CHARACTERISTIC BOND LENGTHS IN FREE MOLECULES

This is a summary of typical bond lengths in gas-phase molecules. The value given for each bond is near the mid-range of values found in simple molecules. Bond lengths usually vary by 1 or 2%, and often by more, depending on the nature of the other bonds attached to the two atoms in question. References 1 and 2 give bond lengths in individual gas-phase molecules, as determined by spectroscopic and electron diffraction methods.

All bond distances are given in Å ($1 \text{ \AA} = 10^{-10} \text{ m}$).

ATOMIC RADII OF THE ELEMENTS

The simple model of an atom as a hard sphere that can approach only to a fixed distance from another atom to which it is not bonded has proved useful in interpreting crystal structures and other molecular properties. The term van der Waals radius, r_{vdw} , was originally introduced by Pauling as a measure of this atomic size. Thus in a closely packed structure two non-bonded atoms A and B will be separated by the sum of their van der Waals radii r_{vdw} (A) and r_{vdw} (B). The set of van der Waals radii proposed by Pauling was refined by Bondi (Reference 1) based on crystallographic data, gas kinetic collision cross sections, and liquid state properties. The non-bonded contact distances predicted from the recommended r_{vdw} of Bondi have been compared with actual data in the collection of the Cambridge Crystallographic Data Center by Rowland and Taylor (Reference 2) and modified slightly. Their recommended van der Waals radii are given in the third column of this table.

The Cambridge Crystallographic Data Center also makes use of a set of "covalent radii" to determine which atoms in a crystal are bonded to each other. Thus two atoms A and B are judged to be connected by a covalent bond if their separation falls within a tolerance of $\pm 0.4 \text{ \AA}$ of the sum r_{cov} (A) + r_{cov} (B). The covalent radii are given in the fourth column of the table.

DIPOLE MOMENTS

This table gives selected values of the electric dipole moment for over 800 molecules. When available, values determined by microwave spectroscopy, molecular beam electric resonance, and other high-resolution spectroscopic techniques were selected. Otherwise, the values come from measurements of the dielectric constant in the gas phase or, if these do not exist, in the liquid phase. Entries are listed alphabetically; compounds not containing carbon are listed first, followed by compounds containing carbon.

The dipole moment is given in debye units (D). The conversion factor to SI units is $1 \text{ D} = 3.33564 \times 10^{-30} \text{ C m}$.

Dipole moments of individual conformers (rotational isomers) are given when they have been measured. The conformers are designated as *gauche*, *trans*, *axial*, etc. The meaning of these terms can be found in the references. In some cases an average value, obtained from measurements on the bulk gas, is also given. Other information on molecules that have been studied by spectroscopy, such as the components of the dipole moment in the molecular framework and the variation with vibrational state and isotopic species, is given in the references.

When the accuracy of a value is explicitly stated (i.e., 1.234 ± 0.005), the stated uncertainty generally indicates two or three standard deviations. When no uncertainty is given, the value may be assumed to be precise to a few units in the last decimal place. However, if more than three decimal places are given, the exact interpretation of the final digits may require analysis of the vibrational averaging.

Values measured in the gas phase that are questionable because of undetermined error sources are indicated as approximate (\approx). Values obtained by liquid phase measurements, which sometimes have large errors because of association effects, are enclosed in brackets, e.g., [1.8].

HINDERED INTERNAL ROTATION

I. Ozier and N. Moazzen-Ahmadi

In asymmetric tops like methyl alcohol, CH_3OH , and symmetric rotors like CH_3SiH_3 , the methyl group can undergo internal rotation relative to the rest of the molecule, traditionally called the frame (LS59, OM07). Although various different tops are considered here, all have three-fold symmetry. In such cases, the potential V hindering the internal rotation can be written:

$$V(\alpha) = V_3\left(\frac{1}{2}\right)(1 - \cos 3\alpha) + V_6\left(\frac{1}{2}\right)(1 - \cos 6\alpha) + V_9\left(\frac{1}{2}\right)(1 - \cos 9\alpha) + \dots,$$

where α is the deviation from equilibrium of the angle between the top and frame that measures the torsional motion. If only the first two terms are retained, then V_3 is the height of the hindering potential and V_6 is the shape parameter. For symmetric tops like CH_3CH_3 where the top and frame are identical, α is replaced by 2γ and the origin for γ is often taken as the eclipsed configuration. In the expansion, $-\cos 6n\gamma$ is then replaced by $(-1)^{n+1}\cos 6n\gamma$, where $n = 1, 2, \dots$. In cases where different forms of the expansion have been used in the original works, the values of the parameters published there have been converted to the conventions defined here.

In Tables 1 and 2, values are given for V_3 for a selection of asymmetric and symmetric tops, respectively. In cases where the higher order parameters have been determined, these are given in the Comments column. Where appropriate, this column also indicates the specific top, isomer, state, and/or isotopomer that has been studied. For ethane, three symmetric top isotopomer are listed to illustrate the isotopic dependence of V_3 and V_6 . In all other cases, only one isotopomer is listed, even if several have been studied. In all but one of these cases, the isotopomer reported is the one with the highest natural abundance. However, CH_3OCDO is listed because the results obtained are more precise than for CH_3OCHO . The molecules are listed alphabetically in Hill order according to the molecular formula.

The determinations listed for the potential parameters are effective values that incorporate to varying degrees effects from other molecular parameters. For example, the apparent value of V_3 can be changed significantly if the reduced rotational constant F is calculated from the structure, rather than being determined independently (LS59). Other examples include such mechanisms as coupling to excited skeletal vibrations (OM07) and redundancies connecting some of the torsional parameters (LB68, MO87). The experimental uncertainties quoted are taken from the original works; no attempt has been made to standardize the definitions. All the potential parameters are given in cm^{-1} . Where the original work has reported these values in other units, the conversion to cm^{-1} has been carried out using standard factors (LB02):

$$1 \text{ calorie} = 4.1868 \text{ joules};$$

$$1 \text{ calorie/mole} = 0.34998915 \text{ cm}^{-1}.$$

A variety of different methods have been used to measure V_3 , V_6 , and V_9 (LS59, OM07); only a few of the more important will be discussed here. For asymmetric rotors, both the pure rotational spectrum and its torsion-rotation counterpart are electric dipole allowed and are affected in lowest order by the leading terms in the torsional Hamiltonian. Both types of spectra have been used extensively to determine V_3 (LS59). For symmetric tops with a single torsional degree of freedom, either the permanent electric dipole moment vanishes, as in CH_3CH_3 , or the normal rotational spectrum is independent of V_3 in lowest order, as in CH_3SiH_3 . In

the latter case, the molecular beam avoided crossing method can often be used (OM07). The torsion-rotation spectrum is forbidden in lowest order, but becomes weakly allowed through interactions with the infrared active skeletal vibrations (OM07). By employing long absorption path lengths, this spectrum has been used to determine V_3 in a number of molecules. For both asymmetric and symmetric tops, the most precise determinations of the molecular parameters have been made in cases where both rotational and torsion-rotation spectra have been investigated.

TABLE 1. Asymmetric Top Potential Parameters

Name	Molecular Formula	Line Formula	Ref.	V_3/cm^{-1}	Comments
1 Trifluoromethanethiol	CH ₃ S	CF ₃ SH	LB02	500.83 ± 0.03	
2 Methylphosphonic difluoride	CH ₃ F ₂ OP	CH ₃ P(=O)F ₂	SL06	676 ± 25	
3 Methanol	CH ₄ O	CH ₃ OH	LB02	373.594 ± 0.007	V ₆ = -1.597 ± 0.051 V ₉ = 1.04 ± 0.20
4 Methanethiol	CH ₄ S	CH ₃ SH	SH86	443.029 ± 0.070	V ₆ = -1.6451 ± 0.0144
5 Methylsulfane	CH ₄ S ₂	CH ₃ SSH	TH86	609.0 ± 14.0	
6 Trifluoromethyl isocyanate	C ₂ F ₃ NO	CF ₃ N=C=O	LB02	47.8769 ± 0.0051	
7 Trifluoroacetaldehyde	C ₂ HF ₃ O	CF ₃ C(H)=O	DG87	298 ± 10	
8 Pentafluoroethane	C ₂ HF ₅	CF ₃ CHF ₂	EG96	1190 ± 4	
9 Acetyl bromide	C ₂ H ₃ BrO	CH ₃ C(Br)=O	K60	456.7 ± 10.5	
10 1-Chloro-1,1-difluoroethane	C ₂ H ₃ ClF ₂	CH ₃ CClF ₂	ALB97	1311.8 ± 1.4	
11 Acetyl chloride	C ₂ H ₃ ClO	CH ₃ C(Cl)=O	LB02	442.74 ± 1.05	³⁵ Cl
12 Acetyl fluoride	C ₂ H ₃ FO	CH ₃ C(F)=O	PK59	364.3 ± 2.1	
13 Methyl fluoroformate	C ₂ H ₃ FO ₂	CH ₃ OC(F)=O	LB02	374.1 ± 0.2	
14 Methyl trifluoromethyl ether	C ₂ H ₃ F ₃ O	CH ₃ OCF ₃	LB02	382 ± 10	CH ₃
15 Acetyl iodide	C ₂ H ₃ IO	CH ₃ C(=O)I	MK66	455.3 ± 10.5	
16 Methyl cyanate	C ₂ H ₃ NO	CH ₃ OC≡N	LB02	399.0 ± 17.5	
17 1-Chloro-1-fluoroethane	C ₂ H ₄ ClF	CH ₃ CHClF	LB02	1334.9 ± 3.8	
18 1,1-Difluoroethane	C ₂ H ₄ F ₂	CH ₃ CHF ₂	LB02	1163.0 ± 2.5	
19 Acetaldehyde	C ₂ H ₄ O	CH ₃ C(H)=O	KH96	407.716 ± 0.010	V ₆ = -12.068 ± 0.037
20 Thioacetaldehyde S-oxide	C ₂ H ₄ OS	CH ₃ C(H)=S=O	LB02	285.6 ± 0.3	Z isomer
21 Acetic acid	C ₂ H ₄ O ₂	CH ₃ COOH	IA03	170.1742 ± 0.0002	V ₆ = -6.4725 ± 0.0001
22 Methyl formate	C ₂ H ₃ DO ₂	CH ₃ OC(D)=O	LB02	400.60 ± 0.03	deuterated
23 Fluoroethane	C ₂ H ₅ F	CH ₃ CH ₂ F	FD83	1172.1 ± 1.4	
24 Nitrosoethane	C ₂ H ₅ NO	CH ₃ CH ₂ N=O	LB02	903 ± 25	gauche conformer
	C ₂ H ₅ NO	CH ₃ CH ₂ N=O	LB02	911 ± 25	cis conformer
25 Acetamide	C ₂ H ₅ NO	CH ₃ C(NH ₂)=O	LB02	24.949 ± 0.008	
26 Difluorodimethylsilane	C ₂ H ₆ F ₂ Si	(CH ₃) ₂ SiF ₂	SG05	439.4 ± 2.5	

Name	Molecular Formula	Line Formula	Ref.	V_3/cm^{-1}	Comments
27 <i>N</i> -Nitrosodimethylamine	$\text{C}_2\text{H}_6\text{N}_2\text{O}$	$(\text{CH}_3)_2\text{NN}=\text{O}$	LB02	145.8 ± 0.25	<i>cis</i> CH_3
	$\text{C}_2\text{H}_6\text{N}_2\text{O}$	$(\text{CH}_3)_2\text{NN}=\text{O}$	LB02	737.4 ± 13.3	<i>trans</i> CH_3

BOND DISSOCIATION ENERGIES

Yu-Ran Luo

The bond dissociation energy (enthalpy) is also referred to as bond disruption energy, bond energy, bond strength, or binding energy (abbreviation: BDE, BE, or D). It is defined as the standard enthalpy change of the following fission: $R-X \rightarrow R + X$. The BDE, denoted by $D^\circ(R-X)$, is usually derived by the thermochemical equation, $D^\circ(R-X) = \Delta_f H^\circ(R) + \Delta_f H^\circ(X) - \Delta_f H^\circ(RX)$. The enthalpy of formation $\Delta_f H^\circ$ of a large number of atoms, free radicals, ions, clusters and compounds is available from the websites of NIST, NASA, CODATA, and IUPAC. Most authors prefer to use the BDE values at 298.15 K.

The following seven tables provide essential information of experimental BDE values of R-X and R⁺-X bonds.

- (1) Table 1: Bond Dissociation Energies in Diatomic Molecules
- (2) Table 2: Enthalpy of Formation of Gaseous Atoms
- (3) Table 3: Bond Dissociation Energies in Polyatomic Molecules
- (4) Table 4: Enthalpies of Formation of Free Radicals and Other Transient Species
- (5) Table 5: Bond Dissociation Energies of Common Organic Molecules
- (6) Table 6: Bond Dissociation Energies in Diatomic Cations
- (7) Table 7: Bond Dissociation Energies in Polyatomic Cations

The data in these tables have been revised through September 2008.

TABLE 1. Bond Dissociation Energies in Diatomic Molecules

The BDEs in diatomic species have usually been measured by spectroscopy or mass spectrometry. In the absence of data on the enthalpy function, the values at 0 K, $D^\circ(A-B)$, are converted to D°_{298} by the approximate equation:

$$D^\circ_{298}(A-B) \approx D^\circ(A-B) + (3/2)RT = D^\circ(A-B) + 3.7181 \text{ kJ mol}^{-1}$$

This table has been arranged in an alphabetical order of the atoms A in the diatomics A-B.

TABLE 3. Bond Dissociation Energies in Polyatomic Molecules

The D°_{298} values in polyatomic molecules are notoriously difficult to measure accurately since the mechanism of the kinetic systems involved in many of the measurements are seldom straightforward. Thus, much lively controversy has taken place in the literature and is likely to continue for some time to come. We will continue updating and presenting our assessment of the most reliable BDE data every year.

The references relating to each of the D°_{298} values listed in Table 3 are contained in the *Comprehensive Handbook of Chemical Bond Energies*, by Yu-Ran Luo, CRC Press, 2007. Many D°_{298} in Table 3 are derived from the equation

$$D^\circ_{298}(\text{R-X}) = \Delta_f H^\circ(\text{R}) + \Delta_f H^\circ(\text{X}) - \Delta_f H^\circ(\text{RX})$$

Here, the enthalpies of formation of the atoms and radicals are taken from Tables 2 and 4, respectively, and the enthalpies of formation of the molecules are from reference sources listed in the above *Comprehensive Handbook of Chemical Bond Energies*.

Table 3 presents H-C, C-C, C-halogen, O-, N-, S-, Si-, Ge-, Sn-, Pb-, P-, As-, Sb-, Bi-, Se-, Te-, and metal-X BDEs. The **boldface** in the species indicates the dissociated fragment. The **metal-X** BDEs are arranged on the basis of the Periodic Table with the new IUPAC notation for Groups 1 to 18, see inside front cover of this *Handbook*.

TABLE 6. Bond Dissociation Energies in Diatomic Cations

From thermochemistry, we have

$$D_{298}^{\circ}(\text{A}^+-\text{B}) \equiv \Delta_f H^{\circ}(\text{A}^+) + \Delta_f H^{\circ}(\text{B}) - \Delta_f H^{\circ}(\text{AB}^+) = D_{298}^{\circ}(\text{A}-\text{B}) + IP(\text{A}) - IP(\text{AB})$$

Thus, $D_{298}^{\circ}(\text{A}^+-\text{B})$ may be derived using the Table 1 and the ionization potentials of species A and AB. The following Table has been arranged in an alphabetical order of the atoms. The **boldface** in the species indicates the dissociated fragment.

TABLE 7. Bond Dissociation Energies in Polyatomic Cations

This Table has been arranged on the basis of the Periodic Table with the IUPAC notation for Groups 1 to 18, see inside front cover of this *Handbook*. The **boldface** in the species indicates the dissociated fragment.

Bond	$Do^2_{98}/\text{kJ mol}^{-1}$	Ref.	Bond	$Do^2_{98}/\text{kJ mol}^{-1}$	Ref.

ELECTRONEGATIVITY

Electronegativity is a parameter originally introduced by Pauling which describes, on a relative basis, the tendency of an atom in a molecule to attract bonding electrons. While electronegativity is not a precisely defined molecular property, the electronegativity difference between two atoms provides a useful measure of the polarity and ionic character of the bond between them. This table gives the electronegativity X , on the Pauling scale, for the most common oxidation state. Other scales are described in the references.

FORCE CONSTANTS FOR BOND STRETCHING

Representative force constants (f) for stretching of chemical bonds are listed in this table. Except where noted, all force constants are derived from values of the harmonic vibrational frequencies ω_e . Values derived from the observed vibrational fundamentals ν , which are noted by a, are lower than the harmonic force constants, typically by 2 to 3% in the case of heavy atoms (often by 5 to 10% if one of the atoms is hydrogen). Values are given in the SI unit newton per centimeter (N/cm), which is identical to the commonly used cgs unit mdyn/Å.

^b Average of symmetric and antisymmetric (or degenerate) modes.

^c Calculated from Local Symmetry Force Field (see Reference 2).

FUNDAMENTAL VIBRATIONAL FREQUENCIES OF SMALL MOLECULES

This table lists the fundamental vibrational frequencies of selected three-, four-, and five-atom molecules. Both stable molecules and transient free radicals are included. The data have been taken from evaluated sources. In general, the selected values are based on gas-phase infrared, Raman, or ultraviolet spectra; when these were not available, liquid-phase or matrix-isolation spectra were used.

Molecules are grouped by structural type. Within each group, related molecules appear together for convenient comparison.

The vibrational modes are described by their approximate character in terms of stretching, bending, deformation, etc. However, it should be emphasized that most such descriptions are only approximate, and that the true normal mode usually involves a mixture of motions. Abbreviations are:

sym.	symmetric
antisym.	antisymmetric
str.	stretch
deform.	deformation
scis.	scissors
rock.	rocking
deg.	degenerate

In the case of free radicals, strong interactions may exist between the electronic and bending vibrational motions. Details can be found in References 3 and 4. The references should be consulted for information on the accuracy of the data and for data on other molecules not listed here.

All fundamental frequencies (more precisely, wavenumbers) are given in units of cm^{-1} .

SPECTROSCOPIC CONSTANTS OF DIATOMIC MOLECULES

This table lists the leading spectroscopic constants and equilibrium internuclear distance r_e in the ground electronic state for selected diatomic molecules. The constants are those describing the vibrational and rotational energy through the expressions:

$$E_{\text{vib}}/hc = \omega_e(v + 1/2) - \omega_e x_e(v + 1/2)^2 + \dots$$

$$E_{\text{rot}}/hc = B_v J(J + 1) - D_v [J(J + 1)]^2 + \dots$$

where

$$B_v = B_e - \alpha_e(v + 1/2) + \dots$$

$$D_v = D_e + \dots$$

Here v and J are the vibrational and rotational quantum numbers, respectively, h is Planck's constant, and c is the speed of light. In this customary formulation the constants ω_e , B_e , etc. have dimensions of inverse length; in this table they are given in units of cm^{-1} .

Users should note that higher order terms in the above energy expressions are required for very precise calculations; constants for many of these terms can be found in the references. Also, if the ground electronic state is not $^1\Sigma$, additional terms are needed to account for the interaction between electronic and pure rotational angular momentum. For some molecules in the table the data have been analyzed in terms of the Dunham series expansion:

$$E/hc = \sum_{lm} Y_{lm}(v + 1/2)^l J^m (J + 1)^m$$

In such cases it has been assumed that $Y_{10} = \omega_e$, $Y_{01} = B_e$, etc., although in the highest approximations these identities are not precisely correct. Some of the values of r_e in the table have been corrected for breakdown of the Born-Oppenheimer approximation, which can affect the last decimal place. Because of differences in the method of data analysis and limitations in the model, care should be taken in comparing r_e values for different molecules to a precision beyond 0.001 Å.

Molecules are listed in alphabetical order by formula as written in the most common form. In most cases this form places the more electropositive element first, but there are exceptions such as OH, NH, CH, etc.

* Indicates a value for the interval between $v = 0$ and $v = 1$ states instead of a value of ω_e .

NUCLEAR SPINS, MOMENTS, AND OTHER DATA RELATED TO NMR SPECTROSCOPY

This table presents the following data relevant to nuclear magnetic resonance spectroscopy:

Z: Atomic number

Isotope: Element symbol and mass number

Abundance: Natural abundance of the isotope in percent. An * indicates a radioactive nuclide; if no value is given, the nuclide is not present in nature or its abundance is highly variable.

I: Nuclear spin

ν : Resonant frequency in megahertz for an applied field H_0 of 1 tesla (in cgs units, 10 kilogauss). The resonant frequency scales with H_0 .

Relative sensitivity: Sensitivity relative to ^1H (=1) assuming an equal number of nuclei and constant temperature. Values were calculated from the expressions:

$$\text{For constant } H_0: 0.0076508(\mu/\mu_N)^3(I+1)/I^2$$

$$\text{For constant } \nu: 0.23871(\mu/\mu_N)(I+1)$$

μ/μ_N : Nuclear magnetic moment in units of the nuclear magneton μ_N

Q: Nuclear quadrupole moment in units of femtometers squared ($1 \text{ fm}^2 = 10^{-2} \text{ barn}$). Because the determination of quadrupole moments requires knowledge of the electron configuration

near the nucleus, values of Q in the literature tend to scatter considerably. The values quoted here come mainly from the review of Pyykkö (Ref. 3), otherwise from Ref. 1.

The table includes all stable nuclides of non-zero spin for which spin and magnetic moment values have been measured, as well as selected radioactive nuclides of current or potential interest. At least one isotope is included for each element through $Z = 95$ for which data are available. See Reference 1 for a complete listing of spins and moments.

The assistance of P. Pyykkö in providing data on nuclear quadrupole moments is gratefully acknowledged.

PROTON NMR CHEMICAL SHIFTS FOR CHARACTERISTIC ORGANIC STRUCTURES

The chart below summarizes the range of chemical shifts for protons in several classes of organic compounds and substituent groups. The chemical shifts δ are given in parts per million relative to tetramethylsilane.

¹³C-NMR ABSORPTIONS OF MAJOR FUNCTIONAL GROUPS

The table below lists the range of ¹³C chemical shifts δ in parts per million relative to tetramethylsilane, in descending order, for various functional groups. Examples of simple compounds for each family are given to illustrate the correlations. The shifts for the carbons of interest, which are italicized, are given in parentheses; when two or more values appear, they refer to the sequence of italicized carbon atoms from left to right in the formula.

δ (ppm)	Group	Family	Example (δ of italicized carbon)			
220-165	>C=O	Ketones	(CH ₃) ₂ CO	(206.0)		
			(CH ₃) ₂ CHCOCH ₃	(212.1)		
			CH ₃ CHO	(199.7)		
		Aldehydes	α,β-Unsaturated carbonyls	CH ₃ CH=CHCHO	(192.4)	
				CH ₂ =CHCOCH ₃	(169.9)	
		Carboxylic acids	Amides	HCO ₂ H	(166.0)	
				CH ₃ CO ₂ H	(178.1)	
				HCONH ₂	(165.0)	
		Esters	Aromatic	CH ₃ CONH ₂	(172.7)	
				CH ₃ CO ₂ CH ₂ CH ₃	(170.3)	
				CH ₂ =CHCO ₂ CH ₃	(165.5)	
		140-120	>C=C<	Alkenes	C ₆ H ₆	(128.5)
					CH ₂ =CH ₂	(123.2)
Nitriles	CH ₂ =CHCH ₃			(115.9, 136.2)		
	CH ₂ =CHCH ₂ Cl			(117.5, 133.7)		
	CH ₃ CH=CHCH ₂ CH ₃			(132.7)		
	CH ₃ -CN			(117.7)		
80-70	-CC-	Alkynes	HCCH	(71.9)		
			CH ₃ CCH ₃	(73.9)		
70-45	-C-O	Esters	CH ₃ OOCH ₂ CH ₃	(57.6, 67.9)		
			Alcohols	HOCH ₃	(49.0)	
40-20	-C-NH ₂	Amines		HOCH ₂ CH ₃	(57.0)	
			CH ₃ NH ₂	(26.9)		
			CH ₃ CH ₂ NH ₂	(35.9)		
30-15	-S-CH ₃	Sulfides (thioethers)	C ₆ H ₅ -S-CH ₃	15.6		
			30-(-2.3)	-C-H	Alkanes, cycloalkanes	CH ₄
CH ₃ CH ₃	(5.7)					
CH ₃ CH ₂ CH ₃	(15.8, 16.3)					
CH ₃ CH ₂ CH ₂ CH ₃	(13.4, 25.2)					
CH ₃ CH ₂ CH ₂ CH ₂ CH ₃	(13.9, 22.8, 34.7)					
Cyclohexane	(26.9)

LINE SPECTRA OF THE ELEMENTS

Joseph Reader and Charles H. Corliss

The original tables from which this table was derived were prepared under the auspices of the Committee on Line Spectra of the Elements of the National Academy of Sciences-National Research Council. The table contains the outstanding spectral lines of neutral (I) and singly ionized (II) atoms of the elements from hydrogen through plutonium ($Z = 1-94$); selected strong lines from doubly ionized (III), triply ionized (IV), and quadruply ionized (V) atoms are also included. Listed are lines that appear in emission from the vacuum ultraviolet to the far infrared. These lines were selected from much larger lists in such a way as to include the stronger observed lines in each spectral region. A more extensive list may be found in Reference 1.

The data were compiled by the following contributors.

J. G. Conway — Lawrence Berkeley Laboratory
C. H. Corliss — National Bureau of Standards
R. D. Cowan — Los Alamos Scientific Laboratory
C. R. Cowley — University of Michigan
Henry M. and Hannah Crosswhite — Argonne National Laboratory
S. P. Davis — University of California, Berkeley
V. Kaufman — National Bureau of Standards
R. L. Kelly — Naval Postgraduate School
J. F. Kielkopf — University of Louisville
W. C. Martin — National Bureau of Standards
T. K. McCubbin — Pennsylvania State University
L. J. Radziemski — Los Alamos Scientific Laboratory
J. Reader — National Bureau of Standards
C. J. Sansonetti — National Bureau of Standards
G. V. Shalimoff — Lawrence Berkeley Laboratory
R. W. Stanley — Purdue University
J. O. Stoner, Jr. — University of Arizona
H. H. Stroke — New York University
D. R. Wood — Wright State University
E. F. Worden — Lawrence Livermore Laboratory
J. J. Wynne — International Business Machines Corporation
R. Zalubas — National Bureau of Standards

All wavelengths are given in Ångstrom units (10^{-10} m). Below 2000 Å the wavelengths are in vacuum (except for the Cu II line at 1999.698 Å, which is in air); above 2000 Å the wavelengths are in air. Wavelengths given to three decimal places have an uncertainty of less than 0.001 Å and are therefore suitable for calibration purposes. In the air region, the elements used most commonly for calibration are Ne, Ar, Kr, Fe, Th, and Hg; in the vacuum region, the most common are C, N, O, Si, Cu.

All data refer to natural isotopic abundance of the elements except that Kr I and Kr II lines below 11,000 Å given to three decimal

places are for ^{86}Kr . A separate table for ^{198}Hg contains accurately known wavelengths that are frequently used for calibration.

A large number of the lines for neutral and singly ionized atoms were extracted from the National Bureau of Standards (NBS) *Tables of Spectral-Line Intensities* (Reference 2). The intensities of these lines represent quantitative estimates of relative line strengths that take account of varying detection sensitivity at different wavelengths. They are on a linear scale. For nearly all of the other lines the intensities represent qualitative estimates of the relative strengths of lines not greatly separated in wavelength. Because different observers frequently use different scales for their intensity estimates, these intensities are useful only as a rough indication of the appearance of a spectrum. In some cases the intensity scale is not intended to be linear. In the first and second spectra the intensities of the lines of the singly ionized atom (II) relative to those of the neutral atom (I) should be used with caution, inasmuch as the concentration of ions in a light source depends greatly on the excitation conditions.

Descriptive symbols that follow the wavelength have the following meanings:

c — complex
d — line consists of two unresolved lines
h — hazy
l — shaded to longer wavelengths
s — shaded to shorter wavelengths
p — perturbed by a close line
r — easily reversed
w — wide

The table is arranged alphabetically by element name (not symbol); for each element the lines are listed by wavelength. References to the sources of data for each element are given at the end of the table, starting on page 10-89.

Sources of Data for Each Element

Numbers following the element name refer to the references on the following pages.

Actinium: 193

Aluminum: 6,8,81,89,127,144,146,227,228,282

Americium: 92

Antimony: 164,167,194,386,406

Argon: 190,203,204,219,367,368,372,373,374,375,414,421

Arsenic: 163,168,197,244,280

Astatine: 188

Barium: 1,78,111,252,259,277,279

Berkelium: 53,339

Beryllium: 15,44,73,102,115,134,135,171,175,198,335

Bismuth: 1,357,358,359,360,361

Boron: 66,69,74,94,104,171,221,222

Bromine: 42,122,124,139,142,240,243,246,248,249,250,316

Cadmium: 44,285,296,353,399

Calcium: 16,25,70,150,270

Californium: 52,331

Carbon: 22,66,211

Cerium: 1,136,166,261,305

Cesium: 78,82,154,155,200,201,259,263,325

Chlorine: 11,28,30,31,85,233,238,239

Chromium: 1,379,380,412

Cobalt: 1,100,125,159,236,276,291

Copper: 199,273,290,295,324

Curium: 51,332

Dysprosium: 1

Einsteinium: 333

Erbium: 1,301

Europium: 1,312

Fluorine: 68,169,224,225,226

Francium: 408

Gadolinium: 1,46,137,151,152

Gallium: 2,19,62,132,140,141,143,195,281

Germanium: 5,119,293,340,341,342

Gold: 38,72,234,393,395

Hafnium: 1,369,404,410,425

Helium: 16,94,173,183,317

Holmium: 1

Hydrogen: 214

Indium: 1,132,348,349,350,351,352,353,435,436

Iodine: 20,21,58,84,124,153,161,176,184

Iridium: 1

Iron: 56,63,71,101,105,138,174,278,381,382

Krypton: 61,121,123,147,208,232,366,390,409,417,421

Lanthanum: 1,78,79,220,309

Lead: 54,64,106,256,274,297,283,329,330

Lithium: 3,15,17,18,37,44,112,284,321,335

Lutetium: 1,148,310,401

Magnesium: 4,7,49,83,103,128,129,177,217,269,315,335

Manganese: 1,126,385,405,433

Mercury (198): 43,50,69,145,229,242

Mercury (Natural): 34,45,90,117,133,189,235,304,327,328,343

Molybdenum: 1,383,420

Neodymium: 1

Neon: 56,58,69,118,150,230,364,365,371,388,389,400,402,413,430

Neptunium: 93

Nickel: 1,294,415,416,422

Niobium: 1,392,407,431

Nitrogen: 66,107,108,212,213,318

Osmium: 1

Oxygen: 23,24,36,66,69,209,210,215

Palladium: 1,287,424

Phosphorus: 179,180,182,336

Platinum: 1,288

Plutonium: 91

Polonium: 47,48

Potassium: 32,59,60,75,76,86,150,160,172,268,314,322

Praseodymium: 1,149,306,308,337,338

Promethium: 196,260

Protactinium: 96

Radium: 253,254

Radon: 251

Rhenium: 1

Rhodium: 1,396

Rubidium: 12,109,130,241,257,258,262,264

Ruthenium: 1,423

Samarium: 1

Scandium: 1,88,150,298,323

Selenium: 9,80,181,216,245,247,275

Silicon: 87,170,237,292,319,320

Silver: 13,99,255,286,289,363,387,398

Sodium: 178,205,206,207,268,299,334

Strontium: 1,109,110,218,231,265,279,313

Sulfur: 29,144,202,209,210,266

Tantalum: 1,411,426

Technetium: 35

Tellurium: 1,344,345,346,347

Terbium: 1,302

Thallium: 1,195,348,354,355,356

Thorium: 1,97,98,156,157,165,434

Thulium: 1,307

Tin: 187,191,399,423

Titanium: 1,378,427,428

Tungsten: 1

Uranium: 1,303

Vanadium: 1,394,397,432

Xenon: 33,116,118,120,232,384,391,429

Ytterbium: 1,40,192,311

Yttrium: 1,77,265,419

Zinc: 39,55,113,131,185,186,370,376,377

Zirconium: 1,362,403,418

NIST ATOMIC TRANSITION PROBABILITIES

J. R. Fuhr and W. L. Wiese

For the 2005 edition of this *Handbook*, we include new, more accurate data for Fe I and Fe II,¹ and Ba I and Ba II.² The new tables contain critically evaluated atomic transition probabilities for over 10500 selected lines of all elements for which reliable data are available on an absolute scale. The material is largely for neutral and singly ionized spectra, but also includes a number of prominent lines of more highly charged ions of important elements.

Many of the data are obtained from comprehensive compilations of the Data Center on Atomic Transition Probabilities at the National Institute of Standards and Technology. Specifically, data have been taken from three recent comprehensive critical compilations on C, N and O,³ on Sc through Mn⁴ and Fe through Ni,⁵ and special compilations on neutral and singly ionized iron and barium. Material from earlier compilations for the elements H through Ne⁶ and Na through Ca⁷ was supplemented by more recent material taken directly from the original literature. For the highly charged ions, some of the data were derived from studies of the systematic behavior of transition probabilities.⁸⁻¹⁰ Most of the original literature is cited in the above tables and in recent bibliographies;^{11,12} for lack of space, individual literature references are not cited here.

The wavelength range for the neutral species is normally the visible spectrum or shorter wavelengths; only the very prominent near infrared lines are included. For the higher ions, most of the strong lines are located in the far UV. The tabulation is limited to electric dipole — including intercombination — lines and comprises essentially the fairly strong transitions with estimated uncertainties in the 10% to 50% range. With the exception of hydrogen, helium, and the alkali metals, most transitions are between states with low principal quantum numbers.

The transition probability, A , is given in units of 10^8 s^{-1} and is listed to as many digits as is consistent with the indicated accuracy. The power of 10 is indicated by the E notation (i.e., E-02 means 10^{-2}). Generally, the estimated uncertainties of the A -values are ± 25 to 50% for two-digit numbers, ± 10 to 25% for three-digit numbers and $\pm 1\%$ or better for four- and five-digit numbers.

Each transition is identified by the wavelength λ in ångströms ($1 \text{ Å} = 10^{-10} \text{ m}$); and the statistical weights, g_i and g_k , of the lower (i) and upper (k) states [the product $g_k A$ (or $g_i f$) is needed for many applications]. Whenever the wavelengths of individual lines within a multiplet are extremely close, only an average wavelength for the multiplet as well as the multiplet A -value are given, and this is indicated by an asterisk (*) to the left of the wavelength. This also has been done when the transition probability for an entire multiplet has been taken from the literature and values for individual lines cannot be determined because of insufficient knowledge of the coupling of electrons. The wavelength data have been taken either from recent compilations or from the original literature cited in bibliographies published by the Atomic Energy Levels Data Center^{13,14} at the National Institute of Standards and Technology. Wavelength values are consistent with those given in the table "Line Spectra of the Elements," which appears elsewhere in this *Handbook*.

In addition to the transition probability A , the atomic oscillator strength f and the line strength S are often used in the literature. The conversion factors between these quantities are (for electric-dipole transitions):

$$g_i f = 1.499 \cdot 10^{-8} \lambda^2 g_k A = 303.8 \lambda^{-1} S$$

where λ is in ångströms, A is in 10^8 s^{-1} , and S is in atomic units, which are

$$a_0^2 e^2 = 7.188 \cdot 10^{-59} \text{ m}^2 \text{ C}^2.$$

The table for hydrogen is presented first, followed by the tables for other elements in alphabetical sequence by element name (not symbol). Within each element, the tables are ordered by increasing ionization stage (e.g., Al I, Al II, etc.).

The transition probabilities for hydrogen and hydrogen-like ions are known precisely. Because of the hydrogen degeneracy, a "transition" is actually the sum of all fine-structure transitions between the principal quantum numbers; therefore, the hydrogen table gives weighted average A -values. For hydrogen-like ions of nuclear charge Z , the following scaling laws hold:

$$A_Z = Z^4 A_{\text{Hydrogen}}$$

$$f_Z = f_{\text{Hydrogen}}$$

$$S_Z = Z^{-2} S_{\text{Hydrogen}}$$

$$\lambda_Z = Z^{-2} \lambda_{\text{Hydrogen}}$$

For very highly charged hydrogen-like ions, starting at about $Z > 25$, relativistic corrections¹⁵ must be applied.

ELECTRON AFFINITIES

Thomas M. Miller

Electron affinity is defined as the energy difference between the lowest (ground) state of the neutral and the lowest state of the corresponding negative ion. The accuracy of electron affinity measurements has been greatly improved since the advent of laser photodetachment experiments with negative ions. Electron affinities can be determined with optical precision, though a detailed understanding of atomic and molecular states and splittings is required to specify the photodetachment threshold corresponding to the electron affinity.

Atomic and molecular electron affinities are discussed in two excellent articles reviewing photodetachment studies which appear in *Gas Phase Ion Chemistry*, Vol. 3, Bowers, M. T., Ed., Academic Press, Orlando, 1984: Chapter 21 by Drzaic, P. S., Marks, J., and Brauman, J. I., "Electron Photodetachment from Gas Phase Negative Ions," p. 167, and Chapter 22 by Mead, R. D., Stevens, A. E., and Lineberger, W. C., "Photodetachment in Negative Ion Beams," p. 213. Persons interested in photodetachment details should consult these articles and the critical reviews of Andersen, T., Haugen, H. K., and Hotop, H., *J. Phys. Chem. Ref. Data*, 28, 1511, 1999; Hotop, H. and Lineberger, W. C., *J. Phys. Chem. Ref. Data*, 14, 731, 1985; and Andersen, T., Haugen, H. K., and Hotop, H., *J. Phys. Chem. Ref. Data* 28, 1511, 1999. For simplicity in the tables below, any electron affinity that was discussed in the articles by Drzaic et al. or Hotop and Lineberger is referenced to these sources, where original references are given. The development of cluster-ion pho-

todetachment apparatuses has brought an explosion of electron affinity estimates for atomic and molecular clusters. The policy in this tabulation is to list the electron affinities for the atoms, diatoms, and triatoms, if adiabatic electron affinities have been determined, but to refer the reader to original sources for higher-order clusters. Additional data on molecular electron affinities may be found in Lias, S. G., Bartmess, J. E., Liebman, J. F., Holmes, J. L., Levin, R. D., and Mallard, W. G., *Gas Phase Ion and Neutral Thermochemistry*, *J. Phys. Chem. Ref. Data*, 17, (Supplement No. 1), 1988 and on the NIST WebBook at the Internet address <http://webbook.nist.gov/>.

For the present tabulation the 2002 CODATA value $e/hc = 8065.54445 \pm 0.00069 \text{ cm}^{-1} \text{ eV}^{-1}$ (<http://physics.nist.gov>) has been used to convert electron affinities from the units used in spectroscopic work, cm^{-1} , into eV for these tables. The 86 ppb uncertainty in e/hc is insignificant compared to uncertainties in the electron affinity measurements.

Abbreviations used in the tables: calc = calculated value; PT = photodetachment threshold using a lamp as a light source; LPT = laser photodetachment threshold; LPES = laser photoelectron spectroscopy; DA = dissociative attachment; attach = electron attachment/detachment equilibrium; e-scat = electron scattering; kinetic = dissociation kinetics; Knud=Knudsen cell; CT = charge transfer; CD = collisional detachment; and ZEKE = zero electron kinetic energy spectroscopy.

PROTON AFFINITIES

Proton affinity is a useful parameter for describing gas phase ion-molecule reactions in fields such as atmospheric chemistry, plasma chemistry, mass spectrometry, and astrophysics. The proton affinity E_{pa} (often designated in the literature as PA) of a molecular species M is defined as the negative of the enthalpy change for the gas phase reaction

A closely related quantity is the gas phase basicity $\Delta_{\text{base}} G^\circ$ (often designated as GB), which is the negative of the Gibbs energy change for the same reaction. Thus the two are related by

$$\Delta_{\text{base}} G^\circ = E_{\text{pa}} + T\Delta S,$$

where T is the temperature and ΔS is the entropy change in the reaction (which can be calculated if the molecular structure of M and M^+ is known).

Direct measurement of the proton affinity is possible for only a few molecules, mainly olefins and carbonyl compounds. However, these measurements have been used to establish a scale of E_{pa} values that permits proton affinities to be determined for many other molecules, including unstable species and reaction intermediates. The basis for this scale is described by Hunter and Lias in Reference 1.

The E_{pa} and $\Delta_{\text{base}} G^\circ$ values at a temperature of 298 K are tabulated below for selected molecules. Many values are given to one decimal place, but the majority are not accurate to better than one or two kilojoules per mole. The methods of measurement are de-

scribed in Reference 1, which contains a much more extensive and detailed tabulation.

Compounds are listed by molecular formula in the Hill order, but with all compounds that do not contain carbon appearing before those that do contain carbon.

ATOMIC AND MOLECULAR POLARIZABILITIES

Thomas M. Miller

The *polarizability* of an atom or molecule describes the response of the electron cloud to an external field. The atomic or molecular energy shift ΔW due to an external electric field E is proportional to E^2 for external fields that are weak compared to the internal electric fields between the nucleus and electron cloud. The *electric dipole polarizability* α is the constant of proportionality defined by $\Delta W = -\alpha E^2/2$. The induced electric dipole moment is αE . *Hyperpolarizabilities*, coefficients of higher powers of E , are less often required. Technically, the polarizability is a tensor quantity but for spherically symmetric charge distributions reduces to a single number. In any case, an *average polarizability* is usually adequate in calculations. Frequency-dependent or *dynamic polarizabilities* are needed for electric fields that vary in time, except for frequencies that are much lower than electron orbital frequencies, where *static polarizabilities* suffice.

Polarizabilities for atoms and molecules in excited states are found to be larger than for ground states and may be positive or negative. Molecular polarizabilities are very slightly temperature dependent since the size of the molecule depends on its rovibrational state. Only in the case of dihydrogen has this effect been studied enough to warrant consideration in Table 3.

Polarizabilities are normally expressed in c.g.s. units of cm^3 . Ground state polarizabilities are in the range of $10^{-24} \text{ cm}^3 = 1 \text{ \AA}^3$ and hence are often given in \AA^3 units. Theorists tend to use atomic units of a_0^3 where a_0 is the Bohr radius. The conversion is $\alpha(\text{cm}^3) = 0.148184 \times 10^{-24} \times \alpha(a_0^3)$. Polarizabilities are only recently encountered in SI units, $\text{C m}^2/\text{V} = \text{J}/(\text{V}/\text{m})^2$. The conversion from c.g.s. units to SI units is $\alpha(\text{C m}^2/\text{V}) = 4\pi\epsilon_0 \times 10^{-6} \alpha(\text{cm}^3)$, where ϵ_0 is

the permittivity of free space in SI units and the factor 10^{-6} simply converts cm^3 into m^3 . Thus, $\alpha(\text{C m}^2/\text{V}) = 1.11265 \times 10^{-16} \times \alpha(\text{cm}^3)$. Persons measuring excited state polarizabilities by optical methods tend to use units of $\text{MHz}/(\text{V}/\text{cm})^2$, where the energy shift, ΔW , is expressed in frequency units with a factor of h understood. The polarizability is $-2 \Delta W/E^2$. The conversion into c.g.s. units is $\alpha(\text{cm}^3) = 5.95531 \times 10^{-16} \times \alpha[\text{MHz}/(\text{V}/\text{cm})^2]$.

The polarizability appears in many formulas for low-energy processes involving the valence electrons of atoms or molecules. These formulas are given below in c.g.s. units: the polarizability α is in cm^3 ; masses m or μ are in grams; energies are in ergs; and electric charges are in esu, where $e = 4.8032 \times 10^{-10}$ esu. The symbol $\alpha(\nu)$ denotes a frequency (ν) dependent polarizability, where $\alpha(\nu)$ reduces to the static polarizability α for $\nu = 0$. For further information, see Bonin, K. D., and Kresin, V. V., *Electric Dipole Polarizabilities of Atoms, Molecules, and Clusters*, World Scientific, Singapore, 1997; Bonin, K. D., and Kadar-Kallen, *Int. J. Mod. Phys. B*, 24, 3313, 1994; and Miller, T. M., and Bederson, B., *Advances in Atomic and Molecular Physics*, 13, 1, 1977, and Gould, H., and Miller, T. M., *Advances in Atomic, Molecular, and Optical Physics*, 51, 243, 2005. Details on polarizability-related interactions, especially in regard to hyperpolarizabilities and nonlinear optical phenomena, are given by Bogaard, M. P., and Orr, B. J., in *Physical Chemistry, Series Two, Vol. 2, Molecular Structure and Properties*, Buckingham, A. D., Ed., Butterworths, London, 1975, pp. 149–194. A tabulation of tensor and hyperpolarizabilities is included. The gas number density, n , in Table 1 is usually taken to be that of 1 atm at 0 °C in reporting experimental data.

TABLE 1. Formulas Involving Polarizability

Description	Formula	Remarks
Lorentz-Lorenz relation	$\alpha(\nu) = \frac{3}{4\pi n} \left[\frac{\eta^2(\nu) - 1}{\eta^2(\nu) + 2} \right]$	For a gas of atoms or nonpolar molecules; the index of refraction is $\eta(\nu)$
Refraction by polar molecules	$\alpha(\nu) + \frac{d^2}{3kT} = \frac{3}{4\pi n} \left[\frac{\eta^2(\nu) - 1}{\eta^2(\nu) + 2} \right]$	The dipole moment is d , in esu cm ($= 10^{-18}$ D)
Dielectric constant (dimensionless)	$\kappa(\nu) = 1 + 4\pi n \alpha(\nu)$	From the Lorentz-Lorenz relation for the usual case of $\kappa(\nu) \approx 1$
Index of refraction (dimensionless)	$\eta(\nu) = 1 + 2\pi n \alpha(\nu)$	From $\eta^2(\nu) = \kappa(\nu)$
Diamagnetic susceptibility	$\chi_m = e^2 (a_0 N \alpha)^{1/2} / 4m_e c^2$	From the approximation that the static polarizability is given by the variational formula $\alpha = (4/9a_0) \Sigma(N r_i^2)^2$; N is the number of electrons, m_e is the electron mass; a crude approximation is $\chi_m = (E_i/4m_e c^2) \alpha$, where E_i is the ionization energy
Long-range electron- or ion-molecule interaction energy	$V(r) = -e^2 \alpha / 2r^4$	The target molecule polarizability is α
Ion mobility in a gas	$\kappa = -13.87 / (\alpha \mu)^{1/2} \text{ cm}^2 / \text{V} \cdot \text{s}$	This one formula is not in c.g.s. units. Enter α in \AA^3 or 10^{-24} cm^3 units and the reduced mass μ of the ion-molecule pair in amu. Classical limit; pure polarization potential
Langevin capture cross section	$\sigma(v_o) = (2\pi e / v_o) (\alpha / \mu)^{1/2}$	The relative velocity of approach for an ion-molecule pair is v_o ; the target molecular polarizability is α and the reduced mass of the ion-molecule pair is μ
Langevin reaction rate coefficient	$k = 2\pi e (\alpha / \mu)^{1/2}$	Collisional rate coefficient for an ion-molecule reaction
Rate coefficient for polar molecules	$k_d = 2\pi e \left[(\alpha / \mu)^{1/2} + cd(2 / \mu \pi kT)^{1/2} \right]$	The dipole moment of the neutral is d in esu cm; the number c is a "locking factor" that depends on α and d , and is between 0 and 1

Description	Formula	Remarks
Modified effective range cross section for electron-neutral scattering	$\sigma(k) = 4\pi A^2 + 32\pi^4 \mu e^2 \alpha A k / 3h^2 + \dots$	Here, k is the electron momentum divided by $h/2\pi$, where h is Planck's constant; A is called the "scattering length"; the reduced mass is μ
van der Waals constant between two systems A, B	$C_6 = \frac{3}{2} \left[\frac{\alpha^A \alpha^B E^A E^B}{E^A + E^B} \right]$	For the interaction potential term $V_6(r) = -C_6 r^{-6}$; $E^{A,B}$ represents average dipole transition energies and $\alpha^{A,B}$ the respective polarizabilities of A, B
Dipole-quadrupole constant between two systems A, B	$C_8 = \frac{15}{4} \left[\frac{\alpha^A \alpha_q^B E^A E_q^B}{E^A + E_q^B} \right] + \frac{15}{4} \left[\frac{\alpha_q^A \alpha^B E_q^A E^B}{E_q^A + E^B} \right]$	For the interaction potential term $V_8(r) = -C_8 r^{-8}$; $E_q^{A,B}$ represents average quadrupole transition energies and $\alpha_q^{A,B}$ are the respective quadrupole polarizabilities of A, B
van der Waals constant between an atom and a surface	$C_3 = \frac{\alpha g E^A E^S}{8(E^A + E^S)}$	For an interaction potential $V_3(r) = -C_3 r^{-3}$; $E^{A,S}$ are characteristic energies of the atom and surface; $g = 1$ for a free-electron metal and $g = (\epsilon_\infty - 1)/(\epsilon_\infty + 1)$ for an ionic crystal
Relationship between $\alpha(\nu)$ and oscillator strengths	$\alpha(\nu) = \frac{e^2 h^2}{4\pi^2 m_e} \sum \frac{f_k}{E_k^2 - (h\nu)^2}$	Here, f_k is the oscillator strength from the ground state to an excited state k , with excitation energy E_k . This formula is often used to estimate static polarizabilities ($\nu = 0$)
Dynamic polarizability	$\alpha(\nu) = \frac{\alpha E_r^2}{E_r^2 - (h\nu)^2}$	Approximate variation of the frequency-dependent polarizability $\alpha(\nu)$ from $\nu = 0$ up to the first dipole-allowed electronic transition, of energy E_r ; the static dipole polarizability is $\alpha(0)$; infrared contributions ignored
Rayleigh scattering cross section	$\alpha(\nu) = \frac{8\pi}{9c^4} (2\pi\nu)^4 \times [3\alpha^2(\nu) + 2\gamma^2(\nu) / 3]$	The photon frequency is ν ; the polarizability anisotropy (the difference between polarizabilities parallel and perpendicular to the molecular axis) is $\gamma(\nu)$
Verdet constant	$V(\nu) = \frac{\nu n}{2m_e c^2} \left[\frac{d\alpha(\nu)}{d\nu} \right]$	Defined from $\theta = V(\nu)B$, where θ is the angle of rotation of linearly polarized light through a medium of number density n , per unit length, for a longitudinal magnetic field strength B (Faraday effect)

Note: All polarizabilities in the tables are experimental values except those values marked by an asterisk (*), which indicates a calculated result. The experimental polarizabilities are mostly determined by measurements of a dielectric constant or refractive index that are quite accurate (0.5% or better). However, one should treat many of the results with several percent of caution because of the age of the data and because some of the results refer to optical frequencies rather than static. Comments given with the references are intended to allow one to judge the degree of caution required. Interested persons should consult these references. In many cases, the reference given is to a theoretical paper in which the experimental results are quoted. These papers, noted in the References, contain valuable information on polarizability calculations and experimental data which often includes the tensor components of the polarizability.

An empirical additive formula for molecular polarizabilities at 589 nm frequency has been given in Bosque, R., and Sales, J., *J. Chem. Inf. Comput. Sci.* 42, 1154, 2002: $\alpha = 0.32 + 1.51\#C + 0.17\#H + 0.57\#O + 1.05\#N + 2.99\#S + 2.48\#P + 2.16\#Cl + 3.29\#Br + 5.45\#I$, where "#C" denotes the number of carbon atoms in the molecule, etc.

- Maryott, A. A., and Buckley, F., *U. S. National Bureau of Standards Circular No. 537*, 1953. A tabulation of dipole moments, dielectric constants, and molar refractions measured between 1910 and 1952, and used here to determine polarizabilities if no more recent result exists. The polarizability is $3/(4\pi N_A)$ times the molar polarization or molar refraction, where N_A is Avogadro's number. The value $3/(4\pi N_A) = 0.3964308 \times 10^{-24} \text{ cm}^3$ was used for this conversion. A dagger (†) following the reference number in the tables indicates that the polarizability was derived from the molar refraction and hence may not include some low-frequency contributions to the static polarizability; these "static" polarizabilities are therefore low by 1 to 30%.

IONIZATION ENERGIES OF ATOMS AND ATOMIC IONS

The ionization energies (often called ionization potentials) of neutral and partially ionized atoms are listed in this table. Data were obtained from the compilations cited below, supplemented by results from the recent research literature. Values for the first and second ionization energies come from Reference 6. All values are given in electron volts (eV).

Following the traditional spectroscopic notation, columns are headed I, II, III, etc. up to VIII, where I indicates the neutral atom, II the singly ionized atom, III the doubly ionized atom, etc. The first section of the table includes spectra I to VIII of all the elements through rutherfordium; subsequent sections cover higher spectra (ionization stages) for those elements for which data are available.

IONIZATION ENERGIES OF GAS-PHASE MOLECULES

Sharon G. Lias

This table presents values for the first ionization energies (IP) of approximately 1000 molecules and atoms. Substances are listed by molecular formula in the modified Hill order (see Preface). Values enclosed in parentheses are considered not to be well established. Data appearing in the 1988 reference were updated in 1996 for inclusion in the database of ionization energies available at the Internet site of the Standard Reference Data program of the National Institute of Standards and Technology (<http://webbook.nist.gov>). The list appearing here includes these updates.

The list also includes values for enthalpies of formation of the ions at 298 K, $\Delta_f H_{\text{ion}}$, given according to the ion convention used by

mass spectrometrists; to convert these values to the electron convention used by thermodynamicists, add 6 kJ/mol. Details on the calculation of $\Delta_f H_{\text{ion}}$, as well as data for a much larger number of molecules, may be found in the reference and on the Internet site.

X-RAY ATOMIC ENERGY LEVELS

The energy levels in this tables are the values recommended by Bearden and Burr on the basis of a thorough review of the literature on x-ray wavelengths and related data. All values are in electron volts (eV). Values in parentheses are interpolated, and an asterisk * indicates a level which is not resolved from the level above it. See Reference 1 for uncertainties in the levels and a complete description of how the recommended values were obtained.

ELECTRON BINDING ENERGIES OF THE ELEMENTS

Gwyn P. Williams

This table gives the binding energies in electron volts (eV) for selected electronic levels of the elements. For metallic elements the binding energy is referred to the Fermi level; for semiconductors, to the valence band maximum; and for gases and insulators, to the vacuum level. The atomic number is listed after the element name.

PHOTON ATTENUATION COEFFICIENTS

Martin J. Berger and John H. Hubbell

This table gives mass attenuation coefficients for photons for all elements at energies between 1 keV (soft x-rays) and 1 GeV (hard gamma rays). The mass attenuation coefficient μ describes the attenuation of radiation as it passes through matter by the relation

$$I(x)/I_0 = e^{-\mu\rho x}$$

where I_0 is the initial intensity, $I(x)$ the intensity after path length x , and ρ is the mass density of the element in question. To a high approximation the mass attenuation coefficient is additive for the elements present, independent of the way in which they are bound in chemical compounds.

The power of ten is indicated beside each number in the table; i.e., 7.41 + 03 means 7.41×10^3 . A vertical line between two columns indicates that an absorption edge lies between those energy values. The various edges are labeled at the bottom of the table.

The attenuation coefficients were calculated with the computer program XCOM (Reference 1), which uses a cross-section database compiled at the Photon and Charged Particle Data Center at the National Institute of Standards and Technology. Their accuracy has been confirmed at all energies by extensive comparisons with experimental attenuation coefficients. Such comparisons for X-ray energies up to 100 keV can be found in Reference 2.

CLASSIFICATION OF ELECTROMAGNETIC RADIATION

Hans Dolezalek

Basic Conversions:

$$c = \lambda\nu = v/k$$

$$\nu = c/\lambda = ck$$

$$\lambda = c/\nu = 1/k$$

$$k = \nu/c = 1/\lambda$$

$$c = \text{speed of light} = 2.99792458 \times 10^8 \text{ m/s}$$

Frequency (ν)	Wavelength (λ)	Wave number (k)	Names of bands	Approximate photon energies
$3 \times 10^0 - 3 \times 10^1$ Hz 3 – 30 Hz	$10^8 - 10^7$ m 100 – 10 Mm	$10^8 - 10^7$ m ⁻¹ 10 – 100 Gm ⁻¹	ELF-(ELF 1), ITU band no. 1	
$3 \times 10^1 - 3 \times 10^2$ Hz 30 – 300 Hz	$10^7 - 10^6$ m 10 – 1 Mm	$10^7 - 10^6$ m ⁻¹ 100 Gm ⁻¹ – 1Mm ⁻¹	SLF-(ELF 2), ITU band no. 2, megameter waves	
$3 \times 10^2 - 3 \times 10^3$ Hz 300 Hz – 3 kHz	$10^6 - 10^5$ m 1 Mm – 100 km	$10^6 - 10^5$ m ⁻¹ 1 – 10 Mm ⁻¹	ULF-(ELF 3), ITU band no. 3	
$3 \times 10^3 - 3 \times 10^4$ Hz 3 – 30 kHz	$10^5 - 10^4$ m 100 – 10 km	$10^5 - 10^4$ m ⁻¹ 100 Mm ⁻¹	VLF, ITU band no. 4, myriameter waves	
$3 \times 10^4 - 3 \times 10^5$ Hz 30 – 300 kHz	$10^4 - 10^3$ m 10 – 1 km	$10^4 - 10^3$ m ⁻¹ 100 Mm ⁻¹ – 1 km ⁻¹	LF, ITU band no. 5, kilometer waves	
$3 \times 10^5 - 3 \times 10^6$ Hz 300 kHz – 3 MHz	$10^3 - 10^2$ m 1 km – 100 m	$10^3 - 10^2$ m ⁻¹ 1 – 10 km ⁻¹	MF, ITU band no. 6, hectometer waves	
$3 \times 10^6 - 3 \times 10^7$ Hz 3 – 30 MHz	$10^2 - 10^1$ m 100 – 10 m	$10^2 - 10^1$ m ⁻¹ 10 – 100 km ⁻¹	HF, ITU band no. 7, decameter waves	
$3 \times 10^7 - 3 \times 10^8$ Hz 30 – 300 MHz	$10^1 - 10^0$ m 10 – 1 m	$10^1 - 10^0$ m ⁻¹ 100 km ⁻¹ – 1 mm ⁻¹	VHF, ITU band no. 8, meter waves	
$3 \times 10^8 - 3 \times 10^9$ Hz 300 MHz – 3 GHz	$10^0 - 10^{-1}$ m 1 m – 100 mm	$10^0 - 10^1$ m ⁻¹ 1 – 10 m ⁻¹	UHF, ITU band no. 9, decimeter waves ^a	
$3 \times 10^9 - 3 \times 10^{10}$ Hz 3 – 30 GHz	$10^{-1} - 10^{-2}$ m 100 – 10 mm	$10^1 - 10^2$ m ⁻¹ 10 – 100 m ⁻¹	SHF, ITU band no. 10, centimeter waves ^a	
$3 \times 10^{10} - 3 \times 10^{11}$ Hz 30 – 300 GHz	$10^{-2} - 10^{-3}$ m 10 – 1 mm	$10^2 - 10^3$ m ⁻¹ 100 m ⁻¹ – 1 mm ⁻¹ (1 – 10 cm ⁻¹)	EHF, ITU band no. 11, millimeter waves	
$3 \times 10^{11} - 3 \times 10^{12}$ Hz 300 GHz – 3 THz	$10^{-3} - 10^{-4}$ m 1 mm – 100 μ m	$10^3 - 10^4$ m ⁻¹ (1 – 10 mm ⁻¹) (10 – 100 cm ⁻¹)	Part of micrometer waves, includes part of far or thermal infrared; ITU band no. 12	
$3 \times 10^{12} - 3 \times 10^{13}$ Hz 3 – 30 THz	$10^{-4} - 10^{-5}$ m 100 – 10 μ m	$10^4 - 10^5$ m ⁻¹ 10 – 100 mm ⁻¹ (100 – 1000 cm ⁻¹)	Part of micrometer waves includes part of far (thermal) infrared	
$3 \times 10^{13} - 3 \times 10^{14}$ Hz 30 – 300 THz	$10^{-5} - 10^{-6}$ m 10 – 1 μ m (100,000 – 10,000 Å)	$10^5 - 10^6$ m ⁻¹ 100 mm ⁻¹ – 1 μ m ⁻¹	Part of μ m waves, part of infrared	$(1.6 - 16) \times 10^{-20}$ joule {0.1 – 1 eV}
$3 \times 10^{14} - 3 \times 10^{15}$ Hz 300 THz – 3 PHz	$10^{-6} - 10^{-7}$ m 1 μ m – 100 m (10,000 – 1000 Å)	$10^6 - 10^7$ m ⁻¹ 1 – 10 μ m ⁻¹	Near infrared, visible, near ultraviolet	$(1.6 - 16) \times 10^{-19}$ joule {1 – 10 eV}
$3 \times 10^{15} - 3 \times 10^{16}$ Hz 3 – 30 PHz	$10^{-7} - 10^{-8}$ m 100 – 10 nm (1000 – 100 Å)	$10^7 - 10^8$ m ⁻¹ 10 – 100 μ m ⁻¹	Part of vacuum ultraviolet	$(1.6 - 16) \times 10^{-18}$ joule {10 – 100 eV}
$3 \times 10^{16} - 3 \times 10^{17}$ Hz 30 – 300 PHz	$10^{-8} - 10^{-9}$ m 10 – 1 nm (100 – 10 Å)	$10^8 - 10^9$ m ⁻¹ 100 μ m ⁻¹ – 1 nm ⁻¹	Part of soft X-rays	$(1.6 - 16) \times 10^{-17}$ joule {100 – 1000 eV}
$3 \times 10^{17} - 3 \times 10^{18}$ Hz 300 PHz – 3 EHz	$10^{-9} - 10^{-10}$ m 1 nm – 100 pm (10 – 1 Å)	$10^9 - 10^{10}$ m ⁻¹ 1 – 10 nm ⁻¹	Part of soft X-rays	$(1.6 - 16) \times 10^{-16}$ joule {1 – 10 keV}
$3 \times 10^{18} - 3 \times 10^{19}$ Hz 3 – 30 EHz	$10^{-10} - 10^{-11}$ m 100 – 10 pm (1 – 0.1 Å)	$10^{10} - 10^{11}$ m ⁻¹ 10 – 100 nm ⁻¹	Hard X-rays and part of soft γ -rays	$(1.6 - 16) \times 10^{-15}$ joule {10 – 100 keV}
$3 \times 10^{19} - 3 \times 10^{20}$ Hz 30 – 300 EHz	$10^{-11} - 10^{-12}$ m 10 – 1 pm (0.1 – 0.01 Å)	$10^{11} - 10^{12}$ m ⁻¹ 100 nm ⁻¹ – 1 pm ⁻¹	Part of soft and part of hard γ -rays (limit at 510 keV)	$(1.6 - 16) \times 10^{-14}$ joule {100 keV – 1 MeV}
$3 \times 10^{20} - 3 \times 10^{21}$ Hz 300 – 3000 EHz	$10^{-12} - 10^{-13}$ m 1 pm – 100 fm (0.01 – 0.001 Å)	$10^{12} - 10^{13}$ m ⁻¹ 1 – 10 pm ⁻¹	Part of hard γ -rays and part of “cosmic” γ -rays	$(1.6 - 16) \times 10^{-13}$ joule {1 – 10 MeV}
$3 \times 10^{21} - 3 \times 10^{22}$ Hz 3000 – 30,000 EHz	$10^{-13} - 10^{-14}$ m 100 – 10 fm (0.001 – 0.0001 Å)	$10^{13} - 10^{14}$ m ⁻¹ 10 – 100 pm ⁻¹	γ -rays produced by cosmic rays	$(1.6 - 16) \times 10^{-12}$ joule {10 – 100 MeV}

Note: Abbreviations used in this table: Å—ångstrom ($1 \text{ Å} = 10^{-10} \text{ m}$); EHz—exahertz (10^{18} hertz); EHF—extremely high frequency; ELF—extremely low frequency; eV—electron volt ($1 \text{ eV} = 1.60218 \times 10^{-19}$ joule); fm—femtometer (10^{-15} m); GHz—gigahertz (10^9 hertz); Gm—gigameter (10^9 m); HF—high frequency; Hz—hertz (s^{-1}); ITU—International Telecommunications Union; keV—kiloelectron volt (10^3 eV); km—kilometer (10^3 m); LF—low frequency; m—meter; MeV—megaelectron volt (10^6 eV); MF—medium frequency; MHz—megahertz (10^6 hertz); Mm—megameter (10^6 meter); mm—millimeter (10^{-3} meter); μm —micrometer (10^{-6} meter); nm—nanometer (10^{-9} meter); PHz—petahertz (10^{15} hertz); pm—picometer (10^{-12} meter); SHF—super high frequency; SLF—super low frequency; THz—terahertz; UHF—ultra high frequency; ULF—ultra low frequency; VHF—very high frequency; VLF—very low frequency.

^a Also called “microwaves”; not to be confused with “micrometer waves”.

Letter Designations of Microwave Bands

Frequency (GHz)	Wavelength (cm)	Wavenumber (cm^{-1})	Band
1–2	30–15	0.033–0.067	L-Band
2–4	15–7.5	0.067–0.133	S-Band
4–8	7.5–3.7	0.133–0.267	C-Band
8–12	3.7–2.5	0.267–0.4	X-Band
12–18	2.5–1.7	0.4–0.6	Ku-Band
18–27	1.7–1.1	0.6–0.9	K-Band
27–40	1.1–0.75	0.9–1.33	Ka-Band

SENSITIVITY OF THE HUMAN EYE TO LIGHT OF DIFFERENT WAVELENGTHS

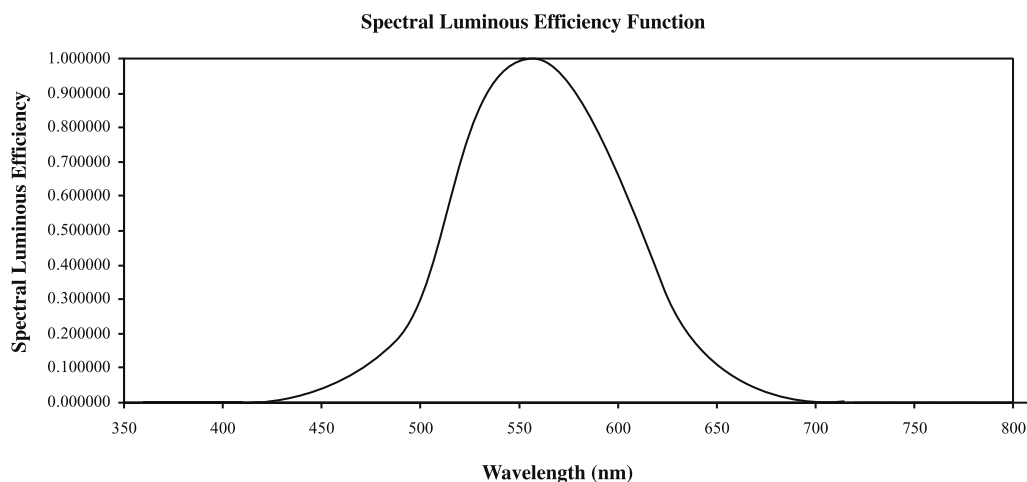

The human eye responds to electromagnetic radiation in the wavelength range from about 360 nm (violet) to 820 nm (red), with a peak sensitivity near 555 nm (green). While the detailed shape of this response curve depends on the individual person, studies on representative samples of human subjects have led to adoption of a standard function relating the perceived brightness (luminous flux) to the actual power of the spectral radiation. This function is referred to as $V(\lambda)$, the photopic spectral luminous efficiency function, and it plays an important role in photometry.

The function $V(\lambda)$, as adopted by the International Commission on Illumination (CIE), is tabulated and plotted below.

BLACK BODY RADIATION

The total power radiated from an ideal black body and the wavelength corresponding to maximum power are given here as a function of absolute temperature. Constants used in the calculation are taken from the table "Fundamental Physical Constants" in

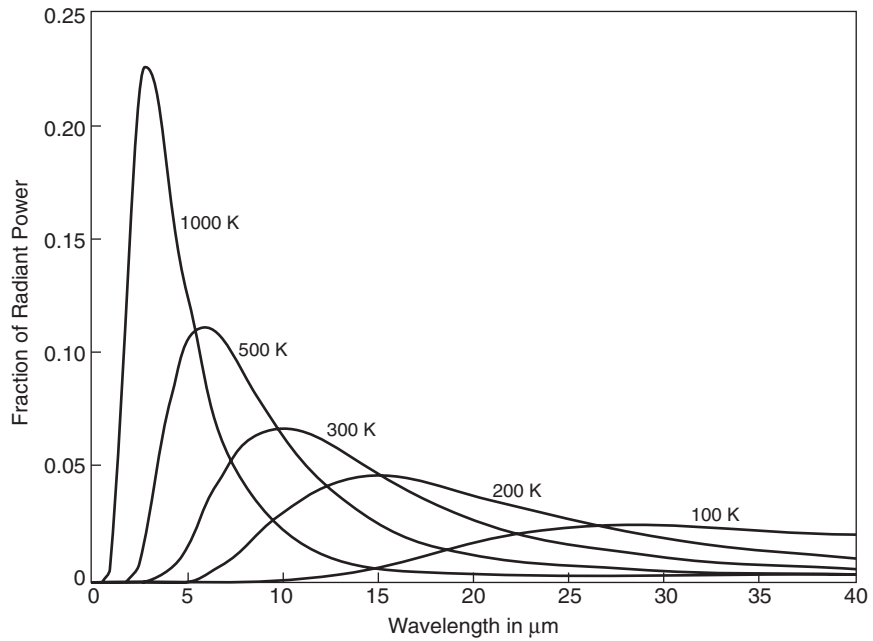

Section 1. The radiated power in a band $\Delta\lambda$ at λ_{\max} may be calculated from:

$$P_{\max} = 0.657548 (\Delta\lambda/\lambda_{\max}) P_{\text{tot}}$$

T/K	P_{tot}	$\lambda_{\max}/\mu\text{m}$	T/K	P_{tot}	$\lambda_{\max}/\mu\text{m}$	T/K	P_{tot}	$\lambda_{\max}/\mu\text{m}$

The curves below show, for various temperatures, the fraction of radiant power as a function of wavelength. The function plotted is $P_\lambda/\Delta\lambda P_{tot}$, where P_λ is the power at wavelength λ in a small interval $\Delta\lambda$ (in μm), and P_{tot} is the total power.

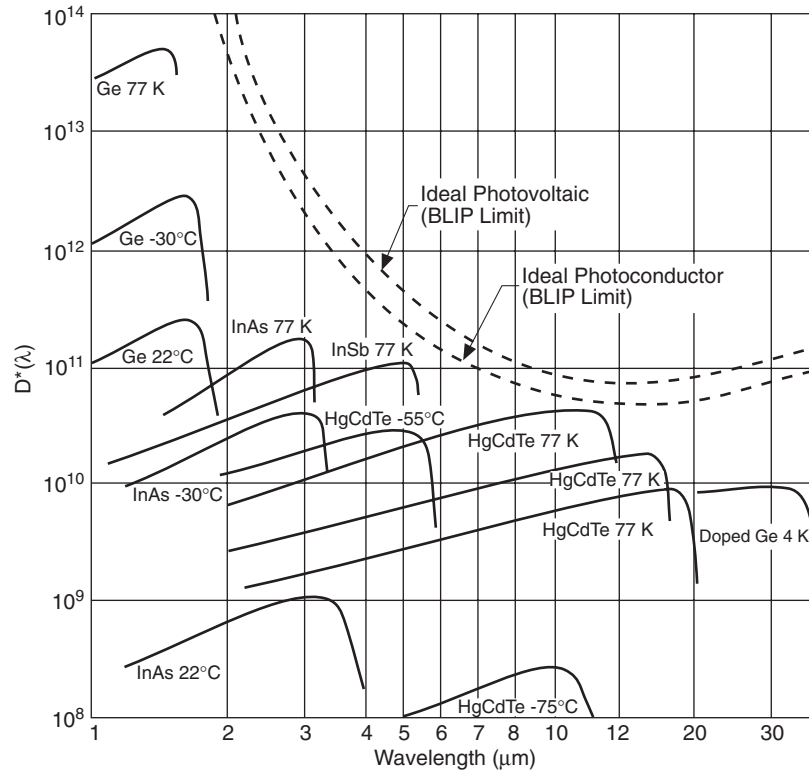

CHARACTERISTICS OF INFRARED DETECTORS

This graph summarizes the wavelength response of some semiconductors used as detectors for infrared radiation. The quantity $D^*(\lambda)$ is the signal to noise ratio for an incident radiant power density of 1 W/cm^2 and a bandwidth of 1 Hz (60° field of view). The Ge, InAs, and InSb detectors are photovoltaics, while the HgCdTe series are photoconductive devices. The cutoff wavelength of the latter can be varied by adjusting the relative amounts of Hg, Cd,

and Te (three examples are shown at 77 K). The graph also shows the theoretical background limited sensitivity for ideal detectors which introduce no intrinsic noise.

INDEX OF REFRACTION OF INORGANIC CRYSTALS

This table lists the index of refraction of selected crystalline inorganic compounds. When, available, values are given as a function of wavelength in the range from the ultraviolet to the far infrared region. For each compound a value at 589 nm, the wavelength of the principal sodium line, is given. The data have been taken from the references indicated; in many cases, data from a reference have been refitted to generate the index of refraction at the wavelengths used in this table. All values refer to ambient temperature. Entries marked by * are based on extrapolation beyond the range of available experimental data.

Compounds belonging to the cubic crystal system have only a single refractive index value, but other systems are anisotropic, so that the crystal is characterized by two or three unique indexes. Hexagonal, rhombohedral, and tetragonal crystals have two unique indexes which are traditionally labeled n_o and n_e for "ordinary ray" and "extraordinary ray". Orthorhombic, monoclinic, and triclinic crystals are characterized by three indexes which are here called n_x , n_y , and n_z . The table indicates the crystal system for each entry in order to identify the material uniquely.

The refractive index and other optical properties for metals, semiconductors, and certain other compounds can be found in the tables "Optical Properties of Selected Elements" and "Optical Properties of Selected Inorganic and Organic Solids" in Section 12 of this *Handbook*.

REFRACTIVE INDEX AND TRANSMITTANCE OF REPRESENTATIVE GLASSES

Typical values of the index of refraction and internal transmittance (fraction of light transmitted through a one centimeter thickness) are tabulated here for selected types of glasses, as well as for synthetic fused (vitreous) silica. Nominal compositions are given in the first part of the table. The second part gives the index of refraction, relative to air, and the internal transmittance for representative samples of each glass at wavelengths in the infrared, visible, and near-ultraviolet regions. It should be emphasized that wide variation of these parameters may be found among subtypes of each glass. More detailed data may be found in Reference 3.

Assuming that the Lambert-Beer Law is followed, the transmittance of a glass plate of thickness d (in centimeters) can be obtained by raising the transmittance value in the table to the power d .

INDEX OF REFRACTION OF WATER

This table gives the index of refraction of liquid water at atmospheric pressure, relative to a vacuum, at several temperatures and wavelengths. It is generated from the formulation in Reference 1, which covers a wide range of temperature, pressure, and wavelength. The wavelengths listed here correspond to prominent lines of cadmium (226.50 and 361.05 nm), potassium (404.41 nm), sodium (589.00 nm), Ne (632.80 nm, from a helium - neon laser), and mercury (1.01398 μm).

INDEX OF REFRACTION OF LIQUIDS FOR CALIBRATION PURPOSES

This table gives the index of refraction of six liquids which are available in highly pure form and whose index of refraction has been accurately measured as a function of wavelength and temperature. They are therefore useful for calibration of refractometers. The estimated uncertainty in the values is:

2,2,4-Trimethylpentane	±0.00003
Hexadecane	±0.00008
<i>trans</i> -Bicyclo[4.0.0]decane	±0.00008
1-Methylnaphthalene	±0.00008
Toluene	±0.00003
Methylcyclohexane	±0.00003

Full details are given in the references. This table is reprinted from Reference 1 by permission of the International Union of Pure and Applied Chemistry.

INDEX OF REFRACTION OF AIR

This is a table of the index of refraction n of dry air at 15°C and a pressure of 101.325 kPa and containing 0.045% by volume of carbon dioxide (“standard air”). The index of refraction is defined by $n = \lambda_{\text{vac}} / \lambda_{\text{air}}$ where λ is the wavelength of the radiation. The index is calculated from the expression

$$(n-1) \times 10^8 = 8342.54 + 2406147(130 - \sigma^2)^{-1} + 15998(38.9 - \sigma^2)^{-1}$$

where $\sigma = 1/\lambda_{\text{vac}}$ and λ_{vac} has units of μm . The equation is valid for λ_{vac} from 200 nm to 2 μm . The table also gives the correction $(n-1)\lambda_{\text{air}}$ which must be added to the wavelength in air to obtain λ_{vac} .

If the air is at a temperature t in °C (ITS-90) and a pressure p in pascals, a value of $(n - 1)$ from this table should be multiplied by

$$p[1 + p(60.1 - 0.972t) \times 10^{-10}]/96095.43(1 + 0.003661t)$$

INDEX OF REFRACTION OF GASES

This table gives the index of refraction of several gases at selected wavelengths ranging from the blue to the red region of the spectrum. The entries at 0.5893 μm correspond to the prominent sodium D line in the yellow region. All values refer to gas at a pressure of one atmosphere (101.325 kPa) and at a temperature of 0°C.

CHARACTERISTICS OF LASER SOURCES

William F. Krupke

Light amplification by stimulated emission of radiation was first demonstrated by Maiman in 1960, the result of a population inversion produced between energy levels of chromium ions in a ruby crystal when irradiated with a xenon flashlamp. Since then population inversions and coherent emission have been generated in literally thousands of substances (neutral and ionized gases, liquids, and solids) using a variety of incoherent excitation techniques (optical pumping, electrical discharges, gas-dynamic flow, electron-beams, chemical reactions, nuclear decay).

The extrema of laser output parameters that have been demonstrated to date and the laser media used are summarized in Table 1. Note that the extreme power and energy parameters listed in this table were attained with laser systems rather than with simple laser oscillators.

Laser sources are commonly classified in terms of the state-of-matter of the active medium: gas, liquid, and solid. Each of these classes is further subdivided into one or more types as shown in Table 2. A well-known representative example of each type of laser is also given in Table 2 together with its nominal operation wavelength and the methods by which it is pumped.

The various lasers together cover a wide spectral range from the far ultraviolet to the far infrared. The particular wavelength of emission (usually a narrow line) is presented for some six dozen lasers in Figures 1A and 1B.

By suitably designing the excitation source and/or by controlling the laser resonator structure, laser systems can provide continuous or pulsed radiation as shown in Table 3.

Besides the method of excitation and the temporal behavior of a laser, there are many other parameters that characterize its operation and efficiency, as shown in Tables 4 and 5.

Although many lasers only emit in one or more narrow spectral "lines," an increasing number of lasers can be tuned by changing the composition or the pressure of the medium, or by varying the wavelength of the pump bands. The spectral regions in which these tunable lasers operate are presented in Figure 2.

TABLE 1. Extrema of Output Parameters of Laser Devices or Systems

Parameter	Value	Laser medium
Peak power	1×10^{14} W (collimated)	Nd:glass
Peak power density	10^{18} W/cm ² (focused)	Nd:glass
Pulse energy	$>10^5$ J	CO ₂ , Nd:glass
Average power	10^5 W	CO ₂
Pulse duration	3×10^{-15} s continuous wave (cw)	Rh6G dye; various gases, liquids, solids
Wavelength	60 nm \leftrightarrow 385 μ m	Many required
Efficiency (nonlaser pumped)	70%	CO
Beam quality	Diffraction limited	Various gases, liquids, solids
Spectral linewidth	20 Hz (for 10^{-1} s)	Neon-helium
Spatial coherence	10 m	Ruby

TABLE 2. Classes, Types, and Representative Examples of Laser Sources

Class	Type (characteristic)	Representative example	Nominal operating wavelength (nm)	Method(s) of excitation
Gas	Atom, neutral (electronic transition)	Neon-Helium (Ne-He)	633	Glow discharge
	Atom, ionic (electronic transition)	Argon (Ar ⁺)	488	Arc discharge
	Molecule, neutral (electronic transition)	Krypton fluoride (KrF)	248	Glow discharge; e-beam
	Molecule, neutral (vibrational transition)	Carbon dioxide (CO ₂)	10600	Glow discharge; gasdynamic flow
	Molecule, neutral (rotational transition)	Methyl fluoride (CH ₃ F)	496000	Laser pumping
	Molecule, ionic (electronic transition)	Nitrogen ion (N ₂ ⁺)	420	E-beam
Liquid	Organic solvent (dye-chromophore)	Rhodamine dye (Rh6G)	580-610	Flashlamp; laser pumping
	Organic solvent (rare earth chelate)	Europium:TTF	612	Flashlamp
	Inorganic solvent (trivalent rare earth ion)	Neodymium:POCl ₄	1060	Flashlamp
Solid	Insulator, crystal (impurity)	Neodymium:YAG	1064	Flashlamp, arc lamp
	Insulator, crystal (stoichiometric)	Neodymium:UP(NdP ₅ O ₁₄)	1052	Flashlamp
	Insulator, crystal (color center)	F ₂ ⁻ :LiF	1120	Laser pumping
	Insulator, amorphous (impurity)	Neodymium:glass	1061	Flashlamp
	Semiconductor (p-n junction)	GaAs	820	Injection current
Semiconductor (electron-hole plasma)	GaAs	890	E-beam, laser pumping

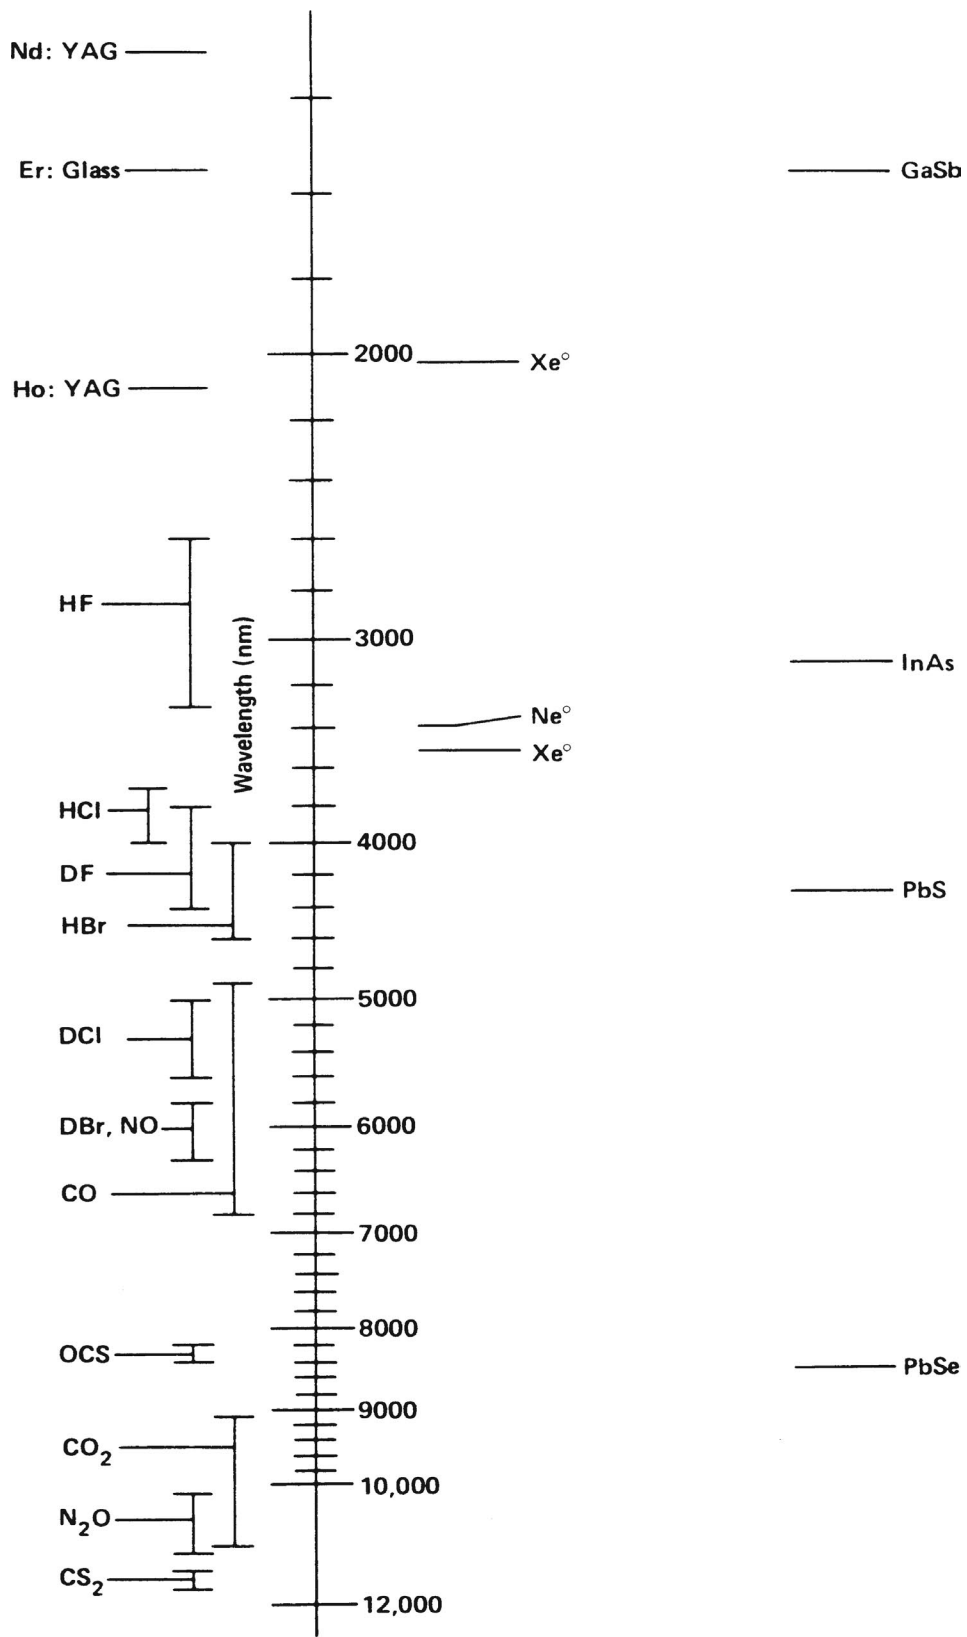

FIGURE 1B. Wavelength of lasers operating in the 1300 to 12,000 nm spectral region.

TABLE 3. Temporal Characteristics of Lasers and Laser Systems

Form	Technique	Pulse width range (s)
Continuous wave	Excitation is continuous; resonator Q is held constant at some moderate value	∞
Pulsed	Excitation is pulsed; resonator Q is held constant at some moderate value	$10^{-8} - 10^{-3}$
Q-Switched	Excitation is continuous or pulsed; resonator Q is switched from a very low value to a moderate value	$10^{-8} - 10^{-6}$
Cavity dumped	Excitation is continuous or pulsed; resonator Q is switched from a very high value to a low value	$10^{-7} - 10^{-5}$
Mode locked	Excitation is continuous or pulsed; phase or loss of the resonator modes is modulated at a rate related to the resonator transit time	$10^{-12} - 10^{-9}$

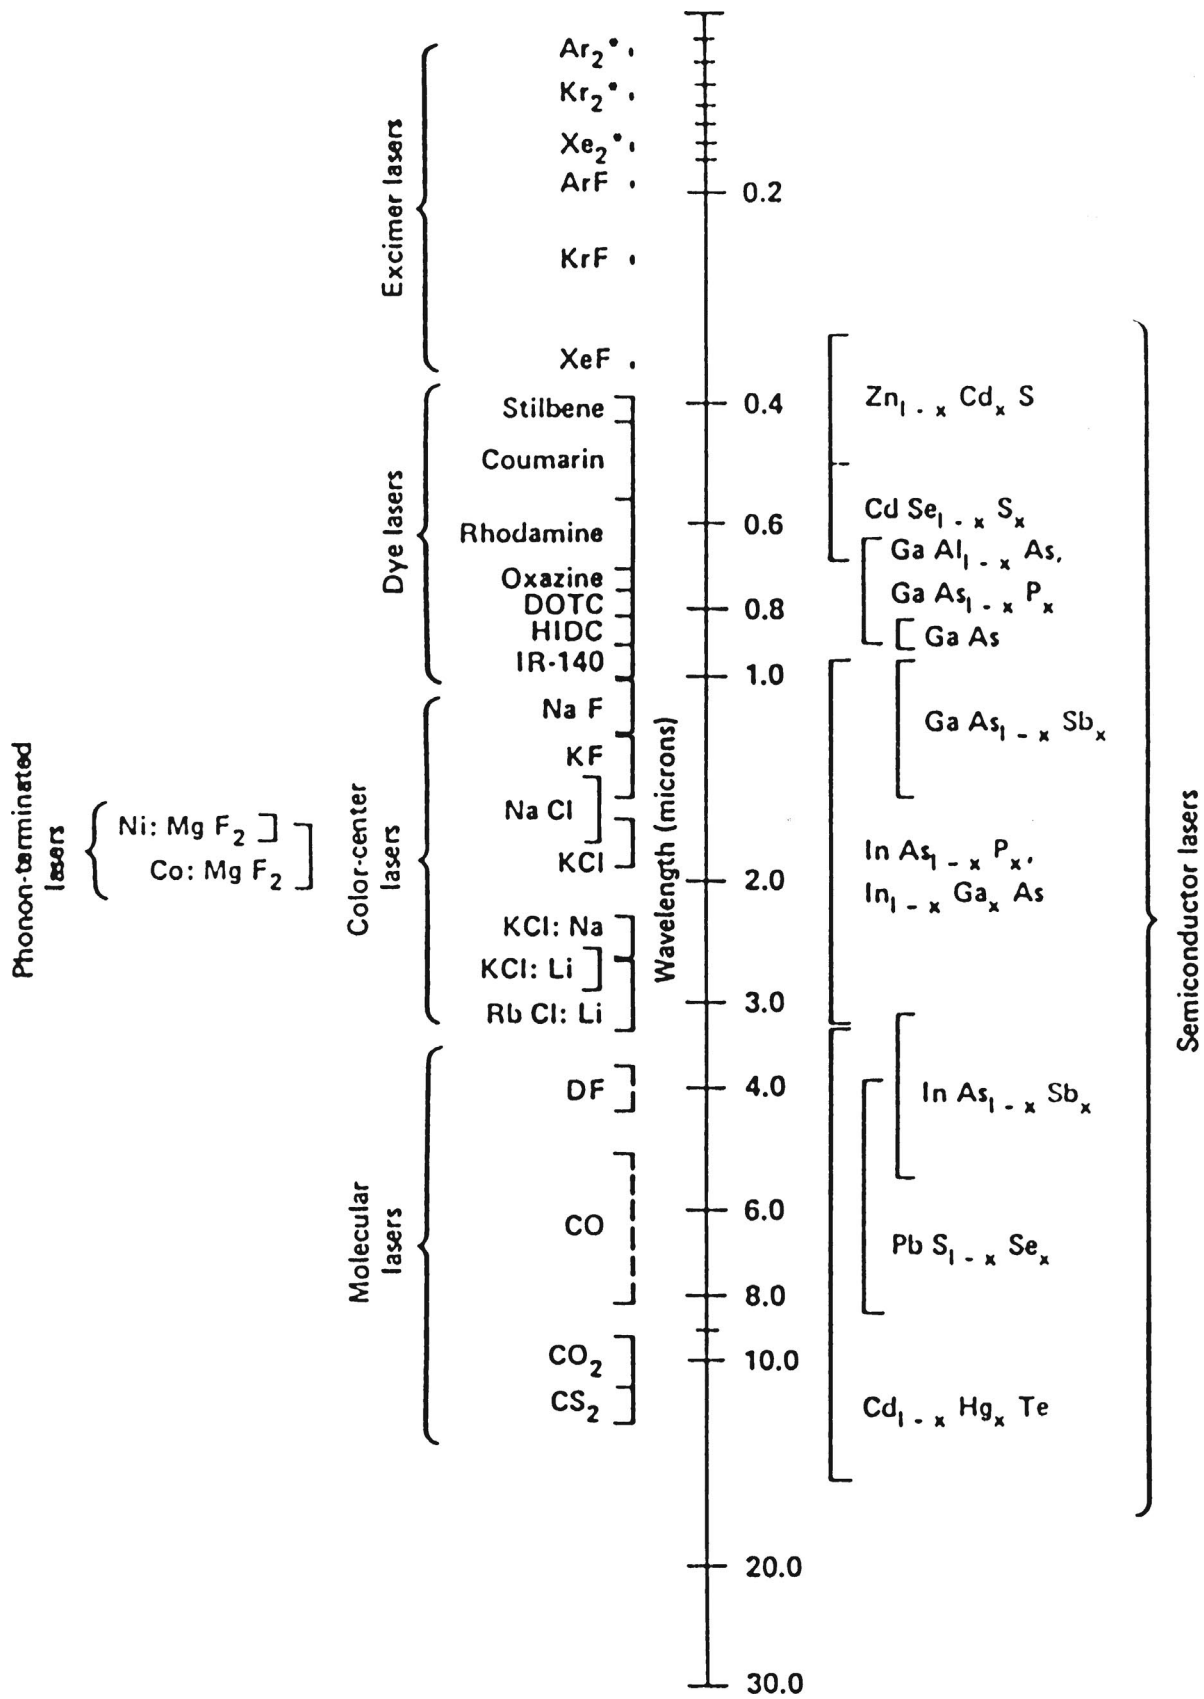

FIGURE 2. Spectral tuning ranges of various types of tunable lasers.

INFRARED LASER FREQUENCIES

Arthur Maki

The CO₂ laser has been the subject of a number of very accurate frequency measurements. Most of the earlier measurements are given by Bradley et al.¹ That analysis was based on a single absolute frequency measurement and many laser frequency differences. New measurements of the methane frequency²⁻⁴ have made it necessary to slightly revise that single absolute frequency measurement. In addition, there have been several other absolute frequency measurements⁵⁻⁷ that have been used here to improve the accuracy of the present tables. New frequency difference measurements have also been added to the database used for the present tables.⁸

INFRARED AND FAR-INFRARED ABSORPTION FREQUENCY STANDARDS

Arthur Maki

Aside from the CO₂ laser transitions, the absorption spectrum of CO has been more accurately and thoroughly measured than any other spectrum. A bibliography of earlier measurements on CO is given by Maki and Wells,¹ and the present tables were calculated from the measurements referred to in that work. In addition, some new and very accurate frequency measurements^{2,3} have been made and were incorporated in the present tables. The frequencies of the rotational transitions of HF and HCl were calculated from constants obtained from fitting the measurements of Evenson et al.^{4,5} and Jennings and Wells.⁶

A new report on infrared wavenumber standards from the International Union of Pure and Applied Chemistry, Commission on Molecular Structure and Spectroscopy, may be found in Reference 7.

GAUGE AND HIGGS BOSONS

γ $I(J^{PC}) = 0, 1(1^{--})$

Mass $m < 6 \times 10^{-17}$ eV
Charge $q < 5 \times 10^{-30}$ e
Mean life $\tau = \text{Stable}$

**g
or gluon** $I(J^P) = 0(1^-)$

Mass $m = 0^{[a]}$
SU(3) color octet

W $J = 1$

Charge = $\pm 1e$
Mass $m = 80.403 \pm 0.029$ GeV
 $m_Z - m_W = 10.785 \pm 0.029$ GeV
 $m_{W^+} - m_{W^-} = -0.2 \pm 0.6$ GeV
Full width $\Gamma = 2.141 \pm 0.041$ GeV
 $\langle N_{\pi^\pm} \rangle = 15.70 \pm 0.35$
 $\langle N_{K^\pm} \rangle = 2.20 \pm 0.19$
 $\langle N_p \rangle = 0.92 \pm 0.14$
 $\langle N_{\text{charged}} \rangle = 19.41 \pm 0.15$
 W^- modes are charge conjugates of the modes below.

W^+ DECAY MODES	Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$\ell^+ \nu$	[b] (10.80 \pm 0.09) %		–
$e^+ \nu$	(10.75 \pm 0.13) %		40201
$\mu^+ \nu$	(10.57 \pm 0.15) %		40201
$\tau^+ \nu$	(11.25 \pm 0.20) %		40182
hadrons	(67.60 \pm 0.27) %		–
$\pi^+ \gamma$	$< 8 \times 10^{-5}$	95%	40201
$D_s^+ \gamma$	$< 1.3 \times 10^{-3}$	95%	40177
$c\bar{X}$	(33.4 \pm 2.6) %		–
$c\bar{s}$	(31 $^\pm$) %		–
invisible	[c] (1.4 \pm 2.8) %		–

Z $J = 1$

Charge = 0
Mass $m = 91.1876 \pm 0.0021$ GeV^[d]
Full width $\Gamma = 2.4952 \pm 0.0023$ GeV
 $\Gamma(\ell^+ \ell^-) = 83.984 \pm 0.086$ MeV^[e]
 $\Gamma(\text{invisible}) = 499.0 \pm 1.5$ MeV^[e]
 $\Gamma(\text{hadrons}) = 1744.4 \pm 2.0$ MeV
 $\Gamma(\mu^+ \mu^-)/\Gamma(e^+ e^-) = 1.0009 \pm 0.0028$
 $\Gamma(\tau^+ \tau^-)/\Gamma(e^+ e^-) = 1.0019 \pm 0.0032$ ^[f]

Average charged multiplicity

$\langle N_{\text{charged}} \rangle = 20.76 \pm 0.16$ ($S = 2.1$)

Couplings to leptons

Higgs Bosons — H^0 and H^\pm , Searches for

H^0 Mass $m > 114.4$ GeV, CL = 95%

H^0 in Supersymmetric Models ($m_{H_1^0} < m_{H_2^0}$)

Mass $m > 89.8$ GeV, CL = 95%

A^0 Pseudoscalar Higgs Boson in Supersymmetric Models [k]

Mass $m > 90.4$ GeV, CL = 95% $\tan\beta > 0.4$

H^\pm Mass $m > 79.3$ GeV, CL = 95%

(See the Particle Listings for a Note giving details of Higgs Bosons.)

Heavy Bosons Other than Higgs Bosons, Searches for

Additional W Bosons

W' with standard couplings decaying to $e\nu, \mu\nu$

Mass $m > 800$ GeV, CL = 95%

W_R — right-handed W

Mass $m > 715$ GeV, CL = 90% (electroweak fit)

Additional Z Bosons

Z_{SM} with standard couplings

Mass $m > 825$ GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m > 1500$ GeV, CL = 95% (electroweak fit)

Z_{LR} of $SU(2)_L \times SU(2)_R \times U(1)$

(with $g_L = g_R$)

Mass $m > 630$ GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m > 860$ GeV, CL = 95% (electroweak fit)

Z_X of $SO(10) \times SU(5) \times U(1)_X$ (with $g_X = e \cos\theta_W$)

Mass $m > 690$ GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m > 781$ GeV, CL = 95% (electroweak fit)

Z_ψ of $E_6 \rightarrow SO(10) \times U(1)_\psi$ (with $g_\psi = e \cos\theta_W$)

Mass $m > 675$ GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m > 366$ GeV, CL = 95% (electroweak fit)

Z_η of $E_6 \rightarrow SU(3) \times SU(2) \times U(1) \times U(1)_\eta$ (with $g_\eta = e \cos\theta_W$)

Mass $m > 720$ GeV, CL = 95% ($p\bar{p}$ direct search)

Mass $m > 619$ GeV, CL = 95% (electroweak fit)

Scalar Leptoquarks

Mass $m > 256$ GeV, CL = 95% (1st generation, pair prod.)

Mass $m > 298$ GeV, CL = 95% (1st gener., single prod.)

Mass $m > 202$ GeV, CL = 95% (2nd gener., pair prod.)

Mass $m > 73$ GeV, CL = 95% (2nd gener., single prod.)

Mass $m > 148$ GeV, CL = 95% (3rd gener., pair prod.)

(See the Particle Listings for assumptions on leptoquark quantum numbers and branching fractions.)

Axions (A^0) and Other Very Light Bosons, Searches for

The standard Peccei–Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Particle Listings in the full *Review* contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is $> 7.2 \times 10^{24}$ years (CL = 90%).

NOTES

In this Summary Table:

When a quantity has “(S = . . .)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] Theoretical value. A mass as large as a few MeV may not be precluded.
- [b] ℓ indicates each type of lepton (e, μ , and τ), not sum over them.
- [c] This represents the width for the decay of the W boson into a charged particle with momentum below detectability, $p < 200$ MeV.
- [d] The Z-boson mass listed here corresponds to a Breit–Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator.
- [e] This partial width takes into account Z decays into $\nu\bar{\nu}$ and any other possible undetected modes.
- [f] This ratio has not been corrected for the τ mass.
- [g] Here $A \equiv 2g_V g_A / (g_V^2 + g_A^2)$.
- [h] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [i] See the Z Particle Listings for the γ energy range used in this measurement.
- [j] For $m_{\gamma\gamma} = (60 \pm 5)$ GeV.
- [k] The limits assume no invisible decays.

Lepton Family number (LF), Lepton number (L), or Baryon number (B) violating modes

L means lepton number violation (e.g. $\tau^- \rightarrow e^+ \pi^- \pi^-$). Following common usage, LF means lepton family violation and not lepton number violation (e.g., $\tau^- \rightarrow e^- \pi^+ \pi^-$). B means baryon number violation.

Heavy Charged Lepton Searches

L^\pm – charged lepton

Mass $m > 100.8$ GeV, CL = 95% ^[h] Decay to νW .

L^\pm – stable charged heavy lepton

Mass $m > 102.6$ GeV, CL = 95%

Neutrino Properties

See the note on “Neutrino properties listings” in the Particle Listings.

Mass $m < 2$ eV (tritium decay)

Mean life/mass, $\tau/m > 300$ s/eV, CL = 90% (reactor)

Mean life/mass, $\tau/m > 7 \times 10^9$ s/eV (solar)

Mean life/mass, $\tau/m > 15.4$ s/eV, CL = 90% (accelerator)

Magnetic moment $\mu < 0.9 \times 10^{-10} \mu_B$, CL = 90% (reactor)

Number of Neutrino Types

Number $N = 2.994 \pm 0.012$ (Standard Model fits to LEP data)

Number $N = 2.92 \pm 0.06$ (Direct measurement of invisible Z width)

Neutrino Mixing

The following values are obtained through data analyses based on the 3-neutrino mixing scheme described in the review “Neutrino mass, mixing, and flavor change” by B. Kayser in this *Review*.

$$\sin^2(2\theta_{12}) = 0.86_{-0.04}^{+0.03}$$

$$\Delta m_{21}^2 = (8.0_{-0.3}^{+0.4}) \times 10^{-5} \text{eV}^2$$

The ranges below for $\sin^2(2\theta_{23})$ and Δm_{32}^2 correspond to the projections onto the appropriate axes of the 90% CL contours

in the $\sin^2(2\theta_{23})$ - Δm_{32}^2 plane.

$$\begin{aligned} \sin^2(2\theta_{23}) &> 0.92 \\ \Delta m_{32}^2 &= 1.9 \text{ to } 3.0 \times 10^{-3} \text{eV}^{2[i]} \\ \sin^2(2\theta_{13}) &< 0.19, \text{ CL} = 90\% \end{aligned}$$

Heavy Neutral Leptons, Searches for

For excited leptons, see Compositeness Limits below (see page A-54).

Stable Neutral Heavy Lepton Mass Limits

Mass $m > 45.0$ GeV, CL = 95% (Dirac)

Mass $m > 39.5$ GeV, CL = 95% (Majorana)

Neutral Heavy Lepton Mass Limits

Mass $m > 90.3$ GeV, CL = 95%

(Dirac ν_L coupling to e, μ, τ ; conservative case(τ))

Mass $m > 80.5$ GeV, CL = 95%

(Majorana ν_L coupling to e, μ, τ ; conservative case(τ))

NOTES

In this Summary Table:

When a quantity has “(S = ...)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] This is the best limit for the mode $e^- \rightarrow \nu \gamma$. The best limit for “electron disappearance” is 6.4×10^{24} yr.
- [b] See the “Note on Muon Decay Parameters” in the μ Particle Listings for definitions and details.
- [c] P_μ is the longitudinal polarization of the muon from pion decay. In standard $V-A$ theory, $P_\mu = 1$ and $\rho = \delta = 3/4$.
- [d] This only includes events with the γ energy > 10 MeV. Since the $e^- \bar{\nu}_e \nu_\mu$ and $e^- \bar{\nu}_e \nu_\mu \gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [e] See the relevant Particle Listings for the energy limits used in this measurement.
- [f] A test of additive vs. multiplicative lepton family number conservation.
- [g] Basis mode for the τ .
- [h] L^\pm mass limit depends on decay assumptions; see the Full Listings.
- [i] The sign of Δm_{32}^2 is not known at this time. The range quoted is for the absolute value.

QUARK SUMMARY TABLE

QUARKS

The u -, d -, and s -quark masses are estimates of so-called “current-quark masses,” in a mass-independent subtraction scheme such as $\overline{\text{MS}}$ at a scale $\mu \approx 2$ GeV. The c - and b -quark masses are the “running” masses in the $\overline{\text{MS}}$ scheme. For the b -quark we also quote the 1S mass. These can be different from the heavy quark masses obtained in potential models.

u	$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$	
	Mass $m = 1.5$ to 3.0 MeV ^[a]	Charge = $\frac{2}{3}e$ $I_z = +\frac{1}{2}$ $m_u/m_d = 0.3$ to 0.6
d	$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$

Mass $m > 190$ GeV, CL = 95% ($p\bar{p}$, quasi-stable b')
 Mass $m > 199$ GeV, CL = 95% ($p\bar{p}$, neutral-current decays)
 Mass $m > 128$ GeV, CL = 95% ($p\bar{p}$, charged-current decays)
 Mass $m > 46.0$ GeV, CL = 95% (e^+e^- , all decays)

Free Quark Searches

All searches since 1977 have had negative results.

NOTES

- [a] The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of u and d masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u quark could be essentially massless. The s -quark mass is estimated from SU(3) splittings in hadron masses.
- [b] Based on published top mass measurements using data from Tevatron Run-I and Run-II. Including also the most recent unpublished results from Run-II, the Tevatron Electroweak Working Group reports a top mass of $172.5 \pm 1.3 \pm 1.9$ GeV. See the note “The Top Quark” in the Quark Particle Listings of this Review.
- [c] ℓ means e or μ decay mode, not the sum over them.
- [d] Assumes lepton universality and W -decay acceptance.
- [e] This limit is for $\Gamma(t \rightarrow \gamma q)/\Gamma(t \rightarrow Wb)$.
- [f] This limit is for $\Gamma(t \rightarrow Zq)/\Gamma(t \rightarrow Wb)$.

MESON SUMMARY TABLE

LIGHT UNFLAVORED MESONS

$$(S = C = B = 0)$$

For $I = 1(\pi, b, \rho, a)$: $u\bar{d}, (u\bar{u} - d\bar{d})/\sqrt{2}, d\bar{u}$;
for $I = 0(\eta, \eta', b, b', \omega, \phi, f, f')$: $c_1(u\bar{u} + d\bar{d}) + c_2(s\bar{s})$

π^\pm

$$I^G(J^{PC}) = 1^-(0^-)$$

Mass $m = 139.57018 \pm 0.00035$ MeV ($S = 1.2$)

Mean life $\tau = (2.6033 \pm 0.0005) \times 10^{-8}$ s ($S = 1.2$)

$c\tau = 7.8045$ m

$\pi^\pm \rightarrow \ell^\pm \nu \gamma$ form factors ^[a]

$F_V = 0.017 \pm 0.008$

$F_A = 0.0115 \pm 0.0005$ ($S = 1.2$)

$R = 0.059_{-0.008}^{+0.009}$

π^- modes are charge conjugates of the modes below.

For decay limits to particles which are not established, see the appropriate Search sections (Massive Neutrino Peak Search Test, A^0 (axion), and Other Light Boson (X^0) Searches, etc.).

π^\pm DECAY MODES	Fraction (Γ_i/Γ)	Confidence level	ρ (MeV/c)

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \bar{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$.

CPT-violation decay-rate asymmetry

$$A_{CPT}(K^{\mp}\pi^{\pm}) = 0.008 \pm 0.008$$

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as K_S^0 modes, not as \bar{K}^0 modes. Nearly always it is a K_S^0 that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$.

BOTTOM MESONS

$$(B = \pm 1)$$

$$B^+ = u\bar{b}, B^0 = d\bar{b}, \bar{B}^0 = \bar{d}b, B^- = \bar{u}b, \quad \text{similarly for } B^{*s}$$

B-particle organization

Many measurements of B decays involve admixtures of B hadrons. Previously we arbitrarily included such admixtures in the B^\pm section, but because of their importance we have created two new sections: “ B^\pm/B^0 Admixture” for $\Upsilon(4S)$ results and “ $B^\pm/B^0/B_s^0/b$ -baryon Admixture” for results at higher energies. Most inclusive decay branching fractions and χ_b at high energy are found in the Admixture sections. $B^0\text{-}\bar{B}^0$ mixing data are found in the B^0 section, while $B_s^0\text{-}\bar{B}_s^0$ mixing data and $B\text{-}\bar{B}$ mixing data for a B^0/B_s^0 admixture are found in the B_s^0 section. CP -violation data are found in the $B^\pm, B^0,$ and $B^\pm B^0$ Admixture sections. b -baryons are found near the end of the Baryon section.

The organization of the B sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

- B^\pm
mass, mean life, branching fractions CP violation
- B^0
mass, mean life, branching fractions
polarization in B^0 decay, $B^0\text{-}\bar{B}^0$ mixing, CP violation
- $B^\pm B^0$ Admixtures
branching fractions, CP violation
- $B^\pm/B^0/B_s^0/b$ -baryon Admixtures
mean life, production fractions, branching fractions
 χ_b at high energy, V_{cb} measurements
- B^*
mass
- B_s^0
mass, mean life, branching fractions
polarization in B_s^0 decay, $B_s^0\text{-}\bar{B}_s^0$ mixing
- B_c^\pm
mass, mean life, branching fractions

At end of Baryon Listings:

- Λ_b
mass, mean life, branching fractions
- b -baryon Admixture
mean life, branching fractions

B^\pm

$$I(J^P) = \frac{1}{2}(0^-)$$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

$$\text{Mass } m_{B^\pm} = 5279.0 \pm 0.5 \text{ MeV}$$

$$\text{Mean life } \tau_{B^\pm} = (1.638 \pm 0.011) \times 10^{-12} \text{ s}$$

$$c\tau = 491.1 \mu\text{m}$$

B^- modes are charge conjugates of the modes below. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0\bar{B}^0$ and 50% B^+B^- production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

\end{aligned}$$

\bar{B}^0 modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the B are listed in the B^\pm/B^0 ADMIXTURE section.

The branching fractions listed below assume 50% $B^0 \bar{B}^0$ and 50% $B^+ B^-$ production at the $\Upsilon(4S)$. We have attempted to bring older measurements up to date by rescaling their assumed $\Upsilon(4S)$ production ratio to 50:50 and their assumed D, D_s, D^* , and ψ branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

B^0 DECAY MODES	Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)
$\ell^+ \nu_\ell$ anything	[ggg] (10.4 ± 0.4) %		–
$D^- \ell^+ \nu_\ell$	[ggg] (2.12 ± 0.20) %		2309
$D^*(2010)^- \ell^+ \nu_\ell$	[ggg] (5.35 ± 0.20) %		2257
$\bar{D}^0 \pi^+ \ell^+ \nu_\ell$	(3.2 ± 1.0) × 10 ⁻³		2308
$\bar{D}^{*0} \pi^+ \ell^+ \nu_\ell$	(6.5 ± 1.5) × 10 ⁻³		2256
$\rho^- \ell^+ \nu_\ell$	[ggg] (2.3 ± 0.4) × 10 ⁻⁴		2583
$\pi^- \ell^+ \nu_\ell$	[ggg] (1.36 ± 0.15) × 10 ⁻⁴		2638

B^\pm/B^0 ADMIXTURE**CP violation**

$$A_{CP}(B \rightarrow K^*(892)\gamma) = -0.010 \pm 0.028$$

$$A_{CP}(B \rightarrow s\gamma) = 0.00 \pm 0.04$$

$$A_{CP}(b \rightarrow X_s \ell^+ \ell^-) = -0.22 \pm 0.26$$

The branching fraction measurements are for an admixture of B mesons at the $\Upsilon(4S)$. The values quoted assume that $B(\Upsilon(4S) \rightarrow B\bar{B}) = 100\%$.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

\bar{B} modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

B DECAY MODES	Fraction (Γ_i/Γ)	Scale factor/ Confidence level	p (MeV/c)

$B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

These measurements are for an admixture of bottom particles at high energy (LEP, Tevatron, $S\bar{p}\bar{p}S$).

$$\text{Mean life } \tau = (1.568 \pm 0.009) \times 10^{-12} \text{ s}$$

$$\text{Mean life } \tau = (1.72 \pm 0.10) \times 10^{-12} \text{ s} \quad \text{Charged } b\text{-hadron admixture}$$

$$\text{Mean life } \tau = (1.58 \pm 0.14) \times 10^{-12} \text{ s} \quad \text{Neutral } b\text{-hadron admixture}$$

$$\tau_{\text{charged } b\text{-hadron}}/\tau_{\text{neutral } b\text{-hadron}} = 1.09 \pm 0.13$$

$$|\Delta\tau_b|/\tau_{b,\bar{b}} = -0.001 \pm 0.014$$

The branching fraction measurements are for an admixture of B mesons and baryons at energies above the $\Upsilon(4S)$. Only the highest energy results (LEP, Tevatron, $S\bar{p}\bar{p}S$) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LEP and at the Tevatron.

For inclusive branching fractions, e.g., $B \rightarrow D^\pm$ anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a \bar{b} initial state. b modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

\bar{b} DECAY MODES	Scale factor/ Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
-----------------------	-------------------------------------------------	------------------	----------------

PRODUCTION FRACTIONS

The production fractions for weakly decaying b -hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note “ B^0 - \bar{B}^0 Mixing” in the B^0 Particle Listings. Values assume

$$B(\bar{b} \rightarrow B^+) = B(\bar{b} \rightarrow B^0)$$

$$B(\bar{b} \rightarrow B^+) + B(\bar{b} \rightarrow B^0) + B(\bar{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) = 100\%.$$

The notation for production fractions varies in the literature ($f_d, d_{B^0}, f(b \rightarrow \bar{B}^0)$, $Br(b \rightarrow \bar{B}^0)$). We use our own branching fraction notation here, $B(\bar{b} \rightarrow B^0)$.

$$B^* \quad I(J^P) = \frac{1}{2}(1^-)$$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

$$\text{Mass } m_{B^*} = 5325.0 \pm 0.6 \text{ MeV}$$

$$m_{B^*} - m_B = 45.78 \pm 0.35 \text{ MeV}$$

B^* DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$B\gamma$	dominant	45

BOTTOM, STRANGE MESONS

$$(B = \pm 1, S = \mp 1)$$

$$B_s^0 = s\bar{b}, \bar{B}_s^0 = \bar{s}b, \text{ similarly for } B_s^{*\pm}$$

$$B_s^0 \quad I(J^P) = 0(0^-)$$

I, J, P need confirmation. Quantum numbers shown are quark-model predictions.

$$\text{Mass } m_{B_s^0} = 5367.5 \pm 1.8 \text{ MeV} \quad (S = 1.1)$$

$$\text{Mean life } \tau = (1.466 \pm 0.059) \times 10^{-12} \text{ s}$$

$$c\tau = 439 \mu\text{m}$$

$B_s^0 \bar{B}_s^0$ mixing parameters

$$\Delta m_{B_s^0} = m_{B_s^0 H} - m_{B_s^0 L} > 14.4 \times 10^{12} \hbar \text{ s}^{-1}, \text{ CL} = 95\%$$

$$> 94.8 \times 10^{-10} \text{ MeV}, \text{ CL} = 95\%$$

$$x_s = \Delta m_{B_s^0} / \Gamma_{B_s^0} > 19.9, \text{ CL} = 95\%$$

$$\chi_s > 0.49878, \text{ CL} = 95\%$$

These branching fractions all scale with $B(\bar{b} \rightarrow B_s^0)$, the LEP B_s^0 production fraction. The first four were evaluated using $B(\bar{b} \rightarrow B_s^0) = (10.7 \pm 1.4)\%$ and the rest assume $B(\bar{b} \rightarrow B_s^0) = 12\%$.

The branching fraction $B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$ is not a pure measurement since the measured product branching fraction $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$ was used to determine $B(\bar{b} \rightarrow B_s^0)$, as described in the note on " $B^0 - \bar{B}^0$ Mixing"

For inclusive branching fractions, e.g., $B \rightarrow D^\pm \text{ anything}$, the values usually are multiplicities, not branching fractions. They can be greater than one.

 $\psi(3770)$

$$I^G(J^{PC}) = 0^-(1^{--})$$

Mass $m = 3771.1 \pm 2.4$ MeV
 Full width $\Gamma = 23.0 \pm 2.7$ MeV ($S = 1.1$)
 $\Gamma_{ee} = 0.242_{-0.024}^{+0.027}$ keV ($S = 1.1$)

In addition to the dominant decay mode to $D\bar{D}$, $\psi(3770)$ was found to decay into the final states containing the J/ψ (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to $\phi\eta$ only (ADAMS 06).

NOTES

In this Summary Table:

When a quantity has “($S = \dots$)” to its right, the error on the quantity has been enlarged by the “scale factor” S , defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S , see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame.

- [a] See the “Note on $\pi^\pm \rightarrow \ell^\pm \nu \gamma$ and $K^\pm \rightarrow \ell^\pm \nu \gamma$ Form Factors” in the π^\pm Particle Listings for definitions and details.
- [b] Measurements of $\Gamma(e^+ \nu_e)/\Gamma(\mu^+ \nu_\mu)$ always include decays with γ 's, and measurements of $\Gamma(e^+ \nu_e \gamma)$ and $\Gamma(\mu^+ \nu_\mu \gamma)$ never include low-energy γ 's. Therefore, since no clean separation is possible, we consider the modes with γ 's to be subreactions of the modes without them, and let $[\Gamma(e^+ \nu_e) + \Gamma(\mu^+ \nu_\mu)]/\Gamma_{\text{total}} = 100\%$.
- [c] See the π^\pm Particle Listings for the energy limits used in this measurement; low-energy γ 's are not included.
- [d] Derived from an analysis of neutrino-oscillation experiments.
- [e] Astrophysical and cosmological arguments give limits of order 10^{-13} ; see the π^0 Particle Listings.
- [f] Due to a new measurement in the average, this is 0.45 MeV larger than the mass we gave in our 2002 edition, 547.30 ± 0.12 MeV.
- [g] Due to removing an old measurement from the average, this is 0.11 keV larger than the width we gave in our 2002 edition, 1.18 ± 0.11 keV. See the $\Gamma(2\gamma)$ data block in the Data Listings.
- [h] C parity forbids this to occur as a single-photon process.
- [i] See the “Note on scalar mesons” in the $f_0(1370)$ Particle Listings. The interpretation of this entry as a particle is controversial.
- [j] See the “Note on $\rho(770)$ ” in the $\rho(770)$ Particle Listings.
- [k] The $\omega\rho$ interference is then due to $\omega\rho$ mixing only, and is expected to be small. If $e\mu$ universality holds, $\Gamma(\rho^0 \rightarrow \mu^+ \mu^-) = \Gamma(\rho^0 \rightarrow e^+ e^-) \times 0.99785$.
- [l] See the “Note on scalar mesons” in the $f_0(1370)$ Particle Listings.
- [m] See the “Note on $a_1(1260)$ ” in the $a_1(1260)$ Particle Listings.
- [n] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Particle Listings for details.
- [o] See the “Note on non- $q\bar{q}$ mesons” in the Particle Listings (see the index for the page number).
- [p] See the “Note on the $\eta(1405)$ ” in the $\eta(1405)$ Particle Listings.
- [q] See the “Note on the $f_1(1420)$ ” in the $\eta(1405)$ Particle Listings.
- [r] See also the $\omega(1650)$ Particle Listings.
- [s] See the “Note on the $\rho(1450)$ and the $\rho(1700)$ ” in the $\rho(1700)$ Particle Listings.
- [t] See also the $\omega(1420)$ Particle Listings.
- [u] See the “Note on $f_0(1710)$ ” in the $f_0(1710)$ Particle Listings.
- [v] See the note in the K^\pm Particle Listings.
- [w] The definition of the slope parameter g of the $K \rightarrow 3\pi$ Dalitz plot is as follows (see also “Note on Dalitz Plot Parameters for $K \rightarrow 3\pi$ Decays” in the K^\pm Particle Listings):
$$|M|^2 = 1 + g(s_3 - s_0)/m_{\pi^+}^2 + \dots$$
- [x] For more details and definitions of parameters see the Particle Listings.
- [y] Most of this radiative mode, the low-momentum γ part, is also included in the parent mode listed without γ 's.
- [z] See the K^\pm Particle Listings for the energy limits used in this measurement.
- [aa] Structure-dependent part.
- [bb] Direct-emission branching fraction.
- [cc] Violates angular-momentum conservation.
- [dd] Derived from measured values of ϕ_{+-} , ϕ_{00} , $|\eta|$, $|m_{K_L^0} - m_{K_S^0}|$, and $\tau_{K_S^0}$, as described in the introduction to “Tests of Conservation Laws.”

[ee] The CP -violation parameters are defined as follows (see also “Note on CP Violation in $K_S \rightarrow 3\pi$ ” and “Note on CP Violation in K_L^0 Decay” in the Particle Listings):

$$\begin{aligned}\eta_{+-} &= |\eta_{+-}|e^{i\phi_{+-}} = \frac{A(K_L^0 \rightarrow \pi^+\pi^-)}{A(K_S^0 \rightarrow \pi^+\pi^-)} = \epsilon + \epsilon' \\ \eta_{00} &= |\eta_{00}|e^{i\phi_{00}} = \frac{A(K_L^0 \rightarrow \pi^0\pi^0)}{A(K_S^0 \rightarrow \pi^0\pi^0)} = \epsilon - 2\epsilon' \\ \delta &= \frac{\Gamma(K_L^0 \rightarrow \pi^-\ell^+\nu) - \Gamma(K_L^0 \rightarrow \pi^+\ell^-\nu)}{\Gamma(K_L^0 \rightarrow \pi^-\ell^+\nu) + \Gamma(K_L^0 \rightarrow \pi^+\ell^-\nu)}, \\ \text{Im}(\eta_{+-0})^2 &= \frac{\Gamma(K_S^0 \rightarrow \pi^+\pi^-\pi^0)^{CP \text{ viol.}}}{\Gamma(K_L^0 \rightarrow \pi^+\pi^-\pi^0)}, \\ \text{Im}(\eta_{000})^2 &= \frac{\Gamma(K_S^0 \rightarrow \pi^0\pi^0\pi^0)}{\Gamma(K_L^0 \rightarrow \pi^0\pi^0\pi^0)}\end{aligned}$$

where for the last two relations CPT is assumed valid, i.e., $\text{Re}(\eta_{+-0}) \simeq 0$ and $\text{Re}(\eta_{000}) \simeq 0$.

- [ff] See the K_S^0 Particle Listings for the energy limits used in this measurement.
- [gg] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [hh] $\text{Re}(\epsilon'/\epsilon) = \epsilon'/\epsilon$ to a very good approximation provided the phases satisfy CPT invariance.
- [ii] See the K_L^0 Particle Listings for the energy limits used in this measurement.
- [jj] Allowed by higher-order electroweak interactions.
- [kk] Violates CP in leading order. Test of direct CP violation since the indirect CP -violating and CP -conserving contributions are expected to be suppressed.
- [ll] See the “Note on $f_0(1370)$ ” in the $f_0(1370)$ Particle Listings and in the 1994 edition.
- [mm] See the note in the $L(1770)$ Particle Listings in Reviews of Modern Physics 56 No. 2 Pt. II (1984), p. S200. See also the “Note on $K_2(1770)$ and the $K_2(1820)$ ” in the $K_2(1770)$ Particle Listings.
- [nn] See the “Note on $K_2(1770)$ and the $K_2(1820)$ ” in the $K_2(1770)$ Particle Listings.
- [oo] This result applies to $Z^0 \rightarrow c\bar{c}$ decays only. Here ℓ^+ is an average (not a sum) of e^+ and μ^+ decays.
- [pp] This is a weighted average of D^\pm (44%) and D^0 (56%) branching fractions. See “ D^+ and $D^0 \rightarrow (\eta \text{ anything})/(\text{total } D^+ \text{ and } D^0)$ ” under “ D^+ Branching Ratios” in the Particle Listings.
- [qq] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings.
- [rr] These subfractions of the $K^-\pi^+\pi^+$ mode are uncertain: see the Particle Listings.
- [ss] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.
- [tt] This is *not* a test for the $\Delta C = 1$ weak neutral current, but leads to the $\pi^+e^+e^-$ final state.
- [uu] This mode is not a useful test for a $\Delta C = 1$ weak neutral current because both quarks must change flavor in this decay.
- [vv] This $D_1^0 - D_2^0$ limit is inferred from the $D^0 - \bar{D}^0$ mixing ratio $\Gamma(K^+\pi^- \text{ (via } \bar{D}^0)) / \Gamma(K^-\pi^+ \text{ near the end of the } D^0 \text{ Listings)}$.
- [uvw] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.
- [xx] This is the sum of our $K^-\pi^+\pi^+\pi^-$, $K^-\pi^+\pi^+\pi^-\pi^0$, $\bar{K}^0 2\pi^+2\pi^-$, $2\pi^+2\pi^-$, $2\pi^+2\pi^-\pi^0$, $K^+K^-\pi^+\pi^-$, and $K^+K^-\pi^+\pi^-\pi^0$, branching fractions.
- [yy] The branching fractions for the $K^-e^+\nu_e$, $K^*(892)^-e^+\nu_e$, $\pi^-e^+\nu_e$, and $\rho^-e^+\nu_e$ modes add up to $6.14 \pm 0.20\%$.
- [zz] This is a doubly Cabibbo-suppressed mode.
- [aaa] This branching fraction includes all the decay modes of the resonance in the final state.
- [bbb] The experiments on the division of this charge mode among its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.
- [ccc] However, these upper limits are in serious disagreement with values obtained in another experiment.
- [ddd] For now, we average together measurements of the $Xe^+\nu_e$ and $X\mu^+\nu_\mu$ branching fractions. This is the *average*, not the *sum*.
- [eee] This branching fraction includes all the decay modes of the final-state resonance.
- [fff] This comes from a K -matrix parametrization of the $\pi^+\pi^- S$ -wave and is a sum over the $f_0(980)$, $f_0(1300)$, $f_0(1200-1600)$, $f_0(1500)$, and $f_0(1750)$. Not all of these correspond to particles in our Tables.
- [ggg] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [hhh] An $CP(\pm 1)$ indicates the $CP = +1$ and $CP = -1$ eigenstates of the $D^0 - \bar{D}^0$ system.
- [iii] D denotes D^0 or \bar{D}^0 .
- [jjj] $X(3872)^+$ is a hypothetical charged partner of the $X(3872)$.
- [kkk] $\Theta(1710)^{++}$ is a possible narrow pentaquark state and $G(2220)$ is a possible glueball resonance.
- [lll] Stands for the possible candidates of $K^*(1410)$, $K_0^*(1430)$ and $K_2^*(1430)$.
- [mmm] B^0 and B_s^0 contributions not separated. Limit is on weighted average of the two decay rates.
- [nmm] $\Theta(1540)^+$ denotes a possible narrow pentaquark state.
- [ooo] These values are model dependent.
- [ppp] Here “anything” means at least one particle observed.
- [qqq] D^{**} stands for the sum of the $D(1^1P_1)$, $D(1^3P_0)$, $D(1^3P_1)$, $D(1^3P_2)$, $D(2^1S_0)$, and $D(2^1S_1)$ resonances.
- [rrr] $D^{(*)}\bar{D}^{(*)}$ stands for the sum of $D^*\bar{D}^*$, $D^*\bar{D}$, $D\bar{D}^*$, and $D\bar{D}$.
- [sss] $Y(3940)$ denotes a near-threshold enhancement in the $\omega J/\psi$ mass spectrum.
- [ttt] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.
- [uuu] D_j represents an unresolved mixture of pseudoscalar and tensor D^{**} (P -wave) states.
- [vvv] Not a pure measurement. See note at head of B_s^0 Decay Modes.
- [www] Includes $p\bar{p}\pi^+\pi^-\gamma$ and excludes $p\bar{p}\eta$, $p\bar{p}\omega$, $p\bar{p}\eta'$.
- [xxx] J^{PC} known by production in e^+e^- via single photon annihilation. I^G is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.
- [yyy] Spectroscopic labeling for these states is theoretical, pending experimental information.

See also the table of suggested $q\bar{q}$ quark-model assignments in the Quark Model section.

• Indicates particles that appear in the preceding Meson Summary Table. We do not regard the other entries as being established.

† Indicates that the value of J given is preferred, but needs confirmation.

BARYON SUMMARY TABLE

This short table gives the name, the quantum numbers (where known), and the status of baryons in the *Review*. Only the baryons with 3- or 4-star status are included in the main Baryon Summary Table. Due to insufficient data or uncertain interpretation, the other entries in the short table are not established as baryons. The names with masses are of baryons that decay strongly. For N , Δ , and Ξ resonances, the partial wave is indicated by the symbol $L_{2i,2j}$, where L is the orbital angular momentum (S, P, D, \dots), I is the isospin, and J is the total angular momentum. For Λ and Σ resonances, the symbol is $L_{i,2j}$.

 Magnetic polarizability $\beta = (1.9 \pm 0.5) \times 10^{-4}$ fm³
 Charge radius = 0.875 \pm 0.007 fm
 Mean life $\tau > 1.9 \times 10^{29}$ years, CL = 90% ($p \rightarrow$ invisible mode)
 Mean life $\tau > 10^{31}$ to 10^{33} years^[d] (mode dependent)

See the “Note on Nucleon Decay” in our 1994 edition (*Phys. Rev. D*50, 1673) for a short review.

The “partial mean life” limits tabulated here are the limits on τ/B_i , where τ is the total mean life and B_i is the branching fraction for the mode in question. For N decays, p and n indicate proton and neutron partial lifetimes.

p DECAY MODES	Partial mean life (10 ³⁰ years)	Confidence level	p (MeV/c)
Antilepton + meson

$\Sigma^+\pi^0$	$\alpha = -0.45 \pm 0.32$
$\Lambda\ell^+\nu_\ell$	$\alpha = -0.86 \pm 0.04$
$[\alpha(\Lambda_c^+) + \alpha(\bar{\Lambda}_c^-)]/[\alpha(\Lambda_c^+) - \alpha(\bar{\Lambda}_c^-)]$ in $\Lambda_c^+ \rightarrow \Lambda\pi^+, \bar{\Lambda}_c^- \rightarrow \bar{\Lambda}\pi^- = -0.07 \pm 0.31$	
$[\alpha(\Lambda_c^+) + \alpha(\bar{\Lambda}_c^-)]/[\alpha(\Lambda_c^+) - \alpha(\bar{\Lambda}_c^-)]$ in $\Lambda_c^+ \rightarrow \Lambda e^+\nu_e, \bar{\Lambda}_c^- \rightarrow \bar{\Lambda}e^-\bar{\nu}_e = 0.00 \pm 0.04$	

Nearly all branching fractions of the Λ_c^+ are measured relative to the $pK^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of $B(\Lambda_c^+ \rightarrow pK^-\pi^+)$ in a Note at the beginning of the branching-ratio measurements in the Listings. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

$$\Lambda_c(2593)^+ \quad I(J^P) = 0(\frac{1}{2}^-)$$

The spin-parity follows from the fact that $\Sigma_c(2455)\pi$ decays, with little available phase space, are dominant. This assumes that $J^P = 1/2^+$ for the $\Sigma_c(2455)$.

$$\text{Mass } m = 2595.4 \pm 0.6 \text{ MeV } (S = 1.1)$$

$$m - m_{\Lambda_c^+} = 308.9 \pm 0.6 \text{ MeV } (S = 1.1)$$

$$\text{Full width } \Gamma = 3.6_{-1.3}^{+2.0} \text{ MeV}$$

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

$\Lambda_c(2593)^+$ DECAY MODES	Fraction (Γ_i/Γ)	p (MeV/c)
$\Lambda_c^+\pi^+\pi^-$	$[q] \approx 67\%$	124
$\Sigma_c(2455)^{++}\pi^-$	$24 \pm 7\%$	28
$\Sigma_c(2455)^0\pi^+$	$24 \pm 7\%$	28
$\Lambda_c^+\pi^+\pi^-$ 3-body	$18 \pm 10\%$	124
$\Lambda_c^+\pi^0$	$[r]$ not seen	261
$\Lambda_c^+\gamma$	not seen	291

$$\Lambda_c(2625)^+ \quad I(J^P) = 0(\frac{3}{2}^-)$$

J^P has not been measured; $\frac{3}{2}^-$ is the quark-model prediction.

$$\text{Mass } m = 2628.1 \pm 0.6 \text{ MeV } (S = 1.5)$$

$$m - m_{\Lambda_c^+} = 341.7 \pm 0.6 \text{ MeV } (S = 1.6)$$

$$\text{Full width } \Gamma < 1.9 \text{ MeV, CL} = 90\%$$

$\Lambda_c^+\pi\pi$ and its submode $\Sigma(2455)\pi$ are the only strong decays allowed to an excited Λ_c^+ having this mass.

$\Lambda_c(2625)^+$ DECAY MODES	Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)

Mass $m = 5624 \pm 9$ MeV (S = 1.8)

Mean life $\tau = (1.230 \pm 0.074) \times 10^{-12}$ s

$$c\tau = 369\mu\text{m}$$

These branching fractions are actually an average over weakly decaying b -baryons weighted by their production rates in Z decay (or high-energy $p\bar{p}$), branching ratios, and detection efficiencies. They scale with the LEP b -baryon production fraction $B(b \rightarrow b\text{-baryon})$ and are evaluated for our value $B(b \rightarrow b\text{-baryon}) = (10.0 \pm 2.0)\%$.

The branching fractions $B(b\text{-baryon} \rightarrow \Lambda\ell^-\bar{\nu}_\ell \text{ anything})$ and $B(\Lambda_b^0 \rightarrow \Lambda_c^+\ell^-\bar{\nu}_\ell \text{ anything})$ are not pure measurements because the underlying measured products of these with $B(b \rightarrow b\text{-baryon})$ were used to determine $B(b \rightarrow b\text{-baryon})$, as described in the note "Production and Decay of b -Flavored Hadrons."

For inclusive branching fractions, e.g., $B \rightarrow D^\pm \text{ anything}$, the values usually are multiplicities, not branching fractions. They can be greater than one.

Λ_b^0 DECAY MODES	Fraction (Γ_i/Γ)	Confidence level	p (MeV/c)
$J/\psi(1S)\Lambda$	$(4.7 \pm 2.8) \times 10^{-4}$		1744
$\Lambda_c^+\pi^-$	seen		2345

$\Xi^-\ell^-\bar{\nu}_\ell$ anything	$(5.5 \pm 1.6) \times 10^{-3}$	-

NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit–Wigner parameters, but pole positions are also given for most of the N and Δ resonances.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together. Furthermore, the systematic errors on the results are not well understood. Thus, we usually only give ranges for the parameters. We then also give a best guess for the mass (as part of the name of the resonance) and for the width. The *Note on N and Δ Resonances* and the *Note on Λ and Σ Resonances* in the Particle Listings review the partial-wave analyses.

When a quantity has “(S = . . .)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as $S = \sqrt{\chi^2/(N-1)}$, where N is the number of measurements used in calculating the quantity. We do this when $S > 1$, which often indicates that the measurements are inconsistent. When $S > 1.25$, we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum p is given for each decay mode. For a 2-body decay, p is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay, p is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating p . A dagger (“†”) in this column indicates that the mode is forbidden when the nominal masses of resonances are used, but is in fact allowed due to the nonzero widths of the resonances.

- [a] The masses of the p and n are most precisely known in u (unified atomic mass units). The conversion factor to MeV, $1 \text{ u} = 931.494043 \pm 0.000080 \text{ MeV}$, is less well known than are the masses in u.
- [b] These two results are not independent, and both use the more precise measurement of $|q_p/m_p|/(q_p/m_p)$.
- [c] The limit is from neutrality-of-matter experiments; it assumes $q_n = q_p + q_e$. See also the charge of the neutron.
- [d] The first limit is for $p \rightarrow$ anything or “disappearance” modes of a bound proton. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray \bar{p} 's is $\tau_{\bar{p}} > 10^7 \text{ yr}$, the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives $\tau_{\bar{p}}/B(\bar{p} \rightarrow e^- \gamma) > 7 \times 10^5 \text{ yr}$.

- [e] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.
- [f] The parameters g_A , g_V , and g_{WM} for semileptonic modes are defined by $\bar{B}_f[\gamma_\lambda(g_V + g_A \gamma_5) + i(g_{WM}/m_{B_f}) \sigma_{\lambda\nu} q^\nu]B_i$, and ϕ_{AV} is defined by $g_A/g_V = |g_A/g_V|e^{i\phi_{AV}}$. See the “Note on Baryon Decay Parameters” in the neutron Particle Listings.
- [g] Time-reversal invariance requires this to be 0° or 180° .
- [h] This limit is for γ energies between 35 and 100 keV.
- [i] The decay parameters γ and Δ are calculated from α and ϕ using

$$\gamma = \sqrt{1-\alpha^2} \cos \phi, \quad \tan \Delta = -\frac{1}{\alpha} \sqrt{1-\alpha^2} \sin \phi.$$

See the “Note on Baryon Decay Parameters” in the neutron Particle Listings.

- [j] See the Listings for the pion momentum range used in this measurement.
- [k] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.
- [l] A theoretical value using QED.
- [m] See the note on “ Λ_c^+ Branching Fractions” in the Λ_c^+ Particle Listings.
- [n] This branching fraction includes all the decay modes of the final-state resonance.
- [o] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [p] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [q] Assuming isospin conservation, so that the other third is $\Lambda_c^+ \pi^0 \pi^0$.
- [r] A test that the isospin is indeed 0, so that the particle is indeed a Λ_c^+ .
- [s] No absolute branching fractions have been measured. The value here is the branching *ratio* relative to $\Xi^- \pi^+ \pi^+$.
- [t] Not a pure measurement. See note at head of Λ_b^0 Decay Modes.
- [u] Here h^- means π^- or K^- .

SEARCHES SUMMARY TABLE

**SEARCHES FOR
MONOPOLES,
SUPERSYMMETRY,
TECHNICOLOR,
COMPOSITENESS,
EXTRA DIMENSIONS, etc.**

Magnetic Monopole Searches

Isolated supermassive monopole candidate events have not been confirmed. The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:
 $< 1.0 \times 10^{-15} \text{ cm}^{-2} \text{sr}^{-1} \text{s}^{-1}$ for $1.1 \times 10^{-4} < \beta < 0.1$

Supersymmetric Particle Searches

Limits are based on the Minimal Supersymmetric Standard Model. Assumptions include: 1) $\tilde{\chi}_1^0$ (or $\tilde{\gamma}$) is lightest supersymmetric particle; 2) R-parity is conserved; 3) with the exception of \tilde{t} and \tilde{b} , all scalar quarks are assumed to be degenerate in mass and $m_{\tilde{q}_R} = m_{\tilde{q}_L}$. 4) Limits for sleptons refer to the $\tilde{\ell}_R$ states.

See the Particle Listings for a Note giving details of supersymmetry.

$\tilde{\chi}_i^0$ — neutralinos (mixtures of $\tilde{\gamma}$, \tilde{Z}^0 , and \tilde{H}^0)
 Mass $m_{\tilde{\chi}_1^0} > 46 \text{ GeV}$, CL = 95% [all $\tan\beta$, all Δm_0 , all m_0]

Mass $m_{\tilde{\chi}_2^0} > 62.4 \text{ GeV}$, CL = 95%
 [$1 < \tan\beta < 40$, all m_0 , all $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$]

Mass $m_{\tilde{\chi}_3^0} > 99.9 \text{ GeV}$, CL = 95%
 [$1 < \tan\beta < 40$, all m_0 , all $m_{\tilde{\chi}_3^0} - m_{\tilde{\chi}_1^0}$]

$\tilde{\chi}_i^\pm$ — charginos (mixtures of \tilde{W}^\pm and \tilde{H}_i^\pm)

Mass $m_{\tilde{\chi}_1^\pm} > 94 \text{ GeV}$, CL = 95%
 [$\tan\beta < 40$, $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} > 3 \text{ GeV}$, all m_0]

\tilde{e} — scalar electron (selectron)
 Mass $m > 73 \text{ GeV}$, CL = 95% [all $m_{\tilde{e}_R} - m_{\tilde{\chi}_1^0}$]

$\tilde{\mu}$ — scalar muon (smuon)
 Mass $m > 94 \text{ GeV}$, CL = 95%
 [$1 \leq \tan\beta \leq 40$, $m_{\tilde{\mu}_R} - m_{\tilde{\chi}_1^0} > 10 \text{ GeV}$]

$\tilde{\tau}$ — scalar tau (stau)
 Mass $m > 81.9 \text{ GeV}$, CL = 95%
 [$m_{\tilde{\tau}_R} - m_{\tilde{\chi}_1^0} > 15 \text{ GeV}$, all θ_τ]

\tilde{q} — scalar quark (squark)

These limits include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling.
 Mass $m > 250 \text{ GeV}$, CL = 95% [$\tan\beta = 2$, $\mu < 0$, $A = 0$]

\tilde{b} — scalar bottom (sbottom)
 Mass $m > 89 \text{ GeV}$, CL = 95% [$m_{\tilde{b}_1} - m_{\tilde{\chi}_1^0} > 8 \text{ GeV}$, all θ_b]

\tilde{t} — scalar top (stop)
 Mass $m > 95.7 \text{ GeV}$, CL = 95%
 [$\tilde{t} \rightarrow c\tilde{\chi}_1^0$, all θ_t , $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} > 10 \text{ GeV}$]

\tilde{g} — gluino

The limits summarized here refer to the high-mass region ($m_{\tilde{g}} \sim 5 \text{ GeV}$), and include the effects of cascade decays, evaluated assuming a fixed value of the parameters μ and $\tan\beta$. The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling.

Mass $m > 195 \text{ GeV}$, CL = 95% [any $m_{\tilde{q}}$]

Mass $m > 300 \text{ GeV}$, CL = 95% [$m_{\tilde{q}} = m_{\tilde{g}}$]

Technicolor

Searches for a color-octet techni- ρ constrain its mass to be greater than 260 to 480 GeV, depending on allowed decay channels. Similar bounds exist on the color-octet techni- o .

Quark and Lepton Compositeness, Searches for

Scale Limits Λ for Contact Interactions
 (the lowest dimensional interactions with four fermions)
 If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \bar{\psi}_L \gamma_\mu \psi_L \bar{\psi}_L \gamma^\mu \psi_L$$

(with $g^2/4\pi$ set equal to 1), then we define $\Lambda \equiv \Lambda_{LL}^\pm$. For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

$\Lambda_{LL}^+(eeee)$	$> 8.3 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(eeee)$	$> 10.3 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(ee\mu\mu)$	$> 8.5 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(ee\mu\mu)$	$> 6.3 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(ee\tau\tau)$	$> 5.4 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(ee\tau\tau)$	$> 6.5 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(llll)$	$> 9.0 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(llll)$	$> 7.8 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(eeuu)$	$> 23.3 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(eeuu)$	$> 12.5 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(eedd)$	$> 11.1 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(eedd)$	$> 26.4 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(eccc)$	$> 1.0 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(eccc)$	$> 2.1 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(eebb)$	$> 5.6 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(eebb)$	$> 4.9 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(\mu\mu qq)$	$> 2.9 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(\mu\mu qq)$	$> 4.2 \text{ TeV}$, CL = 95%
$\Lambda(\ell\nu\ell\nu)$	$> 3.10 \text{ TeV}$, CL = 90%
$\Lambda(e\nu qq)$	$> 2.81 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(qqqq)$	$> 2.7 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(qqqq)$	$> 2.4 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^+(\nu\nu qq)$	$> 5.0 \text{ TeV}$, CL = 95%
$\Lambda_{LL}^-(\nu\nu qq)$	$> 5.4 \text{ TeV}$, CL = 95%

Excited Leptons

The limits from $\ell^* \ell^{*-}$ do not depend on λ (where λ is the $\ell \ell^*$ transition coupling). The λ -dependent limits assume chiral coupling.

$e^{*\pm}$ — excited electron

Mass $m > 103.2$ GeV, CL = 95% (from $e^* e^*$)

Mass $m > 255$ GeV, CL = 95% (from $e e^*$)

Mass $m > 310$ GeV, CL = 95% (if $\lambda_\gamma = 1$)

$\mu^{*\pm}$ — excited muon

Mass $m > 103.2$ GeV, CL = 95% (from $\mu^* \mu^*$)

Mass $m > 190$ GeV, CL = 95% (from $\mu \mu^*$)

$\tau^{*\pm}$ — excited tau

Mass $m > 103.2$ GeV, CL = 95% (from $\tau^* \tau^*$)

Mass $m > 185$ GeV, CL = 95% (from $\tau \tau^*$)

ν^* — excited neutrino

Mass $m > 102.6$ GeV, CL = 95% (from $\nu^* \nu^*$)

Mass $m > 190$ GeV, CL = 95% (from $\nu \nu^*$)

q^* — excited quark

Mass $m > 45.6$ GeV, CL = 95% (from $q^* q^*$)

Mass m (from $q^* X$)

Color Sextet and Octet Particles

Color Sextet Quarks (q_6)

Mass $m > 84$ GeV, CL = 95% (Stable q_6)

Color Octet Charged Leptons (ℓ_8)

Mass $m > 86$ GeV, CL = 95% (Stable ℓ_8)

Color Octet Neutrinos (ν_8)

Mass $m > 110$ GeV, CL = 90% ($\nu_8 \rightarrow \nu g$)

Extra Dimensions

Please refer to the Extra Dimensions section of the full *Review* for a discussion of the model-dependence of these bounds, and further constraints.

Constraints on the fundamental gravity scale

$M_H > 1.1$ TeV, CL = 95% (dim-8 operators; $p\bar{p} \rightarrow e^+ e^-, \gamma\gamma$)

$M_D > 1.1$ TeV, CL = 95% ($e^+ e^- \rightarrow G\gamma$; 2-flat dimensions)

$M_D > 3\text{--}1000$ TeV (astrophys. and cosmology; 2-flat dimensions; limits depend on technique and assumptions)

Constraints on the radius of the extra dimensions, for the case of two-flat dimensions of equal radii

$r < 90\text{--}660$ nm (astrophysics; limits depend on technique and assumptions)

$r < 0.22$ mm, CL = 95% (direct tests of Newton's law; cited in Extra Dimensions review)

TABLE OF THE ISOTOPES

Norman E. Holden

This table presents an evaluated set of values for the experimental quantities that characterize the decay of radioactive nuclides. A list of the major references used in this evaluation is given below. When uncertainties are not listed, they are assumed to be five or less in the last digit quoted. If they exceed five in the last digit, the value is prefaced by an approximate sign. For quasi-stable nu-

clides, the measured width, Γ , of the resonance is given. To estimate the approximate half-life, the Heisenberg relationship may be used, the half-life = 4.56×10^{22} seconds / $\Gamma(\text{MeV})$. The effective literature cutoff date for data in this edition of the Table is December, 2005.

Table Layout

Column No.	Column title	Description
1	Isotope or Element	For elements, the atomic number and chemical symbol are listed. For nuclides, the mass number and chemical symbol are listed. Isomers are indicated by the addition of m, m1, or m2.
2	Isotopic Abundance	In atom percent.
3	Atomic Mass or Atomic Weight	Atomic mass relative to $^{12}\text{C} = 12$. Atomic weight of elements is given on the same scale.
4	Half-life/Resonance Width	Half-life in decimal notation. μs = microseconds; ms = milliseconds; s = seconds; m = minutes; h = hours; d = days; and y = years. For quasi-stable nuclides, the measured width at half maximum of the energy resonance is given
5	Decay Mode/Energy	Decay modes are α = alpha particle emission; β^- = negative beta emission; β^+ = positron emission; EC = orbital electron capture; IT = isomeric transition from upper to lower isomeric state; n = neutron emission; sf = spontaneous fission; $\beta\beta$ = double beta decay. Total disintegration energy in MeV units.
6	Particle Energy/Intensity	End point energies of beta transitions and discrete energies of alpha particles in MeV and their intensities in percent.
7	Spin and Parity	Nuclear spin or angular momentum of the nuclides in units of $h/2\pi$; parity is positive or negative.
8	Magnetic Dipole Moment	Magnetic dipole moments in nuclear magneton units.
9	Electric Quadrupole Moment	Electric quadrupole moments in barn units (10^{-24} cm^2).
10	Gamma Ray Energy/Intensity	Gamma ray energies in MeV and intensities in percent. Ann. rad. refers to the 511.006 keV photons emitted in the annihilation of positrons in matter.

NEUTRON SCATTERING AND ABSORPTION PROPERTIES

Norman E. Holden

This table presents an evaluated set of values for experimental quantities that characterize the properties for scattering and absorption of neutrons. The neutron cross section is given for room temperature neutrons, 20.43°C, corresponding to a thermal neutron energy of 0.0253 electron volts (eV) or a neutron velocity of 2200 meters/second. The neutron resonance integral is defined over the energy range from 0.5 eV to 0.1×10^6 eV, or 0.1 MeV.

Bound neutron scattering lengths and neutron cross sections averaged over a Maxwellian spectrum at 30 keV for astrophysical applications are also presented. A list of the major references used is given below. The literature cutoff date is January 2003. Uncertainties are given in parentheses. Parentheses with two or more numbers indicate values to the excited state(s) and to the ground state of the product nucleus.

Table Layout

Column Number	Column Title	Description
1	Isotope/Element	For elements, atomic number and chemical symbol are listed. For nuclides, mass number and chemical symbol are listed. Isomers are indicated by the addition of m, m1, or m2.
2	Isotopic Abundance	in atom percent
3	Half-life	Half-life in decimal notation. μ s = microsecond; ms = millisecond; s = second; m = minute; h = hour; d = day; y = year.
4	Thermal Neutron Cross Sections	Cross sections for neutron capture reactions in units of barns (10^{-24} cm ²) or millibarns (mb). Proton, alpha production and fission reactions are designated by σ_p , σ_α , σ_f , respectively. Separate values are listed for isomeric production.
5	Neutron Resonance Integrals	Resonance integrals for neutron capture reactions in barns (10^{-24} cm ²) or millibarns (mb). Proton, alpha production and fission reactions are designated by R.I. _p , R.I. _α , R.I. _f , respectively. Separate values are listed for isomeric production.
6	Neutron Scattering Lengths	Bound coherent scattering lengths for neutron scattering reactions in units of femtometers (fm), which is equal to fermis (10^{-13} cm).
7	Maxwellian Averaged Cross Section	Astrophysical Cross Sections, averaged over a stellar neutron maxwellian spectrum characterized by a thermal energy of 30 keV, expressed in barns (10^{-24} cm ²), millibarns (mb) or microbarns (μ b).

COSMIC RADIATION

A.G. Gregory and R.W. Clay

The Nature of Cosmic Rays

Primary cosmic radiation, in the form of high energy nuclear particles, electrons and photons from outside the solar system and from the Sun, continually bombards our atmosphere. Secondary radiation, resulting from the interaction of the primary cosmic rays with atmospheric gas, is present at sea-level and throughout the atmosphere.

The secondary radiation is collimated by absorption and scattering in the atmosphere and consists of a number of components associated with different particle species. High energy primary particles can produce large numbers of secondary particles forming an extensive air shower. Thus, a number of particles may then be detected simultaneously at sea-level.

Primary particle energies accessible in the vicinity of the earth range from $\sim 10^8$ eV to $\sim 10^{20}$ eV. At the lower energies, the limit is determined by the inability of charged particles to traverse the heliosphere to us through the outward-moving solar wind. The upper energy limit is set by the practicality of building detectors to record particles with the extremely low fluxes found at those energies (J.G. Wilson, 1976; O.C. Allkofer, 1975a).

Primary Cosmic Rays

Primary Particle Energy Spectrum

Figure 1 shows the spectrum of primary particle energies. This includes all particle species. In differential form it is roughly a power law of intensity versus energy with an index of ~ -3 . There appears to be a knee (a steepening) at a little above 10^{15} eV and an ankle (a flattening) above $\sim 10^{18}$ eV. Figure 2 emphasizes the features in the spectrum at the highest energies through multiplying the flux with a strongly rising power law of energy. This figure should be used with caution as errors for the two axes are not now independent.

Data on the high energy cosmic ray spectrum are uncertain largely because of limited event statistics due to the very low flux which might best be measured in particles per square kilometer per century. The highest energy event recorded to 1995 had an energy of 3×10^{20} eV (D.J. Bird et al., 1993).

It is expected that the highest energy cosmic rays will interact with the 2.7 K cosmic microwave background through photoproduction or photodisintegration. These interactions will appreciably reduce the observed flux of cosmic rays with energies above 5×10^{19} eV if they travel further than ~ 150 million light years. This process is known as the Greisen-Zatsepin-Kuz'min (GZK) cut off (P. Sokolsky, 1989).

At energies below $\sim 10^{13}$ eV, solar system magnetic fields and plasma can modulate the primary component and Figure 3 shows the extent of this modulation between solar maximum and minimum (E. Juliusson, 1975; J. Linsley, 1981).

Primary Particle Energy Density

If the above spectrum is corrected for solar effects, the energy density above a particle energy of 10^9 eV outside the solar system is found to be $\sim 5 \times 10^5$ eV m^{-3} . As the threshold energy is increased, the energy density decreases rapidly, being 2×10^4 eV m^{-3} above 10^{12} eV and 10^2 eV m^{-3} above 10^{15} eV. The energy density at lower energies outside the heliosphere is unknown but may be substan-

tially greater if the particle rest mass energy is included together with the kinetic energy (A. W. Wolfendale, 1979).

Primary Particle Isotropy

This is measured as an anisotropy $(I_{\max} - I_{\min}) / (I_{\max} + I_{\min}) \times 100\%$, where I , the intensity ($m^{-2}s^{-1}sr^{-1}$), is usually measured with an angular resolution of a few degrees.

The measured anisotropy is small and energy dependent. It is roughly constant in amplitude at between 0.05 and 0.1% (with a phase of 0 to 6 hours in right ascension) for energies between 10^{11} eV and 10^{14} eV and appears to increase at higher energies roughly as $0.4 \times (\text{Energy}(eV)/10^{16})^{0.5}$ up to $\sim 10^{18}$ eV. The latter rise may well be an artifact of the progressively more limited statistics as the flux drops rapidly with energy. It appears possible that a real anisotropy has been observed at the highest energies (above a few times 10^{19} eV) with a directional preference for the supergalactic plane (this plane reflects the directions of galaxies within about 100 million light years) (A.W. Wolfendale, 1979; R.W. Clay, 1987; T. Stanev et al., 1995).

Primary Particle Composition

The composition of low energy cosmic rays is close to universal nuclear abundances except where propagation effects are present. For example, Li, Be, and B which are spallation products, are over-abundant by about six orders of magnitude.

Composition at 10^{11} eV per nucleus

Charge	1	2	(3-5)	(6-8)	(10-14)	(16-24)	(26-28)	≥ 30
% Composition	50	25	1	12	7	4	4	0.1
(10% uncertainty)								

Measurements at higher energies indicate that there is an increase in the relative abundances of nuclei with charge greater than 6 at energies above 50 TeV/nucleus (K. Asakimori et al., 1993) ($1 \text{ TeV} = 10^{12}$ eV).

Cosmic ray composition at low energies is often quoted at a fixed energy per nucleon. When presented in this way, protons constitute roughly 90% of the flux, helium nuclei about 10% and the remainder sum to a total of about 1%.

Certain radioactive isotopic ratios show lifetime effects. The ratio of Be^{10}/B^9 abundances is used to measure an "age" of cosmic rays since Be^{10} is unstable with a half life of about 1.6×10^6 years. A ratio of 0.6 is expected in the absence of Be^{10} decay and a ratio of about 0.2 is found experimentally (E. Juliusson, 1975; P. Meyer, 1981).

At higher energies, composition determinations are indirect and are rather contradictory and controversial. Experiments aim to differentiate between broad composition models. The measurement technique is based on studies of cosmic ray shower development. A rather direct technique for such studies is to use fluorescence observations of the shower development to determine the atmospheric depth of maximum development of the shower. Such observations suggest a heavy composition (large atomic number) at energies $\sim 10^{17}$ eV which changes with increasing energy to a light composition (perhaps protonic) above $\sim 10^{19}$ eV (T. K. Gaisser et al., 1993).

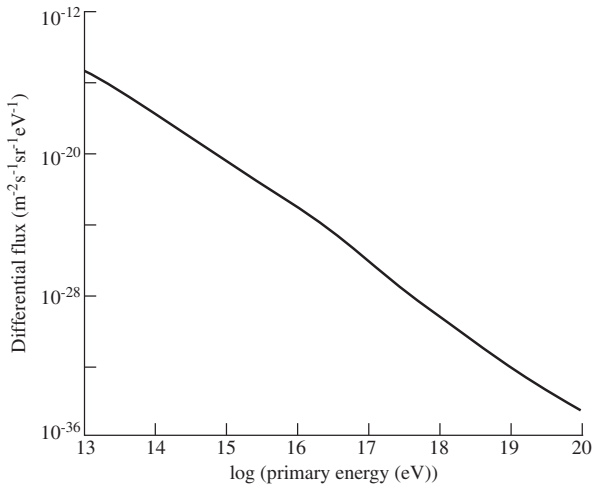

FIGURE 1. The energy spectrum of cosmic ray particles. This spectrum is of a differential form and can be converted to an integral spectrum by integration over all energies above a required threshold (E). Insofar as the spectrum approximates a power law of index -3 , a simple conversion to the integral at an energy $E/1.8$ is obtained by multiplying the differential flux by the energy and dividing by 0.62 .

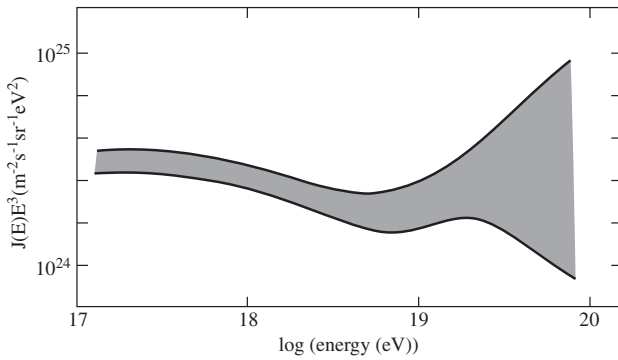

FIGURE 2. Energy spectrum at the highest energies. This spectrum (after Yoshida et al., 1995) has the differential spectrum multiplied by energy cubed. It is from a compilation of a number of measurements and indicates the good general agreement at the lower energies and a spread due to inadequate statistics at the highest energies.

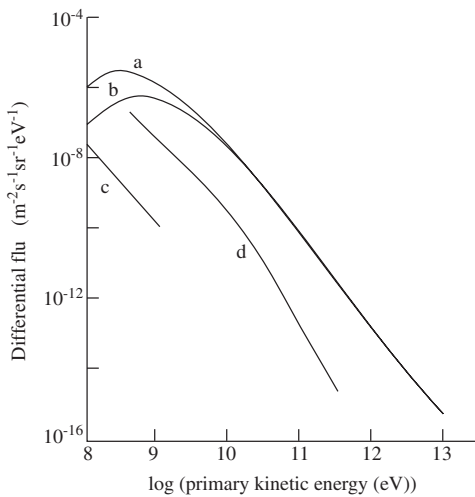

FIGURE 3. Energy spectrum of particles at lower energies. (a) Solar minimum proton energy spectrum. (b) Solar maximum proton energy spectrum. (c) Gamma-ray energy spectrum. (d) Local interstellar electron spectrum.

Primary Electrons

Primary electrons constitute about 1% of the cosmic ray beam. The positron to negative electron ratio is about 10% (J. M. Clem et al., 1995).

Antimatter in the Primary Beam

The ratio of antiprotons to protons in the primary cosmic ray beam (at about 400 MeV) is about 10^{-5} . At about 10 GeV the ratio is about 10^{-3} . At the highest measured energies (10 TeV), the upper limit to the ratio is about 20% (S. Orito et al., 1995; M. Amenomori et al., 1995).

Primary Gamma-Rays

The flux of primary gamma-rays is low at high energies. At 1 GeV the ratio of gamma-rays to protons is about 10^{-6} . The arrival directions of these gamma-rays are strongly concentrated in the plane of the Milky Way although there is a diffuse, near isotropic background flux and some point sources have been detected.

Since the absorption cross section for gamma-rays above 100 MeV is approximately 20 mbarn/electron, less than 10% of gamma-rays reach mountain altitudes (A. W. Wolfendale, 1979; P. F. Michelson, 1994).

Sea Level Cosmic Radiation

The sea level cosmic ray dose is 300 millirad-yr⁻¹ and the sea level ionization is 2.2×10^6 ion pairs m⁻³s⁻¹. The sea level flux has a soft component, which can be absorbed in about 100 mm of lead (about 100 g·cm⁻² of absorber) and a more penetrating (largely muon) hard component. The sea level radiation is largely produced in the atmosphere and is a secondary component from interactions of the primary particles. The steep primary energy spectrum means that most secondaries at sea level are from rather low energy primaries. Thus the secondary flux is dependent on the solar cycle and the geomagnetic latitude of the observer.

Absolute Flux of the Hard Component

Vertical Integral Intensity $I(0) \sim 100 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$
 Angular dependence $I(\theta) \sim I(0) \cos^2(\theta)$
 Integrated Intensity $\sim 200 \text{ m}^{-2}\text{s}^{-1}$
 (O.C. Allkofer, 1975b).

Flux of the Soft Component

In free air, the soft component comprises about one third of the total cosmic ray flux.

Latitude Effect

The geomagnetic field influences the trajectories of lower energy cosmic rays approaching the Earth. As a result, the background flux is reduced by about 7% at the geomagnetic equator. The effect decreases towards the poles and is negligible at latitudes above about 40°.

Flux of Protons

The proton component is strongly attenuated by the atmosphere with an attenuation length (reduction by a factor of e) of about 120 g·cm⁻². It constitutes about 1% of the total vertical sea level flux.

Absorption

The soft component is absorbed in about 100 g·cm⁻² of matter. The hard component is absorbed much more slowly:

Absorption in lead, 6% per 100 g·cm⁻²
 Absorption in rock, 8.5% per 100 g·cm⁻²

Absorption in water, 10% per 100 g·cm⁻²
 (Absorption for depths less than 100 g·pd cm⁻² is given by K. Greisen, 1943.)

Altitude Dependence

The cosmic ray background in the atmosphere has a maximum intensity of about 15 times that at sea level at a depth of about 150 g·cm⁻² (15 km altitude). At maximum intensity, the soft and hard components contribute roughly equally but the hard component is then attenuated more slowly (S. Hayakawa, 1969).

Cosmic Ray Showers

High energy cosmic rays produce particle cascades in the atmosphere which can be detected at sea level provided that their energy exceeds about 100 GeV (such low energy cascades may be detected by using the most sensitive atmospheric Cerenkov detectors). The primary particle progressively loses energy which is transferred through the production of successive generations of secondary particles to a cascade of hadrons, an electromagnetic shower component (both positively and negatively charged electrons and gamma-rays) and muons. The secondary particles are relativistic and all travel effectively at the speed of light. As a result, they reach sea level at approximately the same time but, due to Coulomb scattering (for the electrons) and production angles (for the pions producing the muons), are spread laterally into a disk-like shower front with a characteristic lateral width of several tens of meters and thickness (near the central shower core) of 2 to 3 m. The number of particles at sea level is roughly proportional to the primary particle energy:

Number of particles at sea level $\sim 10^{-10} \times \text{energy (eV)}$.

At altitudes below a few kilometers, the number of particles in a shower attenuates with an *attenuation length* of about 200 g·cm⁻².

i.e., particle number = original number $\times \exp(-(\text{depth increase})/200)$

The above applies to an individual shower. The rate of observation of showers of a given size (particle number at the detector) at different depths of absorber attenuates with an *absorption length* of about 100 g·cm⁻² (J.G. Wilson, 1976).

Atmospheric Background Light from Cosmic Rays

Cosmic ray particles produce Cerenkov light in the atmosphere and produce fluorescent light through the excitation of atmospheric molecules.

Cerenkov Light

High energy charged particles will cause the emission of Cerenkov light in air if their energies are above about 30 MeV (electrons). This threshold is pressure (and hence altitude) dependent. A typical Cerenkov light pulse (at sea level, 100 m from the central shower core) has a time spread of a few nanoseconds. Over this time, the photon flux between 430 and 530 nm would be $\sim 10^{14} \text{ m}^{-2}\text{s}^{-1}$ for a primary particle energy of 10^{16} eV. For comparison, the night sky background flux is $\sim 6 \times 10^{11} \text{ photons m}^{-2}\text{s}^{-1}\text{sr}^{-1}$ in the same wavelength band (J.V. Jelley, 1967).

Fluorescence Light

Cosmic ray particles in the atmosphere excite atmospheric molecules which then emit fluorescence light. This is weak compared to the highly collimated Cerenkov component when viewed in the direction of the incident cosmic ray particle but is emitted

isotropically. Typical pulse widths are longer than 50 ns and may be up to several microseconds for the total pulse from distant large showers (R.M. Baltrusaitis et al., 1985).

Effects of Cosmic Rays

Cerenkov Effects in Transparent Media

Background cosmic ray particles will produce Cerenkov light in transparent material with a photon yield between wavelengths λ_1 and λ_2

$$\sim (2\pi/137)\sin^2(\theta_c) \int_{\lambda_1}^{\lambda_2} d\lambda / \lambda^2 \text{ photons}(\text{unit length})^{-1}$$

where θ_c (the Cerenkov angle) = $\cos^{-1}(1/\text{refractive index})$.

This background light is known to affect light detectors, e.g., photomultipliers, and can be a major source of background noise (R.W. Clay and A.G. Gregory, 1977).

Effects on Electronic Components

If background cosmic ray particles pass through electronic components, they may deposit sufficient energy to affect the state of, e.g., a transistor flip-flop. This effect may be significant where reliability is of great importance or the background flux is high. For instance, it has been estimated that, in communication satellite operation, an error rate of about 2×10^{-3} per transistor per year may be found. Permanent damage may also result. A significant error rate may be found even at sea level in large electronic memories. This error rate is dependent on the sensitivity of the component devices to the deposition of electrons in their sensitive volumes (J.F. Ziegler, 1981).

Biophysical Significance

When cosmic rays interact with living tissue, they produce radiation damage. The amount of the damage depends on the total dose of radiation. At sea level, this dose is small compared with doses from other sources but both the quantity and quality of the radiation change rapidly with altitude. Approximate dose rates under various conditions are:

- Dose rates (mrem·yr⁻¹)
- Sea level cosmic rays, 30
- Cosmic rays at 10 km (subsonic jets), 2000
- Cosmic rays at 18 km (supersonic transports), 10,000
- (c.f., mean total sea level dose, 300)

Astronauts would be subject to radiation from galactic (0.05 rads per day) and solar (a few hundred rads per solar flare) cosmic rays as well as large fluxes of low energy radiation when passing through the Van Allen belts (about 0.3 rads per traverse).

Both astronauts and SST travellers would be subject to a small flux of low energy heavy nuclei stopping in the body. Such particles are capable of destroying cell nuclei and could be particularly harmful in the early stages of the development of an embryo. The rates of heavy nuclei stopping in tissue in supersonic transports and spacecraft are approximately as follows:

- Stopping nuclei ((cm³ tissue)⁻¹ hr⁻¹)
- Supersonic transport (16 km), 0.0005
- Supersonic transport (20 km), 0.005
- Spacecraft, 0.15
- (O. C. Allkofer, 1975a; O. C. Allkofer et al., 1974).

Carbon Dating

Radiocarbon is produced in the atmosphere due to the action of cosmic ray slow neutrons. Solar cycle modulation of the very low energy cosmic rays causes an anticorrelation of the atmospheric ¹⁴C activity with sunspot number with a mean amplitude of about 0.5%. In the long term, modulation of cosmic rays by a varying magnetic field may be important (A.A. Burchuladze et al., 1979).

Practical Uses of Cosmic Rays

There are few direct practical uses of cosmic rays. Their attenuation in water and snow have, however, enabled automatic monitors of water and snow depth to be constructed. A search for hidden cavities in pyramids has been carried out using a muon "telescope".

Other Effects

Stellar X-rays have been observed to affect the transmission times of radio signals between distant stations by altering the depth of the ionospheric reflecting layer. It has also been suggested that variations in ionization of the atmosphere due to solar modulation may have observable effects on climatic conditions.

TECHNIQUES FOR MATERIALS CHARACTERIZATION

Experimental Techniques Used to Determine the Composition, Structure, and Energy States of Solids and Liquids

H.P.R. Frederikse

The many experimental methods, originally designed to study the chemical and physical behavior of solids and liquids, have grown into a new field known as Materials Characterization (or Materials Analysis). During the past 30 years a host of techniques aimed at the study of surfaces and thin films has been added to the many tools for the analysis of bulk samples. The field has benefited particularly from the development of computers and micro-processors, which have vastly increased the speed and accuracy of the measuring devices and the recording of their output. Materials characterization was and is a very important tool in the search for new physical and chemical phenomena. It plays an essential role in new applications of solids and liquids in industry, communications, and medicine. Many of its techniques are used in quality control, in safety regulations, and in the fight against pollution.

In most Materials Characterization experiments the sample is subjected to some kind of radiation: electromagnetic, acoustic, thermal, or particles (electrons, ions, neutrons, etc.). The surface

analysis techniques usually require a high vacuum. As a result of interactions between the solid (or liquid) and the incoming radiation a beam of a similar (or a different) nature will emerge from the sample. Measurement of the physical and/or chemical attributes of this emerging radiation will yield qualitative, and often quantitative, information about the composition and the properties of the material being probed.

The modern tendency of describing practically everything in this world by a combination of a few letters (acronyms) has also penetrated the field of Materials Characterization. The table below gives the meaning of the acronym for every technique listed, the form and size of the required sample (bulk, surface, film, liquid, powder, etc.), the nature of the incoming and of the emerging radiation, the depth and the lateral spatial resolution that can be probed, and the information obtained from the experiment. The last column lists one or two major references to the technique described.

	Technique	Sample	In	Out	Depth	Lateral resolution	Information obtained	Ref.
Optical and Mass Spectroscopies for Chemical Analysis								
1.	AAS Atomic Absorption Spectroscopy	Atomize (flame, electro, thermal, etc.)	Light e.g., glow discharge	Absorption spectrum	—	—	Concentration of atomic species (quantitative, using standards)	1,2
2.	ICP-AES Induct. Coupled Plasma – Atomic Emission Spectroscopy	Atomize (flame, electro, thermal, ICP, etc.)	—	Emission spectrum	—	—	Concentration of atomic species (quantitative, using standards)	3
3.	Dynamic SIMS Dynamic Secondary Ion Mass Spectroscopy	Surface	Ion beam (1–20 keV)	Secondary ions; analysis with mass spectrometer	2 nm–1 μm (or deeper: ion milling)	0.50 nm	Elemental and isotopic analysis; depth profile (all elements); detection limits: ppb–ppm	4
4.	Static SIMS Static Secondary Ion Mass Spectroscopy	Surface	Ion beam (0.5–20 keV)	Secondary ions, analysis with mass spectrometer	0.1–0.5 nm	10 μm	Elemental analysis of surface layers; molecular analysis; detection limits: ppb–ppm	4
5.	SNMS Sputtered Neutral Mass Spectroscopy	Surface, bulk	Plasma discharge; noble gases: 0.5–20 keV	Sputtered atoms ionized by atoms or electrons; then mass analyzed	0.1–0.5 nm (or deeper: ion milling)	1 cm	Elemental analysis $Z \geq 3$; depth profile; detection limit: ppm	4,6
6.	SALI Surface Analysis by Laser Ionization	Surface	e-beam, ion-beam, or laser for sputtering	Sputtered atoms ionized by laser; then mass analyzed	0.1–0.5 nm up to 3 μm in milling mode	60 nm	Surface analysis; depth profiling	7
7.	LIMS Laser Ionization Mass Spectroscopy	Surface, bulk	u.v. laser (ns pulses)	Ionized species; analyzed with mass spectrometer	50–150 nm	5 μm–1 mm	Elemental (micro)analysis; detection limits: 1–100 ppm	8
8.	SSMS Spark Source Mass Spectroscopy	Sample in the form of two electrodes	High voltage R.F. spark produces ions	Ions – analyzed in mass spectrometer	1–5 μm	—	Survey of trace elements; detection limit: 0.01–0.05 ppm	9
9.	GDMS Glow Discharge Mass Spectroscopy	Sample forms the cathode for a D.C. glow discharge	Sputtered atoms ionized in plasma	Ions – analyzed in mass spectrometer	0.1–100 μm	3–4 mm	(Bulk) trace element analysis; detection limit: sub-ppb	9,10
10.	ICPMS Induct. Coupled Plasma Mass Spectroscopy	Liquid-dissolved sample carried by gas stream into R.F. induction coil	Ions produced in argon plasma	Ions – analyzed in quadrupole mass spectrometer	—	—	High sensitivity analysis of trace elements	11
Photons — Absorption, Reflection and Electron Emission								
11.	IRS Infrared Spectroscopy	Thin crystal, glass, liquid	I.R. light (W-filament, globar, Hg-arc)	I.R. spectrum	—	—	Electronic transitions (mainly in semiconductors and superconductors); vibrational modes (in crystals and molecules)	12,13,14
12.	FTIR Fourier Transform I.R. Spectroscopy	Solid, liquid; transmission or reflection	White light (all frequencies)	Fourier Transform of spectrum (interferometer)	—	—	Spectra obtained at higher speed and resolution	15
13.	ATR Attenuated Total Reflection	Surface or thin crystal	—	—	μm's	—	Atomic or molecular spectra of surfaces and films	16
14.	(μ)-RS (Micro-) Raman Spectroscopy	Solid, liquid (1 μm–1 cm)	Laser beam, e.g., Ar-line, YAG-line	Raman spectra	0.5 μm	0.5 μm	Molecular and crystal vibrations	12,14,17

	Technique	Sample	In	Out	Depth	Lateral resolution	Information obtained	Ref.
15.	CARS Coherent Anti-Stokes Raman Spectroscopy	Solid, liquid (50 μm –3 cm)	Pump beam (ω_p)+ probe beam (ω_s)	Anti-Stokes spectrum	–	–	High resolution Raman spectra	14
16.	Ellipsometry	Transparent films, crystals, adsorbed layers	Polarized light	Change in polarization	0.05 nm–5 μm	25 μm (or sample thickness)	Refractive index and absorption	18,19
17.	UPS Ultraviolet Photo-electron Spectroscopy	Surfaces, adsorbed layers	u.v. light, 10–100 eV; 200 eV (synchrotron)	Electrons	0.2–10 nm	0.1–10 nm	Energies of electronic states of surfaces and free molecules	20,21
18.	PSD Photon Stimulated Desorption	Surfaces with adsorbed species	Far u.v. light $E > 10$ eV	Ions – analyzed with mass spectrometer	0.1–2 nm	–	Structure and desorption kinetics of adsorbed atoms and molecules	22
X-Rays								
19.	XRD X-Ray Diffraction	Single crystals, powders films	X-rays: $\lambda = 0.05$ –0.2 nm (6–17 keV)	Diffacted X-ray beam	1–1000 μm	0.1–10 nm	Identification of crystallographic structures; all elements (low Z difficult)	23,24
20.	XRF/EDS X-Ray Fluorescence/Energy Dispersive Spectroscopy	Thin films, single layer	Prim. X-ray beam $\lambda = 0.02$ –0.1 nm 12–80 keV	Fluorescent X-rays	1–100 μm	10 nm	Elemental analysis; all elements except H, He, Li – (EDS also used in XRD, SEM, TEM and EPMA)	25,26
21.	EXAFS Extended X-Ray Absorption Fine Structure	Films, foils	High intensity X-rays (synchrotron)	Spectrum near absorption edge	nm– μm	–	Local atomic structure: order/disorder in vicinity of absorbing atom	27
22.	XPS/ESCA X-Ray Photo-electron Spectroscopy/ Electron Spect. for Chemical Analysis	Surfaces, thin films (≈ 20 atomic layers)	Soft X-rays (1–20 keV)	Core electrons; valence electrons	0.5–10 nm	5 nm–50 μm	(Quantitative) identification of all elements in surface layer or film	28,29
Electrons								
23.	CL Cathode Luminescence	Insulators, semiconductors	Electrons 5–50 keV	Photons 0.1–5 eV	1 nm–2 μm	1 or 2 μm	Energy levels of impurities and point defects	30
24.	APS Appearance Potential Spectroscopy	Surface (≈ 20 atomic layers)	Electrons (energy scan) 50–2000 eV	X-rays to pinpoint electron energy threshold	–	–	Identification of surface species	21, see also C
25.	AES Auger Electron Spectroscopy	Thin films, surfaces	Electrons 3–10 keV	Auger electrons 20–2000 eV	0.3–3 nm	≈ 30 nm	Elemental composition of surface (except H, He); detection limit 0.1–1%	28,29
26.	EELS Electron Energy Loss Spectroscopy	Very thin samples (<200 nm)	Electrons (100–400 keV)	(Retarded) electrons; minus 1–1000 eV	<200 nm	1–100 nm	Local elemental concentration; electronic structure, chem. bonding; interatomic distances	31
27.	EXELFS Extended Electron Energy Loss Fine Structure	Thin films	Electrons (100–400 keV)	Electrons energies 0–30 eV above edge	<200 nm	1–100 nm	Density of states of valence electrons (above Fermi level)	27,32
28.	ESD Electron Stimulated Desorption	Adsorbed species	Electrons $E > 10$ eV	Ions – analyzed with mass spectrometer	–	–	Structure and desorption properties of adsorbed atoms and molecules	22
29.	ESDIAD ESD-Ion Angular Distribution	(See ESD)	(See ESD)	Directional dependence of emitted ions	–	–	Geometries of adsorbed species (atoms or molecules)	22
30.	EPMA Electron Probe (X-Ray) Micro Analysis	Solid conductors and insulators <1 cm thick	Electrons 5–30 keV	Characteristic X-ray 0.1–15 keV	100 nm–5 μm	1 μm	Elemental analysis, $Z \leq 4$, major, minor and trace amounts	33,34
31.	LEED Low Energy Electron Diffraction	Surface	Mono-energetic electron beam 10–1000 eV	Diffacted electrons	0.4–2 nm	<5 μm	Crystallographic structure of surface; resolution: 0.01 nm	35
32.	RHEED Reflection High Energy Electron Diffraction	Surface	Electron beam at grazing angle 5–50 keV	Reflected electrons	0.2–10 nm	<5 μm	Surface symmetry	36,37
33.	SEM Scanning Electron Microscopy	Bulk, films (conducting)	High energy electrons usually ≈ 30 keV	Secondary and backscattered electrons	1 nm–5 μm	1–20 nm	Surface image, defect structure; resolution 5–15 nm; magnification 300,000 \times	33,34
34.	(S)TEM (Scanning) Transmission Electron Microscopy	Thin specimen – <200 nm	High energy electrons typically 300 keV	Transmitted and diffracted electrons	(Sample thickness)	2–20 nm	(Defect) structure of cryst. solids; microchemistry; high resol.: 0.2 nm	33
35.	FEM Field Emission Microscopy	Metals, alloys (sharp point)	–	Electron emission (with appl. electric field – 50 kV)	≈ 0.5 nm	10–100 nm	Surface image, crystallographic structure	34
36.	STM Scanning Tunneling Microscopy	Polished or cleaved surface (conducting)	Tunneling current controls distance between sample and very sharp tip		1–5 nm	2–10 nm	Atomic-scale relief map of surface; resolution: vert. 0.002 nm, hor. 0.2 nm	39
37.	SPM Scanned Probe Microscopy	Very flat surface	Any field: e.g. mechan. vibration recorded with laser probe; same with magnetic, electric or thermal field		1–100 nm	1–100 nm	Surface-magnetic field, surface-thermal conductivity, etc.	39a
38.	AFM Atomic Force Microscopy	Very flat surface	Similar to STM; force measured with cantilever spring		0.5–5 nm	0.2–130 nm	Surface topography with atomic resolution; interatomic force	40

	Technique	Sample	In	Out	Depth	Lateral resolution	Information obtained	Ref.
Ions and Neutrons								
39.	ISS (or LEIS) Ion Scattering Spectroscopy (Low Energy Ion Scattering)	Surface	Ion beam He ⁺ or Ne ⁺ <3 keV	Sputtered ions (energy analysis)	0.1–0.5 nm	1–100 μm	Elemental analysis (better for low Z) detection limits: 0.01–1%	41
40.	FIM Field Ion Microscopy	Surface: metals, alloys; very sharp tip	(He gas above sample)	He ions + high electric field produce image	≈0.1 nm	0.1–2 nm	Atomic structure of surface	34,42
41.	RBS Rutherford Back Scattering	Solids, thin films	Mono-energetic ions (H ⁺ or He ⁺) 0.5–3 MeV	Backscattered ions	10 nm–1 μm	1 mm	Element identification (Li to U) detection limit: 0.01–1%	46
42.	NRA Nuclear Reaction Analysis	Solids, thin films	Mono-energetic ions (Li, Be, B, etc.) 200 keV–6 MeV	Protons, deuterons ³ He, α-particles, γ-rays	0.1–5 μm	10 μm–10 mm	Element identification (all) detection limit: 10 ⁻¹² –10 ⁻²	47
43.	PIXE Particle Induced X-ray Emission	Thin films, surface layers	High energy ions (H ⁺ or He ⁺)	Characteristic X-rays	<10 μm	1 μm–2 mm	Trace impurities: Z>3 detection limit: 0.1–100 ppm (depending on sample thickness)	48
44.	INS Ion Neutralization Spectroscopy	Surface	He-ions (≈5 eV)	Electrons	–	–	Energies of valence electrons	49
45.	NAA Neutron Activation Analysis	Bulk, >0.5 g	Thermal neutrons	Characteristic γ-rays, (≈1 MeV)	Bulk	–	Trace concentrations (of isotopes) of elements: trans. metals, Pt-group; detection limit: 10 ⁹ –10 ¹⁴ atoms/cm ³	43
46.	N(P)D Neutron (Powder) Diffraction	Crystalline solids	Thermal neutrons E ≈0.0025 eV	Diffacted neutrons	Bulk	–	Crystallographic structure; porosity, particle size	44
47.	SANS Small Angle Neutron Scattering	Inhomogeneous solids; powders; porous samples	Thermal neutrons 2 θ = 10 ⁻² –10 ⁻⁴	Scattered neutrons	1–25 mm	–	Average size of inhomogeneities; range: 1 nm–1 mm	45
Acoustic								
48.	SLAM Scanning Laser Acoustic Microscopy	Bulk, film	Acoustic wave produced by laser 1 MHz–1 GHz	Reflected acoustic wave	μm–cm	0.1–20 mm	Defect structure; thickness measurement	50
Thermal								
49.	DTA Differential Thermal Analysis	Specimen and reference sample	Uniform heating	Temperature difference	Bulk	–	Phase transitions, crystallization	51
50.	DSC Differential Scanning Calorimetry	Specimen and ref. sample	Controlled heating	Measure heat required for equal temperature	Bulk	–	Phase transitions, crystallization; activation energies	51
51.	TGA Thermo Gravimetric Analysis	Bulk, 1–100 g	Controlled heating	Weight as function of temperature (and time)	Bulk	–	Decomposition, non-stoichiometry, kinetics of reaction	52
Resonance								
52.	EPR (ESR) Electron Paramagnetic (Spin) Resonance	Paramagnetic solids or liquids	Microwave radiation in magnetic field 3–300 GHz; 1–100 kG	Microwave absorption (at resonance)	Bulk	–	Local environment of paramagnetic ion; concentration of paramagnetic, species; detection limit: 10 ¹¹ spins/cm ³	53,54
53.	ECR Electron Cyclotron Resonance	Semiconductors, metals; free electrons (low temperature)	Microwave radiation in magnetic field 10–30 GHz; 5–10 kG	Microwave absorption (at resonance)	Bulk	–	Electronic energy bands, effective masses	55
54.	Mössbauer Effect	Source and absorber	Mono-energetic γ-rays: 5–100 keV	Mössbauer spectrum (Doppler shifted (lines))	50 m	1 cm	Interaction between nucleus and its environment (local electric, magnetic fields; bonds; valency; diffusion, etc.)	56
55.	NMR (MRI) Nuclear Magnetic Resonance (Magnetic Resonance Imaging)	Solids, liquids	R.F. radiation + magnetic field; e.g. for protons: 60 MHz, 14 kG	R.F. absorption	<1 cm	1 cm	Quant. analysis; local magnetic environment; diffusion; imaging	58
56.	ENDOR Electron Nuclear Double Resonance	Solids, liquids	R.F. + microwave radiation in magn. field.	Microwave absorption	–	–	Hyperfine interaction → local atomic structure	54
57.	NQR Nuclear Quadrupole Resonance	Solids	R.F. radiation 0.5–1000 MHz	R.F. absorption	–	–	Asymmetry of the charge distribution at the nucleus	55,59
Other								
58.	BET Brunauer-Emmett-Teller	(Large) surface area 1–20 m ² /g	Adsorbed gas (e.g., N ₂ at low temp.) as function of pressure (monolayer coverage)	–	–	–	Surface area measurement	60

SYMMETRY OF CRYSTALS

L. I. Berger

The ability of a body to coincide with itself in its different positions regarding a coordinate system is called its symmetry. This property reveals itself in iteration of the parts of the body in space. The iteration may be done by reflection in mirror planes, rotation about certain axes, inversions and translations. These actions are called the symmetry operations. The planes, axes, points, etc., are known as symmetry elements. Essentially, mirror reflection is the only truly primitive symmetry operation. All other operations may be done by a sequence of reflections in certain mirror planes. Hence, the mirror plane is the only true basic symmetry element. But for clarity, it is convenient to use the other symmetry operations, and accordingly, the other aforementioned symmetry elements. The symmetry elements and operations are presented in Table 1.

The entire set of symmetry elements of a body is called its symmetry class. There are thirty-two symmetry classes that describe all crystals that have ever been noted in mineralogy or been synthesized (more than 150,000). The denominations and symbols of the symmetry classes are presented in Table 2.

There are several known approaches to classification of individual crystals in accordance with their symmetry and crystallochemistry. The particles that form a crystal are distributed in certain points in space. These points are separated by certain distances (translations) equal to each other in any chosen direction in the crystal. Crystal lattice is a diagram that describes the location of particles (individual or groups) in a crystal. The lattice parameters

are three non-coplanar translations that form the crystal lattice. Three basic translations form the unit cell of a crystal. August Bravais (1848) has shown that all possible crystal lattice structures belong to one or another of fourteen lattice types (Bravais lattices). The Bravais lattices, both primitive and non-primitive, are the contents of Table 3.

Among the three-dimensional figures, there is a group of polyhedrons that are called regular, which have all faces of the same shape and all edges of the same size (regular polygons). It has been shown that there are only five regular polyhedrons. Because of their importance in crystallography and solid state physics, a brief description of these polyhedrons is included in Table 4.

The systematic description of crystal structures is presented primarily in the well-known *Structurbericht*. The classification of crystals by the *Structurbericht* does not reflect their crystal class, the Bravais lattice, but is based on the crystallochemical type. This makes it inconvenient to use the *Structurbericht* categories for comparison of some individual crystals. Thus, there have been several attempts to provide a more convenient classification of crystals. Table 5 presents a compilation of different classifications which allows the reader to correlate the *Structurbericht* type with the international and Schoenflies point and space groups and with Pearson's symbols, based on the Bravais lattice and chemical composition of the class prototype. The information included in Table 5 has been chosen as an introduction to a more detailed crystallophysical and crystallochemical description of solids.

TABLE 1. Symmetry Operations and Elements
Symmetry element

Symmetry operation	Name	Symbol		Presentation on the stereographic projection	
		International (Hermann-Mauguin)	Schoenflies	Parallel	Perpendicular
Reflection in a plane	Plane	m	C_s		
Rotation by angle $\alpha = 360^\circ/n$ about an axis	Axis	n = 1, 2, 3, 4 or 6	C_n		
		n = 2	C_2		
		n = 3	C_3		
		n = 4	C_4		
		n = 6	C_6		
Rotation about an axis and inversion in a symmetry center lying on the axis	Inversion (improper) axis	$\bar{n} = \bar{3}, \bar{4}, \bar{6}$	C_{ni}		
		$\bar{n} = \bar{3}$	C_{3i}		
		$\bar{n} = \bar{4}$	C_{4i}		

TABLE 1. Symmetry Operations and Elements
Symmetry element

Symmetry operation	Name	Symbol		Presentation on the stereographic projection	
		International (Hermann-Mauguin)	Schoenflies	Parallel	Perpendicular
		$\bar{n} = \bar{6}$	C_{6i}		
Inversion in a point	Center	$\bar{1}$	C_i		
Parallel translation	Translation vector \vec{a} , \vec{b} , \vec{c}				
Reflection in a plane and translation parallel to the plane	Glide-plane	a, b, c, n, d			
Rotation about an axis and translation parallel to the axis	Screw axis	n_m ($m = 1, 2, \dots, n - 1$)			
Rotation about an axis and reflection in a plane perpendicular to the axis	Rotatory-reflection axis	\bar{n} $\bar{n} = \bar{1}, \bar{2}, \bar{3}, \bar{4}, \bar{6}$	S_n		

TABLE 2. The Thirty-Two Symmetry Classes
Class name^a and its symbol – International (Int) and Schoenflies (Sch)

Crystal symbol	Primitive		Central		Planal		Axial		Plane-axial		Inversion primitive		Inversion-planal	
	Int	Sch	Int	Sch	Int	Sch	Int	Sch	Int	Sch	Int	Sch	Int	Sch
Triclinic	1	C_1	1	C_1										
Monoclinic			—		m	C_s	2	C_2	2/m	C_{2h}				
Orthorhombic					mm2	C_{2v}	222	D_2	mmm	D_{2h}

Cubic	23	T	m3	T_h	$\bar{4}3m$	T_d	432	O	m3m	O_h				

^a Per Fedorov Institute of Crystallography, Russian Academy of Sciences, nomenclature.

TABLE 3. The Fourteen Possible Space Lattices (Bravais Lattices)

Crystal system	Metric category of the system	No. of different lattices in the system	Lattice type ^a (marked by +)					No. of identi-points per unit cell	Characteristic parameters (marked by +)						Description of characteristic parameters $a < X, b < Y, c < Z$		Symmetry of the lattice	
			P	C	I	F	R		a	b	c	α	β	γ	$\alpha = (b, c), \beta = (a, c), \gamma = (a, b)$	Int	Sch	
Triclinic	Trimetric	1	+					1	+	+	+	+	+	+	$a \neq b \neq c, \alpha \neq \beta \neq \gamma$	1	C	
Monoclinic	Trimetric	2	+	+				1 or 2	+	+	+	+			$a \neq b \neq c, \alpha = \gamma = 90^\circ \neq \beta$	2/m	C_{2h}	
Orthorhombic	Trimetric	4	+	+	+	+		1, 2 or 4	+	+	+				$a \neq b \neq c, \alpha = \beta = \gamma = 90^\circ$	mmm	D_{2h}	
Trigonal (rhombohedral)	Dimetric	1					+	1	+		+				$a = b = c, 120^\circ > \alpha = \beta = \gamma \neq 90^\circ$	3m	D_{3d}	
Tetragonal	Dimetric	2	+	+				1 or 2	+	+					$a = b \neq c, \alpha = \beta = \gamma = 90^\circ$	4/mmm	D_{4h}	
Hexagonal	Dimetric	1	+					1	+	+					$a = b \neq c, \alpha = \beta = 90^\circ, \gamma = 120^\circ$	6/mmm	D_{6h}	
Isometric (cubic)	Monometric	3	+	+	+			1, 2 or 4	+						$a = b = c, \alpha = \beta = \gamma = 90^\circ$	m3m	O_h	

^a Designations of the space-lattice types: P – primitive, C – side-centered (base-centered), I – body-centered, F – face-centered, R – rhombohedral.

TABLE 4. The Five Possible Regular Polyhedrons

Polyhedron	Symmetry (Schoenflies)			Form of faces	Number of ^a		
	Class	Elements	Faces (F)		Edges (E)	Vertices (V)	
Tetrahedron	T	$4C_3, 3C_2$	Equilateral triangle	4	6	4	

Cube (hexahedron)	O	$3C_4 4C_3 6C_2$	Square	6	12	8
Octahedron	O	$3C_4 4C_3 6C_2$	Equilateral triangle	8	12	6
Pentagonal dodecahedron	J	$6C_5 10C_3 15C_2$	Regular pentagon	12	30	20
Icosahedron	J	$6C_5 10C_3 15C_2$	Equilateral triangle	20	30	12

^a Per formula by Leonhard Euler: $F + V - E = 2$

^a The first letter denotes the crystal system: triclinic (a), monoclinic (m), orthorhombic (o), tetragonal (t), hexagonal (h) and cubic (c). Trigonal (rhombohedral) system is denoted by combination hR. The second letter of Pearson's symbol denotes lattice type: primitive (P), edge-(base-) centered (C), body-centered (I) or face-centered (F). The following number denotes number of atoms in the crystal unit cell.

^b Standard ASTM E157-82a has the Bravais lattices designations as following: C – primitive cubic; B – body-centered cubic; F – face-centered cubic; T – primitive tetragonal; U – body-centered tetragonal; R – rhombohedral; H – hexagonal; O – primitive orthorhombic; P – body-centered orthorhombic; Q – base-centered orthorhombic; S – face-centered orthorhombic; M – primitive monoclinic; N – centered monoclinic; A – triclinic.

IONIC RADII IN CRYSTALS

Ionic radii are a useful tool for predicting and visualizing crystal structures. This table lists a set of ionic radii R_i in Å units for the most common coordination numbers CN of positive and negative ions. The values are based on experimental crystal structure determinations, supplemented by empirical relationships, and theoretical calculations. The notation sq after the coordination number indicates a square configuration, while py indicates pyramidal.

The advice of Howard T. Evans and Marvin J. Weber in preparing this table is appreciated.

POLARIZABILITIES OF ATOMS AND IONS IN SOLIDS

H. P. R. Frederikse

The polarization of a solid dielectric medium, \mathbf{P} , is defined as the dipole moment per unit volume averaged over the volume of a crystal cell. A component of \mathbf{P} can be expanded as a function of the electric field \mathbf{E} :

$$P_i = \sum_j a_j E_j + \sum_{jk} b_{jk} E_j E_k$$

For relatively small electric fields in isotropic substances $\mathbf{P} = \chi_e \mathbf{E}$, where χ_e is the electric susceptibility. If the medium is made up of N atoms (or ions) per unit volume, the polarization is $\mathbf{P} = N \mathbf{p}_m$ where \mathbf{p}_m is the average dipole moment per atom. The polarizability α can be defined as $\mathbf{p}_m = \alpha \mathbf{E}_0$, where \mathbf{E}_0 is the local field at the position of the atom. Using the Lorentz method to calculate the local field one finds:

$$\mathbf{P} = N\alpha(\mathbf{E} + 4\pi\mathbf{P}) = \chi_e \mathbf{E}$$

Together with the definition of the dielectric constant (relative permittivity), $\epsilon = 1 + 4\pi\chi_e$, this leads to:

$$\alpha = \frac{3}{4\pi N} \left(\frac{\epsilon - 1}{\epsilon + 2} \right)$$

This expression is known as the Clausius-Mossotti equation.

The total polarization associated with atoms, ions, or molecules is due to three different sources:

1. Electronic polarization arises because the center of the local electronic charge cloud around the nucleus is displaced under the action of the field: $\mathbf{P}_e = N\alpha_e \mathbf{E}_0$ where α_e is the *electronic polarizability*.

2. Ionic polarization occurs in ionic materials because the electric field displaces cations and anions in opposite directions: $\mathbf{P}_i = N\alpha_i \mathbf{E}_0$, where α_i is the *ionic polarizability*.
3. Orientational polarization can occur in substances composed of molecules that have permanent electric dipoles. The alignment of these dipoles depends on temperature and leads to an *orientational polarizability* per molecule: $\alpha_{or} = p^2/3kT$, where p is the permanent dipole moment per molecule, k is the Boltzmann constant, and T is the temperature.

Because of the different nature of these three polarization processes the response of a dielectric solid to an applied electric field will strongly depend on the frequency of the field. The resonance of the electronic excitation in insulators (dielectrics) takes place in the ultraviolet part of the spectrum; the characteristic frequency of the lattice vibrations is located in the infrared, while the orientation of dipoles requires fields of much lower frequencies (below 10^{10} Hz). This response to electric fields of different frequencies is shown in Figure 1. Values of the electronic polarizabilities for selected atoms and ions are given in Table 1.

To convert to SI, use the relation $\alpha(\text{SI})/\text{C m}^2\text{V}^{-1} = 1.11265 \cdot 10^{-16} \alpha(\text{cgs})/\text{cm}^3$

CRYSTAL STRUCTURES AND LATTICE PARAMETERS OF ALLOTTROPES OF THE ELEMENTS

H. W. King

The crystal structures of the allotropic forms of the elements are presented in terms of the Pearson symbol, the Strukturbericht designation, and the prototype of the structure. The temperatures of the phase transformations are listed in degrees Celsius and the pressures are in GPa. A consistent nomenclature is used, whereby all allotropes are labeled by Greek letters. The lattice parameters of the units cells are given in nanometers (nm) and are considered to be accurate to ± 2 in the last reported digit.

This compilation is restricted to changes in crystal structures that occur as a result of a change in temperature or pressure. Low-

temperature structures are included for the diatomic and rare gases, which show many similarities with respect to the metallic elements. The elements identified with an asterisk (*) have polymorphic structures based on different molecular configurations. The crystal data given for these elements refer to the most stable structure at room temperature.

Reprinted with the permission of ASM International from T.B. Massalski, Ed., *Binary Alloy Phase Diagrams*, ASM International, Metals Park, Ohio, 1986; certain data on rare earth elements were provided by K.A. Gschneidner.

PHASE TRANSITIONS IN THE SOLID ELEMENTS AT ATMOSPHERIC PRESSURE

This table gives the phase transition temperatures for the elements that can exist in two or more crystalline forms (allotropes). The crystal phases are labeled by Greek letters in the most common conventions, although some variation is found. All data refer to normal atmospheric pressure.

LATTICE ENERGIES

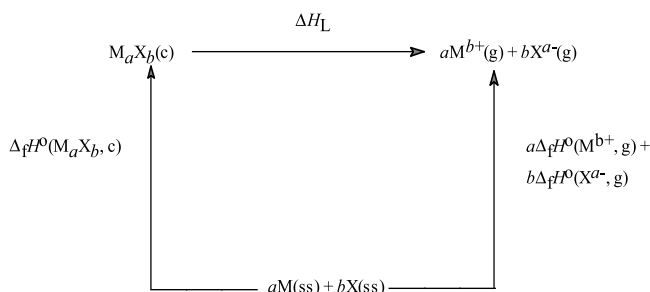

H. D. B. Jenkins and H. K. Roobottom

THERMOCHEMICAL CYCLE AND CALCULATED VALUES

Table 1 contains calculated values of the lattice energies (total lattice potential energies), U_{POT} , of crystalline salts, M_aX_b . U_{POT} is expressed in units of kilojoules per mole, kJ mol^{-1} . M and X can be either simple or complex ions. Substances are arranged by chemical class.

Also listed in the table is the lattice energy, $U_{\text{POT}}^{\text{BFHC}}$, obtained from the application of the Born - Fajans - Haber cycle (BFHC) described below, using the "Standard Thermochemical Properties of Chemical Substances" table in Section 5 of this *Handbook*, References 1 through 4, and certain other data which are given in Table 3 below.

The lattice enthalpy, ΔH_L , is given by the cycle:

where (ss) is the standard state of the element concerned.

The lattice enthalpy, ΔH_L , is obtained using the equation:

$$\Delta H_L = a\Delta_f H^\circ(M^{b+}, g) + b\Delta_f H^\circ(X^{a-}, g) - \Delta_f H^\circ(M_aX_b, c)$$

and is further related to the total lattice potential energy, U_{POT} , by the relationship:

$$\Delta H_L = U_{\text{POT}} + \left[a \left(\frac{n_M}{2} - 2 \right) + b \left(\frac{n_X}{2} - 2 \right) \right] RT$$

where n_M and n_X equal 3 for monatomic ions, 5 for linear polyatomic ions and 6 for polyatomic non-linear ions.

METHOD OF ESTIMATION OF VALUES NOT TABULATED

In cases where the lattice energy is not tabulated and we want to furnish an estimate, then the Kapustinskii equation⁵ can be used to obtain a value (in kJ mol^{-1}):

$$U_{\text{POT}} = \frac{121.4z_a z_b v}{(r_a + r_b)} \left(1 - \frac{0.0345}{(r_a + r_b)} \right)$$

where z_a and z_b are the moduli of the charges on the v ions in the lattice and r_a and r_b (in nm) are the thermochemical radii given in Table 2. The r_a for metal ions is taken to be the Goldschmidt⁶ radius.

To cite an example, if we wish to estimate the lattice energy of the salt $[\text{NH}_4^+][\text{HF}_2^-]$ using the above procedure, we see that Table 2 gives the thermochemical radius (r_a) for NH_4^+ to be 0.136 nm and that for HF_2^- (r_b) to be 0.172 nm. The lattice potential energy is then estimated to be 700 kJ mol^{-1} compared with the calculated value of 705 kJ mol^{-1} and the Born - Fajans - Haber cycle value of 658 kJ mol^{-1} .

THE MADELUNG CONSTANT AND CRYSTAL LATTICE ENERGY

If U is the crystal lattice energy and M is the Madelung constant, then^a

$$U = \frac{NMz_1z_2e^2}{r}(1 - 1/n)$$

Substance	Ion type	Crystal form ^b	M
Sodium chloride, NaCl	M ⁺ , X ⁻	FCC	1.74756
Cesium chloride, CsCl	M ⁺ , X ⁻	BCC	1.76267
Calcium chloride, CaCl ₂	M ⁺⁺ , 2X ⁻	Cubic	2.365
Calcium fluoride (fluorite), CaF ₂	M ⁺⁺ , 2X ⁻	Cubic	2.51939
Cadmium chloride, CdCl ₂	M ⁺⁺ , 2X ⁻	Hexagonal	2.244 ^c
Cadmium iodide (α), CdI ₂	M ⁺⁺ , 2X ⁻	Hexagonal	2.355 ^c
Magnesium fluoride, MgF ₂	M ⁺⁺ , 2X ⁻	Tetragonal	2.381 ^c
Cuprous oxide (cuprite), Cu ₂ O	2M ⁺ , X ⁻⁻	Cubic	2.22124
Zinc oxide, ZnO	M ⁺⁺ , X ⁻⁻	Hexagonal	1.4985 ^c
Sphalerite (zinc blende), ZnS	M ⁺⁺ , X ⁻⁻	FCC	1.63806
Wurtzite, ZnS	M ⁺⁺ , X ⁻⁻	Hexagonal	1.64132 ^c
Titanium dioxide (anatase), TiO ₂	M ⁴⁺ , 2X ⁻⁻	Tetragonal	2.400 ^c
Titanium dioxide (rutile), TiO ₂	M ⁴⁺ , 2X ⁻⁻	Tetragonal	2.408 ^c
β-Quartz, SiO ₂	M ⁴⁺ , 2X ⁻⁻	Hexagonal	2.2197 ^c
Corundum, Al ₂ O ₃	2M ³⁺ , 3X ⁻⁻	Rhombohedral	4.1719

^a N is Avogadro's number, z_1 and z_2 are the integral charges on the ions (in units of e), and e is the charge on the electron in electrostatic units ($e = 4.803 \times 10^{-10}$ esu). r is the shortest distance between cation-anion pairs in centimeters. Then U is in ergs ($1 \text{ erg} = 10^{-7} \text{ J}$).

^b FCC = face centered cubic; BCC = body centered cubic.

^c For tetragonal and hexagonal crystals the value of M depends on the details of the lattice parameters.

The Born Exponent, n is:

Ion type	n
He, Li ⁺	5
Ne, Na ⁺ , F ⁻	7
Ar, K ⁺ , Cu ⁺ , Cl ⁻	9
Kr, Rb ⁺ , Ag ⁺ , Br ⁻	10
Xe, Cs ⁺ , Au ⁺ , I ⁻	12

For a crystal with a mixed-ion type, an average of the values of n in this table is to be used (6 for LiF, for example).

ELASTIC CONSTANTS OF SINGLE CRYSTALS

H. P. R. Frederikse

This table gives selected values of elastic constants for single crystals. The values believed most reliable were selected from the original literature. The substances are arranged by crystal system and, within each system, alphabetically by name. A reference to the original literature is given for each value; a useful compilation of published values from many sources may be found in Reference 1 below.

Data are given for the single-crystal density and for the elastic constants c_{ij} , in units of 10^{11} N/m², which is equivalent to 10^{12} dyn/cm².

ELECTRICAL RESISTIVITY OF PURE METALS

The first part of this table gives the electrical resistivity, in units of $10^{-8} \Omega \text{ m}$, for 28 common metallic elements as a function of temperature. The data refer to polycrystalline samples. The number of significant figures indicates the accuracy of the values. However, at low temperatures (especially below 50 K) the electrical resistivity is extremely sensitive to sample purity. Thus the low-temperature values refer to samples of specified purity and treatment. The references should be consulted for further information on this point, as well as for values at additional temperatures.

The second part of the table gives resistivity values in the neighborhood of room temperature for other metallic elements that have not been studied over an extended temperature range.

ELECTRICAL RESISTIVITY OF SELECTED ALLOYS

These values were obtained by fitting all available measurements to a theoretical formulation describing the temperature and composition dependence of the electrical resistivity of metals. Some of the values listed here fall in regions of temperature and composition where no actual measurements exist. Details of the procedure may be found in the reference.

Values of the resistivity are given in units of $10^{-8} \Omega \text{ m}$. General comments in the preceding table for pure metals also apply here

ELECTRICAL RESISTIVITY OF GRAPHITE MATERIALS

L. I. Berger

At normal conditions, the only stable crystallographic modification of carbon is graphite. The quasi-stable diamond turns into graphite starting from about 1000°C in the air. In industry, a graphitic material is commonly called either *carbon*, if it consists of small and low-oriented crystallites, or *graphite*, the material with highly ordered structure. In the 1970s, the first carbon filaments of about 7 nm in diameter were grown by Morinobu Endo at the University of Orleans, France, by the vapor-growth technique. In 1985, Sir Harold Walter Kroto of Sussex University, UK, and Richard E. Smalley and co-workers at Rice University discovered spherical carbon molecules, C₆₀ (or C60), consisting of combinations of carbon atoms organized into hexagons and pentagons, named *buckminsterfullerenes* or *fullerenes* and possessing very promising mechanical and electrical properties. In 1991, Sumio Iijima, NEC Labs, Japan, and David S. Bethune, IBM Almaden Labs, observed the carbon atomic groups in the form of tubes capped by halves of the fullerene molecules and formed on the cathodes of carbon arc devices. The length of the tubes could be up to tens of micrometers and the diameter, naturally, is equal to that of the fullerene molecule. These tubes, called *nanotubes*, may be single wall (SWNT) or consist of several concentric tubes with a common axis (multi-walled nanotubes, MWNT). Two-dimensional *graphene* is another crystallographic modification of

graphite (Saroj Nayak, Rensselaer U., 2004) that is a flat hexagonal network of carbon atoms with a thickness equal to the carbon atom size. The nanotube may be considered as formed by strips of graphenes turned into a cylinder. The character of the electrical conductivity (metallic or semiconductive) of a SWNT depends on orientation of the carbon hexagons of the nanotube surface regarding its axis (the chiral angle [Ref. 1]). The following table contains some typical data on electrical and electronic properties of graphite materials.

PERMITTIVITY (DIELECTRIC CONSTANT) OF INORGANIC SOLIDS

H. P. R. Frederikse

This table lists the permittivity ϵ , frequently called the dielectric constant, of a number of inorganic solids. When the material is not isotropic, the individual components of the permittivity are given. A superscript S indicates a measurement made under constant strain ("clamped" dielectric constant). If the constraint is removed, the measurement yields ϵ^T , the "unclamped" or free dielectric constant.

The temperature of the measurement is given when available; the symbol r.t. indicates a value at nominal room temperature. The

frequency of the measurement is given in the last column (i.r. indicates a measurement in the infrared).

Substances are listed in alphabetical order by chemical formula.

CDDA	CsD_2AsO_4	212
<i>Rochelle salt group</i>		
Rochelle salt	$\text{NaKC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$	255–297
Deuterated Rochelle salt	$\text{NaKC}_4\text{H}_2\text{D}_2\text{O}_6 \cdot 4\text{H}_2\text{O}$	251–308
Ammonium Rochelle salt	$\text{NaNH}_4\text{C}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$	109
LAT	$\text{LiNH}_4\text{C}_4\text{H}_4\text{O}_6 \cdot \text{H}_2\text{O}$	106
<i>Triglycine sulfate group</i>		
TGS	$(\text{NH}_2\text{CH}_2\text{COOH})_3 \cdot \text{H}_2\text{SO}_4$	322
TGSe	$(\text{NH}_2\text{CH}_2\text{COOH})_3 \cdot \text{H}_2\text{SeO}_4$	295
TGFB	$(\text{NH}_2\text{CH}_2\text{COOH})_3 \cdot \text{H}_2\text{BeF}_4$	346
AFB	$(\text{NH}_4)_2\text{BeF}_4$	176
HADA	$\text{HNH}_4(\text{ClCH}_2\text{COO})_2$	128
<i>Perovskites and related compounds</i>		
Barium titanate	BaTiO_3	406, 278, 193
Lead titanate	PbTiO_3	765
Potassium niobate	KNbO_3	712
Potassium tantalate niobate	$\text{KTa}_{2/3}\text{Nb}_{1/3}\text{O}_3$	241, 220, 170
Lithium niobate	LiNbO_3	1483
Lithium tantalate	LiTaO_3	891
Barium titanium niobate	$\text{Ba}_6\text{Ti}_2\text{Nb}_8\text{O}_{30}$	521
Ba-Na niobate ("Bananas")	$\text{Ba}_2\text{NaNb}_5\text{O}_{15}$	833
Potassium iodate	KIO_3	485, 343, 257–263, 83
Lithium iodate	LiIO_3	529
Potassium nitrate	KNO_3	397
Sodium nitrate	NaNO_3	548
Rubidium nitrate	RbNO_3	437–487
<i>Miscellaneous compounds</i>		
Cesium trihydrogen selenite	$\text{CsH}_3(\text{SeO}_3)_2$	143
Lithium trihydrogen selenite	$\text{LiH}_3(\text{SeO}_3)_2$	$T_C > T_{\text{mp}}$
Potassium selenate	K_2SeO_4	93
Methyl ammonium alum (MASD)	$\text{CH}_3\text{NH}_3\text{Al}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$	177
Ammonium cadmium sulfate	$(\text{NH}_4)_2\text{Cd}_2(\text{SO}_4)_3$	95
Ammonium bisulfate	$(\text{NH}_4)\text{HSO}_4$	271
Ammonium sulfate	$(\text{NH}_4)_2\text{SO}_4$	224
Ammonium nitrate	NH_4NO_3	398, 357, 305, 255
Colemanite	$\text{CaB}_3\text{O}_4(\text{OH})_3 \cdot \text{H}_2\text{O}$	266
Cadmium pyroniobite	$\text{Cd}_2\text{Nb}_2\text{O}_7$	185
Gadolinium molybdate	$\text{Gd}_2(\text{MoO}_4)_3$	432

PROPERTIES OF ANTIFERROELECTRIC CRYSTALS

H. P. R. Frederikse

Some important antiferroelectric crystals are listed here with their Curie Temperatures T_c . The last column gives the constant T_0 which appears in the Curie-Weiss law describing the dielectric constant of these materials above the Curie Temperature:

$$\varepsilon = \text{const.}/(T - T_0)$$

Name or acronym	Formula	T_c /K	T_0 /K
ADP	$\text{NH}_4\text{H}_2\text{PO}_4$	148	
ADA	$\text{NH}_4\text{H}_2\text{AsO}_4$	216	
ADDP	$\text{NH}_4\text{D}_2\text{PO}_4$	242, 245	
ADDA	$\text{NH}_4\text{D}_2\text{AsO}_4$	299

PROPERTIES OF SUPERCONDUCTORS

L. I. Berger and B. W. Roberts

The following tables include superconductive properties of selected elements, compounds, and alloys. Individual tables are given for thin films, elements at high pressures, superconductors with high critical magnetic fields, and high critical temperature superconductors.

The historically first observed and most distinctive property of a superconductive body is the near total loss of resistance at a critical temperature (T_c) that is characteristic of each material. Figure 1(a) below illustrates schematically two types of possible transitions. The sharp vertical discontinuity in resistance is indicated

of that found for a single crystal of a very pure element or one of a few well annealed alloy compositions. The broad transition, illustrated by broken lines, suggests the transition shape seen for materials that are not homogeneous and contain unusual strain distributions. Careful testing of the resistivity limit for superconductors shows that it is less than 4×10^{-23} ohm cm, while the lowest resistivity observed in metals is of the order of 10^{-13} ohm cm. If one compares the resistivity of a superconductive body to that of copper at room temperature, the superconductive body is at least 10^{17} times less resistive.

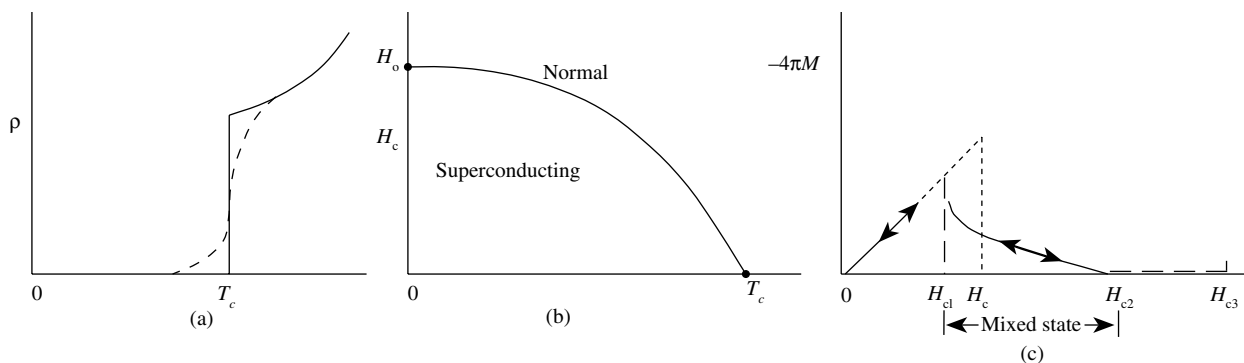

FIGURE 1. Physical properties of superconductors. (a) Resistivity vs. temperature for a pure and perfect lattice (solid line); impure and/or imperfect lattice (broken line). (b) Magnetic-field temperature dependence for Type-I or "soft" superconductors. (c) Schematic magnetization curve for "hard" or Type-II superconductors.

The temperature interval ΔT_c , over which the transition between the normal and superconductive states takes place, may be of the order of as little as 2×10^{-5} K or several K in width, depending on the material state. The narrow transition width was attained in 99.9999% pure gallium single crystals.

A Type-I superconductor below T_c , as exemplified by a pure metal, exhibits perfect diamagnetism and excludes a magnetic field up to some critical field H_c , whereupon it reverts to the normal state as shown in the H - T diagram of Figure 1(b).

The magnetization of a typical high-field superconductor is shown in Figure 1(c). The discovery of the large current-carrying capability of Nb_3Sn and other similar alloys has led to an extensive study of the physical properties of these alloys. In brief, a high-field superconductor, or Type-II superconductor, passes from the perfect diamagnetic state at low magnetic fields to a mixed state and finally to a sheathed state before attaining the normal resistive state of the metal. The magnetic field values separating the four stages are given as H_{c1} , H_{c2} , and H_{c3} . The superconductive state below H_{c1} is perfectly diamagnetic, identical to the state of most pure metals of the "soft" or Type-I superconductor. Between H_{c1} and H_{c2} a "mixed superconductive state" is found in which fluxons (a minimal unit of magnetic flux) create lines of normal flux in a superconductive matrix. The volume of the normal state is proportional to $-4\pi M$ in the "mixed state" region. Thus at H_{c2} the fluxon density has become so great as to drive the interior volume of the superconductive body completely normal. Between H_{c2} and H_{c3} the superconductor has a sheath of current-carrying superconductive material at the body surface, and above H_{c3} the normal state exists. With several types of careful measurement, it is possible to determine H_{c1} , H_{c2} , and H_{c3} . Table 6 contains some of the available data on high-field superconductive materials.

High-field superconductive phenomena are also related to specimen dimension and configuration. For example, the Type-I superconductor, Hg, has entirely different magnetization behavior in high magnetic fields when contained in the very fine sets of filamentary tunnels found in an unprocessed Vycor glass. The great majority of superconductive materials are Type-II. The elements in very pure form and a very few precisely stoichiometric and well annealed compounds are Type I with the possible exceptions of vanadium and niobium.

Metallurgical Aspects. The sensitivity of superconductive properties to the material state is most pronounced and has been used in a reverse sense to study and specify the detailed state of alloys. The mechanical state, the homogeneity, and the presence of impurity atoms and other electron-scattering centers are all capable of controlling the critical temperature and the current-carrying capabilities in high-magnetic fields. Well annealed specimens tend to show sharper transitions than those that are strained or inhomogeneous. This sensitivity to mechanical state underlines a general problem in the tabulation of properties for superconductive materials. The occasional divergent values of the critical temperature and of the critical fields quoted for a Type-II superconductor may lie in the variation in sample preparation. Critical temperatures of materials studied early in the history of superconductivity must be evaluated in light of the probable metallurgical state of the material, as well as the availability of less pure starting elements. It has been noted that recent work has given extended consideration to the metallurgical aspects of sample preparation.

Symbols in tables: T_c : Critical temperature; H_0 : Critical magnetic field in the $T = 0$ limit; θ_D : Debye temperature; and γ : Electronic specific heat.

TABLE 4. Superconductive Compounds and Alloys

All compositions are denoted on an atomic basis, i.e., AB, AB₂, or AB₃ for compounds, unless noted. Solid solutions or odd compositions may be denoted as A_xB_{1-z} or A_zB. A series of three or more alloys is indicated as A_xB_{1-x} or by actual indication of the atomic fraction range, such as A_{0-0.6}B_{1-0.4}. The critical temperature of such a series of alloys is denoted by a range of values or possibly the maximum value.

The selection of the critical temperature from a transition in the effective permeability, or the change in resistance, or possibly the incremental changes in frequency observed by certain techniques is not often obvious from the literature. Most authors choose the

mid-point of such curves as the probable critical temperature of the idealized material, while others will choose the highest temperature at which a deviation from the normal state property is observed. In view of the previous discussion concerning the variability of the superconductive properties as a function of purity and other metallurgical aspects, it is recommended that appropriate literature be checked to determine the most probable critical temperature or critical field of a given alloy.

A very limited amount of data on critical fields, H_c , is available for these compounds and alloys; these values are given at the end of the table.

HIGH TEMPERATURE SUPERCONDUCTORS

C. N. R. Rao and A. K. Raychaudhuri

The following tables give properties of a number of high temperature superconductors. Table 1 lists the crystal structure (space group and lattice constants) and the critical transition temperature T_c for the more important high temperature superconductors so far studied. Table 2 gives energy gap, critical current density, and penetration depth in the superconducting state. Table 3 gives electrical and thermal properties of some of these materials in the normal state. The tables were prepared in November 1992 and updated in November 1994.

ORGANIC SUPERCONDUCTORS

H.P.R. Frederikse

Although the vast majority of organic compounds are insulators, a small number of organic solids show considerable electrical conductivity. Some of these materials appear to be superconductors. The superconducting organics fall primarily into two groups: those containing fulvalenes (pentagonal rings containing sulfur or selenium) and those based on fullerenes, involving the nearly spherical cluster C_{60} .

The transition temperatures T_c of the fulvalene derivatives are shown in Table 1. The abbreviations of the various molecular groups are listed in Table 2 and their chemical structures are depicted in Figure 1. Most of the T_c 's are between 1 and 12 K. Several of the compounds only show superconductivity under pressure.

The fullerenes are A_3C_{60} compounds, where A represents a single or a combination of alkali atoms. The C_{60} cluster is shown in

Figure 2a, while Figure 2b illustrates how the alkali atoms fit into the A_3C_{60} molecule to form the A15 crystallographic structure. Their superconducting transition temperatures range from 8 to 31.3 K (see Table 3).

PROPERTIES OF SEMICONDUCTORS

L. I. Berger

The term *semiconductor* is applied to a material in which electric current is carried by electrons or holes and whose electrical conductivity, when extremely pure, rises exponentially with temperature and may be increased from its low "intrinsic" value by many orders of magnitude by "doping" with electrically active impurities.

Semiconductors are characterized by an energy gap in the allowed energies of electrons in the material that separates the normally filled energy levels of the *valence band* (where "missing" electrons behave like positively charged current carriers "holes") and the *conduction band* (where electrons behave rather like a gas of free negatively charged carriers with an effective mass dependent on the material and the direction of the electrons' motion). This energy gap depends on the nature of the material and varies with direction in anisotropic crystals. It is slightly dependent on

temperature and pressure, and this dependence is usually almost linear at normal temperatures and pressures.

Data are presented in five tables. Table 1 lists the main crystallographic and semiconducting properties of a large number of semiconducting materials in three main categories: "Tetrahedral Semiconductors" in which every atom is tetrahedrally coordinated to four nearest neighbor atoms (or atomic sites) as for example in the diamond structure; "Octahedral Semiconductors" in which every atom is octahedrally coordinated to six nearest neighbor atoms—as for example the halite structure; and "Other Semiconductors."

Table 2 gives electrical, magnetic, and optical properties, while Tables 3 and 4 give more details on the semiconducting properties and band structures of the most common semiconductors. Table 5 lists semiconducting minerals with typical resistivity ranges.

TABLE 1. Physico-Chemical Properties of Semiconductors (Listed by Crystal Structure)

Substance	Molecular weight	Average atomic weight	Lattice parameters (Å, room temp.)	Density (g/cm ³)	Melting point (K)	Microhardness, N/mm ² (M-Mohs Scale)	Specific heat, J/kg-K (300 K)	Debye temp. (K)	Coefficient of thermal linear expansion [10 ⁻⁶ K ⁻¹ (300K)]	Thermal conductivity [mW/cm-K (300K)]
