It is suggested that care be taken to increase the mineral content of the soil, and to increase the general vitality of the soil, to give the plants resistance to the onslaughts of disease and insect pests.

B – D COMPOST PREPARATIONS

æ.

B - D COMPOST PLANT PROTEIN

COMPOST PROTEIN			PROTEIN
Prepar- ation	Herb or Material	Individual Element	Result
502 25-34	Yarrow Flower	Sulfur (S) Potas- sium (K)	Permits plants to attract these elements in extremely dilute quantities for their best nutrition.
503 37-33.5	Canne- mile Flower	Calcium (Ca) Sulfur (S)	Stabilizes nitrogen within the compost and increases soil life so as to stimulate plant growth.
504 47-34:5	Stinging Nettle	Sulfur (S) Potas. (K) Calcium (Ca) Iron (Fe)	Stimulates soil health, provid- ing plants with the individual nutrition components needed. "Enlivens" the earth (soil).
505 43-38	Oak Bark	Calcium (Ca)	Provides healing forces (or qualities) to combat harmful plant diseases.
506 52.5- 41.5	Dandelion Flower	Silicon (Si) or Silicic Acid, Potas- sium (K)	Stimulates relation between Si & K so that the Si can attract cosmic forces to the soil.
507 48.5-38	Valerian Flower	Phos- phorus (P)	Stimulates compost so that phosphorus component will be properly used by the soil.

Collectively, the preparations improve soil nitrogen (N) by a process of transmuting K into N, Ca into N, and so forth.

Steiner designed these particular herbs/materials as those in the plant kingdom which hold the particular elements in the best possible form.

CHEMICALS

These Chemical rates are given here so that you can identify the rates you find in scanning soil samples or feed or water.

CAUTION: never put chemicals such as herbicides and Pesticides in the well of your Analyzer, Anapathic, Beam Projector, Rate Treatment Unit, or Cosmic Pipe. These instruments will become contaminated and unfit for use. There is no successful method to clear the instrument in which poison has been treated or broadcast.

76-79 Vitamin E Deficiency of: White muscle disease, heart failure, paralysis Vitamin A 19.5 - 8.5Deficiency of: Nasal discharge, coughing, scouring, watering eyes, hardening of mucous membranes, calves with weak horns, severe diarrhea in young calves, redness and swelling around dewclaws, stiffness in hock and knee joints, swelling in brisket, mastitis, udder problems, loss of appetite, loss of sexual interest. Zinc 68 - 97Deficiency of: Low ash rations 32-53 Vitamin D Deficiency of: Backs swell and stiffen, backaches, increased need for calcium and phosphorus, stiffness (of gait, drags hind feet, rickets Excess Vitamin D: Deposits of calcium in heart Lack of Vitamin K: Failure of blood to clot Excess of Cobalt: Riemen bacteria fails to manufacture B_{12} , starved appearance, pale skin, decreased fertility, milk or wool production, cellulose digestion sharply reduced. (Some cobalt necessary for utilization of propionic acid) Excess Nickel: (ration unpalitable) nickel poisoning Vitamin B 86 - 24Vitamin C 69 - 35Vitamin D 32-53 1 Vitamin F 70-84 Vitamin G 85-81

(c) Dr. T. Galen Hieronymus

Vitamin A Deficiency 19-33; 8-19; 35-19.

Symptoms: Eyes clouded, with discharge. Ulcers form. Infection can cause loss of visions.

Treat 8-18, 8-19, 60-18, 34-18, 60-19, 34-18, using vitamin A as Reagent.

Treat specimen on 0-0 with Vitamin A as a Reagent.

To raise the 9-49, Treat on 37-18; 37-19, plus vitamin A as ReAgent. Treat 35-18 and 18-12, 38-18 plus Vitamin A as a Reagent.

C Dr. T. Galen Hieronymus

Vitamin E Deficiency 63.25-82.25 (Muscular dystrophy or white muscle disease) 54-41 (do not treat on this rate. Symptoms: Rapid deterioration of skeletal muscles. When the heart muscles are affected, death occurs in a few days. Cause: Starvation and a lack of Vitamin E

Treatment: Treat 31.25-41 using Vitamin E as a Reagent, until condition is zero, and remains at 0. Feed a vitamin and mineral rich supplement to regular feed. Check to see that 63.25-82.25 is diminishing, and treat to 0.

(C) Dr. T. Galen Hieronymus

HOMEOPATHIC HERB RATES

These rates may be used to charge vials of water to be used as Homeopathic remedies.

They may be charged into vials of water, intensified 10 to 15 times and used as ReAgents for treating ailments by checking against disease rates. If 9-49 of specimen is raised as much as 50 points, and disease rate is lowered appreciably, then treatment in Analyzer or Beam Projector is indicated.

By checking these against each other for compatability, it is possible to combine several of these rates by charging them into 1 vial of water for use as reagents.

C Dr. T. Galen Hieronymus

ESTRUS CYCLE OF MARE

Puberty begins between 10 and 24 months with average onset at about 18 months. The length of time elapsed from the beginning of one estrus period to the next can vary in the mare from 7 to 124 days. The average time is usually close to 21 or 22 days. Abnormally long cycles probably include a number of skipped cycles. Length of estrus period is from 2 to 3 days, 4 to 6 days, or 7 to 9 days and occasionally over 10 days.

Heat periods tend to become shorter from spring to mid-summer. During March and April, heat periods are irregular and long, frequently with no ovulation occurring. From May to July the periods become shorter and more regular with ovulation a normal part of the cycle. Ovulation usually occurs from one to two days before the end of estrus.

Mares with heat periods of one to three days should be bred on the first day. Mares with longer heat periods should be bred on the third or fourth day and again 48 to 72 hours later. Mares with regular, short heat periods may be bred at any time.

RATES FOR MARE

Oviduct Vagina Ovary Uterus 15.5 -54.5 48.5 -81.5 69-54.25 30.5 -61.75

(C) Dr. T. Galen Hieronymus

HORSES - PREGNANCY 3-37

The period of gestation is approximately 11 months, more or less. The mare will be ready for service every 3 weeks. If the foal is to be born in April, the service should be in May. The ideal time for conception to take place is towards the end of her heat period.

DISEASES OF CATTLE

Anaplasmosis

Symptoms: High temperature (103° to 107°)

Yellowish membranes, depression, constipation, anemia, extreme weakness, unsteady gait, depression, rough hair coats.

1

(

T by scanning liver for metallic and chemical poisons. Treat to 0 when found.

Make Reagent. Broadcast by treating specimen and reagent on 0-0 until all negative conditions are 0.

Reagent: Transfer to vial of neutralized water. Check 9-49 for intensity. Be certain intensity is at least 500.

Anthrax (Bacillus Anthracis)

Sudden deaths in herd--sick animals show high temperatures (to 107°). Excitement and hypertension, followed by stupor, depression, spasms, staggering, rapid breathing, swelling on various parts of the body, bloody discharge from body openings.

Check for metallic and chemical poisons in kidneys, stomach, liver and nerves. Check for viruses, 34-; 60-; 46-; 20.5-; 56-; 48-; 56-84; 56-82; 56-44; 56-29; 56-23; 56-17; make reagent and treat all virus infections to zero.

Blackleg

Affects young cattle 6-24 months old. Sudden deaths in young cattle, gaseous swellings beneath shoulder skin, back of flank, hip breast which make rustling sound when pressed by hand. Complete loss of appetite. The course of the disease is very rapid.

C Dr. T. Galen Hieronymus

Scan for metallic and chemical poisons, check for 6-. Treat to 0 when found. Make reagent charging with 12.5-15 (800 intensity into water) and treat on 0-0, or with "Genuine Hieronymus" Anapathic until all signs of disease are gone. Early treatment is most effective.

(C) Dr. T. Galen Hieronymus

Stress of shipping cattle causes upper and/or lower respiratory infections. Thus cattle, brought into the feedlot with other cattle, exhibit viral and bacterial infections and can expose other cattle to these respiratory diseases.

Stress in shipped cattle reduces their resistance to disease, causes lack of appetite. Lack of food intake makes cattle weak and vulnerable to increased infections.

These feedlot cattle may be treated as a unit, if not too many for Polaroid Snapshot. If too many, get pictures of several dimensions of herd. If only a few show heavy symptoms, saliva specimens, (saliva on Q-Tips, in test tubes) may be used.

STRESS:

Check 9-49

check for hypertension

and treat to zero.

Recheck the 9-49.

This reading will have a higher intensity than it had before treatment.

22-11

To make a ReAgent for stress, use the "Genuine Hieronymus" Analyzer-Treatment Instrument. Set the dials on 37.5-42.

Put a neutralized vial of water on the plate. Put specimen (picture side out) in left hand well. Turn the power switch on, count to 25 and turn it off Check the 9-49 of vial of water. Charge again and again, and check 9-49 after each charge. When the intensity of the vial of water has reached 750, use the ReAgent you have created to treat specimen on 22-11 and treat it to 0. Put the Reagent, which you should number and list in your ReAgent file, and not that its function is to treat out stress. In treating specimen, check intensity of 22-11 every 30 minutes. Treat to 0 (zero). (C) Dr. T. Galen Hieronymus

DISEASES OF FEED LOT CATTLE

SHIPPING FEVER-Stress due to cold, hunger, loss of appetite, weariness, fear, and disorientation. Significantly reduces cattle's resistance to bacterial and viral infections. ESTRUS CYCLE OF COW

In cattle, puberty varies with the breed and with nutrition. Puberty occurs usually when the heifer is about two-thirds of its adult body size, measured by height and length, rather than weight.

The Estrus cycle length averages 20 days for heifers and 21 to 22 days for mature cows. The Estrus period in a cow is defined as the time she will stand when mounted by a bull. This period averages about 18 hours in both dairy and beef cows. This is somewhat shorter in heifers. The normal range is from 12 to 24 hours.

Ovulation normally occurs about 10 to 15 hours following the end of estrus in a cow.

Rates for Cows

Vagina Bovine Ovary Corpus Luteum Mammary Gland Cystic Ovary Uterus 18.25-81.5 14.5 -54 22.5 -54.5 52-62.75 58-54.5 53-61

C Dr. T. Galen Hieronymus

ARTIFICIAL INSEMINATION

Cows that come into "standing" heat in the morning are bred the same afternoon. Cows that come into "standing" heat in the afternoon are bred the next morning. A cow in "standing" heat will stand when mounted by a bull, a steer or another cow.

Bleeding from the vulva occurs in a high percentage of heifers and cows one to three days following the end of estrus. This phenomena is called "metestrous" bleeding and if breeding is done at this time, conception rarely takes place. If breeding takes place at the proper time, fertility and conception are not impaired because of "matestrous" bleeding.

LOSS OF HAIR, HOOVES, FEATHERS, FUR, ETC.

These conditions are related to excess Selenium (35-79) especially prevalent in Alkaline soil. Selenium is Light sensitive, and is affected by hydrogen sulphide and ammonium sulphide. This results in loss of hair, fur, nails, hooves, (sulphur) and high levels of ammonia in urine (affecting efficiency of Kidneys). Usually in horses, the ankle bone will push through the flesh and hoof in the presence of a high selenium reading. Take horse off Selenium medication and treat out excess Selenium immediately.

ESTROUS CYCLE OF THE SOW

Sexual maturity in the gilt usually occurd about seven months of age. As in other species, it is delayed by an inadequate diet.

Length of Estrous Cycle. The average estrous cycle in swine is about 21 days, with a reported range from 11 to 41 days. A range from 18 to 24 days is considered normal.

Length of Estrus. The estrous period may range from 15 to 96 hours, with an average duration between 40 and 46 hours. The first estrus after weaning is usually longer and may average 65 hours; it occurs about 7 to 9 days after weaning of the pigs.

Many sows exhibit a nonfertile estrus one to three days following parturition. In nearly all of these animals, ovulation does not occur. It has been suggested that this heat may be caused by estrogen from some source other than the ovary.

Time of Ovulation. Ovulation occurs during the latter part of estrus about the second day of the cycle. At each period, 10 to 25 ova are shed, with an average of 16.4.

RATES FOR SWINE (SOW)

Phosphorus Deficiency

87.25-76.5

Symptoms: In young growing sheep, from four months old, the bones do not develop properly. Sheep are light, thin, and coats are rough. Bones at frong of skull are thin, flexible and when pressed an inner layer of bone can be felt. This is the characteristic "double scalp".

Recommendation: Change to a better pasture. Feed a better quality hay which has been "cleaned" of all poisons (see Eloptic Feed Analysis Chart in manual.) Before moving, check for gastro-intestinal worms: 2-100, 3-73, 86-85, 39-89, 3-82, 3-73, 3-75, 61-78, 90-37, 4-93. If any of these rates are found, treat to zero.

T on 0-0, using Vitamin D as a Reagent. T on 0-0, using phosphorus sample as a Reagent. Check 9-49 and keep 9-49 high.

Rickets

68-71

T on rate plus Vitamin D as a Reagent.

Symptoms: Young lambs suddenly go lame. One or more legs start to bend at joints or in shafts of long bones. Affected joints will be swollen and painful.

Open Mouth Disease

77-21 8-81 11-81

Symptoms: Lambs cannot close mouth, so cannot graze properly. Lower jaw bone deteriorates, is easily bent and spongy. T 77-21; 8-81; 11-81. Treat to 0.

T 3-9 to raise intensity. 89-70, Raise intensity by T on rate.

(c) Dr. T. Galen Hieronymus -141-

Sheep Diseases Conc. a

Use Calcium and Vitamins A, D and C as Reagents. Feed grind alfalfa pellets and dampen with warm water, plus liquid trace minerals and vitamin supplements until improvement in vitality and feeding is noted.

Cerebrocortical Necrosis (CCN) 54-10

A nervous disease associated with dead tissue in the brain of sheep. (DO NOT TREAT ON RATE)

Symptoms: Lambs or ewes wander in continuous circles or stand motionless. They also seem to be blind. In second stages they fall forward, throw heads back and kick legs. Legs may stiffen.

T on 22-10 to 0.

T 11-82 with Vitamin B,

T 48-55 with Vitamin B_1 T 24-39 if found

This will require treatment on all these rates, 30 minutes daily until the 9-49 remains high.

Cobalt is a trace mineral. Sheep should have a certain amount available as a trace mineral supplement to their feed.

Lambing Fever

82.25- 4.5

Cause: Calcium Deficiency

Symptoms: Fatigue, no appetite, ears turn ice cold. Muscles in twitching spasm, staggering. Get down and cannot rise. Fast breathing. Final stages, bloated, constipation is common.

Treat with Reagent Calcium Boroglyconate on lambing fever rate. Scan thyroid and treat to raise the vitality of 6-81.

Calcium Borogluconate

66.5 -24

Lime applications to pasture may help prevent lambing fever.

C) Dr. T. Galen Hieronymus

Sheep Diseases Cont'd Hypo Magnesaemia 50.75-93.75 This is the result of a lack of magnesium. Symptoms: Staggering, twitching muscles, grinding teeth, high 22's. The sheep froths at the mouth, falls in a fit, becomes comatose and dies. hypomagnesaemia, massive hemorrhages soon In occur in heart muscle and in brain. T on 29-30; 35.5-41; 86-4 Swayback 76.75-12.75 (Disease of newborn lambs) Cause: Blood copper of Ewe is too low. Effect: Brain damage in new born lamb, causing difficulty in standing after birth and no control of hind quarters. T on 48-55 plus copper as Reagent. T on 0-5 plus Trace Minerals Reagent T on 0-10 " 11 11 T on 0-15 " ** 11 11 T on 0-20 " 11 11 ** T on 0-30 " " 11 ., Border Disease 51.25-31 34-31

Cause: A filterable virus

Border disease in pregnant ewes produces conditions in which the virus affects the unborn lamb. Many times this results in the death of the fetus and abortion in later stages of pregnancy. If lamb is born alive, its coat is fuzzy with hairs and there is excessive coloring of skin. The baby lamb often trembles violently, except in sleep, with marked shaking in hind quarters and head. There is a further deterioration of condition, with diarrhea before death.

Check for virus, and treat out. Try 34-, 62-, 60-, 3-, 4-, 14.5-, 46-, 14.5-, 2-. Treat out (C) Dr. T. Galen Hieronymus

-143-

Sheep Diseases Cont'd

virus found and locations -41, -11, -49. Check and treat daily until condition remains 0.

<u>Pine Disease</u>

21.75-32.75

This condition is a "wasting" condition affecting sheep. It is like pernicious anemia.

Cause: Lack of Cobalt in system, causing animal to be unable to manufacture Vitamin B₁₂ in system.

Emergency Treatment: Measure 9-49 vial of neutralized water. Set vial in instrument plate. Set dials on 72-84. Turn instrument on. Treat on 72-84 for 10 minutes. Turn off instrument. Put vial of water in instrument, check intensity of 72-84 in water. Treat specimen of sheep on 0-49, using vial of water as Reagent, for 30 minutes. Check 9-49 of specimen. Treat specimen on 50-76 for 30 minutes, using Vitamin B and Iron as Reagent.

(C) Dr. T. Galen Hieronymus

ESTROUS CYCLE OF THE EWE

Puberty usually occurs the first fall at four to 12 months of age if the ewes are well fed.

Breeding Season. The ewe is probably the best example of a seasonally polyestrous animal, with a long period of anestrus followed bv a breeding season that may vary from 1 to 20 consecutive estrous cycles. The length of breeding season appears to be related to the severity of climatic conditions under which the breed developed. In severe climates, a suitable lambing period is restricted and consequently the breeding, or sexual, season is likewise restricted, so that lambing occurs only during the favorable time (Scotch Black Face is an example of such a breed). Breeds developed in milder climates may lamb successfully over a longer period, so the breeding or sexual season is also extended (example: Merino sheep).

Length of Estrous Cycle. The average estrous cycle in the ewe is between 16.5 and 17.5 days. Unusually long or unusually short cycles tend to appear during the early and later parts of the sexual season, rather than during the middle part.

Length of Estrus. Duration of estrus averages about 30 hours. It has been reported to range from 3 to 84 hours, but most ewes will accept a ram during a period of 24 to 48 hours. The ram may be attracted both during proestrus and metestrus as well as estrus, but the ewe will accept him only during the actual estrous period.

C Dr. T. Galen Hieronymus

SHEEP REMEDIES

Pregnancy Toxemia

78.25-10.75 (

Check 3-37. Treat out 78.25-10.75 to raise 3-37.

Pregnancy Toxemia is caused by poor nutrition, verging on starvation. Usually the disease occurs when the food deteriorates during the final two months of pregnancy. It happens many times when the flock is on poor pasture with little or no supplementary feed, or in severe weather when pasture is covered with frost or snow.

If the Ewe isn't getting enough food to eat she uses up her sugar reserves. Blood sugar levels drop. Then the body fat is broken down, producing ketones. They accumulate in the blood, producing symptoms like those of excessive alcohol.

Symptoms:

The Ewe's actions are slowed. She acts "stupid". Then the head is carried in an odd or unnatural position, to the side, held high or dropped low. There is poor appetite and ewe is constipated and cannot stand. Death occurs in 1 to 6 days.

Good leaf hay, plenty of water. Treat "chemicals" or 37's out of blood. Treat on Pregnancy Toxemia rate with concentrated vitamins and minerals.

C Dr. T. Galen Hieronymus

ESTROUS CYCLE OF. THE BITCH

The appearance of the first estrus varies considerably between breeds and also between individuals within a breed. The smaller breeds may attain puberty as early as 6 to 8 months, while larger breeds may be $1\frac{1}{2}$ to 2 years old before the first heat.

Length of Estrous Cycle. The dog is a monestrous animal with a variable period of anestrus between estrous periods. While the bitch is commonly considered to come in season twice a year with approximately 6 months between heat periods, the interval averages between 7 and 8 months. The length of the anestrous period may vary from 4 months in small breeds to 8 months or more in large breeds. The estrous cycle itself is much less variable, with an average proestrus of 9 days, estrus of 9 days and metestrus o/ 80 to 90 days. Some authorities consider metestrus to be limited to the early luteal phase, while the bitch is still receptive to the male. They consider diestrus to continue from the loss of sexual receptivity.

Length of Estrus. Estrus may range from 5 to 19 days, with a higher conception rate occurring in bitches with estrous periods that last from 5 to 10 days and a much lower conception rate in those extending from 17 to 19 days.

Time of Ovulation. The bitch appears to ovulate spontaneously during the first three or four days of true estrus. It is not known whether all follicles ovulate at one time or whether ovulation is a continuing process during th early part of estrus.

Time of Breeding. During proestrus the vulva C Dr. T. Galen Hieronymus -148swells considerably, and a more or less moderate flow of blood occurs. The advent of estrus can be definitely determined by the willingness of the female to accept a male. At this time, the flow of blood decreases.

C Dr. T. Galen Hieronymus

CITRUS RUST MITES

Citrus Rust Mites 11.25-47.25 This rate is for identification purposes.

Rust mites reduce citrus value and market quality. The mites cause stunted growth and deformed fruit. Citrus mites are very small, lemon-yellow, wedge shaped insects. They may be seen plainly by the use of a 10/power magnifying glass. Heavily infested appears to be dusty or fuzzy. fruit The fruit leaves and tender new shoots are infested. causing leaves to lose gloss and drop off tree. The rust mite can mummify fruit.

SOY BEAN SUDDEN DEATH SYNDROME

Soy Bean Sudden Death Syndrome 64.5-9

Plants are environmentally stressed Ъv drop in temperature before June 15th. The Soy Bean Sudden Death Syndrome features yellowing of foliage, dropping of leaves, stems remaining on plant. The Soy Bean Syndrome is usually found where high infestation of cyst nematodes is prevalent, with resulting abortions. pod Stunted plant growth is associated with nematode activity.

Recommended Reagent: F-89

Check for nematodes: 39 - 892 - 10015 - 4212-27 6.5 - 117-13 2.5 - 4348 - 137.5 - 282-9 3 - 732 - 9552-58.5 13 - 4Treat on rates found with Reagent F60.

TEAS

To make teas, you will need one full ounce of dried herb (28 grams) and 1 pint of distilled water, 16 Fl. Ounces.

Infusion - steep herb in boiled water (decoction 20 minutes. Simmer on Low heat for 10 minutes to 1 hour.

Ant-Acids

Comfrey leaves Comfrey root Mullein Hops Flax Seed Red Raspberry Slippery Elm Wood Betony

Antibiotics

Chaparral, hops, golden seal, myrrh, Ehinacea Juniper berries, garlic, rosemary, thyme

Anti-Catarrhals

Angelica, Anise, Bayberry, Bistort, Cayenne, Coltsfoot, Garlic, Irish Moss, Longwort, Raisins, Wild Cherry, Cranesbill, Cubelis, Elcampane, Figs, Flax seed, Ginger, Horseradish, Labelia, Marsh Mallow, Tormentil, Yerba Santa.

Aphrodisiacs

Cloves, Damiana, False Unicorn, Kava Kava, Saw Palmetto, Fennel, Fenngrell, Ginseng, Sarsaparilla roots.

Deolistruents

Barberry (liver, gall bladder) Culver's root (bowel) Golden Seal (glands) Gravel Root (Kidneys) Hydrangea Root (Kidneys) Plantain (Blood, Kidneys)

C) Dr. T. Galen Hieronymus

Descutients (to dissolve growths & tumors) Black Walnut, Burdock root, Chapparal, Red Clover, Gota Kola, Garlic, Devils Claw

Diuretics

Backache, Prostatitis, Sciatica, Kidney Stones, Bladder Ache, Scalding Urine, Gonorrhea, Skin Eruption, Water Retention, Obesity.

Blackberry, Black Cohosh, Blue Cohosh, Bucho, Burdock root, Celery seed, Chaparral, Cleavers, Corn silk, Damiana, Dandelion, Eleconpane, False Unicorn, Fennel, Juniper Berries, Kelp, Miltletoe (American), Mullien, Pepsissenia, Rosemary, Saw Palmetto Shepards Purse, St. Johns wort, Uva Vusi, White Willow, Gota Kola, Gravel root, Hawthorne berries, Horse Radish, Horse tail, Hydrangea, Kava Kava, Marshmallow, Mistletoe (European), Parsley, Pleurisy Root, Sassafras, Senna, Squaw vine, Stone root, White Oak Bark.

Expectorants - loosens mucous

Chaparral, Coltsfoot, Comfrey, Elecampane, Ephedru, Fennel, Fenvgreek, Garlic, Nettles, Plantain, Thyme, Wild Cherry, Horehound, Horseradish, Hyssop, Licoriu root, Luhelia, Lungwort, Mullein, Myrrh, Parsley, Pleuresy root, Vervain, Yerba Santa.

Lymphatics

Black walnut, Chaparral, Dandelion, Poke weed, Ehinacea, Garlic, Oregon Grape root, Yellow dock.

Hepatics

Aloe Vera, Boneset, Elder, Yellow Dock, Dandelion, Carrot, Bayberry.

Nerves - Nervines

Catnip, Celery, Chamomile, Parsley, Peach husk, Pleurisy root, St. Johns wort, Vervain.

INSTRUCTIONS FOR INSTALLING A FGENUINE HIERONYMUS" COSMIC PIPELINE

يو المر

10

2

- 1. Locate point near the center of the field, but out of the equipment traffic. The location is not critical to the function of the Cosmic Pipeline, nor is the orientation of the pipe head. Locate near the center.
- 2. Dig a "post-hole" to the depth of the painted section of the "bottom" piece of the instrument. (20" for the Small Cosmic Pipe and 24" for all other sizes.)
- 3. Install "bottom" section in post-hole and tamp lightly. (Be sure that the "ground-plate" is firmly in pondact with the bottom of the hole.)
- 4. Fit the "bell" end of the too section together with the "top" of the bottom section. Press firmly together.
- 5. Attach enclosed wire to both terminal clips on the side of the assembled Cosmic Pipeline. (This wire connector may be used on a switch.)

6. The Cosmic Pipeline is now in operation.

- Selected reagents may be added to the "well" located in the "Y" of the bottom section, as desired.
- If livestock are, or will later be present in the field it would be wise to protect the Cosmic Pipeline with a fence placed approximately three feet distant around the instrument.

NOTE: No batteries or electrical connections are need for operation.

TO OPERATE THE ANAPATHIC INSTRUMENT

Fut visi of water in the "right hand" well. Turn on the power awitch. Depress the neutraliser switch. Turn off the power switch, Fut specimen in the "left hand" well. Nove dial knob as far to right as it vill go. Turn on the scan light. Turn on the power switch. Knob will slowly turn pointer to the left. When the pointer has reached to point at left, turn off power awitch. Turn Scan Switch to Treet. Take specimen out of "left hand" well and put the vial of charged water in the left well. Turn on power switch and set your times for the amount of time you wish to treat, usually this is twenty minutes.

When the timer rings, turn off power switch and take the wiel out of the well. Put your species in the well of your Analyzer and check original condition. It should give you a reading of condition lower than the original reading (the condition you wished to lower by treating in the Anepathic). If you wish to treat this condition again (if it is not to zero with the initial Anapathic treatment) then go through the process again, first neutralizing the viel of water and recharging it with the specimen's energy.

Always check with the Analyzer to know when the condition has a zero reading.
