Asymmetric reduction with very high enantioselectivity has also been achieved with achiral reducing agents and optically active catalysts.<sup>1601</sup> Homogeneous catalytic asymmetric hydrogenation<sup>1602</sup> leads to reduction of substrates with high enantioselectivity.<sup>1603</sup> Several catalytic systems have been developed, including those using a Ru,<sup>1604</sup> Fe,<sup>1605</sup> Cu,<sup>1606</sup> Mn,<sup>1607</sup> or Ir<sup>1608</sup> catalyst. The development of new chiral ligands is an active area of research, for use with metal catalysts.<sup>1609</sup> A chirally modified Pt catalyst has been used,<sup>1610</sup> as have Fe complexes.<sup>1611</sup>  $\beta$ -Keto esters are reduced enantioselectively, for example.<sup>1612</sup> A variety of chiral additives and/or ligands have been used with catalytic hydrogenation reactions, and many functional groups can be tolerated.<sup>1613</sup> Asymmetric catalytic hydrogenation has been done in ionic liquids.<sup>1614</sup>

The use of chiral metal complexes leads to chiral hydrogen transfer.<sup>1615</sup> Asymmetric transfer hydrogenation has been reported using an Fe complex to reduce ketones to the

corresponding alcohol.<sup>1616</sup> Ru,<sup>1617</sup> Mn,<sup>1618</sup> Ir,<sup>1619</sup> and Wilkinson-type catalysts,<sup>1620</sup> and Fe complexes<sup>1621</sup> have also been used. A Ru/PNNP catalyst has been used for the 1,2-reduction of conjugated ketones.<sup>1622</sup> New chiral ligands have been developed.<sup>1623</sup> Sugar-based ligands have been developed for asymmetric transfer hydrogenation.<sup>1624</sup> Aldehydes have been reduced to the alcohol by reaction with a *Hantzsch ester*, catalyzed by an organoborane in the presence of tri(3,5-trifluoromethyl)phenylborane.<sup>1625</sup> Organocatalysts have been developed for the asymmetric transfer hydrogenation of conjugated aldehydes.<sup>1626</sup> The enantioselective reduction of  $\beta$ -keto esters via pH-independent transfer hydrogenation in water has been reported.<sup>1627</sup>

Another approach is reduction with  $\text{BH}_3/\text{THF}$  or catecholborane,<sup>1628</sup> using oxazaborolidines<sup>1629</sup> or other chiral compounds<sup>1630</sup> as a catalyst. The Co-catalyzed hydroboration of aryl ketones with pinacolborane has been reported.<sup>1631</sup> Chiral sulfonamides have been used as additives,<sup>1632</sup> and other chiral additives can be used.<sup>1633</sup> Spiroborate esters were used.<sup>1634</sup>

Lithium aluminum hydride in combination with a chiral diol<sup>1635</sup> or other chiral ligands<sup>1636</sup> leads to enantioselective reduction, often in the presence of a transition metal complex.<sup>1637</sup> Chiral additives have also been used with  $\text{NaBH}_4$ .<sup>1638</sup> Examples include

LiBH<sub>4</sub>/NiCl<sub>2</sub> and a chiral amino alcohol,<sup>1639</sup> NaBH<sub>4</sub> with chiral Lewis acid complexes,<sup>1640</sup> or NaBH<sub>4</sub>/Me<sub>3</sub>SiCl and a chiral ligand.<sup>1641</sup> A mixture of NaBH<sub>4</sub> and Me<sub>3</sub>SiCl with a catalytic amount of a chiral, polymer-bound sulfonamide leads to asymmetric reduction.<sup>1642</sup> Potassium borohydride catalyzed by a Sc complex gave 1,2-reduction of enones with good enantioselectivity.<sup>1643</sup> Reduction with sodium borohydride in a chiral ionic liquid has been used for reductions in water.<sup>1644</sup>

Enantioselective reduction is possible with the other methods mentioned above. Transition metal-catalyzed asymmetric transfer hydrogenation is effective for the preparation of chiral alcohols.<sup>1645</sup> Reduction with silanes and transition metal catalysts, such as Ru<sup>1646</sup> or Fe,<sup>1647</sup> is also very effective. Chiral Ru catalysts have been used with triethylammonium formate for the enantioselective reduction.<sup>1648</sup> The transition metal-catalyzed hydrosilylation of ketones gives chiral alcohols in the presence of suitable chiral ligands.<sup>1649</sup> Enantioselective reduction was observed with PhSiH<sub>3</sub> and Cu compounds with a chiral ligand,<sup>1650</sup> with a mixture of Ru and Ag catalysts,<sup>1651</sup> or with Mn(dpm)<sub>3</sub> and oxygen (dpm = diphenylmethylene).<sup>1652</sup> Enantioselective hydrosilylation is possible using chiral organocatalysts.<sup>1653</sup> A chiral Sm complex has been used in conjunction with propan-2-ol.<sup>1654</sup> Chiral mercapto alcohols have also been used for asymmetric reduction.<sup>1655</sup> An asymmetric *Piers hydrosilylation* has been reported.<sup>1656</sup> The hydrosilylation reduction of ketones was catalyzed by a *N*-heterocyclic carbene/Ir complex,<sup>1657</sup> and a Co-catalyzed asymmetric hydrosilylation has been reported.<sup>1658</sup> Asymmetric reduction of ketones has also been achieved with an achiral reducing agent, if the ketone is complexed to an optically active transition metal Lewis acid.<sup>1659</sup>

Enantioselective reduction is not usually possible for aldehydes,<sup>1660</sup> since the products are primary alcohols in which the reduced carbon is not chiral, but deuterated aldehydes RCDO give a chiral product, and these have been reduced enantioselectively with *B*-(3-pinanyl)-9-borabicyclo[3.3.1]nonane (*Alpine-Borane*) with almost complete optical purity.<sup>1661</sup> Other chiral boranes can be used to reduce aldehydes or ketones.<sup>1662</sup>

There are other stereochemical aspects to the reduction of aldehydes and ketones. If there is a stereogenic center  $\alpha$  to the carbonyl group,<sup>1663</sup> even an achiral reducing agent can give more of one diastereomer than of the other (a diastereoselective reduction). Such reductions have been carried out with considerable success.<sup>1664</sup> In most such cases *Cram's rule* (Sec. 4.H, category 1) is followed, but exceptions are known.<sup>1665</sup>

### 19-41 Reduction of Carboxylic Acids to Alcohols

Carboxylic acids are easily reduced to primary alcohols by  $\text{LiAlH}_4$ .<sup>1666</sup> The conditions are particularly mild, the reduction proceeding quite well at room temperature. Other hydrides have also been used,<sup>1667</sup> but not  $\text{NaBH}_4$  (see Table 19.2).<sup>1668</sup> A combination of  $\text{NaBH}_4$  and an arylboronic acid (**12-27**) is also effective.<sup>1669</sup> A mixture of  $\text{NaBH}_4$ ,  $\text{Me}_2\text{SO}_4$ , and  $\text{B}(\text{OMe})_3$  is effective for the reduction of hydroxyl-substituted aromatic carboxylic acids.<sup>1670</sup> Benzyltriethylammonium borohydride in dichloromethane reduces carboxylic acids to the alcohol.<sup>1671</sup> Catalytic hydrogenation is generally ineffective,<sup>1672</sup> although a Ru-catalyzed hydrogenation has been reported.<sup>1673</sup> A mixture of  $\text{NaBH}_4$  and  $\text{I}_2$  has been used to reduce amino acids to amino alcohols.<sup>1674</sup>

Carboxylic acids were reduced to the corresponding alcohol by reaction with  $\text{SmI}_2/\text{H}_2\text{O}/\text{NEt}_3$ .<sup>1675</sup> The reaction of carboxylic acids with 1-propanephosphonic acid cyclic anhydride (T3P) and DIPEA, in the presence of  $\text{NaBH}_4$ , gave the corresponding primary alcohol.<sup>1676</sup> Carboxylic acids were reduced to primary alcohols using 1,1,3,3-tetramethyldisiloxane (TMDS) and a Cu catalyst.<sup>1677</sup> The reaction of carboxylic acids with phenylsilane and  $(\text{COD})\text{Fe}(\text{CO})_3$  as catalyst under UV irradiation gave the primary alcohol, whereas reaction with TMDS and  $(t\text{-PBO})\text{Fe}(\text{CO})_3$  as catalyst under thermal activation gave the aldehyde.<sup>1678</sup>

Carboxylic acids were mixed with the hyperthermophile *Pyrococcus furiosus*, which catalyzed the hydrogenation and gave the corresponding primary alcohol without reduction of a variety of functional groups that may be present.<sup>1679</sup>

Borane ( $\text{BH}_3$ ) is particularly useful because carboxyl groups and esters are selectively reduced in the presence of many other groups, although the reaction with double bonds takes place at about the same rate in ether solvents.<sup>1680</sup> For many years, borane was the reagent of choice for this reduction. Borane also reduces carboxylic acid salts.<sup>1681</sup> Aluminum hydride reduces COOH groups without affecting carbon-halogen bonds in the same molecule. The reduction has also been carried out with  $\text{SmI}_2$  in basic media<sup>1682</sup> or aqueous  $\text{H}_3\text{PO}_4$ ,<sup>1683</sup> or simply with  $\text{SmI}_2$  in water.<sup>1684</sup>

## 19-42 Reduction of Carboxylic Acid Derivatives

Lithium aluminum hydride reduces carboxylic esters to give 2 molar equivalents of alcohol, as shown.<sup>1685</sup> The reaction is of wide scope and has been used to reduce many esters. Where the interest is in obtaining  $\text{R}'\text{OH}$ , this is a method that is often a working equivalent of “hydrolyzing” esters. Reduction of lactones yields diols.<sup>1686</sup> Among the reagents used for this reduction<sup>1687</sup> are DIBALH, lithium triethylborohydride,  $\text{LiAlH}(\text{O}t\text{-Bu})_3$ ,<sup>1688</sup> and  $\text{BH}_3/\text{SMe}_2$  in refluxing THF.<sup>1689</sup> Although  $\text{NaBH}_4$  reduces other esters but it is usually so

slow that it is not the reagent of choice, but there are many exceptions.<sup>1690</sup> However, it is generally possible to reduce an aldehyde or ketone without reducing an ester function in the same molecule. Note that NaBH<sub>4</sub> reduces esters in the presence of certain compounds (see Table 19.2).<sup>1691</sup> Note that NaBH<sub>4</sub> in DMF/MeOH reduces aryl carboxylic esters to benzylic alcohols,<sup>1692</sup> and NaBH<sub>4</sub>/LiCl with microwave irradiation also reduces esters to primary alcohols.<sup>1693</sup>

Carboxylic esters can also be reduced to alcohols by hydrogenation over copper chromite catalysts,<sup>1694</sup> although high pressures and temperatures are required. Ester functions generally survive low-pressure catalytic hydrogenations, but homogeneous catalytic hydrogenation procedures have been developed.<sup>1695</sup> Before the discovery of LiAlH<sub>4</sub>, the most common way of carrying out the reaction was with sodium in ethanol, a method known as the *Bouveault-Blanc procedure*.<sup>1696</sup> This procedure is still sometimes used where selectivity is necessary (see also, reactions **19-67**, **19-69**, and **19-62**). The ester moiety of  $\beta$ -keto esters has been selectively reduced using LiHMDS and LiAlH<sub>4</sub>.<sup>1697</sup> The reduction of carboxylic acids to the corresponding alcohol proceeded via the *in situ* formation of hydroxy benzotriazole esters followed by reaction with sodium borohydride.<sup>1698</sup> Esters were reduced to alcohols via reaction with SmI<sub>2</sub>/H<sub>2</sub>O.<sup>1699</sup> Esters have been reduced to the alcohol by Fe,<sup>1700</sup> Mn,<sup>1701</sup> Ru,<sup>1702</sup> Ni/Re,<sup>1703</sup> or cobalt-catalyzed<sup>1704</sup> catalytic hydrogenation. Lactones were reduced to the diol via catalytic hydrogenation using a Ru catalyst, and lactams

### 19-43 Reduction of Acyl Halides

Acyl halides can be reduced to aldehydes<sup>1719</sup> by treatment with lithium tri-*tert*-butoxyaluminum hydride in diglyme at –78 °C.<sup>1720</sup> The R group may be alkyl or aryl and may contain many types of substituents, including NO<sub>2</sub>, CN, and EtOOC groups. The reaction stops at the aldehyde stage because steric hindrance prevents further reduction with this reagent. Acyl halides can also be reduced to aldehydes by hydrogenolysis with Pd-on-barium sulfate as catalyst in what is called the *Rosenmund reduction*.<sup>1721</sup> A convenient hydrogenolysis procedure involves Pd-on-charcoal as the catalyst, with

#### 19-44 Reduction of Carboxylic Acids, Esters, and Anhydrides to Aldehydes<sup>1734</sup>

With most reducing agents, reduction of carboxylic acids generally gives the primary alcohol (**19-41**) and the isolation of aldehydes is not feasible. However, simple straight-chain carboxylic acids have been reduced to aldehydes<sup>1735</sup> by treatment with Li in  $\text{MeNH}_2$  or  $\text{NH}_3$  followed by hydrolysis of the resulting imine,<sup>1736</sup> with hexylchloroborane/ $\text{SMe}_2$  or hexylbromoborane/ $\text{SMe}_2$ <sup>1737</sup> (see **15-11** for the hexyl group),  $\text{Me}_2\text{N}=\text{CHCl}^+ \text{Cl}^-$  in pyridine,<sup>1738</sup> and with diaminoaluminum hydrides.<sup>1739</sup> Benzoic acid derivatives were reduced to benzaldehyde derivatives with  $\text{NaH}_2\text{PO}_2$ , a diacylperoxide, and a Pd catalyst.<sup>1740</sup> Caproic

and isovaleric acids have been reduced to aldehydes in 50% yields or better with DibalH at  $-75$  to  $-70$  °C.<sup>1741</sup> The chemoselective reduction of carbonyl groups in the presence of aldehydes has been reported.<sup>1742</sup>

Carboxylic acids reacted with trialkylsilanes with  $B(C_6F_5)_3$  as catalyst to give the disilyl acetal, and a subsequent acidic workup gave the aldehyde.<sup>1743</sup> An Fe catalyst has also been used, with  $R_2SiH_2$  and UV irradiation,<sup>1744</sup> and a Mn-catalyzed hydrosilation is known.<sup>1745</sup> Carboxylic acids were reduced to aldehydes by a Ru-catalyzed reaction with 1,2-bis(dimethylsilyl)benzene followed by hydrolysis of the resulting cyclic disilyl-acetal.<sup>1746</sup>

The Ir-catalyzed hydrosilation of esters with  $EtMe_2SiH$  and 1,3,5-trimethoxybenzene gave the aldehyde.<sup>1747</sup> *N*-Protected  $\alpha$ -amino acids were reduced to the chiral  $\alpha$ -amino aldehydes using 1,1'-carbonyldiimidazole/DibalH.<sup>1748</sup> Carboxylic acids were reduced to the aldehyde by a reaction with  $(TMS)_3SiH$  and an Ir catalyst under photoredox conditions.<sup>1749</sup>

Carboxylic esters have been reduced to aldehydes with DibalH at  $-70$  °C with diaminoaluminum hydrides,<sup>1750</sup> and with  $LiAlH(O-t-Bu)_3$  at 0 °C for phenolic esters.<sup>1751</sup> Esters have been reduced to the aldehyde using flow conditions (Sec. 7.D).<sup>1752</sup> Esters were reduced to aldehydes via an Ir-catalyzed hydrosilation reaction.<sup>1753</sup> Pretreatment of the acid with  $Me_3SiCl$  followed by reduction with DibalH also gives the aldehyde.<sup>1754</sup> Aldehydes have also been prepared by reducing ethyl thiol esters (RCOSET) with  $Et_3SiH$  and a Pd/C catalyst.<sup>1755</sup> Thioesters have been reduced to the aldehyde with lithium metal in THF at  $-78$  °C, followed by quenching with methanol.<sup>1756</sup>

Anhydrides, both aliphatic and aromatic, as well as mixed anhydrides of carboxylic and carbonic acids, have been reduced to aldehydes in moderate yields with disodium tetracarbonylferrate,  $Na_2Fe(CO)_4$ .<sup>1757</sup> Heating a carboxylic acid, presumably to form the anhydride, and then reaction with Na/EtOH leads to the aldehyde.<sup>1758</sup>

## 19-45 Reduction of Amides to Aldehydes

*N,N*-Disubstituted amides can be reduced to amines with  $\text{LiAlH}_4$  (see **19-68**), but reduction to an aldehyde is possible.<sup>1759</sup> Keeping the amide in excess gives the aldehyde rather than the amine. Sometimes it is not possible to prevent further reduction and primary alcohols are obtained instead. Other reagents<sup>1760</sup> that give good yields of aldehydes are  $\text{DibalH}$ ,<sup>1761</sup>  $\text{LiAlH}(\text{O}-t\text{-Bu})_3$ , diaminoaluminum hydrides,<sup>1762</sup> and disiamylborane (see **15-11** for the disiamyl group).<sup>1763</sup>

Aldehydes have been prepared from carboxylic acids or acyl halides by first converting them to certain types of amides that are easily reducible. There are several examples:<sup>1764</sup>

1. *Reissert compounds*.<sup>1765</sup> Compounds such as **27** are prepared from the acyl halide by treatment with quinoline and cyanide ion. Treatment of **27** with sulfuric acid gives the corresponding aldehyde.

2. *Acyl sulfonylhydrazides*. Compounds such as **28** are cleaved with base to give aldehydes. This reaction is known as the *McFadyen-Stevens reduction* and is applicable *only* to aromatic aldehydes or aliphatic aldehydes with no  $\alpha$  hydrogen.<sup>1766</sup> Diimide  $\text{RCON}=\text{NH}$  (see **19-71**) has been proposed as an intermediate in this reaction.<sup>1767</sup>
3. *Acyl imidazoles*. Compounds **29**<sup>1768</sup> can be reduced to aldehydes with  $\text{LiAlH}_4$ .
4. *Weinreb amides*. An *N*-methoxy-*N*-methyl amide such as **30** is referred to as a Weinreb amide.<sup>1769</sup> Reduction with an excess of  $\text{LiAlH}_4$  or  $\text{DibalH}$  leads to the corresponding aldehyde.<sup>1770</sup> Magnesium borohydride has been used for the reduction of

### C. Attack at Non-Carbonyl Multiple Bonded Heteroatoms

#### 19-46 Reduction of the Carbon-Nitrogen Double Bond (C=N)

Imines and *Schiff bases* (R ≠ H),<sup>1775</sup> hydrazones,<sup>1776</sup> and other C=N compounds can be reduced with LiAlH<sub>4</sub>, NaBH<sub>4</sub>,<sup>1777</sup> Na/EtOH, hydrogen and a catalyst, as well as with other reducing agents.<sup>1778</sup> Metal-free catalytic hydrogenation is known.<sup>1779</sup> Transfer hydrogenation of imines leads to amines.<sup>1780</sup> A mixture of Sm/I<sub>2</sub><sup>1781</sup> or In/NH<sub>4</sub>Cl<sup>1782</sup> also reduces imines. Iminium salts are reduced by LiAlH<sub>4</sub> to the corresponding amine, although the hydrogen on the nitrogen arises from hydrolysis.<sup>1783</sup> Silanes<sup>1784</sup> with a triarylborane catalyst reduced *N*-sulfonyl imines,<sup>1785</sup> as did TiI<sub>4</sub>.<sup>1786</sup> Imines are reduced with SmBr<sub>2</sub> in HMPA,<sup>1787</sup> with propan-2-ol and a Ru catalyst,<sup>1788</sup> and with triethylammonium formate and

Oximes are generally reduced to amines (**19-52**),<sup>1834</sup> but simple reduction to give hydroxylamines can be accomplished with borane<sup>1835</sup> or sodium cyanoborohydride.<sup>1836</sup> Oximes are reduced with hydrogen gas and a catalytic amount of 48% HBr.<sup>1837</sup> Hydrogenation of oximes with Pd/C and a Ni complex gives the imine, and in the presence of a lipase and ethyl acetate the final product was an acetamide, formed with high enantioselectivity.<sup>1838</sup> Oxime *O*-ethers are reduced with Bu<sub>3</sub>SnH and BF<sub>3</sub>•OEt<sub>2</sub>.<sup>1839</sup> Oxime ethers are reduced with borane and a chiral spiroborate ester catalyst.<sup>1840</sup> The Rh-catalyzed enantioselective hydrogenation of oxime acetals has been reported.<sup>1841</sup> The Ni-catalyzed asymmetric transfer hydrogenation of hydrazones and ketimines used formic acid/triethanolamine in ethanol.<sup>1842</sup>

Isocyanates have been catalytically hydrogenated to *N*-substituted formamides: RNCO → R–NH–CHO.<sup>1843</sup> Isothiocyanates were reduced to thioformamides with SmI<sub>2</sub> in HMPA/*t*-BuOH.<sup>1844</sup>

Lithium dimethylaminoborohydride ( $\text{LiBH}_3\text{NMe}_2$ ) reduces aryl nitriles to the corresponding benzylamines.<sup>1853</sup>

The reduction of nitriles is of wide scope and has been applied to many nitriles. Catalytic hydrogenation converts nitriles to primary amines,<sup>1854</sup> but secondary amines,  $(\text{RCH}_2)_2\text{NH}$ , are often side products.<sup>1855</sup> These can be avoided by adding a compound, such as acetic anhydride, which removes the primary amine as soon as it is formed,<sup>1856</sup> or by the use of excess ammonia to drive the equilibria backward.<sup>1857</sup> Sponge Ni,<sup>1858</sup> Ni on silica gel,<sup>1859</sup> or Rh<sup>1860</sup> have been used for the catalytic hydrogenation of aryl nitriles to amines. Attempts to convert a nitrile to an imine by stopping the reaction with only 1 equivalent of hydrogen have failed, except where the imine is subsequently hydrolyzed (**19-48**).

Photoirradiation with visible light stimulates reaction with  $\text{SmI}_2$  and methanol to reduce nitriles to amines.<sup>1861</sup> The use of  $\text{PhSiH}_3$  and a Re catalyst has been used for the reduction of nitriles to amines.<sup>1862</sup> The reduction of nitriles using  $\text{B}(\text{C}_6\text{F}_5)_3$  as a catalyst with hydrosilanes as a reductant gave primary amines, but bulky hydrosilanes gave the imine.<sup>1863</sup> Symmetrical secondary amines were prepared by the reductive amination of nitriles using  $\text{H}_2$  and Pt nanowires as catalyst, and unsymmetrical secondary amines were prepared by identical reaction conditions with a primary amine.<sup>1864</sup> Tertiary alkyl amines were prepared from their corresponding alkyl nitriles using a heterogeneous Pd catalyst and ammonium formate in aprotic solvents.<sup>1865</sup> The Co-catalyzed transfer hydrogenation of nitriles has been reported.<sup>1866</sup>

*N*-Alkylnitrilium ions ( $\text{R}-\text{C}\equiv\text{N}^+-\text{R}'$ ) are reduced to secondary amines by  $\text{NaBH}_4$ .<sup>1867</sup> Since nitrilium salts can be prepared by treatment of nitriles with trialkyloxonium salts (see **16-7**), this is a method for the conversion of nitriles to secondary amines. Note that the related compounds, the isonitriles ( $\text{R}-\text{N}\equiv\text{CO}^-$ , also called isocyanides) have been reduced to *N*-methylamines with  $\text{LiAlH}_4$ , as well as with other reducing agents.

<sup>1867</sup> Borch, R.F. *Chem. Commun.* **1968**, 442.

There are two principal methods for the reduction of nitriles to aldehydes.<sup>1868</sup> In one of these, known as the *Stephen reduction*, the nitrile is treated with HCl to form an iminium salt,  $R(Cl)C=N^+H_2 Cl^-$ . Subsequent reduction of the chloroiminium salt with anhydrous  $SnCl_2$  gives  $RCH=NH$ , which precipitates as a complex with  $SnCl_4$  and is then hydrolyzed (**16-2**) to the aldehyde. The Stephen reduction is most successful when R is aromatic, but it can be done for aliphatic R up to about six carbons.<sup>1869</sup> It is also possible to prepare the iminium salt in a different way, by treating  $ArCONHPh$  with  $PCl_5$ , which can then be converted to the aldehyde. This is known as the *Sonn-Müller method*. Aqueous formic acid in the presence of  $PtO_2$ , followed by treatment with aqueous acid, converts aryl nitriles to aryl aldehydes.<sup>1870</sup> The DibalH reduction of nitriles to an aldehyde was reported using flow conditions (Sec. 7.D).<sup>1871</sup> Nitriles were reduced to aldehydes using 1,1,3,3-tetramethyldisiloxane/triisopropoxyvanadium oxide.<sup>1872</sup>

The other way of reducing nitriles to aldehydes involves using a metal hydride reducing agent to add 1 molar equivalent of hydrogen, with subsequent hydrolysis, *in situ*, of the resulting imine (which is undoubtedly coordinated to the metal). This has been carried out with  $LiAlH_4$ ,  $LiAlH(OEt)_3$ ,<sup>1873</sup>  $LiAlH(NR_2)_3$ ,<sup>1874</sup> and DibalH.<sup>1875</sup> The metal hydride method is useful for aliphatic and aromatic nitriles.

OS III, 626, 818; VI, 631.

### 19-49 Reduction of Nitro Compounds to Amines

Both aliphatic<sup>1876</sup> and aromatic nitro compounds can be reduced to amines, although the reaction has been applied much more often to aromatic nitro compounds, owing to their greater availability. Many reducing agents have been used to reduce aromatic nitro compounds, including Zn, Sn, Pt,<sup>1877</sup>  $Ru/SiO_2$ ,<sup>1878</sup> Fe,<sup>1879</sup> or Fe (or sometimes other metals)

and acid, and catalytic hydrogenation.<sup>1880</sup> Chemoselective catalytic hydrogenation of nitro compounds is possible.<sup>1881</sup> Indium metal in aqueous ethanol with ammonium chloride<sup>1882</sup> or with water in aqueous THF<sup>1883</sup> also reduces aromatic nitro compounds to the corresponding aniline derivative. Indium metal in methanol, with acetic anhydride and acetic acid, converts aromatic nitro compounds to the acetanilide.<sup>1884</sup> Both Sm metal in methanol with ultrasound,<sup>1885</sup> and a mixture of SmI<sub>2</sub>/water and an amine reduce nitro compounds.<sup>1886</sup> Alternative reduction methods use ultrasound with Al(Hg) in aqueous THF<sup>1887</sup> or with stannous chloride in an ionic liquid.<sup>1888</sup> The reaction with sulfides or polysulfides is called the *Zinin reduction*.<sup>1889</sup> Amines are also the products when nitro compounds, both alkyl and aryl, are reduced with HCOONH<sub>4</sub>/Pd/C.<sup>1890</sup> With optically active alkyl substrates this method gives retention of configuration.<sup>1891</sup>

The mechanisms of these reductions have not been much studied, although it is usually presumed that, at least with some reducing agents, nitroso compounds and hydroxylamines are intermediates. Both of these types of compounds give amines when exposed to most of these reducing agents (**19-51**), and hydroxylamines can be isolated (**19-50**). With metals and acid the following path has been suggested:<sup>1892</sup>

Lithium aluminum hydride reduces aliphatic nitro compounds to amines, but with aromatic nitro compounds the products with this reagent are azo compounds (**19-84**). The LiAlH<sub>4</sub>/TiCl<sub>4</sub> reduction of aromatic nitro compound to the corresponding aniline was reported.<sup>1893</sup> Most metal hydrides, including NaBH<sub>4</sub> and BH<sub>3</sub>, do not reduce nitro groups at all, although both aliphatic and aromatic nitro compounds have been reduced to amines

with  $\text{NaBH}_4$  and various catalysts, such as  $\text{NiCl}_2$  or  $\text{CoCl}_2$ <sup>1894</sup> and  $\text{ZrCl}_4$ .<sup>1895</sup> Borohydride exchange resin (BER) in the presence of  $\text{Ni}(\text{OAc})_2$ , however, gives the amine.<sup>1896</sup> Transition metal sulfides and  $\text{NaBH}_4$  were used to reduce nitrobenzene derivatives.<sup>1897</sup> Treatment of aromatic nitro compounds with  $\text{NaBH}_4$  alone has resulted in reduction of the ring to a cyclohexane ring with the nitro group still intact<sup>1898</sup> or in cleavage of the nitro group from the ring.<sup>1899</sup> With  $(\text{NH}_4)_2\text{S}$  or other sulfides or polysulfides it is often possible to reduce just one of two or three nitro groups on an aromatic ring or on two different rings in one molecule.<sup>1900</sup> Baker's yeast reduces aromatic nitro compounds to aniline derivatives.<sup>1901</sup> A combination of  $\text{NaH}_2\text{PO}_2/\text{FeSO}_4$  with microwave irradiation reduces aromatic nitro compounds to aniline derivatives.<sup>1902</sup> Hydrazine on alumina, with  $\text{FeCl}_3$  and microwave irradiation, accomplishes this reduction.<sup>1903</sup> Hydrazine/formic acid with Raney nickel in methanol reduces aromatic nitro compounds.<sup>1904</sup> Nitrobenzene was reduced to aniline using  $\text{SnCl}_2$  and  $\text{HCl}$ .<sup>1905</sup>

With some reducing agents, especially with aromatic nitro compounds, the reduction can be stopped at an intermediate stage, and hydroxylamines (**19-50**), hydrazobenzenes, azobenzenes (**19-84**), and azoxybenzenes (**19-83**) can be obtained in this manner. However, nitroso compounds, which are often postulated as intermediates, are too reactive to be isolated, if indeed they are intermediates. Reduction by metals in mineral acids cannot be stopped, but always produces the amine.

The  $\text{Cl}_3\text{SiH}$ -mediated reduction of nitro compounds to the amine has been reported.<sup>1906</sup> Nitro groups were reduced to the corresponding amine in the designer surfactant TPGS-750-M in water, using Zn dust and ammonium chloride.<sup>1907</sup> Aromatic nitro compounds were reduced to the aromatic amine with  $\text{B}_2\text{pin}_2$  in propan-2-ol.<sup>1908</sup> Nitro groups have been reduced using carbonyl iron powder using aqueous micellar catalysis.<sup>1909</sup>

Transfer hydrogenation is used to reduce nitro compounds.<sup>1910</sup> The transfer hydrogenation of nitroarenes to amines used a Rh catalyst and microwave irradiation.<sup>1911</sup> Transfer hydrogenation has been used with flow conditions (Sec. 7.D).<sup>1912</sup> The Ru-catalyzed

When aromatic nitro compounds are reduced with zinc and water under neutral conditions,<sup>1929</sup> hydroxylamines are formed. Among other reagents used for this purpose have been SmI<sub>2</sub>,<sup>1930</sup> N<sub>2</sub>H<sub>4</sub>/Rh/C,<sup>1931</sup> and KBH<sub>4</sub>/BiCl<sub>3</sub>.<sup>1932</sup> Borane in THF reduces aliphatic nitro enolate anions to hydroxylamines.<sup>1933</sup> Nitro compounds have been reduced electrochemically to hydroxylamines, as well as to other products.<sup>1934</sup>

OS I, 445; III, 668; IV, 148; VI, 803; VIII, 16.

### 19-51 Reduction of Nitroso Compounds and Hydroxylamines to Amines

Nitroso compounds and hydroxylamines can be reduced to amines by the same reagents that reduce nitro compounds (19-49). Reaction with CuCl, and then phenylboronic acid (12-27), also reduces nitroso compounds to the amine.<sup>1935</sup> A hydroxylamine can be reduced to the amine with CS<sub>2</sub> in acetonitrile.<sup>1936</sup> Indium metal in EtOH/aqueous NH<sub>4</sub>Cl reduces hydroxylamines to the amine.<sup>1937</sup> *N*-Nitroso compounds are similarly reduced to hydrazines, R<sub>2</sub>N–NO → R<sub>2</sub>N–NH<sub>2</sub>.<sup>1938</sup> Deoxygenation of amine *N*-oxides to give a tertiary amine by reaction with phenylboronic acid has been reported.<sup>1939</sup>

OS I, 511; II, 33, 202, 211, 418; III, 91; IV, 247. See also, OS VIII, 93.

### 19-52 Reduction of Oximes to Primary Amines or Aziridines

Both aldoximes and ketoximes can be reduced to primary amines with LiAlH<sub>4</sub>. The reaction is slower than the similar reduction of ketones, so that, for example, PhCOCH=NOH gave 34% PhCHOHCH=NOH.<sup>1940</sup> Among other reducing agents that give this reduction<sup>1941</sup> are Zn/acetic acid, BH<sub>3</sub>,<sup>1942</sup> NaBH<sub>3</sub>CN/TiCl<sub>3</sub>,<sup>1943</sup> polymethylhydrosiloxane (PMHS) with

Pd/C,<sup>1944</sup> and sodium and an alcohol.<sup>1945</sup> Catalytic hydrogenation is also effective.<sup>1946</sup> Reduction of oximes with In metal in acetic anhydride/acetic acid/THF leads to the acetamide.<sup>1947</sup>

The reduction has been performed enantioselectively with baker's yeast<sup>1948</sup> and with Ph<sub>2</sub>SiH<sub>2</sub> and an optically active Rh-complex catalyst.<sup>1949</sup> Oxime *O*-ethers are reduced to the amine with modest enantioselectivity using a chiral boron compound.<sup>1950</sup>

When the reducing agent is DibalH, the product is a secondary amine, arising from a rearrangement: RR'C=N-OH → RNH-CH<sub>2</sub>R'.<sup>1951</sup> With certain oximes (e.g., those of the type ArCH<sub>2</sub>CR=NOH), treatment with LiAlH<sub>4</sub> gives aziridines.<sup>1952</sup> Hydrazones, arylhydrazones, and semicarbazones can also be reduced to amines with various reducing agents, including Zn/HCl and H<sub>2</sub> and Raney nickel.

Oximes have been reduced in a different way, to give imines (RR'C=NOH → RR'C=NH), which are generally unstable but which can be trapped to give useful products. Among reagents used for this purpose have been Bu<sub>3</sub>P/SPh<sub>2</sub><sup>1953</sup> and Ru<sub>3</sub>(CO)<sub>12</sub>.<sup>1954</sup> Oximes can also be reduced to hydroxylamines (19-42). Nitrones have been reduced to imines using AlCl<sub>3</sub>•6H<sub>2</sub>O/KI followed by Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>/H<sub>2</sub>O.<sup>1955</sup>

OS II, 318; III, 513; V, 32, 83, 373, 376.

### 19-53 Reduction of Aliphatic Nitro Compounds to Oximes or Nitriles

Nitro compounds that contain an α hydrogen can be reduced to oximes with Zn dust in acetic acid<sup>1956</sup> or with other reagents, among them CS<sub>2</sub>/NEt<sub>3</sub>,<sup>1957</sup> CrCl<sub>2</sub>,<sup>1958</sup> and (for α-nitro sulfones) NaNO<sub>2</sub>.<sup>1959</sup> α-Nitro alkenes have been converted to oximes (-C=C-NO<sub>2</sub> → -CH-C=NOH) with sodium hypophosphite, with In in aqueous NH<sub>4</sub>Cl/MeOH,<sup>1960</sup> and with Pb/HOAc/DMF, as well as with certain other reagents.<sup>1961</sup> Primary aliphatic nitro

amines by reaction with NaI in the presence of acidic ion-exchange resin at 40 °C and 200 mbar pressure.<sup>1982</sup>

Reaction with PPh<sub>3</sub> leads to a phosphazide, Ph<sub>3</sub>P=N=N-R, which loses nitrogen in what is called the *Staudinger reaction*.<sup>1983</sup> this is a method to prepare phosphazo compounds, but in this case leads to reduction. Diazirines have been prepared by a traceless Staudinger reaction.<sup>1984</sup> The reaction is diastereoselective.<sup>1985</sup> This reaction, combined with RX → RN<sub>3</sub> (**10-42**), is an important way of converting alkyl halides RX to primary amines RNH<sub>2</sub>; in some cases the two procedures have been combined into one laboratory step.<sup>1986</sup> Alkylation is possible, and the reaction of an alkyl azide with PMe<sub>3</sub>, and then an excess of iodomethane leads to the *N*-methylated amine.<sup>1987</sup> Sulfonyl azides (RSO<sub>2</sub>N<sub>3</sub>) have been reduced to sulfonamides (RSO<sub>2</sub>NH<sub>2</sub>) by irradiation in isopropyl alcohol<sup>1988</sup> and with NaH.<sup>1989</sup>

OS V, 586; VII, 433.

### 19-55 Reduction of Miscellaneous Nitrogen Compounds

Isocyanates and isothiocyanates are reduced to methylamines on treatment with LiAlH<sub>4</sub>. Azo compounds are not usually reduced by LiAlH<sub>4</sub><sup>1990</sup> (indeed these are the products from LiAlH<sub>4</sub> reduction of nitro compounds, **19-84**), but they can be reduced to hydrazo compounds by catalytic hydrogenation or with diimide<sup>1991</sup> (see **19-34**). Diazonium salts are reduced to hydrazines by sodium sulfite. This reaction probably has a nucleophilic mechanism.<sup>1992</sup> The initial product is a salt of hydrazinesulfonic acid, which is converted to the hydrazine by acid treatment. Diazonium salts can also be reduced to arenes (**19-73**). *N*-Nitrosoamines can be denitrosated to secondary amines by a number of reducing agents,

including  $H_2$  and a catalyst,<sup>1993</sup>  $BF_3/THF/NaHCO_3$ ,<sup>1994</sup> and  $NaBH_4/TiCl_4$ ,<sup>1995</sup> as well as by hydrolysis.<sup>1996</sup>

A cyano group can be reduced to a methyl group ( $RCN \rightarrow RCH_3$ ) by treatment with a terpene, such as limonene [which acts as reducing agent, giving 4-methyl-(1-methyl-1-ethene)benzene] in the presence of Pd charcoal.<sup>1997</sup> Hydrogen gas ( $H_2$ ) is also effective,<sup>1998</sup> although higher temperatures are required. The R group may be alkyl or aryl. Aryl nitro compounds are reduced to diaryl hydrazines with Al/KOH in methanol.<sup>1999</sup>

The reductive ring opening of aziridine-2-carboxylates by reaction with  $SmI_2$  gave  $\beta$ -amino esters.<sup>2000</sup> Secondary and tertiary phosphine oxides were reduced to the corresponding phosphine by the Cu-catalyzed reaction with silanes.<sup>2001</sup> Phosphine oxides were also reduced using a Mg/TMSCl/1,3-dimethyl-2-imidazolidinone system.<sup>2002</sup>

OS I, 442; III, 475. Also see, OS V, 43.

## D. Reactions in Which a Heteroatom Is Removed From the Substrate

### 19-56 Reduction of Silanes to Methylene Compounds

In certain cases, the C—Si bond of silanes can be converted to C—H.  $\alpha$ -Silyl esters are reduced to esters with mercuric acetate and tetrabutylammonium fluoride, for example.<sup>2003</sup>

### 19-57 Reduction of Alkyl Halides

This type of reduction can be accomplished with many reducing agents.<sup>2004</sup> A powerful but highly useful reagent is  $LiAlH_4$ ,<sup>2005</sup> which reduces almost all types of alkyl halide, including vinylic, bridgehead, and cyclopropyl halides.<sup>2006</sup> Reduction with  $LiAlD_4$  serves to introduce deuterium into organic compounds. An even more powerful reducing agent, lithium triethylborohydride ( $LiEt_3BH$ ; Super hydride), rapidly reduces primary, secondary, allylic, benzylic, and neopentyl halides, but not tertiary (these give elimination) or aryl

halides.<sup>2007</sup> A complex formed from lithium trimethoxyaluminum hydride  $\text{LiAlH}(\text{OMe})_3$  and  $\text{CuI}$  is also a powerful reagent that reduces primary, secondary, tertiary, allylic, vinylic, aryl, and neopentyl halides.<sup>2008</sup> Sodium borohydride ( $\text{NaBH}_4$ ) is a milder reducing agent that reduces primary, secondary, and some tertiary<sup>2009</sup> halides in good yield, in a dipolar aprotic solvent such as  $\text{Me}_2\text{SO}$ , DMF, or sulfolane,<sup>2010</sup> at room temperature or above, without affecting other functional groups that would be reduced by  $\text{LiAlH}_4$ , for example,  $\text{CO}_2\text{H}$ ,  $\text{CO}_2\text{R}$ ,  $\text{CN}$ .<sup>2011</sup> A mixture of  $\text{NaBH}_4$  and  $\text{InCl}_3$  efficiently reduces secondary bromides.<sup>2012</sup> Borohydride exchange resin (BER) is also an effective reducing agent in the presence of metal catalysts such as  $\text{Ni}(\text{OAc})_2$ .<sup>2013</sup> Heating *gem*-difluoromethylene derivatives with  $\text{LiAlH}_4$  and  $\text{ZnCl}_2$  as a catalyst led to dehydrodefluorination.<sup>2014</sup> The Pd-catalyzed reaction of vinyl bromides with  $\text{NaBH}_4/\text{TMEDA}$  gave the alkene.<sup>2015</sup>

Other reducing agents<sup>2016</sup> include Zn (with acid or base),  $\text{SnCl}_2$ , and  $\text{Et}_3\text{SiH}$  in the presence of an  $\text{AlCl}_3$ ,<sup>2017</sup> an Ir,<sup>2018</sup> or an In<sup>2019</sup> catalyst. Diethyl phosphonate/ $\text{Et}_3\text{N}$ ,<sup>2020</sup> phosphorus tris(dimethylamide) ( $\text{Me}_2\text{N})_3\text{P}$ ,<sup>2021</sup> and organotin hydrides  $\text{R}_n\text{SnH}_{4-n}$ <sup>2022</sup> (chiefly  $\text{Bu}_3\text{SnH}$ )<sup>2023</sup> are usually used in conjunction with a radical initiator such as AIBN<sup>2024</sup> or with transition metal salts such as  $\text{InCl}_3$ .<sup>2025</sup> A water-soluble organotin hydride,  $(\text{MeOCH}_2\text{CH}_2\text{OCH}_2\text{CH}_2\text{CH}_2)_3\text{SnH}$ , has been developed that reduces alkyl halides.<sup>2026</sup> Aluminum amalgam efficiently reduced an iodohydrin to the alcohol.<sup>2027</sup> The mono-dechlorination of trichloromethyl groups to give the *gem*-dichloromethyl group used Pt/C in DMA under a hydrogen atmosphere, but the mono-dechlorination of alkyl- and aryl-trichloromethyl groups also required the use of  $\text{Bu}_3\text{SnH}$ .<sup>2028</sup>

Reduction, especially of bromides and iodides, can also be effected by catalytic hydrogenation.<sup>2029</sup> Raney nickel by itself can reduce alkyl halides.<sup>2030</sup> Homogeneous, chiral transition metal complexes can be used for the asymmetric hydrogenation of halides.<sup>2031</sup>

Alkali metals such as Li<sup>2032</sup> or Na<sup>2033</sup> in *t*-BuOH or THF are good reducing agents for the removal of all halogen atoms in a polyhalo compound (including vinylic, allylic, geminal, and even bridgehead halogens). Zinc and ammonium chloride in alcohol facilitates dehalogenation with microwave irradiation.<sup>2034</sup> Nickel boride facilitates debromination.<sup>2035</sup> Propargylic halides can often be reduced with allylic rearrangement to give allenes.<sup>2036</sup> Reductive defluorination of C–F bonds in alkyl fluorides was accomplished using Sm(hexamethyldisilazane)<sub>2</sub>.<sup>2037</sup> Bromonitroalkanes were reduced to the corresponding dehalogenated compounds using In metal and a Pd catalyst.<sup>2038</sup> Using a visible light-excited iridium catalyst induces reductive scission of the carbon–halogen bond of an organohalide to give the corresponding alkyl, alkenyl, and aryl radical that can undergo cyclization and hydrodehalogenation reactions.<sup>2039</sup> Alkyl iodides were heated with triethylborane, 4-*tert*-butylcatechol, air, and di-*tert*-butyl hyponitrite to give the deiodination reaction.<sup>2040</sup>

The choice of a reducing agent usually depends on what other functional groups are present, since each reducing agent reduces certain groups and not others. This type of selectivity is called *chemoselectivity*. A chemoselective reagent is one that reacts with one functional group (e.g., halide), but not another (e.g., C=O). For example, there are several reagents that reduce only the halogen of  $\alpha$ -halo ketones, leaving the carbonyl group intact.<sup>2041</sup> Among them are decaborane with 10% Pd/C,<sup>2042</sup> Bi in aqueous THF,<sup>2043</sup> or In metal in water.<sup>2044</sup> Ionic liquids promote the selective debromination of  $\alpha$ -bromo ketones.<sup>2045</sup> Debromination is also induced by In metal in a carboxylic acid.<sup>2046</sup> Finally, the halogen in  $\alpha$ -haloimines has been reduced with SnCl<sub>2</sub>/MeOH without reducing the C=N bond.<sup>2047</sup>

Tertiary alkyl, benzylic, and allylic halides are reduced by NaBH<sub>3</sub>CN/SnCl<sub>2</sub>,<sup>2048</sup> but these reagents do not react with primary or secondary alkyl or aryl halides. Sodium

cyanoborohydride,  $\text{NaBH}_3\text{CN}$ , in HMPA is another highly selective reagent, in this case for primary and secondary iodo and bromo groups.<sup>2049</sup> Most of the reducing agents mentioned reduce chlorides, bromides, and iodides, but organotin hydrides also reduce fluorides.<sup>2050</sup>

Alkyl halides, including fluorides and polyhalides, can be dehalogenated by initial reaction with Mg to give the Grignard reagent, followed by treatment with an acidic solvent such as ethanol or propan-2-ol.<sup>2051</sup> Vinyl halides can be reduced to the corresponding alkene in some cases.<sup>2052</sup> When vinyl dibromides such as  $\text{RCH}=\text{CBr}_2$  are treated with  $(\text{MeO})_2\text{P}(=\text{O})\text{H}$  and triethylamine, for example, the product is the vinyl bromide  $\text{RCH}=\text{CHBr}$ .<sup>2053</sup> Indium metal in ethanol accomplishes the same transformation.<sup>2054</sup> Similar reduction occurs when vinyl diiodides are treated with Zn/Cu in acetic acid.<sup>2055</sup>

Rearrangements have been found in the reduction of bicyclic tosylates with  $\text{LiAlH}_4$ , indicating that an  $\text{S}_{\text{N}}1$ -like mechanism can take place.<sup>2056</sup> There is evidence that  $\text{LiAlH}_4$  and other metal hydrides can also reduce halides by an SET mechanism,<sup>2057</sup> especially those, such as vinylic,<sup>2058</sup> cyclopropyl,<sup>2059</sup> or bridgehead halides, that are resistant to nucleophilic substitution. Reduction of halides by  $\text{NaBH}_4$  in 80% aqueous diglyme<sup>2060</sup> and by  $\text{BH}_3$  in nitromethane<sup>2061</sup> takes place by an  $\text{S}_{\text{N}}1$  mechanism. It is known that  $\text{NaBH}_4$  in sulfolane reduces tertiary halides possessing a  $\beta$  hydrogen by an elimination-addition mechanism.<sup>2062</sup> The mechanism for reduction of alkyl halides is not always nucleophilic substitution. For example, reductions with organotin hydrides generally<sup>2063</sup> take place by free-radical mechanisms,<sup>2064</sup> as do those with  $\text{Fe}(\text{CO})_5$ .

<sup>2064</sup> Tanner, D.D.; Singh, H.K. *J. Org. Chem.* **1986**, *51*, 5182.

reaction is most successful when a reducing agent, say  $\text{Br}^-$  or  $\text{I}^-$ , is present to combine with the  $\text{I}^+$  or  $\text{Br}^+$  coming off.<sup>2065</sup> Except for deiodination, the reaction is seldom used for preparative purposes. Migration of halogen is also found,<sup>2066</sup> both intramolecular<sup>2067</sup> and intermolecular.<sup>2068</sup> The mechanism is probably the reverse of that of **11-10**.<sup>2069</sup> Debromination of aromatic rings having two attached amino groups was accomplished by refluxing in aniline containing acetic acid/HBr.<sup>2070</sup>

Removal of halogen from aromatic rings or heteroaromatic rings<sup>2071</sup> can also be accomplished by various reducing agents, among them  $\text{Bu}_3\text{SnH}$ ,<sup>2072</sup> catalytic hydrogenolysis,<sup>2073</sup> catalytic transfer hydrogenolysis,<sup>2074</sup>  $\text{Na/Hg}$  in liquid  $\text{NH}_3$ ,<sup>2075</sup>  $\text{LiAlH}_4$ ,<sup>2076</sup>  $\text{NaBH}_4$  and a catalyst,<sup>2077</sup>  $\text{Pd/C}$ ,<sup>2078</sup> and Raney nickel in alkaline solution.<sup>2079</sup> The last method is effective for fluorine as well as for the other halogens. Aryl iodides are reduced with 4-DMAP methiodide salt.<sup>2080</sup> Not all these reagents operate by electrophilic substitution mechanisms. Some are nucleophilic substitutions and some are free-radical processes. Photochemical<sup>2081</sup> and electrochemical<sup>2082</sup> reduction are also known. Halogen can also be removed from aromatic rings indirectly by conversion to *Grignard reagents* (**12-37**) followed by hydrolysis (**11-38**).

Aryl fluorides were defluorinated by electrolysis in 0.2 M  $\text{Bu}_4\text{NBF}_4$  and in the presence of  $\text{NaBH}_4$ .<sup>2083</sup> Aryl bromides were dibrominated using a large excess of  $\text{KOH}$  and a  $\text{Co}$  catalyst.<sup>2084</sup> The dehalogenation of aryl halides is possible under metal-free conditions, at 70–110 °C, in the presence of a catalytic amount of 1,10-phenanthroline and  $\text{KOT-Bu}$ .<sup>2085</sup> The  $\text{Pd}$ -catalyzed, silane-mediated hydrodehalogenation reaction of aryl halides

### 19-59 Reduction of Alcohols:<sup>2090</sup> Hydrogenolysis

The hydroxyl groups of most alcohols can seldom be cleaved by catalytic hydrogenation; remember that alcohols are often used as solvents for hydrogenation of other compounds. However, benzyl-type alcohols undergo the reaction readily and have often been reduced.<sup>2091</sup> Diaryl and triarylcarbinols are similarly easy to reduce with  $\text{LiAlH}_4/\text{AlCl}_3$ ,<sup>2092</sup> with  $\text{NaBH}_4$  in  $\text{F}_3\text{CCOOH}$ ,<sup>2093</sup> and with iodine, water, and red phosphorus (OS I, 224). Other reagents have been used,<sup>2094</sup> including  $\text{Me}_3\text{SiCl}/\text{NaI}$ ,<sup>2095</sup>  $\text{Et}_3\text{SiH}/\text{BF}_3$ ,<sup>2096</sup>  $\text{SmI}_2/\text{THF}/\text{HMPA}$ ,<sup>2097</sup> and  $\text{Sn}/\text{HCl}$ . The reduction of secondary alcohols was accomplished using  $\text{Ph}_2\text{SiClH}$  and  $\text{InCl}_3$ .<sup>2098</sup> 1,3-Diols are especially susceptible to hydrogenolysis. Tertiary alcohols can be reduced by catalytic hydrogenolysis when the catalyst is Raney nickel.<sup>2099</sup> Allylic alcohols (and ethers and acetates) can be reduced (often with accompanying allylic rearrangement) with Zn amalgam and HCl, as well as with certain other reagents.<sup>2100</sup> Reagents that reduce the OH group of  $\alpha$ -hydroxy ketones without affecting the C=O group include red phosphorus/iodine<sup>2101</sup> and  $\text{Me}_3\text{SiI}$ .<sup>2102</sup> Tertiary and secondary

benzylic alcohols were reduced to alkanes by reaction with  $\text{Et}_3\text{SiH}$  and a tin complex catalyst.<sup>2103</sup>

Alcohols can also be reduced indirectly by conversion to a sulfonate and reduction of that compound (**19-63**). The two reactions can be carried out without isolation of the sulfonate if the alcohol is treated with pyridine/ $\text{SO}_3$  in THF, followed by  $\text{LiAlH}_4$ .<sup>2104</sup> Another indirect reduction that can be done in one step involves treatment of the alcohol (primary, secondary, or benzylic) with NaI, Zn, and  $\text{Me}_3\text{SiCl}$ .<sup>2105</sup> In this case, the alcohol is first converted to the iodide, which is then reduced.

The mechanisms of most alcohol reductions are obscure.<sup>2106</sup> Hydrogenolysis of benzylic alcohols can give inversion or retention of configuration, depending on the catalyst.<sup>2107</sup> The mechanism of electroreduction of allylic alcohols in acidic aqueous media has been examined.<sup>2108</sup>

OS I, 224; IV, 25, 218, 482; V, 339; VI, 769.

### 19-60 Reduction of Phenolic and Other Hydroxyaryl Compounds

Oxygenated compounds, such as phenols, phenolic esters, and ethers, can be reduced to the corresponding hydrocarbon.<sup>2109</sup> Phenols can be reduced by distillation over zinc dust or with HI and red phosphorus, but these methods are quite poor and are seldom feasible. Catalytic hydrogenation has also been used, but the corresponding cyclohexanol (see **19-36**) is a side product.<sup>2110</sup> Much better results have been obtained by conversion of phenols to certain esters or ethers and reduction of the latter. For example the reduction of  $\text{ArOSO}_2\text{CF}_3$  with formic acid and a Pd catalyst gave  $\text{ArH}$ <sup>2111</sup> and  $\text{ArOTs}$  was reduced with  $\text{NaBH}_4/\text{NiCl}_2$  to give  $\text{ArH}$ .<sup>2112</sup>

With a Pd/C catalyst, phenol derivatives are deoxygenated using Mg and MeO in the presence of ammonium acetate.<sup>2113</sup> Palladium on carbon also mediated hydrodeoxygenation of phenol derivatives in the presence of diethylamine.<sup>2114</sup>

## 19-61 Replacement of OR or NR by Hydrogen: Hydrogenolysis

Simple ethers are not normally cleaved by reducing agents, although such cleavage has sometimes been reported.<sup>2115</sup> For example, THF treated with  $\text{LiAlH}_4/\text{AlCl}_3$ <sup>2116</sup> or with a mixture of  $\text{LiAlH}(\text{O}-t\text{-Bu})_3$  and  $\text{Et}_3\text{B}$ <sup>2117</sup> gave butan-1-ol; the latter reagent also cleaves methyl alkyl ethers.<sup>2118</sup> Certain types of ethers can be cleaved quite well by reducing agents.<sup>2119</sup> Among these are allyl aryl,<sup>2120</sup> vinyl aryl,<sup>2121</sup> benzylic ethers,<sup>2091,2122</sup> and anisole.<sup>2123</sup> 7-Oxobicyclo[2.2.1]heptanes can be reductively cleaved with DibalH and Ni catalysts.

The reaction of allyl aryl ethers with  $\text{NaBH}_4$  and a Ru catalyst in aqueous *N*-methylformamide gave the phenol derivative as the major product.<sup>2124</sup> A Ni-catalyzed  $\text{NaBH}_4$  hydrogenolysis for deallylation and debenylation has been reported.<sup>2125</sup> The *p*-methoxybenzyl unit has been used as a protecting group for alcohols, and reaction with a Ag catalyst with 1,3,5-trimethoxybenzene facilitated deprotection via hydrogenolysis.<sup>2126</sup> The deprotection of benzyl-type ethers to give the alcohol used catalytic amounts of DDQ and *tert*-butyl nitrite under atmospheric pressure of  $\text{O}_2$ .<sup>2127</sup> Oxalyl chloride cleaved the PMB group from alkyl and aryl PMB ethers to give corresponding alcohols.<sup>2128</sup> cleavage of the *p*-methoxybenzyl protecting group of alcohols with *tert*-butyl bromide in acetonitrile at reflux gave the alcohol.<sup>2129</sup> The Rh-catalyzed reductive cleavage of the  $\text{C}^{\text{aryl}}-\text{C}$  bond of 1,1-biaryl methanols with  $\text{H}_2$  gave a benzylic alcohol and the arene.<sup>2130</sup> The Ir-catalyzed reaction of aryl alkyl ethers gave the phenol derivative and an alkene when heated.<sup>2131</sup> The reaction of aryl ethers and aryl pivalates with  $(\text{MeO})_2\text{MeSiH}$  and a Ni catalyst gave C—O

<sup>2131</sup> Ren, Y.; Yan, M.; Wang, J.; Zhang, Z.C.; Yao, K. *Angew. Chem. Int. Ed.* **2013**, 52, 12674.

cleavage to form the arene.<sup>2132</sup> Unsaturated cyclic ethers were reduced with catalytic amounts of  $B(C_6F_5)_3$  in the presence of an alkylsilane with ring cleavage to give the alkene alcohol.<sup>2133</sup> Reductive cleavage of the aryl C–O bonds of aryl alkyl ethers using  $LiAlH_4/KOtBu$  gave the arene and an alcohol.<sup>2134</sup> The  $NaBH_4$ -promoted electrochemical cleavage of aryl C–O bonds in diaryl ethers gave phenols and arenes.<sup>2135</sup>

Acetals and ketals are resistant to  $LiAlH_4$  and similar hydrides, and carbonyl groups are often converted to acetals or ketals for protection (**16-5**). However, a combination of  $LiAlH_4$  and  $AlCl_3$ <sup>2136</sup> does reduce acetals and ketals, removing one group to give the mono ether.<sup>2137</sup> The actual reducing agents in this case are primarily chloroaluminum hydride ( $AlH_2Cl$ ) and dichloroaluminum hydride ( $AlHCl_2$ ), which are formed from the two reagents.<sup>2138</sup> This conversion can also be accomplished with  $DibalH$ ,<sup>2139</sup> as well as with other reagents.<sup>2140</sup> Ortho esters are easily reduced to acetals by  $LiAlH_4$  alone, offering a route to aldehydes, as these are easily prepared by hydrolysis of the acetals (**10-6**). Mixed ketals [ $R(OMe)OR'$ ] can be demethoxylated (to give  $RHOR'$ ) with  $Bn_3SnCl/NaCHBH_3$  in the presence of AIBN.<sup>2141</sup>

OS **III**, 693; **IV**, 798; **V**, 303. Also see, OS **III**, 742; **VII**, 386.

In a few cases it is possible to remove an oxygen substituent directly from the aromatic ring. Treatment of an aryl mesylate ( $ArOMs$ ) with a nickel catalyst in DMF, for example, leads to the deoxygenated product,  $Ar-H$ .<sup>2142</sup>

Primary alcohols were deoxygenated to the corresponding hydrocarbon first by reaction with  $(PhO)_2P(O)Cl$  and then with  $LiBHET_3$  reduction of the first formed diphenyl phosphate esters.<sup>2143</sup> Alcohols have been first converted to alkyl triflates or alkyl iodides, after which the Cu-catalyzed reduction with tetramethyldisiloxane and  $CsF$  gave the deoxygenated hydrocarbon.<sup>2144</sup> The gold-catalyzed photochemical bromination of alcohols was combined with reductive dehalogenation via photoredox catalysis for a one-pot reductive deoxygenation protocol for primary alcohols.<sup>2145</sup>

The alkyl group R of certain carboxylic esters can be reduced to RH<sup>2146</sup> by treatment with lithium in ethylamine.<sup>2147</sup> The reaction is successful when R is a tertiary or a sterically hindered secondary alkyl group. A free-radical mechanism is likely.<sup>2148</sup> Similar reduction, also by a free-radical mechanism, has been reported with sodium in HMPA/*t*-BuOH.<sup>2149</sup> In the latter case, tertiary R groups give high yields of RH, but primary and secondary R are converted to a mixture of RH and ROH. Both of these methods provide an indirect method of accomplishing **19-59** for tertiary R.<sup>2150</sup> The same thing can be done for primary and secondary R by treating alkyl chloroformates, ROCOCl, with tri-*n*-propylsilane in the presence of *tert*-butylperoxide<sup>2151</sup> and by treating thiono ethers ROC(=S)W (where W can be OAr or other groups) with Ph<sub>2</sub>SiH<sub>2</sub><sup>2152</sup> or Ph<sub>3</sub>SiH<sup>2153</sup> and a free-radical initiator. Allylic acetates can be reduced with NaBH<sub>4</sub> and a Pd complex,<sup>2154</sup> and with SmI<sub>2</sub>/Pd(0).<sup>2155</sup>

OS VII, 139.

### 19-63 Reduction of Tosylates and Similar Compounds: Hydrogenolysis

Tosylates and other sulfonates can be reduced<sup>2156</sup> with LiAlH<sub>4</sub>,<sup>2157</sup> with NaBH<sub>4</sub> in a dipolar aprotic solvent,<sup>2158</sup> with LiEt<sub>3</sub>BH, with *i*-Bu<sub>2</sub>AlH (Dibal-H),<sup>2159</sup> or with Bu<sub>3</sub>SnH/NaI.<sup>2160</sup> The Ni-catalyzed reduction of aryl tosylates proceeds in the presence of borane hydrides.<sup>2161</sup> The scope of the reaction seems to be similar to that of **19-57**. When the reagent is LiAlH<sub>4</sub>, alkyl tosylates are reduced more rapidly than iodides or bromides if the solvent is Et<sub>2</sub>O, but the order is reversed in diglyme.<sup>2162</sup> The reactivity difference is great enough that a tosylate function can be reduced in the presence of a halide and vice versa.

## 19-64 Hydrogenolysis of Esters (Barton-McCombie Reaction)

Alcohols can readily be converted to carbonate and thiocarbonate derivatives. Under radical conditions,<sup>2163</sup> using *azobis*-isobutyronitrile (AIBN, Sec. 14.A.i) and  $\text{Bu}_3\text{SnH}$ , the carbonate or thiocarbonate unit is reduced and replaced with hydrogen. The overall process is reduction of the ROH unit to RH and is called the *Barton-McCombie reaction*.<sup>2164</sup> Both  $\text{PhSiH}_3/\text{AIBN}$ <sup>2165</sup> and  $\text{PhSiH}_2/\text{BET}_3\cdot\text{O}_2$  can be used.<sup>2166</sup> This reaction can be catalytic in  $\text{Bu}_3\text{SnH}$ .<sup>2167</sup> Variations include reduction of ROCSNHPH derivatives using  $\text{Ph}_3\text{SiH}/\text{BET}_3$ .<sup>2168</sup> Another variation used water as the hydrogen atom source when  $\text{BMe}_3$  was used.<sup>2169</sup> Tetrabutylammonium peroxydisulfate and formate ion have been used.<sup>2170</sup>

## 19-65 Reduction of Hydroperoxides and Peroxides

Hydroperoxides can be reduced to alcohols with  $\text{LiAlH}_4$  or  $\text{Ph}_3\text{P}$ <sup>2171</sup> or by catalytic hydrogenation. The hydroperoxide functional group is very susceptible to catalytic hydrogenation, as shown by the fact that a double bond may be present in the same molecule without being reduced.<sup>2172</sup> The reaction is an important step in a method for the oxidative decyanation of nitriles containing an  $\alpha$  hydrogen.<sup>2173</sup> The nitrile is first converted to the  $\alpha$ -hydroperoxy nitrile by treatment with base at  $-78^\circ\text{C}$  followed by  $\text{O}_2$ . The hydroperoxy nitrile is then reduced to the cyanohydrin, which is cleaved (the reverse of **16-51**) to the corresponding ketone. The method is not successful for the preparation of aldehydes ( $\text{R}' = \text{H}$ ). Peroxides are cleaved to 2 molar equivalents of alcohols by  $\text{LiAlH}_4$ , by  $\text{Mg}/\text{MeOH}$ ,<sup>2174</sup> or by catalytic hydrogenation. Peroxides can be reduced to ethers with  $\text{P}(\text{OEt})_3$ .<sup>2175</sup>

### 19-66 Reduction of Carbonyl to Methylene in Aldehydes and Ketones: Hydrogenolysis

There are various ways of reducing the C=O group of aldehydes and ketones to CH<sub>2</sub>.<sup>2176</sup> Two old but still popular methods are the *Clemmensen reduction*<sup>2177</sup> and the *Wolff-Kishner reduction*. The Clemmensen reduction consists of heating the aldehyde or ketone with zinc amalgam, Zn/(Hg), and aqueous HCl.<sup>2178</sup> Ketones are reduced more often than aldehydes. In the Wolff-Kishner reduction,<sup>2179</sup> the aldehyde or ketone is heated with hydrazine hydrate and a base (usually NaOH or KOH). The *Huang-Minlon modification*<sup>2180</sup> of the Wolff-Kishner reduction, in which the reaction is carried out in refluxing diethylene glycol, has completely replaced the original procedure. A microwave-assisted Huang-Minlon procedure has been reported.<sup>2181</sup> The reaction can be carried out under more moderate conditions (room temperature) in DMSO with potassium *tert*-butoxide as base.<sup>2182</sup> A new modification of the reduction treats a ketone with hydrazine in toluene with microwave irradiation, and subsequent reaction with KOH with microwave irradiation completes the Wolff-Kishner reduction.<sup>2183</sup> The Wolff-Kishner reduction can also be applied to the semicarbazones of aldehydes or ketones.

The Clemmensen reduction is usually easier to perform, but it fails for acid-sensitive and high molecular weight substrates. For these cases, the Wolff-Kishner reduction is quite useful. For high molecular weight substrates, a modified Clemmensen reduction, using activated zinc and gaseous HCl in an organic solvent, such as ether or acetic anhydride, has proved successful.<sup>2184</sup> The Clemmensen and Wolff-Kishner reductions are complementary, since the former uses acidic conditions and the latter basic conditions.

Both methods are fairly specific for aldehydes and ketones and can be carried out with many other functional groups present. However, certain types of aldehydes and ketones do not give normal reduction products. Under Clemmensen conditions,<sup>2185</sup>  $\alpha$ -hydroxy ketones give either ketones (hydrogenolysis of the OH, **19-59**) or alkenes, and 1,3-diones usually undergo rearrangement (e.g., MeCOCH<sub>2</sub>COMe  $\rightarrow$  MeCOCHMe<sub>2</sub>).<sup>2186</sup> Neither method is suitable for  $\alpha,\beta$ -unsaturated ketones, which give pyrazolines<sup>2187</sup> under Wolff-Kishner conditions. Under Clemmensen conditions, both groups of  $\alpha,\beta$ -unsaturated ketones may be

<sup>2187</sup> Pyrazolines can be converted to cyclopropanes; see **17-32**.

reduced or if only one group is reduced, it is the C=C bond.<sup>2188</sup> Sterically hindered ketones are resistant to both the Clemmensen and Huang-Minlon procedures, but can be reduced by vigorous treatment with anhydrous hydrazine.<sup>2189</sup> In the Clemmensen reduction, pinacols (**19-76**) are often side products.

The first step in the mechanism<sup>2190</sup> of the Wolff-Kishner reduction consists of formation of the hydrazone (**16-13**). It is this species that undergoes reduction in the presence of base, most likely in the following manner:

Not much is known about the mechanism of the Clemmensen reduction. Several mechanisms have been proposed,<sup>2191</sup> including one going through a zinc/carbene intermediate.<sup>2192</sup> One thing reasonably certain is that the corresponding alcohol is not an intermediate, since alcohols prepared in other ways fail to give the reaction. Note that the alcohol is not an intermediate in the Wolff-Kishner reduction either.

Other reagents have also been used to reduce the C=O of aldehydes and ketones to CH<sub>2</sub>.<sup>2193</sup> Among these are Me<sub>3</sub>SiCl followed by Et<sub>3</sub>SiH/TiCl<sub>4</sub>,<sup>2194</sup> Ni(OAc)<sub>2</sub> on borohydride-exchange resin,<sup>2195</sup> and, for aryl ketones (ArCOR and ArCOAr), NaBH<sub>3</sub>CN in THF/aqueous HCl,<sup>2196</sup> Ni/Al in H<sub>2</sub>O,<sup>2197</sup> HCOONH<sub>4</sub>/Pd/C,<sup>2198</sup> or trialkylsilanes in F<sub>3</sub>CCOOH.<sup>2199</sup> Hydrogenation with a heterogeneous Cu/silica catalyst has been used.<sup>2200</sup> Silanes such as Et<sub>3</sub>SiH and a triarylborane catalyst reduce aliphatic aldehydes to methyl, -CHO → -CH<sub>3</sub>.<sup>2201</sup> Zinc oxide/triethylsilane has been used,<sup>2202</sup> as has titanocene dichloride, (C<sub>5</sub>H<sub>5</sub>)<sub>2</sub>TiCl<sub>2</sub>.<sup>2203</sup> Most of these reagents also reduce aryl aldehydes (ArCHO) to methylbenzenes (ArCH<sub>3</sub>).<sup>2204</sup> One carbonyl group of 1,2-diketones can be selectively

reduced by H<sub>2</sub>S with an amine catalyst<sup>2205</sup> or by HI in refluxing acetic acid.<sup>2206</sup> One carbonyl group of quinones, such as anthracene-9,10-dione, can be reduced with Cu metal and sulfuric acid or with Sn and HCl.<sup>2207</sup> One carbonyl group of 1,3-diketones was selectively reduced by catalytic hydrogenolysis.<sup>2208</sup> Simply heating a ketone in supercritical propan-2-ol reduces the ketone to the methylene compound.<sup>2209</sup>

Heating carbonyl compounds with a cationic ruthenium hydride complex with a phenol ligand led to hydrogenolysis that gave the corresponding aliphatic product.<sup>2210</sup> The use of a Pd catalyst, polymethylhydrosiloxane (PMHS), aqueous KF, and a catalytic amount of an aromatic chloride gave the deoxygenation of benzylic carbonyl substrates.<sup>2211</sup> The hydrosilation of ketones, mediated by phosphonium cations, led to deoxygenation.<sup>2212</sup> The deoxygenation of aromatic ketones via transfer hydrogenolysis used Raney Ni in propan-2-ol.<sup>2213</sup> A silica-supported, chitosan-Schiff base Pd catalyst has also been used.<sup>2214</sup>

The reduction of  $\alpha,\beta$ -unsaturated tosylhydrazones with NaBH<sub>3</sub>CN, with NaBH<sub>4</sub>/HOAc, or with catecholborane proceeds with migration of the double bond to the position formerly occupied by the carbonyl carbon, even if this removes the double bond from conjugation with an aromatic ring,<sup>2215</sup> to give the allylic aryl derivative. A cyclic mechanism is apparently involved, with loss of N<sub>2</sub>. Another indirect method is conversion of the aldehyde or ketone to a dithioacetal or ketal, and desulfurization using Raney nickel or another reagent (14-22).

It is interesting to note that amines can be deaminated to give the corresponding methylene compounds with low-valent titanium (TiCl<sub>3</sub>/Li/THF).<sup>2216</sup>

### 19-67 Reduction of Carboxylic Acid Derivative Carbonyls to Methylene

Carboxylic esters and lactones have been reduced to ethers, although 2 molar equivalents of alcohol are more commonly obtained (19-42). Reduction to ethers has been accomplished with a reagent prepared from BF<sub>3</sub>-etherate and either LiAlH<sub>4</sub>, LiBH<sub>4</sub>, or NaBH<sub>4</sub>,<sup>2217</sup> with trichlorosilane and UV light,<sup>2218</sup> and with catalytic hydrogenation. The reaction with the

<sup>2218</sup> Baldwin, S.W.; Haut, S.A. *J. Org. Chem.* **1975**, *40*, 3885. See also, Kraus, G.A.; Frazier, K.A.; Roth, B.D.; Taschner, M.J.; Neuenschwander, K. *J. Org. Chem.* **1981**, *46*, 2417.

BF<sub>3</sub> reagent apparently succeeds with secondary R', but not with primary R', which give **19-42**. Acyloxy groups are reduced by cleavage of the C—C=O bond, R(Ar)COO—C → C—H with an excess of Ph<sub>2</sub>SiH<sub>2</sub> and di-*tert*-butyl peroxide.<sup>2219</sup> Esters are reduced to ethers using Et<sub>3</sub>SiH and TiCl<sub>4</sub>,<sup>2220</sup> BF<sub>3</sub>,<sup>2221</sup> In(III) compounds,<sup>2222</sup> or FeCl<sub>3</sub>.<sup>2223</sup> Lactones are converted to cyclic ethers<sup>2224</sup> by treatment with Cp<sub>2</sub>TiCl<sub>2</sub> followed by Et<sub>3</sub>SiH on Amberlyst 15.<sup>2225</sup> Esters and lactones reacted with hydrogen in the presence of a Ru/phosphine complex and aluminum triflate to give the corresponding ether via deoxygenation of the carbonyl moiety.<sup>2226</sup>

Thiono esters RCSOR' can be reduced to ethers RCH<sub>2</sub>OR' with Raney nickel (**14-27**).<sup>2227</sup> Reaction of thioesters such as R(C=S)SR with Ph<sub>2</sub>SiH<sub>2</sub> and Ph<sub>3</sub>SnH with BEt<sub>3</sub>, followed by AIBN (Sec. 14.A.i) leads to reduction of the C=S unit to give an ether.<sup>2228</sup> Since the thiono esters can be prepared from carboxylic esters (**16-11**), this provides an indirect method for the conversion of carboxylic esters to ethers. Thiol esters (RCOSR') have been reduced to thioethers (RCH<sub>2</sub>SR').<sup>2229</sup>

See also, **19-69**, **19-62**.

Cyclic anhydrides are reduced with Zn/HOAc to give lactones, and are also reduced with hydrogen and Pt or RuCl<sub>2</sub>(Ph<sub>3</sub>P)<sub>3</sub>,<sup>2230</sup> and with NaBH<sub>4</sub>.<sup>2231</sup> With cyclic anhydrides, the reaction with LiAlH<sub>4</sub> can be controlled to give either diols or lactones,<sup>2232</sup> although diols are the more usual product. A BINOL/LiAlH<sub>4</sub>/EtOH complex, however, gives smooth reduction to the lactone.<sup>2233</sup> With some reagents the reaction can be accomplished regioselectively, that is, only a specific one of the two C=O groups of an unsymmetrical anhydride is reduced.<sup>2234</sup> Open-chain anhydrides either are not reduced at all (e.g., with LiAlH<sub>4</sub> or NaBH<sub>4</sub>) or give 2 molar equivalents of alcohol. NaBH<sub>4</sub> in THF, with dropwise addition of methanol, reduces open-chain anhydrides to 1 equivalent of primary alcohol and 1 equivalent of carboxylic acid.<sup>2235</sup> Acyl halides are reduced<sup>2236</sup> to alcohols by LiAlH<sub>4</sub> or NaBH<sub>4</sub>, as well as by other metal hydrides (Table 19.2), but not by borane.

In general, reduction of amides to alcohols is difficult. More commonly the amide is reduced to an amine. An exception uses LiH<sub>2</sub>NBH<sub>3</sub> to give the alcohol.<sup>2237</sup> Reduction with

### 19-68 Reduction of Amides to Amines

Amides have been reduced to the amine, an alcohol or an aldehyde, depending on the steric demands of the amide and the nature of the reducing agent.<sup>2240</sup> A useful reagent is LiAlH<sub>4</sub>, although the reaction is more difficult than the reduction of most other functional groups, and other groups are often reduced without disturbing an amide function. Although NaBH<sub>4</sub> by itself does not reduce amides, it does so in the presence of certain other reagents,<sup>2241</sup> including iodine.<sup>2242</sup> Lithium borohydride reduces acetamides.<sup>2243</sup> Substituted amides can be reduced with these powerful reagents; secondary amides are reduced to secondary amines and tertiary amides are reduced to tertiary amines. Borane<sup>2244</sup> and sodium in propan-1-ol<sup>2245</sup> are good reducing agents for all three types of amides. Lithium triethylborohydride produces the alcohol with most *N,N*-disubstituted amides, but not with unsubstituted or *N*-substituted amides.<sup>2246</sup> Sodium (dimethylamino)borohydride reduces unsubstituted and disubstituted amides but not monosubstituted amides.<sup>2247</sup>

With some RCONR<sub>2</sub>, LiAlH<sub>4</sub> causes cleavage, and the aldehyde (**10-40**) or alcohol is obtained. Lactams are reduced to cyclic amines in high yields with LiAlH<sub>4</sub>, although cleavage sometimes occurs here too. A mixture of LiBHET<sub>3</sub>/Et<sub>3</sub>SiH is also effective.<sup>2248</sup> Lactams are also reduced to cyclic amines with 9-BBN<sup>2249</sup> (**15-11**) or LiBH<sub>3</sub>NMe<sub>2</sub>.<sup>2250</sup> *Hantzsch esters* (see **19-37**, **16-15**) have been used for metal-free reduction of amides to amines.<sup>2251</sup> Selenoamides were reduced to the amine by Sml<sub>2</sub> with H<sub>2</sub>O.<sup>2252</sup>

The reaction of secondary amides with 4 equivalents of Et<sub>2</sub>SiH<sub>2</sub> and an Ir catalyst gave the amine, whereas the use of 2 equivalents gave the imine.<sup>2253</sup> The reaction of tertiary and *N*-phenyl secondary amides with tetramethyldisiloxane (TMDS) and B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> as catalyst

gave the amine.<sup>2254</sup> Activation of an amide by Tf<sub>2</sub>O with B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub>-catalyzed hydrosilylation using TMDS gave reduction of secondary amides to amines.<sup>2255</sup> The reaction of amides with Et<sub>2</sub>Zn as catalyst using polymethylhydrosiloxane (PMHS) and a sub-stoichiometric amount of LiCl gave the amine.<sup>2256</sup> Primary amides were reduced to the corresponding amine using polymethylhydrosiloxane (PMHS)–Ti(Oi-Pr)<sub>4</sub>.<sup>2257</sup> Reduction of aromatic or aliphatic secondary amides with InI<sub>3</sub> and TMDS (1,1,3,3-tetramethyldisiloxane) gave the corresponding secondary amines.<sup>2258</sup> The Ni-catalyzed<sup>2259</sup> or Ru-catalyzed<sup>2260</sup> reduction of amides with PhSiH<sub>3</sub> gave the amine. An *in situ* formation of an iron/N-heterocyclic carbene catalyst has been used for the hydrosilylation of tertiary amides.<sup>2261</sup>

The transfer hydrogenation of aryl nitriles to the amine using a Ru catalyst has been reported.<sup>2262</sup> The Ru-catalyzed hydrogenation of functionalized  $\alpha$ -phenoxy and related amides gave chiral alcohols with high enantioselectivity.<sup>2263</sup> Amides were reduced to amines by reaction with LiAlH<sub>4</sub>/TMSCl.<sup>2264</sup> Two iron catalysts were used with (EtO)<sub>2</sub>MeSiH to reduce primary amides to amines.<sup>2265</sup> Lactams reacted with propan-2-ol, hydrogen, MsOH, and a Ru catalyst to give the cyclic amine.<sup>2266</sup> Zinc catalysts were used with (EtO)<sub>2</sub>MeSiH and secondary amides or with Me<sub>2</sub>HSi–O–SiHMe<sub>2</sub> and tertiary amides to give the corresponding amine.<sup>2267</sup> A cationic Cu/pybox catalyst with TMDS led to reduction of secondary amides to the corresponding amine.<sup>2268</sup>

Amides can be reduced<sup>2269</sup> to amines by catalytic hydrogenation,<sup>2270</sup> but high temperatures and pressures are usually required. Ruthenium,<sup>2271</sup> Pt/V,<sup>2272</sup> or a Ru complex/Zn salt catalyst have been used for hydrogenation.<sup>2273</sup> Another reagent that reduces disubstituted

amides to amines is trichlorosilane.<sup>2274</sup> Other silanes, such as Et<sub>3</sub>SiH, in the presence of a Re,<sup>2275</sup> Pt,<sup>2276</sup> In,<sup>2277</sup> Zn,<sup>2278</sup> or Ru<sup>2279</sup> catalyst, reduce amides to amines. Electrolytic reduction of carbamates to give an amine are possible.<sup>2280</sup>

Imides are generally reduced on both sides,<sup>2281</sup> although it is sometimes possible to stop with just one. Both cyclic and acyclic imides have been reduced in this manner, although with acyclic imides cleavage often takes place.<sup>2282</sup> It is noted that imides can be reduced to hydroxy lactams using different reagents, including NaBH<sub>4</sub>.<sup>2283</sup>

OS IV, 339, 354, 564; VI, 382; VII, 41.

### 19-69 Reduction of Carboxylic Acids and Esters to Alkanes

Titanocene dichloride reduces carboxylic esters in a different manner from that of **19-62**, **19-67**, or **19-42**. The products are the alkane RCH<sub>3</sub> and the alcohol R'OH. The mechanism probably involves an alkene intermediate. Aromatic acids can be reduced to methylbenzenes by a procedure involving refluxing first with trichlorosilane in MeCN, then with tripropylamine added, and finally with KOH and MeOH (after removal of the MeCN).<sup>2284</sup> Esters of aromatic acids are not reduced by this procedure, so an aromatic COOH group can be reduced in the presence of a COOR' group.<sup>2285</sup> However, it is also possible to reduce aromatic ester groups, by a variation of the trichlorosilane procedure.<sup>2286</sup> Both *o*- and *p*-hydroxybenzoic acids and their esters have been reduced to cresols (HOC<sub>6</sub>H<sub>4</sub>CH<sub>3</sub>) with Red-Al.<sup>2287</sup> Heating a 2-pyridylbenzyl ester with ammonium formate and a Ru catalyst leads to reduction of the CH<sub>3</sub>COO unit to the alkane.<sup>2288</sup> Carboxylic acids can also be converted to alkanes, indirectly,<sup>2289</sup> by reduction of the corresponding tosylhydrazides (RCONHNH<sub>2</sub>) with LiAlH<sub>4</sub> or borane.<sup>2290</sup>

OS VI, 747.

### 19-70 Hydrogenolysis of Nitriles

This transformation is not common, but given the proliferation of nitriles in organic chemistry, it is potentially quite useful. In the presence of mercuric compounds, tertiary nitriles can be reduced to the hydrocarbon with sodium cyanoborohydride.<sup>2291</sup> *gem*-Dinitriles can be reduced to the corresponding mono-nitrile with SmI<sub>2</sub>.<sup>2292</sup> Hydrosilanes facilitate reductive cleavage of nitriles in the presence of a Rh catalyst.<sup>2293</sup> The Ni-catalyzed decyanation of aryl and aliphatic cyanides using (Me<sub>2</sub>SiH)<sub>2</sub>O gave the alkane.<sup>2294</sup> Decyanation of alkyl nitriles has been reported using Ni-catalyzed hydrogenation.<sup>2295</sup>

### 19-71 Reduction of the C—N Bond

Benzylic amines are particularly susceptible to hydrogenolysis by catalytic hydrogenation<sup>2296</sup> or dissolving metal reduction.<sup>2297</sup> The transition metal-catalyzed cleavage of C—N bonds has been reviewed.<sup>2298</sup> Note that the *Wolff-Kishner reduction* in **19-66** involved formation of a hydrazone and deprotonation by base that led to loss of nitrogen and reduction. Ceric ammonium nitrate in aqueous acetonitrile has also been shown to reductively cleave the *N*-benzyl group.<sup>2299</sup> Primary amines have been reduced to RH with hydroxylamine-*O*-sulfonic acid and aqueous NaOH to give the hydrocarbon, nitrogen gas, and the sulfate anion.<sup>2300</sup> It is postulated that R—N=N—H is an intermediate that decomposes to the carbocation. An indirect means of achieving the same result is the conversion of the primary amine to the sulfonamide RNHSO<sub>2</sub>R' (**16-96**) and subsequent treatment with NH<sub>2</sub>OSO<sub>2</sub>OH<sup>2301</sup> or NaOH and then NH<sub>2</sub>Cl.<sup>2302</sup> Tosylaziridines derived from terminal alkenes are reduced to the corresponding primary tosylamine with polymethylhydrosiloxane/Pd/C.<sup>2303</sup> Aziridines can be reduced in the same way as epoxides (**19-39**).

The Ni-catalyzed cleavage of C—N bonds has been used to convert amides to esters.<sup>2304</sup> The reaction of *N*-tosylamines or *N*-benzylamines with electron-rich alkenes such as tetrakis(dimethylamino)ethene led to C—N bond cleavage and formation of the amine.<sup>2305</sup> The photochemical cleavage of the benzylic C—N bond in 3-(diethylamino)benzyl derivatives generates the amine.<sup>2306</sup> Tertiary amides with an *N*-isopropyl group were deprotected by heating in methanesulfonic acid.<sup>2307</sup>

Other indirect methods involve reduction of *N,N*-ditosylates (Sec. 10.G.iii) with NaBH<sub>4</sub> in HMPA<sup>2308</sup> and modifications of the *Katritzky pyrylium-pyridinium method*.<sup>2309</sup> Allylic and benzylic amines<sup>2091</sup> can be reduced by catalytic hydrogenolysis. Aziridines can be reductively opened with SmI<sub>2</sub><sup>2310</sup> or with Bu<sub>3</sub>SnH and AIBN.<sup>2311</sup> The C–N bond of enamines is reductively cleaved to give an alkene with alane (AlH<sub>3</sub>),<sup>2312</sup> and with 9-BBN (**15-11**) or borane methyl sulfide (BMS).<sup>2313</sup> Since enamines can be prepared from ketones (**16-12**), this is a way of converting ketones to alkenes. In the latter case BMS gives retention of configuration [an (*E*) isomer gives the (*E*) product], while 9-BBN gives the other isomer.<sup>2313</sup> Diazo ketones are reduced to methyl ketones by HI.<sup>2314</sup>

Quaternary ammonium salts can be cleaved with LiAlH<sub>4</sub>:

as can quaternary phosphonium salts R<sub>4</sub>P<sup>+</sup>. Other reducing agents have also been used, for example, lithium triethylborohydride (which preferentially cleaves methyl groups)<sup>2315</sup> and Na in liquid ammonia. When quaternary salts are reduced with Na(Hg) in water, the reaction is known as the *Emde reduction*. However, this reagent is not applicable to the cleavage of ammonium salts with four *saturated* alkyl groups.

Nitro compounds, RNO<sub>2</sub>, can be reduced to RH<sup>2316</sup> by sodium methylmercaptide, CH<sub>3</sub>SNa, in an aprotic solvent<sup>2317</sup> or by Bu<sub>3</sub>SnH.<sup>2318</sup> Both reactions have free-radical mechanisms.<sup>2319</sup> Tertiary nitro compounds can be reduced to RH by NaHTe.<sup>2320</sup> The nitro group of aromatic nitro compounds has been removed with sodium borohydride.<sup>2321</sup> Reduction of the C–N bond of aromatic amines with Li metal in THF generates the aryl compounds.<sup>2322</sup> Conversion of the aniline derivative to the methanesulfonamide and subsequent treatment with NaH and NH<sub>2</sub>Cl gives the same result.<sup>2323</sup>

## 19-72 Reduction of Amine Oxides and Azoxy Compounds

Amine oxides<sup>2324</sup> and azoxy compounds (both alkyl and aryl)<sup>2325</sup> can be reduced practically quantitatively with triphenylphosphine.<sup>2326</sup> Other reducing agents have also been used, including LiAlH<sub>4</sub>, NaBH<sub>4</sub>/LiCl,<sup>2327</sup> H<sub>2</sub>/Ni, PCl<sub>3</sub>, Ga/H<sub>2</sub>O,<sup>2328</sup> or In/TiCl<sub>4</sub>.<sup>2329</sup> Indium metal with aqueous ammonium chloride in methanol gives good yields of pyridine from pyridine *N*-oxide.<sup>2330</sup> Similar results are obtained using ammonium formate and Raney nickel<sup>2331</sup> or ammonium formate and zinc.<sup>2332</sup> Sodium in ethanol, in a sealed tube, reduces pyridine *N*-oxide to pyridine.<sup>2333</sup> Similar reduction was accomplished with Mo(CO)<sub>6</sub> in ethanol.<sup>2334</sup> Indium(III) chloride has been used for the reduction of quinoline *N*-oxide to quinoline.<sup>2335</sup> Nitrile oxides<sup>2336</sup> (R—C≡N<sup>+</sup>—O<sup>-</sup>) can be reduced to nitriles with trialkylphosphines,<sup>2337</sup> and isocyanates (RNCO) to isocyanides (RNC) with Cl<sub>3</sub>SiH/Et<sub>3</sub>N.<sup>2338</sup>

Analogous to amino *N*-oxides, phosphine oxides (R<sub>3</sub>P=O) are reduced to phosphines (R<sub>3</sub>P). Treatment of a phosphine oxide with MeOTf followed by reduction with LiAlH<sub>4</sub><sup>2339</sup> or DibalH<sup>2340</sup> gives the phosphine. Chiral phosphine oxides are reduced to the phosphine with excellent enantioselectivity using PPh<sub>3</sub> and Cl<sub>3</sub>SiH.<sup>2341</sup> Phosphine oxides were reduced to phosphines with an In catalyst and TMDS (1,1,3,3-tetramethyldisilazane).<sup>2342</sup> The TMSCl-promoted electroreduction of triphenylphosphine oxide to triphenylphosphine has been reported.<sup>2343</sup>

## 19-73 Replacement of the Diazonium Group by Hydrogen

Reduction of a diazonium group (*dediazonation*) provides an indirect method for the removal of an amino group from an aromatic ring.<sup>2344</sup> A common method uses hypophosphorus acid ( $\text{H}_3\text{PO}_2$ ), although many other reducing agents<sup>2345</sup> have been used, including HMPA,<sup>2346</sup> thiophenol,<sup>2347</sup> and sodium stannite ( $\text{Na}_2\text{SnO}_2$ ). Ethanol was the earliest reagent used, and it frequently gives good yields, but ethers ( $\text{ArOEt}$ ) are frequent side products. When  $\text{H}_3\text{PO}_2$  is used, 5–15 molar equivalents of this reagent are required per molar equivalent of substrate. Diazonium salts can be reduced in nonaqueous media by several methods, including treatment with  $\text{Bu}_3\text{SnH}$  or  $\text{Et}_3\text{SiH}$  in ethers or  $\text{MeCN}$ <sup>2348</sup> and by isolation as the  $\text{BF}_4^-$  salt and reduction of this with  $\text{NaBH}_4$  in DMF.<sup>2349</sup> Aromatic amines can be deaminated ( $\text{ArNH}_2 \rightarrow \text{ArH}$ ) in one laboratory step by treatment with an alkyl nitrite in DMF<sup>2350</sup> or boiling THF.<sup>2351</sup> The corresponding diazonium salt is an intermediate.

Not many investigations of the mechanism have been carried out. It is generally assumed that the reaction of diazonium salts with ethanol to produce ethers takes place by an ionic ( $\text{S}_{\text{N}}1$ ) mechanism while the reduction to  $\text{ArH}$  proceeds by a free-radical process.<sup>2352</sup> The reduction with  $\text{H}_3\text{PO}_2$  is also believed to have a free-radical mechanism.<sup>2353</sup> In the reduction with  $\text{NaBH}_4$ , an aryl diazene intermediate ( $\text{ArN}=\text{NH}$ ) has been demonstrated,<sup>2354</sup> arising from nucleophilic attack by  $\text{BH}_4^-$  on the  $\beta$  nitrogen. Such diazenes can be obtained as moderately stable (half-life of several hours) species in solution.<sup>2355</sup> It is not entirely clear how the aryl diazene decomposes, but there are indications that either the aryl radical  $\text{Ar}\cdot$  or the corresponding anion  $\text{Ar}^-$  may be involved.<sup>2356</sup>

The dediazonation reaction is used for functionalization of aromatic rings, to remove an amino group after it has been used to direct one or more other groups to *ortho* and *para* positions. For example, the compound 1,3,5-tribromobenzene cannot be prepared by direct bromination of benzene because the bromo group is *ortho/para* directing; however, this compound is easily prepared by nitration of benzene, reduction to aniline, tribromination, and then treatment with  $\text{HONO}$  and finally  $\text{H}_2\text{PO}_2$  gave 1,3,5-tribromobenzene. Many other compounds that would otherwise be difficult to prepare are easily synthesized with the

### 19-74 Desulfurization

Thiols and thioethers,<sup>2358</sup> both alkyl and aryl, can be desulfurized by hydrogenolysis with Raney nickel.<sup>2359</sup> The hydrogen is usually not applied externally, since Raney nickel typically contains enough hydrogen for the reaction. Other sulfur compounds can be similarly desulfurized, including disulfides, thiono esters,<sup>2360</sup> thioamides, sulfoxides, and thioacetals.<sup>2361</sup> Reduction of thioacetals is an indirect way of accomplishing reduction of a carbonyl to a methylene group (**19-66**), and it can also give the alkene if a hydrogen atom is present.<sup>2362</sup> In most of the examples given, R can also be aryl. Other reagents<sup>2363</sup> have also been used.<sup>2364</sup> Reductive cleavage of sulfones and sulfonamides occurs with organobases such as bis(imidazolylidenes).<sup>2365</sup> The use of baker's yeast in the reduction of sulfur-containing compounds has been reviewed.<sup>2366</sup>

The desulfurization of heterocyclic thiols to give the sulfur-free heterocycle used Et<sub>3</sub>SiH and Pd/C.<sup>2367</sup> Aryl and benzyl methyl sulfide were reduced with C–S cleavage to give the arene using EtMe<sub>2</sub>SiH and a Ni catalyst.<sup>2368</sup> Sulfides were reduced with Et<sub>3</sub>SiH, using B(C<sub>6</sub>F<sub>5</sub>)<sub>3</sub> as a catalyst, and gave hydrodesulfurization of C–S bond.<sup>2369</sup> Aryl sulfides were reduced with C–S bond cleavage to give the arene using the Pd-catalyzed reaction with Et<sub>3</sub>SiH and TMSCl.<sup>2370</sup>

Lithium aluminum hydride reduces most sulfur compounds with cleavage of the C–S bond, including thiols.<sup>2371</sup> Thioesters can be reduced with Ni<sub>2</sub>B (from NiBr<sub>2</sub>/NaBH<sub>4</sub>).<sup>2372</sup> β-Ketosulfones are reduced with TiCl<sub>4</sub>/Zn<sup>2373</sup> or TiCl<sub>4</sub>/Sm.<sup>2374</sup> An important special case of

RSR reduction is desulfurization of thiophene derivatives. This proceeds with concomitant reduction of the double bonds. Many compounds have been made by alkylation of thiophene to 1,5-dialkylthiophenes, followed by reduction to give the alkane. Thiophenes can also be desulfurized to alkenes ( $\text{RCH}_2\text{CH}=\text{CHCH}_2\text{R}'$ ) with a nickel boride catalyst prepared from  $\text{NiCl}_2$  and  $\text{NaBH}_4$  in methanol.<sup>2375</sup> Only one SR group of a dithioacetal is reduced by treatment with borane/pyridine in trifluoroacetic acid or in  $\text{CH}_2\text{Cl}_2$  in the presence of  $\text{AlCl}_3$ .<sup>2376</sup> Phenyl selenides  $\text{RSePh}$  can be reduced to  $\text{RH}$  with  $\text{Ph}_3\text{SnH}$ <sup>2377</sup> and with nickel boride.<sup>2378</sup> Cleavage of the C–Se bond can also be achieved with  $\text{SmI}_2$ .<sup>2379</sup>

The desulfurization reduction of 1,3-dithianes and 1,3-dithiolanes used *t*-BuOK/1,4-cyclohexadiene with photostimulation.<sup>2380</sup> Aryl thiols were desulfurized to the arene using molybdenum hexacarbonyl.<sup>2381</sup> The reduction of *cis*-*N*-triflylaziridines or *N,N*-dialkyltriflylamides used 10 equivalents of Red-Al in toluene at  $-40$  to  $0$  °C to give deprotected parent aziridines or amides.<sup>2382</sup>

The exact mechanism of the Raney nickel reactions is still in doubt, although they are probably of the free-radical type.<sup>2383</sup> It has been shown that reduction of thiophene proceeds through butadiene and butene, not through butane-1-thiol or other sulfur compounds, that is the sulfur is removed before the double bonds are reduced. This was demonstrated by isolation of the alkenes and the failure to isolate any potential sulfur-containing intermediates.<sup>2384</sup>

OS IV, 638; V, 419; VI, 109, 581, 601. See also, OS VII, 124, 476.

The cleavage of sulfo groups from aromatic rings is the reverse of **11-7**.<sup>2385</sup> By the principle of microscopic reversibility, the mechanism is also the reverse.<sup>2386</sup> Dilution is generally used, as the reversibility of sulfonation decreases with increasing  $\text{H}_2\text{SO}_4$  concentration. The reaction permits the sulfo group to be used as a blocking group to direct *meta* and then to be removed. The sulfo group has also been replaced by nitro and halogen groups. Sulfo groups have also been removed from the ring by heating with an alkaline solution of Raney nickel.<sup>2387</sup> In another catalytic process, aromatic sulfonyl bromides or chlorides are converted to aryl bromides or chlorides, respectively, on heating with a Rh

### 19-75 Reduction of Sulfonyl Halides and Sulfonic Acid Derivatives to Thiols or Disulfides

Thiols can be prepared by the reduction of sulfonyl halides<sup>2389</sup> with  $\text{LiAlH}_4$ . Usually, the reaction is carried out on aromatic sulfonyl chlorides. Zinc and acetic acid, and HI, also give the reduction. Sulfonic acids have been reduced to thiols with a mixture of triphenylphosphine and either  $\text{I}_2$  or a diaryl disulfide.<sup>2390</sup>

Disulfides  $\text{RSSR}$  can also be produced.<sup>2391</sup> Other sulfonic acid derivatives can be converted to disulfides. Esters such as PhSAc are converted to disulfides  $\text{PhS-SPh}$  with the reagent Clayan and microwave irradiation.<sup>2392</sup> Thiobenzoate derivatives PhSBz are similarly converted to  $\text{PhS-SPh}$  with  $\text{SmI}_2$ .<sup>2393</sup> In a similar manner,  $\text{RS-SO}_3\text{Na}$  is converted to  $\text{RS-SR}$  when heated with Sm metal in water.<sup>2394</sup>

OS **I**, 504; **IV**, 695; **V**, 843.

This reaction is done mostly on aromatic sulfonyl chlorides, but the reaction has also been applied to alkyl compounds. Zinc, sodium sulfite, hydrazine, sodium sulfide, and other reducing agents have been used. For reduction of sulfonyl chlorides to thiols, see **19-82**.

OS **I**, 7, 492; **IV**, 674.

### 19-76 Reduction of Sulfoxides and Sulfones

Sulfoxides can be reduced to sulfides by many reagents,<sup>2395</sup> including  $\text{LiAlH}_4$ , HI,  $\text{Bu}_3\text{SnH}$ ,<sup>2396</sup>  $\text{H}_2/\text{Pd/C}$ ,<sup>2397</sup>  $\text{NaBH}_4/\text{NiCl}_2$ ,<sup>2398</sup>  $\text{NaBH}_4/\text{I}_2$ ,<sup>2399</sup>  $\text{NaBH}_4/\text{CoCl}_2$ ,<sup>2400</sup>

<sup>2400</sup> Yakabe, S.; Hirano, M.; Morimoto, T. *Synth. Commun.* **2010–2011**, *41*, 2251.

catecholborane,<sup>2401</sup>  $\text{BH}_3$  with a Mo catalyst,<sup>2402</sup> a Mo/In system,<sup>2403</sup> Ti compounds,<sup>2404</sup> and Sm/methanolic  $\text{NH}_4\text{Cl}$  with ultrasound.<sup>2405</sup> Sulfones, however, are usually more difficult to reduce, but they have been reduced to sulfides with DibalH.<sup>2406</sup> Both sulfoxides and sulfones can be reduced by heating with sulfur (which is oxidized to  $\text{SO}_2$ ), although the reaction with sulfoxides proceeds at a lower temperature.

The reaction of sulfoxides with  $\text{SOCl}_2$  and  $\text{Ph}_3\text{P}$  gave the corresponding sulfide.<sup>2407</sup> Deoxygenation of sulfoxides to the corresponding sulfides used  $\text{NaHSO}_3$  in the presence of catalytic  $\text{I}_2$ .<sup>2408</sup> An oxo rhenium complex was used for the deoxygenation of aromatic and aliphatic sulfoxides.<sup>2409</sup> The Ru-catalyzed hydrogenation of sulfoxides gave the sulfide.<sup>2410</sup> Diarylsulfoxides were reduced to the sulfide using  $\text{PhSiH}_3$  with a Re catalyst.<sup>2411</sup> The electrochemical deoxygenation of aromatic amides or aromatic and aliphatic sulfoxides to obtain the corresponding sulfide was reported.<sup>2412</sup> Sulfoxides were reduced to the sulfide using the  $\text{Cp}_2\text{TiCl}_2/\text{Ga}$  system.<sup>2413</sup> A  $\text{NbCl}_5/\text{In}$  system has also been used.<sup>2414</sup> Ascorbic acid and NBS has been used to reduce sulfoxides to sulfides.<sup>2415</sup> The ionic liquids  $[\text{DMIIm}][\text{MoO}_2(\text{NCS})_4]$ ,  $[\text{RPy}][\text{MoO}_2(\text{NCS})_4]$ , or  $[\text{BMIIm}][\text{MoO}_2(\text{NCS})_4]$  catalyzed the  $\text{PPh}_3$  reduction of sulfoxides.<sup>2416</sup>

It has been shown by using substrate labeled with  $^{35}\text{S}$  that sulfoxides simply give up the oxygen to the sulfur, but that the reaction with sulfones is more complex, since  $\sim 75\%$  of the original radioactivity of the sulfone is lost.<sup>2417</sup> This indicates that most of the sulfur in the sulfide product comes in this case from the *reagent*. There is no direct general method for the reduction of sulfones to sulfoxides, but an indirect method has been reported.<sup>2418</sup> Selenoxides can be reduced to selenides with a number of reagents.<sup>2419</sup>

OS IX, 446.

## E. Reduction With Cleavage

### 19-77 Dealkylation of Amines and Amides

Certain amines can be dealkylated, usually under reductive conditions. Both *N*-allylamines and *N,N*-dialkyl allylamines are converted to the corresponding amine,  $R_2N-H$ , with  $DibalH/NiCl_2dppp$ <sup>2420</sup> and with  $Pd(dba)_2dppb$ .<sup>2421</sup> A mixture of  $TiCl_3$  and  $Li$  converts *N*-benzylamines to the amine.<sup>2422</sup> In the case of *N,N*-dimethylamines,  $RuCl_3$  and  $H_2O_2$  demethylate the amine ( $ArNMe_2 \rightarrow ArNHMe$ ).<sup>2423</sup> Tribenzylamines are dealkylated with ceric ammonium nitrate in aqueous acetonitrile to give the dibenzylamine.<sup>2424</sup> *N*-Benzyl indoles are cleaved to indoles with  $O_2$ ,  $DMSO/KOt-Bu$ ,<sup>2425</sup> or with tetrabutylammonium fluoride.<sup>2426</sup> *N*-Demethylation of alkaloids was reported using a Fe-mediated two-step procedure.<sup>2427</sup> *N*-Deallylation and *N*-debenzylation of amines occurs with alkali metals on silica.<sup>2428</sup>

The process is not limited to amines. Amides can also be dealkylated. *N*-Benzyl amides are debenzylated in the presence of NBS and AIBN.<sup>2429</sup> Scandium triflate removes *N*-*tert*-butyl from amides.<sup>2430</sup>

*N*-Alkyl sulfonamides are dealkylated with  $PhI(OAc)_2$  and  $I_2$  with ultrasound to give a primary sulfonamide.<sup>2431</sup> Similar results are obtained with  $H_5IO_6$  and a Cr catalyst.<sup>2432</sup> *tert*-Butyl sulfonamides are cleaved to the primary sulfonamide with  $BCl_3$ .<sup>2433</sup>

### 19-78 Reduction of Azo, Azoxy, and Hydrazo Compounds to Amines

Azo, azoxy, and hydrazo compounds can all be reduced to amines.<sup>2434</sup> Metals (notably Zn) and acids, and  $Na_2S_2O_4$ , are frequently used as reducing agents, and  $Bu_3SnH$  with a Cu catalyst has been used.<sup>2435</sup> Borane reduces azo compounds to amines, although it does not reduce nitro compounds.<sup>2436</sup>  $LiAlH_4$  does not reduce hydrazo compounds or azo compounds, although with the latter, hydrazo compounds are sometimes isolated. With azoxy compounds,  $LiAlH_4$  gives only azo compounds (19-72). Note that azo compounds

are reduced to the hydrazine by reaction with hydrazine hydrate in ethanol,<sup>2437</sup> or with Fe powder in ammonium chloride.<sup>2438</sup>

OS I, 49; II, 35, 39; III, 360; X, 327. Also see, OS II, 290.

### 19-79 Reduction of Disulfides to Thiols

Disulfides can be reduced to thiols by mild reducing agents,<sup>2439</sup> such as Zn and dilute acid, In and  $\text{NH}_4\text{Cl}/\text{EtOH}$ ,<sup>2440</sup> or  $\text{Ph}_3\text{P}$  and  $\text{H}_2\text{O}$ .<sup>2441</sup> The reaction can also be accomplished simply by heating with alkali.<sup>2442</sup> Among other reagents used have been  $\text{LiAlH}_4$ ,  $\text{NaBH}_4/\text{ZrCl}_4$ ,<sup>2443</sup>  $\text{Mg}/\text{MeOH}$ ,<sup>2444</sup> and hydrazine or substituted hydrazines.<sup>2445</sup>

Aryl diselenides are similarly cleaved to selenols ( $\text{ArSeH}$ ) with  $\text{Cp}_2\text{TiH}$  followed by  $\text{Ph}_2\text{I}^+ \text{X}^-$ .<sup>2446</sup>

OS II, 580. Also see, OS IV, 295.

## F. Reductive Coupling

### 19-80 Bimolecular Reduction of Aldehydes and Ketones to 1,2-Diols and Imines to 1,2-Diamines: Pinacol Coupling

1,2-Diols (pinacols) can be synthesized by reduction of aldehydes and ketones with active metals, such as Na, Mg, Ti,<sup>2447</sup> or Al.<sup>2448</sup> Aromatic ketones give better yields than aliphatic ones. The use of a  $\text{Mg}/\text{MgI}_2$  mixture has been called the *Gomberg-Bachmann pinacol synthesis*.<sup>2449</sup> As with a number of other reactions involving Na, there is a direct electron transfer that converts the ketone or aldehyde to a ketyl, which dimerizes.

reported.<sup>2475</sup> A conjugated polymer poly-(*p*)-phenylene was used as a photoredox catalyst to promote pinacol coupling of aryl aldehydes with visible light to give the *vic*-diol.<sup>2476</sup> An Fe-catalyzed coupling reaction of aryl ketones has been reported, using a phenyltitanium reagent.<sup>2477</sup> Enantioselective pinacol couplings have been reported.<sup>2478</sup> A reversal of the pinacol coupling has been described.<sup>2479</sup>

Stereoselective pinacol coupling reactions are well known.<sup>2480</sup> Chiral additives with pinacol couplings lead to formation of a diol with moderate to good enantioselectivity.<sup>2481</sup> A crossed pinacol coupling was reported using Et<sub>2</sub>Zn and, with a BINOL catalyst, gave good enantioselectivity.<sup>2482</sup> Enantioselective coupling was reported using a chiral salen/Mo complex.<sup>2483</sup> A combination of Mg and Me<sub>3</sub>SiCl was also used to effect a crossed-pinacol.<sup>2484</sup> Chiral metal complexes in conjunction with a metal leads to diol formation with good enantioselectivity.<sup>2485</sup>

Intramolecular pinacol coupling reactions are known, giving cyclic 1,2-diols.<sup>2486</sup> Dialdehydes have been cyclized by reaction with TiCl<sub>3</sub> to give cyclic 1,2-diols in good yield.<sup>2487</sup> A variation of the pinacol coupling treats acyl nitriles with In metal and ultrasound to give a 1,2-diketone.<sup>2488</sup> Another variation couples acetals to give 1,2-diols.<sup>2489</sup>

The photochemical dimerization of ketones to 1,2-diols is one of the most common photochemical reactions.<sup>2490</sup> The substrate, which is usually a diaryl or aryl alkyl ketone, is irradiated with UV light in the presence of a hydrogen donor, such as isopropyl alcohol, toluene, or an amine.<sup>2491</sup> In the case of benzophenone, irradiated in the presence of propan-2-ol, the ketone molecule initially undergoes  $n \rightarrow \pi^*$  excitation, and the singlet species thus formed crosses to the  $T_1$  state with high efficiency. The  $T_1$  species abstracts hydrogen from the alcohol (Sec. 7.A.vii, category 4) and then dimerizes. The *i*-PrO• radical, which is formed by this process, reacts by atom transfer of H• to another molecule of ground-state benzophenone, producing acetone and a ketyl. This mechanism<sup>2492</sup> predicts that the quantum yield for the disappearance of benzophenone should be 2, since each quantum of light results in

the conversion of 2 equivalents of benzophenone to a ketyl. Under favorable experimental conditions, the observed quantum yield does approach 2. Benzophenone abstracts hydrogen with very high efficiency. Other aromatic ketones are dimerized with lower quantum yields, and some (e.g., *p*-aminobenzophenone, *o*-methylacetophenone) cannot be dimerized at all in 2-propanol (although *p*-aminobenzophenone, for example, can be dimerized in cyclohexane<sup>2493</sup>). The reaction has also been carried out electrochemically.<sup>2494</sup>

A coupling reaction similar to pinacol coupling has been used with imines, which dimerize to give 1,2-diamines. A number of reagents have been used, including treatment with  $\text{TiCl}_4/\text{Mg}$ ,<sup>2495</sup>  $\text{In}/\text{aqueous EtOH}$ ,<sup>2496</sup>  $\text{Zn}/\text{aqueous NaOH}$ ,<sup>2497</sup> or  $\text{SmI}_2$ .<sup>2498</sup>

Aldehydes are converted to 1,2-diamines by treatment with  $\text{TMS}_2\text{NH}$ , NaH, and Li metal in 5 M  $\text{LiClO}_4$  in ether, with sonication.<sup>2499</sup> The reaction of an imine with Yb in THF/HMPA and then an aldehyde gives a 1,2-bis(imine).<sup>2500</sup> Aldehydes are coupled with *N*-sulfinyl imines to give *N*-sulfinyl amino alcohols in the presence of  $\text{SmI}_2$ .<sup>2501</sup> Hemi-aminals are coupled to give 1,2-diamines with  $\text{TiI}_4/\text{Zn}$ .<sup>2502</sup> Amides are converted to 1,2-diamines with  $\text{Cp}_2\text{TiF}_2$  and  $\text{PhMeSiH}_2$ .<sup>2503</sup> Samarium(II) iodide was used to couple iminium salts, giving the 1,2-diamine.<sup>2504</sup> Ketones can be treated with Yb and then an imine to give amino alcohols.<sup>2505</sup> When electroreduction was used, it was possible to obtain cross products by coupling a ketone to an *O*-methyl oxime.<sup>2506</sup> The *N*-methoxyamino alcohol could then be reduced to the amino alcohol.<sup>2506</sup>

*O*-Methyl oxime ethers are coupled to give 1,2-diamines using Zn and  $\text{TiCl}_4$ .<sup>2507</sup> A photochemical coupling has also been reported.<sup>2508</sup>

An asymmetric aza-pinacol reaction has been developed using photoredox catalysis.<sup>2509</sup> OS **I**, 459; **II**, 71; **X**, 312; **81**, 26.

## 19-81 Bimolecular Reduction of Aldehydes or Ketones to Alkenes

Aldehydes and ketones, both aromatic and aliphatic (including cyclic ketones), can be converted in high yields to dimeric alkenes by treatment with low valent Ti,<sup>2510</sup> initially generated with TiCl<sub>3</sub> and a Zn/Cu couple.<sup>2511</sup> This is called the *McMurry reaction*.<sup>2512</sup> The reagent produced in this way is called a *low-valent titanium reagent*, and the reaction has also been accomplished<sup>2513</sup> with low-valent Ti reagents prepared in other ways, for example, from Mg and a TiCl<sub>3</sub>/THF complex,<sup>2514</sup> from TiCl<sub>4</sub> and Zn or Mg,<sup>2515</sup> from TiCl<sub>3</sub> and LiAlH<sub>4</sub>,<sup>2516</sup> and from TiCl<sub>3</sub> and K or Li<sup>2517</sup> (see 17-16). Microwave irradiation has been used to facilitate the coupling.<sup>2518</sup> Unsymmetrical alkenes can be prepared from a mixture of two ketones in a cross-coupling reaction, if one is in excess.<sup>2519</sup> An aldehyde and a ketone were cross-coupled using Yb(OTf)<sub>3</sub>, for example.<sup>2520</sup> The mechanism consists of initial coupling of two radical species to give a 1,2-dioxygen compound (a titanium pinacolate), which is then deoxygenated.<sup>2521</sup>

The reaction has been used to convert dialdehydes and diketones to cycloalkenes.<sup>2522</sup> Rings of 3–16 and 22 members have been closed in this way, as in the conversion of 2,2-dimethyl-1,3-diphenylpropane-1,3-dione to 1,2-diphenyl-3,3-dimethylcyclopropene.<sup>2523</sup> The same reaction on an ester with a distal keto moiety gives a cycloalkanone.<sup>2524</sup> Esters were coupled to diaryl ketones using TiCl<sub>4</sub>/Zn to give α,α-diaryl α-hydroxy ketones.<sup>2525</sup> Indoles have been prepared from ortho-acyl amides with Ti(powder) and Me<sub>3</sub>SiCl<sup>2526</sup> or with TiCl<sub>3</sub>/C<sub>8</sub>K.<sup>2527</sup>

## 19-82 Acyloin Ester Condensation

When carboxylic esters are heated with sodium in refluxing ether or benzene, a bimolecular reduction takes place to give a bis(alkoxide), **31**. After hydrolysis, the product is an  $\alpha$ -hydroxy ketone (called an acyloin).<sup>2528</sup> The reaction, called the *acyloin ester condensation* (or just *acyloin condensation*),<sup>2529</sup> is quite successful when R is alkyl. Acyloins with long chains have been prepared in this way, for example, R = C<sub>17</sub>H<sub>35</sub>, but for high molecular weight esters, toluene or xylene is used as the solvent. Modifications to this procedure have been reported, including an ultrasound-promoted acyloin condensation in ether,<sup>2530</sup> which improved the yields of four-, five-, and six-membered rings, and Olah's procedure, which was also done in ether.<sup>2531</sup> Triazolium precatalysts in the presence of base were used for crossed acyloin condensation reactions of aliphatic and *ortho*-substituted aromatic aldehydes.<sup>2532</sup> The crossed acyloin condensation of aromatic aldehydes and acetaldehyde was catalyzed by *N*-heterocyclic carbenes.<sup>2533</sup>

The acyloin condensation has been used with great success, in xylene at reflux, to prepare cyclic acyloins from diesters.<sup>2534</sup> The yields are 50–60% for the preparation of 6- and 7-membered rings, 30–40% for 8- and 9-membered, and 60–95% for rings of 10–20 members. Even larger rings have been closed in this manner. Indeed, this is one of the best ways of closing rings of 10 members or more. The reaction has been used to close four-membered rings,<sup>2535</sup> although this is generally unsuccessful. For larger rings, the presence of double or triple bonds does not interfere.<sup>2536</sup> Even a benzene ring can be present, and many paracyclophane derivatives (**32**) with  $n = 9$  or more have been synthesized in this manner.<sup>2537</sup> The acyloin condensation was used to prepare the first reported catenane<sup>2538</sup> (Sec. 3.D). This synthesis of a catenane was produced in low yield and relied on chance for threading the molecules before ring closure.

Yields in the acyloin condensation can be improved by running the reaction in the presence of chlorotrimethylsilane (Me<sub>3</sub>SiCl), in which case the dianion **31** is converted to the bis(silyl) enol ether **33**, which can be isolated and subsequently hydrolyzed to the acyloin

with aqueous acid.<sup>2539</sup> This is now the standard way to conduct the acyloin condensation. Among other things, this method inhibits the *Dieckmann condensation*<sup>2540</sup> (**16-81**), which otherwise competes with the acyloin condensation when a five-, six-, or seven-membered ring can be closed. (Note that the ring formed by a Dieckmann condensation is always one carbon atom smaller than that formed by an acyloin condensation of the same substrate.) The Me<sub>3</sub>SiCl method is especially good for the closing of four-membered rings.<sup>2541</sup>

The mechanism is usually presumed to have a diketone (RCOCOR) as an intermediate,<sup>2542</sup> since small amounts of it are usually isolated as side products, and when it is resistant to reduction (e.g., *t*-Bu-COCO-*t*-Bu) it is the major product. A possible sequence involves formation of a ketyl and coupling. Subsequent loss of two alkoxide units to give a 1,2-diketone and final reaction with sodium to give **31**. A large surface area for the Na is usually required for good results in this coupling, consistent with a surface reaction. In order to form large rings, the two ends of the chain must approach each other even although this is conformationally unfavorable for long chains. However, it may be postulated that the two ends become attached to nearby sites on the surface<sup>2543</sup> of the Na. Although high dilution techniques are not always necessary, effective stirring (high speed stirrer at 2000–2500 rpm) is usually required to generate “sodium sand.” Highly pure Na gives poorer results because the presence of a small percentage of K is important. Up to 50% potassium (1:1 Na/K)<sup>2544</sup> has been used in acyloin condensations.

In a related reaction, aromatic carboxylic acids were condensed to  $\alpha$ -diketones (2ArCOOH  $\rightarrow$  ArCOCOAr) on treatment with excess Li in dry THF in the presence of ultrasound.<sup>2545</sup> It is noted that the organocatalytic rearrangement of  $\alpha$ -hydroxy acetals to  $\alpha$ -alkoxy ketones proceeded with good enantioselectivity.<sup>2546</sup>

OS II, 114; IV, 840; VI, 167.

### 19-83 Reduction of Nitro Compounds to Azoxy Compounds

Azoxy compounds can be obtained from nitro compounds with certain reducing agents, notably sodium arsenite, sodium ethoxide, NaTeH,<sup>2547</sup> and glucose. The most probable

<sup>2545</sup> Karaman, R.; Fry, J.L. *Tetrahedron Lett.* **1989**, *30*, 6267.

<sup>2546</sup> Wu, H.; Wang, Q.; Zhu, J. *Angew. Chem. Int. Ed.* **2017**, *56*, 5858.

<sup>2547</sup> Osuka, A.; Shimizu, H.; Suzuki, H. *Chem. Lett.* **1983**, 1373. See Ohe, K.; Uemura, S.; Sugita, N.; Masuda, H.; Taga, T. *J. Org. Chem.* **1989**, *54*, 4169.

mechanism with most reagents is that one molecule of nitro compound is reduced to a nitroso compound and another to a hydroxylamine (**19-50**), and these combine (**12-50**). The combination step is rapid compared to the reduction process.<sup>2548</sup> Nitroso compounds can be reduced to azoxy compounds with triethylphosphite or triphenylphosphine<sup>2549</sup> or with an alkaline aqueous solution of an alcohol.<sup>2550</sup>

OS II, 57.

### 19-84 Reduction of Nitro Compounds to Azo Compounds

Nitro compounds can be reduced to azo compounds with various reducing agents, of which  $\text{LiAlH}_4$  and Zn and alkali are the most common. A combination of triethylammonium formate and lead in methanol is also effective.<sup>2551</sup> With many of these reagents, slight differences in conditions can lead either to the azo or azoxy (**19-83**) compound. When the reducing agent was  $\text{NaBH}_4$ ,<sup>2552</sup> it was shown that azoxy compounds were intermediates. Nitro compounds can be reduced to azo compounds with  $\text{LiAlH}_4$ . Dicarborane, with a catalytic amount of acetic acid, reduces aromatic nitro compounds to the amine.<sup>2553</sup>

Nitro compounds can be further reduced to hydrazo compounds with Zn and sodium hydroxide, with hydrazine hydrate and Raney nickel,<sup>2554</sup> or with  $\text{LiAlH}_4$  mixed with a metal chloride such as  $\text{TiCl}_4$  or  $\text{VCl}_3$ .<sup>2555</sup> The reduction has also been accomplished electrochemically.

OS III, 103.

### G. Reactions in Which an Organic Substrate Is Both Oxidized and Reduced

Some reactions that belong in this category have been considered in earlier chapters. Among these are the *Tollens' condensation* (**16-43**), the benzil-benzilic acid rearrangement (**18-6**), and the *Wallach rearrangement* (**18-43**).

### 19-85 The Cannizzaro Reaction

Aromatic aldehydes, and aliphatic ones with no  $\alpha$  hydrogen, give the *Cannizzaro reaction* when treated with NaOH or other strong bases.<sup>2556</sup> Reaction with triethylamine and

MgBr<sub>2</sub> gave a room temperature Cannizzaro reaction.<sup>2557</sup> The reaction is mediated by organobases.<sup>2558</sup> In this reaction, one molecule of aldehyde oxidizes another to the acid and is itself reduced to the primary alcohol. Aldehydes with an  $\alpha$  hydrogen do not give the reaction, because when these compounds are treated with base the aldol reaction (16-34) is much faster.<sup>2559</sup> Normally, the best yield of acid or alcohol is 50% each, but this can be altered in certain cases. Solvent-free reactions are known.<sup>2560</sup> On the other hand, high yields of alcohol can be obtained from almost any aldehyde by running the reaction in the presence of formaldehyde.<sup>2561</sup> In this case, the formaldehyde reduces the aldehyde to the alcohol and is itself oxidized to formic acid. In such a case, where the oxidant aldehyde differs from the reductant aldehyde, the reaction is called the *crossed-Cannizzaro reaction*.<sup>2562</sup> The *Tollens' condensation* (16-43) includes a crossed Cannizzaro reaction as its last step. A Cannizzaro reaction with 1,4-dialdehydes (note that  $\alpha$  hydrogen atoms are present here) and a Rh catalyst gives ring closure to form a lactone, as in the closure of succinaldehyde (1,4-butanedial) to  $\gamma$ -butyrolactone [dihydrofuran-2(3*H*)-one].<sup>2563</sup> The lactone is derived from the hydroxy acid that would form and spontaneously cyclize from a normal Cannizzaro reaction. Chiral additives have been used, but with bis(oxazolidine) derivatives the reaction proceeded with poor enantioselectivity.<sup>2564</sup> Polyurethane nanomicelles and polymeric ionic solvents have been used for the Cannizzaro reaction.<sup>2565</sup> The asymmetric intramolecular Cannizzaro reaction of aryl and alkyl glyoxals with alcohols, with a Cu/sterically hindered trisoxazoline catalyst, gave the  $\alpha$ -hydroxy ester.<sup>2566</sup> Cannizzaro-type reactions were catalyzed by lipase and done in water.<sup>2567</sup>  $\alpha$ -Keto aldehydes undergo an internal Cannizzaro reaction, where the product is an  $\alpha$ -hydroxy carboxylate.<sup>2568</sup> This product is also obtained on alkaline hydrolysis of compounds of the formula RCOCHX<sub>2</sub>. Similar reactions have been performed on  $\alpha$ -keto acetals<sup>2569</sup> and  $\gamma$ -keto aldehydes.

The mechanism<sup>2570</sup> of the Cannizzaro reaction<sup>2571</sup> involves a hydride shift (an example of mechanism type 2, Sec. 19.A). First, hydroxide adds to the C=O to give a tetrahedral intermediate, RCHC(OH)O<sup>-</sup>, which may lose a proton in the basic solution to give the di-ion, RCHC(O<sup>-</sup>)<sub>2</sub>. The strong electron-donating character of O<sup>-</sup> greatly facilitates the ability of the aldehyde hydrogen to leave with its electron pair. Hydride is transferred to

another molecule of aldehyde. The hydride can come from the tetrahedral intermediate or the dianion. Evidence for this mechanism is: (i) the reaction can be first order in base and second order in substrate or, at higher base concentrations, second order in each; and (ii) when the reaction was run in D<sub>2</sub>O, the recovered alcohol contained no α deuterium,<sup>2572</sup> indicating that the hydrogen comes from another equivalent of aldehyde and not from the medium.<sup>2573</sup>

An aza-Cannizzaro reaction is known.<sup>2574</sup>

### 19-86 The Tishchenko Reaction

When aldehydes, with or without an α hydrogen, are treated with aluminum ethoxide, one molecule is oxidized and another reduced, as in **19-85**, but here they are found as the ester. The process is called the *Tishchenko reaction*.<sup>2575</sup> Crossed-Tishchenko reactions are also possible. With more strongly basic alkoxides, such as Mg or sodium alkoxides, aldehydes with an α hydrogen give the *aldol reaction*. Treatment of a dialdehyde, such as phthalic dicarboxaldehyde (phthalaldehyde) with CaO, leads to a lactone.<sup>2576</sup> Like **19-85**, this reaction has a mechanism that involves hydride transfer.<sup>2577</sup> The Tishchenko reaction can also be catalyzed<sup>2578</sup> by Ru complexes,<sup>2579</sup> organoactinides,<sup>2580</sup> and alkaline earth amides.<sup>2581</sup> Both CaO (noted above) and SrO have been used as catalysts.<sup>2582</sup> The bis Al(*O-i-Pr*)<sub>2</sub> derivative of catechol has also been used as a catalyst.<sup>2583</sup>

Selenide ions, generated *in situ* from Bu<sub>2</sub>Se<sub>2</sub> and Bu<sub>2</sub>Mg, catalyzed the Tishchenko reaction.<sup>2584</sup> The crossed Tishchenko reaction of two aldehydes, catalyzed by Ni with a NHC ligand, gave the corresponding ester.<sup>2585</sup> A *Tishchenko-aldol transfer reaction* was reported using β-hydroxy ketones and an aldehydes with an AlMe<sub>3</sub> catalyst, giving a mono acyl diol.<sup>2586</sup> Thiolate has been used to catalyze the crossed Tishchenko reaction.<sup>2587</sup>

19-87 The Pummerer Rearrangement<sup>2588</sup>

When sulfoxides bearing an  $\alpha$  hydrogen are treated with acetic anhydride, the product is an  $\alpha$ -acetoxy sulfide. This is one example of *the Pummerer rearrangement*,<sup>2589</sup> in which the sulfur is reduced while an adjacent carbon is oxidized.<sup>2590</sup> The product is readily hydrolyzed (**10-6**) to the aldehyde  $\text{R}_2\text{CHO}$ .<sup>2591</sup> Besides acetic anhydride, other anhydrides and acyl halides give similar products. Inorganic acids, such as HCl, also give the reaction, and  $\text{RSOCH}_2\text{R}'$  can be converted to  $\text{RSClR}'$  in this way. Sulfoxides can also be converted to  $\alpha$ -halo sulfides<sup>2592</sup> by other reagents, including sulfonyl chloride, NBS, and NCS. Enantioselective Pummerer rearrangements are known.<sup>2593</sup> Uncatalyzed thermal rearrangements are also known.<sup>2594</sup>

A four-step mechanism<sup>2595</sup> has been proposed for the reaction between acetic anhydride and DMSO.<sup>2596</sup>

For DMSO and acetic anhydride, the final step is intermolecular, as shown by <sup>18</sup>O isotopic labeling studies.<sup>2597</sup> With other substrates, however, this step can be inter- or intramolecular, depending on the structure of the sulfoxide.<sup>2598</sup> Depending on the substrate and reagent, any of the first three steps can be rate determining. In the case of DMSO treated with  $(\text{F}_3\text{CCO})_2\text{O}$ , the intermediate corresponding to **34**<sup>2599</sup> could be isolated at low

temperature, and on warming gave the expected product.<sup>2600</sup> There is much other evidence for this mechanism.<sup>2601</sup>

Methiothiomethyl esters were prepared from carboxylic acids via a microwave-assisted Pummerer rearrangement with DMSO.<sup>2602</sup> A Cu-catalyzed Pummerer-type reaction has been reported.<sup>2603</sup> A sila-Pummerer rearrangement has been reported.<sup>2604</sup> A seleno-Pummerer reaction gave O, Se acetals.<sup>2605</sup>

### 19-88 The Willgerodt Reaction

In the *Willgerodt reaction*, a straight- or branched-chain aryl alkyl ketone is converted to the amide and/or the ammonium salt of the acid by heating with ammonium polysulfide.<sup>2606</sup> The carbonyl group of the product is always at the end of the chain. Thus ArCOCH<sub>2</sub>CH<sub>3</sub> gives the amide and the salt of ArCH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>H, and ArCOCH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub> gives derivatives of ArCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub>H. However, yields sharply decrease with increasing length of chain. The reaction has also been carried out on vinylic and ethynyl aromatic compounds and on aliphatic ketones, but yields are usually lower in these cases. Unlike the *Pummerer rearrangement* (19-87), which involves transposition of an oxygen from S to C, the Willgerodt reaction involves oxygen migration *and* oxidation of the organic species. The use of sulfur and a dry primary or secondary amine (or ammonia) as the reagent is called the *Kindler modification* of the Willgerodt reaction.<sup>2607</sup> The product in this case is Ar(CH<sub>2</sub>)<sub>n</sub>CSNR<sub>2</sub>,<sup>2608</sup> which can be hydrolyzed to the acid. Particularly good results are obtained with morpholine as the amine. For volatile amines, the HCl salts can be used instead, with NaOAc in DMF at 100 °C.<sup>2609</sup> The Kindler modification has also been applied to aliphatic ketones.<sup>2610</sup> Thioamides have been prepared from ketones in a base-catalyzed reaction.<sup>2611</sup>

Alkyl aryl ketones can be converted to aryl acetic acid derivatives in an entirely different manner. The reaction consists of treatment of the substrate with silver nitrate and I<sub>2</sub> or Br<sub>2</sub>.<sup>2612</sup>

<sup>2611</sup> For a review, see Poupaert, J.H.; Bouinidane, K.; Renard, M.; Lambert, D.; Isa, M. *Org. Prep. Proceed. Int.* **2001**, 33, 335.

<sup>2612</sup> Higgins, S.D.; Thomas, C.B. *J. Chem. Soc., Perkin Trans. I* **1982**, 235. See also, Higgins, S.D.; Thomas, C.B. *J. Chem. Soc., Perkin Trans. I* **1983**, 1483.

The mechanism of the Willgerodt reaction is not completely known, but some conceivable mechanisms can be excluded. Thus, one might suppose that the alkyl group becomes completely detached from the ring, and then attacks it with its other end. However, this possibility is ruled out by experiments results. When isobutyl phenyl ketone (**35**) is subjected to the Willgerodt reaction, the product is **36**, not **37**; **37** would arise if the end carbon of the ketone became bonded to the ring in the product.<sup>2613</sup>

This mechanism also excludes a cyclic intermediate similar to that of the *Claisen rearrangement* (**18-33**). Another important fact is that the reaction is successful for singly branched side chains, such as **35**, but not for doubly branched side chains, as in  $\text{PhCOCMe}_3$ .<sup>2613</sup> Still another piece of evidence is that compounds oxygenated along the chain give the same products; thus  $\text{PhCOCH}_2\text{CH}_3$ ,  $\text{PhCH}_2\text{COMe}$ , and  $\text{PhCH}_2\text{CH}_2\text{CHO}$  all give  $\text{PhCH}_2\text{CH}_2\text{CONH}_2$ .<sup>2614</sup> All these facts point to a mechanism consisting of consecutive oxidations and reductions along the chain, although just what form these take is not certain. Initial reduction to the hydrocarbon can be ruled out, since alkylbenzenes do not give the reaction. In certain cases, imines<sup>2615</sup> or enamines<sup>2616</sup> have been isolated from primary and secondary amines, respectively, and these have been shown to give the normal products, leading to the suggestion that they may be reaction intermediates.

## The Literature of Organic Chemistry

All discoveries in the laboratory must be published if the information is to be made available to the scientific community. A new experimental result that is not published is useless to the chemical community. Traditionally, the total body of chemical knowledge (called *the literature*) is located on the combined shelves of all the chemical libraries in the world. Nowadays, books remain on library shelves, but many, if not most, chemical journals are available online. As e-books are increasingly available, books are increasingly available online or for personal electronic reading devices. Anyone who wishes to learn the answer to a chemical question will need to access the chemical literature, both books and original articles in journals. Perhaps the most expedient method of searching a question is to “Google™” it, but extreme caution must be exercised to evaluate the source of the information, since there is little or no control of what may be posted on the internet. The answers to simple questions are quickly obtained by this method, but the answers for more complex questions should be confirmed by examining the original journal references (see below) and/or by using multiple sources.

The expressions “is known,” “has been done,” etc., usually means “has been published.” The contents of the scientific literature may appear formidably large, but the process of extracting information from the literature of organic chemistry is usually manageable. This appendix examines both the print literature of organic chemistry<sup>1</sup> and, within reasonable limits, electronic forms of the literature.

It is quite clear that the literature can be divided into two broad categories: primary sources and secondary sources. A *primary source* publishes the original results of laboratory investigations, usually in scientific journals but also in patents. Books, indexes, and other publications that cover material that has previously been published in primary sources are called *secondary sources*. Electronic search engines that use primary sources as a database are also considered to be secondary sources. It is because of the excellence of the secondary sources in organic chemistry (especially *Chemical Abstracts*, *SciFinder*) that literature searching is comparatively straightforward.

## A. PRIMARY SOURCES

### A.i. Journals

From the mid-nineteenth century onwards, nearly all new work in organic chemistry (except for that disclosed in patents) has been published in journals. There are many journals that publish chemical papers, in many countries, and in many languages. Nowadays, a high percentage of the journals are published in English, but not all. Some printed journals cover all fields of science, some are restricted to chemistry, some to organic chemistry, and some are still more specialized. Most journals are now available in electronic form.<sup>2</sup> The actual article is usually offered as both an html file and a PDF file, often with links to the cited references. The concept of “pure” organic chemistry is not as useful nowadays because organic chemistry is important in many areas, and multi-disciplinary research often includes organic chemistry. Literature that is important to an organic chemist is found in journals and patents that focus on bioorganic, organometallic, materials science, polymer science, separation science, medicinal chemistry, pharmaceutical sciences, and medicine, to name a few. The reader is therefore cautioned that the journals listed in this section have organic chemistry as their primary focus, but are by no means the only sources of information concerning organic chemistry. The literature is vast and many journals are published weekly and some semi-monthly.

Ordinary papers, usually referred to as full papers, may include full experimental details as part of the paper itself. With the increase in the volume of chemical literature, and especially with the proliferation of electronic journals, many journals now place full experimental details into “Supplemental Information.” For journals published by the American Chemical Society, a URL link is provided for each article that contains the supplemental information: experimental details, spectral data, visual reproductions of spectral data, X-ray crystallographic data, etc. Other publishers offer similar links. Such details are the mainstay of modern research, providing a guide to what has been done, and the experimental details allow one to repeat that work, assuming the reader has the expertise in the laboratory, at the same level as the authors of the work. Once a paper is accepted, the online version (such as American Chemical Society ASAP papers) can be found before the print version or the full electronic version that contains the page numbers appear.

In addition to full papers, there are two other types of publications in which original work is reported: *notes* and *communications*. A note is a brief paper, often without a summary (nearly all papers are published with summaries or abstracts prepared by the author). Otherwise, a note is similar to a paper.<sup>3</sup> Some journals specialize in publishing only notes. Communications (also called *letters*) are also brief and usually without summaries (some journals now publish summaries along with their communications), and there are journals that publish only communications or letters.

Communications differ from notes and papers in three respects:

1. They are brief, not because the work is of small scope, but because they are condensed. Usually they include only the most important experimental details or none at all.

<sup>2</sup> For examples of the contents of an academic electronic library see <http://lib.uconn.edu/> or <http://www.chem.ox.ac.uk/cheminfo/ejournals.html>. Also see eJournal Locator.

<sup>3</sup> In some journals notes are called “short communications,” an unfortunate practice, because they are not communications as that term is defined in this text.

2. They are often of immediate significance. Journals that publish communications make every effort to have them appear as soon as possible after they are received. With modern computer technology, communications can often be published in a matter of weeks.
3. Communications are preliminary reports, and the material in them may be republished as papers at a later date, in contrast to the material in papers and notes, which cannot be republished.

The number of journals is in flux, as is the languages of publication. The six prominent traditional European journals (*Chemische Berichte*, *Liebigs Annalen der Chemie*, *Bulletin de la Société Chimique de France*, *Bulletin des Sociétés Chimique Belges*, *Recueil des Travaux Chimiques des Pays-Bas*, and *Gazzetta Chimica Italiana*) were discontinued. In their place is the *European Journal of Organic Chemistry*, published in English. Many of the articles published in other languages have summaries printed in English also. Important papers were published in German and French for over 200 years, and these were generally not available in translation, so that the organic chemist was required to have at least a reading knowledge of these languages. Before about 1920, more than half of the important chemical papers were in these languages. In recent years, however, fewer papers in French or German have appeared without an English translation, and computer technology often allows relatively rapid translation of many languages. It can be argued that a reading knowledge of French and German (especially German) is critical for the older literature. Many, if not most, chemistry departments have modified their language requirements, or dropped them altogether. However, it should be realized that the original literature is never obsolete. Nineteenth century journals with primary literature are found in most chemical libraries and are still consulted, although they are often not available electronically and the archive section of modern university libraries must be consulted. With the rise of Japan and China in the scientific community, journals are published in Japanese and Chinese. However, work by Chinese and Japanese scientists regularly appears in English-language journals.

Table A.1 presents a list of important current journals that publish original papers<sup>4</sup> and communications in organic chemistry. Some of them also publish review articles, book reviews, and other material.

For some years, the American Chemical Society journals, including *J. Am. Chem. Soc.* and *J. Org. Chem.*, provided supplementary material for some of their papers on microfilm or microfiche. As noted above, this material is now available online, and for older literature is available from the Microforms and Back Issues Office at the ACS Washington office, either on microfiche or as a photocopy. These newer methods have not yet succeeded in substantially reducing the total volume of the world's primary chemical literature since many new journals have appeared, and the yearly page count for most journals has doubled or tripled.

## A.ii. Patents

In many countries, including the United States, it is possible to patent a new compound or a new method for making a known compound (either laboratory or industrial procedures). It comes as a surprise to many to learn that a substantial proportion of the patents granted have been chemical patents. Chemical patents are part of the chemical literature, and both U.S.

<sup>4</sup> In Table A.1 notes are counted as papers.

**TABLE A.1 A list of the more important *current* journals that currently publish original papers in organic chemistry, listed in alphabetical order of *Chemical Abstracts* abbreviations, which are given. Also given are the year of founding, number of issues per year as of 2018, and whether the journal primarily publishes papers (P), communications (C), or both**

No.	Name, year of founding and abbreviation	Papers or communications	Issues per year

<sup>6</sup> Before 1978 this journal was called *Roczniki Chemii (Rocz. Chem.)*.<sup>7</sup> *Pure Appl. Chem.* publishes IUPAC reports and lectures given at IUPAC meetings.<sup>8</sup> Before 1989 this journal was called *Reviews of Chemical Intermediates*, abbreviated as *Rev. Chem. Intermed.*

and foreign patents were regularly abstracted by *Chemical Abstracts* and now *SciFinder*. In addition to learning about the contents of patents from this source, chemists may consult the *Official Gazette* of the U.S. Patent Office,<sup>9</sup> published weekly and available in many libraries, which lists the titles of all the patents issued that week. Bound volumes of all U.S. patents are kept in a number of large libraries, including the New York Public Library, which also has an extensive collection of foreign patents. Patents are available via *SciFinder* (formerly, *CAS Online*).

Although patents are often very useful to the laboratory chemist, and no literature search is complete that neglects relevant patents, as a rule they are not as reliable as papers. There are two reasons for this:

1. It is in the interest of the inventor to claim as much as possible. The patent may show, for example, that a reaction was actually carried with ethanol and with propan-1-ol, but will claim all primary alcohols, and perhaps even secondary and tertiary alcohols, glycols, and phenols. An investigator repeating the reaction on an alcohol that the inventor did not use may find that the reaction gives no yield at all. In general, it is safest to duplicate the actual examples given, of which most chemical patents contain one or more.
2. Although legally a patent gives an inventor a monopoly, any alleged infringements must be protected in court, and this may cost a good deal of money. Therefore some patents are written so that certain essential details are concealed or entirely omitted. A patent is supposed to be a full disclosure, but patent attorneys are generally skilled in the art of writing patents, and procedures given are not always sufficient to duplicate the results.

It is important to state that the above statements do not apply to all chemical patents: many make full disclosures and claim only what was actually done. It must also be pointed out that it is not always possible to duplicate the work reported in every paper in a journal due to the use of proprietary catalysts or equipment not available to the public, and it is not uncommon for the patent owner to buy up what is literally the world's supply of a key ingredient. It is noted, however, that some work is not published or patented but rather maintained within the company as a trade secret. Such work is, of course, not available to the public.

## B. SECONDARY SOURCES

Journal articles and patents contain virtually all of the original work in organic chemistry. However, if this were all, if there were no indexes, abstracts, review articles, and other secondary sources, the literature would be unusable. It is so vast that no one could hope to find anything in particular. Fortunately, the secondary sources are excellent. There are various kinds and the classification shown here is somewhat arbitrary.

### B.i. Listings of Titles

The profusion of original papers is vast, but publications usually provide a Table of Contents with a graphical abstract that allows one to scan the contents rather quickly.

<sup>9</sup> <https://www.uspto.gov/learning-and-resources/official-gazette/>

*Chemical Abstracts* was available online as *CAS Online*, but this service has been supplanted by *SciFinder* (see Appendix A, D.iii). University libraries and companies pay the appropriate fees so access to the journals is usually quite easy if one is affiliated with these organizations. Search engines allow one to quickly scan an enormous amount of literature from office or home. However, the number of pertinent “hits” can be enormous, depending on the scan parameters. In other words, the search may return several hundred thousand or even millions of “hits,” and for the most part only 5–20 of the returned items will be surveyed. In addition, most browsers have online searching capabilities via various search engines, and simply typing in an author, a topic, a chemical, or a few key words can lead to important articles or information. “Google® searching”<sup>10</sup> is commonly employed for a “quick and dirty” search, but, as noted above, the source of much information is not clear and one is strongly urged to use one of the established scientific search engines for a proper search. The more important online technology will be discussed below.

Other resources<sup>11</sup> include *Specialty Citation Indexes*, *Science Citation Index Expanded*<sup>TM</sup>, *Web of Science*<sup>®</sup>, *Science Citation Index*<sup>®</sup>, *ISI Proceedings*<sup>SM</sup>, *Reaction Citation Index*<sup>TM</sup>, and the *Derwent Innovations Index*<sup>SM</sup>. The discussion will begin with the older print versions for chemical searches.

A print-version “title” publication covering the whole of chemistry is *Current Contents Physical, Chemical & Earth Sciences*,<sup>12</sup> which began in 1967 and appears weekly, contains the contents pages of all issues of about 800 journals in chemistry, physics, earth sciences, mathematics, and allied sciences. Each issue contains an index of important words taken from the titles of the papers listed in that issue, and an author index, which, however, lists only the first-named author of each paper. The author’s address is also given, so that one may write for reprints. An online service is available and is a multi-disciplinary Web resource.<sup>13</sup>

## B.ii. Abstracts

This section is largely devoted to using the printed *Chemical Abstracts*. With *SciFinder* and *Reaxys*, it is likely that many if not most readers will have no need of this section. However, the section remains for those who may need to access and use the more arcane search methods. If nothing else, this section is a reminder that there are alternative search methods that may be of value.

Listings of titles are valuable, as far as they go, but they do not tell what is in the paper, beyond the implications carried by the titles. Most current journals contain a graphic abstract as well as a title and a brief print description of the research. The graphical abstract is extremely useful for scanning the literature presented in a journal, and both the print and graphical abstracts are available online for most journals.

From the earliest days of organic chemistry, abstracts of papers have been widely available. A publication entirely devoted to abstracts covering the whole field of chemistry was *Chemical Abstracts (CA)*, which was published until 2010. Abstracts are now available online via *SciFinder*. Although now out of print, knowledge of *Chemical Abstracts* may be important to properly do a literature search that includes older literature, although with

<sup>10</sup> [www.google.com/](http://www.google.com/)

<sup>11</sup> See <http://scientific.thomson.com/products/categories/citation/>

<sup>12</sup> Title pages of organic chemistry journals are also carried by *Current Contents Life Sciences*, which is a similar publication covering biochemistry and medicine.

<sup>13</sup> <http://www.ovid.com/site/catalog/databases/862.jsp>

modern computer searching such a statement may be out of date. *Chemical Abstracts* appeared weekly, printing abstracts in English of virtually every paper containing original work in pure or applied chemistry published anywhere in the world.<sup>14</sup> The abstracts appeared in 80 sections, with sections 21 to 34 devoted to organic chemistry, under such headings as “Alicyclic Compounds,” “Alkaloids,” “Physical Organic Chemistry,” “Heterocyclic Compounds (One Heteroatom),” etc. Each abstract of a paper had a heading that gave (i) the abstract number;<sup>15</sup> (ii) the title of the paper; (iii) the authors’ names as given in the paper; (iv) the authors’ address; (v) the abbreviated name of the journal (see Table A.1);<sup>16</sup> (vi) the year, volume, issue, and page numbers; and (vii) the language of the paper. In earlier years *CA* gave the language only if it differed from the language of the journal title. Abstracts of patents showed the abstract number, title, inventor and company (if any), patent number, patent class number, date patent issued, country of priority, patent application number, date patent applied for, and number of pages in the patent. The body of the abstract contained a concise summary of the information in the paper. For many common journals the author’s summary (if there is one) was used in *CA* as it appeared in the original paper, with perhaps some editing and additional information. Each issue of *CA* contained an author index, a patent index, and an index of keywords taken from the titles and the texts or contexts of the abstracts. The patent index listed all patents in order of number. The same compound or method is often patented in several countries. *CA* abstracted only the first patent, but listed the patent numbers of the duplicated patents in the patent index along with all previous patent numbers that correspond to it. Before 1981 there were separate Patent Number Indexes and Patent Concordances (the latter began in 1963).

*Chemical Abstracts* is useful as a repository of chemical information, a place for finding out what was done in the past. This value stems from the excellent indexes, which enable the chemist in most cases to ascertain quickly where information is located. From the time of its founding in 1907 until 1961, *CA* published annual indexes. After 1962 there were two volumes published each year, and a separate index was issued for each volume. Beginning in 1972 the subject index was issued in two parts, a chemical substance index and a general subject index, which included all entries that are not the names of single chemical substances. However, the indexes to each volume were essentially superseded by each collective index. The first collective indexes were ten-year (decennial) indexes, but the volume of information made five-year indexes necessary from 1956. Collective indexes so far published are shown in Table A.2.

As noted above, the print form of *Chemical Abstracts* has been superseded by *SciFinder* (see Appendix A, D.iii).

Beginning with the *Eighth Collective Index* period, *CA* has published an *Index Guide*. This publication gave structural formulas and/or alternate names for thousands of compounds, as well as many other cross-references. It was designed to help the user find *CA* references to subjects of interest in the general subject, formula, and chemical substance indexes efficiently and rapidly. Each collective index contained its own *Index Guide*. The *Index Guide* was necessary because the *CA* general subject index was a “controlled index,” meaning it restricted its entries only to certain terms.

For example, anyone looking for the term “refraction” in the printed general subject index would not find the term. The *Index Guide* included this term, and directed the reader

<sup>14</sup> For a guide to the use of *CA*, see Schulz, H. *From CA to CAS ONLINE*, VCH, NY, 1988.

<sup>15</sup> Began in 1967. See Appendix A/B.ii.

<sup>16</sup> These abbreviations are changed from time to time. Therefore the reader may notice inconsistencies.

TABLE A.2 CA collective indexes

Collective Index	General Subject Index	Chemical Substance Index	Author Index	Formula Index	Patent Index
1	1907–1916		1907–1916		
2	1917–1926		1917–1926		1907–1936
3	1927–1936		1927–1936	1920–1946	
4	1937–1946		1937–1946		1937–1946

13	1992–1996	1992–1996	1992–1996	1992–1996	1992–1996
14	1997–2001	1997–2001	1997–2001	1997–2001	1997–2001
15	2002–2006	2002–2006	2002–2006	2002–2006	2002–2006

Note that Volumes 146–167 are published, but Collective Volumes are unavailable.

to “Electromagnetic wave, refraction of,” “Sound and ultrasound, refraction of,” and other terms, all of which *were* found in the general subject index. Similarly, the chemical substance index usually listed a compound only under one name, the approved CA name. Trivial and other names were found in the *Index Guide*. For example, the term “methyl carbonate” is not in the chemical substance index, but the *Index Guide* does have this term, and directs the reader to the chemical substance index under the headings “carbonic acid, esters, dimethyl ester” (for  $\text{Me}_2\text{CO}_3$ ) and “carbonic acid, esters, monomethyl ester” (for  $\text{MeHCO}_3$ ). Furthermore, the *Index Guide* gives terms related to the chosen term, helping users to broaden a search. For example, one who looks for “Atomic orbital” in the *Index Guide* will find the terms “Energy Level,” “Molecular orbital,” “Atomic integral,” and “Exchange, quantum mechanical, integrals for,” all of which are controlled index terms.

Each index (annual, semiannual, or collective) also provided an index of ring systems. This valuable index enables the user to ascertain immediately if any ring system appears in the corresponding subject or chemical substance index and under what names.

Benz(*h*)isoquinoline

For example, someone wishing to determine whether any compounds containing the benz(*h*)isoquinoline ring system are reported in the 1982–1986 collective index would locate, under the heading “3-ring systems,” the listing **6,6,6** (since the compound has three rings of six members each), and would find the sublisting  $\text{C}_5\text{N}-\text{C}_6-\text{C}_6$  (since one ring contains five carbons and a nitrogen while the others are all carbon), under which is listed the name benz(*h*)isoquinoline, as well as the names of 30 other  $\text{C}_5\text{N}-\text{C}_6-\text{C}_6$  systems. A search of the chemical substance index under these names will give all references to these ring systems that appeared in CA from 1982 to 1986.

However, this method of search is now probably outdated. Nowadays, the drawing tools of *SciFinder* (see Appendix A, D.iii) or *Reaxys* (Appendix A, D.vi) are used to *draw* this structure and then perform the search.

Before 1967, *CA* used a two-column page, with each column separately numbered. A row of letters from *a* to *h* appeared down the center of the page for the guidance of the user. Thus an entry 7337*b* refers to the *b* section of column 7337. In early years superscript numbers, e.g., 4327<sup>5</sup>, were used in a similar manner. In very early years these numbers were not printed on the page at all, though they are given in the decennial indexes, so that the user needed to mentally divide the page into nine parts. Beginning with 1967, abstracts were individually numbered and column numbers were discarded. Therefore, beginning with 1967, index entries give the abstract number rather than the column number. The abstract numbers are followed by a letter that serves as a check character to prevent miscopying errors in computer handling. To use the *CA* general subject, chemical substance, and formula indexes intelligently requires practice, and the student should become familiar with representative volumes of these indexes and with the introductory sections to them, as well as with the *Index Guides*.

In the *CA* formula indexes formulas were listed in order of: (i) number of carbon atoms; (ii) number of hydrogen atoms; (iii) other elements in alphabetic order. Thus, all C<sub>3</sub> compounds are listed before any C<sub>4</sub> compound, all C<sub>5</sub>H<sub>7</sub> compounds before any C<sub>5</sub>H<sub>8</sub> compound, C<sub>7</sub>H<sub>11</sub>Br before C<sub>7</sub>H<sub>11</sub>N, C<sub>9</sub>H<sub>6</sub>N<sub>4</sub>S before C<sub>9</sub>H<sub>6</sub>O, etc. Deuterium and tritium are represented by D and T and treated alphabetically, e.g., C<sub>2</sub>H<sub>5</sub>DO after C<sub>2</sub>H<sub>5</sub>Cl and before C<sub>2</sub>H<sub>5</sub>F or C<sub>2</sub>H<sub>6</sub>.

Since 1965, *CA* has assigned a Registry Number<sup>17</sup> to each unique chemical substance. This is a number of the form [766-51-8] (which is 2-chloroanisole) and which remains invariant, no matter what names are used in the literature. More than 137 million numbers have already been assigned and thousands are added each week. Registry Numbers are primarily for computer use, but chemical suppliers use CAS registry numbers to identify chemicals that are available for sale.

There were a number of earlier abstracting publications now defunct. The most important were *Chemisches Zentralblatt* and *British Abstracts*.

### B.iii. Beilstein

This publication has been so important to organic chemistry that it deserves a section by itself. Beilstein's *Handbuch der Organischen Chemie*, usually referred to just as *Beilstein*, lists all the known organic compounds reported in the literature during its period of coverage. The print version will be described first, as it is particularly important for older literature. Although the online version may be used most often, a working knowledge of the print version remains an important tool in a chemist's literature arsenal.

For each compound in *Beilstein*, the following data are given: all names; the molecular formula; the structural formula; all methods of preparation (briefly, e.g., "by refluxing 1-butanol with NaBr and sulfuric acid"); physical constants such as melting point, refractive index, etc.; other physical properties; chemical properties including reactions; occurrence in nature (i.e., which species it was isolated from); biological properties, if any; derivatives with melting points; analytical data; and any other information that has been reported in the literature.<sup>18</sup> Equally importantly, for every piece of information, a reference is given to the

<sup>17</sup> See <http://www.cas.org/expertise/cascontent/registry/regsyst.html>

<sup>18</sup> For a discussion of how data are processed for inclusion in Beilstein, see Luckenbach, R.; Ecker, R.; Sunkel, J. *Angew. Chem. Int. Ed. Engl.* **1981**, *20*, 841 [*Angew. Chem.* *93*, 876].

original literature. Furthermore, the data in *Beilstein* have been critically evaluated. That is, all information is carefully researched and documented, and duplicate and erroneous results are eliminated. Some compounds are discussed in two or three lines and others require several pages.

The print editions are invaluable for searching older literature, but, even today, they provide valuable data for many compounds that are used every day. A discussion of using *Beilstein* is therefore essential.

The first three editions of *Beilstein* are obsolete. The fourth edition (*vierte Auflage*), fifth supplement edition, covers the literature from 1960 through 1979. In this edition, the earliest work is covered in *das Hauptwerk* (the basic work), which consists of 27 volumes. The compounds are arranged in order of a system too elaborate to discuss fully here.<sup>19</sup> The compounds are divided into three divisions that are further subdivided into “systems”:

Division	Volumes	System numbers
I. Acyclic Compounds	1–4	1–499
II. Carbocyclic Compounds	5–16	450–2359
III. Heterocyclic Compounds	17–27	2360–4720

*Das Hauptwerk* is still the basis of *Beilstein* and has not been superseded. The later literature is covered by supplements that have been arranged to parallel *das Hauptwerk*. The same system is used, so that the compounds are treated in the same order. The first supplement (*erstes Ergänzungswerk*) covers 1910–1919; the second supplement (*zweites Ergänzungswerk*) covers 1920–1929; the third supplement (*drittes Ergänzungswerk*) covers 1930–1949; the fourth supplement (*viertes Ergänzungswerk*) covers 1950–1959, and the fifth supplement covers 1960–1979. Like *das Hauptwerk*, each supplement contains 27 volumes,<sup>20</sup> except that supplements 3 and 4 are combined for vols. 17 to 27, so that for these volumes the combined third and fourth supplement covers the years 1930–1959.

Each supplement has been divided into volumes in the same way as *das Hauptwerk*, and, for example, compounds found in vol. 3, system number 199, of *das Hauptwerk* will also be found in vol. 3, system number 199, of each supplement. To make cross-referencing even easier, each supplement gives, for each compound, the page numbers at which the same compound can be found in the earlier books. Thus, on page 554 of vol. 6 of the fourth supplement, under the listing “phenetole” are found the symbols (H 140; E I 80; E II 142; E III 545) indicating that earlier information on phenetole is given on page 140 of vol. 6 of *das Hauptwerk*, on page 80 of the first, page 142 of the second, and page 545 of the third supplement. Furthermore, each page of the supplements contains, at the top center, the corresponding page numbers of *das Hauptwerk*. Since the same systematic order is followed in all six series, location of a compound in any one series gives its location in the other five. If a compound is found, for example, in vol. 5 of *das Hauptwerk*, one only has to note the page number and scan vol. 5 of each supplement until that number appears in

<sup>19</sup> For descriptions of the *Beilstein* system and directions for using it, see Sunkel, J.; Hoffmann, E.; Luckenbach, R. *J. Chem. Educ.* **1981**, *58*, 982; Luckenbach, R. *CHEMTECH* **1979**, 612. The *Beilstein* Institute has also published two English-language guides to the system. One, available free, is *How to Use Beilstein*, *Beilstein Institute, Frankfurt/Main, 1979*. The other is by Weissbach, O. *A Manual for the Use of Beilstein's Handbuch der Organischen Chemie*, Springer, NY, **1976**. An older work, which many students will find easier to follow, is by Huntress, E.H. *A Brief Introduction to the Use of Beilstein's Handbuch der Organischen Chemie*, 2nd ed., Wiley, NY, **1938**.

<sup>20</sup> In some cases, to keep the system parallel and to avoid books that are too big or too small, volumes are issued in two or more parts, and, in other cases, two volumes are bound as one.

the top center of the page (the same number often covers several pages). Of course, many compounds are found in only one, two, three, four, or five of the series, since no work may have been published on that compound during a particular period covered.

From *das Hauptwerk* to the fourth supplement, *Beilstein* is in German, but it is not difficult to read since most of the words are the names of compounds. Also, a *Beilstein* German–English Dictionary, available free from the publisher, is in many libraries. For the fifth supplement (covering 1960–1979), and which is in English, publication of Division III began before the earlier divisions. Volumes 17 to 22 (totaling 70 separate parts exclusive of index volumes) of this supplement have been published, as well as a combined index for volumes 17–19. This index covers only the fifth supplement. The subject portion of this index, which lists compound names only, gives these names in English.

Volumes 28 and 29 of *Beilstein* are subject and formula indexes, respectively. The most recent complete edition of these volumes is part of the second supplement and covers only *das Hauptwerk* and the first two supplements (though complete indexes covering *das Hauptwerk* and the first four supplements have been announced to appear in the next few years). For vol. 1 there is a cumulative subject and a cumulative formula index, which combine *das Hauptwerk* and the first four supplements.<sup>21</sup> Similar index volumes, covering all four supplements, have been issued for the other volumes, 2 to 27. Some of these are combined, e.g., 2–3, 12–14, and 23–25. For English-speaking chemists (and probably for many German-speaking chemists) the formula indexes are more convenient. Of course (except for the fifth supplement indexes), one must still know some German, because most formula listings contain the names of many isomers. If a compound is found only in *das Hauptwerk*, the index listing is merely the volume and page numbers, e.g., 1, 501. Roman numbers are used to indicate the supplements, for example, 26, 15, I 5, II 7. Thus the subject and formula indexes lead at once to locations in *das Hauptwerk* and the first four supplements. The *Beilstein* formula indexes are constructed the same way as the *CA* indexes (see Appendix A, B.ii).

There is also a fourth division of *Beilstein* (systems 4721 to 4877) that covers natural products of uncertain structure: rubbers, sugars, etc. These are treated in vols. 30 and 31, which do not go beyond 1935 and which are covered in the collective indexes. These volumes will not be updated. All such compounds are now included in the regular *Beilstein* volumes.

In recent years, *Beilstein* was available online, with the useful search engine *CrossFire*. However, this database is now incorporated into *Reaxys* (see Appendix A, D.vi).

#### B.iv. Tables of Information

In addition to *Beilstein*, there are many other print reference works in organic chemistry that are essentially compilations of data. These books are very useful and often save the research worker a great deal of time. In this section we discuss some of the more important of such works.

1. The sixth edition of *Heilbron's Dictionary of Organic Compounds*, J. Buckingham, Ed., 9 vols., Chapman and Hall, London, 1996, contains brief listings of more

<sup>21</sup> Most page number entries in the combined indexes contain a letter, e.g., CHBr<sub>2</sub>Cl 67f, II 33a, III 87d, IV, 81. These letters tell where on the page to find the compound and are useful because the names given in the index are not necessarily those used in the earlier series. The letter “a” means the compound is the first on its page, “b” is the second, etc. No letters are given for the fourth supplement.

- than 150 000 organic compounds, giving names, structural formulas, physical properties, and derivatives, with references. Additional data concerning occurrence, biological activity, and toxicity hazard information are also given for many entries. The arrangement is alphabetical. The dictionary contains indexes of names, formulas, heteroatoms, and CA Registry Numbers. Annual supplements, with cumulative indexes, have appeared since 1983. A similar work, devoted to organometallic compounds, is the 2nd edition of the *Dictionary of Organometallic Compounds*, 6 vols. in its 5th Supplement, published by Chapman and Hall in **1989**. Another, *Dictionary of Steroids*, 2 vols., 1991, is also published by Chapman and Hall.
2. A multi-volume compendium of physical data is *Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, Geophysik, und Technik*, 6th ed., by H. Landolt and R. Börnstein, Springer, Berlin, **1950**. There is also a "New Series," for which the volumes are given the English title *Numerical Data and Functional Relationships in Science and Technology*, as well as the German title. This compendium, which is not yet complete, lists a great deal of data, some of which are of interest to organic chemists, e.g., indexes of refraction, heats of combustion, optical rotations, and spectral data. Literature references are given for all data.
  3. *The Handbook of Chemistry and Physics*, CRC Press, Boca Raton, FL (called the "rubber handbook"), which is revised annually (99th ed., **2018**; Ruble, J., ed.), is a valuable repository of data that can be quickly found. For organic chemists an important table is *Physical Constants of Organic Compounds*, which lists names, formulas, color, solubility, and physical properties of thousands of compounds. However, there are many other useful tables. A similar work is *Lange's Handbook of Chemistry*, 17th ed., McGraw-Hill, New York, **2016**; Speight, J., ed. Another such handbook, but restricted to data of interest to organic chemists, is *Dean's Handbook of Organic Chemistry*, 2nd ed., McGraw-Hill, New York, **2003**. This book also contains a long table of *Physical Constants of Organic Compounds* and has much other information, including tables of thermodynamic properties, spectral peaks,  $pK_a$  values, bond distances, and dipole moments.
  4. A list of most of the known natural compounds, e.g., terpenes, alkaloids, carbohydrates, to which structures have been assigned, along with structural formulas, melting points, optical rotations, and references, is provided in T.K. Devon and A.J. Scott, *Handbook of Naturally Occurring Compounds*, 3 vols., Academic Press, New York, **1972**.
  5. R.R. Dreisbach, *Physical Properties of Chemical Compounds*, Advances in Chemistry Series nos. 15, 22, 29, American Chemical Society, Washington, **1955–1961**, lists many physical properties of more than 1000 organic compounds.
  6. Physical properties of thousands of organometallic compounds, with references, are collected in five large compendia: the *Dictionary of Organometallic Compounds*, mentioned earlier in this list under item 1, above; M. Dub, *Organometallic Compounds*, 2nd ed., 3 vols. with supplements and index, Springer, New York, **1966–1975**; N. Hagihara, M. Kumada, and R. Okawara, *Handbook of Organometallic Compounds*, W.A. Benjamin, New York, **1968**; and H.C. Kaufman, *Handbook of Organometallic Compounds*, Van Nostrand, Princeton, NJ, **1961**; *Comprehensive Organometallic Chemistry II*, 14 vols., Pergamon, **1995**.
  7. The *Merck Index*, 14th ed., Merck and Company, Rahway, NJ, **2006**, is a good source of information about chemicals of medicinal importance. The newest *Merck Index* is

available online from the Royal Society of Chemistry.<sup>22</sup> Many drugs are given three types of name: chemical *name* (which is the name an organic chemist would give it; of course, there may well be more than one); *generic name*, which must be placed on all containers of the drug; and *trade names*, which are different for each company that markets the drug. For example, the generic name for 1-(4-chlorobenzhydryl)-4-methylpiperazine is chlorcyclazine. Among the trade names for this drug, which is an antihistamine, are Trihistan, Perazyl, and Alergicide. The *Merck Index* is especially valuable because it gives all known names of all three types for each compound and the names are cross-indexed. Also given, for each compound, are the structural formula, *CA* preferred name and Registry Number, physical properties, medicinal and other uses, toxicity indications, and references to methods of synthesis. There are indexes of formulas and Registry Numbers, and miscellaneous tables. The *Merck Index* also includes a lengthy list of organic name reactions, with references.

8. There are two publications that list properties of azeotropic mixtures. J. Timmermans, *The Physico-chemical Constants of Binary Systems in Concentrated Solutions*, 4 vols., Interscience, New York, **1959–1960**, is by far the more comprehensive. The other is *Azeotropic Data*, 2 vols., Advances in Chemistry Series no. 6 and no. 35, American Chemical Society, Washington, **1952, 1962**.
9. Thousands of dipole moments, with references, are collected in V.A.L. McClellan, *Tables of Experimental Dipole Moments*, vol. 1, W.H. Freeman, San Francisco, CA, **1963**; vol. 2, Rahaara Enterprises, El Cerrita, CA, **1974**.
10. *Tables of Interatomic Distances and Configurations in Molecules and Ions*, London Chemical Society Special publication no. 11, **1958**, and its supplement, Special publication no. 18, **1965**, include bond distances and angles for hundreds of compounds, along with references.
11. The *Ring Systems Handbook*, published in 1988 by the Chemical Abstracts Service, provides the names and formulas of ring and cage systems that have been published in *CA*. The ring systems are listed under a system essentially the same as that used for the *CA* index of ring systems (see Appendix A, B.i, Appendix A, B.ii). Each entry gives the *CA* index name and Registry Number for that ring system. In many cases a *CA* reference is also given. There is a separate *Formula Index* (for the parent ring systems) and a *Ring Name Index*. Cumulative supplements are issued twice a year. The *Ring Systems Handbook* supersedes earlier publications called *The Parent Compound Handbook* and *The Ring Index*.
12. Spectra Data. The Sadtler Research Laboratories published large collections of IR, UV, NMR, and other spectra, in loose-leaf form. Indexes are available. An usable online site is available that has extensive spectral data, known as Spectral Database for Organic Compounds, SDBS, managed by the National Institute of Advanced Industrial Science and Technology (AIST), Japan. See [http://sdbs.db.aist.go.jp/sdbs/cgi-bin/cre\\_index.cgi](http://sdbs.db.aist.go.jp/sdbs/cgi-bin/cre_index.cgi)
13. Infrared, UV, NMR, Raman, and mass spectral data, as well as melting-point, boiling-point, solubility, density, and other data for more than 30 000 organic compounds are collected in the *CRC Handbook of Data on Organic Compounds*, 2nd ed., 9 vols., CRC Press, Boca Raton, FL, **1988**, edited by R.C. Weast and J.G. Grasselli. It differs from the Sadtler collection in that the data are given in tabular

<sup>22</sup> <https://www.rsc.org/merck-index?e=1>

form (lists of peaks) rather than reproduction of the actual spectra, but this book has the advantage that all the spectral and physical data for a given compound appear in one place. References are given to the Sadtler and other collections of spectra. Volumes 7 to 9 contain indexes of spectral peaks for IR, UV, NMR,  $^{13}\text{C}$  NMR, mass, and Raman spectra, as well as indexes of other names, molecular formulas, molecular weights, and physical constants. Annual updates began appearing in 1990 (the first one is called volume 10).

14. The *Aldrich Library of Infrared Spectra*, 3rd ed., Aldrich Chemical Company, Milwaukee, WI, **1981** (C. Pouchert), contains more than 12 000 IR spectra so arranged that the user could readily see the change that takes place in a given spectrum when a slight change is made in the structure of a molecule. The same company also publishes the *Aldrich Library of FT-IR Spectra* and the *Aldrich Library of NMR Spectra*, both also by C. Pouchert. A similar volume, which has IR and Raman spectra of about 1000 compounds, is *Raman/Infrared Atlas of Organic Compounds*, 2nd ed., VCH, New York, **1989**, by B. Schrader.
15. An extensive list of visible and UV peaks is given in *Organic Electronic Spectral Data*, Wiley, New York. Twenty-six volumes have appeared so far, covering the literature through 1984.
16. A collection of 500  $^{13}\text{C}$  NMR spectra is found in L.F. Johnson and W.C. Jankowski, *Carbon-13 NMR Spectra*, Wiley, New York, **1972**.

### C. REVIEWS

A review article is an intensive survey of a rather narrow field. For example, the titles of some recent reviews are “Frustrated Lewis Pairs Catalyzed Asymmetric Metal-Free Hydrogenations and Hydrosilylations,”<sup>23</sup> and “Green and Sustainable Solvents in Chemical Processes.”<sup>24</sup> A good review article is of enormous value, because it is a thorough survey of all the work done in the field under discussion. Review articles are printed in review journals and in certain books. The most important review journals in organic chemistry (though most are not exclusively devoted to organic chemistry) are shown in Table A.3. Some of the journals listed in Table A.1 also publish occasional review articles.

There are several open-ended serial publications that are similar in content to the review journals but are published irregularly (seldom more often than once a year) and are hard-bound. Some of these publish reviews in all fields of chemistry; some cover only organic chemistry; some specialize further. The coverage is indicated by the titles. Table A.4 shows some of the more important such publications, with their *CA* abbreviations.

Another publication is the *Index of Reviews in Organic Chemistry*, compiled by D.A. Lewis, Chemical Society, London, a classified listing of review articles. Classified lists of review articles on organometallic chemistry are found in articles by Smith and Walton<sup>25</sup> and by Bruce.<sup>26</sup> A similar list for heterocyclic chemistry is found in articles by A. Katritzky and others.<sup>27</sup> See also the discussion of the *Index of Scientific Reviews* in sec. Appendix A, D.iv.

<sup>23</sup> Meng, W.; Feng, X.; Du, H. *Acc. Chem. Res.* **2018**, *51*, 191.

<sup>24</sup> Clarke, C.J.; Tu, W.-C.; Levers, O.; Bröhl, A.; Hallett, J.P. *Chem. Rev.* **2018**, *118*, 747.

<sup>25</sup> Smith, J.D.; Walton, D.R.M. *Adv. Organomet. Chem.* **1975**, *13*, 453.

<sup>26</sup> Bruce, M.I. *Adv. Organomet. Chem.* **1972**, *10*, 273; **1973**, *11*, 447; **1974**, *12*, 380.

<sup>27</sup> Belen'kii, L.I. *Adv. Heterocycl. Chem.* **1988**, *44*, 269; Katritzky, A.R.; Jones, P.M. *Adv. Heterocycl. Chem.* **1979**, *25*, 303; Katritzky, A.R.; Weeds, S.M. *Adv. Heterocycl. Chem.* **1966**, *7*, 225.

### C.i. Annual Reviews

The review articles discussed in Table A.3 are each devoted to a narrow topic covering the work done in that area over a period of years. An annual review is a publication that covers a broad area but limits the period covered, usually to 1 or 2 years.

1. The oldest annual review publication still publishing is *Annual Reports on the Progress of Chemistry*, published by the Royal Society of Chemistry (formerly the Chemical Society), which began in 1905 and which covers the whole field of chemistry. Since 1967 it has been divided into sections. Organic chemistry is found in Section B.
2. Because the number of papers in chemistry has become so large, the Royal Society of Chemistry publishes annual review-type volumes of smaller scope, called *Specialist Periodical Reports*. Among those of interest to organic chemists are *Carbohydrate Chemistry* (vol. 22 covers 1988), *Photochemistry* (vol. 21 covers 1988–1989), and *General and Synthetic Methods*, (vol. 12 covers 1987).
3. *Organic Reaction Mechanisms*, published by Wiley, New York, is an annual survey that covers the latest developments in the field of mechanisms. The first volume, covering 1965, appeared in 1966.
4. There are two annual reviews devoted to progress in organic synthesis. Theilheimer, *Synthetic Methods of Organic Chemistry*, S. Karger, Verlag, Basel, is an annual

<sup>28</sup> Successor to *Quarterly Reviews* (abbreviated as *Q. Rev., Chem. Soc.*).

<sup>29</sup> Formerly called *Fortschritte der Chemischen Forschung* (abbreviated as *Fortschr. Chem. Forsch.*).

TABLE A.4 Irregularly published serial publications

Title	Abbreviation
Advances in Carbocation Chemistry	<i>Adv. Carbocation Chem.</i>
Advances in Carbohydrate Chemistry and Biochemistry	<i>Adv. Carbohydr. Chem. Biochem.</i>
Advances in Catalysis	<i>Adv. Catal.</i>

Survey of Progress in Chemistry	<i>Surv. Prog. Chem.</i>
Topics in Physical Organometallic Chemistry	<i>Top. Phys. Organomet. Chem.</i>
Topics in Stereochemistry	<i>Top. Stereochem.</i>

compilation, beginning in 1946, of new methods for the synthesis of organic compounds, arranged according to a system based on bond-closing and bond-breaking reactions. Equations, brief procedures, yields, and literature references are given. Volume 44 was issued in 1990. Volumes 3 and 4 are available only in German, but all the rest are in English. There is an index to each volume. Cumulative indexes appear in every fifth volume. Beginning with vol. 8, each volume includes a short summary of trends in synthetic organic chemistry. A more recent series is *Annual Reports in Organic Synthesis*, Academic Press, New York, which has covered the literature of each year since 1970. Equations are listed with yields and references according to a fairly simple system.

### C.ii. Awareness Services

Besides the annual reviews and the title and abstract services previously mentioned, there exist a number of publications designed to keep readers aware of new developments in organic chemistry or in specific areas of it.

1. *Chemtracts: Organic Chemistry* is a bimonthly periodical, begun in 1988, that prints abstracts of certain recently published papers (those that the editors consider most important), with commentaries on these papers by distinguished organic chemists. Important current research in bioorganic, organometallic, synthesis, physical-organic and theoretical chemistry, and pharmaceutical/medicinal chemistry is covered in each issue, giving readers updates on the newest trends and developments in organic chemistry by summarizing and commenting on current and past research.
2. The Institute for Scientific Information (ISI), besides publishing *Current Contents* (see Appendix A, B.i) and the *Science Citation Index* (see Appendix A, B.i), also publishes *Index Chemicus* (formerly called *Current Abstracts of Chemistry and Index Chemicus*). This publication, begun in 1960 and appearing weekly, is devoted to printing structural formulas of all new compounds appearing in more than 100 journals, along with equations to show how they were synthesized, and an author's summary of the work. Each issue contains five indexes: author, journal, biological activity, labeled compounds, and intermediates that were not isolated. These indexes are cumulated annually.
3. Theilheimer and the *Annual Reports on Organic Synthesis*, mentioned in the previous section, list new synthetic methods once a year. There are several publications that do this monthly. Among these are *Current Chemical Reactions* (begun in 1979 and published by ISI), *Journal of Synthetic Methods* (begun in 1975 and published by Derwent Publications), and *Methods in Organic Synthesis*, begun in 1984 and published by the Royal Society of Chemistry. *Methods in Organic Synthesis* also lists books and review articles pertaining to organic synthesis.
4. *Natural Product Updates*, a monthly publication (begun in 1987 and published by the Royal Society of Chemistry), lists recent results in the chemistry of natural products, along with structural formulas. It covers new compounds, structure determinations, new properties, and total syntheses, among other topics.

### C.iii. General Treatises

There are a number of large-scale multi-volume treatises that cover the whole field of organic chemistry or large areas of it.

1. *Rodd's Chemistry of Carbon Compounds*, edited by S. Coffey, Elsevier, Amsterdam, is a treatise consisting of five main volumes, each of which contains several parts. Publication began in 1964 and is not yet complete. The organization is not greatly different from most textbooks, but the coverage is much broader and deeper. Supplements to many of the volumes have appeared. An earlier edition, called *Chemistry of Carbon Compounds*, edited by E.H. Rodd, was published in 10 parts from 1951 to 1962.
2. Houben-Weyl's *Methoden der Organischen Chemie*, Georg Thieme Verlag, Stuttgart, is a major treatise in German devoted to laboratory methods. The fourth edition, which was begun in 1952 and consists of 20 volumes, most of them in several parts, is edited by E. Muller. The series includes supplementary volumes. The first four volumes contain general laboratory methods, analytical methods, physical methods, and general chemical methods. The later volumes are devoted to the

- synthesis of specific types of compounds, e.g., hydrocarbons, oxygen compounds, nitrogen compounds, etc. Beginning in 1990 parts of the series have appeared in English.
3. *Comprehensive Organic Chemistry*, Pergamon, Oxford, **1979**, is a six-volume treatise on the synthesis and reactions of organic compounds. The first three volumes cover the various functional groups, vol. 4 covers heterocyclic compounds, and vol. 5 covers biological compounds such as proteins, carbohydrates, and lipids. Probably the most useful volume is vol. 6, which contains formula, subject, and author indexes, as well as indexes of reactions and reagents. The last two of these not only refer to pages within the treatise, but directly give references to review articles and original papers. Several similar treatises, including the nine-volume *Comprehensive Organometallic Chemistry* (**1982**), the eight-volume *Comprehensive Heterocyclic Chemistry* (**1984**), and the six-volume *Comprehensive Medicinal Chemistry* (**1989**) were also published by Pergamon, Oxford. The indexes to these works also include references.
  4. A major treatise devoted to experimental methods of chemistry is *Techniques of Chemistry*, edited first by A. Weissberger and then by J.K.M. Saunders, Wiley, New York. This publication, which began in 1970, so far consists of 21 volumes, most of them in several parts, covers such topics as electrochemical and spectral methods, kinetic methods, photochromism, and organic solvents. *Techniques of Chemistry* is a successor to an earlier series, called *Techniques of Organic Chemistry*, which appeared in 14 volumes, some of them in more than one edition, from 1945 to 1969.
  5. *Comprehensive Chemical Kinetics*, edited by C.H. Bamford and C.F.H. Tipper, **1969**-, Elsevier, Amsterdam, is a multi-volume treatise covering the area of reaction kinetics. Six of these volumes (not all published at the time of writing) deal with the kinetics and mechanisms of organic reactions in a thorough and comprehensive manner.
  6. Three multi-volume treatises that cover specific areas are R.C. Elderfield, *Heterocyclic Compounds*, Wiley, New York, **1950**-; R.H.F. Manske and H.L. Holmes, *The Alkaloids*, Academic Press, New York, **1950**; and J.L. Simonson, L.N. Owen, D.H.R. Barton, and W.C.J. Ross, *The Terpenes*, Cambridge University Press, London, **1947–1957**.
  7. *Encyclopedia of Reagents for Organic Synthesis*, edited by L. Paquette, Wiley, New York, was published in 1995. It is an 8-volume, alphabetic listing of reagents used in organic chemistry with descriptions of the preparation, use, and chemistry, with references. Each reagent was researched by organic chemists active in research, who contributed to the total publication. This work is available online as *eEROS*, which provides updated information on approximately 3800 reagents with a database of close to 50 000 reactions. Each reagent entry includes properties such as physical data, solubility, form supplied in, purification, and preparative methods; examples of use in reactions; and literature references. Search options include: name, CAS number, structure, and reaction.
  8. *Comprehensive Organic Synthesis*, edited by B.M. Trost and I. Fleming, Pergamon, Oxford, was published in **1991**. It is a 9-volume compilation.
  9. *Comprehensive Organic Functional Group Transformations*, edited by A.R. Katritzky, O. Meth-Cohn, and C.W. Rees, Pergamon, was published in **1995**. It is a 7-volume compilation.

#### C.iv. Monographs and Treatises on Specific Areas

There are many books devoted to organic chemistry that provide a thorough coverage of a specific area. Many of these are essentially very long review articles, differing from ordinary review articles only in size and scope. Some are comprised of a series of articles, edited by an organic chemist for a specific area of research. Some of the books are by a single author, and others have chapters by different authors but all are carefully planned to cover a specific area. Many of these books have been referred to in footnotes in appropriate places in this book. There have been several series of monographs, one of which is worth special mention: *The Chemistry of Functional Groups*, under the general editorship of Z. Rappoport (S. Patai was the original editor), published by Wiley, New York. Each volume deals with the preparation, reactions, and physical and chemical properties of compounds containing a given functional group. There are more than 130 volumes in the series, including books on alkenes, cyano compounds, amines, carboxylic acids and esters, quinones, etc. Since 2003, the series has appeared both in print and online.

#### C.v. Textbooks

There are many excellent textbooks in the field of organic chemistry. Only a few of those published are listed, mostly since 1985. Some of these are first-year texts and some are advanced (advanced texts generally give references; first-year texts do not, though they may give general bibliographies, suggestions for further reading, etc.). Some books cover the whole field, and others cover reactions, structure, and/or mechanism only. All the books listed here are good textbooks and the advanced books are valuable reference books for graduate students and practicing chemists.

#### Undergraduate Level Books

- Smith, M.B. *Organic Chemistry: An Acid-Base Approach*, 2nd ed., CRC Press, Boca Raton, FL, **2018**.
- McMurry, *Organic Chemistry*, 9th ed., Cengage Learning, Independence, KY, **2015**.
- Carey and Giuliano, *Organic Chemistry*, 10th ed., McGraw-Hill, Columbus, OH, **2016**.
- Smith, J.H. *Organic Chemistry*, 5th ed., McGraw-Hill, **2016**.
- Vollhardt and Schore, *Organic Chemistry, Structure and Function*, 7th ed., W.H. Freeman, NY, **2014**.
- Bruice, *Organic Chemistry*, 8th ed., Prentice-Hall, NJ, **2016**.
- Jones and Fleming, *Organic Chemistry*, 5th ed., W.W. Norton, New York, **2014**.
- Klein, *Organic Chemistry*, 2nd ed., Wiley, NJ, **2013**.
- Loudon, *Organic Chemistry*, 6th ed., W.H. Freeman, NY, **2015**.
- Solomons and Fryhle, *Organic Chemistry*, 12th ed., Wiley, NY, **2016**.
- Streitwieser, Heathcock, and Kosower, *Clayton's Introduction to Organic Chemistry*, Medtech, **2017**.

#### Graduate Level Books

- Smith, M.B. *Organic Synthesis*, 4th ed., Academic Press (Elsevier), NY/London, **2016**.
- Carey and Sundberg, *Advanced Organic Chemistry: Structure and Mechanisms (Part A)*, 5th ed., Springer, **2008**.

- Carey and Sundberg, *Advanced Organic Chemistry: Structure and Mechanisms (Part B)*, 5th ed., Springer, **2010**.
- Carruthers and Coldham, *Some Modern Methods of Organic Synthesis*, 4th ed., Cambridge University Press, Cambridge, **2004**.
- Lowry and Richardson, *Mechanism and Theory in Organic Chemistry*, 3rd ed., Harper and Row, New York, **1987**.
- Mundy, Ellerd, and Favalaro Jr., *Name Reactions and Reagents in Organic Synthesis*, 2nd ed., Wiley, **2005**.
- House, *Modern Synthetic Reactions*, 2nd ed., W.A. Benjamin, New York, **1972**.
- Bruckner, *Advanced Organic Chemistry: Reaction Mechanisms*, Academic Press, **2001**.
- Grossman, *The Art of Writing Reasonable Organic Reaction Mechanisms*, 2nd ed., Springer, **2007**.
- Sykes, *A Guidebook to Mechanism in Organic Chemistry*, 6th ed., Longmans Scientific and Technical, Essex, **1986**.
- Ritchie, *Physical Organic Chemistry*, 2nd ed., Marcel Dekker, New York, **1989**.
- Isaacs, *Physical Organic Chemistry*, Wiley, New York, **1987**.
- Maskill, *The Physical Basis of Organic Chemistry*, Oxford University Press, Oxford, **1985**.
- Ingold, *Structure and Mechanism in Organic Chemistry*, 2nd ed., Cornell University Press, Ithaca, NY, **1969**.

### C.vi. Other Books

In this section several books are mentioned that do not fit conveniently into the previous categories. All but the last have to do with laboratory synthesis.

1. *Organic Syntheses*, published by Wiley, New York, is a collection of procedures for the preparation of specific compounds. *Organic Syntheses* is currently available online.<sup>30</sup> The annual volumes have appeared each year since 1921 and currently volume 95 is available. For the first 59 volumes, the procedures for each 10- (or 9-) year period are collected in cumulative volumes. Beginning with vol. 60, the cumulative volumes cover five-year periods. The cumulative volumes published so far are:

Annual volumes	Collective volumes
1–9	<b>I</b>
10–19	<b>II</b>
20–29	<b>III</b>
30–39	<b>IV</b>
40–49	<b>V</b>
50–59	<b>VI</b>
60–64	<b>VII</b>
65–69	<b>VIII</b>
70–74	<b>IX</b>
75–80	<b>X</b>
81–84	<b>XI</b>

<sup>30</sup> <http://www.orgsyn.org/>

The advantage of the procedures in *Organic Syntheses*, compared with those found in original journals, is that these procedures are *tested*. Each preparation is carried out first by its author and then by a member of the *Organic Syntheses* editorial board, and only if the yield is essentially duplicated is the procedure published. While it is possible to repeat most procedures given in journals, this is not always the case. All *Organic Syntheses* preparations are noted in *Beilstein* and in *CA*. In order to locate a given reaction in *Organic Syntheses*, the reader may use the OS references given in the present volume (through OS 69); the indexes in *Organic Syntheses* itself; R. Shriner and R. Shriner, "*Organic Syntheses* Collective Volumes I, II, III, IV, V Cumulative Indices," Wiley, New York, 1976, or S. Sugasawa and S. Nakai; "Reaction Index of *Organic Syntheses*," Wiley, New York, 1967 (through OS 45). Another book classifies virtually all the reactions in *Organic Syntheses* (collective vols. I to VII and annual vols. 65 to 68) into eleven categories: annulation, rearrangement, oxidation, reduction, addition, elimination, substitution, C–C bond formation, cleavage, protection/deprotection, and miscellaneous. This is *Organic Syntheses: Reaction Guide*, by D. Liotta and M. Volmer, published by Wiley, New York, in 1991. Some of the categories are subdivided further, and some reactions are listed in more than one category. What is given under each entry are the equation and the volume and page reference to *Organic Syntheses*.

2. Volume 1 of *Reagents for Organic Synthesis*, by L. Fieser and M. Fieser, Wiley, New York, 1967, is a 1457-page volume that discusses, in separate sections, some 1120 reagents and catalysts. It tells how each reagent is used in organic synthesis (with references) and, for each, tells which companies sell it, or how to prepare it, or both. The listing is alphabetical. There are now a total of 25 volumes published as of 2009, which continue the format of vol. 1 and add more recent material. A cumulative index for vols. 1 to 12, by J. Smith and M. Fieser, was published in 1990. A cumulative index for volumes 1–22 was published in 2005, by M.B. Smith. The series included volumes 1–18 with Mary Fieser. After the death of Mary Fieser, the series was resumed by T.-L. Ho and now includes volumes 19–25.
3. *Comprehensive Organic Transformations*, 2nd ed., by R.C. Larock, Wiley-VCH, New York, 1999, has been frequently referred to in footnotes in Part II of this book. This compendium is devoted to listings of methods for the conversion of one functional group into another, and covers the literature through 1987. It is divided into nine sections covering the preparation of alkanes and arenes, alkenes, alkynes, halides, amines, ethers, alcohols and phenols, aldehydes and ketones, and nitriles, carboxylic acids, and derivatives. Within each section are given many methods for synthesizing the given type of compound, arranged in a logical system. A schematic equation is given for each method, and then a list of references (without author names, to save space) for locating examples of the use of that method. When different reagents are used for the same functional group transformation, the particular reagent is shown for each reference. There is a 164-page index of group transformations. The 2nd edition has only recently been published (and is *not* referenced in this edition) and a CD-ROM version is available.
4. *Survey of Organic Synthesis*, by C.A. Buehler and D.E. Pearson, Wiley, New York, 2 vols., 1970, 1977, discusses hundreds of reactions used to prepare the principal types of organic compounds. The arrangement is by chapters, each covering a functional group, e.g., ketones, acyl halides, amines, etc. Each reaction is thoroughly discussed and brief synthetic procedures are given. There are many references.

5. A similar publication is S. Sandler and W. Karo, *Organic Functional Group Preparations*, 2nd ed., 3 vols., Academic Press, New York, **1983–1989**. This publication covers more functional groups than Buehler and Pearson.
6. *Compendium of Organic Synthetic Methods*, Wiley, New York, contains equations describing the preparation of thousands of mono-functional and difunctional compounds, with references. Twelve volumes have been published so far (volumes 1–2, edited by I.T. Harrison and S. Harrison; volume 3, edited by L. Hegedus and L.G. Wade Jr.; volumes 4–5, edited by L.G. Wade Jr.; volumes 6–13, edited by M.B. Smith). The series has now been terminated.
7. *The Vocabulary of Organic Chemistry*, by M. Orchin, F. Kaplan, R.S. Macomber, R.M. Wilson, and H. Zimmer, Wiley, New York, **1980**, presents definitions of more than 1000 terms used in many branches of organic chemistry, including stereochemistry, thermodynamics, wave mechanics, natural products, and fossil fuels. There are also lists of classes of organic compounds, types of mechanism, and name reactions (with mechanisms). The arrangement is topical rather than alphabetical, but there is a good index. *Compendium of Chemical Terminology*, by V. Gold, K.L. Loening, A.D. McNaught, and P. Sehmi (the “Gold Book”), published by Blackwell Scientific Publications, Oxford, **1987**, is an official IUPAC list of definitions of terms in several areas of chemistry, including organic.

## D. LITERATURE SEARCHING

Until recently, searching the chemical literature meant looking only at printed materials (some of which might be on microfilm or microfiche). Now, however, virtually all of the literature can be searched online. Whether the search is online or uses only the printed material, there are two basic types of search: (i) searches for information about one or more specific compounds or classes of compounds and (ii) other types of searches. Searches using only printed materials will be discussed first and then online searching will be covered.<sup>31</sup>

### D.i. Literature Searching Using Printed Materials

#### Searching for Specific Compounds

Organic chemists often need to know if a compound has ever been prepared and, if so, how, and/or they may be seeking a melting point, an IR spectrum, or some other property. Someone who wants all the information that has ever been published on any compound begins by consulting the formula indexes in *Beilstein* (see Appendix A, B.iii). At the time of writing, there are two ways to do this.

1. The formula index to the second supplement (Vol. 29, see Appendix A, B.iii) will quickly show whether the compound is mentioned in the literature through 1929. If it is there, the searcher turns to the pages indicated, where all methods used to prepare the compound are given, as well as all physical properties, with references. Use of the page heading method described in Appendix A, B.iii will then show the locations, if any, in the third and later supplements.

<sup>31</sup> For a monograph that covers both online searching and searching using printed materials, see Wiggins, G. *Chemical Information Sources*, McGraw-Hill, NY, **1991**.

2. If one has an idea of the volume of *Beilstein* the compound is in (and the tables of contents at the front of the volumes may help), one may search the cumulative index for that volume. If not sure, one may consult several indexes.

One of these two procedures will locate all compounds mentioned in the literature through 1959. If the compound is heterocyclic, it may be in the fifth supplement. If it is in vols. 17–19 (or in a later volume whose index has been published), the corresponding indexes may be consulted. If not, the page heading method will find it, if it was reported before 1960.<sup>32</sup>

However, there is a way by which all of the above can be avoided. At this point the investigator will know (i) all information published through 1959 or 1979,<sup>31</sup> or (ii) that the compound is not mentioned in the literature through 1959 or 1979.<sup>33</sup> In some cases, scrutiny of *Beilstein* will be sufficient, perhaps if only a boiling point or a refractive index is required. In other cases, especially where specific laboratory directions are needed, the investigator will have to turn to the original papers.

To carry the search to more recent articles, the chemist needs to turn to the collective formula indexes of *Chemical Abstracts* and such later collective indexes as have appeared and the semiannual indexes thereafter. However, such searches now would use *SciFinder*.

If a compound has not been reported, the investigator *must know this fact* before proceeding with any research or attempts to publish. Indeed, this knowledge is perhaps the most important consideration when considering a new area of research. It should be pointed out that for common compounds, such as benzene, ether, acetone, etc., trivial mentions in the literature are not indexed (so they will not be found by this procedure), only significant ones. Thus, if acetone is converted to another compound, an index entry will be found, but not if it is used as a solvent or an eluant in a common procedure.

While online searching is extraordinarily powerful, it should be pointed out that there are two problems with computer searches.

First of all, far too many “hits” may be returned. For example, a 2011 research topic search (see Appendix A, D.iii) of the topic “macrolactones from hydroxy acids” using *SciFinder* gave these results:

Research Topic Candidates	Number of references
159 references were found containing the two concepts “macrolactones” and “hydroxy acids” closely associated with one another	159
474 references were found where the two concepts “macrolactones” and “hydroxy acids” were present anywhere in the reference	474
35157 references were found containing the concept “macrolactones”	35157
193323 references were found containing the concept “hydroxy acids”	193323

Clearly, only examining a few of these many references is practical. The search can, and must be, refined. Depending on the scope of the search, this fact can be a limitation.

<sup>32</sup> Compounds newly reported in the fifth supplement that are in a volume whose index has not yet been published will not be found by this procedure. To find them in *Beilstein* it is necessary to know something about the system, but they may also be found by consulting *SciFinder*.

<sup>33</sup> For those heterocyclic compounds that would naturally belong to a volume for which the fifth supplement has been published.

The second problem relates to the search words used (the keywords). If they are too broad, little useful information is returned. If the keywords are too narrow in scope, many useful references may be missed.

The point of these two cautions is to take care in choosing keywords. On the other hand, using many related keywords and doing multiple searches is very easy using *SciFinder*, and is probably a good strategy.

Often, all the information one needs about a compound will be found in one of the handbooks (see Appendix A, C.i), in the *Dictionary of Organic Compounds* (see Appendix A, C.i), or in one of the other compendia listed in this chapter, most of which give references to the original literature.

## Other Searches

There is no definite procedure for making other literature searches using only printed materials. Any chemist who wishes to learn all that is known about the mechanism of the reaction between aldehydes and HCN, for example, or which compounds of the general formula  $\text{Ar}_3\text{CR}$  have been prepared, or which are the best catalysts for *Friedel-Crafts acylation* of naphthalene derivatives with anhydrides, or where the group  $-\text{C}(\text{NH}_2)=\text{N}-$  absorbs in the IR, is dependent on ingenuity and knowledge of the literature.

If a specific piece of information is needed, it may be possible to find it in one of the compendia mentioned previously. If the topic is more general, the best procedure is often to begin by consulting one or more monographs, treatises, or textbooks that will give general background information and often provide references to review articles and original papers.

In many cases this is sufficient, but when a complete search is required, it is necessary to consult the *CA* subject and/or chemical substance indexes, and also *SciFinder*, where the ingenuity of the investigator is most required, because now it must be decided which words to look under. This statement relates to the keyword used for a computer search, as indicated above. If one is interested in the mechanism of the reaction between aldehydes and HCN, one might look under "aldehydes," or "hydrogen cyanide," or even under "acetaldehyde" or "benzaldehyde," etc., but then the search is likely to prove long. A better choice in this case would be "cyanohydrin," since these are the normal products and references there would be fewer. It would be a waste of time to look under "mechanism." In any case, many of the abstracts would not prove helpful. If it is necessary to search before 1907 (and even before 1920, since *CA* was not very complete from 1907 to about 1920), recourse may be made to *Chemisches Zentralblatt* and the abstracts in the *Journal of the Chemical Society*.

## D.ii. Literature Searching Online<sup>17</sup>

Most of the *Chemical Abstracts* literature can be accessed online via *CAS*, using *SciFinder* (see Appendix A, D.iii), which is the largest and most current database of chemical substance information in the world. *CAS* is located in Columbus, Ohio, and is a division of the American Chemical Society. *CAS* can be contacted at Chemical Abstracts Service, 2540 Olentangy River Road, P.O. Box 3012, Columbus, Ohio 43210 (E-mail: help@cas.org; online, [http://web.cas.org/forms/feedback.html?\\_ga=2.160480317.1255697471.1528740358-141076529.1528740358](http://web.cas.org/forms/feedback.html?_ga=2.160480317.1255697471.1528740358-141076529.1528740358)). *CAS* is a team of scientists who provide a digital information environment for scientific research and discovery. *CAS* provides pathways to published research in the world's journal and patent literature back to the beginning of the 20th century. Since 1907, *CAS* has indexed and summarized chemistry-related articles from more

than 40 000 scientific journals, in addition to patents, conference proceedings, and other documents pertinent to chemistry, life sciences, and many other fields. Through the printed *CA (Chemical Abstracts)*, *CA* on CD, STN (The Scientific & Technical Information Network), the *CAS* files distributed through licensed vendors, the *SciFinder* and *SciFinder Scholar* desktop research tools, and the *STN Easy* or *STN* on the Web services, data produced by *CAS* is accessible to virtually any scientific researcher worldwide in industry, governmental research institutions, and academia.

Substance identification is a special strength of *CAS*. It is widely known as the *CAS Registry*, the largest substance identification system in existence. When a chemical substance, newly encountered in the literature, is processed by *CAS*, its molecular structure diagram, systematic chemical name, molecular formula, and other identifying information are added to the Registry and it is assigned a unique *CAS Registry Number*.

The *CAS REGISTRY* mostly covers substances identified in the scientific literature from 1957 to the present, with some classes (fluorine- and silicon-containing compounds) going back to the early 1900s. An important piece of information that assists in such a search is the *CAS Registry Number*. Each substance in *REGISTRY* is identified by a unique numeric identifier called a *CAS Registry Number*.<sup>34</sup> “The *CAS Registry Number* is a unique number assigned to a chemical by the Chemical Abstracts Service.<sup>35</sup> A fairly large collection of *CAS* numbers, with links to safety data for many chemicals, can be found at the listing of chemicals by *CAS* number at the Safety Home Page of the Physical and Theoretical Chemistry Laboratory at Oxford University.”<sup>36</sup> The *CAS Registry Number* is a unique numeric identifier that designates only one substance, has no chemical significance, and is a link to finding information about a specific chemical substance. A *CAS Registry Number* includes up to 9 digits that are separated into 3 groups by hyphens. The first part of the number, starting from the left, has up to 6 digits; the second part has 2 digits. The final part consists of a single check digit.<sup>37</sup>

Online searching means using a computer terminal to search a *database*. Although databases in chemistry are available from several organizations, STN International is important because it is comprehensive and available in many countries. STN has dozens of databases, including many that cover chemistry and chemical engineering. To access these databases a chemistry department, a library, or an individual subscribes to STN (for a nominal fee), and receives code numbers that will permit access to the system, usually via a desktop computer.

### D.iii. Sci-Finder – the *CAS* database<sup>38</sup>

Tutorials are available to help use *SciFinder*.<sup>39</sup> *SciFinder* can search a research topic<sup>40</sup> or a compound can be searched by structure.<sup>41</sup> The search engine is known as STN Express with Discover!<sup>42</sup> and can easily and efficiently search over 200 scientific and technical databases

<sup>34</sup> <http://www.cas.org/EO/regsys.html>

<sup>35</sup> <http://www.cas.org/>

<sup>36</sup> <http://ptcl.chem.ox.ac.uk/MSDS/glossary/casnumber.html>

<sup>37</sup> <http://www.cas.org/EO/checkdig.html>

<sup>38</sup> <http://www.cas.org/>

<sup>39</sup> <http://www.cas.org/SCIFINDER/SCHOLAR/interact/>

<sup>40</sup> <http://www.cas.org/SCIFINDER/SCHOLAR/page2a.html>

<sup>41</sup> <http://www.cas.org/SCIFINDER/SCHOLAR/scholstruc.html>

<sup>42</sup> <http://www.cas.org/ONLINE/STN/discover.html>

online through STN<sup>®</sup>.<sup>43</sup> The Analysis Edition of STN Express with Discover! allows one to search, analyze, visualize, and discover sci-tech information by the ability to create a table for substance analysis that identifies the common substructure for an answer set of structurally related substances:

- Group related author/inventor names and company names for better analysis and visualization results.
- Analyze and tabulate data from single- or multi-file search results, and create a data table and 3-D chart
- Save an answer set from databases such as CAPLUS<sup>SM</sup>, PCTFULL, and USPATFULL with the Save for STN AnaVist Wizard, and then import and open it in STN<sup>®</sup> AnaVist<sup>TM</sup>.
- Create an interactive spreadsheet from all or only hit CAS Registry Numbers and their corresponding CAS Roles through the CAS Registry Number<sup>®</sup>.
- Upload lengthy genetic sequences automatically for searching in DGENE and PCTGEN via the Upload Query Wizard.

STN Express was developed in collaboration with Hampden Data Services.

To illustrate how STN is used, an online tutorial is available.<sup>44</sup> A few online windows from a *SciFinder* search are provided to illustrate how searches can be done. This presentation is by no means complete or intended as an alternative to the actual tutorial. Indeed, one could *not* use *SciFinder* properly after simply reading this discussion. The intent is to illustrate some features that are available and to present an overview of the use of this important tool.

Using *SciFinder*<sup>®</sup>, a search can be done in one of several different ways. Searches can be done by research topic, by substances, or by reactions. The latter two searches use drawing tools that are part of *SciFinder*. An example is shown of a search done by research topic.<sup>45</sup> The example shown in Figure A.1 shows a search for intramolecular hydroamination of aminoalkenes. To begin, click “Explore by Research Topic” and enter the appropriate information.

It is possible to use filters (see Figure A.1) in order to refine the search by year, document type (journal, patent, review, etc.), author, or company. A window is returned that contains references categorized by their relationship to the search phrase, as shown in Figure A.2. One simply checks those reference lists that appear closest to those of interest.

After clicking on “Get References,” a screen is returned (Figure A.3) that has the original references, as shown in the window. One is given the option of refining this list further, and for each reference, most browsers allow viewing the abstract or the full references as an HTML or a PDF file. However, your library must have paid the appropriate fees so the journal and volumes of interest are available online. Otherwise, interlibrary loan or direct ordering of the article may be necessary.

Other examples of typical searches allowed by *SciFinder* include search by author's name,<sup>46</sup> as with the example of Professor K. Barry Sharpless shown in Figure A.4. Search by structure is also possible,<sup>47</sup> such as the example shown in Figure A.5, using the *SciFinder*

<sup>43</sup> <http://www.cas.org/stn.html>

<sup>44</sup> <http://www.cas.org/ONLINE/STN/expressmac.pdf>

<sup>45</sup> <http://www.cas.org/SCIFINDER/topic.html>

<sup>46</sup> <http://www.cas.org/SCIFINDER/author.html>

<sup>47</sup> <http://www.cas.org/SCIFINDER/structure.html>

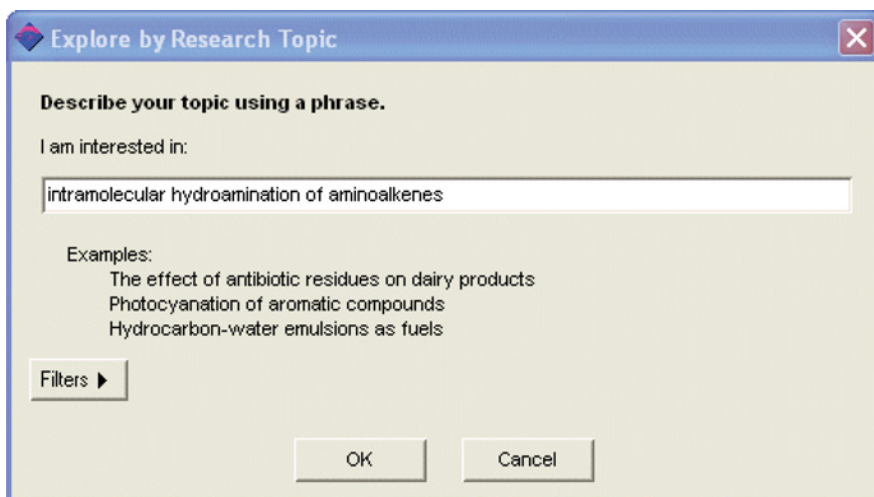

FIGURE A.1. Explore by research topic.

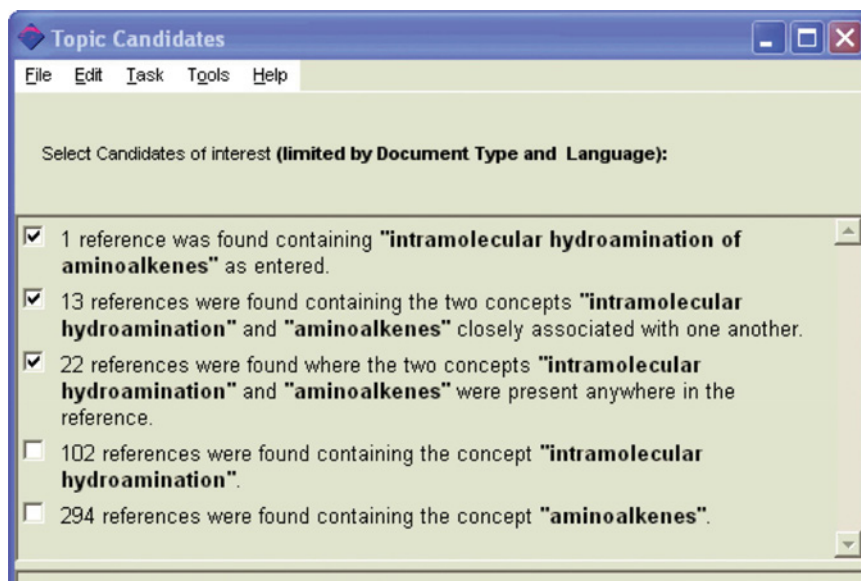

FIGURE A.2. Selection of candidates of interest for search by research topic.

drawing tools. Once a structure is drawn, *SciFinder* searches to find matches based on that structure. The drawing tools can be used to show a reaction, and reaction information is returned, as shown in Figure A.6. Ultimately, journal article and/or patents are returned that provide direct access to the literature of interest.

#### D.iv. Science Citation Index

As seen in the *SciFinder* search tutorials, it is possible to track papers that have cited a particular article or author. A publication that can greatly facilitate literature searching is

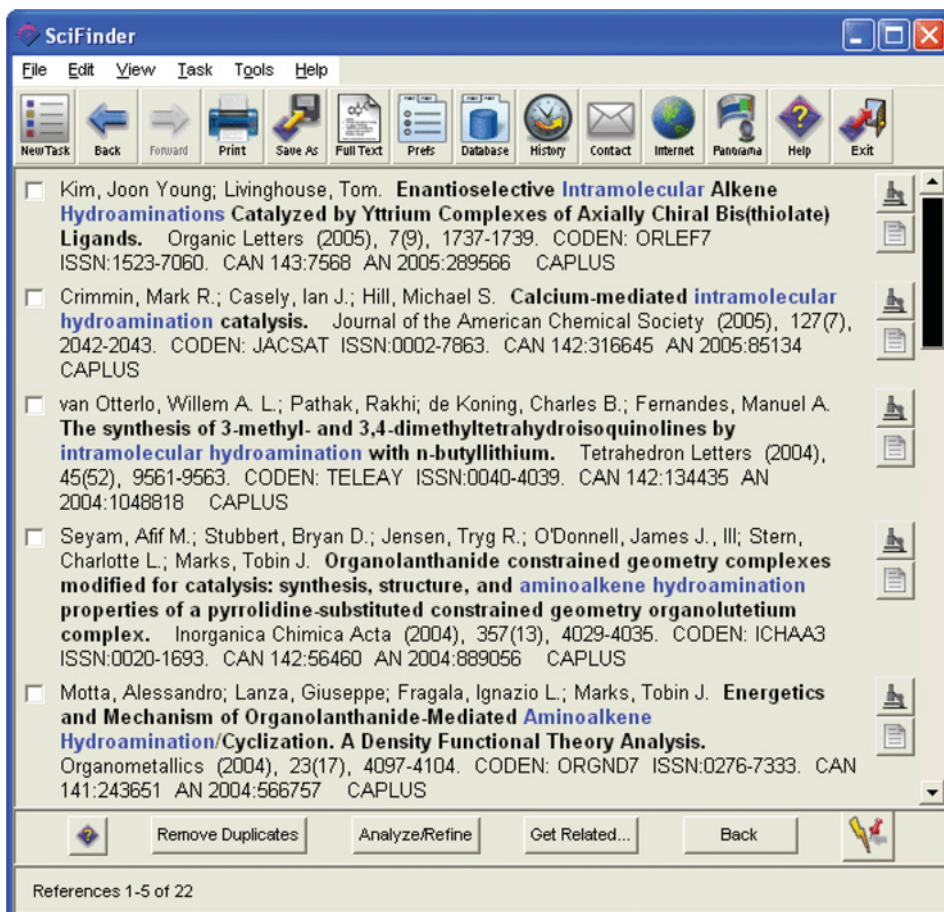

FIGURE A.3. Original literature references returned for search by research topic.

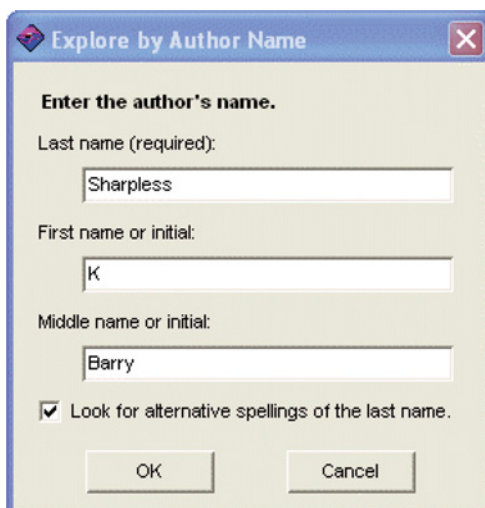

FIGURE A.4. Screen shot for beginning a search by author.

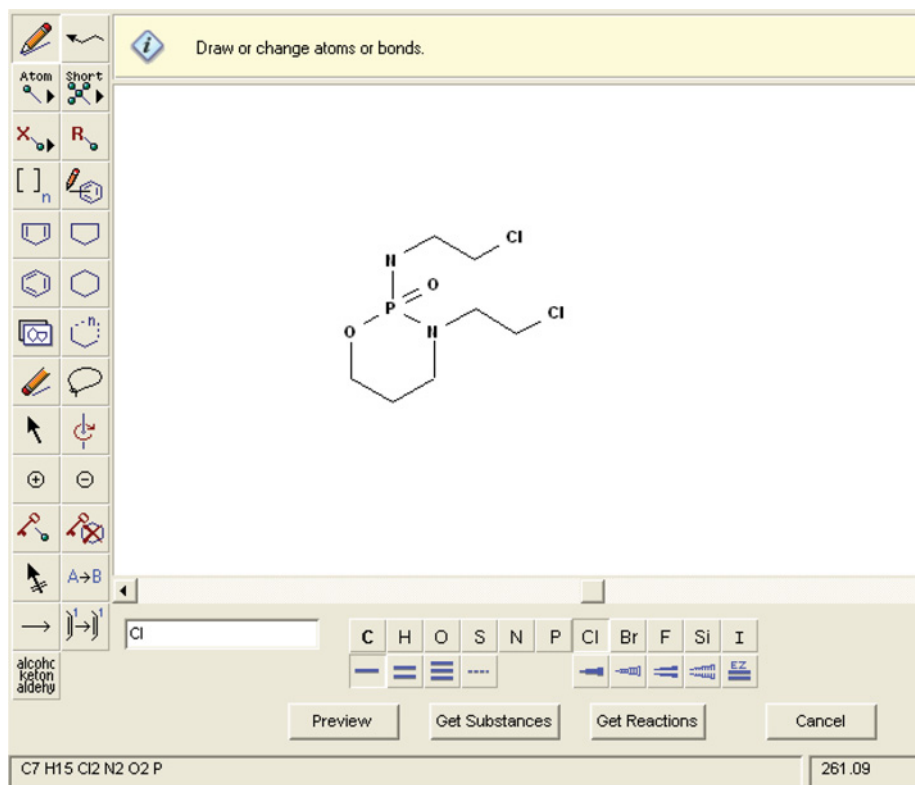

FIGURE A.5. Screen shot for beginning a search by structure, using the drawing tools.

*Science Citation Index (SCI)*, begun in 1961. This publication, which is quite different from any other mentioned in this chapter, gives a list of all papers in a given year that have cited a given paper, patent, or book. Its utility lies in the fact that it enables the user to search *forward* from a given paper or patent, rather than backward, as is usually the case. For example, suppose a chemist is familiar with a paper by W.P. Jencks and M. Gilchrist (*J. Am. Chem. Soc.*, **1968**, 90, 2622) entitled "Nonlinear Structure-Reactivity Correlations. The Reactivity of Nucleophilic Reagents toward Esters." The chemist is easily able to begin a search for earlier papers by using references supplied in this paper and can then go further backward with the aid of references in those papers, etc. But for obvious reasons the paper itself supplies no way to locate *later* papers. *SCI* is designed to make up for this gap. The citation index of *SCI* lists all papers, patents, or books cited in a given year or 2-month period (by first author only) and then gives a list of papers that have done the citing. The index is published bimonthly and cumulated annually. For example, column 43901 of the 1989 citation index shows that the Jencks paper mentioned above was cited as a footnote in 16 papers published in 1989. It is reasonable to assume that most of the papers that cited the Jencks paper were on closely related subjects. For each of the 16 papers the first author, journal abbreviation, volume number, page numbers, and year are listed. In a similar manner, if one consulted *SCI* for all the years from 1968 on, one would have a complete list of papers that cited that paper. One could obviously broaden the search by then consulting *SCI* (from 1989 on) for papers that cited these 16 papers and so on. Papers, patents, or books

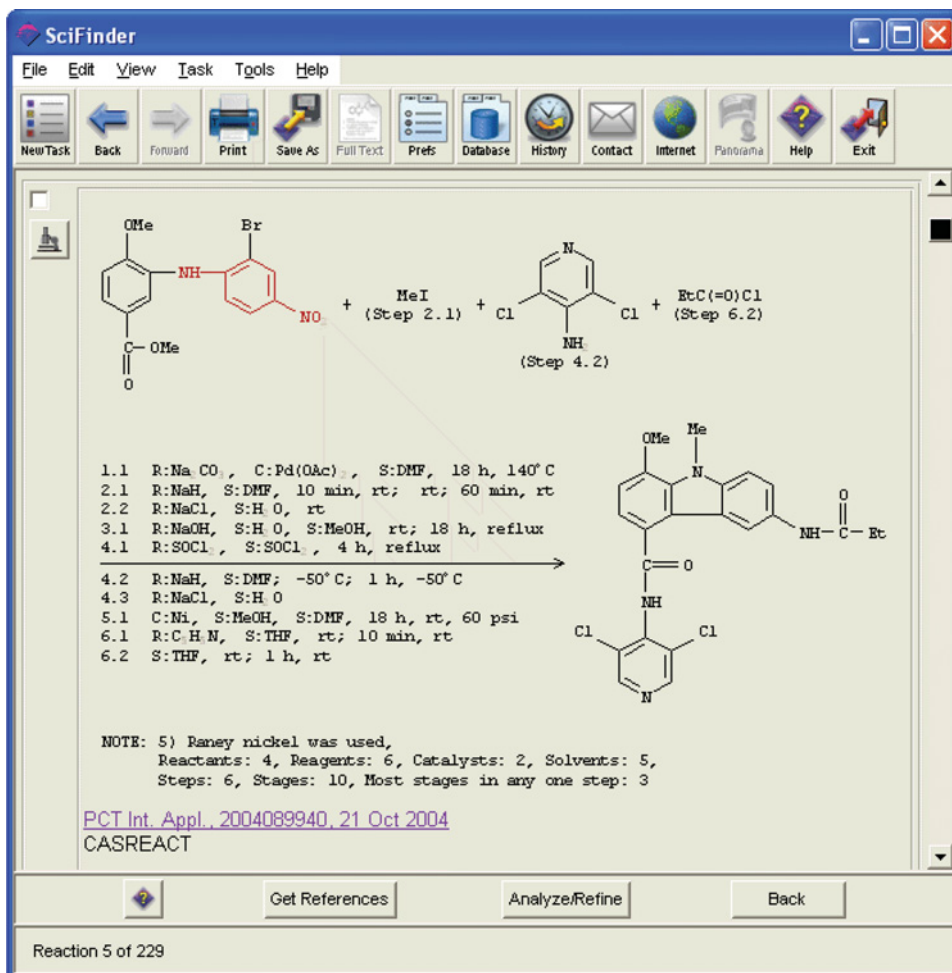

FIGURE A.6. Screen shot of results for a search by reaction, using the drawing tools.

listed, for example, in the 1989 *SCI* may go back many years, e.g., papers published by A. Einstein in 1905 and 1906 are included. The only requirement is that a paper published in 1989 (or late 1988) has mentioned the earlier paper in a footnote. The arrangement of cited papers or books is alphabetical by cited first author and then by cited year. Cited patents are listed in a separate table, in order of patent number, though the inventor and country are also given.

*SCI* covers about 3200 journals in the physical and biological sciences, as well as in medicine, agriculture, and technology. In addition to the citation index, each bimonthly and annual *SCI* also includes three other indexes. One of these, called *Source Index*, is similar to the *CA* author index. It lists the titles, journal abbreviations, volume, issue, page numbers, and year of all papers published by a given author during that two-month period or year. All authors are listed, not just first authors. The second, called the *Corporate Index*, lists all publications that have been published from a given institution during that period, by first author. Thus, the corporate index for 1989 lists 63 papers by 45 different first authors

emanating from the Department of Chemistry of Rutgers University, New Brunswick, NJ. The main section of the corporate index (the Geographic Section) lists institutions by country or (for the U.S.) by state. There is also an Organization Section, which lists the names of institutions alphabetically, and for each gives the location, so it can be found in the geographic section. The third index included in *SCI* is the *Permuterm*<sup>48</sup> *Subject Index*. This index alphabetically lists every significant word in the titles of all papers published in that year or bimonthly period, paired with all other significant words in the same title. Thus, for example, a title with seven significant words appears at 42 separate places in the index. Each of the seven words appears six times as the main word, each time paired with a different word as the co-word. The user is then led to the *Source Index*, where the full reference is given. *SCI* is also available online (though not through STN) and on CD-ROM discs. A version of *SCI* that is restricted to chemistry, but also includes searchable abstracts, is available only in the CD-ROM format.

The publishers of *SCI* also produce another publication, called *Index to Scientific Reviews*, that appears semiannually. This publication, which began in 1974, is very similar to *SCI* but confines itself to listing citations to review articles. The citations come from about 2500 journals in the same general areas as covered by *SCI*. The review articles cited appeared in about 215 review journals and books, as well as in those journals that publish occasional review articles. Like *SCI*, the *Index to Scientific Reviews* contains citation, source, corporate, and *Permuterm* indexes. It also contains a "Research Front Specialty Index," which classifies reviews by subject.

#### D.v. How to Locate Journal Articles

Having obtained a reference from various sources or searches, one often needs to consult the original journal (patents are discussed in Appendix A, A.ii). The first step is to ascertain the full name of the journal, since it is the abbreviation that is generally given. Of course, everyone should be familiar with the abbreviations of the very important journals, such as *J. Org. Chem.*, *Chem. Ber.*, etc., but references are often found to journals whose titles are not at all familiar (e.g., *K. Skogs Lantbruksakad. Tidskr. or Nauchn. Tr. Mosk. Lesotekh. Inst.*). In such cases, one consults the chemical *Abstracts Service Source Index (CASSI)*, 1989 edition, which contains the names of all the journals covered by *CA* from 1907 to 1989 (even those no longer published), with the most recent abbreviations in bold print. *CASSI* also lists journals covered by *Chemisches Zentralblatt* and its predecessors from 1830 to 1969, and journals cited in *Beilstein* before 1907. The journals are listed in alphabetical order of the *abbreviations*, not of the titles. Journal title changes have not been infrequent, and *CASSI* also contains all former names, with cross-references to the current names. Quarterly supplements to *CASSI*, cumulated annually, have appeared since 1990, listing new journals and recent changes in journal titles. It should be pointed out that, while many publications use the *CA* abbreviations, not all do. Usage will vary from country to country, and even from journal to journal within a country. Furthermore, the *CA* abbreviations have changed from time to time. This latter point is particularly important when doing keywords searches. Using a structure search in *SciFinder* may get around this problem.

Once the complete title is known, the journal can easily be obtained if it is in the library customarily used by the chemist, or if that journal is available in electronic form. If not, one

<sup>48</sup> Registered trade name.

must use another library, and the next step is to find out which libraries carry the journal. *CASSI* answers this question too, since it carries a list of some 360 libraries in the United States and other countries, and for each journal it tells which of these libraries carries it and, furthermore, says which volumes of that journal are carried by each library if the holdings are incomplete. However, most libraries have an inter-library loan service that will provide access to such journal articles. It may be possible to visit the closest library personally. *CASSI* also includes lists of journal publishers, sales agents, and document depositories. Photocopies of most documents cited in *CA* can be obtained from Chemical Abstracts Document Delivery Service, Customer Services, 2540 Olentangy River Road, Columbus OH, 43210, U.S.A. Orders for documents can be placed by mail, telephone, telex, fax, or online through STN or other services.

These latter comments are largely out of date given the online status of most journals. As mentioned above, PDF files of an article can be downloaded, or they can be read directly via the HTML file using any current browser. The reader is encouraged to contact the librarian in your establishment that is responsible for chemical literature and so learn which online services are available through your local library.

#### D.vi. REAXYS®<sup>49</sup>

Launched in 2009, *Reaxys* was created through the merger of the existing *CrossFire* databases [see Appendix A, B.iii] into a single database with a new and intuitive user interface. *Reaxys* is a fully integrated content source providing in-depth coverage of inorganic, organic and organometallic small molecule chemistries excerpted from appropriate journal and patent literature.<sup>50</sup> *Reaxys* is available online with drawing tools that allows entry of a structure, or multiple structures as part of a reaction. Once the structure is drawn, *Reaxys* offers several options for the search.

*Reaxys* is a unique workflow solution for research chemists providing in depth coverage of inorganic, organic, and organometallic small molecule chemistries. The database consists of chemical compounds and related factual properties, chemical reaction and synthesis information, related bibliographic data, all of which have been excerpted from a carefully selected list of journals and patents, with the patent information being sourced from carefully selected patent classes and patent offices. This content is delivered through a web-based interface, designed for chemists, with powerful functionality which delivers the content in a flexible and intuitive way and which helps a chemist with his/her major information tasks. A method has been promoted that uses *Reaxys* and also *SciFinder* in a “hybrid retrosynthesis” approach to organic synthesis.<sup>51</sup>

At the heart of *Reaxys* is the concept of “Chemistry as the organizing principle.” This means that the chemical compound or reaction is central to the way in which the data is organized in the database. This is fundamentally different from bibliographic databases, in which a journal or patent record is at the center. This chemically focused approach allows all data from multiple sources to be combined together in one de-duplicated record for a

<sup>49</sup> <https://www.reaxys.com/info/>

<sup>50</sup> [https://www.elsevier.com/\\_data/assets/pdf\\_file/0005/91616/RDS\\_FactSheet\\_Reaxys\\_Oct.2016-WEB.pdf](https://www.elsevier.com/_data/assets/pdf_file/0005/91616/RDS_FactSheet_Reaxys_Oct.2016-WEB.pdf)

<sup>51</sup> *Hybrid Retrosynthesis. Organic Synthesis using Reaxys and SciFinder*, D'Angelo, J.D.; Smith, M.B. Elsevier, 2015. Designed to supplement existing organic textbooks, *Hybrid Retrosynthesis* presents a relatively simple approach to solving synthesis problems, using a small library of basic reactions along with the computer-searching capabilities of *Reaxys* and *SciFinder*.

given compound or reaction (i.e. a single compound or reaction can have multiple source citations whereas a bibliographic database will have one record per published item, so the same compound or reaction may be found in multiple records).

The value of *Reaxys* to organic chemists may be understood best in relation to the synthesis of compounds, which is at the core of organic chemistry. Devising new routes to unique and artificial scaffolds requires the skills of planning and executing multi-step syntheses and having a toolbox of methodologies at one's disposal. However, even the best conceived synthesis plans may require modifications, fine-tuning, or entire rerouting, and chemists are faced with the daily challenge of choosing the right combination of reagents and building blocks for a whole set of problems: Which building blocks are optimal? In which sequence should they be assembled? Which reactions accomplish the task best? The *Reaxys* synthesis planning tool has been designed to make these choices as painless as possible using information and data from the journal and patent literature to investigate a number of possible alternative synthetic routes.

As an example, we will search for papers that have reported direct arylation of indoles at the C3 position. A graphical search query is constructed, using one of the common graphical chemical structure editors, such as ChemDraw, with GH on the indole nitrogen and also at the 5- and 6-positions of indole. The screen in Figure A.7 shows the entry information required for the search. This query retrieved 164 reactions from 45 citations (search results obtained in February 2012).

The *Reaxys* version used in the above example is Application version: 1.0.9619; Content last updated: February 2012; Reactions: 31.681.788; Substances: 20.286.045; Citations: 4.504.504. Figure A.8 shows details for one of the reactions returned for this search. Also shown on this screen are various parameters that are available for searching for this example. The original publication from which the reaction was taken is readily available.

It is also possible to expand the literature review by viewing the details of any recent articles that cite articles of interest. This is easily achieved by clicking on the "view citing

The screenshot shows the Reaxys web application interface. At the top, there is a navigation bar with tabs for 'Query', 'Results', 'Synthesis Plans', 'History', 'My Alerts', 'My Settings', 'Help', 'Forum', and 'Info'. Below this, there is a search area with a 'Generate structure from name' field and a 'Search' button. The search criteria are defined in the 'Search as / by' section, which includes options like 'Product', 'Starting material', 'Any role', 'Reagent/ Catalyst', 'As drawn', 'Substructure', and 'Similarity'. The 'Substructure' option is selected, and the search is performed on all atoms. The interface also displays a chemical reaction scheme for the direct arylation of indole at the C3 position, showing the starting material (indole with a substituent 'R') and the product (indole with a substituent 'R' at the C3 position). The search results are displayed in a table below the search area, with columns for 'Reaction Data' and 'Bibliographic Data'.

FIGURE A.7. Search for direct arylation of indoles at C3.

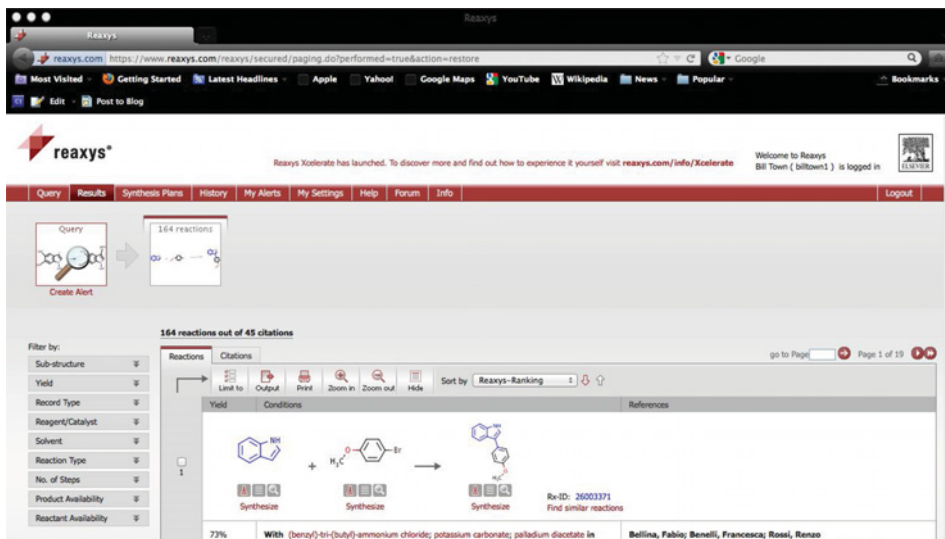

FIGURE A.8. One reaction returned for this search.

articles” hyperlink. The reaction shown in Figure A.8 was cited in the patent literature and also in the *Journal of Organic Chemistry*, as shown in Figure A.9. In this manner, relevant, more recent articles may be identified and explored using citation data from *Scopus*. A few citations are shown in Figure A.10.

The synthesis planning tool allows a more in depth investigation. The *Reaxys* synthesis tool makes it easy to add more steps to the synthesis plan by searching the journal and patent literature for reactions designed to prepare the precursor molecules in any reaction

The screenshot shows the citation data for the reaction in Figure A.8. The table below lists the citation information:

Title of the Document	Authors	Year	Source	Times cited
1,3,6-SUBSTITUTED INDOLE DERIVATIVES HAVING INHIBITORY ACTIVITY FOR PROTEIN KINASE	Korea Institute of Science and Technology	2011	Patent: US2011/46370 A1, 2011 ; Patent Family: US2011/46370 A1; Full Text	

Below the table, the title and abstract of the cited document are shown:

**Title/Abstract**  
**1,3,6-SUBSTITUTED INDOLE DERIVATIVES HAVING INHIBITORY ACTIVITY FOR PROTEIN KINASE**  
 Disclosed are a 1,3,6-substituted indole compound having inhibitory activity for protein kinases, a pharmaceutically acceptable thereof, and a pharmaceutical composition for prevention and treatment of diseases caused by abnormal cell growth including the compound as an active ingredient. Since the novel indole compound exhibits superior inhibitory activity for various protein kinases (indicated in results) further signal transduction, it is useful as an agent for suppression or treatment processes caused by abnormal cell growth.

## Classification of Reactions by Type of Compounds Synthesized

<b>ACETALS</b>		conjugate reduction	19-37
acetals + RM	10-64	epoxides + organometallics	10-65
aldehydes + alcohols	16-05	epoxides + silanes	10-54
by transesterification	10-13	from alcohols	10-17
from dihalides	10-08	from amines	10-23
from hydroxy ethers	14-05	from boranes	10-01
ortho esters + RM	10-64	from boranes	12-27
reductive cleavage of ortho esters	19-61	from boranes	18-23
		from boronates	18-23
<b>ACYLALS (DIESTERS)</b>		from epoxides	10-65
aldehydes + anhydrides	16-05	from ethers	10-13
		from silanes	10-16
<b>ACYLOINS: see Hydroxy ketones</b>		Grignard addition to aldehydes or ketones	16-22
<b>ALCOHOLS</b>		hydration of alkenes	15-03
addition of other organometallics to carbonyls	16-23	hydrolysis of acetals and ketals	10-06
aldehydes + allylic silanes	16-50	hydrolysis of alkyl halides	10-01
aldehydes + organoboranes	16-24	hydrolysis of inorganic esters	10-04
alkenes + alcohols	15-29	hydrolysis of sulfonate esters	10-04
alkenes + aldehydes or ketones	16-53	hydrolysis of vinyl ethers	10-06
alkenes: oxymercuration	15-03	hydroxylation at aliphatic carbon	19-14
amides + organometallic compounds	16-29	hydroxymethylation of arenes	11-12
amines + KOH	10-23	ketones + organoboranes	16-24
anhydrides + organometallic compounds	16-29	organolithium addition to aldehydes or ketones	16-22
aromatics + carbonyls	11-12	organometallics + oxygen	12-25
arylation of ketones	11-12	oxidation of boranes	12-27
boranes + CO; oxidation	18-23	oxidation of boranes	15-11
boranes + CO; reduction	18-24	oxidation of boranes	18-23
by the Cannizzaro reaction	19-85	oxidation of methylene	19-16
by Wittig rearrangement	18-22	oxidation of silanes	10-16
carboxylic esters + organometallics	16-29	radical addition to carbonyl compounds	16-55
cleavage of ethers	10-48	rearrangement of ethers	18-22
condensation of aldehydes	19-85	rearrangement of peroxides	18-20

reduction of acyl halides	19-67	hydrolysis of vinyl ethers	10-06
reduction of aldehydes or ketones	19-40	hydrolysis of vinyl halides	10-04
reduction of carbonyls with Grignard reagents	16-22	Michael addition	15-20
reduction of carboxylic acids	19-41	oxidation of alcohols	19-03
reduction of carboxylic esters	19-42	oxidation of aryl methyl groups	19-15
reduction of carboxylic esters	19-69	oxidation of nitro compounds	19-21
reduction of conjugated ketones	15-40	oxidation of primary alkyl halides	19-20
reduction of epoxides	19-39	oxidative cleavage of diols	19-07
reduction of peroxides	19-65	oxidative cleavage of epoxides	19-07
ring expansion of amines	18-03	ozonolysis of alkenes	19-09
silanes + aldehydes or ketones	16-25	reduction of acid anhydrides	19-44
		reduction of acyl halides	19-43
		reduction of amides	19-45
		reduction of anhydrides	19-44
		reduction of carboxylic acids	19-44
		reduction of carboxylic esters	19-44
		reduction of nitriles	19-45
<b>ALCOHOLS, ALLYLIC</b>		<b>ALDEHYDES, CONJUGATED</b>	
addition of allylic organometallics to carbonyls	16-23	by aldol condensation	16-34
alkenes + formaldehyde	16-53		
allylic silanes + aldehydes or ketones	16-25		
deprotonation of epoxides	17-03		
rearrangement of alkene sulfoxides	18-35		
<b>ALDEHYDES</b>		<b>ALKANES</b>	
alkenes + aldehydes	15-29	alcohols + RM	10-63
alkyl halides + organoiron compounds	10-77	alkane addition to alkenes	15-13
alkylation of aldehydes	10-68	alkenes + alkyl radicals	15-25
alkylation of imines	10-68	alkenes + diimide	19-35
alkylation reactions	10-67	alkenes + metals	19-35
and keto-enol tautomerism	12-03	alkenes + organometallics	15-16
aromatic compounds (Friedel-Crafts)	11-18	alkyl halides + metals	10-56
arylation of aldehydes	13-15	alkyl halides + metals	10-57
boranes + MeO(ArS)CH <sub>2</sub> Li	18-24	alkyl halides + organocuprates	10-58
by decarboxylation	12-39	alkyl halides + RM (Li, Na, K)	10-57
by rearrangement of aldehydes	18-04	alkyl halides + RM (other metals)	10-59
by the Wacker process	19-25	alkyl halides + silanes	10-54
carbonylation of alkenes	15-33	Barton-McCombie reaction	19-64
carbonylation of aromatic compounds	11-18	by [2 + 2] cycloaddition	15-59
carbonylation of hydrocarbons	12-32	by [3 + 2] cycloaddition	15-55
formylation of aromatic compounds	11-18	by decarboxylation	12-39
from alkyl halides	10-64	cleavage of alkanes	12-46
from alkyl halides	10-77	cleavage of ketones	12-45

halogens + alkyl organometallics	12-30
halogens + boranes	12-30
halomethylation of arenes	11-14
Hunsdiecker reaction	14-24

**HALIDES, ALLYLIC**

alkanes + halo succinimides	14-03
alkenes + halogens	14-03

**HALIDES, ARYL**

aromatic compounds + halogen	11-10
aromatic compounds + halo succinimides	11-10
aryl ammonium salts + halide ion	11-32
aryl halides + halogenating agent	13-06
aryldiazonium salts + metal halides	13-22
aryldiazonium salts + metal iodides	13-22
by Sandmeyer reaction	13-22
from aryl amines	13-22
from phenols	13-22
heating aryldiazonium tetrafluoroborates	13-22

phenols + phosphonium halides	13-06
rearrangement of <i>N</i> -halo amides	11-31
sulfonyl halides + transition metal halides	19-74

**HALIDES, SILYL**

from silanes	14-02
--------------	-------

**HALIDES, SULFONYL**

alkanes + SO <sub>2</sub> + halogens	14-09
aromatic compounds + sulfonyl halides	11-08
aryldiazonium salts + sulfur dioxide	13-21
sulfonic acids + halogenating agents	16-97

**HALIDES, VINYL**

elimination of dihalides	17-20
elimination of halides (by base)	17-11
from aldehydes or ketones	11-23
from alkynes	12-30
halide exchange with vinyl halides	10-45
halogens + vinyl boranes	12-30
halogens + vinyl—M (M = a metal)	12-30

**HALO ALCOHOLS (Halohydrins)**

cleavage of cyclic ethers	10-48
from aldehydes or ketones	16-22
from alkenes	15-36

**HALO ALDEHYDES**

aldehydes + halogen	12-04
aldehydes + halogenating agent	12-04
alkenes + formamides	15-43

**HALO ALKYNES**

from alkynes	12-30
--------------	-------

**HALO AMIDES**

from amides	12-52
from aziridines	10-49

**HALO AMINES**

alkenes + <i>N</i> -halo amines	15-39
from amines	12-51

**HALO AZIDES**

alkenes + X—N <sub>3</sub>	15-41
----------------------------	-------

**HALO CARBOXYLIC ACIDS**

carboxylic acid + halogen	12-05
carboxylic acid + halogenating agents	12-05
from amino acids	10-51

<b>HALO ESTERS</b>		rearrangement of acyl aziridines	18-31

Schmidt reaction	18-16	metal cyanides + aryl organometallics	13-08
		Michael addition	15-20
<b>LACTAMS, <math>\beta</math></b>		oxidation of hydrazones	19-06
diazo [2 + 2] cycloaddition	15-59	rearrangement of isonitriles	18-21
enamines + ketenimines	16-90	reduction of nitro compounds	19-53
ketenes + $\text{C}=\text{N}$ compounds	16-90		
ketones + $\text{C}=\text{N}$ compounds	16-90	<b>NITRILES, CONJUGATED</b>	
rearrangement of hydroxy halo amines	18-18	by the Knoevenagel reaction	16-38
<b>LACTONES</b>		<b>NITRITES: see Inorganic esters</b>	
alkenes + carboxylic acids and Michael addition	15-53		
Baeyer-Villiger rearrangement	15-27	<b>NITRO COMPOUNDS</b>	
condensation of dialdehydes	18-19	alkanes + alkyl nitrates	12-09
cyclization of allene carboxylic acids	19-85	alkanes + nitronium salts	12-09
from halo carboxylic acids	15-06	alkenes + nitric acid	12-09
from hydroxy carboxylic acids	10-17	aryldiazonium salts + metal nitrites	13-07
oxidation of methylene in ethers	16-62	by Michael addition	15-20
photolysis of halo amides	19-18	from alcohols	10-41
rearrangement of cyclic ketones	18-40	from alkyl halides	10-41
rearrangement of lactones	18-19	from aromatics	11-02
reduction of anhydrides	18-44	from aromatics	13-22
	19-67	from conjugated carboxylic acids	14-12
		nitration of aromatic rings	11-02

oxidation of amines	19-27	aldehydes or ketones + hydroxylamine	16-13
oxidation of isocyanates	19-27	alkenes + NOX	15-40
oxidation of oximes	19-27	aryldiazonium salts + oximes	13-26
rearrangement of nitro amines	11-28	Barton rearrangement	18-40
		carbonyl compounds + HONO	12-08
<b>NITRO ALCOHOLS: see Hydroxy nitro compounds</b>		<i>O</i> -alkylation of oximes	10-24
		reduction of nitro compounds	19-53
<b>NITRONES</b>		<b>OXONIUM SALTS</b>	
from oximes	10-24	alkyl halides + ethers	10-20
oxidation of hydroxylamines	19-06		
<b>NITROSO COMPOUNDS</b>		<b>OXIRANES: see Epoxides</b>	
Barton reaction	18-40	<b>PEROXIDES</b>	
from active methylene compounds	12-08	acid halides + alkyl hydroperoxides	10-21
nitrosation of aromatic rings	11-03	acid halides + hydrogen peroxide	10-21
oxidation of amines	19-27	alkanes + oxygen	14-06
rearrangement of nitrosoamines	11-29	alkanes + peroxides	14-07
		alkenes + oxygen	15-58
<b>NITROSOAMINES</b>		alkyl halides + hydroperoxide anion	10-21
amines + HONO	12-49	anhydrides + hydrogen peroxide	10-21
		dienes + oxygen	15-58
<b>ORGANOMETALLICS</b>		from organometallics	12-28
alkanes + alkyl organometallics	12-22	oxidation of carboxylic acids	19-24
alkanes + metals	12-23	oxygen + alkyl organometallics	12-25
alkenes + alkyl organometallics	15-16	oxygen + organoboranes	12-25
alkenes + metal hydrides	15-12	photooxidation of dienes	15-58
alkyl halides + alkyl organometallics	12-38		
alkyl halides + metals	12-37, 10-55	<b>PHENOLS</b>	
alkynes + metal hydrides	15-12	aromatic compounds + peroxides	14-04
aryl halides + metals	11-37	aromatic compounds + peroxyacids	11-26
aryl halides + R—M (M = a metal)	11-37	aryl diazonium salts + water	13-20
formation of enolate anions	12-23	aryl halides + hydroxide	13-01
isonitriles + organolithium reagents	16-93	aryl sulfonic acids + hydroxide	13-01
metal halides + R—M (where M = a metal)	12-35	Claisen rearrangement	18-33
metalation of aromatic compounds	13-12	Fries rearrangement	11-27
metals + R—M (where M = a metal)	12-34	oxidation of aromatic compounds	11-26
thioethers + organometallics	14-22	oxidation of aryl borates	13-01
transmetalation	12-34 to 12-36	oxidation of arylboronic acids	13-01
		rearrangement of allyl aryl ethers	18-33
<b>ORTHO ESTERS</b>		rearrangement of aryl esters	11-27
by transesterification	10-13	rearrangement of aryl hydroxylamines	13-33
carboxylic acids + alcohols	16-05	rearrangement of dienones	18-05
from trihalides	10-08	Wallach rearrangement	18-43
		<b>PHOSPHINES</b>	
<b>OSAZONES</b>		alkenes + phosphines	15-08
hydrazines + hydroxy aldehydes or ketones	16-13	phosphines + aryl halides	13-04
		reduction of phosphine oxides	19-72
<b>OXIMES</b>		<b>PHOSPHONATE ESTERS: see Inorganic esters</b>	
alcohols + NOCl	18-40		

<b>PHOSPHONIUM SALTS</b>		sulfonamides + alcohols	16-95
alkyl halides + amines	10-30	sulfonyl halides + alcohols	16-95
phosphines + ammonium salts	10-30		
<b>PHOSPHORANES</b>		<b>SULFONES</b>	
and the Wittig reaction	16-43	alkenes + sulfonyl halides	15-38
		alkyl halides + sulfinic acid salts	10-28
		alkyl halides + sulfonyl halides	10-28
<b>QUINONES</b>		alkylation of sulfones	10-67
dyotropic rearrangement	18-44	alkylation of sulfones	10-71
oxidation of aromatic compounds	19-04	and Michael addition	15-27
oxidation of aromatic compounds	19-19	aromatic compounds + sulfonic acids	11-09
oxidation of phenols	19-04	aromatic compounds + sulfonyl halides	11-09
		aryl halides + sulfonate	13-03
<b>SELENIDES</b>		oxidation of sulfoxides	19-30
aryl halides + selenide	13-03	oxidation of thioethers	19-30
from alkyl halides	10-26	sulfones + organometallics	10-61
		sulfonyl halides + arylboronic acids	16-98
<b>SELENOCARBONATES</b>		sulfonyl halides + organometallics	16-98
from isocyanates	16-07		
		<b>SULFONIC ACIDS</b>	
<b>SELENOETHER ALDEHYDES</b>		aromatic compounds + sulfuric acid	11-07
aldehyde + diselenide	12-14	aromatic compounds + sulfuric acid	11-36
		aryl halides + sulfonates	13-03
<b>SELENOETHER KETONES</b>		hydrolysis of sulfonyl halides	19-75
ketone + diselenide	12-14	oxidation of sulfur compounds	19-29
		oxidation of thiols	19-29
<b>SELENOXIDES</b>		rearrangement of aryl sulfones	13-34
alkylation of selenoxides	10-71	reduction of sulfonyl halides	16-98
		sulfonation of aromatic compounds	11-07
<b>SILANES</b>		sulfonation of aromatic compounds	11-36
addition of silanes to alkenes	15-14	sulfonation of methylene	19-17
and dyotropic rearrangement	18-44		
aryl halides + silanes	13-17	<b>SULFONIUM SALTS</b>	
from metallated aryls	10-54	alkyl halides + thioethers	10-26
<b>SULFIDES: see Thioethers</b>		<b>SULFONYL IMINES: see Halides, sulfonyl</b>	
<b>SULFINIC ACIDS</b>		<b>SULFONYL IMINES</b>	
RM + sulfonating agents (M = a metal)	12-29	sulfonamides + aldehydes	16-16
<b>SULFONAMIDES</b>		<b>SULFOXIDES</b>	
addition of arylboronates to C=N	16-31	alkylation of sulfoxides	10-67
dealkylation of sulfonamides	19-77	aromatic compounds + sulfonyl halides	11-09
reduction of acyl sulfonamides	19-68	oxidation of thioethers	19-30
reduction of sulfonyl azides	19-54		
sulfonyl halides + ammonia or amines	16-96	<b>TELLURIDES</b>	
		from alkyl halides	10-26
<b>SULFONATE ESTERS</b>		<b>THIRANES (EPISULFIDES)</b>	
alkenes + sulfonic acids	15-06	alkenes + sulfur reagents	15-46
from ethers	10-22		

diazo compounds + sulfur	16-48	rearrangement of sulfonium salts	18-21
from epoxides	10-26	reduction of sulfones	19-76
from halo alcohols	10-09	reduction of sulfoxides	19-76
from halo ketones	10-09	sulfur + alkyl organometallics	12-29
thioketones + sulfur ylids	16-48	thiols + arylboronic acids	13-03
		thiomethylation of aromatics	11-23
		thiophenols + aromatic compounds	13-03
<b>THIOAMIDES</b>			
amides + sulfur reagents	16-10		
amides + sulfur reagents	16-69	<b>THIOKETONES</b>	
from nitriles	16-04	ketones + sulfur reagents	16-10
<b>THIOCARBAMATES</b>		<b>THIOLACTAMS</b>	
from isocyanates	16-07	lactams + sulfur reagents	16-10
hydrolysis of thiocyanates	16-04	lactones + sulfur reagents	16-10
<b>THIOCARBOXYLIC ACIDS</b>		<b>THIOLS</b>	
acyl halides + sulfur reagents	16-68	alkyl halides + H <sub>2</sub> S or HS <sup>-</sup>	10-25
		aryl halides + sulfide	13-03
		aryldiazonium salts + H <sub>2</sub> S	13-21
		from alcohols	10-25
		from Bunte salts	10-27
		hydrolysis of Bunte salts	10-27
		reduction of disulfides	19-79
		reduction of sulfonyl halides	19-75
		sulfur + alkyl organometallics	12-29
<b>THIOCYANATES</b>		<b>THIOUREAS</b>	
aryl halides + thiocyanate	13-03	amines + CS <sub>2</sub>	16-22
aryldiazonium salts + thiocyanate	13-21	isothiocyanates + amines	16-20
from alkyl halides	10-29		
from alkenes	15-38		
from amines	10-29		
<b>THIOESTERS</b>		<b>TRIAZOLES</b>	
acyl halides + thiols	16-68	alkenes + alkyl halides	15-54
esters + sulfur reagents	16-10		
<b>THIOETHER ALDEHYDES</b>		<b>TRIAZOLINES</b>	
aldehyde + disulfides	12-14	alkenes + alkyl azides	15-54
<b>THIOETHER KETONES</b>		<b>TRIENES</b>	
enol ethers + disulfides	12-14	aromatic compounds + carbenes	15-60
ketone + disulfides	12-14	cycloaddition of dienes	15-62
		ring opening of cyclic dienes	18-27
<b>THIOETHERS (SULFIDES)</b>		<b>TRIHALIDES</b>	
alcohols + thiols	10-26	acyl halides + halogenating agents	16-21
alkenes + thiols	15-07	cleavage of methyl ketones	12-43
alkyl halides + thiolate anions	10-26		
aromatic compounds + sulfones	11-23		
aryl halides + alkyl sulfides	13-03	<b>TRIOXANES</b>	
aryldiazonium salts + sulfide	13-19	from aldehydes	16-86
aryldiazonium salts + thiols	13-19		
from alcohols	10-26		
from alkyl halides	10-26	<b>UREAS</b>	
from ammonium salts	10-26	amines + CO <sub>2</sub>	16-20
from dihalides	10-26	isocyanates + amines	16-18
from organometallics	12-29		
from phenols	11-23		
Michael addition with <i>S</i> -nucleophiles	15-27		

<b>VINYL ETHERS (including Silyl enol ethers)</b>		<b>VINYL PHOSPHINES</b>	
alcohols + alkynes	<b>15-05</b>	alkynes + phosphines	<b>15-08</b>
alcohols + enol esters	<b>10-13</b>	<b>VINYL SILANES</b>	
alcohols + enol ethers	<b>10-13</b>	addition of silanes to alkynes	<b>15-14</b>
by the Wittig reaction	<b>16-44</b>	<b>VINYL SULFIDES</b>	
cleavage of acetals or ketones	<b>17-02</b>	alkynes + thiols	<b>15-07</b>
from aldehydes	<b>12-17</b>	ketones + thiols	<b>16-10</b>
from enol esters or enol ethers	<b>10-13</b>	<b>VINYL SULFONES</b>	
from esters	<b>16-45</b>	alkynes + sulfonyl halides	<b>15-38</b>
from ketones	<b>12-17</b>	from sulfinic acid salts	<b>10-28</b>
from phenols	<b>10-08</b>	<b>XANTHATES</b>	
peroxides + vinyl—M (M = a metal)	<b>12-26</b>	carbon disulfide + alcohols	<b>16-09</b>
Petasis alkenylation	<b>16-45</b>		
Tebbe alkenylation	<b>16-45</b>		

## AUTHOR INDEX

Note that only initials are used with each surname. Therefore, several different authors may be represented by a single entry. There are several authors named Smith, M.B., for example, and citations for all are listed after the single entry.

Entries in the index refer to chapter number (**boldface**) and reference number.

## SUBJECT INDEX

The vast use of transition metal catalysts in organic chemistry makes the citation of every individual metal impractical, so there are limited citations of individual metals. Palladium is one exception where individual citations are common, in keeping with the widespread use of that metal. However, in most cases, the term metal catalyst, or catalyst, metal is used as a heading, usually representing transition metals.

- A-S<sub>E</sub>2 mechanism 893
    - reactions 487

 reaction 876  
 with aldehydes or ketones 1145
- halides, reactivity as a function of  
 the halide 513  
 and hydrolysis of acyl halides  
 1218  
 in benzyne formation 773  
 in benzyne mechanism 773  
 order, in acyl halide hydrolysis  
 1218
- halides, selenyl 863
- silyl, with alkenes and DMSO  
 1000  
 with allylsilanes 545
- sulfonyl 999
- halides, sulfonyl and the Reed  
 reaction 872
- reduction to thiols 1590
- addition to alkenes or alkynes  
 999
- aromatic 641
- base induced elimination to  
 sulfenes 1314
- formation of sulfenes 1267
- from diazonium salts 785
- from hydrocarbons 872
- from sulfonic acids 1270
- halogenation of sulfonic acids  
 1269
- hydrolysis 1267
- with alcohols 504, 1268
- with alkenes 999
- with alkyl halides 511

- with alkynes 999  
 with amines 1208, 1313  
 with ammonia or amines 1269  
 with arylboronic acids 1271  
 with Grignard reagents 1270  
 with halo esters, Lewis acids catalysis 559  
 with organometallic reagents 1270
- halides, symmetric coupling 551  
 tertiary alkyl, elimination in the Stork enamine reaction 587  
 trialkylsilyl, and indirect hydration 914  
 with alkenes 911  
 with organocuprates 961
- halides, vinyl 708  
 and addition–elimination 446  
 and elimination–addition reactions 449  
 and  $S_N2$  449  
 and  $S_{RN}1$  reactions 449  
 and Stille coupling 717  
 and substitution 446  
 and the element effect 446  
 and the tetrahedral mechanism 446  
 and thiol anions 446  
 by addition of alkyl halides to alkynes 1004  
 coupling with alkyl organometallics 719  
 coupling with metals 560  
 from aldehydes or ketones with phosphorous pentachloride 1127  
 from alkynes 911–912  
 and microwaves 912  
 from vinyl halides 534  
 from vinyliodonium tetrafluoroborates 739  
 metathesis 1430  
 oxymercuration 483  
 with Grignard reagents 553  
 with organometallics 559
- halides, with conjugated carbonyls 1151
- Haller-Bauer reaction 759, 1249  
 mechanism 759
- halo acetoxylation, of alkenes 1025
- halo amides, and the Hofmann rearrangement 1371
- halo ammonium salts, cyclization 1433
- halo azides *see* azides
- halo azides, with  $LiAlH_4$  1003
- halo ethers *see* ethers  
 from alcohols and halogens 997
- halo ketones, and the Favorskii rearrangement 1361  
 by oxidation of alkenes 1500  
 with tributyltin hydride 1359
- halo organolithium reagents 750
- halo sulfides, Pummerer rearrangement of sulfoxides 1603
- halo sulfones, and Ramberg-Bäcklund reaction 1316  
 based induced elimination to alkenes 1316
- halo-acetals, from vinyl ethers 997
- halo-acids, from carboxylic acids 708  
 Hell-Vollhard-Zelenskii reaction 708  
 lactone formation 286
- halo-alkenes, radical cyclization 971
- halo-amines, by addition of haloamines to alkenes 1000  
 formation of aziridines 515  
 formation of cyclic amines 515
- halo-carboxylic acids 543
- halo-ethers 1019
- halo-ketones, addition of acyl halides to alkenes 1004  
 Friedel-Crafts catalysts 1004  
 from ketones 704
- halo-lactams, from alkene–amides 1000  
 from sulfonyl-amino-alkenes 1000
- halo-nitro compounds, from alkenes and nitril chloride 1001
- halo-nitroso compounds, from alkenes 1001
- halo-thioethers, from alkenes and silyl halides 1000
- haloacylation of alkenes, and the Vilsmeier reaction 1005
- haloalcohols *see* alcohols, halo
- haloalkenes *see* halides, vinyl
- haloalkylation 656  
 and Friedel-Crafts catalysts 656
- haloalkynes, and metal catalyst 598  
 by electrolysis 740  
 metal mediated arylation 597
- haloamidation 1001  
 intramolecular 1001
- haloamines 1371 *See also* amines  
 addition to alkenes 1000  
 conversion to methoxyamines 1378  
 from amines 763
- halo *see* haloamines  
 reaction with acids 1433  
 with acid 1434  
 with radical 860
- haloammonium salts, heating 1434
- haloarenes 776
- haloarenes, nucleophilic substitution and ultrasound 333
- halocarbenes 269, 1068–1069  
 and insertion 725
- halocarbonyl compounds, coupling with alkenes 801
- halochromates, phosphonium 1449  
 picolinium 1449  
 tetraalkylammonium 1449
- halocyclopropanes, flash vacuum pyrolysis 1358
- haloesters, and the Reformatsky reaction 1152  
 metal mediated addition to aldehydes or ketones 1152  
 from alkenes 996
- halogenation, aldehydes, enantioselectivity 704  
 alkenes, and Cinchona alkaloids 994  
 amino 1001  
 and acyl anilines 679  
 and hydantoins 863  
 and peroxides 863  
 and UV light 863  
 aniline derivatives 644  
 aromatic side chain 644  
 and ate complex of halogens 643  
 arenium ions 643  
 aryl, and Lewis acids 644  
 carbonyl, and enols 706
- halogenation, carboxylic acids 708–709  
 and NBS 708  
 and radicals 709
- halogenation, conjugated ketones 708  
 electrophilic 857  
 formation of acyl chlorides 862  
 in water 992  
 ketones, enantioselective 707  
 metal mediated 861  
 mixed 995
- halogenation, of alcohols 536  
 of alkanes 857  
 and UV 857  
 fluorination 857  
 mechanism 859
- halogenation, of alkenes 894, 910  
 and bridged ions 992  
 and radicals 992  
 and the Prins reaction 1004  
 enantioselectivity 994  
 halonium ions 992  
 iodossaccharin or bromosaccharin 997

nitrile, [3+2]-cycloaddition  
1029  
of ketones 1488  
proton affinity 1097  
radical addition 1217  
reaction conditions for  
formation 1114  
reagents for reduction 1554
- imines, reduction, by silanes 1553  
to amines 1553  
enantioselectivity 1555  
flow reactions 1554  
reagents 1554  
transfer hydrogenation 1554  
enantioselectivity 1554  
reagents 1554  
strained 1023  
strained bicyclic 218  
sulfonyl 1122

- tosyl, base catalyzed,  
 rearrangement to amino  
 ketones 1369  
 cyclopropyl, rearrangement  
 1407  
 with ylids 1208
- imines, with alkynes 1164  
 with benzylic halides 1217  
 with boranes, radicals 1165  
 with boronates,  
 enantioselectivity 1165  
 metal catalyzed 1165  
 with boronic acids 1165  
 metal catalyzed 1165  
 with carbenes 1167  
 with diazo compounds, metal  
 catalyzed 1167  
 with diazoketones 1263  
 with dienes 1054  
 with Grignard reagents 1162  
 metal catalyzed 1163  
 with ketenes 1261–1262, 1565  
 enantioselectivity 1262  
 intramolecular 1262  
 ultrasound 1263  
 with metals 1262  
 with nitro compounds,  
 enantioselectivity 1166  
 with organolithium reagents  
 1162  
 with organometallic reagents,  
 ionic liquids 1163  
 sonication 1164  
 with silanes, enantioselectivity  
 1165–1166  
 with silyl enol ethers 1182  
 with silyl ketene acetals 1182  
 with sulfonic acids 1264  
 with tellurium ylids 1207  
 with trifluoroborates 1166
- iminium ions, and Eschenmoser's  
 salts 1124  
 and the Bruylants reaction 568  
 dienophiles 1053  
 hydrolysis, and Stork enamine  
 reaction 1098  
 mechanism 1098  
 protonolysis 235  
 with Grignard reagents 568
- iminium salts, addition of cyanide  
 1212  
 and Fischer indole synthesis  
 1420  
 and Hoesch reaction 672  
 and reductive amination 1119  
 chiral 1015  
 conversion to amines 1165  
 conversion to diamines 1595  
 formation of nitriles 672  
 fragmentation of amines 1321  
 from dialkylamino halides  
 1321  
 from oxazines 591
- from Stork enamine reaction  
 587  
 hydrogenation, metal catalyst  
 1554  
 hydrolysis 672  
 loss of water 1113  
 preformed 1123  
 reaction with HONO 761  
 reactivity 1124  
 reduction to amines 1554  
 stability 1113  
 with Oxone 1014
- imino esters 1106  
 and Hoesch reaction 672  
 and ketone formation 672  
 and the Chapman  
 rearrangement 1435  
 and the Pinner synthesis 1106  
 from amides and phosphorus  
 pentachloride 1435  
 from nitriles and alcohols 1106  
 hydrolysis 1106  
 rearrangement to amides 1435
- imino-ene reactions 953  
 in-in isomers 182  
 in-out isomerism 111  
 in-out isomers 181–182  
 inclusion compounds 114, 122,  
 125  
 and rotaxanes 130  
 rotaxanes 130  
 thiourea 123
- indacene, and antiaromaticity  
 86
- indanol derivatives 728  
 indanones 663  
 indene, pK<sub>a</sub> 64  
*Index Chemicus* 1625

- aromatic halogenation 644
- aryl halides and carbon dioxide 667
- arylation, of alkenes, the Heck reaction 811  
 of amines 786–787  
 of silanes 822
- arylboronic acids with alkenes 803  
 coupling with arylmetallic 808–809
- asymmetric hydrogen transfer 1544
- Baeyer-Villiger rearrangement 1378
- boranes, alkylation 593  
 conjugate addition 967  
 with aldehydes 1146
- boronates, with imines 1165
- boronic acids, alkene coupling 803  
 with aldehydes 1146  
 with imines 1165  
 with nitriles 1169
- boronic esters with aldehydes 1147
- borylation 792
- carbenes 1070–1071
- carbon dioxide, with organoboronates 1161
- carbon monoxide, aryl halides and aryl iodonium compounds 670  
 and phenylboronic 670
- carbonylation 605, 982  
 of alkyl halides 604  
 of amines 764  
 of aryl halides 670, 821
- carboxylation 606  
 of alkenes 988
- carboxylic acids, reduction with borane 1547  
 with alkenes 920
- carboxylic esters 1548
- metal catalyzed, catalytic hydrogenation, aldehydes and ketones 1536
- chiral 1053
- Claisen rearrangement 1416
- cleavage, of benzofurans 571
- conjugate addition, organolithium reagents 979  
 trifluoroborates 969
- Cope rearrangement 1410
- coupling 564  
 alkenes to alkenes 945  
 alkyl halides 562  
 aryl halides 562  
 Grignard reagents 881  
 mechanism 562  
 organometallics 558–563  
 with silanes 545
- cyanation 723
- cyclization of diynes 943  
 of en-yne 985
- [2+2]-cycloaddition 1057, 1059  
 forbidden 1396
- [2+2+2]-cycloaddition 1081, 1083
- [3+2]-cycloaddition 1032  
 intramolecular 1034
- cyclopropanation 1073  
 alkenes 1071
- metal catalyzed, cyclopropyl ring opening 599
- cyclotrimerization, triynes 1078
- decarbonylation, of acyl halides to alkenes 1315
- decarboxylation 754
- decarboxylative addition 887
- decarboxylative coupling alkynyl acids 888
- dehalogenation of acyl halides to ketenes 1320
- dehydration of alcohols 1300
- dihydrohalogenation 1312
- diazoacetates with alkenes 1022

- diazoalkanes, and  
   cyclopropanation 1068  
 elimination of halo ethers to  
   alkenes 1320  
 enamines, from amines 1446  
 ene reaction 952  
   carbonyl- 954  
 enol esters from alkynes 920  
 enol ether reactions 581  
 enolate anions 583, 1175  
 epoxidation 1011–1012  
 epoxides, and amines 523  
   with cyanides 601  
 esterification of aldehydes with  
   alcohols 1497  
 esters from alkyl halides 605  
 Finkelstein reaction 534  
 metal catalyzed, for addition of  
   silanes to alkenes 940  
 for carbonylation 982  
   enantioselective 982  
   mechanism 983  
 for carboxylation of alkenes  
   988  
 for catalytic dehydrogenation of  
   alcohols 1454  
 for dehydration of oximes to  
   nitriles 1325  
 for dehydrogenation 1445  
 for hydroboration 936  
 for hydroformylation 989  
 for oxidation of alcohols with  
   TEMPO 1452  
 for pinacol coupling 1594  
 for transesterification 1233  
 metal catalyzed, formation of aryl  
   nitriles 673  
 formation of silyl enol ethers  
   721  
 metal catalyzed, Friedel-Crafts  
   alkylation 650  
 Fries rearrangement 676  
 Grignard reagents coupling 880  
   ultrasound 1163  
   with imines 1163  
 halides, aryl, coupling with  
   arylmatallic 808–809  
   heteroaryl, hydrogenation  
   1570  
 Henry reaction 1186  
 heteroatom Diels-Alder  
   reaction 1053  
 hydration of alkenes 913  
 hydration of alkynes 914–915  
 hydride reagents, reduction of  
   nitriles 1556  
 hydroamination 929  
   intramolecular 926  
   of alkenes 1020  
 hydrocarboxylation,  
   mechanisms 984  
 hydroformylation 989  
   of alkynes 990  
 hydrogen exchange, aromatic  
   compounds 630  
 metal catalyzed, hydrogenation  
   1515  
   of amides 1583

- reagents, alcohol reduction 1571  
 alcohols, from hydrocarbons, by  
   oxygen insertion 1477  
 aldehydes, deoxygenation  
   1578–1579  
   oxidation to carboxylic acids  
     1495–1496  
 amines, by reduction of nitro  
   compounds 1558  
   from nitro compounds 1560  
 and CH oxidation of aryl  
   methyl 1481  
 and Hofmann rearrangement  
   1370  
 and oxidation of amines to  
   amine oxides 1504  
 anhydrides, reduction to  
   aldehydes 1551  
 by oxidation of hydrocarbons,  
   reagents 1476  
 conversion to alkenes,  
   mechanism 1302  
 dealkylation of amines 1592  
 dealkylation, of sulfonamides  
   1592  
 deoxygenation, of aldehydes or  
   ketones 1578–1579  
 diols, oxidation to lactones  
   1494  
 elimination of dihalides to  
   alkenes 1319  
 enantioselective reduction 1545  
 esterification of aldehydes with  
   alcohols 1497  
 esters, reduction to aldehydes  
   1551  
   reduction to alkanes 1575  
 ethers, cyclic, oxidation to  
   lactones, reagents 1488  
   reduction of esters 1579  
 reagents, for allylic and benzylic  
   oxidation 1478–1480  
 for aromatization 1442–1443,  
   1445  
 for Beckman rearrangement  
   1375  
 for conjugate reduction 1527  
 for dehydration of amides, to  
   isonitriles 1328  
   to nitriles 1327  
 for dehydration of oximes to  
   nitriles 1325  
 for dehydrogenation of amines  
   to nitriles 1460  
 for epoxidation of alkenes 1011  
 for formation of acylals 1104  
 for halogenation of ketones 704  
 for hydrolysis of C=N  
   compounds 1097  
   of dithioacetals and  
   dithioketals 1110  
 for  $\alpha$ -hydroxylation of carbonyl  
   compounds 1483  
 for,  $\alpha$ -hydroxylation of ketones  
   1485  
 for hydroxylation of  
   hydrocarbons 1476  
 for isonitriles, dehydration of  
   amides 1327  
 for McMurry coupling 1597  
 for  $\alpha$ -oxidation of ketones  
   1487  
 for oxidation of alcohols to  
   carboxylic acids  
   1492–1493  
   of aldehydes to carboxylic  
   acids 1495–1496  
   of aldehydes to carboxylic  
   esters 1497  
   of amines 1492  
   of aromatic side chains 1473  
   of thioethers 1505–1508  
 for oxidative cleavage of  
   alkenes 1470  
   of alkenes 1472  
   of aromatic compounds 1472  
   of diols 1463  
 for pinacol coupling 1594  
 for preparation of thiocarbonyls  
   1109  
 reagents, for reduction of  
   aldehydes or ketones to  
   alcohols 1532  
   of alkenes to alkanes 1520  
   of conjugated alkenes 1526  
   of conjugated carbonyls 1533  
   of nitriles 1558  
   of ozonides 1466  
   of sulfonate esters 1575  
 reagents, for reductive alkylation  
   of aldehydes or ketones  
   1119  
   from reduction of oximes 1562  
   hydride 1533  
   chiral additives 1544  
   hydrogenolysis, of esters 1576  
    $\alpha$ -hydroxylation of ketones  
     1483  
   imine reduction 1554  
   Katritzky pyrylium–pyridinium  
     method 1585  
   ketones, deoxygenation  
     1578–1579  
   miscellaneous, conjugated  
     alkenes 1529  
     for oxidation of alcohols  
       1455–1458  
   nitro compounds, reagents for  
     reduction 1563  
   oxidation of alkenes to ketones  
     1499  
     of alkynes to diketones 1501  
     of Cathecols and  
       hydroquinones 1459  
     of hydrazones 1462  
   of phenols 1459  
   peroxyacids from acids,  
     reagents 1498  
   pinacol coupling,  
     enantioselectivity 1595  
 reagents, reduction of alkenes  
   1519  
   of alkyl halides 1568  
   of amine oxides 1586  
   of azoxy compounds 1586  
   of conjugated alkenes 1528  
   of diazonium salts 1587  
   of esters to alcohols 1548  
   of ethers 1573  
   of imines 1554  
 reagents, self-immolative 164  
   sulfides, by reduction of  
     sulfoxides 1590  
   thiols, oxidation to disulfides  
     1510  
   transfer hydrogenation,  
     reduction of imines 1554  
 1,2-rearrangements 1348  
 isocyanides 1384  
 of alkyne anions, ab initio study
