Not all unintended consequences are bad; many innovations have beneficial side effects, and effects can be mixed. For example, 2004 studies on some pain relievers, such as Vioxx or Celebrex, suggest that they may reduce cancer risks while enhancing risks of heart attacks. From the perspective of social scientist Michel de Certeau creative, unintended uses may actually serve as a means for the assertion of human autonomy; using products in ways unintended by the designer is a way of resisting technological determination. Some writers see occasional benefits even in negative unintended consequences. Fikret Berkes and Carl Folke suggest that in some cases, "breakdown may be a necessary condition to provide the understanding for system change," although crisis cannot be allowed to reach the point where it imperils the survival of the system (Berkes and Folke 1998, p. 350). Complexity theorists have even argued the emergence of new forms of spontaneous order from unintended chaotic situations.

Managing Unintended Consequences

How should unintended consequences be managed? Some impacts may be avoided with more careful planning in the design and implementation of innovations, but many writers assume that unexpected negative consequences are inevitable, *normal accidents* (Perrow 1984), and advocate systems that either minimize such effects or try to manage them.

Unintended consequences often cross temporal and spatial boundaries. When effects cross physical or political barriers, unintended consequences raise questions about responsibility. Indeed, one ethical response to such technological changes in the scope and reach of human action is to argue for the articulation of a new *imperative of responsibility* (Jonas 1984). How does one country hold another responsible when pollution or other effects cross borders? This is a major question in climate change, where industrialized countries have been the major human source of greenhouse gases but developing countries will suffer the most severe impacts expected, such as sea rise and increased and prolonged regional droughts. In some limited cases national tort law provides compensation for injuries caused by actions taking place outside the borders of the sovereign state. International law is even more problematic, since there is no sovereign providing enforcement, and countries must rely on their ability to reach international agreements to deal with novel and intractable problems such as the hole in the ozone.

Conventional methods of dealing with risk, such as insurance, legal remedies, and emergency procedures, were not designed to deal with the current spread of side effects. When effects occur much later in time they affect future generations, raising issues of *intergenerational* equity. Is it fair to leave a seriously degraded and hazardous world for future generations?

Three types of errors may be made at the more mundane level of managing unintended consequences (Tenner 1997). *Type I errors* are those where unnecessary preventive measures are taken, such as keeping a safe and effective product off the market. *Type II errors* occur when an important protective measure is not taken, such as allowing the use of a very harmful product. *Type III errors* involve displaced risks, new risks created by protective measures, such as the economic effects of unnecessary environmental regulations.

David Collingridge describes the essential problem with technology, the *dilemma of control:* "Attempting to control a technology is difficult, and not rarely impossible, because during its early stages, when it can be controlled, not enough can be known about its harmful social consequences to warrant controlling its development; but by the time those consequences are apparent, control has become costly and slow" (Collingridge 1980, p. 19) He proposes "a theory of decision making under ignorance" to make decisions more "reversible, corrigible, and flexible" (p. 12). He works within the *fallibilist tradition,* which "denies the possibility of justification, and sees rationality as the search for error and the willingness to respond to its discovery" (p. 29). Collingridge advocates a decision process that allows errors to be identified quickly and managed inexpensively. Options should be kept open so that changes can be made as new information becomes available, but this becomes more difficult the longer a technology is in use.

Others have suggested similar systems. Aaron Wildavsky talks about the *resilience* of systems and advocates a gradual system of response as new information becomes available. Steve Rayner (2000) also stresses the importance of developing resilience to improve society's ability to deal with surprises. Sheila Jasanoff (1994) advocates planning in both the anticipation of and the response to disasters. Kai Lee (1993) and Berkes and Folke (1998) propose using *adaptive management* to build resilience into the management of natural resources.

Arguing that science and technology themselves can play multiple roles, not only as a source of risks but as means to help identify and prevent problems, as well as to develop adaptation measures to ease negative impacts, Posner (2004) recommends the use of *cost-benefit analysis* to evaluate risks, saying it is an essential component of rational decisions. He also recognizes that uncertainties create many ethical, conceptual, and factual problems and suggests several methods for coping. Some application of the *precautionary principle*, or the *better safe than sorry* approach to decisions, may be appropriate as a variation of cost-benefit analysis in which people choose to avoid certain risks.

John D. Graham and Jonathon B. Wiener (1993) describe the *risk tradeoffs* that are inevitably faced in protecting human health and the environment; minimizing one risk may actually increase other *countervailing risks*. In some cases, reducing one risk will cause other *coincident risks* to decrease, as well. The authors propose a *risk trade-off analysis* to reveal the tradeoffs likely in any decision, and examine ethical as well as scientific issues. Factors to be considered in evaluating risks include "magnitude, degree of population exposure, certainty, type of adverse outcome, distribution, and timing" (Graham and Wiener 1993, p. 30). Consideration of these factors before making a decision may make it possible to reduce but not eliminate surprise effects.

Corporations, think tanks, universities, or other private institutions may not consult the public about their scientific and technological decisions. Even government-sponsored research and regulation typically involve little public participation. Yet the public is usually the intended user of innovations and bears many of the benefits and burdens of both intended and unintended consequences. Questions for a democratic society include whether the public should play a larger role in decisions regarding science and technology, how meaningful public involvement can be achieved, and how public opinions should be balanced with scientific expertise. Greater public involvement would increase the diversity of interests and values brought to an analysis of and debate about the risks and benefits of innovations in science and technology.

Science and technology funding raise questions about the optimal allocation of public and private funds. Funding rarely is devoted to assessing risks of innovations. Funding to develop solutions to one problem may end up creating other unintended consequences. Should funding agencies require more analysis of possible consequences of funded projects, and should the agencies be held partially responsible for consequences?

Conclusion

The unintended consequences of science and technology are ubiquitous and complex in the contemporary world. They raise important questions about the kind of society in which humans choose to live in, including issues relating to allocation of scarce societal resources; the types and levels of risks society is willing to tolerate; the attribution of responsibility and liability; the right to compensation for injury, the equitable distributions of societal costs and benefits; and the role of individuals, corporations, governments, and other public and private institutions in the control of science and technology.

Tenner, Edward. (1997). *Why Things Bite Back: Technology and the Revenge of Unintended Consequences*. New York: Vintage Books. Unintended consequences are at the center of this book, which describes how and why technology, when combined with human behavior and institutions sometimes seems to turn on the society that produced it. Extensive examples are provided relating to medicine, the environment, computers, and the spread of pests.

UNION OF CONCERNED SCIENTISTS

The Union of Concerned Scientists (UCS) is a nonprofit alliance of more than 100,000 scientists and citizens that works to promote environmental and global security solutions based on sound science. UCS scientists, engineers, and analysts collaborate with colleagues across the country to conduct technical studies on renewable energy options, cleaner cars and trucks, the impacts of and solutions to global warming, the risks of genetically engineered crops, deforestation, invasive species, nuclear power plant safety, missile defense, the security of nuclear material, and other issues. Research results are shared with policy makers, the news media, and the public in order to shape public policy, corporate practices, and consumer choices.

Founding and Finances

UCS was founded in 1969 out of a movement at the Massachusetts Institute of Technology, where an ad hoc group of faculty and students joined together to protest the misuse of science and technology. They put forth a Faculty Statement—the genesis of UCS—calling for greater emphasis on the application of scientific research to environmental and social problems, rather than military programs.

UCS derives approximately 50 percent of its operating revenue from foundations, 40 percent from membership, and 10 percent from planned giving and other sources. Member and foundation support has grown steadily over the years, and in the early twenty-first century UCS has an operating budget of nearly $10 million. More than 75 percent of the operating budget is applied directly to program work.

Historical Development

In its early work, the UCS focused on nuclear weapons, weapons-related research, and nuclear power plant safety. In April 1969, it released its first report, *ABM ABC,* criticizing President Nixon's proposed Safeguard anti-ballistic missile system. UCS's ongoing opposition helped build public support for the ABM Treaty, signed by the United States and the Soviet Union in 1972. In 1979, when Three Mile Island Unit II experienced a near meltdown, UCS provided crucial independent information to the media and the public seeking to understand the accident and the risks to neighboring communities.

In the early 1980s, when the Reagan administration proposed a missile defense program called the Strategic Defense Initiative (SDI), also known as "Star Wars," UCS mobilized swift and sweeping opposition in the scientific community to the SDI program, and analyzed its technical and strategic drawbacks, providing a crucial counterweight to the claims and promises of its proponents.

In 1987, UCS successfully sued the Nuclear Regulatory Commission to strengthen safety enforcement at nuclear power plants. Four years later, UCS forced the shutdown of the Yankee Rowe nuclear plant in Massachusetts due to safety concerns.

UCS kicked off its new climate change campaign in 1990, when 700 members of the National Academy of Sciences signed UCS's Appeal by American Scientists to Prevent Global Warming. In 1992, some 1,700 scientists worldwide, including a majority of Nobel laureates in the sciences, issued the World Scientists' Warning to Humanity. UCS Chair Henry Kendall, a Nobel laureate in physics, wrote and spearheaded the statement, an unprecedented appeal from the world's leading scientists on the destruction of the earth's natural resources.

In 1993, UCS pioneered new analytical techniques to demonstrate the breadth of renewable energy resources in twelve Midwestern states. The attention and commitment to clean energy that the research generated continues into the twenty-first century. UCS also launched a new program the same year, focusing on sustainable agriculture and biotechnology. The program's first report, *Perils Amidst the Promise,* analyzes the ecological risks of the commercialization of transgenic (genetically engineered) crops. Two years later, in response to grassroots pressure generated by UCS, the U.S. Environmental Protection Agency imposed new transgenic crop standards.

The UCS Clean Vehicles program, which was launched in 1991, had a number of major policy victories in the mid- to late-1990s. UCS led the successful campaign to open the market to clean, nonpolluting cars in California in 1996. The state's low-emission vehicle (LEV) standards, which include zero-emission vehicle (ZEV) production requirements, have been adopted by several states in the northeastern United States. In 1998, UCS helped convince California to require SUVs, light trucks, and diesel cars to meet the same tailpipe emissions standards as gasoline cars. *Greener SUVs,* a 1999 report demonstrating numerous "off the shelf" technologies available to automakers to cost-effectively increase the gas mileage of their cars and trucks, has provided a technical basis for the environmental community's efforts to raise national fuel economy standards.

Success and Shortcomings

UCS has secured some major policy victories in the early twenty-first century. Its 2000 report *Countermeasures,* which demonstrated that the proposed national missile defense system could be defeated by missiles equipped with simple countermeasures, convinced President Clinton not to deploy the system. In 2001, UCS issued the first-ever analysis of antibiotic use in livestock feed, demonstrating that widespread overuse threatens the efficacy of drugs used in human medicine. And UCS continues to play a key role in shaping California environmental policy; in 2002, the state passed the first global warming emission rules for cars and light trucks, and the nation's strongest renewable energy standard (20% by 2017). The U.S. Senate also passed a 10 percent renewable energy standard in 2002, the first-ever renewable energy legislation of its kind in Congress.

USC's advocacy of forward-thinking solutions on environmental and arms control issues have prompted some national media label to UCS a "liberal" group and has also made it a target of criticism of various groups invested in the status quo. Despite these challenges, UCS has forged relationships with leaders, on both sides of the aisle, who understand that independent scientific analysis has an important role to play in the decisions about public health, safety and the environment.

Since its inception, however, the Union of Concerned Scientists has played an influential role in environmental and security policy development. It has brought independent scientific analysis to pressing issues facing the global society and effectively communicated these findings to the public and policy makers to demonstrate their meanings at the national, regional, and community level. UCS believes scientists can and should play an important role informing public policy choices. As long-time UCS board chair Henry Kendall put it, "If scientists do not speak out, significant opportunities are lost" (Kendall 2000, p. 1).

UNITED NATIONS EDUCATIONAL, SCIENTIFIC AND CULTURAL ORGANIZATION

The United Nations Educational, Scientific and Cultural Organization (UNESCO) was conceived within the United Nations (UN) Charter, which was ratified on October 24, 1945. In the view of its founders, it was to revive within the new UN system, the International Institute of Intellectual Cooperation (IIIC), created, in 1924, by the League of Nations' International Committee on International Cooperation (ICIC). The institute had counted among its members such eminent world personalities as Albert Einstein, Henri Bergson, Sigmund Freud, Marie Curie, Gabriela Mistral, Aldous Huxley, Miguel de Unamuno, Paul Valéry, and Rabindranath Tagore. The UNESCO Constitution was adopted on October 24, 1945, by thirty-seven countries, By October 2003, it was composed of 190 Member States and six Associate Members.

At the outset, some of its more influential members were of the opinion that UNESCO should be the world organization in which "intellect would be allowed to have more scope and real power in the things of this world" (an expression used by Valéry, a leading member of the first French delegation to the new organization, who had also represented France in the old IIIC). It was thought that this approach could better protect the institution from excessive dependence on changing political pressures. The same concerns could explain why, at the outset, the members of the Executive Board were conceived to be more than just representatives of their respective governments; they would be chosen by the General Conference (the highest organ of UNESCO) on the basis of their personal qualifications and independence of mind, as had been the case with the IIIC. But because of political considerations, the practice moved in a different if not opposite direction. Accordingly, the UNESCO Constitution was amended in 1992 to make it clear that the representatives on the Board would always follow the instructions of their respective governments.

UNESCO's five original fields of competence were placed under the headings of education, exact and natural sciences, social sciences, culture, and communication. To these were later added intersectoral activities that embrace both the sciences and culture as well as fundamentally multidisciplinary projects such as the Protection of the World and Cultural Heritage and collaboration with other organizations of the UN system and with international nongovernmental organizations (NGOs).

Education

UNESCO's first publication was a report titled *Fundamental Education: Common Ground for All Peoples* (1946). Although, ten years later, a working party of the General Conference proposed a new definition of this concept ("to help people who have not obtained such help from established educational institutions to understand the problems of their environment and their rights and duties to acquire a body of knowledge and skills for the progressive improvement of their living conditions and to participate more effectively in the economic and social development of their community"), the term *fundamental* or *basic* education stopped being used, on the ground that it was liable to confer official status on a "cut-rate" educational goal that would run counter to the goal of universal primary education.

The pursuit of a world model of schooling based on the experience of industrially developed countries had often exacerbated the difficulties of the poorer populations in developing their vernacular modes of learning. Therefore, at the World Education Forum (held in Dakar, Senegal, in 2000), UNESCO adopted a new approach under the name Education for All. This program was designed to reach six goals by the year 2015: (1) expand early childhood care and education, (2) improve access to and complete free schooling of good quality for all children of primary school age, (3) greatly increase learning opportunities for youth and adults, (4) improve adult literacy rates by 50 percent, (5) eliminate gender disparities in schooling, and (6) improve all aspects of educational quality (UNESCO, "World Education Forum").

Since 1964 UNESCO has taken a similar approach in working toward its goal of eradicating literacy in the world. At the 1965 World Conference of Ministers of Education in Tehran, the organization introduced the notion of "functional literacy," a conception in which learning to read and write was no longer regarded as an end in itself, but was more closely linked to the exercise of rights, responsibilities, and aptitudes in the professional, social, civic, and cultural fields. Despite some technically impressive results, these massive interventions did not succeed in absorbing the residual number of some 900 million "illiterate" persons who live in the world. Even the UN Literacy Decade Program, launched in 2003, seems to have accepted that despite the intensification of the efforts aimed at accelerating the literacy campaigns, the number of the illiterate will still be of the order of 820 million by 2010.

Natural Sciences

The International Hydrological Programme and the Man and the Biosphere Programme are two of the most important UNESCO programs in the field of natural sciences.

INTERNATIONAL HYDROLOGICAL PROGRAMME (IHP). IHP aims to provide technical training and policy advice required to manage water resources efficiently, fairly, and in an environmentally sound manner. The program is also involved in developing tools and strategies to prevent water conflicts from erupting between and within states.

UNESCO hosts the secretariat of twenty-three UN partners, which constitute the World Water Assessment Programme. The *U.N. World Water Development Report* (WWDR) provides a comprehensive, up-to-date overview of this resource. The first edition of the report, *Water for People, Water for Life* was launched on World Water Day, May 22, 2003, at the Third World Water Forum in Kyoto, Japan.

MAN AND THE BIOSPHERE (MAB) PROGRAMME. MAB is a most innovative program. In 1968, four years before the UN Conference on the Human Environment in Stockholm, UNESCO held the Conference on the Biosphere in Paris with a view to reconciling the environment and "development." The term *biosphere* was used to designate all living systems covering Earth and the processes allowing them to function. MAB got underway in 1971 as an intergovernmental interdisciplinary activity aimed at developing scientific knowledge about the rational management of natural resources and their conservation in the light of the different types of human activity and the world's different land systems. More than 10,000 researchers from some 110 countries participated in this worldwide effort. More than 400 "biosphere reserves" have also been created that work as "living laboratories," each testing ways of managing natural resources while fostering economic development.

OTHER MAJOR ACTIVITIES IN THE NATURAL SCIENCES. The list of UNESCO's other activities in the natural sciences includes the following:

Intergovernmental Oceanographic Commission (IOC): This coordinating body of UN agencies and institutes monitors ocean conditions to improve weather forecasts, predict the onset of El Niño, and provide early warnings of tsunamis and storm surges. IOC also helps build the Global Ocean Observing System, which weaves together data from special buoys, ships, and satellites to better understand the links between ocean currents and climate.

International Geoscience Programme: Formerly called the International Geological Correlation Programme (IGCP), this joint endeavor of UNESCO and the International Union of Geological Sciences (IUGS) was launched in 1972. It maintains active interfaces with disciplines such as water, ecological, marine, atmospheric and biological sciences. As an international forum for multi-disciplinary geo-environmental research, it is designed to help scientists in more than 150 countries assess energy and mineral resources, while expanding the knowledge base of Earth's geological processes and reducing the risks of natural disasters in less-equipped countries.

Environment and Development in Coastal Regions and Small Islands (CSI): The CSI platform for intersectoral action was initiated in 1996 to contribute to environmentally sustainable, socially equitable, culturally respectful and economically viable development in small islands and coastal regions. The program is based upon three complementary and mutually reinforcing approaches: field-based projects on the ground; UNESCO chairs and University Twinning (UNITWIN) arrangements; and a multi-lingual, Internet-based forum on "wise coastal practices for sustainable human development."

The CSI platform has generated two cross-cutting projects: the Local and Indigenous Knowledge Systems (LINKS) project and the Small Islands Voice (SIV) project. The LINKS project focuses on this interface between local and indigenous knowledge and the Millennium Development Goals of poverty eradication and environmental sustainability. It addresses the different ways that indigenous knowledge, practices and worldviews are drawn into development and resource management processes.

Social and Human Sciences

Often perceived as the conscience of the United Nations, UNESCO is further mandated to develop ethical guidelines, standards, and legal instruments in the field of science and technology—specifically bioethics. The ongoing revolution in science and technology has indeed given rise to some fears that unbridled scientific progress poses a threat to the culturally established ethics of world societies in dealing with their life and their human and natural environment. UNESCO's Programme on the Ethics of Science and Technology was designed to place such progress in the framework of ethical reflection rooted in the cultural, legal, philosophical, and religious heritage of the various human communities. This program includes the Bioethics Programme, the International Bioethics Committee (IBC), the Intergovernmental Bioethics Committee (IGBC), and the World Commission on the Ethics of Scientific Knowledge and Technology.

BIOETHICS PROGRAMME. Created in 1993, this program has been a principal priority of UNESCO since 2002. With its standard-setting work and the multicultural and multidisciplinary forums it has helped to organize, the program has played a leading institutional role at the international level. The Bioethics Programme oversees the activities of the IBC and the IGBC.

UNIVERSAL DECLARATION ON THE HUMAN GENOME AND HUMAN RIGHTS. The first major success of the Bioethics Programme came in 1997, when the General Conference adopted the Universal Declaration on the Human Genome and Human Rights. The only international instrument in the fields of bioethics, this landmark declaration was also endorsed by the UN General Assembly in 1998. Adopted unanimously and by acclamation by the twenty-ninth session of the General Conference, the declaration serves as a legal reference and a basis for reflection on such critical issues as human cloning. In the early twenty-first century, work was underway to evaluate the impact of the declaration worldwide, in accordance with the Guidelines for the Implementation of the Declaration (1999), and to develop a new international declaration on human genetic data.

INTERNATIONAL BIOETHICS COMMITTEE. Created in 1993, this body, composed of thirty-six independent experts named by UNESCO's Director General, follows progress in the life sciences and its applications in order to ensure respect for human dignity and freedom. As the only internationally recognized global body for in-depth bioethical reflection, the IBC acts as a unique forum for exposing the issues at stake. It does not pass judgment on one position or another. Instead, it invites each country, and particularly the lawmakers therein, to decide between the different positions and to legislate accordingly.

INTERGOVERNMENTAL BIOETHICS COMMITTEE. The IGBC, created in 1998, comprises thirty-six member states whose representatives meet at least once every two years to examine the advice and recommendations of IBC. It informs the IBC of its opinions and submits these opinions along with proposals for follow-up of the IBC's work to the Director General for transmission to member states, the Executive Board, and the General Conference.

WORLD COMMISSION ON THE ETHICS OF SCIENTIFIC KNOWLEDGE AND TECHNOLOGY (COMEST). Also created in 1998, this commission formulates the ethical principles that provide noneconomic criteria for decision makers concerning sensitive areas such as sustainable development; freshwater use and management; energy production, distribution, and use; outer space exploration and technology; and issues of rights, regulations, and equity related to the rapid growth of the information society.

From the 1999 World Conference on Science, COMEST also received a mandate to pursue research and come up with recommendations on instilling ethics and responsibility into science education. As a first step toward fulfillment of this mandate, COMEST organized a Working Group on the Teaching of Ethics. This group was asked to give the necessary advice on how to integrate awareness and competence in the field of ethics and responsibility of scientific education and research in the training of every young scientist. The report of the group, endorsed in December 2003, includes a survey of existing programs, an analysis of their structure and content, and detailed curriculum advice on how to integrate into scientific education both ethics and training in the history, philosophy, and cultural impact of science.

MANAGEMENT OF SOCIAL TRANSFORMATION (MOST) PROGRAMME. The list of the programs started by UNESCO with a view to setting ethical frameworks for the advancement of scientific discoveries cannot be completed without mentioning MOST, a program aimed at extending UNESCO's new ethical approach to the larger social transformations linked to globalization. Through this program, which was created in 1993, UNESCO seeks to conduct studies on issues such as urban development and governance through a range of grassroots projects, consultations, and academic networks. MOST increasingly focuses on research to help national and local governments develop appropriate governance policies and structures in multicultural societies, even addressing such issues as social inclusion and the eradication of poverty.

A Critical Assessment of UNESCO's Activities

UNESCO has often been criticized for having failed to act as "the conscience" of the people composing the United Nations and, in the particular field of science and technology, to fully implement its mandate to contain their unbridled development within internationally accepted ethical principles. Such criticisms need to be assessed against philosophical, structural, and institutional limits to UNESCO actions.

A first limit is the fact that the "conscience" attributed to UNESCO is nothing but a metaphor. It represents, at best, the hopes placed by the world populations in the performance of its organizational mandate. In practice, however, an insurmountable gap exists between these populations and the politicians, experts, and economists who often act in their name in the way that each side perceives how science, technology, education, and communication affect their lives. For the latter side, composed of the dominant groups of power and knowledge, ethics have seldom had the same meanings as have been conferred to it by the overwhelming number of humans suffering from the so-called fallouts of modern economic and technological development.

A second serious limit to attempts by UNESCO—or any other similar organization—to humanize science and technology or to curtail their unbridled advancement, stems from the very nature of these institutions. Ethics, by definition, poses questions of morality and of adherence to a set of humanly and socially defined *moral* values, whereas the advancement of science and technology remains solely defined by the state of the art in knowledge and performance. As Jacques Ellul (1954) has argued, technology, in particular, is not neutral. It tends to colonize the very behavior and worldview of the subjects it serves. The same way that an unbridled economy tends to "dis-embed" itself from the society that needs it, technologies such as human cloning or genetic engineering create for themselves an autonomous or transcending "ethics" that tends to defy that of a historically defined culture.

The twin set of reasons mentioned above have been quite detrimental to the hopes raised by UNESCO in the implementation of its "grand design" to act as the "conscience of the world." In their greatest majority, the delegates composing its General Conference and its Executive Board were led, more or less, to defend the passing interests of their respective governments rather than uphold the spirit of its constitution. Some of the more politically or financially powerful members of the organization did not even hesitate to openly impose on it their particular views, regardless of their obligations. On the other hand, the power of experts and specialists defending the dominant discourse in the fields of governance, development, market economy, science, and technology have had a steady repressive effect on the growth of different forms of resistance to that power. The result has been that, despite the fact that UNESCO can be credited with some important technical and legal achievements in its fields of competence, these have fallen far short of fulfilling the hopes that the people of the world had placed in its potentialities.

UNITED NATIONS ENVIRONMENTAL PROGRAM

As "the voice for the environment" in the United Nations system, the United Nations Environment Programme (UNEP) speaks on behalf of generations not yet born and acts as a clearinghouse for scientific information. It works with other U.N. entities as well as international organizations, national governments, nongovernmental organizations, and the private sector, reporting on the changing state of the world environment, tracking the causes of change, and working collaboratively to develop responses to those changes. Based in Nairobi, Kenya, UNEP has six regional offices and centers, including the Global Resource Information Database and the World Conservation Monitoring Center. Its Division of Technology, Industry, and Economics is headquartered in Paris. UNEP also hosts several secretariats that were formed in response to the passage of international treaties, conventions, and protocols relating to the environment.

Origins

At the time of the first Earth Day celebration in 1970 there was growing awareness of the transnational threats posed by pollution but no international body to advocate for global environmental health. That void was filled in 1972 in Stockholm, Sweden, at the United Nations General Assembly Conference on the Human Environment, which established UNEP.

Delegates to the conference, which was convened to examine the relationship between the environment and development, agreed that humankind had the fundamental right to "freedom, equality, and adequate conditions of life, in an environment of a quality that permits a life of dignity and well-being" and that human beings bear "a solemn responsibility to protect and improve the environment for present and future generations" (*Declaration of the United Nations Conference on the Human Environment,* Stockholm, June 1972).

However, agreement was not forthcoming about how to balance concern for the environment and development to achieve those ends. Officials from developing countries worried, for example, that the resource-protection policies suggested by many of the delegates would hinder economic development in poor nations. At the urging of developing-world leaders such as Indira Gandhi, philosophical statements about "loyalty to the earth" were displaced by practical considerations of economic growth.

From Stockholm onward UNEP has tried to set a course that both is visionary and grapples with the realities of life. To that end it has underscored the fact that poverty, hunger, and misery in the developing world must be addressed if an environmental agenda is to be successful, emphasizing the need for economic growth that would allow developing countries to make progress without repeating the environmentally disastrous mistakes of the industrialized world. The term *sustainable development* came into use in the 1980s to describe that approach.

Areas of Concern

In the 1980s UNEP defined several areas of environmental concern, including climate change and atmospheric pollution; pollution and the shortage of freshwater resources, along with the deterioration of coastal areas and oceans; and land degradation, including desertification and the loss of biological diversity.

AIR. Since the first book on air pollution was written in the seventeenth century, the situation has gotten decidedly worse. There is still urban air pollution, and with it concern about sulfur dioxide, nitrogen oxides, carbon monoxide, ozone, and suspended particulate matter. Every day nearly one billion people in urban areas breathe air with unacceptable levels of pollution. The problem has widened to include the depletion of the stratospheric ozone layer caused by chloroflourocarbons, acid rain that burns forests with heavy doses of sulphur dioxide and nitrogen oxides, and climate change, which is melting glaciers and raising sea levels at an alarming rate and has been studied in a concerted way since 1980 by UNEP's World Climate Programme. UNEP's efforts to improve understanding about the sources of atmospheric pollution and climate change helped bring about the entry into force of a Global Convention (Vienna 1985) and a Global Protocol (Montreal 1988) for the protection of the ozone layer. UNEP collaborated with other groups in the development of the Climate Change Convention that was signed in 1992.

WATER. As far back as 1977 at the United Nations Water Conference delegates were alarmed about rising levels of water consumption and pollution. The conference's Mar del Plata Action Plan challenged the international community to create an integrated long-term plan for water management. The first step was taken in 1985, when UNEP launched the Programme for Environmentally Sound Management of Inland Waters (EMINWA) in an effort to protect the world's supplies of fresh water.

Oceans and seas, which cover 70 percent of the earth's surface, are another area of concern, particularly with regard to coastal development, discharges of municipal and industrial waste, and the overexploitation of water through the use of long-line and drift nets. In the early twenty-first century more than 120 countries take part in UNEP's Regional Seas Programme, which encourages research, monitoring, and the control of pollution and the development of coastal and marine resources.

LAND. The degradation of drylands, which is known as desertification, is an increasingly severe problem that affects more than a sixth of the world's population. Caused mostly by agricultural and grazing practices that ignore the fragility and productive limits of the land, desertification also is brought about by prolonged drought. More humid areas are at risk of degradation as a result of urbanization, unsustainable agriculture, and deforestation, which clears more than 11 million hectares (27.2 acres) of forest per year. In 1977 UNEP was designated to coordinate the United Nations Plan of Action to Combat Desertification. With regard to deforestation and habitat loss, agreement on a set of nonbinding principles for forest conservation was reached in 1992. UNEP also initiated a series of in-depth country-by-country studies of biodiversity that led in 1992 to the Convention on Biological Diversity.

Results and Successes

The success of UNEP-instigated treaties, conventions, and protocols has resulted from the agency's effective use of scientific and expert advice to inform decision makers about complex environmental problems. For instance, the Global Biodiversity Assessment of 1995, which led to the Convention on Biodiversity, involved roughly 1,500 scientists. UNEP helped develop ways to produce, synthesize, and legitimize the expert knowledge of those scientists and then to provide reliable and accessible scientific advice on environmental policy options. In 1988 the World Meteorological Organization and UNEP set up the Intergovernmental Panel on Climate Change (IPCC). Since that time the 2,500 scientists associated with IPCC have produced a series of reports that have been highly influential in the debate about climate change. UNEP is not an environmental protection agency as such but more of a scientific advisory institution.

Historical Development

Twenty years after the Stockholm conference UNEP continued to explore the relationship of the environment and development at the 1992 United Nations Conference on Environment and Development (Earth Summit) in Rio de Janeiro, Brazil. One hundred seventy countries came together in Rio and adopted by consensus a common global strategy for environmental protection called Agenda 21. Among other things, Agenda 21 laid the groundwork for the 1997 Kyoto Protocol of the Framework Convention on Climate Change. Some participants felt that the recommendations of the Earth Summit favored development over environmental protection. Examples include state sovereignty over resources (and environmental and development policies), the promotion of global free trade and open markets, and a "polluter pays" approach in which market instruments and not strict regulatory mechanisms are used to curb environmental degradation.

It was also at the Earth Summit that the Precautionary Principle received a global hearing. The delegates agreed in Principle 15 of the Rio declaration on environment and development that "where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation." The Precautionary Principle became a cornerstone for the 2000 Cartagena Protocol on Biosafety of the Convention on Biodiversity and has been used in additional forums to argue against genetically modified agricultural products and other forms of biotechnology. The European Union calls the Precautionary Principle a "principle of common sense" and uses it in judging food safety; San Francisco was the first American city to adopt the principle for its purchases and building projects.

In 2002 at the United Nations World Summit on Sustainable Development in Johannesburg, South Africa, development again seemed to occupy center stage. UNEP's executive director, Klaus Toepfer, diplomatically called the summit "satisfactory," but many delegates were angered by efforts, most notably those of the United States, to derail timetables and targets for environmental policies such as the use of renewable energy. Nevertheless, UNEP continues to be the best hope for international cooperation and global governance on life-threatening issues that know no boundaries.

URBANIZATION

Urbanization is a historical phenomenon closely linked to changes in technology and to some extent science that also influences and is influenced by ethical ideals. Both technology and science develop with more intensity in cities, in part promoted by urban models of human behavior, which in turn may be reinforced by notions of technological instrumentalism and scientific objectivity.

Urbanization, Ancient and Modern

The term *urbanization* refers to the increasing concentration of people in cities. The first cities appeared after the development of plant cultivation and animal domestication. Formerly nomadic tribes settled in fertile river valleys and became increasingly dependent on agriculture.

The ancient cities of Mesopotamia were established between about 4000 and 3000 B.C.E. The cities of ancient Egypt appeared around 3300 B.C.E. and were closely linked to the increasing power of the pharaohs, who were both secular and spiritual leaders who could use their power to create new cities. By about 2500 B.C.E. urban societies had developed in other parts of the world, such as the Indus River Valley in India and Pakistan and the Yellow River Valley of China. Subsequent urban developments of a classical form occurred in Athens, Rome, and other parts of the eastern Mediterranean. Despite urbanization in these ancient forms most people continued to live outside cities.

The modern city is linked closely to the development of industrialization, especially in Europe and North America. Before the Industrial Revolution cities were primarily centers for trade, political power, and religious authority. The rise of the machine in the late 1700s in both Europe and North America led to new city forms characterized by larger numbers of people living in areas with greater population density. As machines were developed and manufacturing increased, people began to migrate to cities from rural areas as laborers and consumers.

Technological change is not exclusive to the post–Industrial Revolution era. What distinguished that historical period was the unprecedented rapid increase in the number, kind, and effects of technological innovation and associated increases in urbanization. About 3 percent of the world population lived in urban areas in 1800, a number that rose to 13 percent in 1900 and more than 40 percent in 2000.

The Modern City

The rise of the modern city had significant economic, social, and cultural impacts. Urbanization changed many of the traditional institutions, values, and human experiences that characterized preindustrial cities. For example, while cities grew in importance in economic terms, they also became centers of poverty. Cities also brought together people of different cultures with different worldviews, traditions, and values. In addition, the concentration of people in urban areas created a host of ethical issues related to living together closely.

In 1905 the German social theorist Max Weber (1864–1920) observed that industrialization represented a fundamental process of social change that was embedded in the development of rationality and scientific knowledge. According to Weber, "demystification" challenged traditional religious ideas by providing an alternative basis of knowledge. Weber concluded that this brought about a notable decline in the acceptance of the spiritual explanations that are at the heart of religious beliefs and practices. As a result human activities that previously had been dominated by religious authority were controlled by an appeal to scientific and rational thinking.

In 1965 the Harvard professor of divinity Harvey Cox observed a close interconnectedness between the rise of urban civilization and the collapse of traditional religion. "Urbanization," Cox stated, "constitutes a massive change in the way men live together, and became possible in its contemporary form only with scientific and technological advances which sprang from the wreckage of traditional views" (Cox 1965, p. 1). Cox argued that that epochal change in worldviews resulted directly from the changing nature and character of cities. As cities became more cosmopolitan and as technology fostered greater interconnectedness through travel and communications, religion, Cox argued, lost its centrality in the hearts and minds of people. Nonreligious perspectives on the human condition replaced Christian religious norms and standards for conduct.

Urbanization in a Global Context

The patterns of economic, social, and cultural changes caused by rapid urbanization in the nineteenth and twentieth centuries are observable in modern cities. In general terms the world population is becoming predominantly urban. Industrialized or more developed countries were more than 75 percent urbanized in 2000, compared with 39 percent for less developed countries. To a certain extent economic gain and higher incomes are associated with urbanization. The expansion of production, communication, knowledge, and trade helped raise standards of living in the more developed countries.

In developing countries the urbanization experience has been vastly different: Industrialization accounts for a much lower proportion of the national economy, and these countries also have significantly lower income per capita. The concern in developing countries is the rate at which increases in the numbers of people living in urban areas are occurring. According to the United Nations Center for Human Settlements (2001), 40 percent of the population of developing countries was living in urban areas in 2001. By 2020 that number is expected to increase to 52 percent.

In 2001 three-quarters of global population growth occurred in urban areas in developing countries, posing significant problems associated with rapid growth in the parts of the world least capable of accommodating it. Most of the projected growth will occur in megacities:

cities with a population of ten million or more. These areas already face increasing difficulties in providing their inhabitants with adequate water, food, shelter, employment, sanitation, and basic services. Poverty has become increasingly urbanized as more people migrate from rural to urban areas. The United Nations Center for Human Settlements (2001) estimates that more than a billion people live in crowed slums in inner cities or in squatter settlements on the periphery of large urbanized areas. Not only does this result in strained local conditions, the rapid growth and concentration of poverty in urban areas in the developing world often leads to adverse consequences for national economies.

Although modern cities are part of a highly interdependent global network fostered by new information, communication, and transportation technologies, one significant characteristic of cities in the twenty-first century is the growth of disparities between the rich and the poor. The United Nations calls this the "divided city," and it is characteristic of urban areas in both developed and developing countries. Some researchers predict a new wave of rapid technological change in urban areas driven by information and communications technologies, which reinforce urban polarization and cause further erosion of traditional economic, social, and cultural activities. New technologies, they observe, reinforce and extend the reach of the economically and culturally powerful. Those who already have access to new technologies and most able to benefit from the potential of new technologies will use them to their advantage to assure their place as the principal beneficiaries of the "information revolution."

Another phenomenon closely linked to the modern city, especially in North America and parts of Europe, is suburbanization. Driven by advances in transportation and communication technologies, sprawl patterns of urbanization from central cities to suburbs began to emerge after 1945. By 1960, 60 million people in the United States were living in suburbs, compared with only 45 million in cities. Since 1980 suburban populations have grown ten times faster than have central-city populations.

In response to the problems associated with the rapid rise of modern urbanization and its attendant problems, urban planning emerged in the United States around the end of the nineteenth century. Although examples of planned cities date back several thousand years, urban planning developed from demands for social reform in both England and the United States. In the early twenty-first century urban planners are part of a distinct occupational skill group that applies a specified body of knowledge and techniques addressing land use, city functions, and a wide variety of other urban characteristics.

Callahan, Daniel, ed. (1966). *The Secular City Debate*. New York: Macmillan. This collection of essays, critiques, and book reviews by a diverse group of authors was compiled in response to Harvard professor Harvey Cox's book *The Secular City*. The editor notes that the response to Cox's work was surprising, with more than 225,000 million copies sold in the first printing. An afterword by professor Cox is included.

Cox, Harvey. (1965). *The Secular City*, rev. edition. New York: Macmillan. Explores the theological significance of the modern city and includes an interpretation of the relationship between urbanization and modern secular society. Cox contrasts the modern city (technopolis) with traditional forms of human communities, particularly with regard to the influence of religion and religious institutions.

Ginsburg, Norton. (1966). "The City and Modernization." In *Modernization*, ed. Myron Weiner. New York: Basic Books.

Hetzler, Stanley A. (1969). *Technological Growth and Social Change*. London: Routledge & Kegan Paul. This collection of essays was originally prepared as lectures for *Forum*, an educational radio program sponsored by Voice of America. Twenty-five scholars explore how modernization, defined as technological development, occurs and how it can be accelerated. Ginsburg's essay reviews the history of cities and their historical functions. He describes the distinctly different characteristics of the modern city.

Lebebvre, Henri. (2003). *The Urban Revolution*, trans. Robert Bononno. Minneapolis: University of Minnesota Press. Henri Lefebre (1901–1991) was an influential French philosopher and sociologist. This work was originally published in 1970, but not translated into English until this edition. Highly theoretical, connecting urban research with social theory and philosophy, Lefebre's work marked a new view of "urbanism." Lefebre posited that "urban society" more aptly describes modern societies, rather than the term "postindustrial society," arguing that all forms of human settlements have been altered due to industrialization and urbanization. He noted that agricultural activity is inextricably linked to "industrialization." Even traditional forms of village life around the globe have been permanently transformed by industrial production and consumption.

Mumford, Lewis. (1961). *The City in History: Its Origins, Its Transformations, and Its Prospects*. New York: Harcourt Brace Jovanovich. An extensive exploration of the history of the city, beginning with Ancient Mesopotamia and Egypt, through the modern. In addition to an historical overview, Mumford critiques many of the historical urban forms. He is especially critical of the modern manifestation of urban communities and the negative influence of capitalism resulting in resource depletion. The annotated bibliography is extensive and very helpful to anyone interested in in-depth material.

Prud'Homme, Remy. (1989). "New Trends in Cities of the World." In *Cities in a Global Society*, ed. Richard V. Knight and Gary Gappert. Newbury Park, CA: Sage. Collection of essays that details the phenomenon of rapid global urbanization and the forces influencing the extraordinary changes in modern human settlements. Prud'Homme observes that the cities will have increasingly distinct "global" as opposed to "national" roles to play as economic forces become more global.

United Nations Center for Human Settlements. (2001). *Cities in a Globalizing World*. London: Earthscan. Compilation of work by more than eighty international researchers. The report reviews the status of the world's cities and summarizes global trends that will impact the cities of the future. Especially notable is the observation regarding the increased isolation of the urban poor in both developed and developing countries.

UTILITARIANISM

SEE *Consequentialism*.

UTOPIA AND DYSTOPIA

Part of being human is the ability to dream of a better (or worse) life, either in this world or the next. Some dreams have led to the study of nature and humans, from the deep mysteries of the atom and the gene, to the even deeper challenges of individual and collective sanities—all with an understanding that how one acts can be as important as why, especially when studies of nature (science) and how to transform nature (technology) confer ever greater powers and responsibilities on human beings. Some of humanity's best thinkers and artists have, for 2,500 years, created moral compasses by distilling human wisdom (and folly) into imaginative works called utopias and dystopias (sometimes called anti-utopias). These compasses are neither timeless nor universal; instead, their poles are constantly aligned and realigned by the forces of history, economics, politics, and aesthetics. Messages from these explorers of science, technology, and ethics have long had the potential to both frighten and enlighten. Indeed, they have been doing so at least since the hero escaped from that allegorical cave of shadows in Plato's classic utopia, *The Republic* (360 B.C.E.)—a parable clearly revisited and updated in the film *The Matrix* (1999).

Utopia Defined: Thomas More's Pun and the Myth of Utopianism

The word *utopia* originated in December 1516, when Thomas More published a book with that one word, capitalized, as its title. More wrote his text in Latin. Its complete, twenty-seven word title—*De optimo reipublicae statu deque nova insula utopia libellus vere aureus, nec minus salutaris quam festivus, clarissimi disertissimique viri Thomae Mori inclutae civitatis Londinensis civis et Vicecomitis*—features not only a latinizing of his own name and city but also a brand-new word coined as a trilingual pun. In Latin and English, utopia minimally disguises its truncated roots in two made-up, latinized homophones from the Greek words for a *good place* (*eu-topos*) and for *no place* (*ou-topos*). Hence, "Utopia: the good place which is no place" (Sargisson, p. 1). Since 1516 More's readers and translators alike have wrestled with the many puns and ambiguities of this multivoiced dialogue that is, in Vita Fortunati's words, "a bewildering mixture of reality and fiction" (Fortunati and Trousson 2000, p. 153).

The full title of More's book, in its first English translation by Ralph Robinson in 1551, was *On the best State of a Commonwealth and on the new Island of Utopia A Truly Golden Handbook, No Less Beneficial than Entertaining by the Most Distinguished and Eloquent Author Thomas More Citizen and Undersheriff of the Famous City of London*. This language—especially *best* and *Handbook*, *Commonwealth* and *Beneficial*—evokes the common understanding of *utopia* and *Utopia* as a blueprint for a perfect society. Such an initial reading makes it easy to dismiss utopian arguments as just unrealistic. Since the late twentieth century, scholars such as Ruth Levitas, Tom Moylan, Lyman Tower Sargent, Lucy Sargisson, and W. Warren Wagar have challenged this colloquial, negative view of utopian texts, thoughts, and theories.

The recorded usages of utopia expose a long history of undervaluing the impulse for social dreaming, for collectively desiring a better way of being. Denotations for utopia show a sustained effort to disempower minority reports from the critics of the dominant ideologies that have sustained (mostly premodern) heads of state and (mostly modern) captains of capital. A distinction between *imaginary* and *imaginative* is helpful here. After first asserting, "Utopian thought is imaginative," Northrop Frye observes that "The word *imaginative* refers to hypothetical constructions, like those of literature or mathematics. The word *imaginary* refers to something that does not exist" (Frye 1957, p. 193). More's island is a new *no place* that people can hold in their hands and in their minds; it is imaginative, not imaginary.

Another, less nuanced point is raised by the adjective *perfect* being applied to this system depicted by More. There is a figure—it is tempting to call him a character—in More's *Utopia* called "More," who spends much of his time listening to the exploits of Raphael Hythloday, a sailor and scholar who has been to Utopia. As Hythloday (an imagined figure whose name means *peddler of nonsense*) tells his tale, "More," the character, expresses several reservations. For "More"—and, one could surmise, for More, the man,—many of the Utopians' laws and customs "were really absurd" (More 1995, p. 110). Then, when Hythloday has finished, "More" says, "Meanwhile I can hardly agree with everything he has said (though he is a man of unquestionable learning and enormous experience of human affairs), yet I freely confess that in the Utopian commonwealth there are many features that in our own societies I would like rather than expect to see" (More 1995, p. 110–111). *Utopia* depicts, not a perfect social, legal, and political system, but instead a complex debate, enriched by humor, between More's earned political realism of low expectations and his cautious optimism of higher desires for society.

Utopian Studies: Modern Scholarship Challenges Utopian Stereotypes

The debilitating myth of utopianism as unrealistic perfectionism comes, in part, from concentrating on the content and form of utopias—on what is held and what is doing the holding—rather than on the function of utopia. Some important work has been done with the content and form approaches, most significantly the magisterial tome by Frank and Fritzie Manuel, *Utopian Thought in the Western World* (1979). But as Ruth Levitas notes, "to focus on the function of utopia is already to move away from colloquial usage, which says nothing about what utopia is for, but implies that it is useless" (Levitas 1990, p. 5).

Turning attention to how utopias function, scholars, led by Lyman Tower Sargent (1988), have challenged the dominant commonplace understanding of utopia by reexamining the history of utopian expressions, locating many newly-discovered and rediscovered resources. Other scholars, following the example of Ernst Bloch (1970), have expanded utopia by finding it "immanent in popular culture, in the fashion industry, dance, film, adventure stories, art, architecture, music, and even medical science" (Sargisson, p. 12). Even a Parisian graffito from May 1968—"Be realistic. Demand the impossible"—becomes fodder for utopian analysis, with its second command serving as the apt title for Tom Moylan's 1986 study of science fictional treatments of the critical utopian impulse by Joanna Russ, Ursula K. Le Guin, Marge Piercy, and Samuel R. Delany.

This new wave of utopian studies operates not as a small, monolithic cabal but rather as a growing international community. For example, Fortunati and Raymond Troussan's 700-page *Dictionary of Literary Utopias* (2000) has ninety-nine contributors from more than a dozen countries. This key reference work offers a thorough comparative and interdisciplinary perspective on literary utopias and dystopias, yet even it cannot claim anything approaching complete coverage of utopian and dystopian thought. For a sweeping overview, historian and novelist W. Warren Wagar, contends, "At least two great rivers of utopian dreaming flow through the history of ideas, corresponding to the two great families of world-views, the naturalist and the idealist, which have contended with one another for thousands of years in every philosophical arena in the world" (Wagar 1991, p. 56). Furthermore "Since the seventeenth century, most blueprints for good societies have emanated from the naturalist family, as represented by the classic texts of Bacon, Condorcet, Comte, Cabet, Marx, Bellamy, Wells, and Skinner. But not all. Many utopian visions are grounded in such members of the idealist family of world-views as Platonism, mysticism, orthodox religious piety, and modern and postmodern irrationalism" (Wagar 1991, p. 56). Key writers, for Wagar, in this second tradition include William Morris, George Bernard Shaw, Herman Hesse, Aldous Huxley, Teilhard de Chardin, C. S, Lewis, William Burroughs, and Doris Lessing. In their idealist works, "utopia is not a bustling city registering worldly progress but a community of spirit earning grace" (Wagar 1991, p. 56).

Naturalistic Utopias: Bacon and Science

For present purposes, the name at the head of Wagar's naturalist tradition should be highlighted, Francis Bacon. His *New Atlantis* (1627) brings the politically responsible use of science and technology to the forefront of utopianism by way of its House of Salomon, a grand research institution that, historically speaking, serves as the prototype for modern laboratory science. Writing in 1665, Joseph Glanville affirms, "Salomon's House in the *New Atlantis* was a prophetic scheme of the Royal Society" (Fortunati and Trousson, p. 448). Before detailing its personnel, equipment, and methods, an Elder of the House of Salomon first explains its underlying goals: "The end of our foundation is the knowledge of causes, and the secret motions of things; and the enlarging of the bounds of human empire, to the effecting of all things possible" (Bacon 1627, p. 240).

Their division of labor anticipates such ventures as the Massachusetts Institute of Technology (MIT), the Manhattan Project, and Bell Laboratories. One subgroup of Elders functions, in Bacon's words, as *interpreters of Nature,* whose role foreshadows the modern scientific method itself. These protoscientists "raise the former discoveries by experiments into greater observations, axioms, and aphorisms" (Bacon 1627, p. 240). That is to say, two hundred years before the word *scientist* was coined, Bacon divided practitioners into the experimenters and the theorists. Moreover, his *New Atlantis* initiates the major model of modern utopias, ones that imagine liberating humanity through enhanced production and consumption, including Louis-Sebastien Mercier's *The Year 2440* (1770), Etienne Cabet's *Voyage en Icarie* (1840), and, after *Uncle Tom's Cabin* (1852) by Harriet Beecher Stowe, the most popular nineteen-century American novel, Edward Bellamy's *Looking Backward* (1888).

Idealist Utopias: Morris and Community

Idealist utopias are quieter than their naturalistic cousins. A sense of community is earned in them not by way of technology but through the avenues of spirit in Hermann Hesse's *The Glass Bead Game* (1949). In the naturalistic utopias (and in their dark avatars, the naturalistic dystopias), communication is enhanced (or thwarted) through the agency of faster and better telephones, telegraphs, and computers, among others, while in the idealist utopias (and their avatars) communication honors its root in *communing,* in the fullest sense of a people sharing life. (Tom Moylan [2000] provides an analysis of key examples of these science fictional utopias and dystopias from the 1980s and 1990s.) Idealist utopias are often explicit responses to naturalistic texts, as in Morris's *News from Nowhere* (1890) as a pastoral reply to Bellamy's *Looking Backward* (1888) and its shiny vision of an industrial army circa 2000. On rare occasions, a naturalist dystopia and its paired idealist utopia are written by the same author— for example, Aldous Huxley's *Brave New World* (1932) and *Island* (1962). Taken together, these major utopian streams engage in a complex critique of science and technology, especially in the twenty-first century science fiction short story, novel, and (to a lesser degree) film.

Charting Wilde's Map of the World and Beyond

In "The Soul of Man Under Socialism" (1891), Oscar Wilde poeticizes the positive utopian impulse, saying, "A map of the world that does not include Utopia is not worth even glancing at, for it leaves out the one country at which Humanity is always landing. And when Humanity lands there, it looks out, and seeing a better country, sets sail. Progress is the realization of Utopias." (Wilde 1891, p. 34). Yet while many anticipated and welcomed the rise of modern industry, science, and technology, a minority questioned their impact, wondering not about the feasibility but the wisdom of utopian schemes. Utopias and dystopia are asymmetrical concepts, akin to health and disease, whereby one person's hopeful dream is another's dyspeptic nightmare. One key example is behaviorist B. F. Skinner's *Walden Two* (1948), written as a positive, naturalistic utopia, yet often read as a dystopia—and one Henry David Thoreau would not have warmed to.

Overall, the miscoupling of science (natural and psychological) and power (political and economic) found its most compelling expressions in the great twentieth-century dystopias, especially Yevgeny Zamyatin's *We* (1920), Huxley's *Brave New World* (1932), and George Orwell's *1984* (1949). *We* is especially germane because of its moral calculus. That is, in Zamyatin's hyper-rational world, ethical values are literally, not metaphorically, based on mathematical calculations. Even more disturbing is Huxley's prophetic extrapolation of modern consumerism. He invented the perfect narcotics—soma and the *feelies*—for the dystopian year of our Ford, 632; in the twenty-first century, both can be found at the local mall. Lastly, *1984*'s impact on the understanding of power and politics, language and truth, and banality and desire are difficult to underestimate. After all, not every writer has his name become a ubiquitous adjective—Orwellian.

V

VACCINES AND VACCINATION

Nowhere is the effort to use science and technology for human benefit clearer than in the development of vaccines against serious infectious diseases. Although vaccinations seldom have unintended consequences they can, on occasion, pose complex ethical issues.

Historical Developments

One of the key figures in Western vaccine history is the English physician Edward Jenner, who developed an effective prophylactic against smallpox in 1796. The protective material that Jenner used came originally from a cow infected with cowpox. When infected cows were milked, Jenner noted, as others had before him, that the milkmaids who did the milking developed pustules or sores on their hands that disappeared in time and did not harm the girls. These girls, it was further observed, did not get smallpox, which is a disease that left unsightly pockmarks on the face and skin where the pustular sores had been, and in about 30 percent of the cases was lethal. On May 14, 1796, Jenner took liquid from the developing sores of the hand of a milkmaid named Sarah Nelms and injected it into the skin of eight-year-old James Phipps. After about six weeks, when the sore had resolved and disappeared, Jenner injected Phipps's skin with virulent human smallpox. Phipps did not get the generalized disease and was protected against the widespread eruption of sores. After many such experiments, Jenner called the material he injected to achieve protection against virulent human smallpox, a vaccine deriving the term from the Latin *vacca* (cow).

In the decades following Jenner's discovery many other vaccinators took up the procedure, and gradually the number of smallpox outbreaks started to decrease noticeably. By the time Louis Pasteur was developing his vaccines (for fowl cholera, rabies, and anthrax) in the late nineteenth century, smallpox was so much on the wane that Jenner's contribution to human well-being was much lauded in all the countries that had adopted his methods.

The continued use of the vaccine, made for mass distribution by collecting the pustular material from the skin of deliberately infected calves, led eventually to a campaign spearheaded by Donald Henderson, working with the World Health Organization (WHO), to completely eradicate human smallpox from planet Earth. In this they were successful, as attested by a declaration of the chief WHO scientists on December 9, 1979. This was the first time that a serious and socially debilitating human infectious disease had been entirely eradicated, and is one of the highest achievements of humankind. A second disease targeted for elimination through the use of vaccines is polio. By 2004, the disease notification returns showed that there were but several tens of cases in fewer than five countries per annum. It is held that elimination will have occurred when there will have been zero notified cases worldwide for at least two years, and this is confidently expected to occur before 2010.

The consequence of these pioneering results in vaccine use has been that many infectious diseases afflicting humans throughout history are now so much in the past that people have forgotten how dangerous, damaging, and deadly they can be. Human diseases that are in this category include diphtheria, tetanus, pertussis or whooping cough, polio, measles, mumps, rubella, rabies, hepa-

titis A and B, *Haemophilus influenzae* b, and yellow fever. A similar list for veterinary diseases includes foot-and-mouth disease, Newcastle disease, Marek's disease, anthrax, and canine distemper.

Vaccine Science

Vaccines that are intended to prevent infectious diseases are normally made from the organisms or close relatives of the organisms that cause the disease. In the former case, before the organism is used as a vaccine, it is killed or inactivated by a variety of techniques that include heating, treating with inactivating agents such as formaldehyde or acetyl-ethylene-imine, exposing to ultraviolet light or gamma radiation, and using denaturing agents such as urea and/or proteolytic enzymes. A further option when using an inactive vaccine is to use a part or subunit of the pathogenic agent. Here the bacterium or virus is disrupted and one or several of its component parts are used in the vaccine to which is added an adjuvant. This latter material is a nonspecific stimulator of the immune system that greatly potentiates the killed organism or its components as used in the vaccine.

When a live organism is used for a vaccine it is chosen for its relatedness to the disease-causing organism plus its *in*ability to cause disease, normally as a result of its attenuated or weakened nature. Both types of vaccines benefit from stabilizers and preservatives, but while the killed vaccines are more likely to survive at room temperature the live vaccines must be either held in refrigerated conditions or freeze-dried, in which state they will withstand limited exposure to more elevated temperatures.

The actual materials of the killed or live organisms that are active in the achievement of the vaccination effect are either the proteins or complex carbohydrates that exist on the outer skins or envelopes of the pathogenic microorganisms. While most carbohydrates are generally inert, they can be made into powerful and active agents when they are covalently joined to proteins. For the proteins themselves, scientists can identify immunogenic sites that are either dependent on a linear string of not less that six amino acids or a region of a protein molecule wherein an amino acid from one part of the linear chain comes into proximity with other amino acids to make up an immunogenically active area or site; these are called conformational immunogens. Normally two or three amino acids would be involved in such a conformational determinant. Lipids and nucleic acids are not normally involved in the immunogenicity of pathogenic organisms except in that they participate in creating an environment in which proteins and carbohydrates take up their active three-dimensional configurations.

These immunogenic materials can be found on all types of viruses and bacteria, and some protozoa. Whole animal cells that express proteins or glycoproteins (proteins to which carbohydrate groups are attached) at the exterior surface have also been used as vaccines, such as the anticancer vaccine for chickens that utilizes infection by the herpes virus that causes Marek's disease in poultry. There have been experiments demonstrating the feasibility of this approach to vaccinate against some human cancers, but more testing needs to be done.

Vaccines work by stimulating the human or animal immune system to produce glycoprotein antibodies and specialized cells that seek out and kill body cells that contain infecting organisms or materials they do not recognize as belonging to the normal body. In this way they are able to recognize cancer cells because such cells make unique molecules that are exposed at the surface of the cancerous cell and label that cell as one of the abnormal cells of the body that may be killed by the killer T cells of the immune system. Many such cancerous cells are made in the lifetime of a human and are dealt with in this way, thus protecting the human from the uncontrolled and killing effects of a rapidly expanding cancer. While much is known about these reactions, scientists are yet uncertain about many of the details that relate the invading or foreign microorganism to the response it evokes and the consequences of that response. Some of the complexity of the immune system may be gleaned from the overview diagram of Figure 1.

When a microorganism penetrates the skin barrier and survives the antimicrobial agents in the skin and tissues, it is ingested into a macrophage-dendritic cell. These cells (of which there are more than twenty tissue-specific types) engulf foreign particles and then break them down to smaller molecules that are released to become expressed on the outer surface of the cell. From this exposed site they attract another kind of cell of the immune system known as the T cell. This cell, found in the white cells of the blood, is formed when an undifferentiated white cell passes through the thymus gland.

There are many different and specialized T cells. T cells sport receptors on their surfaces that interact with specialized molecules on the surface of the macrophage cells, which proffer the broken-down piece of the invading organism to the T-cell receptor system. When this interaction occurs, the T cell excretes a number of locally acting hormones (parachrines) that cause other cells of the immune system, such as the antibody-producing B cells, to reproduce and differentiate to plasma cells. These cells excrete antibody molecules that bind to the foreign invading organism or foreign molecule, forming an antibody-antigen complex. Several such antibody molecules with differing binding specificities may bind to a single invading organism or complex molecule. The consequence of these attachments is that the foreign molecule or organism is marked for destruction by either the other specialized killer T cells or scavenger macrophages. Other T cells retain a "memory" of the immunogenic components of the foreign organisms, so that when the body is invaded at a later date (which may be many years later) the body is primed to respond in a more rapid and vigorous way to the invader. There are two main processes involved here. Each has its own cells, cell receptors, and parachrine hormones; each has its specialized cells with their own unique growth and differentiation responses. The resulting complexities have, so far, prevented the design of a new vaccine based solely on knowledge of how a vaccine works.

Notwithstanding these complexities, many new diseases are being targeted for control or elimination by vaccination. Among these, many new types of vaccine are being tested for acquired immunodeficiency syndrome (AIDS), caused by the human immunodeficiency virus (HIV), as well as novel vaccines that may protect children against malaria infection. Diarrhea and pneumonia are other killer diseases affecting young children and neonates (resulting in 2 million deaths per year). These bacterial diseases are preventable by vaccination, but the means for the inexpensive and safe delivery of

Incredulous people grouped around Dr. Edward Jenner as he administers the first vaccine, 1796. *(The Library of Congress.)*

the vaccine materials is still under investigation. Vaccines for herpes simplex, papilloma virus cancers of the uterus, and staphylococcal infections are under development, as are the new techniques of DNA vaccines and powerful adjuvants such as CpG (multiples of the dinucleotide cytosine-guanine).

Ethical Issues

Vaccines are generally given to people and neonatal infants in good health. As with any medical treatment, it is possible that, as a side effect, serious illness or disease may result from the administration of a vaccine. This raises ethical questions: How much harm should be incurred to achieve a benefit that is expressed as an increase in the well-being of a population or society? How much individual suffering justifies a particular social gain? Because the suffering has been inflicted by an individual vaccinator, this might be thought less acceptable than the natural suffering that would otherwise afflict an unvaccinated population. One or two seriously diseased children may be the result of a vaccination campaign that has prevented several hundred deaths and thousands of diseased and disabled people. This ethical issue can be approached on the basis of a calculus of suffering. The chance that any one individual will experience harm, pain, or loss (with no advance knowledge of who will be so affected) has to be set against the thousands of people who would almost certainly suffer if they were not vaccinated. This utilitarian calculus tends to hold sway in most parts of the world, but there will be individuals in advanced as well as developing societies with dissenting views.

Those of a fundamentalist persuasion might argue that preventing people from becoming diseased is preventing God from exacting a punishment by causing a disease on those that have turned to idols or otherwise misbehaved by disobeying God's commandments. Another similar statement might be that by taking action to prevent disease, humans are acting unnaturally. Counterarguments to these statements is that one of God's commandments is "Therefore choose life" (*Deut* 30:19), so vaccines are acceptable in that they preeminently save lives. The argument about unnaturalness turns on the definition of the natural or that which obeys the laws of thermodynamics. Vaccines are in the latter category and should, thereby, be both natural and acceptable.

In the early days of the smallpox vaccination campaigns, and before Jenner, the argument from the pulpit was that as there was a small chance that the vaccinee would catch smallpox from the vaccination (then called variolation), thus creating a way that an individual could commit suicide (albeit inefficiently), which was forbidden by both religious and secular authorities. Clearly the intent of the vaccinee is normally to avoid death so the commitment of a crime that involves an evil mind or intent is not applicable in this area.

A case can be made that by vaccinating all the young children of the developing world against neonatal infections there will be increases in population numbers that will eventually lead to starvation and further suffering. But as developing populations advance and more of the female population receive some education, birthrates decline—a situation aided by the increased probability that newly born children will survive the hurdles of the infectious diseases of childhood.

Some vaccines are expensive; for example, a three-dose course of vaccination for hepatitis B when it first became available was about $1,000. The U.S. Food and Drug Administration, or a comparable agency in another country, must license the marketing and widespread use of a vaccine. To obtain this license, a company may spend anywhere from $300 million to $800 million testing the vaccine's safety and efficacy and ensuring consistency of production, and this cost must be recouped within the remaining lifetime of whatever patent was taken out when the mere possibility of a vaccine was recognized. The poor or the people of the developing world clearly cannot afford expensive new vaccines. In a decade or so, however, the price of most new vaccines come down to affordable levels, and agencies such as WHO, charitable foundations such as the Bill and Melinda Gates Foundation, and local governments find the funds to buy vaccines purchased at special low prices. For people in the developing world these vaccines are generally free at the point of use.

It clearly costs less to test a vaccine in a developing country where the prevalence of the disease is at a higher level, and so the challenge level (the level of the virus in the population that can constitute a cause of disease infection against which the vaccine generates a protective response) is higher; fewer people therefore have to be enrolled in the efficacy tests. But it is clear that from a safety point of view, the people in the test are exposed to the risks of harmful side effects. Why should people in the developing world accept the risks of harm from a vaccine that is intended to decrease the risk of disease in the advanced or developed world? To obviate this disproportion, arrangements are often made so that those who have participated in the trial and others in their society may obtain preferential supplies of vaccine. But this is not always the case.

Finally, some argue that vaccines both promote more risky sexual behavior and obviate the need for the development of self-control by the use of a technical fix—the vaccine. This latter argument is parried by the contention that without the vaccine the disease situation in the society would be considerably worse and that a person's self-control is a matter for their personal determination and conscience. That a vaccinated person would behave in a way that would increase the chances of becoming infected is a real issue. If, however, the herd effect is to apply, then the increase in risky behavior will come to naught as the herd is so well protected that, no matter the risky behavior, the chances of getting the disease are drastically reduced.

In an era of heightened threats of terrorist attacks, it is important to realize that one such threat is the deliberate release of pathogenic microorganisms. To prevent such an event becoming a disaster it would be important to have available the necessary vaccines to limit the spread of contagious disease. This in turn could lead to further developments of pathogens that are not affected by the vaccines. An escalatory process is thus engendered. Determining how much of a society's resources will be devoted to these contingencies will require much skill in deliberation and adaptation to current conditions and future potential developments. Nevertheless, the relative importance of alternative personal and social expenditures will need to be continually reevaluated.

Notwithstanding the ethical issues, vaccines remain one of the most effective and powerful tools for controlling, reducing, or eliminating debilitating diseases. They also point the way ahead for the development of medicine in that more effort should be expended on the development of methods for the prevention of disease rather than the cure of diseases that could have been prevented.

VALUES AND VALUING

The concept of value is more complex than it might initially appear. Values can range across personal preferences as indicated by pleasures, desires, wants, and needs to more objective goods such as health, efficiency, progress, truth, beauty, and more. Values can also be negative as well as positive, and in the former case they are commonly termed "disvalues," with examples being pain or illness. Values in all these senses both influence and are influenced by science and technology.

However, what precisely makes each of these diverse phenomena into values is more difficult to indicate. The concept of value, its manifestation in values, and the process of valuing (and evaluation) have been subject to diverse economic, social scientific, and philosophical analyses, each of which introduces numerous distinctions of relevance to any description and assessment of values in and resulting from science, engineering, and technology. Because of such difficulties, the present review attempts no more than some general introductions to three areas of discussion and includes a briefly annotated bibliography to mostly philosophical references.

Economic Perspectives

The term *value* is derived from the Latin *valere,* to be worthy or strong, the root as well of *valiant, valor,* and *valid.* It can be used as a noun ("Science is one of the primary *values* in modern culture") or verb ("We *value* modern technology"), or turned into a modifier ("Engineering is a *valuable* activity"). The term first emerged during the rise of the modern period to refer to the monetary worth of some commodity. Eighteenth-century economists conceptualized value as dependent on humans, and as such value was subtly opposed to premodern notions of goodness as a transcendental manifestation (along with truth and beauty) of being as such.

In the labor theory of value, commonly referenced to the English philosopher John Locke (1632–1704), value is created by humans when they technologically transform nature. In classical economics the market price of a commodity was thought to reflect the objective value contributed to it by human labor. But critics of this view argued in favor of price reflecting almost wholly the values that consumers attribute to products in a competitive marketplace. Exchange value replaced use value as the primary form of value. In economic science the basic concern has thus become to analyze interactions between human values and market behavior.

Social Scientific Perspectives

A different analysis of values developed in the social sciences, where the concern was more with how values are rooted in or related to the self and how they constitute society or influence political behavior. One mid-twentieth century effort to promote the scientific study of social values was advanced by the pragmatist philosopher Charles Morris (1901–1979). Extending earlier work, Morris (1956) distinguished between operative, conceived, and object values; did an empirical, cross-cultural analysis of value preferences among college students in Canada, China, India, Japan, Norway, and the United States who completed a "ways to live" inventory; and then speculated about the social, psychological, and biological determinants of values. The results of this psychometric research, which revealed both stability in structures among thirteen different ways of life and differences between national samples, were not especially profound, but they nevertheless promoted the idea that values are amenable to empirical investigation. This was in opposition to any assumption that the fact/value distinction would exclude values from scientific examination.

On a more personal level, one of the most widely referenced psychological analyses of value is that of Abraham H. Maslow (1908–1970). According to Maslow (1971) human beings try to satisfy needs or pursue values in the following order of priority: physiological needs (air, water, food), safety (security, stability), needs of belongingness and love, esteem needs, and self-actualization. The need for self-actualization was further associated by Maslow with the pursuit of what he called B(eing)-values such as truth, goodness, and beauty.

An observation by Langdon Winner bears on the implications for science and technology of many psychological (and even some economic) approaches to values. Once values are subjectivized, "[r]aising the question of value is no longer so much an occasion to think about the qualities of things or conditions outside us [as it is] an opportunity to look within, to perform an inventory of emotions" (Winner 1986, p. 158). Persons no longer purchase objects because the objects themselves have value as they are likely to purchase objects to realize their own values.

In sociology and anthropology values are described not so much in individual or personal terms as dimensions of culture. Shared values create collective identity and solidarity in culture and society. Socialization is a process of inculcating values from one group or generation to another. Sociologists of science analyze what particular values are shared within communities of technical professionals and how the inculcation and reinforcement of such values takes place. Values are both expressive and functional more than cognitive.

It should also be noted that within modern societies as a whole, one of the features that defines them as modern is the shared value placed on science and technology. Some critics of technological society in turn argue that this shared commitment to and/or acceptance of science and technology may undermine other socializing values such as religion. Questions thus arise about the absolute value of scientific knowledge—and about the possibility of technologies configured by alternative values.

Philosophical Perspectives

In philosophy the examination of values is closely linked to ethics. The philosophical examination of values and valuing as distinct from ethics came of age in the mid-twentieth century in different ways in the pragmatic, analytic, and phenomenological traditions.

PRAGMATIC TRADITION. In the pragmatic tradition, work by John Dewey (1859–1952), Ralph Barton Perry (1876–1957), Stephen C. Pepper (1891–1972), and C. I. Lewis (1883–1964) has been central. For Perry, value is defined as "any object of any interest" (1926, p. 115), so that to say that X is valuable means that Y takes an interest in X. Pepper sees Perry's definition as too narrow and argues more generally that values are constituted by "all selections by a selective system that are relevant to human decisions" (1958, pp. 690–691).

Dewey and Lewis continued the pragmatic empiricism of Perry and Pepper by arguing the foundational character of the human creative act of valuing. For Dewey, values are *ends-in-view,* that is, always provisional and able to become means to another end-in-view. Going beyond sheer animal impulses or appetites that produce effects, human interest, desire, "having ends-in-view, and hence involving valuations, is the characteristic that marks off human from nonhuman behavior." Moreover, when science is put to "distinctively human use" its knowledge about the nonhuman world is utilized to assess such ends-in-view in terms both of whether they are likely to be achievable by the proposed means or capable of becoming means themselves for further provisional ends. "In this integration not only is science itself *a* value (since it is the expression and the fulfillment of a special human desire and interest) but it is the supreme means of the valid determination of all valuations in all aspect of human and social life" (1939, p. 66).

Like Dewey, Lewis sees evaluations as forms of empirical knowledge related to courses of human action. Values have empirical content, although this content bears solely on personal preferences and courses of action, which makes values subject to democratic choice and scientific assessment. The general study of values, which can involve more than ethical values, is for pragmatists more properly termed theory of value or axiology than ethics.

ANALYTIC TRADITION. In the analytic tradition, the early leaders were Charles L. Stevenson (1908–1979), A. J. Ayer (1910–1989), and R. M. Hare (1919–2002). According to Ayer, the philosophical analysis of values is better described as *metaethics* than as ethics, because its goal is more the clarification of the meaning of terms than normative argumentation. Adopting a positivist interpretation of science as the paradigm of knowledge, Ayer and Stevenson argued that ethical and value statements were simply noncognitive expressions of likes and dislikes. Hare subsequently merged metaethical analysis with ordinary language philosophy to undertake a critical examination of the "language of morals." Linguistically, value statements were argued to entail a universalization of likes and dislikes.

Another even more abstract metaethical approach to values can be found in the work of G. H. von Wright (1916–2003), a student of Ludwig Wittgenstein. Von Wright (1963) subjects a particular value, goodness, to extended conceptual analysis. For von Wright it is not so much the value of goodness that is a creative projection of human action as a human commitment to a specific value that establishes that value as a norm. Von Wright and others such as Sven Ove Hansson (2001) have further sought to develop a formalized logic of values and norms reasoning.

PHENOMENOLOGICAL TRADITION. In the phenomenological tradition the defining work was that of Max Scheler (1874–1928). Whereas pragmatism focused on the process of valuing and analytic philosophy on the meaning and logic of value propositions, Scheler sought a conceptual elucidation and critical assessment of the substantive value feelings people experience. Scheler undertook his phenomenological descriptions of experienced values in opposition to Kantian formalism and universalism—a formalism echoed in metaethical formalism. For Scheler, prerational or intuitive preferences are at the basis of substantive ethics. These feelings can be grouped into five basic types: sensible values, pragmatic values, life values, intellectual values, and spiritual values. For Scheler (and most subsequent phenomenologists) technology is constituted by pragmatic values and science by intellectual ones.

Implications

The philosophical study of values yields a number of distinctions used in reflecting on relations between science, technology, and values. Such distinctions include those between instrumental and final values (means and ends), between extrinsic and intrinsic values, and subjective and objective values. Although related, these distinctions are subtly different. For instance, instrumental or use values may be extrinsic or designed into technological artifacts so as to become intrinsic values that have subjective and objective dimensions.

In relation more specifically to science and technology there are three interrelated issues with regard to values: What sort of property is involved with having a value or being valuable? (That is, are values primarily aspects of things or of knowers and users?) Is this property subjective or objective? (That is, to what extent is value subject to scientific study?) How might this property be designed into products, processes, or systems? (That is, can values be part of engineering design and technological invention?)

By and large values are taken in economics and in philosophy to be second-order properties that arise in interactions among human beings (markets) or depend on human beings (their interests). Values are thus not determined by science though they are certainly manifested in science, and science can study values in at least three ways: inventorying what values people express, analyzing structural relations among values, and criticizing specific values as likely or not to be able to be realized given the way the world is. The engineering design of products, processes, or systems is always undertaken with some values in view both with regard to process and project termination. That is, questions are increasingly asked about whether certain values such as user-friendliness, gender equity, or democratic participation can be designed into technologies. But the degree to which such a question can be answered in any systematic manner remains problematic.

The problematic character of the values–science relation is another continuing issue. One of the most persistently defended distinctions in science and technology is that between facts and values. Although widely criticized—because it is not clear whether the distinction is itself a fact or a value or both—one of the most persistent difficulties is to figure out how best to relate the two once distinguished. Even those who want to defend the difference also want to argue that values should have some bearing on what kind of science gets done and how it is done, and on which kind of technology gets created and how it should be used.

One general effort to address such questions is Loren R. Graham's *Between Science and Values* (1981), in which the author distinguishes between restrictionist and expansionist relationships. In the restrictionist view, science and values are strongly separated, and science is argued to be autonomous with no univocal influence on values. According to Graham, this is a view that is more defensible in physics than in biology, especially when the biology involves research on human beings. In the expansionist view, science is argued to have either direct or indirect implications for values and vice versa. This is the view that Graham thinks is most reasonable, but also one that he admits is both difficult to determine the boundaries for and dangerous. Indeed, as his historical case studies in physics and biology across the twentieth century reveal, almost any effort to deal with the science–values relation has weaknesses as well as strengths. Values and valuing are as much a challenge to science as science is to values.

In conclusion, it is worth observing that discussions of science, technology, and values in the 2000s have become less central than in the 1950s or 1960s. Were Jacob Bronowski's widely read *Science and Human Values* (1956) to have been published in the 1990s it would more likely have been titled something like "Science and Ethics."

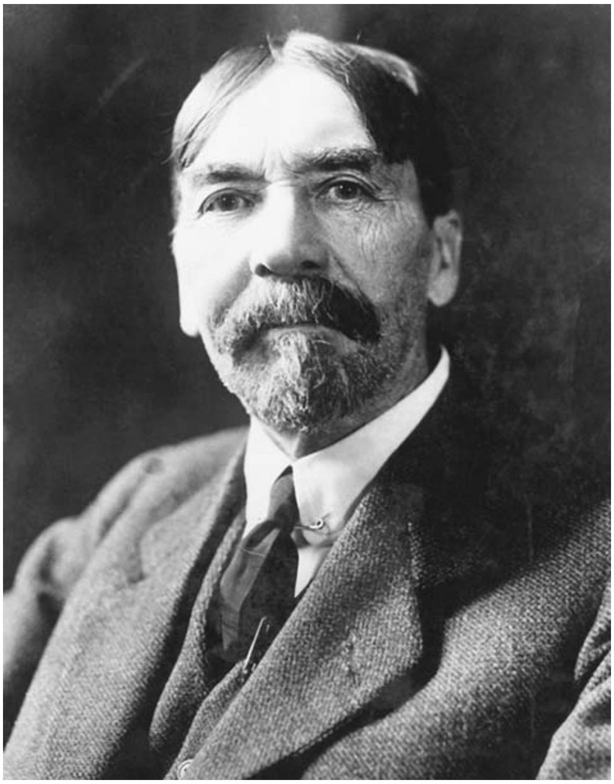
VEBLEN, THORSTEIN

Economist, sociologist, and a founder of institutional economics, Thorstein Bunde Veblen (1857–1929) was born in Manitowoc County, Wisconsin, on July 30. He studied under the economist John Bates Clark at Carleton College in Minnesota, then at Johns Hopkins University before earning his doctorate in philosophy at Yale University in 1884. After a career of teaching at the University of Chicago, Stanford University, the University of Missouri, and the New School for Social Research, he died near Menlo Park, California, on August 3.

Veblen was an iconoclast. During the early twentieth century he was the foremost critic of the business establishment and its effects on culture and society. He alienated other academics by challenging their acquiescence to business interests. He was a prolific writer whose most famous work earned both popular success and intense academic scrutiny.

As one of the first institutional economists, Veblen's writings were often diametrically opposed to classical or neoclassical economics. For Veblen neoclassical economics relies on static notions of individually determined self-interests. In contrast, institutional economics maintains that social institutions, arising from individual economic behavior, influence that behavior in return. This approach views the economy as an evolving system and places a strong emphasis on dynamics, changing structures (including technologies, institutions, and ethics), and shocks to the system arising from technological innovation.

His most famous work, *The Theory of the Leisure Class: An Economic Study of Institutions* (1899), was a scathing sociocultural commentary. Veblen provides both a dynamic theory of class movement and a theory of consumption. He paints a picture of the business class as evolving from an earlier stage of "savagery," in which people peacefully went about their daily lives without any notion of private property and with relatively little material wealth. Culture then evolved from this primitive state to one of "barbarianism" characterized by private ownership and a leisure class that did not have to



Thorstein Veblen, 1857–1929. The American political economist, sociologist, and social critic wrote about the evolutionary development and mounting internal tensions of modern Western society. *(© Corbis-Bettmann.)*

work, but instead derived its wealth from the exploitation of other human beings through technology. Members of the leisure class gained their status through control and knowledge of technology. Veblen maintained that the leisure class would remain in power and receive the economic benefits of being in power as long as they could appropriate technological skills, tools, and labor. This appropriation depends mainly on private property and the profits derived from ownership of economic resources. This ability to remain in power and to maintain a dominant class position depends in turn on creation of institutions through business and government to protect the property rights of the leisure class at the expense of everyone else.

Veblen argued that the concentration of technology and power would often lead to the accumulation of wealth in the hands of a small leisure class at the expense of those at the other end of the economic spectrum. In the absence of institutions, effective property rights, and cultural norms the majority of the population would have access to neither capital nor the means to secure it. This has proven to be the case in many developing countries, where the absence of well-defined and enforceable property rights makes capitalism prone to inequitable outcomes.

Veblen's theory of consumption, especially the idea of consuming something beyond basic necessities, was unique. Conspicuous consumption provides the basis for twentieth-century consumerism in which consumption of goods and services serves not only as a tool to meet basic needs but also as a symbol of status.

Veblen recognized both the importance of science and technology in the creation of wealth and tensions between scientific technology and commercial enterprise. In *The Theory of Business Enterprise* (1904) and again in *The Engineers and the Price System* (1921) he analyzed the tensions between technological efforts to create good products and commercial interests in making money. Because of his praise of the "instinct of workmanship" (in his 1914 book published under that title) in ways that would eventually be echoed by Samuel C. Florman's *The Existential Pleasures of Engineering* (1976), Veblen's analysis inspired the technocracy movement and its effort to place engineers in positions of political power.

Veblen was one of the great thinkers of the twentieth century. Whether it was jealousy of his publishing success or because of his aloof nature, Veblen was shunned by his colleagues during most of his career. Ironically, near the end of his life, the American Economic Association offered him one of the highest honors in the field, the presidency of the association. He declined as he was unconcerned with either fame or recognition by his peers. Instead Veblen focused his efforts on writing and cofounding the New School for Social Research in New York. The posthumous rediscovery of Veblen's ideas has lead to renewed interest in both institutional and evolutionary economics and a new appreciation for and interpretation of Veblen's ideas. His legacy in the creation of social and economic theory continues to grow in importance.

VEGETARIANISM

Vegetarianism is a traditional ethical stance and practice that has been influenced around the turn of the twenty-first century by science and technology. Strictly speaking, vegetarianism is a way of life in which one abstains from eating meat including fowl and fish. The *vegan* (pronounced "veegan") diet excludes all animal products, including eggs and milk. *Lacto-vegetarians* include milk products in their diet, and *lacto-ovo-vegetarians*, both milk and eggs. In the techno-scientific culture, a vegetarian diet may also be conscientious in other ways, such as by taking into account agricultural and food production methods, transportation distances, and the fairness of trade.

History of Vegetarianism

The history of vegetarianism began around the same time in the Mediterranean area and India. In Greece, Pythagoras (circa 569–475 B.C.E.) and his group were the first known to profess vegetarianism programmatically. Later the philosophers Epicurus, Plutarch, and some Neoplatonists recommended a diet without meat.

In India, the newly born Jain and Buddhist religions initiated the practice of vegetarianism in the fifth century B.C.E. Soon their idea of nonviolence (*ahimsa*) spread to Hindu thought and practice. In Buddhism and Hinduism, vegetarianism is still an important religious practice.

The religious reasons for vegetarianism vary from sparing animals from suffering to maintaining one's spiritual purity. In Christianity and Islam, vegetarianism has not been a mainstream practice although some, especially mystical, sects have practiced it. Monasticism in both East and West has often promoted vegetarianism.

In European and North American culture, vegetarianism witnessed a revival beginning in the seventeenth and eighteenth centuries and especially during the nineteenth century in part as a protest against some aspects of the scientific and industrial revolutions. Well-known vegetarians include Leonardo da Vinci (1452–1519), Mary Wollstonecraft Shelley (1797–1851), Richard Wagner (1813–1883), Henry David Thoreau (1817–1862), Leo Tolstoy (1828–1910), George Bernard Shaw (1856–1950), Mohandas Gandhi (1869–1948), and Albert Einstein (1879–1955).

Contemporary Issues

In contemporary culture, individuals have various reasons for pursuing vegetarianism. Although religious and spiritual arguments continue to be made, scientific research has also provided new justifications for vegetarianism. First, there is clear evidence that, contrary to early modern scientific theories that animals were like machines, animals in fact feel pain, anxiety, and other forms of stress. Thus it appears that breeding and killing animals for food causes them suffering. Moreover, some nutritional research indicates that a vegetarian diet is healthier than a carnivorous one. Finally, meat is ecologically more expensive to produce for food than vegetables: On average, the input ratio of units of proteins and energy fed to livestock to produce one unit of meat is ten to one.

Technologically enhanced food production has raised other concerns. For instance, it is highly questionable whether animals live in sufficiently humane conditions on contemporary farms. Indeed, the movement to promote the humane treatment of animals in the 1970s was extended from pets to other animals, and has had an influence on contemporary vegetarianism, as well as on the treatment of laboratory animals. Additionally, pesticides, hormones, and antibiotics involved in raising livestock have caused uneasiness. Similarly, the huge transport distances and the questions of global justice have encouraged people to think about what they eat, since food often is produced in Third World countries for wealthier nations.

The most common rejoinders to such vegetarian arguments are as follows: The ills of meat production do not directly imply any moral obligation for vegetarianism; meat has been a traditional part of human diet for thousands of years, hence it is not clear whether a vegetarian diet really suits everyone; and it is possible to arrange farms so that animals do not suffer unnecessarily. Moreover, often vegetarians have been accused of fanaticism and moralism; one common view is that they are just unbalanced people. In fact, it has also been noted that Adolf Hitler was a vegetarian.

The question of animal rights may also be related to vegetarianism. Just as *racism* involves one race oppressing another, it can be argued that *speciesism* involves one species oppressing another. Those who argue for the existence of animal rights commonly use their view to support vegetarianism. However, acceptance of the idea of animal rights immediately raises problems of the depth and extension of these nonhuman rights. Do animals have more than rights to life? Do all living creatures, including bacteria, have such rights? Usually only moral agents have rights, and duties as well; how does this apply to animals?

VERNE, JULES

The French novelist and playwright Jules Verne (1828–1905) was born in Nantes on February 8 and died in Amiens on March 24. He is best known for a series of novels published under the inclusive title *Voyages extraordinaires* (Extraordinary journeys). Some of these works have been interpreted, especially in English-speaking countries, as early science fiction, or used to stimulate discussion of ethical and political issues related to developments in science and technology—views that are at best only partial appreciations of his achievement.

Verne earned his *licence en droit* (master's degree in law) in Paris in 1850. After twelve years producing plays, opéras comiques, operettas, and short stories, he became famous in 1863 for his first published novel, *Five Weeks in a Balloon.* Verne subsequently published some fifty-three novels, among the best-known titles being *Journey to the Center of the Earth* (1864), *From the Earth to the Moon* (1865), *Twenty Thousand Leagues under the Seas* (1870), *Mysterious Island* (1870), *Around the World in Eighty Days* (1872), and *Michael Strogoff* (1876). After Verne's death, Hetzel, continuing the *Voyages extraordinaires* collection, published several novels, still under the name of Jules Verne, but all modified by his son Michel Verne, who added new chapters and new characters; Michel Verne even wrote a complete novel, *L'Agence Thompson and Co.* (The Thompson Agency and Company), which was edited under his father's name.

The objective of Verne's novels was primarily to teach geography, history, and the sciences to the French family. To make such dry disciplines attractive, Verne created initiatory stories happening in different geographies, such as: a judicial error and the innocence of the supposed culprit demonstrated through a cryptogram during the descent of the river Amazon in *The Jangada* (1881; also known as *The Giant Raft*); the cryptogram opens the novel, but cannot be solved during the whole story, because the key was considered as lost (after the discovery of the key, Jules Verne ends the novel with the readable message hidden in the cryptogram at the opening of the story); a *jeu de l'oie* (goose game, kind of snakes and ladders), allowing the reader to discover the United States in

The Will of an Eccentric (1899); or even a search for the missing link of human evolution in the African jungle in *The Aerial Village* (1902; also known as *The Village in the Treetops*). Writing for the French middle-class family did not prevent Verne from putting into his novels his views about colonialism, politics, and the society of his time. Antimilitarist and against the death penalty, Verne also denounced the misdeeds of slavery. He condemned British Victorian imperialism in such novels as *The Kip Brothers* (1902). During his lifetime he became known as a writer for children and was considered a scientific prophet. These two erroneous opinions continue to persist in the early twenty-first century. In reality, Verne was a writer of his time, using a style in which wordplay and hidden meanings were abundant; his work nevertheless heralded the structure of the modern novel.

Well into the twentieth century, Verne's works were so badly translated in the Anglo-Saxon countries that his readers could appreciate only his rare "futuristic" views, supported by a few extraordinary machines used to support the novelistic intrigue. Since the early 1960s, however, new translations by Walter James Miller, Edward Baxter, and William Butcher have allowed English-language readers to appreciate Verne as a true writer—a precursor of surrealism and other literary movements of the twentieth century such as the Collège de Pataphysique. (Pataphysics, an absurdist concept coined by the French writer Alfred Jarry, is the idea of a philosophy or science dedicated to studying what lies beyond the realm of metaphysics. It is a parody of the theory and methods of modern science and is often expressed in nonsensical language. A practitioner of pataphysics is a pataphysician.) Many scholarly studies in Europe and the United States show the modernity in Verne's novels, where irony and cold humor are always present.

Verne's many plays, usually written in collaboration with other authors, such as Charles Wallut and Adolphe d'Ennery, and most of his vaudeville works, operettas, and so on have grown old and would fail to have appeal in the early twenty-first century. *Journey through the Impossible* (1882), however, is a modern masterpiece, written at the juncture of the optimistic and pessimistic periods of Verne's life. This three-act play, cowritten with d'Ennery and inspired by *The Tales of Hoffmann,* a grand opera by Jacques Offenbach (1819–1880), is one of the main peaks in Verne's output. For the first and only time, the heroes do the impossible, when in the novels they did only what was extraordinary: The heroes from Verne's novels, including Nemo, Ox, and Ardan, meet onstage and go to the center of the earth in the first act, to the bottom of the Sea in the second, and to the far planet Altor in the third. The principal hero is the son of Captain Hatteras, who was the first discoverer of the North Pole. During the three acts, his fiancée Eva shares his adventures and difficulties—an unusual fact in the *Voyages extraordinaires*—and he hesitates between love and knowledge, the same way Hoffmann hesitates between love and art.

Jules Verne, 1828–1905. The French novelist was the first authentic exponent of modern science fiction. The best of his work is characterized by intelligent predictions of technical achievements actually within man's grasp at the time Verne wrote.

Verne's work has provided scenarios for more than four hundred films and television programs, not only in Hollywood but also in countries as far away as China. In many instances they have continued to provide a popular introduction to the wonders of science and technology, propagating the image of Jules Verne as science fiction author. Jules Verne wrote his novels during the time when steel and steam engines became popular, when electrical power was used more and more, and when the Eiffel Tower was built, and he uses all these new technologies in his novels to be an integral part of the adventures he was telling his readers.

There are two ways in reading Jules Verne: the first level is the initiatory story with an adventure and sometimes more or less unusual and fantastic machines. Because of the bad English translations, it was the only way English-speaking readers could enjoy Jules Verne. The second level is appreciating the use of technology and science as narrative tools, enjoying the imaginary solutions of problems and desperate situations of an adventure happening in a world where war, confrontations and intolerance exist.

VIDEO GAMES

Video games may be defined as games involving electronic technology in which real-time interactive game events are depicted graphically on a screen through pixel-based imaging. Elements one would expect to find in a *game* are *conflict* (against opponents or circumstances), *rules* (determining what can or cannot be done and when), use of some *player ability* (skill, strategy, or luck), and some kind of *valued outcome* (winning vs. losing, highest scores, or fastest times, among others). All are usually present in video games in some manner, albeit to varying degrees. In video games, the scoring of points, adherence to the rules, and display of the game's visuals are all monitored by a computer, which also can control the opposing characters within a game, becoming a participant as well as referee. Most arcade video games, home computer games, and home video games using a television would qualify as video games.

The development of the video game was shaped by film, television, and computer technology, and its influences include pinball, arcade games, science fiction, sports, and table-top games. Video games appeared during a time in which interactive art, minimalism and abstraction, and electronic music were developing, and these provided an important part of the cultural context in which the video game evolved.

Modes of Exhibition

Video games have appeared in a number of different modes of exhibition, including mainframe games, coin-operated arcade video games, home video game systems, hand-held portable games and game systems, and home computer games.

The games created on the giant mainframe computers were limited to the large mainframe computers found only in laboratories and research centers. These games were experiments and were neither sold commercially nor generally available.

Coin-operated arcade games come in several forms: stand-alone consoles; cocktail consoles; and sit-inside or ride-on games. A stand-alone console, the most common, is a tall boxlike cabinet that houses the video screen and the control panel for the game. The game controls can include joysticks, track-balls, paddles (round, rotating knobs), buttons, and guns with triggers. Occasionally there are controls for more than one player, although single-player games are the most common.

The *cocktail* console is designed like a small table, with the screen facing upward through a glass tabletop. Often the game is designed for two players, with a set of controls on each end of the table and the screen between them. This type of console is popular in bars or restaurants where patrons can sit and play a video game, while setting their drinks on the tabletop (hence the name cocktail).

Sit-inside or ride-on consoles hold or contain the player's body during play. They may even involve physical movement, usually to simulate the driving or flying of a vehicle in the game, typically with a first-person perspective. In driving and racing games, foot pedals and stick shifts are sometimes included. Other games involve bicycle pedaling, skis, skateboards, and simulated horses.

Home video game systems typically use a television or computer monitor for their graphic displays, although some systems come with their own screens. Home game systems that display their graphics on a television can be console-based, cartridge-based, or use laserdiscs, CD-

Two youngsters play video games at an arcade. *(AP/Wide World Photos.)*

ROMs, or DVD-ROMs (home computer games also appeared on cartridges, floppy disks, diskettes, and audio tape). Console-based systems have their games hard-wired into the console itself, while cartridge-based game systems have their games hardwired into cartridges or cards that are plugged into the game console, allowing new games to be sold separately. CD-ROMs and DVD-ROMs are used for most contemporary game systems, because they can contain far more data than traditional cartridges.

Hand-held portable games and game systems that run on batteries can be carried along with the player. They are usually small enough to fit in the palm of one's hand, and typically have small LCD screens with buttons and controls around the screen. Some of these systems are cartridge-based as well.

Networked games involve multiple participants connected via the Internet to a video game world on a server, where they interact with the world and with each other's characters. Some of these games have hundreds or thousands of players and run twenty-four hours per day, with players logging on and off whenever they want. Players in these on-line worlds meet, converse, and form alliances and friendships without ever meeting face-to-face. Because real people control the player-characters, the social interaction is real, albeit in a more limited bandwidth than in-person interaction.

Ethics

Like film and television, video games have been criticized for having excessive violence, explicit sex, occasional racism, stereotypical characters, and an overall lack of edifying content. As graphics develop toward photo-realism, games grow more concrete in their visual representations and more like the images produced in other media, including those through which the player receives real world information (for example, television) and interacts socially (for example, the Internet). Combined with a simulated world in which players can act, video games can subtly influence players' behavior, beliefs, and outlook in real-life.

Most narrative media embody world-views through the ways in which characters' actions are linked to consequences, while video games link consequences to the player's own actions. Instead of merely watching and identifying with a character, the video game player is an active participant in the action seen on-screen. Whereas watching martial films does not help one develop physical skills, a video game *can* sharpen the player's hand-eye coordination skills and reflex responses, and stimulate aggression. The speed at which game action occurs often requires players to develop reflex responses at the expense of contemplation, sometimes resulting in a kind of repetitive stimulus-response training in which reaction speed is crucial. These responses can vary, from abstract figure manipulation, strategic thinking, and problem solving, to the hair-trigger automatic killing in fast-action games. While games can be designed to develop a variety of skills, shooting and killing are unfortunately among the most common.

On a larger scale, ethical worldviews can also be affected as successful game play often encourages or requires players to think in certain ways, and game narratives may link actions to outcomes and consequences that reinforce certain types of behavior. Thus it is a question of how the medium is used, how games are designed, and what values those designs embody. On-line role-playing games, for example, differ greatly from other forms of video games in that they are played by vast numbers of people in *persistent* (twenty-four-hour-per-day) game worlds, and games are ongoing and cannot be restarted. Some players invest a great deal of time and money in such games, building up their characters' powers and possessions, so there is often more at stake during game play, and ethics takes on greater importance as consequences within the game begin to extend into the real world.

While most people can clearly distinguish between video games and real life, ideas learned through the games can spill over to other behaviors in either positive or negative ways. Clearly there is a difference between real-world morality and that of the on-line game world. *Killing* another player's character may be considered an act of aggression, however the behavior falls within the established rules of play, and players whose characters are killed often come back with new characters. Yet the metaphor of killing remains, as does the fact that many people consider pretend killing to be fun. Likewise the goal-oriented nature of video games focuses more on what a player does and achieves rather than on what a player becomes. Additionally the malleability and repeatability of most video game experiences can lead to both experimentation and desensitization through repetition, because nothing is final or irreversible when a game can be restarted or when a player has multiple *lives*.

Other potential effects involve the player's default assumptions and ways of analyzing the world. For example, in most games everything is structured around the player and is present to produce an experience for the player. Other characters are there to either help or hinder the player-character, and often they speak in direct address to the player-character. Game objects exist for the player to use, take, or consume. The overall effect can be to promote a self-centered, utilitarian point of view in which players consider everything in the game world according to how it will affect or be of use to them.

At the same time, video games can have a positive influence, enhancing problem-solving skills, powers of observation, and patience. Completing an adventure game's objective, for example, usually requires goal-oriented behavior and often single-minded pursuit. Even when laden with puzzles and ambiguity, most adventure game problems and goals are clear-cut and simple relative to the problems and goals encountered in real life. The video game may remove the player momentarily from the complex problems of real life and offer solvable, simplified conflicts and goals that can be solved in a few hours (or days) and for which solutions already exist. In either case, these effects may be subtle, but repeated exposure to situations in which one is required to think a certain way can have gradual, long-term effects. Some values may find affirmation outside the games, such as overcompetitiveness and the accruing of personal wealth and goods.

In order to regulate games and hold game makers accountable, professional codes, such as that of the Association of Computing Machines (ACM) have been created. Additionally, the Entertainment Software Ratings Board (ESRB) provides a series of ratings (Early Childhood (EC), age 3 and up; Everyone (E), age 6 and up; Teen (T), age 13 and up; Mature (M), age 17 and up; and Adults Only (AO), age 18 and up), although these ratings are not always enforced in stores, where games might be sold to underage players.

While it is true that many games in the early twenty-first century are graphically violent and sexually explicit, it should be remembered that some of the best-selling games of all time (*The Sims, Myst,* and *Pac-Man,* for example) have been nonviolent, indicating that it is good game design, not sex or violence, that sells.

VIOLENCE

One of the multiple battlefields of environmental determinists versus biological determinists relates to the causes of violence. The former see violence as a primarily culturally rooted phenomenon, whereas the latter see it as being biologically determined This controversy, however, may be due to a failure to distinguish between aggressiveness and violence.

Aggressiveness and Violence

Aggressiveness is an instinct and therefore is a product of bioevolution. However, nature has not selected for the trait of aggressiveness alone but together with a set of inhibiting factors that are activated in certain circumstances, for instance, when two individuals who belong to the same group fight with each other and the life of one of them is threatened. As Irenäus Eibl-Eibesfeldt (1984) argues, a widely obeyed commandment in nature is "thou shalt not kill thy neighbor." Not even animals with as bad a reputation as wolves are an exception to this law.

In humans aggressiveness is linked primarily to the brainstem and the so-called limbic system or emotional brain (Sanmartín 2002). This part of the brain contains the structures that appear to be responsible for the responses (autonomous, somatic, hormonal, and neurotransmitter) that make up aggressive behavior. These automatic responses are triggered unconsciously by certain stimuli and coordinated by the amygdala, a structure in the inner region of the temporal lobe of both brain hemispheres.

The amygdala sets off the chain of effects that constitute the acting out of aggressive behavior in response to a stimulus. It also is responsible for stopping those effects when it receives inhibiting stimuli such as the emotional expression of fear shown by victims.

If humans were only the product of bioevolution, their aggressiveness would be regulated by the amygdala exclusively. However, humans are much more than a product of biological evolution. Indeed, the amygdala is connected to certain brain regions that are considered the seat of consciousness and that experienced extraordinary growth approximately 1.5 million years ago (Damasio 1994). These regions are in the frontal part of the brain cortex, the so-called prefrontal cortex. Their functions appear to be linked closely to the abilities that traditionally have been considered humankind's noblest: imagination, thought, and feeling. Ideas, thoughts, and feelings make up the framework that analyzes emotions and decides whether to reinforce or extinguish them. If, for instance, one of the emotions that constitute aggressiveness is reinforced, aggressiveness may go out of control and its natural inhibitors may be rendered inoperative. Soldiers and terrorists usually undergo a process of cognitive restructuring in which they learn to view their victims not as persons, but as things or symbols. Once victims are not seen as persons, it is impossible to empathize with them; consequently, their facial expressions have no inhibitory capacity.

Strictly speaking, violence is what occurs when the interaction between the expression and the inhibition of aggressiveness is disrupted in a way that hypertrophies aggressiveness and adds the intention to cause damage knowingly, as in the case of soldiers and terrorists. This disruption is influenced by ideas, thoughts, and feelings acquired over the course of a lifetime. Of equal importance are some of the products of the mind and in particular certain technical products. All of them are cultural elements. Violence therefore can be said to be primarily the result of the effects exerted by certain cultural elements on natural aggressiveness, hypertrophying it and conveying intentionality. The adverb *primarily* is used here because in certain cases (around 20 percent) the alteration of natural aggressiveness is caused by biological pathologies.

Technological Change as a Source of Violence

In most cases violence is born out of culture. Culture in turn is shaped by technology, as Ortega y Gasset (1939) argued, because humans are *a nativitate* (from birth) technical animals. Human beings change and survive because of bioevolution. However, humans do not worry as much about surviving as they do about the quality of life, always striving to achieve higher standards of well-being. This goal is achieved, but at the cost of creating a sort of supranature that consists of instruments or tools, machines, various forms of social organization, and instruments that apparently free humans of all the elements in nature that make them needy beings: cold, food, and the like.

Human beings also have directed technology toward themselves. On the one hand, they have constructed external prostheses that have modified their natural appearance. On the other hand, technology has penetrated so deeply into humans that they can in principle alter even their genetic information and therefore reconstruct themselves by following preestablished patterns and desires.

These technical interventions have had some negative effects, such as the conversion of innate aggressiveness into violence. Technology (not entirely by itself, of course) has upset the balance between natural aggressiveness and its natural mechanisms of control.

In addition, this technical supranature regularly experiences strong convulsions. At these times there take place the great technological changes that seem to drive historical transformations with increasingly greater speed. The mechanical clock, the fifteenth-century arts of navigation, railways, airplanes and spaceships, nuclear weapons, computers, the Internet, gene technology, and cloning are all technical inventions that have shaken traditions and compelled humans to adapt quickly to new situations. Human beings appear to be forced to adapt themselves to the changes in their technical supranature, not the other way round; this process often is described as social progress.

The consequent demand for adaptation generates a certain amount of stress that is becoming increasingly difficult to control. Uncontrolled stress usually degenerates into violence. In this sense, then, technology in general may become a source of violence (Sanmartín 2000).

Television and Violence

Two technologies are especially linked to violence: the mass media (especially visual media) and weapons.

In the early twenty-first century, not even the industry denies that exposure to violent images in television, video games, or the Internet has effects on the audience and, particularly, on children and adolescents. What is under discussion, however, is the type and degree of these effects. Albert Bandura (1977) stressed the idea that children learn violent behavior not only by imitating the real violence that is present in their environments, but also by emulating the violence (fictitious or not) broadcast on television. This correlation was confirmed by a longitudinal study started in 1960 by Leonard Eron, Monroe Lefkowitz, Leopold Walder, and L. Rowell Huesmann (Huesmann and Eron 1986) that used a sample of 800 eight-year-old children. Jeffrey Johnson (2002) published another longitudinal study showing that seeing violence on television at age fourteen correlated significantly with later aggression (assault and battery, violent or armed robbery). According to Johnson and associates (2002), if exposure to television was one hour per day at age fourteen, 5.7 percent of the individuals at a mean age of sixteen or twenty-two exhibited violent behaviors, and if exposure was increased to three or more hours per day, violent behavior went up to 25.3 percent. Craig Anderson and Brad Bushman (2002), in a related meta-analysis of longitudinal studies, cross-sectional studies, field experiments, and laboratory experiments carried out to that date concerning the possible influence of violence on television, demonstrated that all studies supported the existence of a significant correlation between exposure to violence on television and violent behavior.

Other studies have provided more clues to this problem. Foremost among them that of Jo Groebel (1999), which showed that the relationship between real violence and screen violence is interactive: Violent people use audiovisual media to reinforce their beliefs and attitudes, becoming even more violent. This study dealt with a large sample: 5,000 twelve-year-old children from twenty-three different developed and developing countries with social environments containing high or low rates of real violence. One interesting discovery was that 88 percent of the children had seen the move *The Terminator* (1984). An even more interesting discovery was that in high-violence environments half the children wanted to be like the Terminator, whereas in low-violence environments the number was only 37 percent. In other words, the influence of screen violence on real violence depends on the amount of real violence surrounding a child.

Before blaming television for violence in society, especially among children and adolescents, one must consider carefully the social environments of those children. When children live in homes in which they suffer or witness abuse, where there is alcohol or drug abuse, where parents and children do not get along, where the homes have cramped or unhealthy living conditions, without the support of other family members or friends, the result may be an environment in which the spark of television violence has little difficulty causing a fire by adding to preexistent violent attitudes and behaviors.

In the early twenty-first century, this environment often also contains videogames, either on game consoles or computer. Many authors, such as Degaetano and Grossman (1999) and Anderson (2004), state that the effects of violent images on video games are even worse than other kinds of images, for several reasons. Firstly, as opposed to films and television programs, in violent video games the player is forced to identify with the main character (the aggressor). Secondly, violent video games require active participation, and active participation promotes learning. Thirdly, video-game violence is directly rewarded. Finally, the level of violence in video games is far superior to that in films or on television.

Computers, and in particular the Internet, are connected to violence, especially violent crime, in different ways. Rather than generating new forms of crime, the Internet has revolutionized some traditional forms of crime by accelerating their transnationalization. If there is one thing that has rapidly globalized, it is the criminal activities of mafias and extremist organizations. Sexual exploitation—and pornography, in particular (Von Feilitzen and Carlsson, 2000)—drugs trafficking, the smuggling of chemical, nuclear and radioactive material, and especially the money-laundering business, have benefited from the globalizing effect of the World-Wide Web. In fact, every year more than 600 billion dollars (slightly more than 2% of global gross domestic product) are laundered world-wide, practically cost-free.

Weapons and Violence

One particular type of technology is especially linked to violence: weapons. From a naturalistic point of view, bioevolution has poorly equipped the human animal for causing severe damage and especially for killing other humans. Human beings do not have fangs, sharp claws, or pointed horns. In order to kill they have to use their feet or fists with great force and skill or put their hands on a victim's neck for several minutes. In such cases, killing takes place at close quarters and a victim's aggression-inhibiting signals are quite effective.

These inhibitors are bypassed, however, when weapons are used. From knives and swords to guns and bombs, weapons have evolved to increase the distance between users and victims, until the victims have disappeared from direct view. This is not a coincidence. Once distance has blurred facial expressions, postures, and other aggression inhibitors, victims cease to be seen as persons and become things. One cannot empathize with a thing, stop one's destructive actions, or even feel sorry afterward. In this way one of the beings most ill-equipped by nature for killing has become, by virtue of technology, one of the most effective killers.

VIRTUAL REALITY

Virtual reality (VR) technology emerged in the 1980s, with the development and marketing of systems consisting of a *head mounted display* (HMD) and *datasuit* or *dataglove* attached to a computer. These technologies simulated three-dimensional (3-D) environments displayed in surround stereoscopic vision on the head-mounted display. The user could navigate and interact with simulated environments through the datasuit and dataglove, items that tracked the positions and motions of body parts and allowed the computer to modify its output depending on the recorded positions. Other types of VR that arose subsequently included *projection virtual reality*, in which users who wear special glasses interact with three-dimensional virtual models that are projected in a room and can be perceived from different angles, and *desktop virtual reality*, in which users stereoscopically view a virtual environment represented on a computer screen (using special stereo glasses) and interact with it using datagloves, or, more commonly, a mouse.

VR is used to simulate real environments, such as existing buildings or city areas, or to visualize imaginary ones, for instance spaceships or battlegrounds. VR is a technique with great possibilities for training, visualization, and entertainment. Applications are found in computer-aided design, construction, computer gaming, education, military exercises, aviation training (flight simulators), surgical training, therapy, and art.

Meanings of Virtual Reality

As Howard Rheingold (1991) notes, VR merges overlapping interests from the military for more realistic but risk-free training, of the science fiction imagination, and of entertainment industry efforts to intensify the vividness of various media. Although the term "virtual reality" most often refers to systems of the type just described, it is also used in a wider sense, to denote not fully realized virtuality, as in lesser forms of three-dimensional computer-simulated environments that are engaged from a first-person perspective. The most common example is first-person 3-D computer games. Such games are varieties of desktop virtual reality minus the stereo glasses. Wider still, VR sometimes denotes any interactive computer-generated environment, including those represented through two-dimensional graphics or through texts or symbols. In fact, the term *virtual* may be attached to any kind of object, event, or environment that is not realized physically but electronically, as in virtual money, virtual casinos, or virtual doctors (medical doctors that can be consulted over the Internet). In such cases, *virtual* may mean no more than "computer-simulated," or "on the Internet," or "in cyberspace," as opposed to "in physical space." This broad use of the term points to the fact that for many people, the term "virtual reality" and "virtual" are interpreted metaphysically as denoting a new, fictional kind of reality.

Mostly, however, the term *virtual reality* is used more narrowly, to refer to 3-D computer-simulated environments incorporating a first-person perspective that includes some degree of immersion, meaning that users feel that they are situated in an environment. Immersion can be enhanced through such means as realistic graphics and sounds, surround and stereo vision, surround sound, position tracking, and force and tactile feedback.

A distinction can be made between single-user and multi-user or networked VR. In single-user VR, there is only one user, whereas in networked VR, there are multiple users who share a virtual environment and appear to each others as *avatars*, which are graphical representations of the characters played by users in VR. A special type of VR is *augmented reality*, in which aspects of simulated virtual worlds are blended with the real world that is experienced through normal vision or a video link, usually through transparent glasses on which computer graphics or data are overlaid. Related to VR are *telepresence* and *teleoperator systems*, systems that extend a person's sensing and manipulation capability to a remote location by displaying images and transmitting sounds from a real environment that can (optionally) be acted on from a distance through remote handling systems such as robotic arms.

Ethical issues in virtual reality

VR has been the subject of speculation and critique in both academic circles and mass media. Popular culture portrays futures in which immersive VR is routinely used in society, as in science fiction movies such as *The Matrix* (1999), *Lawnmower Man* (1992), *Existenz* (1999), and the Star Trek series (with the Holodeck), and in novels such as William Gibson's Neuromancer (1984) and Neal Stephenson's Snow Crash (1992). VR is portrayed both positively, as a medium that offers endless possibilities for learning, entertainment, social interaction, and self-experimentation; and negatively, as a medium that causes users to flee from or deny everyday reality, that is used by evil minds to manipulate and gain control over others, and that dissolves any distinction between reality and fiction.

In the academic literature, authors have mainly tried to come to grips with the questions of how VR will transform people's conception of reality and how it will transform social life. As for the former question, authors tend to agree that VR will change the concept of reality and cause the distinction between reality and fiction to blur. However, some authors, such as Michael Heim (1993) and Sherry Turkle (1995), have argued that a distinction between physical and virtual reality will always exist because people are biological human beings that are born and die in the physical world and retain their roots there, whereas others, such as Philip Zhai (1998) have argued that such biological background facts are irrelevant and that VR can offer us a limitless world as rich and detailed as physical reality and can even replace the physical world as one's primary habitat.

As for social and ethical aspects of VR, most discussion has focused on the question of how the blurring of reality and fiction in VR may affect its users, on how reality is (mis)represented in VR, and on what forms of immoral behavior may occur in virtual environments. These issues will now be discussed in turn.

VR AND THE REAL WORLD. Some authors who hold that the extensive use of VR applications induces a blurring of the boundary between the real and the imaginary worry about negative social consequences. They worry that the idealized, vacuous and consequenceless worlds of VR come to serve as a model by which people comprehend the real (that is, physical) world, and conversely, that the attention and care that people attach to real-world people, animals, and things is also attached, inappropriately, to virtual things and personae. Another worry is that people may come to prefer the freedom and limitlessness of virtual reality and cyberspace over the limitations of physical existence and invest most of their time and energy in their virtual life, to the neglect of the real people and affairs in their physical lives. Proponents of VR argue instead that most people will be able to maintain a good sense of reality and will strike a healthy balance between their virtual life (which is, in part, also real life) and their physical life.

REPRESENTATION IN VR. VR environments that are intended to simulate actual realities may misrepresent these realities, according to expected standards of accuracy. This may cause their users to make false decisions or act wrongly, with potentially serious consequences, especially in areas in which life-or-death decisions are made, such as medicine and military combat. When VR is used for education and training, therefore, high standards of accuracy and realism should be expected, and developers have a responsibility to adhere to such standards. VR simulations may also contain biased representations that are not necessarily false, but that contain prejudices about people or situations. For example, a surgery training program may only practice surgery on young white males, a VR game may represent women and minorities in stereotypical ways, or a combat simulation program may only simulate combat situations in which civilians are absent. Like other media, VR may also break taboos by depicting morally objectionable situations, including violent, blasphemous, defamatory, and pornographic situations.

A man demonstrates a virtual reality device by lifting a virtual rock on a simulated Martian surface, wearing a video helmet and virtual reality gloves. *(© Roger Ressmeyer/Corbis.)*

BEHAVIOR IN SINGLE-USER VR. Most moral issues regarding representation in VR are not unique to it, and also apply to other types of simulations and pictorial representations. What is unique about VR, however, is the possibility to interact with environments that look real but are not. Because virtual environments are not real, any consequences of one's actions in VR, specifically in single-user VR, are not real-life consequences. It is therefore possible to perform actions in VR that would be cruel and immoral in the real world because they do harm, but can be performed without retribution in VR because no real harm is done. But is it morally defensible for people to act out graphic and detailed scenarios of mass murder, torture, and rape in VR, even when done in private? Are there forms of behavior that should not be encouraged or allowed even in VR, either because of their intrinsically offensive nature, or because such simulations desensitize individuals and may facilitate immoral behavior in the real world? Or is it the case that the possibility to act out fantasies in VR keeps some people, such as sex offenders or people prone to violence, from acting out this behavior in the real world, so that VR may actually prevent crime?

The interactivity made possible by VR developers also raises moral questions. VR applications may invite or discourage, require or prohibit, reward or punish behaviors. They may cheer users who go on killing sprees, or may instead voice moral outrage. Developers may be held to have a moral responsibility to reflect on the way in which they deal with immoral behavior by users, and whether and how they signal approval or disapproval of such behavior, or remain neutral.

INTERACTIONS IN MULTI-USER VR. In multi-user VR, users may engage in immoral or illegal behaviors such as theft, vandalism, murder, sexual assault, and adultery. What is confusing is that some of these behaviors may be real while others are imaginary. A user may harm or kill another user's avatar, but cannot harm or kill another user. Yet a user may also cause real harm to another user, by deeply insulting that user, stealing an identity, or wreaking havoc in a virtual apartment. Such actions are thought of as real and may even lead to criminal prosecution. Sometimes, however, it is not so clear what actions mean. Does genuine sexual assault occur when one user fondles another user's avatar against his or her will? What if such behavior is performed by a programmed avatar (a *bot*) that has been programmed to do so by its owner? Very different moral intuitions may exist about these and many other actions in multi-user VR, and more broadly in cyberspace.

Another issue that plays in multi-user VR and cyberspace is identity. As has been argued extensively in academic studies, VR avatars and role-playing in cyberspace enable people to experiment with identities and to experience otherness more vividly than ever before. A man can learn what it is like to be a woman, a white person can have the experience of a black person, and so forth. Negatively, such role-playing can be used to deceive others about one's true identity. But as psychologist Sherry Turkle (1995) has argued, such experiences may help users expand and develop their own identities and may deepen a distinctly human form of self-awareness.

VIRTUE ETHICS

The prominence of rules, consequences, rights, and duties is a relatively recent phenomenon in moral thought. For Plato, Aristotle, Laozi (or Lao-tzu), Confucius, the Buddha, and Jesus, the primary focus of the good life was on cultivating virtues and battling vices. Yet among these diverse traditions moral character and its significance for personal and social good have been subject to considerable debate—which continues in the early twenty-first century by drawing on the thought and research in sociology, anthropology, film studies, folklore, religion, biology, neurophysiology, pedagogy, medicine, and other disciplines. Both ancient reflection and contemporary scientific inquiries seek to identify the principle virtues and vices and how they develop or weaken. Adversaries debate whether the virtues (and vices) are intertwined, whether they exist independently, or whether there is a chief virtue (or vice). Such inquiries easily lead to more general questions of human flourishing and distinctiveness, so that ultimately at issue are basic questions concerning the nature of human happiness and the good society.

From the perspective of virtue ethics, science and technology are arguably enduring components of the good life. Aristotle (384–322 B.C.E.), for instance, describes virtue as a kind of human excellence or striving for perfection. (The Greek word for virtue is *arête*, which encompasses both moral capability and specific talents. A musician, for example, might give a *virtuoso* performance.) In this sense both *episteme* (knowledge or science) and *techne* (craft, art, skill, know-how) are forerunners to the modern notion of technology and involve human *arête*. Controversies about the responsibility of scientists and engineers evoke this twofold sense of virtue, insofar as they address the special types of knowledge they pursue as well as their moral positions regarding the results and applications.

Scientific discoveries and technological products also pose challenges to understanding and embodying a virtuous life. Studies of animal and human behavior raise questions about possible similarities between animals and humans in promoting cooperation or fostering competition. In place of proposals for political utopias and personal desires for posthumanist transformations, can advanced technosciences be limited or guided by the values found in folk wisdom, venerable sages, or sacred texts? Or do many technical inventions thwart the search for a virtuous life by zealously promoting and catering to ordinary vices? Instead of assisting with the cultivation of temperance, justice, courage, love, or charity, do they perhaps tempt humans with vanity, sloth, anger, lust, and greed?

Background

A virtue-based ethics is agent centered, presumes a telos or purpose for human life, and encompasses both personal and public goods. In light of ecological problems growing out of the human use of technology, critics have charged virtue ethics with being anthropocentric. It neglects or devalues the welfare of animals, natural entities, and the environment. Defenders of virtue ethics respond that a fundamental virtue such as humility promotes recognition of human limits and asks humans to view themselves as simply parts of a larger cosmic whole. Moreover, the concept of virtue as a perfection applies to nonhuman as well as human entities. While the idea of a telos or purpose in nature is problematic for science and technology, the topic remains a source for lively discussion among philosophers of biology who study possible adaptations to ethical theory. Indeed, even in the philosophy of technology, analyses of the role of functions is a research issue of potential relevance to virtue ethics.

As such issues indicate, despite the tendency to portray virtue ethics as a settled tradition of strong consensus and enduring narratives, there have always been lively debates about the scope of a virtuous life, the relative strengths or weaknesses of specific virtues and vices, and the best vision of human happiness. For example, three classic representatives of virtue ethics emphasize contrary views on pride. Aristotle considered it a principal virtue. One should attain a proper sense of self—one's accomplishments and contributions. A proud individual is not driven by vanity or boasting, for these lead to excesses of indulgence that would be unworthy of a free and rational person. The proud individual is courageous—the most fundamental virtue, for without courage one can hardly embody other cardinal virtues such as justice or prudence. A model is the citizen whose democratic participation is free of destructive vices such as envy or rancor.

Augustine of Hippo (354–430) and Thomas Aquinas (1225–1274), though, were among many Christians and religious thinkers who believed pride to be indicative of an exaggerated sense of self, involving vanity or, worse, the temptation to view oneself in godlike or superhuman terms. Pride was the queen of vices, for it spawned the decline toward deadlier ones, such as envy, anger, and lust. Such vices corrupt one's moral character and undermine efforts to become a just person. This distortion of self brings about neither happiness nor salvation, only ruin or damnation.

Buddhism and Daoism, meanwhile, taught that true virtue seeks the no-self or personal transcendence. This involves overcoming the drive for individuality in which satisfying the desires and needs of one's physical self is primary. Intellectual nitpicking may derail this goal. But reflection on the nature of this goal remains essential, and can generate parables and paradoxes that are potential guides to enlightenment (see Saeng 1991, Chuang Tzu 1996). Enlightenment is realized not when one becomes a dutiful citizen or achieves self-esteem, but is moved by compassion for another. This is an experience of insight and joy.

Disciples and pedagogues have continually debated the nature and prominence of the virtues. The Western tradition that featured the seven cardinal virtues—courage, justice, temperance, and prudence among pagans, and love, hope, and charity as the Christian additions—is hardly carved in stone. Seven has been a magical number, but other virtues have also been considered essential to the good life. Aristotle, for instance, devotes more attention to friendship than any other single virtue, and friendship may be considered the basis of scientific and technical communities.

At the same time the underpinnings of virtue have been extensively debated. For example, pagans focus on the meanings and demands of individual courage or the extent of its relation to political justice, whereas monotheists anchored a moral life not in self and society, but primarily in God. The contentiousness of these disputes and their failures to successfully promote virtue eventually led to a radical challenge of virtue ethics that nevertheless did not eliminate its relevance. Rather, according to the historian of modern moral philosophy J. B. Schneewind (1998), these disputes relegated the virtues and vices to secondary status. Displacing them as the primary focus of ethics were duties, happiness or pleasure, autonomy rather than character, and the right rules or laws for gauging ethical conduct.

After more than 200 years of rationalism and emotivism in moral theory, toward the end of the twentieth century virtue ethics underwent a revival. Dissatisfied with the inability of prominent moral theories to address human well-being, resolve concerns about justice in an increasingly technological world, and inform or guide individuals toward the good, philosophers began reassessment of the centrality of virtue. A key contributor to this was Alasdair MacIntyre, author of *After Virtue* (1981) and *Whose Justice? Which Rationality?* (1988). Invoking the wisdom of Aristotle and Thomas Aquinas, along with the lessons of contemporary social and political thought, MacIntyre espoused an enriched view of the integral and narrative self that challenged rival notions of the self as little more than a utility maximizer or logical servant to duty.

MacIntyre's learned eloquence and sharp critique of his own intellectual and moral times spawned a veritable industry. Responses ranged from best-selling children's books on the virtues to theoretical and scientific inquiries into the nature of moral character, whether or how it can be taught, and the relation of individuals to others: other humans, other species and life-forms, even deities. Some scientists have contended that, contrary to MacIntyre's emphasis on human identity as flourishing in cultural and historical storytelling, human morality should more sensibly emulate animals. Monkeys and chimpanzees, birds and elephants, according to zoologists, illuminate more accessible and realistic moral guidance than the (less realistic) heroes and saints who permeate human literature.

Such disputes—interweaving disciplines, incorporating historical and cultural contexts, responding to calls for justice or courage and to temptations of anger or lust—underscore the lasting appeal of virtue ethics. Unable to resolve all the philosophical questions put to it in journals and seminars, nor ready to dictate every moral situation (which theories can?), virtue ethics highlights controversies as vigorously as any other moral theory. Nowhere is this more clearly illustrated than in relation to science and technology.

Sloth, Leisure, Efficiency

Medieval Christians learned the seven deadly sins through the mnemonic device of an acronym—*s-a-l-i-g-i-a*. Each letter represented a deadly sin in order from the queen of vices (*superbia* being pride) to the deadliest (*acedia* or sloth). In between are situated *avaritia* (greed or covetousness), *luxuria* (lust), *invidia* (envy), *gula* (gluttony), and *ira* (anger). Warnings against sloth—from the Benedictine rule concerning the dangers of idleness to popular jokes about couch potatoes—represent it as the death of the soul as well as the spirited body. Sloth is more than laziness or lethargy; it constitutes a lack of purpose, an indifference to others and the goings-on of the world. In his *Pensees* (c. 1660), Blaise Pascal frequently remarked how people fill their time with diversions, such as games, chatter, and sensual delights. These prevent contemplation of more defining matters that include the meaning of one's death or a believer's relation to God.

By contrast, leisure is upheld as a sign of independence and accomplishment. What Pascal denigrates as diversions can be praised as just desserts. In leisure individuals explore their potential, be it in time of play, hobby, volunteer work, or even, as G. K. Chesterton (1874–1936) wryly noted, "the time to do nothing at all." To this end inventions promise to lessen arduous chores while opening more opportunities for whatever one desires. Household gadgets save on cleaning and organizing; robotics and assembly lines spare the sweat and blood of labor; sophisticated weaponry produce greater damage with risk to fewer personnel. Leisure relies on the promises of efficiency. These promises, however, can be misleading insofar as they exchange one set of difficult expectations for another. For example, the historian Ruth Schwartz Cowan (1983) has demonstrated the deceptive attractions of household technologies. The washing machine cuts down the once-a-week ardor of washing by hand and wringers, but introduces the everyday demand for a clean set of clothes, hence making laundry a daily chore. The invention of the four-burner stove with oven shifts family expectations from variations of a pot of stew to a five-course meal, hence the popularity of the cookbook. The overall result is that technologies tend to reduce the physical pressure of housework while increasing the solitariness and frequency of household tasks. The promise of more leisure, concludes Cowan, is often illusory.

From a virtue ethics perspective, however, there remain additional concerns with leisure. While *scholar* derives from the Latin word for leisure—implying both an individual and cultural good—leisure nevertheless poses considerable danger. As studied by Sissela Bok in *Mayhem* (1998), many leisure technologies involve decadent forms of play. Video games, television shows, and movies featuring callous and malicious regard for human (and animal) life have gradual effects on participants and audiences that can be just as pernicious as the tortures of ancient spectacles. This danger prevents individuals from seeking or realizing their potential as genuine human beings.

From the perspective of what might be called a technological virtue—if not technological duty—of efficiency, which emphasizes cost–benefit analysis, convenience, speed, and reliability, these gradual and pernicious effects are difficult to assess. A consequentialist or utilitarian option might consider measurable and substantive results enjoyable in the near future or negative influences on other virtues. Indeed, there are kinds of leisure that mask opportunities for sloth. This is not free time as envisioned by those who endorse human flourishing, but an appeal to vanity that plants the seeds for a slow death of one's humanity and moral character. Worse, humans become less focused on other virtues, such as justice, care, or loyalty.

Pride, Vanity, Control

As noted, Aristotle and his adherents view pride as a positive value, whereas Christian philosophers see it as vicious. Though numerous moral traditions and religions challenge pride, often what they have in mind is hubris or vanity. Hubris involves a kind of arrogance, boasting, or overweening confidence. Vanity involves an undue or unrealistic sense of one's self. Hubris is portrayed in one who fails because of unwarranted sense of self-worth. Vanity is depicted in one who wants to look younger, richer, more powerful, or more knowledgeable than one really is. Boasting, begrudging, and being envious are some of the cravings of vanity. These cravings are often driven by a technological fix, the unshaken belief that a device will always arise—such as diet pills, cosmetic surgery, or transplants—that helps to overcome the effects of aging or unwanted anatomical features. The vain person thus hopes others see a version of oneself that one does not quite believe. That is why medieval moralists pictured the vainglorious person staring into the mirror.

Pride is ambiguously presented in the human trait that desires control. Humans are increasingly adept at withstanding or overcoming natural forces. Protecting themselves from the whims of weather, rechanneling water sources so they can dwell in deserts, or regulating their own predatory or procreative tendencies, they find in science and technology the powers to explain and control the forces of nature. Humans also attempt to extend this control to human domains that were previously resolved in terms of freedom, wisdom, upbringing, or environment. For example, by reclassifying a vivacious or imaginative child as one with attention deficit disorder or disciplinary problems, the child shifts from a subject in need of a certain kind of pedagogy to a candidate for Ritalin.

Determining when technological control should yield to a moral approach is a perennial concern for virtue ethics, particularly for those who support Aristotle's notion that part of a virtuous life is striving for the means between the extremes. With increasing capabilities brought by a variety of technologies, humans still need to strike a balance between turning nature into a managed artifact and resigning themselves to all the challenges and threats nature presents.

The desire for control can nevertheless be another form of vanity. That the world, nature, or other people act without any regard for one's wishes or well-being—indeed, that they seem oblivious to one's very existence—insults a person's own (inflated) sense of self-worth. Symptomatic of this inflation is the ubiquity of cell phones. Owners insist they carry them for possible emergencies. But this claim is betrayed by its omnipresent use. Is the desire to be always and immediately accessible to anyone a symptom of vanity, justified pride, or unending control?

Honesty, Loyalty, Responsibility

Honesty is often described as an intellectual and a moral virtue. The ability to understand things clearly, to know one's own motives and aspirations, and to comprehend circumstances and other humans involves intellectual abilities that precede and accompany moral deliberations and actions. Yet the temptation to deceive others and manipulate the truth also makes honesty a moral issue.

This temptation is especially pronounced in professional ethics. Given their expertise, authority, and the confidence ordinary humans have in them, scientific and technical professionals have a distinctive responsibility to understand and articulate the possible effects of their research. The details of this responsibility can be overshadowed by conflicting loyalties. According to the American philosopher Josiah Royce (1855–1916), loyalty is a virtue essential to the good life. Though its etymology comes from law (*lex* in Latin), Royce views loyalty more in terms of love, purpose, and commitment. Individuals find meaning in their lives when anchored by the object of their loyalty; moreover, this attitude generates respect for the loyalties that give others a purpose.

In professional circles, however, loyalties are not always unified. Among researchers and engineers, for example, there can be obligations to one's employer, the sponsor of a research grant, colleagues and the principles of the discipline, families, and of course the general public. A notable exemplar is the scientist Joseph Rotblat (b. 1908). He was a contributor to the Manhattan Project, in which the United States developed the atomic bomb during World War II. After the defeat of Germany, Rotblat concluded that the project was no longer justified by the danger of Nazi bomb development and left the project. His is a difficult example to follow. Often researchers and even college professors can elucidate the lofty principles that they are supposed to adopt, but when millions of dollars from a grant are at stake, their loyalty to truth can be compromised by loyalty to the research momentum. Some moralists believe the virtues of integrity, self-respect, and honesty can overcome conflicts of loyalty and corruptible compromises. In complex enterprises, however, the notion of personal responsibility can be overshadowed by demands of the workplace or a competitive climate in which one sticks to the proverbial rules and goals of the game rather than challenging the legitimacy of the rules and goals. In such a context, the virtue of responsibility may be torn between courageous criticism and loyal adherence to the team, group, or community.

Justice, Greed, Progress

According to Plato and Aristotle, justice is a virtue that involves harmony or analogy between perfections in citizens and in the state. Modern political philosophy has been skeptical of this view and questioned whether the virtues of individual and society need to reflect one another. In his famous *The Fable of the Bees* (1705) Bernard Mandeville contended that a society can flourish in spite of—and often because of—the vices of its citizens. With appropriate constraints—such as a competitive market or constitutionally separated powers—the natural impulses and selfish appetites of the populace can be harnessed to yield social benefits. As Mandeville poetically noted: "Thus every part was full of vice / Yet the whole mass a paradise." This attitude persists insofar as economists claim that even though gas-guzzling sport-utility vehicles (SUVs) fuel vanity and greed, the Internet indulges lust, and fast food sates gluttony, economic growth and the general welfare are assured.

Virtue ethics theorists nevertheless question such an assessment. For instance, John Casey (1990) argues that justice is first and foremost a disposition within individuals, and defends the traditional view of the truly just person as one who leads a balanced life, recognizing the claims and goods of others. From this perspective, economic greed threatens justice. Though often associated with tycoons, royalty, and celebrities, greed is a temptation in nearly everyone. This is why, A. F. Robertson (2001) writes, stories and concerns about greed cross all ages, and are manifest in everything from children's tales such as "Puss in Boots" to intergenerational squabbles over property and controversies about professionals who appear more devoted to income and prestige than family or service to society. Daniel Callahan (1987) has further argued that with the advances of medical technology, the question needs to be raised whether humans have become greedy for life, attempting to live in excess of a natural life cycle, when they can no longer function or contribute, and at the expense of the well-being of younger generations.

From a virtue perspective, it is essential to ask whether greater affluence spawns generations of more just individuals (and more just societies) or creates more possibilities for vices to thrive (and injustice to grow). How often have parents and grandparents not lamented that increases in the number and glamour of toys among children are not easily correlated with any increases in willingness to share? To what extent does the example of the United States, whose abundance is historically unprecedented, but whose level of government-sponsored foreign aid is not particularly impressive, bear on assessments of political justice? According to Leo Marx (1987), in eighteenth-century America, philosophers such as Benjamin Franklin and Thomas Jefferson saw both personal and social justice as essential measures for assessing national progress. In the nineteenth century, however, the meaning of progress shifted from rights, equality, and personal freedom to material gain and industrial growth, a change that continued across the twentieth century and into the twenty-first.

Scholars such as Dinesh D'Souza contend that many critics miss the central issue on the debates over the meaning or evidence of progress. Instead of seeing wealth as a potential obstacle for the establishment or expansion of justice, D'Souza sees wealth as the key to increasing global well-being. While he acknowledges that enormous increases in scientific knowledge, technological power, and material prosperity characteristic of the 1980s and beyond have carved new gaps between the world's rich and the poor, he points out that in absolute terms the poor and the rich today live much more comfortable lives than did the poor and the rich 500 years ago. Whereas in 1500 only the most wealthy had indoor plumbing and well-heated homes, today even the traditional poor—such as students, seasonally employed, or those too feeble to work—possess cars, reside in secure surroundings, and rely on pricey media such as the Internet, cable TV, and cell phones. Interpreting Thomas Jefferson as a defender of class hierarchies based on a natural aristocracy of individual merits D'Souza believes capitalism has been a gift rather than curse to human life. The desire and search for wealth tames the destructive potential of greed and envy. Guided by a virtue of prosperity, capitalism embodies the prudence to use science and technology that, according to D'Souza, "... has in practice done more to raise the standard of living of the poor than all the government and church programs in history" (D'Souza 2000, p. 240).

This systematic effort towards greater wealth can also be the basis for an essential social virtue—namely, trust. Trust involves a common and cooperative regard for norms or mutual self-interest. In the view of social scientist Francis Fukuyama, this regard is most effective in communities where social capital and ethical values are most prominent. These communities are not, however, rooted in traditional units such as the family. They are instead found in associations that transcend kinship, such as businesses and companies. The benefits of these associations are most notably seen in three advanced technological and capitalist societies: the United States, Germany, and Japan. Here, according to Fukuyama, one understands the basis of other social virtues and their relation to a life of prosperity.

The estimated benefits of capitalism's virtues are not readily supported by research. Contrary to those who assume a millionaire's summer palace that perilously rests on the ledge of a shore cliff is the spark to global justice, demographers and ecologists find that prosperity's recipients are segmented rather than universal. That is, pockets of great wealth often have negligible or negative influences on the range of human (and non-human) suffering, starvation, or disease. Moreover, excesses of fortune foster a sense of obliviousness to the conditions of others. Such obliviousness—a potential vice insofar as it is interpreted as willful ignorance—turns a blind eye to human threats to the climate. It overlooks human causes of continual increases of pollution, thus jeopardizing the traditional lifestyles of native peoples. It downplays the continued emphasis on consumption of natural resources that generate droughts and scarcities among the world's poorer populations. Obliviousness becomes vicious when it pooh-poohs scientific claims that drastic changes in weather patterns brought on by human pollutants—in the year 2000 each American produced 4.5 pounds of garbage per day—endanger the lives of animals and fish throughout the planet (See, for example, De Souza, Williams, and Meyerson 2003, Post and Forchhammer 2004).

Character, Self, Other

Proponents of virtue ethics emphasize the development of moral character. This development assumes that there is an integral person, a core to an individual that is definitive. Moral pedagogy is directed to this core. The lessons about courage, loyalty, justice, or compassion found in traditional narratives, folktales, sacred texts, honest dialogue, or exemplars help form one's true or genuine identity. These sources reside in other humans, those who spin the narratives, relay the tales and texts, or are admired exemplars. Despite Voltaire's quip that character is so inborn humans could no more change it than wolves could lose their instincts, proponents of virtue ethics generally argue that moral character can be developed, taught, changed, and practiced.

This assumption has three challenges. The first is biological. Paul M. Churchland (1998), for one, proposes that human virtues can be more thoroughly understood from a neurophysiological perspective. Pedagogy and environment obviously have some influence, but they play a secondary role to identifying and treating malfunctioning synapses or chemical imbalances that might prevent the moral agent from successfully cooperating in the well-being of the group. Zoologist and ethnologist Frans de Waal (1996) contends humans have much to learn from animals who exhibit uncanny methods for establishing justice, tolerance, and compassion, and resolving conflicts, without resorting to massacres and war.

Second is a scientific and creative challenge. This challenge stems from the ambiguous human disposition of curiosity. Humans want to know, a desire that seems unquenchable. Curiosity is a likely culprit behind the original sin of Adam and Eve. The French philosopher Jean-Paul Sartre (1905–1980) describes the attempt to know another as a form of capture. At the same time, inventions give humans radical new ways for seeing, hearing, and learning about the world and the universe. Anyone with a stereo can hear Beethoven indefinitely more times than residents of nineteenth-century Europe. The depths of the oceans and dark abysses of the universe are as impossible for human curiosity to resist as exploring their own genetic material or the chemical charges that drive their urge to mate. And under the rubric of transhumanism, researchers are exploring how such fields as genetics and nanotechnology can reinvent the human forms of intelligence, emotion, physiology, and communication. This curiosity does not have to lead to identification of a true self; it can introduce possibilities for creating new selves. With the advent of cyberspace, according to Allucquère Rosanne Stone (1995), humans have found evermore ways of experimenting and playing with a variety of identities. The face-to-face encounter is not the ideal, just one of many options. It has its own limitations, from which cybercommunities can be valued as liberating rather than alienating.

Third is a philosophical and pedagogical challenge. The idea of a core self is neither self-evident nor coherent. For example, Alphonso Lingis (2004) describes an array of virtuous deeds—of illiterate mothers, gallant youths, mute guerillas, compassionate prisoners, free-spirited nomads—that cannot be attributed to an integral or holistic self. The realization of a virtuous capacity seldom springs from proper habits, one's internal biology, or the narratives of ancestors or cybercommunities. Instead, humans learn about courage, justice, or love as imperatives from contact with others—in their physical or embodied presence. Science and technology should expand rather than displace the possibilities for face-to-face encounters. Such possibilities suspend the insistence on control and self-respect by emphasizing respect for and openness to others, regardless of whether or not they are neighbors, friends, strangers, or aliens. This respect is not grounded in or preceded by understanding or knowledge of shared values. Instead, writes Lingis, it involves courage rather than caution to trust another insofar as trust dissipates one's own projects and identities. "Trust is a force that can arise and hold on to someone whose motivations are as unknown as those of death. . . . There is an exhilaration in trusting that builds on itself" (Lingis 2004, p. 12).

Such challenges recognize an ambiguity in the human relation to science and technology. Whether this ambiguity demonstrates progress or regress in ethical life is subject to debate. From a virtue-ethics angle, this debate must include the relative strengths of the virtues and vices, their personal and social significance, whether or how they can be taught, and to what extent science and technology primarily guide humans to realization of their true selves or invite them to devise or create other ways of being.

VON NEUMANN, JOHN

One of the most brilliant mathematicians of the twentieth century, John von Neumann (1903–1957) was born in Budapest, Hungary on December 28. He died February 8 in Washington, DC, having created the mathematical foundation for quantum mechanics, one of three competing theories of the physics of the universe, a theory of mathematical economics, the process for creating an implosion atomic bomb, and the theory of automation.

Von Neumann studied at the University of Budapest, the University of Berlin, and the prestigious Technische Hochschule in Zurich. While in Zurich, he worked with two outstanding mathematicians, Hermann (1885–1955) Weyl and George Polya (1887–1985). In 1926, von Neumann was awarded a Ph.D. in mathematics from the University of Budapest and a diploma in chemical engineering from the Zurich University.

Von Neumann lectured at the University of Berlin (1926–1929) and the University of Hamburg (1929–1930). During this later period he also held a Rockefeller fellowship that enabled him to do postdoctoral study with one of the mathematical giants of the time, David Hilbert (1862–1943), at the University at Göttingen. By 1927, von Neumann was acknowledged worldwide as a young mathematical genius, and in 1929, Oswald Veblen (1880–1960) invited him to Princeton University to lecture on quantum theory. In 1930 he became a visiting lecturer at Princeton and in 1931 was appointed a professor. In 1933, the Institute for Advanced Study was formed, and he became one of the first six full time members of the School of Mathematics. Von Neumann held this position for the remainder of his life.

Von Neumann published 130 articles and books during his career, evenly split between pure and applied mathematics, as well as twenty articles and books that made significant contributions to physics.

His 1932 book *Mathematische Grundlagen der Quantenmechanik* created a firm mathematical foundation for quantum mechanics. Quantum theory assumes that energy is not absorbed or radiated continuously, but rather discontinuously and only in multiples of definite invisible units called quanta. Quantum mechanics is a physical theory that describes the motion of objects using the principles of quantum theory. In this work, he also introduced a new form of algebra that he named *rings of operators*. In his monograph *Algebras of Operators in Hilbert Space*, von Neumann extended this algebra to group representation as well as to quantum mechanics. This part of mathematics is now called von Neumann algebras.

John von Neumann, 1903–1957. The Hungarian-born American mathematician was the originator of the theory of games and an important contributor to computer technology. (*© UPI/Corbis Bettmann.*)

Von Neumann's 1937 paper "A Model of General Economic Equilibrium" has been repeatedly cited as the greatest paper in mathematical economics ever written. The paper provided a theory of capitol and economic growth based upon a mathematical foundation.

Von Neumann created the entire field of game theory. His 1944 book (written with Oskar Morgenstern), *Theory of Games and Economic Behavior*, not only completed the theory but also introduced several other sets of axioms in other fields of economics.

During the Second World War, von Neumann worked with the scientists and administrators at Los

Alamos on the development of the atomic bomb. His two principal contributions to the Los Alamos project were the introduction of mathematical decision making and refinement of the implosion or plutonium bomb. He did not originate the idea of an implosion, but he did develop the correct density of explosives required to achieve the correct implosion.

Von Neumann's development of MANIC—an acronym for Mathematical Analyzer, Numerical Integrator, and Computer—enabled the United States to produce and test the world's first hydrogen bomb in 1952. Von Neumann spent much of his later life working in automata theory, a field that attempts to understand multiple automation applications working together to form a process or perform a task. He was also an early advocate of stored programs within a computer. His computer architecture is common to all personal computers and has come to be known as von Neumann architecture.

VON WRIGHT, GEORG HENRIK

• • •

Philosopher and inventor of deontic logic, Georg Henrik von Wright (1916–2003), who was born in Helsinki, Finland, on June 14, was also a cultural critic of techno-scientific progress. In philosophy, von Wright is best known as Ludwig Wittgenstein's successor in the chair of philosophy at Cambridge (1948–1951), and for participating in the publishing of Wittgenstein's papers posthumously. Von Wright was also a major contributor to the rebirth of modal logic in 1950s. Among his most important academic works are *Norm and Action* (1963), *Varieties of Goodness* (1963), and *Explanation and Understanding* (1971). The last had a distinctive role in efforts to bridge the gap between the Anglo-American and continental European traditions in philosophy.

Apart from his work within academic philosophy, von Wright was an important public intellectual in Finland and Scandinavia. Throughout his career he wrote philosophical essays in which he dealt extensively with the questions of the effects of science and technology on human life. He presented his cultural analysis in *Vetenskapet och förnuftet. Ett försök till orienteering* (Science and reason: An attempt at orientation), published in 1986.

Von Wright's cultural philosophy focuses on the critical situation of modern Western civilization, seen as threatening the whole globe. Many of the most serious problems of the modern world can be understood as direct consequences of techno-scientific advance. Von Wright wrote about the ecological crisis, the existence of weapons of mass destruction capable of devastating all human life, the ethical vacuum that has followed secularization and collapse of traditional value systems, and the expansion of instrumental reason in all areas of human life.

Von Wright sought the origins of these problems in the history of ideas. He located the roots of modern science and technology in the objectification of nature, the inclination toward mechanistic and deterministic causal explanations, and reductionism. The manipulative ethos of modern natural science is explicit in the writings of the pioneering philosophers of science, such as Francis Bacon (1561–1626) and René Descartes (1596–1650). It is clear that this conceptual framework has produced impressive results. However, von Wright asserted that the cost has been high.

Furthermore, von Wright noted how science is becoming an ever more important force for production. This development is problematic for science itself. The crucial question concerns what will happen to truth as the goal of science, if science becomes dependent on demands for profit, and if new discoveries are kept secret for commercial and military purposes. Von Wright also doubted the ability of modern science to provide a culturally understandable and meaningful worldview.

Although von Wright arrived at his conclusions independently, his analysis of techno-scientific progress has predecessors. Cultural critics such as Oswald Spengler, Lewis Mumford, Jacques Ellul, and the thinkers of Frankfurt School developed similar themes. Von Wright's achievement is the sobriety and transparency of his analysis. His background in analytical philosophy makes his argument especially interesting, because this tradition has usually been very optimistic concerning modern natural science.

W

WASTE

Advanced industrial societies produce enormous quantities of waste. People know it when they see it, yet waste does not admit of any strictly physical definition. Moreover what is at one point waste can at another point easily be resource. Examples include archaeological digs in archaic trash dumps, artistic creations of *objets trouvés* co-generation plants, and recycling centers.

However waste is defined and measured, it is safe to say that never before have humans produced and thrown away as much as they do in the early twenty-first century. Mass production through industrialization, extensive packaging (to facilitate both shipping and sales), and rapid obsolescence (whether planned or as an accidental effect of technological progress) in a free market economy, driving the compulsion to make things and consume them, have formed a world in which artifacts are produced, consumed, and discarded to an historically unprecedented extent.

Indeed there is a tendency for the lifetime of *durable* products to be shortened to that of *consumables,* and for non-renewable natural resource stocks to be consumed in the same way as renewable production flows, which some critics ascribe to the inability of *free market forces* to distinguish between them. Given the size of the phenomenon and its potential damaging effects on public health, the environment, and future generations, waste is one of the fundamental problems facing the techno-scientific and consumer society.

Regulations

The rapid growth, diversification, and toxicity of waste production have been accompanied, though not matched, by legislation, the development of regulatory institutions, and new methods of treatment and control. Waste has become a priority of environmental risk politics for national and international authorities (for example, the European Union [EU], U.S. Environmental Protection Agency [EPA], Organization for Economic Co-Operation and Development [OECD], World Health Organization [WHO], United Nations Environment Programme [UNEP], and so on), and one of the crucial concerns of social and ecological movements (such as Greenpeace).

The roots of this politicization go back to the nineteenth century and the earliest public health reforms spearheaded by medical scientists and advocates of public hygiene (Melosi 1981). This process is related to growing feelings of repugnance and the formalizing of new rules of conduct, discipline and self-control. Waste, which was increasing as the population of urban areas grew, was synonymous with chaos, disorder, and contagion, and had to be put out of sight. The concept of *matter out of place,* used by Mary Douglas (1966) in an anthropological study of dirt and pollution, offers a vision of waste as something that intrudes on ordered arrangements where everything has its rightful place.

Another impulse for the politicization of waste came in the 1970s with the emergence of ecological movements and environmental ethics. Rachel Carson's pioneering book, *Silent Spring* (1962), was a decisive influence in these developments. In it she denounced the harmful effects on human and animal health of the massive application of DDT and other chemical pesticides in agriculture. Consciousness of ecological frailty and feelings of ambiguity in relation to the unexpected consequences of technological advances were later reinforced by environmental accidents in the fields of technology and energy (for example, Times Beach and Love Canal in the United States, and the Seveso dioxin-contaminated waste drums in Europe).

Waste Policy

Waste policy is formed as part of a wider strategy, either to decrease pollution and protect the environment, or to bring about technological and industrial change and innovation. In each of these aims, there is remarkable ambivalence regarding the technological implications.

On the one hand, technology itself is responsible for much waste production and global pollution. Each technical development, despite its many benefits, has brought an increase in the amounts and types of waste. After the non-degradable waste produced by the steel and iron industries of the early industrial era, plastic, chemical, and pharmaceutical products have given rise to even more waste products that are more toxic and difficult to treat, control, and dispose of. On the other hand, technology is also absolutely necessary for waste prevention and the disposal of pollutants. All the principles of current international waste management strategy—minimization, recycling, reuse, and improving final disposal and monitoring—depend, in general, on techno-scientific solutions. For example, the ability to recycle is built into some products at the design stage; and some technological innovations are created specifically to improve the treatment or recovery of waste.

So-called ecological or green strategies are made difficult by the many sources of waste—domestic, commercial, industrial, medical, agricultural, construction, and so on—and its physical and chemical nature, comprising (among other materials) metals, plastics, glass, paper, and vegetable matter, often in complex and hard-to-separate combinations as in batteries, cartons, and cars. When waste cannot be recycled or reused, it is usually burnt ("incinerated") at high temperatures or dumped into landfill sites. However each of these methods may cause air, water, and soil pollution, and may have harmful effects on human, plant, and animal health.

Hazardous and Radioactive Waste

Hazardous waste, and especially radioactive waste, requires extra care in its treatment and disposal. Because of their potential harmful effects—and the political, social, and ethical questions they raise—hazardous and radioactive wastes are generally the most studied. Most international policies and treaties deal with waste of these types, whose environmental problems are global in scope and indifferent to national, generational, or class boundaries. Yet despite similarities, entirely separate legislation governs the two types, and they have different regulatory institutions and interest groups.

The contents of hazardous wastes may cause serious damage to human health and/or the environment, when improperly treated, stored, transported or disposed of. There are differing definitions and systems of classification in different countries and even between states and regions of the same country. It is symptomatic that there is little agreement on the definition of *hazardous*, on who is responsible for this definition, and on what substances are considered as hazardous waste.

According to Brian Wynne (1987), a sociologist who has addressed environmental issues and in particular the problem of waste, the lack of consensus between countries over hazardous waste is the main difficulty for international regulation. Furthermore this type of waste is usually taken to be not dispersed and diluted in the environment, but *packaged* for further treatment before eventual destruction, containment, and/or dispersal, and is thus more liable to have concentrated and harmful effects. In their life cycles these wastes not only change in physical and chemical terms, but also pass through the control of various human agents. A complex *behavioral-technical system* therefore underpins hazardous waste, bringing together natural processes and human interaction in an unpredictable and imprecise way. This happens all over an industrial network, whose entire infrastructure—for collection, transport, storage, treatment, and disposal of waste—requires extensive regulation.

In general this type of waste is identified in three ways: (a) by reason of certain properties, detected by test procedures such as flammability (may cause or prolong fire), corrosiveness (may destroy live tissue that comes into contact with it), toxicity (inhaling, swallowing or penetration through the skin may involve serious risk or even death), etc.; (b) by the presence of toxic chemical elements or abnormal concentrations of these, also detectable by tests; and (c) by listings of specific categories of waste identified as being hazardous and for which no tests are necessary. Radioactive waste contains substances which emit ionizing radiation. Proper management and safe and environmentally sustainable storage are vital but complex tasks. Nuclear waste, depending on the source, its levels of radioactivity, longevity and hazard, may be classified in two broad categories: "high-level" (from the reprocessing of spent nuclear fuel) and "low-level" (generally in the form of radioactively contaminated industrial or research waste). Other categories are transuranic radioactive waste and uranium mill tailings. One may identify two key problems with this classification: first, "low-level" waste contains some elements that are more radioactive than some of those contained in "high-level" waste; second, the public tends to perceive all radioactive waste as being "high-level."

Regardless of whether the risks are great or small, citizens typically fear toxic products and their carcinogenic effects in general, and nuclear radiation in particular. Despite accusations of irrational "chemophobia," the concerns of ordinary people are based on the impact of accidents such as those at Three Mile Island, Chernobyl, and Bhopal. In addition to these accidents, and compounding the potential threat of chemical products, each year several hundred synthetic chemical products are brought to market without being subjected to any prior tests. This underlies the phenomenon of "bioaccumulation," whereby all substances that are resistant to degradation, whether tested or not, gradually build up in successive stages of the food chain.

Ethical Issues

The regulation of waste raises four key ethical and political issues. The first derives from the need for integrated waste management involving a range of actors on different levels. In addition to international responsibility—which is necessary, for example, to control exports of waste and to avoid illegal dumping in the oceans—the following are also key elements:

(a) the model of economic development, for example one in which recycling and waste reduction activities are encouraged, leading to the idea of sustainable development;

(b) scientific research that can salvage traditional technologies that are less harmful to the environment, invent alternative technologies, and develop products with an ecologically friendly design;

(c) attitudes and incentives in business, where new designs and technologies can be used to minimize the environmental impact of a product;

(d) the civic consciousness of citizens, who may demand environmentally friendlier ("greener") products, less packaging, and access to reliable information through, for example, labeling (such as the "eco-label" – a flower logo in Europe).

A second issue concerns the ethical dilemmas raised by the risks associated with waste technologies. Given the rational impossibility of a *zero-risk* society, the debate about the threshold of acceptable risk and how it ought to be distributed generally swings between utilitarian and egalitarian ethical perspectives. Problems arise because no standard threshold provides all citizens with equal protection from harm. Moreover that threshold, which is an average annual probability of fatality linked to some hazard, may not protect the basic rights of all individuals with their specific characteristics and needs.

For Kristin Shrader-Frechette (1991), a leading investigator of the ethical dilemmas associated with nuclear waste, it is essential to obtain the free and informed consent of those who are exposed or put at risk. Those who impose societal risks on others should compensate them in order to obtain their consent. Informed and freely-given consent and compensation are guidelines which are appropriate for avoiding popular hostility. This arises frequently in discussions on where to site waste treatment facilities, reflecting syndromes known as NIMBY (*not-in-my-backyard*), NIABY (*not-in-anybody's-backyard*), or LULU (*locally-undesirable-land-use*).

A third issue is the link to the methodology used in technological assessment and analysis of environmental impact. A socially acceptable study of these problems cannot be reduced to simple cost-benefit analysis based on calculations of mathematical probabilities while ignoring moral values such as equality, equity, social justice, and common well-being.

Apart from examining the magnitude, risks, and benefits, any assessment should also weigh the moral acceptability of technology, because the issues involved cannot be reduced to factual terms. To fail to recognize this is to commit a version of the *naturalistic fallacy* (Moore 1903) by deducing and justifying ethical conclusions from technical considerations (Shrader-Frechette 1980). This error is even more serious when found in studies used to support policy decisions relating to matters of public interest.

A final ethical consideration is that a significant number of waste-related activities, from collection to recycling, are very profitable. Indeed wastes are a vital part of the capitalist economy: consumerism and an active throwaway mentality encourage constant production and fuel ever-expanding human needs.

However the fact that an entirely new industry has developed, on a for-profit basis, to deal with the waste problem, gives rise to a conflict between public and private interests. The involvement of private groups in matters of public interest may create conflict, even though a strong public sector can encounter problems with excessive bureaucracy and consequent distortions. To avoid exacerbating such conflicts, citizens are often given access to full information on each case and/or committees of experts are appointed to give scientific opinions on the regulation of waste management.

Modern society strives for a balance between economic development and environmental protection, finding a threshold that reconciles the inevitable production of waste with a commitment to ecological sustainability. The depletion of natural resources that may not be renewable, and the (often related) by-production of hazardous waste, is an increasingly important focus of long-running debates regarding conflict between state regulation and market forces, between individual action and collective consequences, and between the practical and the ethical impact of new or newly mass-consumed technologies.

WATER

Water is the liquid of life and is crucial to every type of organism, from simple bacteria to megafauna, as well as to many of the physical processes that shape the planet, as in the weathering of mountains and valleys. For life in all forms, water is more important than even oxygen, because there exist anaerobic bacteria that can live without air but no anhydroxic bacteria that can exist without water. When astrobiologists seek to determine the possibility of life on other planets, their first question concerns the presence of water. Throughout human history, however, water has had as much a symbolic as biological significance, and human beings have adapted to environments both abundant and scarce in water, through different technological, ethical, and political engagements. Water is so rich in metaphor that it cannot be reduced to merely H_2O, nor to a fluid circulated in pipes, metered, and then distributed by authorities. The duality of meaning that water embodies includes the fact that it can be both deep and shallow, life-giving and destructive, a blessing and a curse, and something that cleans the surface and also purifies the inner soul.

Water in Science

As a chemical compound water is composed of one atom of oxygen and two of hydrogen. Because acids are characterized by hydrogen ions (H^+) and bases by hydroxide ions (OH^-); water (H_2O) may be described as neither acidic nor basic, rather equally both:

$$H_2O \rightarrow H^+ + OH^-$$

The structure of water is:

$$H : \ddot{\underset{\cdot\cdot}{O}} : H$$

Oxygen is attached to two hydrogen atoms with two covalent bonds leaving two nonbonding pairs of electrons. Hydrogen bonding is particularly important in biochemical systems, because biochemical molecules contain many oxygen and nitrogen atoms that participate in hydrogen bonding. Hydrogen bonds between water molecules are responsible for the interesting physical properties of water that made it the solvent of life. Together with the extended temperature range between its solid (ice) and gaseous (steam) states, that makes liquid water able to serve as the foundation for those extremely complex carbon formations that constitute living organisms.

When present at a depth of at least two meters (six feet), pure water is a pale blue, odorless, tasteless, and transparent liquid. Other observed colors are due to various impurities, nonliving and living. It is mostly "blue water" that flows in rivers and into lakes and aquifers. "Green water" refers to the precipitation that is directly used by nonirrigated agriculture, pasture, and forests, and to evapotranspiration.

In its liquid and solid forms, water covers 71 percent of the surface area of the globe. Humanity's anthropocentric worldview explains why this mostly "blue" planet was (mis)labeled Earth. Of all the water on the planet, only 3 percent is freshwater, a figure that includes glacial ice and other hard-to-reach water sources. Of this, only 0.003 percent of the surface and subsurface water is usable by humans.

Hydrology is the science of the properties, distribution, and circulation of surface and subsurface water. In hydrologic terms, water that collects in rivers, lakes, or reservoirs is called surface water. That which seeps into the shallow or deeper layers of Earth is called aquifer. The gaseous, solid, or liquid phases of water affect both the element's chemistry such as its bonding and its physics such as its density. Water is an excellent solvent, and hence it has many constituents that are dissolved or suspended in it. These facilitate chemical interactions, which aid complex metabolisms. This explains why water is critical for all life-forms.

Pure water can be obtained through painstakingly and costly mechanical processes. Water is then the most benign of all chemical compounds known to humans. Water that contains dissolved carbonates such as calcium and magnesium is known as hard water. People notice this because it suppresses the formation of lather with soap, and when boiled, it leaves a "lime scale" that is seen in cookware. Soft water is free of such carbonates.

Water circulates from the ocean and surface of Earth to the atmosphere and then gravitates back in various forms including snow, rain, and fog. Human activities affect this hydrological cycle, most prominently through the building of physical barriers such as dams and through modifications of watersheds. Most water resources are renewable except for fossil (or connate) water that is laid down in sedimentary rocks and sealed off by overlying beds. Nevertheless, human contamination of groundwater stock, and alterations of watersheds (or, in British parlance, "drainage basins") through, for example, deforestation or paving over hydrologically critical areas can reduce aquifer recharge, alter flow characteristics, and, in severe cases, deplete a formerly renewable resource.

Many large watersheds lack time series data, and scientists in riparian states (those who study watersheds) often use different methodologies for collecting their data, which makes data sharing among water basin states ineffective and integrated management of the river system difficult.

Technologies of Water

Natural water is managed through a system of wells, dams, artificial reservoirs, conveyance systems, and human-made ponds. Humans withdraw untreated water from surface sources and pump it from aquifers. The water is treated and then pumped into carefully laid-out distribution systems such as water mains, which are connected to underground networks and sometimes to (elevated) storage facilities.

The geographical setting of the source of water, water treatment, its distribution, return flow collection, and return flow treatment—each requires a unique technological approach in order that people can access and use the resource. Economic considerations and regulations regarding human health and environmental protection also affect the choice of technology.

Easy-to-tap water sources were the first to be developed. Growing water needs require new and innovative technologies because water is increasingly extracted from deeper wells and piped in from further and further locations; furthermore, in a growing number of countries that have exhausted their supplies, freshwater is obtained by removing the salts and other contaminants from sea water (desalination). Growing water scarcity is inducing the development of water-efficient technologies. Given that agriculture is by far the largest consumer of water, drip irrigation techniques offer huge water savings, especially when compared to sprinkler irrigation or the traditional, but low-cost, flood irrigation.

Historically, the water wheel, a wheel with paddles or buckets attached to the outside, was first used to lift water from a river onto irrigation channels. Eventually, a water-powered wheel was developed and used in the Middle Ages for extracting power from a flow of water. Its applications included milling flour and machining and pounding linen for use in paper. Similarly, the steam engine contributed to Europe's economic development especially during the Industrial Revolution. This engine coverts the potential energy of the pressure in steam to mechanical work.

Water systems have been targets in warfare, and the threat of terrorism is requiring new technologies and strategies to protect water supply systems, especially in large metropolitan centers, and in countries where in which the majority of the population depends on a few desalination plants. Efforts are afoot to develop remote but real-time water-quality monitoring systems that not only encompass the traditional water-quality parameters but also can detect currently unmonitored biological agents that could threaten freshwater supplies, such as bacteria, viruses, and protozoa.

Ethics of Water

Water is central to the health of the ecosystem, central to the beliefs and customs of many religious communities, and vital to the maintenance of the economic well-being of modern and traditional lifestyles. Allocating water across competing users must thus be tempered by extensive stakeholder participation and weighed against any adverse social or ecological impacts that a solely economic approach may cause.

The increasing demand for freshwater is related to population growth, trends toward more protein-based diets, and overall improvements in the quality of life. Countries typically tap their lowest cost and most reliable sources of water first. As these sources become fully utilized, the development of new sources carries with it heavier financial costs and environmental consequences.

The equitable allocation and sustainable use of water require good governance that is rooted in policies that are scientifically, culturally, and economically sound; in institutional structures that are community friendly and invite public participation; and in decision makers who are competent and fair, and have the support of the political forces. It also requires employing modern technologies that have been adopted in many Western countries but are beyond the reach of poorer ones.

In 2002 the United Nations Committee on Economic, Social and Cultural Rights declared water a human right. It stated that the human right to water entitles everyone to sufficient, safe, acceptable, physically accessible, and affordable water for personal and domestic uses. An adequate amount of safe water is necessary to prevent death from dehydration, reduce the risk of water-related disease, and provide for consumption, cooking, and personal and domestic hygienic requirements. The signatories to the International Covenant on Economic, Social and Cultural Rights are required to progressively ensure access to clean water, equitably and without favoritism.

Politics of Water

Negotiating water-sharing agreements on for international rivers tends to be complex. Allocation agreements among competing users often involve a combination of geoclimatic factors as well as legal, historical, technological, demographic, political, and ethical considerations. In the case of international rivers, upstream states are generally seen as having leverage in influencing the allocation process simply because they control the “water tap.”

Water allocation arguments include the largely discredited view that a country has an absolute sovereignty over resources that originate inside its political boundaries. Prior appropriation agreements state that the earliest users of water have rights to it. This convention is widely used in the American Southwest and by a few other countries, such as Iraq in connection with its share of the waters of the Tigris and Euphrates rivers. Before a balanced allocation formula can be reached, several factors need to be carefully considered and fairly weighted for every riparian country. These factors include a country’s contribution to the total flow of the river, current and projected population size, area of arable land, and the extent to which the health of the national economy is dependent on water. A sustainable and ethical management strategy must also consider and protect the needs of aquatic life, upstream habitats (especially forests), wetlands, and floodplains, as well as the water needs of future generations. International agreements make the integrated (and sustainable) management of river systems easier.

Acute and protracted water scarcity is likely to be a source of violent conflict especially in countries where the agricultural sector is a vital contributor to national economic health. This danger has helped place water scarcity high on the world’s political agenda. Globally, the overwhelming majority of water is consumed by the agricultural sector. There has been a gradual and continuing shift away from supply management to demand management of water, whereby people are asked to make the most out of their existing resources. Communities try to maximize their crop yields per unit of water (more “crop per drop”) and their financial returns by planting suitable, lucrative crops. Similarly, a few arid and semiarid countries are gradually shifting away from water thirsty crops such as citrus to ones that are more suited to their own climatic and physical environments such as wheat, lentils, and chickpeas.

Immense amounts of water are wasted through leakage from antiquated urban supply networks and unsustainable irrigation strategies. Existing technologies such as the efficient, water-saving drip irrigation technique and microsprinklers have been around for decades but used on only around 1 percent of all irrigated lands. Even relatively small improvements in efficiency through the transfer of appropriate irrigation technologies and the implementation of various policy incentives and/or disincentives will result in substantial water savings.

One proposed strategy would involve governments gradually charging farmers the real and full cost of water. Progressively higher charges per unit of water consumed would induce most users to think before they turn on the water. Water quality can be protected by raising people's awareness about the adverse effects of pollution, making it prohibitively expensive to pollute, and by building sanitation infrastructures and wastewater treatment plants. This will minimize pollution levels and provide the public with recycled water to be used in nonhuman ways that do not directly affect food production, such as car washes and irrigation of lawns.

When national sources are exhausted, countries seek alternatives such as importing water, usually from nearby countries. Globalization and the opening of international markets are likely to encourage large-scale trading of freshwater across international borders. This is a controversial because of the likely environmental impacts and the political implications that a dependency on imported water may create.

Desalination, however, is an increasingly promising water-augmentation method. This process entails removing soluble salts from water to make it suitable for various human uses. Technological advances have been steadily decreasing its unit price, which is inducing more countries and facilities to use it. A growing number of countries have been increasingly adopting desalination technologies to augment their national or area-specific freshwater supplies.

James Watson, b. 1928. The American biologist was a discoverer of the double-helical structure of the deoxyribonucleic acid molecule. *(The Library of Congress.)*

WATSON, JAMES

Co-discoverer of the molecular structure of DNA, James Watson (b. 1928) was born in Chicago on April 6, and became a controversial figure in debates about the social and ethical implications of genetic research. Watson received his Ph.D. in zoology from Indiana University in 1950. His partnership with Maurice Wilkins and Francis Crick led to the 1953 discovery of the complementary double-helix configuration of the DNA molecule, for which the three researchers shared the 1962 Nobel Prize in physiology and medicine. In 1968 Watson was named director and in 1994 president of Cold Spring Harbor Laboratory, which he shaped into a leading center of research on the genetic basis of cancer. In 1988 Watson was appointed Associate Director for Human Genome Research at the National Institutes of Health (NIH), where he initiated the Ethical, Legal, and Social Implications (ELSI) program as part of the Human Genome Project (HGP).

Although Watson continued his research, including important work on the function of messenger RNA (mRNA), his career shifted toward administration and the promotion of science (McElheny 2003). In these capacities, he confronted some of the political and ethical dilemmas born of his co-discovery of "the key to life." The subsequent revolution in genetics raised questions about the proper use of this new knowledge. Indeed, Watson on occasion made controversial and sometimes-contradictory statements on several of these issues, including recombinant DNA (rDNA) research, reproductive rights, and germline genetic therapy (see Watson 2000).

During congressional testimony in 1971, Watson expressed strong concerns about genetic engineering and reproductive technologies, and in the mid-1970s he played a role in establishing a moratorium on certain kinds of rDNA research. However, he later came to regret this position and even called critics of the research "a bizarre collection of kooks, sad incompetents, and down-right shits" (Beckwith 2003, p. 357). Watson defended a cornucopian attitude about the promises of genetic technologies to solve societal problems and dismissed public fears as irrational, Luddite paranoia.

In this regard, two of his strongest convictions about the use of genetic technologies were his libertarian ideology and a desire to engineer the human genome. First, he argued that society should not impose rules on individuals concerning their use of genetic knowledge. People should be allowed to make those decisions in private, especially women who are faced with difficult reproductive choices. Second, he maintained that germline gene therapy, despite its similarity to morally reproachable governmental eugenics programs, deserves serious consideration as a personal option because of the potential for human betterment. In other words, "If we could make better human beings by knowing how to add genes, why shouldn't we?" (Wheeler 2003). For Watson, the genome is a cruel limitation on the vast possibilities that scientists could create by manipulating human DNA.

Watson's most lasting legacy in the realm of the politics of science is his creation of the ELSI in the HGP carried out by the National Center for Human Genome Research Institute (NCHGI). In an "unprecedented experiment in American science policy," Watson unilaterally set aside 3 to 5 percent of the HGP budget to support ELSI studies of new advances in genetics with the goals of identifying and defining major issues and developing initial policy options (Juengst 1996).

It is difficult to decipher Watson's intentions in creating the ELSI program. He was quoted as saying, "I wanted a group that would talk and talk and never get anything done" (Andrews 1999, p. 206). Yet he also claimed, "Doing the Genome Project in the real world means thinking about [social impacts] from the start, so that science and society can pull together to optimize the benefits of this new knowledge for human welfare and opportunity" (Watson and Juengst 1992, p. xvi).

Most likely, Watson viewed the ELSI program as a form of enlightened scientific self-interest. It could create a social environment conducive to genetics research by aiding in the development of policies that prevent people from being harmed by the use of genetic information and technologies. In Watson's view, genetics research produces inherently valuable knowledge. As Juengst explains, "The question that the ELSI program addresses is the virtuous genome scientist's professional ethical question: 'What should I know in order to conduct my (otherwise valuable) work in a socially responsible way?'" (1996, p. 68). The societal buffer that the program creates may explain why Watson referred to the creation of the ELSI program as one of his top accomplishments. Although Watson created it on a whim, the ELSI program has had a lasting impact on the practice of science as similar programs are becoming common aspects of scientific research.

WEAPONS OF MASS DESTRUCTION

The phrase *weapons of mass destruction* (WMDs) was first used in the *London Times* in 1937 to describe Germany's blanket-bombing—using conventional weapons—of the city of Guernica, Spain (Mallon 2003). During the Cold War, the Soviet Union adapted the phrase to describe, collectively, nuclear, biological, and chemical (NBC) weapons (Norris and Fowler 1997). The U.S. Department of Defense defines WMDs as "weapons that are capable of a high order of destruction and/or being used in such a manner as to destroy large numbers of people," including high explosives, nuclear, chemical, biological, and radiological weapons. WMDs, however, often refer primarily to nuclear weapons.

History

Historical accounts of WMDs include the use of toxic smoke during the Peloponnesian War and during the Sung Dynasty in China (Hersh 1968); the Tartars catapulted plague-infected corpses into walled cities. Use of a *scorched earth policy* (Langford 2004) was also a common battle tactic in which retreating armies would destroy crops, burn villages, and poison wells and water supplies.

Large-scale production and deployment of nonnuclear WMDs was not possible until the beginning of the twentieth century (Hersh 1968), at which time scientists developed a more comprehensive understanding of how various chemicals functioned and of the manufacturing technologies necessary to synthesize large quantities of toxins. Advances in science thus led to the proliferation and stockpiling of numerous chemical agents such as mustard gas, phosgene, and chlorine. Chemical-weapons use during World War I resulted in the death of at least 90,000 people with more than 1.3 million additional casualties (Hersh 1968). Germany was the first nation to use poison gas during the war, but Great Britain, France, and the United States also used chemical weapons.

During World War II Germany and Japan conducted numerous chemical and biological weapon experiments on civilian and prisoner populations, yet such weapons were not used during combat. The United States was the first nation to use nuclear weapons when it bombed Hiroshima and Nagasaki in 1945. Many historians suggest that the incendiary bombing of Tokyo and Dresden by the United States during World War II, which killed thousands of civilians, also constituted use of WMDs. Use of chemical and biological weapons by several nations continued in the latter half of the twentieth century. One example is the defoliant Agent Orange that was used extensively by the United States in Vietnam to destroy vegetation. Iraq illegally used poison gas against the Iraqi Kurds killing tens of thousands of civilians. Although an exact accounting is impossible, the Federation of American Scientists indicates that dozens of nations possess, are developing, or are capable of developing WMDs.

The September 11, 2001, terror attacks that caused mass destruction and loss of life, however, were not perpetrated with NBC weapons, leading some experts to push for a more expansive definition of WMDs. Everett Langford describes WMDs as "those things which kill people in more horrible ways than bullets or trauma, or which cause effects other than simply damaging or destroying buildings and objects, with an element of fear or panic included" (Langford 2004, p. 1). Using this definition, WMDs would also include the airplanes used in the 2001 terror attacks; fungi used to destroy specific crops; defoliants; large scale incendiary devices; pathogens that kill agricultural animals; and other nonlethal agents. Sohail Hashmi and Steven Lee, however, argue that WMDs are different from conventional weapons because, "when used in war, [they are] inherently indiscriminate, meaning that their use ... would almost certainly result in the deaths of many civilians" (Hashmi and Lee 2004, p 10).

Ethics

For several reasons WMDs, especially NBC weapons, fall into different moral and ethical categories than conventional weapons. Over millennia, humans developed ethical guidelines and rules for *just war*. But Michael Walzer argues that nuclear weapons "are the first of mankind's technological innovations that are simply not encompassable within the familiar moral world" (Hashmi and Lee 2004, p 5).

Unlike more conventional arms, WMDs do not stay in the location in which they were deployed; detonation of NBC weapons invariably produce plumes of radiation and toxins that can travel hundreds of miles, well beyond the boundaries of the battlefield. The plume could kill innocent civilians within the country and in neighboring countries not involved in the conflict. Use of WMDs could also render large tracts of land uninhabitable, not only affecting the short term ability of a nation to feed itself after hostilities cease, but also that of future generations.

With conventional weapons, large numbers of people are needed to deploy enough bombs in order to cause widespread damage, so that there is at least some level of checks and balances in the decision process. WMDs, by contrast, may require just a handful of people whose actions can cause large-scale devastation, and thus WMDs are inherently less democratic than conventional weapons. The strongest ethical argument against using WMDs is quite simply that their use could destroy the world, killing billions of innocent people in *mutually assured destruction* (Hashmi and Lee 2004).

Politics

The world community made several attempts to control WMDs after World War I. The most important treaties are the Geneva Protocol (1925), which prohibits the use of both biological and poison gas methods in warfare; the Nuclear Non-Proliferation Treaty (1968), which prohibits states from acquiring nuclear weapons if they had not already detonated a nuclear weapon by January 1, 1967; the Biological and Toxin Weapons Convention (1972), which prohibits the development, stockpiling, and acquisition of biological weapons; and the Chemical Weapons Convention (1993), which prohibits the use, development, and stockpiling of chemical weapons.

Proliferation of WMDs during the twentieth century was characterized by the activities of large nation-states that possessed the financial resources, infrastructure, and intellectual capital necessary to research, test, and produce such weapons. Rapid technological advances in biological and chemical science coupled with readily accessible how-to information via the Internet and the collapse of the Soviet Union have markedly increased the risk of proliferation of WMDs. Individuals and small groups now have the capability of producing WMDs such as ricin, anthrax, and radioactive *dirty bombs*, without state support.

Through even more rapid technological advances in the years to come, the world may see a future with even more dangerous WMDs capable of being produced and deployed by just a few talented individuals, using genetic engineering, nanotechnology, and robotics (Joy 2000). Unlike the *old WMDs* of the twentieth century that required significant state support to produce, and thus could be controlled to some degree through international treaties, *new WMDs* pose entirely new problems of control, not to mention ethical and moral considerations that have yet to be fully addressed by the scientific community.

A first attempt in this direction is the "Statement on Scientific Publication and Security" produced by a group of scientific journal editors, scientists, and government officials at a National Academy of Science (NAS) meeting in January 2003. In the statement the authors acknowledge that some scientific information "presents enough risk of use by terrorists that it should not be published" (Journal Editors and Authors Group 2003, p. 1149). Rather than establishing strict guidelines for censorship, however, the authors leave such decisions up to the journal editors, who must weigh the possible security threats against the scientific merit and potential societal benefits of publishing the article. There are many more questions to ask, and actions to take, however, if society is to adequately address the threat of WMDs in the twenty-first century.

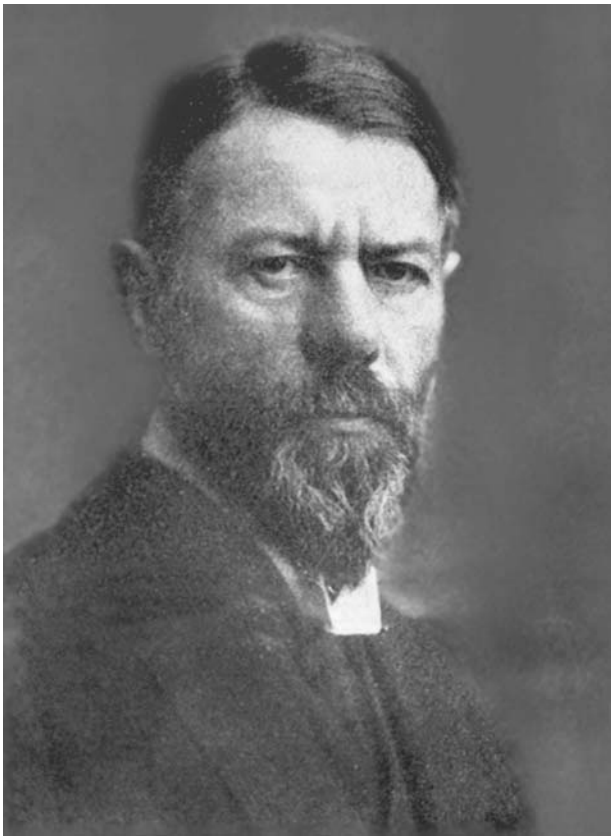
WEBER, MAX

Max Weber (1864–1920) was arguably the most important social and political theorist of the twentieth century, as well as the unwilling father of modern sociology (a role he unknowingly shared with Èmile Durkheim). The eldest of six children (with a brother Alfred, who also became a famous sociologist and cultural analyst), Max Weber was born in Erfurt, Prussia, on April 21, grew up in a suburb of Berlin, and spent his entire adult life in German university towns. He pursued law, economics, and philosophy at Heidelberg, Strassburg, Berlin, and Göttingen (1882–1886), served in the army reserve for two years during college, returned home, and studied law in Berlin, graduating in 1889. He won academic appointments in Berlin and Freiburg, but was forced to retire from teaching after suffering a nervous breakdown that immobilized him between 1897 and 1903—an almost pure example of what Sigmund Freud at precisely the same time had labeled the *Oedipus complex*. Finally recovered enough to take an extended, transformative trip to the United States in 1904, and freed of teaching duties by an inheritance, Weber spent the next sixteen years producing an unrivalled body of sociocultural, economic, and sociological analyses that



Max Weber, 1864–1920. The German social scientist was a founder of modern sociological thought. His historical and comparative studies of the great civilizations are a landmark in the history of sociology. *(The Library of Congress.)*

is second to none in the history of modern social science. He died unexpectedly on June 14 at the age of 56, a victim of the global influenza pandemic. Weber had married his cousin, Marianne Schnitger, in 1893, and it was her tireless work between 1920 and 1924 as editor of his many posthumous books that fixed Weber's rightful place in the social science pantheon, because during his life he had published only a small percentage of what he wrote.

Weber's common fame rests on his *Protestant Ethic and the Spirit of Capitalism* (1904–1905), originally published as two articles in a scholarly journal. Here he demonstrated why northern European Protestant behavior was more conducive to the formation of early capitalism than were southern European Catholic beliefs and practices, a hypothesis that has given rise to thousands of commentaries and critiques. But he also contributed fundamental works to the sociology of law (which he virtually invented), the sociology of music (also a first), the sociology of the economy, the philosophy of social science method, the comparative sociology of religion (also his creation), social stratification, the sociology of bureaucracy, and of power and *charisma* (his term), and so on. His major work is *Economy and Society* (1922), a massive study assembled by his wife (herself an important feminist public intellectual), and translated into English for the first time in 1968. Weber's importance grows with time, and he is the only classic social theorist for whom in the early twenty-first century an entire scholarly journal is named. A recent bibliography of works in English concerning Weber numbers more than 4,900 items, and as Karl Marx and Freud become increasingly less tenable as the major analysts of the modern world, Weber's ideas become ever more pertinent and revealing.

Weber's thoughts about science and ethics are neatly summarized in two of the most famous lectures ever given by a social scientist, "Science as a Vocation" (November 1917) and "Politics as a Vocation" (January 1919). Both were delivered at the University of Munich before large audiences of returning veterans and other students (among them, Rainer Maria Rilke) in a highly politicized atmosphere, with Weber expected to take a strongly nationalistic stance similar to many of his colleagues. Instead he spoke in contrarian terms by insisting that science requires objectivity and *value-freedom* from its practitioners, who must be motivated by a selfless *Beruf* (vocational calling) dedicated solely to the discovery of truth, and never by mundane self-aggrandizement or political values. He warned against the *cult of personality* and the seductive weakness for *selling a worldview* that interferes with proper scientific work. Weber drew on Friedrich Nietzsche, Leo Tolstoy, the Sermon on the Mount, Charles-Pierre Baudelaire, Immanuel Kant, and his young friend, Georg Lukács (1885–1971) in making a strong case for scientific research as a single-minded search for the unprettified truth, and nothing else.

In the companion lecture, "Politics as a Vocation," Weber continued in this vein, introducing one of his most famous distinctions, between *an ethic of ultimate ends* and *an ethic of responsibility*. The former defines the bailiwick of scientists, while the latter belongs to politicians and other activists, whose *raison d'être* is the strategic furthering of an ideological program. Weber warned that when these two ethics are joined within a single person, they inevitably lead to the degeneration of both roles, and to cultural calamity. As Weber explained in one of his most famous and controversial paragraphs:

> We must be clear about the fact that all ethically oriented conduct may be guided by one of two fundamentally differing and irreconcilably opposed maxims: conduct an be oriented to an "ethic of ultimate ends" or to an "ethic of responsibility." This is not to say that an ethic of ultimate ends is

> identical with irresponsibility, or that an ethic of responsibility is identical with unprincipled opportunism. Naturally nobody says that. However, there is an abysmal contract between conduct that follows the maxim of an ethic of ultimate ends—that, is in religious terms, "the Christian does rightly and leaves the results with the Lord"—and conduct that follows the maxim of an ethic of responsibility, in which case one has to give an account of the foreseeable results of one's action ("Politics as a Vocation" in *From Max Weber,* p. 120).

Within a very few years, the scientists and ethicists of Nazi Germany experienced the dire consequences of ignoring the thrust of Weber's speeches—which accounts in part for the Nazi government's interest in discrediting the memory of Weber after his death. Interestingly Weber is one of few German intellectuals of the twentieth century whose reputation was never threatened by world memory of the Third Reich.

WEIL, SIMONE

French philosopher, mystic, and social critic Simone Weil (1909–1943) was born in Paris on February 3 and died in Ashford, Kent, in England on August 24. Though raised in a prosperous bourgeois family and classically educated at the Ecole Normale Supérieure, Weil sympathized from an early age with the plight of the poor, the oppressed, and the afflicted.

Simone Weil, 1909–1943. The French thinker, political activist, and religious mystic was known for the intensity of her commitments and the breadth and depth of her analysis of numerous aspects of modern civilization. *(AP/Wide World Photos.)*

Before the age of twenty Weil identified herself as an anarcho-syndicalist. She was attracted to the philosophy of Marx but refused to join the communist party. Her earliest sustained social analysis, "Reflections Concerning the Causes of Liberty and Social Oppression," provided a critique of Marxism that Albert Camus (1913–1960) judged the most profound of the twentieth century. This critique focused on what Weil thought was the inadequacy of Marx's optimistic view that technological progress would lead inevitably to the liberation of the proletariat. For her, technological development gave humanity more control over nature only at the expense of greater dependency on what she called the *collectivity*. The collectivity includes the bureaucratic structure of the state (political and legal authority, including the government and the police) as well as the private corporations that produce the goods and services of the economy.

Weil argued that labor is not in itself the cause of oppression. For her, genuine human freedom meant freedom from the illusions that, in industrial society, take the form of ideologies and myths, of which the idea of progress is the preeminent example. In order to be free of the tyranny of illusion, human beings must come to know themselves as limited beings. Their finitude is revealed through methodical, thoughtful engagement with necessity; in other words, through work. Work is therefore a good that is not to be eliminated but ought to be the spiritual center of civilization. Weil argued that the problem with modern technology is that methods (mechanical or bureaucratic) are built into machines or organizations, thereby eliminating the need for thinking. A method, once developed, can be applied indefinitely, without ever being understood by the person who applies it. Generally, there is method in the motions of work, but none in the minds of the workers who tend automatic machines. They are reduced to slavery; they have lost their freedom.

This analysis formed the basis of Weil's critique of the industrial system that, in her view, dedicated itself to the maximization of the productivity of the worker rather than the maximization of freedom in the work process. In her two years of factory work (1934–1935), she saw that workers usually cannot understand the techniques they apply and this fact undermined their thinking relationship to reality. Due to the division and coordination of labor which in turn is a function of the techniques of production, there is a virtually complete divorce between thought and action. The manual laborers on a production line are not free, are dehumanized and reduced to slaves, not because they perform physically laborious tasks but because their tasks are so structured as to exclude the possibility of thought. Mental workers, those who make up the essential bureaucratic structure by which the activity of the workers is brought into coordinated relation, may be as enslaved as the manual laborers themselves because their thinking is ordinarily divorced from any direct action or work, and does not involve a dialogue with those whose lives they order. They too have lost touch with necessity.

Weil's critique of modern industry led her to analyze modern science as itself having become a thoughtless collective enterprise that relies on specialization for its advancement. No single mind can grasp even a subdiscipline of physics or chemistry. Researchers take over not only the results but the methods developed by their predecessors without understanding them or their relation to the whole. Weil concluded that the scientist can be crushed by science in much the same way that the workers are crushed by their work.

Toward the end of her life when her most profound religious thinking and social analysis was done, Weil contrasted modern (or, as she called it, classical) science, developed after Galileo and Newton between the sixteenth and the nineteenth centuries, with ancient Greek science. She concluded that modern science had emancipated the study of nature, first understood on the analogy of work (that is, in terms of energy), from the idea of the good, and then from the idea of necessity. In the 1940s, Weil predicted that the incomparable technical achievements of science would become divorced from any ordering principle and destroy human scale, as complexity was piled on complexity and society became uprooted.

Weil died prematurely in England at the age of 34. The significance of her posthumously published writings on religion as well the social and political crises of her times are only beginning to be appreciated for their depth and originality.

rejecting the liberal and Marxist optimism about the liberating potential of technological progress.

WELLS, H. G.

Herbert George Wells (1866–1946) was born in Bromley, Kent, United Kingdom, on September 21, to servants turned shopkeepers. After a poor education in local private schools he was apprenticed to the drapery trade at age fourteen. After a spell as a pharmacist's assistant Wells became a student-teacher in Midhurst, where he won a scholarship to study for a degree under the biologist Thomas Henry Huxley (1825–1895) at the Normal School of Science in South Kensington. After initially failing to earn a degree, he became a schoolteacher and completed his bachelor of science degree in zoology at the University of London in 1890. He died in London on August 13.

Although eventually Wells became world famous as the author of *The Time Machine* (1895), *The Invisible Man* (1897), *The War of the Worlds* (1898), and other novels, his first two books were science textbooks published in 1893. Throughout the 1890s Wells was a regular contributor to scientific periodicals and wrote popular science articles for the mainstream press. Even after becoming famous as a writer of fiction, Wells maintained an interest in science as a Fellow of the Zoological Society after 1890 and joined the Sociological Society (on its foundation in 1904). He debated eugenics with the scientist Francis Galton (1822–1991) and others and published scientific works such as *Anticipations of the Reaction of Mechanical and Scientific Progress upon Human Life and Thought* (1901), *The Science of Life* (1930), and *Science and the World-Mind* (1942).

Wells's contribution to science, technology, and ethics was considerable. He recognized from his university days that although human progress was not inevitable, science would play a key role in human achievement. From Huxley he adopted the notion of ethical evolution: humankind's responsibility to influence the biological destiny of humans and other species positively. That notion ultimately led Wells to promote, at the micro level, a welfare state based on negative eugenics and state provision of a "basic minimum" and, at the macro level, a cosmopolitan world state based on education, cooperation, and socialist planning.

Eugenics was an important subject for Wells during much of his career. He first considered it in *Anticipations* (1901) before analyzing it more closely in works such as *Mankind in the Making* (1903), *A Modern Utopia* (1905), *Men Like Gods* (1923), *The Science of Life* (1930), and *The Work, Wealth and Happiness of Mankind* (1931) and finally rejecting it outright in *The Rights of Man* (1940) and *'42 to '44* (1944). During the Edwardian period Wells believed that negative eugenics could be a viable means of preventing the procreation of "the people of the abyss": the incurably diseased, habitual criminals or drunkards, and those unable to adapt to the rapidly changing modern world. Gradually he tempered his position, seeing welfare provision, education, and medical science as more important factors for improving the quality of successive generations. With the rise of Nazi eugenics after 1933, Wells distanced himself from general eugenic theory, declaring that any form of compulsory or state eugenics would be a fundamental breach of human rights in *The Rights of Man* (1940).

H. G. Wells, 1866–1946. The English author began his career as a novelist with a popular sequence of science fiction that remains the most familiar part of his work. He later wrote realistic novels and novels of ideas.

According to Wells, human progress rests on technological advancement, and he predicted that in the twentieth century humanity would either destroy itself or create material abundance and cosmopolitan unity. His 1935 film *Things to Come* is a marvel of invention, with ultramodern architecture, highly skilled workers, scientific population control, space flight, moving footpaths, and more. However, the society it portrayed was brought about only by generations of warfare, and in this lies the tension that existed between Wells's vision of a technological future and the means to achieve it.

Although Wells preached disarmament and world peace throughout his life, his futuristic utopian societies founded on the power of science consistently had to go through devastating wars to be achieved. Humankind had to learn a severe lesson before it would apply the gifts of science to its destiny. Thus, in *The War in the Air* (1909), powered flight leads to aerial combat; in *The World Set Free* (1914), harnessing the atom leads to nuclear war; and in *The Shape of Things to Come* (1933), material progress leads to global conflict and an "air dictatorship." All these stories end with global human fellowship and peace, but they are achieved at a high price.

Wells's legacy in terms of science, technology, and ethics lies in his imaginative application of science to invention, his hopefulness about what science may produce for humanity, but also his warnings about what the abuse of science may mean for the human race. In his nonfiction writings Wells was ambiguous throughout his life, never able to offer a peaceful route to the achievement of his predicted scientific utopias. Although Wells was never certain in his hope or despair for the future, his ultimate mood on the subject is aptly characterized in the title of his final work, published a few months before the dropping of atomic bombs on Japan, *Mind at the End of Its Tether* (1945).

WHISTLEBLOWING

The origin of the term *whistleblowing* is uncertain. It may refer to English policemen blowing whistles to alert others to an illegal act or to sports referees stopping a game due to a rule infraction. The term began to be used in a way relevant to science, technology, and ethics in the 1960s and became part of the common vocabulary as a result of Ralph Nader's investigative activities during the 1970s. *The American Heritage Dictionary* defines a whistleblower as "one who reveals wrongdoing within an organization to the public or to those in positions of authority," but a more detailed analysis of the term is appropriate.

Analysis of the Concept

Based on the above definition, it is possible to distinguish between internal and external whistleblowing. Internal whistleblowing occurs when the hierarchical chain of command within an organization is violated, so that one's immediate superiors are bypassed, perhaps because they have refused to act or are themselves involved in the wrongdoing. The whistleblowing is internal, however, because it stays within the organization. External whistleblowing refers to going outside the organization, possibly to a regulatory agency, the press, or directly to the public. The philosophical literature often restricts the use of the term to external whistleblowing, but the media typically use it in both senses.

A further distinction may be made between open and anonymous whistleblowing. The former means that the identity of the whistleblower is known, while such identity remains unknown in the latter. Anonymous whistleblowing is generally considered to be less effective, because it is more easily ignored and because no follow-up with the whistleblower is possible. Organizations have also shown themselves willing to devote significant resources to discover the identity of anonymous whistleblowers, a task made easier by the limited number of individuals who typically have access to the information being revealed. At the same time, whistleblowers often want to hide their identities because of possible reprisals from their organizations or colleagues.

The idea of *wrongdoing* also requires clarification. Generally not every wrongdoing is considered to be a legitimate subject for whistleblowing. The wrongdoing must entail serious harm, whether physical, psychological, or financial. Depending on the particular philosophical perspective, the notion of harm might be extended to situations where human beings are only indirectly affected, such as through damage to the environment. Serious harm is considered to be the appropriate criterion in that whistleblowing itself is an act which that tends to harm the parties involved and thus requires a balancing of outcomes.

Finally, although omitted in the popular definition, whistleblowers need to be insiders, that is, either currently or formerly associated with the organization on which they are blowing the whistle. Outsiders might be considered spies, investigative reporters, or moles, but not whistleblowers. Whistleblowing must involve a conflict of loyalties, between the duty of loyalty to an organization and duties to the public or to a principle. For an infiltrator, no such duty of loyalty to the organization exists. It should be noted, however, that whistleblowers often do not perceive themselves as being disloyal, especially in instances of internal whistleblowing, but believe they are working for the long-term organizational good.

Ethical Perspectives

From the perspective of ethics, whistleblowers are faced with deciding whether breaking the bond of loyalty is justified in a particular circumstance. The philosopher Richard DeGeorge proposed the classic criteria for justifying whistleblowing; most other criteria are a reaction to his formulation. DeGeorge argues that external whistleblowing is morally permissible if three conditions are met: (a) substantial harm will be done to persons; (b) the immediate superior is made aware of the problem; and (c) the chain of command of the organization is exhausted. DeGeorge contends that whistleblowing is morally obligatory if two additional conditions are met: (d) enough documented evidence is available to the whistleblower to convince an impartial individual; and (e) the whistleblower has a justified belief that the wrongdoing will be corrected as a result of going public.

A number of critiques have been leveled against DeGeorge's criteria, including questions about the extent to which a future rather than a past harm must be involved, immediacy of the harm, lack of consideration for the fate of the whistleblower, and importance of the motives governing the action. Fundamentally these debates reflect the divergence between consequentialist and deontological approaches to the issue. Consequentialist thinkers emphasize the costs to the institution and to the whistleblower and the detrimental results of mistaken or malicious whistleblowing, while deontological thinkers tend not to distinguish as significantly between degrees of harm and are more concerned with justice being done.

For engineering, in particular, the issue of whistleblowing has been a major focus of ethical discussions because of the potential impact of engineering activities on public safety. Most codes of engineering ethics follow the lead of the Accreditation Board for Engineering and Technology (ABET) by emphasizing that "engineers shall hold paramount the safety, health and welfare of the public in the performance of their professional duties." Preventing physical harm to people is seen as a special professional responsibility of engineers based on their technical expertise. Many codes even obligate engineers to blow the whistle by requiring notification of *the proper authority* when public safety is endangered.

Whistleblowing in science generally has a different justification. Most often it is related to the research process and falsification of data, although research can also directly harm the human subjects involved or the public at large through the introduction of products based on falsified data. The difference in emphasis between science and engineering whistleblowing can be traced to the fundamental emphasis given to truth and accuracy in science, as opposed to the need to protect the public from harmful technologies in engineering.

Due to the serious consequences associated with whistleblowing, most analyses stress that it should be an avenue of last resort. Many discussions have emphasized ways that organizations can avoid whistleblowing, including creating an internal ethics office, fostering open door practices, having clear organizational policies, or appointing an ombudsperson. One reason to highlight such alternatives is that the whistleblower often becomes the target of subsequent investigations, directing attention away from the misconduct that was revealed.

In fact, the consequences for whistleblowers are so universally negative, including shunning by colleagues and organizational reprisals, that whistleblowing is legitimately an act of moral heroism. Commentators such as Kenneth Alpern argue that engineers, given their special responsibility for the public safety, should be required to be moral heroes. Others, such as Mike Martin, believe that whistleblowing is a supererogatory act whose obligatory nature must be evaluated on a case-by-case basis, taking into account both professional duty and personal considerations. Whether certain individuals should be singled out and required to suffer grave consequences for the common good will continues to be a matter of debate.

WIENER, NORBERT

Born in Columbia, Missouri, on November 26, Norbert Wiener (1894–1964) gained prominence as a world-famous mathematician who founded the interdisciplinary field of *cybernetics,* questioned its social implications, and encouraged scientists and engineers to consider the social consequences of their work. He died in Stockholm, Sweden, on March 18.

A child prodigy, Wiener earned a B.S. from Tufts University at the age of fourteen and a Ph.D. from Harvard at eighteen. As a professor of mathematics at the Massachusetts Institute of Technology (MIT), he made his mark in the areas of statistical theory, harmonic analysis, and prediction and filtering. While doing research on an antiaircraft system during Word War II, Wiener developed the key idea behind cybernetics: Humans and machines could both be studied using the principles of control and communication engineering. Both were information-processing entities that interacted with the environment through feedback mechanisms to pursue goals.

The atomic bombings of Japan in August 1945 brought the issue of social responsibility to the fore for Wiener. He wrote a resignation letter to the president of MIT that fall, stating that he intended to leave science because scientists had become the armorers of the military and had no control over their research. Although Wiener may have never sent the letter, he stopped doing military work. He became well-known for this stance in 1947 when the press reported his refusal to attend a military-sponsored symposium on computers and to share his war-time research with a company developing guided missiles. Wiener reasoned that "the bombing of Hiroshima and Nagasaki, has made it clear that to provide scientific information is not a necessarily innocent act, and may entail the gravest consequences" (Wiener 1947, p. 46).

Wiener expressed his views on the ethical and social aspects of science and technology in *Cybernetics* (1948), *The Human Use of Human Beings* (1950), and *God and Golem, Inc.* (1964). All three books warn about the potentially dangerous social consequences of the very field he had founded. Wiener claimed that cybernetics had "unbounded possibilities for good and evil" (Wiener 1948, p. 37). Electronic prostheses would benefit humans, and automated factories, the basis of a *second industrial revolution,* could eliminate inhuman forms of labor. If, however, humans "follow our traditional worship of progress and the fifth freedom—the freedom to exploit—it is practically certain that we shall face a decade more of ruin and despair" in implementing this technology (Wiener, 1950, p. 189). He also criticized game theory and military science for viewing the world as a struggle between good and evil.

Wiener considered whether to stop working on cybernetics because of its dangers. But it belonged "to the age, and the most any of us can do by suppression is to put the development of the subject into the hands of the most irresponsible and most venal of our engineers," namely, those doing military work. He recommended educating the public about the social implications of his field and confining research to areas, "such as physiology and psychology, most remote from war and exploitation" (Wiener, 1948, p. 38–39). Near the end of his life, Wiener said scientists and engineers should stop being amoral *gadget worshipers* (Wiener 1964) and imagine the consequences of their work well into the future. In regard to growing concerns about the dehumanizing effects of computerization, he recommended a cybernetic division of labor: Humans should perform functions best suited to them, computers those best suited to computers.

Cybernetics has led a life of its own outside of Wiener's control. In the late 1940s, philosophers in the Soviet Union criticized Wiener for attacking dialectical materialism, then did an about-face in the 1950s and adopted cybernetics wholeheartedly. In Western Europe and North America, in the 1960s, cybernetics lost prestige among scientists who questioned its rigor and universal claims. Beginning in the 1980s, some humanists praised Wiener's antimilitarism, while others criticized cybernetics for creating a philosophy of nature and a computer-based material culture that turns humans into *cyborgs* (cybernetic organisms). At the same time, historian and philosopher Donna Haraway co-opted Wiener's cybernetic vision to create an ironic cyborg epistemology with which to critique the global corporate-military-university complex and the technosciences that sustain it.

WILDERNESS

Few currents in literature, the arts, and religion run deeper than the cultural fascination with wildness, and its locational concomitant, wilderness—places where primordial reality dominates and the artificialities of humans, including their sciences and technologies, are not apparent. Marks of the depth of the idea are its universality and flexibility. Appeals to wilderness can be found in cultures as diverse as China and North America. In its many intellectual guises and emotional overlays it has proven adaptable and meaningful across great historical divides. Although here the emphasis will be on its Euro-American manifestations, it is important to recognize that wilderness is not an idea exclusive to that culture.

Euro-American Context

In the Euro-American context the idea of wilderness is associated with the view that humans by nature separate themselves from nature, which then provides the backdrop for most considerations of ethics. Yet throughout western history, ethical principles have been formulated to apply only on the human side of the human-wildness divide. This separation of humans from wildness is especially important normatively, because it shapes the context in which new technologies are evaluated, including technologies that radically alter nature and irreversibly destroy wildness in the process of *development* and *progress*. Against the backdrop of wilderness, science has sometimes been judged both tame and distorting. Appeals to wilderness are often the basis for criticizing technologies, especially technologies that radically alter nature or irreversibly destroy wildness in the process of *development* and *progress*.

Max Oelschlaeger (1991) hypothesizes that Mediterranean cultures, especially at the eastern end where agriculture was taking hold, began developing in their mythology a separation of human culture from nature as early as 10,000 B.C.E. in the Yahwist tradition. In later Hebrew history, sojourns in the wilderness became symbols for the spiritual purification of prophets; at the same time, wild lands were treated as wastelands awaiting transformation into *productive* farmland. Oelschlager attributes this ambivalence to residual tensions between settled agriculturalists and nomadic, *wilder* tribes of herders and gatherers. These two themes—wildness and civilization through cultivation—are entwined throughout the Judeo-Christian tradition. Christ's sojourn in the wilderness, in keeping with the Hebrew tradition of seeking purification by retreating from society into wilderness, is portrayed as a time of spiritual strengthening in preparation for a future ministry.

The idea of wilderness as an obstacle to the human will, which grew out of the earlier tendency of agriculturalists to distinguish their works—the domain of their physical control—from wild nature lying beyond civilization, took on a renewed meaning with the discovery of the New World. In this context, the fascination with wilderness was expressed as a struggle between the Enlightenment view of human perfectibility through science and technology, and romanticism as expressed in the French philosopher Jean-Jacques Rousseau's idea of the *noble savage*. According to this view, pre-civilized humans, not yet corrupted by the affectations of society, have a purity not found in contemporary society. This fascination with wildness was inspired by the discovery of *primitive* cultures, and reinforced the romantic critique of the overly rational and mechanical world of the Enlightenment.

Once imported into the New World, the wilderness versus civilization theme took on new vitality as colonists came in direct contact with wilderness and with *wild* tribes they saw as *savages*. Jonathan Edwards—despite his reputation as a brimstone orator—preached benevolence toward the whole of God's nature (Miller 1967, p. 283). More concretely, the battle between civilization and wilderness was fought again each day at the advancing edge of colonial development of lands formerly inhabited by Native American tribes. In a classic analysis of U.S. history, Frederick Jackson Turner (1920) emphasized the importance of the frontier in the identity of the United States, predicting that a huge transformation in consciousness would ensue as the frontier closed. Turner saw the existence of an open frontier, and the idea of *manifest destiny* associated with it, as definitive of the American experience. Accordingly the closing of the frontier was thought to usher in a new era in American life.

Two Views of Wilderness

It is useful to separate two aspects of the wilderness idea as it has developed in American thought. First there was the indicated experience of wildness as a countervailing force resisting the daily transformation of wild lands into farmland and cities in the path of westward expansion. This process of *civilizing* lands that had before been the habitat of nomadic tribes of hunters and gatherers represents a replay of the growth of agricultural societies across the Middle East and Europe in the original expansion of agriculture in the Old World. In this conflict, wilderness was cast as one pole in a dialectic between human culture and wild nature.

The reality of these day-to-day struggles to transform wilderness into productive land may be contrasted with a second, emergent idea of wilderness, an idea—one might say an idealization—of wildness and wilderness that has evolved within academic and intellectual circles, especially in North America and in Australia. The works of Perry Miller (1967), Leo Marx (1967), Roderick Nash (1982) and the philosophers Mark Sagoff (1974) and Max Oelschlager have all articulated and emphasized the importance of the idea of wilderness in the American identity and self-perception. These authors, whose careers correspond to a growing academic interest in environmental studies all brought new dimensions to a vital strain in American intellectual life, as exemplified, for example, in the writings of Ernest Hemingway, Wallace Stegner, Annie Dillard, and many others. These authors reprise a longstanding theme—as exemplified in the Leatherstocking Tales of James Fenimore Cooper and his hero, Natty Bumppo, of associating life at the edge of wilderness as symbolic of freedom, self-reliance, and character.

The emphasis in the United States on the idea of wilderness led to a re-shaping of the related concept, "nature," which came to mean "primordial nature," whereas in Europe—where most land had been altered by humans long ago—people enjoyed the "countryside," with farms, homes, and businesses distributed across the landscape, as "natural." The assimilation of the idea of nature to that of primordial nature, and referring only to lands where humans have no presence, has contributed to the polarization of thought about nature in the United States. Whereas Europeans enjoy mixed landscapes, Americans distinguish wilderness from "the working landscape," and there are bitter disagreements about what activities are appropriate in wilderness areas. Advocates of wilderness thus try to eliminate activities, such as motorized recreation, from wilderness areas, considering such uses inappropriate and damaging to the primordial quality of wilderness.

The complex, often conflicting theme of nature versus culture has been important in environmental thought and action. Henry David Thoreau, the transcendentalist, said "in Wildness is the preservation of the World" (Thoreau 1998 [1862], p. 37), and his ideas are echoed in the work of John Muir (founding president of the Sierra Club) and many other wilderness advocates. Muir's reverence for forests and wild nature clashed with the ideas of Gifford Pinchot, the first Forester of the National Forest Reserves, who argued that all resources should be developed to improve the material lot of humans. So reverence—and passion—for wildness exists in sharp contrast to another, opposing theme: the need to control and civilize nature for human use. This tension in the environmental movement, it could be argued, reflects the broader ambivalence of Euro-American culture toward wildness and civilization.

Wilderness Policy

Muir's respect for wilderness also motivated Aldo Leopold, the philosophical forester who worked tirelessly to protect wild areas from development, from within and, later, outside the U.S. Forest Service. Leopold convinced the Forest Service to set aside the Gila Wilderness in 1922, and he co-founded the Wilderness Society—an activist group that advocates for wilderness protection—in 1935. Leopold advocated for preservation of the wilderness on several bases; he countered the utilitarians and materialists by noting that wilderness backpacking and hiking are uses, too, and that some land has more utility for back-country recreation than for development. He also argued that humans need wild, natural systems as *models* of healthy systems if they are ever to become intelligent managers of the modified systems that are their immediate habitats. Leopold, however, at his most passionate, argued for wildness and wilderness as a *cultural* necessity, and as a matter of *intellectual humility*. "The shallow-minded modern" must, he thought, learn to appreciate wilderness as a symbol of our "untamable past," and "giving definition and meaning to the human enterprise" (Leopold 1949, p. 200–201, 96).

In 1964 the U.S. Congress passed the Wilderness Act, which gave wilderness areas considerable protections. This act, which provides for the designation and protection of wilderness areas, defined wilderness "in contrast with those areas where man and his own works dominate the landscape, is hereby recognized as an area where the earth and its community of life are untrammeled by man, where man is a visitor who does not remain." Far from resolving the conflict between wilderness advocates and advocates of economic development, however, the passage of the act has resulted in a series of political struggles regarding which, and how much, U.S. government land would be designated as wilderness, and what kinds of activities would be allowed on designated land.

A New Wilderness Debate

In the 1990s, a new wilderness debate broke out, as philosophers, historians and scientists all called into question the truth and efficacy of the wilderness *myth*. An early salvo in this new war came from the philosopher J. Baird Callicott, who criticized the entrenched idea/myth of wilderness because it supports an inaccurate view of humans as separate from nature; and because the myth has colonialist overtones, treating members of the cultures who lived there as less than human, whereas these peoples *managed* the land, albeit less intensively than the European colonists. Callicott also thinks the myth confuses policy by emphasizing exclusion of all humans from wilderness. If the emphasis were shifted to protecting *wildness*, protection would only forbid the intrusion of modern, industrial uses, Callicott argues, and one might encourage people to live with nature in unobtrusive ways in order to cohabit with wildlife.

Subsequently this debate was rekindled in two contexts. First the historian William Cronon, who had implicitly raised some of Callicott's issues in his 1983 book, *Changes in the Land,* published a book in which he and his co-authors emphasized that the idealized, mythical idea of wilderness is very much an American construction, a culturally relative idea that should be recognized as very particular to the United States, and prone to hide rather than illuminate the reality of European settlement and colonial land transformations (Cronon 1995).

The wilderness debate also shaped a subsequent debate in conservation biology, as conservation biologists suggested that, whatever the original rationale for wilderness, the wilderness areas in the early twenty-first century are indispensable reserves to protect biological diversity. This idea has since been criticized by Callicott, who argues against the assumption that wilderness areas must be depopulated in order to protect wild species, arguing that conservation biologists requiring wilderness simply perpetuates the old dichotomy between humans and nature. Further the philosopher of biology, Sahotra Sarkar, has argued persuasively that the goals of biodiversity protection and wilderness preservation often conflict; this debate shows signs of continuing well into the twenty-first century. (Sarkar 1999).

The idea of wilderness has been, and remains, both seminal and controversial in ongoing discussions of the American character. Further this idea provides an attitudinal backdrop for explorations in environmental ethics and environmental thought, and also for debates about environmental policy. Given this central role in European and North American—especially U.S.—thought and action, it is not surprising that the idea deeply affects the ways humans understand—and evaluate—new and emerging technologies.

WILDLIFE MANAGEMENT

In some sense, wildlife management is not new. Wildlife was managed for subsistence hunting—by burning fields to create grass for ungulates, for example—by early humans and even perhaps by protohumans. *Game management*—management of animals for *sport* hunting, in particular—has been traced at least as far back as ancient Egyptian civilizations. Large game fields, managed for sport, were maintained for the recreation of Egyptian royalty. Hunting restrictions—which can be thought of as the precursors of modern wildlife management—can be traced back to early tribal customs and taboos. Typically game management involved few species—mostly for food and sport, but also for aesthetics in some cases—and was practiced over relatively small areas in a decentralized manner.

Since the twentieth century, due mainly to a confluence of developments in ecology and society, game management has been supplemented by more comprehensive wildlife management in most developed countries. Game management programs often dominate government wildlife management departments because of their political popularity and because they have, in hunting and fishing license fees, a strong source of revenue. Beginning in the 1920s with the pioneering work of Aldo Leopold, wildlife management took its place next to game programs. Eventually many governments reconceptualized game management as one specialization in the broader field of wildlife management, and in the early-twenty-first century most governments include agencies that accept some responsibility for maintaining healthy populations of almost all indigenous species.

Leopold and Evolution of Wildlife Management in the United States

Leopold, working with his more field-oriented friend, Herbert Stoddard, provided both the intellectual and practical leadership in shifting government agencies, at least in the United States, toward a more holistic approach toward wildlife management. As a consultant and researcher on game populations in the early 1930s, Leopold met and became friends with the British ecologist Charles Elton, an advocate of the empirical study of whole ecosystems. Elton and Leopold both recognized the implication of ecology: It is very difficult to manage single species in isolation without upsetting important ecological processes over time. This insight was driven home to Leopold by the abnormal fluctuations in deer populations in the southwestern United States, where he was director of operations, and sometimes game manager, over national forest holdings. Leopold had employed predator eradication as a means to create an artificially large herd of deer for hunting. During an especially bad winter, more than 60 percent of the deer died because they had eaten all available browse, causing a population crash, destroying vegetation, and encouraging soil erosion. In areas where top predators have been removed and there are no natural checks on wildlife population increases, there are often disagreements about the ethical treatment of animals, including conflict with private hunters and with government management agencies over policies involving culling of wildlife populations. Reducing populations of species whose natural predators have been eliminated is a great challenge. Agencies charged with controlling wildlife populations are sometimes strongly criticized by the public, which has become increasingly concerned with animal welfare and animal rights (Dizard 1999, Sharpe et al. 2001).

Leopold, years later in his classic book of essays *A Sand County Almanac and Sketches Here and There* (1949), included a brief but elegant mea culpa. He said he had mismanaged the land, creating starving deer and eroding hillsides, because he had not yet learned "to think like a mountain" (Leopold 1949, p. 130). Leopold treated his conversion as a revelation and also as a metaphor that must guide the future of wildlife management. Haunted by the "fierce green fire" that he saw in the eye of a dying she-wolf—a wolf shot by his group of forest rangers—Leopold realized, he said, that "there was something new to me in those eyes—something known only to her and the mountain" (Leopold 1949, p. 131). Leopold gradually rejected predator eradication programs and eventually advocated protection of wolves in wilderness areas. He devoted his remaining career to advocating and practicing holistic wildlife management, applying ecological principles to whole ecosystems. He was learning to think on the timescale significant to mountains—and was accepting moral responsibility for the long-term results of his short-term thinking about wolves and deer.

After leaving the U.S. Forest Service in 1928, Leopold became, first, a private consultant on game and sport hunting, and eventually the first professor of game management at the University of Wisconsin. He concluded that predators were an essential element in a healthy ecosystem, and shifted emphasis in his managerial theory and practice toward more holistic habitat management and away from management for single species (Leopold 1939, Flader 1994). By the late 1960s and early 1970s, some states had initiated *nongame wildlife programs*, and since then wildlife programs have flourished in response to strong public support and coexist, more or less easily, with game management programs. Demographic changes also had an impact as more of the population moved to the suburbs and the exurbs. These changes corresponded with an increase in leisure time and an increased demand for opportunities to interact with wildlife in nonconsumptive ways, for example during popular activities such as hiking, camping, and birdwatching. By appealing to this growing interest, governmental and nongovernmental agencies built a political constituency that supported parks, reserves, and wilderness. (Hays 1987).

Leopold, following Henry David Thoreau and John Muir—other *holists* who were very influential in conservation—thus shifted the focus of management from species to systems, and departed from his *resource management* approach. He moved toward a *biotic* view, which sets out to protect the integrity of ecological systems.

Leopold's evolution began with his belief that the goal of management is to maximize game availability; by the time he published his landmark book, *Game Management* in 1933, Leopold had also begun to emphasize the *quality* of game, arguing that quality is inversely related to artificiality. He advocated minimizing interference in the hunter/prey relationship to the greatest extent possible. Leopold believed sportsmanship was enhanced—and moral and aesthetic values supported—

when the sportsman interacts directly with wild game, without the interference of wildlife managers. Leopold realized, however, that growth and dispersion of human populations increases the need for more invasive management. Thus he saw game management as a negotiation between demand for quantity of game for increasing populations and the continuing threat to the quality of game and the hunting/fishing experience.

Leopold also argued that the same methods that he and others had applied to game management should be employed to maximize wildlife more generally, and closed the 1933 book by arguing that managers should apply similar methods to all wildlife. He stated that the goal of wildlife management was "to retain for the average citizen the opportunity to see, admire and enjoy, and to challenge to understand, the varied forms of birds and mammals indigenous to his state" (Leopold 1933, p. 403). Leopold advocated use of agricultural tools to produce more wildlife, claiming that the goals of the profession were not just to keep all life forms in existence, but also to ensure "*that the greatest possible variety of them exist in each community*" (Leopold 1986, p. 403).

By 1939 Leopold had become less optimistic regarding the possibility of managing for particular species, recognizing that ecological relationships are so complex that manipulation of systems to maximize some species will always have unforeseen consequences; species are so intertwined that only habitats can be protected. Leopold advocated protection of whole habitats and argued that society should value whole communities of plants and animals, and stop trying to value and favor some species inordinately. Leopold continued, until his death in 1949, to advocate holistic management, and registered many successes in protecting natural areas. He recognized, however, that truly holistic management remained mostly a dream. His influence, nevertheless, continues, as many wildlife managers follow Leopold's principles and emulate his method of integrating ecological science and management.

Issues in the Twenty-first Century

Since Leopold's time, and especially since the 1980s, concern with wildlife management has been supplemented with attempts to save *biological diversity*, which is a very broad and complex concept that includes wildlife. In the United States, biodiversity policy has been shaped by the Endangered Species Act of 1973, which restricts activities that threaten species of concern, and also mandates species and habitat restoration for species that are listed because of risk of extinction or extirpation from regional habitats. Although the act is politically controversial, protection of species remains a high priority for large majorities of the public. The act has also been criticized for retaining a bias toward *single-species management*, and there have been many efforts to reshape wildlife management to protect ecosystems and habitats. In this broader effort, endangered species protection is an important element, and the act, with its emphasis on single species management, nevertheless protects many species and their habitats through its designation and protection of critical habitats for listed species, which are of course shared with other plants and animals.

One important ethical controversy arises over the treatment of wild animals in captivity. While zoos have since late in the twentieth century shifted their message from purely recreational enjoyment of animals toward a conservation emphasis, animal rights organizations attack zoos as *animal prisons*, and question the holding of wild animals in captivity as a way to supplement or shore up sagging wild populations. Critics of invasive management of specimen animals ask: What gives humans—who have already disrupted animal communities all over the world—the right to capture and hold animals for conservation breeding purposes? (Norton et al. 1995)

Since 1970, as wildlife management and biodiversity protection policies have become more scientific by incorporating ecology and many other physical and social sciences into the management process, several important consensuses regarding both goals and methods have emerged. One important consensus is that large parks and preserves are necessary, but usually not sufficient, to protect all varieties of wildlife, because even large parks often lose significant numbers of mammal species (Newmark 1995). Accordingly there is increasing interest in managing *the matrix* of private lands that embeds reserves. This may involve creating buffer zones of lighter use around reserves, and creation of protected riparian corridors to connect various reserves and populations of animals (Harris 1984).

Gap analysis has emerged as the state of the art method for protecting biological diversity. According to this technique, ecosystem and habitat conservation programs are judged by comparing biodiversity priorities with existing and proposed reserves. By identifying *gaps*—important ecological communities that have no protection—conservation efforts can be concentrated on saving all community types and, in the process, the species of wildlife that depend upon them (Church et al. 1996, Scott and Csuti 1996). The goal of international conservation is to protect representative samples of all the biological communities in the world (McNeely 1989). Efforts are underway to restore some whole ecological systems and to reintroduce predators in some areas, such as the Greater Yellowstone Ecosystem in the western United States. Restoration of wildlife populations and protection of their habitat is praised not only for its ecological benefits, but also as a means to involve communities in local conservation projects, thereby building community leadership and making citizens more aware of environmental values.

The future of wildlife management—and of wildlife itself— in the early twenty-first century is uncertain. As cities expand into countryside, it becomes more difficult to maintain populations of many species, especially large predators. Scientific experts fear that species such as wolves, mountain lions, and bears will become increasingly hard to protect. As areas not dominated by human uses shrink, wildlife will have to be managed more invasively to protect the diverse biological heritage each generation has inherited. Such management, however, undermines the wildness of wildlife and affects, as Leopold stressed, the quality of the human experience of wild creatures.

Learning to protect truly wild populations will be a challenge for the future. Rapidly accelerating rates of extinction demonstrate that humans have not learned these protection methods yet. As the pressures of expanding populations and cities continue though the twenty-first century, much wildlife will be lost as ubiquitous species that easily cohabit with humans take over the remaining, fragmented habitats. Only a concerted effort to understand and to act decisively can avoid a drastic simplification of the biological context in which humans evolved. Such an effort would involve unprecedented cooperation among scientists, governments, private land-owners, and wildlife management agencies, and could only achieve success if techniques are developed to manage whole regions to maintain adequate reserves and other protections to form a complex matrix of human and natural communities.

WITTGENSTEIN, LUDWIG

Engineer, architect, and one of the most influential analytic and linguistic philosophers of the twentieth century, Ludwig Wittgenstein (1889–1951) was born in Vienna, Austria, on April 26 and died a few days after his sixty-second birthday in Cambridge, England, on April 29. Although seldom emphasized in works about the philosopher, Wittgenstein's life was deeply engaged with technology. He studied mechanical engineering in Berlin and aeronautical engineering in Manchester, England, securing the patent for a propeller in 1911. He also conducted combustion chamber research and his ideas were used for helicopter engines after World War II. Even after abandoning his engineering career, Wittgenstein's engineering education continued to exercise an influence on his philosophical work.

Ludwig Wittgenstein, 1889–1951. After making important contributions to logic and the foundations of mathematics, the Austrian philosopher Wittgenstein moved away from formalism to an investigation of the logic of informal language. *(Hulton Archive/ Getty Images.)*

Wittgenstein began his career as a philosopher in 1912 after reading Bertrand Russell and Alfred North Whitehead's *Principia Mathematica* (Volume I, 1910). The logical foundations of mathematics was one of the most important philosophical issues of the day, and between 1914 and 1918 Wittgenstein wrote one of his *Tractatus Logico Philosophicus*. Its spare hundred pages contain a philosophy of logic, of language and meaning, of science, an ontology, and by implication, ethics. Language is the basis for all thought, so that the first philosophical task must be to understand its relation to the world in order to clarify its meaning. Many philosophical problems rest on confusions about the meaning of language; when these confusions are revealed, the problems vanish. Only scientific problems are real and thus able to be truly solved.

Wittgenstein's work was a fundamental influence on the philosophical program of the logical empiricists of the Vienna Circle, including Otto Neurath (1882–1945), Moritz Schlick (1882–1936), and Rudolf Carnap (1891–1970). This program argued that metaphysics, ethics, and religious beliefs were *non-scientific* and therefore beyond serious philosophical enquiry. Ethical values themselves were sometimes presented as no more than expressions of personal or social emotions. This positivist interpretation of Wittgenstein's thought remained influential even into the 1980s. In the *Tractatus* itself, however, Wittgenstein maintained that although only scientific problems are real, what really matters for human beings are unsolvable questions about right and wrong, good and bad, the meaning of life and so on (Wittgenstein classified these as mystical questions). To be unable to give acceptable scientific answers to such questions did not imply their meaninglessness.

After his death the publication of Wittgenstein's *Philosophical Investigations* revealed a very different Wittgenstein than that associated with the *Tractatus*. To some extent, Wittgenstein turned away from a logical, scientific clarification of language, because diversity of language uses demonstrates the futility of the effort. Language does not function as a scientific mirror of the world but as a profound social phenomenon, as a practice among people. The meanings of words are found in their uses in different contexts, as they are used in *language games,* which belong to specific *ways of life* or *forms of life,* and mistakes arise when philosophers try to find essential meanings in words, because such meanings do not exist. Language is also a learned technique, and to some extent all techniques, even scientific ones, are similar: They all have a deeply social element. There is no *super-game* of philosophy or science that could subsume all other games.

Wittgenstein neither considered himself a scientist nor accepted the idea of technological progress, and he departed clearly from the standard interpretations of scientific development as articulated first by the logical empiricists and then in revised form by Karl Popper (1902–1994) and his followers. In scattered remarks, such as those found in *Culture and Value* (1980), Wittgenstein expressed distrust of modern science and technology and considered them, along with industrialization, as the main causes of war. "Man has to awaken to wonder—and so perhaps do peoples. Science is a way of sending him to sleep again," he once wrote (*Culture and Value,* p. 5e). In his view, science not only fails to deal with the most significant issues but also tends to homogenize the world. The scientific age is associated with a decline in culture, and attempts to popularize science are, according to Wittgenstein, largely mistakes.

Influenced by Viennese cultural and artistic critics such as Karl Kraus (1874–1936), Wittgenstein was sensitive to the negative effects of modern science and technology. Skeptical of progress, he wrote, "It isn't absurd, e.g., to believe that the age of science and technology is the beginning of the end for humanity; that the idea of great progress is a delusion" (*Culture and Value,* p. 56e). The experience of both World Wars and the disappearance of a whole way of life help explain Wittgenstein's critical distrust of scientific and technological development alone as inherently beneficial. In response to the use of the atomic bomb, he actually considered the possibility that modern technology might destroy the whole human race. His pessimism was similar to that of many other intellectuals, including his mentor Bertrand Russell (1872–1970). However, Wittgenstein did not pursue these concerns in any rigorous way.

Many of Wittgenstein's ideas are key features in subsequent criticisms of science and technology. The political theorist Langdon Winner (1986) uses the *form of life* concept to explain how technology becomes a part of one's humanity, as a kind of second nature. As a consequence, technological artifacts often acquire a political character. From an epistemic point of view, sociologist David Bloor (1983) also draws on Wittgenstein to develop a critical assessment of the social nature of scientific knowledge. The so-called "strong program" of the Edinburgh school in the sociology of scientific knowledge uses Wittgenstein's ideas as a basis for their research. Wittgenstein's influence is pervasive and his thinking leaks out into many different fields, including discussions of values in science and technology. For instance, John Searle used Wittgensteinian techniques to attack claims for artificial intelligence (1986). Wittgenstein's main contribution to science and technology criticism consists of a heightened sensitivity to "bewitchment" (Wittgenstein's term) in technological discourse.

WORK

Work done by human beings is purposive action guided by intelligence; work that is repetitive or arduous is often called labor. Both purpose and intelligence may originate in persons other than those actually doing the work. Associated with the basic definition are many related usages including effort expended (also called toil); the result of that effort (a work of art); and one's job or employment, workplace, trade, occupation, or profession. In all these senses work is subject to technological modification, scientific and literary study, and ethical reflection.

Historical Background

In early civilized societies, the kind of work people did depended on their class: The elite had slaves do whatever they considered demeaning, notably if it involved unrewarded physical exertion. Certain religious attitudes perpetuated this devaluation. Some Buddhist and Christian monks, for instance, have associated physical inactivity with the highest spiritual states.

By contrast, in medieval Europe, a combination of prayer and work (*ora et labora*) came to be viewed as a more fully human expression of spirituality. Government despoliation of monasteries during the reformation reduced the feasibility of a life devoted primarily to prayer. But comparable lifestyles are still possible. These aside, the Industrial Revolution tied most workers' survivability to remunerative employment.

Throughout recorded history societies have adopted various attitudes and expectations regarding work. Knowledge of this history lends perspective to contemporary attitudes and expectations. Over time, though, vast technological changes have been made in the production, marketing, and distribution of goods and services, so that past arrangements may not pertain to contemporaneous circumstances. The young Karl Marx (1818–1883) thought history pointed toward an egalitarian society in which every worker would freely choose which activities to engage in. Hannah Arendt (1958) preferred instead a socially stratified society, as in ancient Athens, where a knowledgeable few engage in (political) action, while others work (produce something) or labor (exert themselves physically).

History aside, work-related matters are now routinely viewed in economic terms. In particular, all types of paid activity are identified as labor (skilled and unskilled), and labor costs are largely determined by supply and demand. The supply of labor is, in turn, increasingly a function of globalization; and labor is sought mostly for tasks that technology has not mastered. In this context, work is conceptualized as remunerative employment and is commodified.

Indeed, in the early twenty-first century most people associate work with earning a living and, for the career-oriented, enhancing social status. Frequently, though, personal career aspirations exceed what is attainable under the prevailing economic system—whence arise a number of ethical issues.

These ethical issues include the following: Is the character of work determined solely by the market? Who is obliged to work? Under what circumstances? Should remuneration provide a decent living for the worker (a living wage) and for the worker's family (a family wage)? Which if any institution(s) should provide and/or assure employment, humane working conditions, meaningful and satisfying work? Are those unable to find employment entitled to subsistence? The social effects of scientific and technological change increase the salience of these issues.

Established Ways to Think about Work

Practical approaches to such questions involve both ethical determinations and public policies. These, in turn, draw on research findings in such disciplines as history, economics, sociology, psychology, and jurisprudence, most of which have tended to reinforce socially favored attitudes toward work.

Work is now commonly treated as something bought and sold—typically, a service or product. Employers decide which services or products to offer or generate in a given locale and employ workers accordingly. Workers' remuneration is a function of their productivity in their economic environment. This productivity, in turn, is measured by subtracting overhead—that is, the expenses incurred by conducting a business on-site—from revenue received for services or products. Because a large part of overhead is labor costs, management strives to keep these to a competitive minimum, and may therefore resort to workforce downsizing, technological displacement, and/or workplace relocation. From these practices arise many ethical issues directed to fostering cross-cultural fairness in every aspect of the employment relationship, but especially those having to do with hiring, retention, remuneration, and working conditions. Also important, especially to employees, is finding in work both personal fulfillment and conformity with a socially promoted work ethic (Gini 2000).

A work ethic involves making work a key measure of personal success (Rose 1985, Beder 2000). Industrial-era capitalists fostered a work ethic to maintain a sufficient supply of willing workers. But workplace rationalization and globalization (see below) have rendered the work ethic an unreliable incentive. Some theorists nonetheless still call for meaningful work (Schwartz 1982, Byrne 1990) and a right to work. The latter expression sometimes signifies individualist opposition to unionization (Dickman 1987) and sometimes, gainful employment as such (Harvey 2004, Skopcol 1990). In either sense it is stymied by cost-cutting strategies that replace higher- with lower-paid workers and human beings with machines.

Since the Great Depression in the 1930s governments have assumed some responsibility for this problem by funding systems of unemployment compensation (UC): twenty-two countries had done so by 1949, and sixty-eight countries by 2004. Some scholars argue that any structurally unemployed person is entitled to subsistence income. But governments increasingly require a claimant for UC (as distinguished from generic welfare support) to have been employed and/or be actively seeking employment. Thus in the 1990s even Nordic countries, long noted for their generous UC programs, made these programs less accessible and their benefits less supportive.

Many factors enter into the amount of compensation a person receives for work done. These include the level of development and/or indebtedness of the economy within which one works, one's social and political affiliations, and one's gender, race, national origin, and so on. For example, work done by women is sometimes labeled differently from men's work to justify paying women less (Wright et al. 1987; Mohanty 2003). A society may also set ethical limits on the time a worker may devote to play (Byrne 1990). This pro-work mindset (manifested even in the career-oriented way parents view their children's preschool activities) seeks to maintain an abundance of available labor, now on a global scale.

Large corporations increasingly dominate worldwide employment without assuming responsibility for the negative consequences of their decisions regarding workforce size or location. Even in the face of automation (Byrne 1990) and globalization (Goudzwaard 1979), though, less socially disruptive strategies are possible. These are supported by calls for decent working conditions and a living wage (for example, the United Nations' Universal Declaration of Human Rights, arts. 23 and 24; John Paul II, 1981). Such declarations, though, forestall few if any downsizing decisions. Moreover, the unemployed are often stigmatized and considered personally responsible for their situation even as governments dismantle programs that would mitigate the effects of unemployment (Beder 2000). These conflicting attitudes about work show that the ways in which work has been viewed are no longer adequate to the challenges now emerging.

Finding New Ways to Think about Work

The premodern fusion of work and life associated with primitives and studied by cultural anthropologists is now rare. The modern fusion of work and compensation is coming undone as the availability of jobs depends less on individual skills or dedication than on strategic workplace and/or workforce selections that contribute to profit maximization. In short, the industrial-age problem of worker displacement engendered by rationalization of process is now being compounded by globalization. So earlier analyses of work-related problems need to be reviewed through new lenses if a humane approach to work is to be restored.

Already in the eighteenth century some theorists began speculating about the future of work in view of the inroads of mechanization. Building on earlier utopian visions, some social planners proposed founding communes that would use technologies selectively (Manuel and Manuel 1979). But classical economists, including Adam Smith (1723–1790) and David Ricardo (1772–1823), believed that an unfettered market would achieve "full employment equilibrium." As explained by the French economist Jean-Baptiste Say (1767–1832), for example, supply creates its own demand and this engenders full employment. This "law of markets," or Say's law, predicts that as laborsaving devices replace workers more products become available at prices more consumers can afford, thereby creating a need for additional workers. On this theory, unemployment is not structural (inevitable given system priorities) because a machine-challenged workforce will accept lower wages, which in turn diminishes the need for more expensive machinery (Gini 2000). The mature Marx predicted instead that capitalists' continued recourse to laborsaving devices would engender a great mass of marginalized and potentially insubordinate poor. Proving this prediction incorrect has been a priority for theorists and politicians ever since.

In the nineteenth and early twentieth centuries laborers were assumed to have minimal intelligence, which Taylorization and Fordism sought to exploit. But such workplace strategies destroy job satisfaction, lowering productivity. So during much of the twentieth century social scientists were recruited to improve workplace *human relations* and *quality of work life,* in large part to forestall unionization. In this vein, industrialist Henry Ford once raised his workers' wages above then-current rates so his employees could afford to buy his automobiles. Still others, from John Stuart Mill (1806–1873) to Franklin D. Roosevelt, worried about what the British economist John Maynard Keynes (1883–1946) called *technological unemployment* (Gini 2000, Goudzwaard 1979). Contemporary defenders of Say's law do not share these concerns. Their *trickle-down economics,* however, do not address the emerging phenomenon of companies "churning" a literally global workforce to cut costs. So this survey of work-related issues must, finally, take note of recent attempts to evaluate these new approaches to workforce dynamics.

The problem, in brief, is how to accommodate the tendency (a) of employers to pursue the least costly means of production and (b) of employees to seek the most advantageous compensation. In the age of discovery made possible by the development of reliable ships, employers combined on-site production with slave labor. In the industrial era, employers welcomed wage laborers to their fixed-site factories. Now in the age of computers and electronic telecommunications it is possible to locate supplies, employees, equipment, product, and vendors in whatever mix most favors a given business. Enslavement is now a violation of human rights under international law. It still occurs, however, and in other ways as well. Transnational corporations exploit Third World workers and will continue doing so until prohibited under international law (Moran 2002). They will do so because they gain monetary, trade, tax, and other advantages by locating facilities and employees so as to minimize total labor costs and maximize return on capital. Adding these strategies to automation, capitalist management strives to control workers, as did communist managers (Shaiken 1985). Control of the work process now depends, however, not just on routinizing a task but on where and by whom that task is most profitably carried out.

Most workers need to use tools, including highly complex machines that sometimes replace workers. Thus the availability of employment depends in part on what technology and operators are available. With this in mind, contemporary experts, like their forebears, debate whether introducing new technologies expands or contracts job opportunities (Aronowitz and DiFazio 1994, Bix 2000). In fact, it does both, either by requiring additional workers, as did the assembly line, or by rendering skills previously in demand obsolete, as has containerization and automated manufacturing processes, or both eliminating some jobs and creating others, as has the computer. The U.S. Department of Defense's funding of science and engineering since World War II has severely skewed educational and hiring priorities in many technical fields (Standler 2004). And computer-based network technology generally reduces complex layers of jobs to comparatively few, thereby rendering many employees superfluous. Some laid-off workers can be retrained for new jobs (hence the U.S. Workforce Investment Act of 1998). These jobs, however, are often temporary and/or part-time with no employer-provided benefits. In this context employers no longer stress company loyalty but promise their employees heightened skills for placement elsewhere. But those seeking reemployment may be deemed *overqualified,* in part because they are in a labor pool that includes many others, some no less skilled, in or from countries where compensation is substantially lower. Partly because of this migration of work unemployment is much lower in many developing countries, especially in the Asia-Pacific region, than in some developed countries, especially in Europe. This situation remains subject, however, to profit-maximizing strategies, which are ever under review. So however work is distributed around the world, it will enhance a globalized buyer's market that primarily benefits corporate executives and investors.

This noted, economic growth does tend to lower unemployment, albeit not precisely in accord with Okun's law (a 1% increase in the rate of economic growth lowers the unemployment rate by 0.3%). Lower unemployment, though, is not inconsistent with job obsolescence. Individuals with advanced degrees, especially in technical and business-related fields, do have better marketability than do those less or less appropriately educated. And it is true that in developed countries, especially in Europe, new jobs are being created mainly in the service sector. This sector, though, is itself being transformed by the same network technology that has reduced the number of jobs in manufacturing.

Workers' Rights in a Global Workplace

The global marketplace raises pressing ethical issues regarding workers' rights. But workers' rights are difficult to enforce in many countries. So business ethicists recommend codes of ethics that can be applied cross-culturally. These have tended to favor management, but public awareness of corporate executives' malfeasance and disproportionate compensation has generated support for tighter external regulation of business practices. The decades-old debate about corporate responsibility now takes into account stakeholder theories, which extend property rights to groups other than shareholders and management, such as plant-location cities, suppliers, and customers. But such theorizing is difficult to apply to structurally consolidated professional services, such as in health care, or to transnational combinations in industries such as finance, telecommunications, and retail groceries. Government and corporate leaders extol the resulting increases in productivity, even as they blame the unemployed for not having jobs (Beder 2000). Such politically motivated problem skimming, however, does not address people's growing sense that the globalized marketplace is limiting their employment opportunities.

Global employment strategies that are advantageous to an employer disadvantage some potential employees more than others. Protective tariffs may be imposed to safeguard jobs tied to goods not produced at competitive costs. But the availability of substantially cheaper labor in or from developing countries disfavors retention of higher-paid employees in developed countries. Thus by the year 2015 the U.S. electronics industry will have transferred some three million jobs to India, and possibly as many as that to China. Comparable moves are planned in Europe, even in non-English-speaking countries. Meanwhile, China now produces four times as many apples as the United States so that only growers in the state of Washington can still compete without tariff protections. And if U.S. tariffs on orange juice are abolished under a proposed free trade agreement, Brazil's product will capture the U.S. market and Florida orange growers will no longer hire Mexican migrant workers. Changes of this magnitude in job markets cannot be neutralized by extolling the rewards of adhering to a work ethic. A better response might be to somehow apply Marx's maxim: from each according to ability, to each according to need. This ideal, however, is not easily introduced into the corporation-dominated global economy.

Economists who study the effects of globalization disagree about their ultimate ramifications. Some retain the optimism of Say's law by arguing that the global economy as a whole improves whenever something is produced where it can be done efficiently and at a substantially lower cost than elsewhere. This thesis, which economists explain in terms of *comparative advantage*, needs to be modified to take into account both international monetary exchange rates and the losses incurred by displaced workers. Moreover, if the comparative advantage in question depends on exploiting workers (for example, in sweatshops) or engaging in illegal activities (such as laundering money), it is subject to additional ethical objections. To address such distortions of global fairness both the International Labour Organization and its parent body the United Nations (UN) have identified certain core labor standards with which all employers should comply. Subscribed to by many UN member nations, these standards favor workers' right to organize and condemn forced or compulsory labor, child labor, and discrimination in employment or occupation. Much debated is whether the inclusion of these core labor standards in trade agreements would mostly benefit Third World workers or First World corporations (Basu et al. 2003).

Work in the Future

In short, the ethical problems associated with a globalized and technologically challenged workforce involve not only economic but social and political considerations as well, especially because their solution requires moving beyond the modern tendency to base people's income eligibility almost exclusively on their work. This is rarely considered in the United States, where job responsibilities (such as being "on call 24/7") are blurring the line between work and leisure. Meanwhile in the United Kingdom programs are being developed precisely to achieve better "worklife balance." In some places, such as Alaska and Saudi Arabia, resource-based wealth has been distributed to all citizens, even those not participating directly in the generation of that wealth. Expanding such arrangements and devising others not dependent on the market is desirable (Offe and Heinze 1992) but unlikely so long as such traditional capitalist values as property rights and the work ethic remain dominant. For the foreseeable future, then, few besides the independently wealthy will be able to live decent lives without engaging in wage work. Where, then will this work be found?

This question is often answered by extending historical precedents into the future, namely, by viewing past transitions (from agricultural to industrial to service and to information sectors) as an evolutionary indication of another major employment sector to come. This may be so, but present data fail to reveal this new source of work in the world.

In the United States alone, some three-fourths of all workers deal with—create, collect, or use—information. The complexity of their involvement, and thus of their compensation over a lifetime, is partly a function of their education. But only 25 percent of the U.S. workforce have had four years of college, and only 5 percent have advanced degrees. The growth rate of researchers in the United States is a third less than the rate for all OECD countries. A fourth of the scientists in the United States are foreign-born, as are a third of doctorate-level scientists and engineers. Moreover, the United States has in recent years been attracting fewer foreign students to its technical programs. Indeed, it has been lowering annual ceilings for high-skilled (H-1b) visas even as the Japanese have greatly increased theirs. Meanwhile, more than 10 percent of all U.S. workers, mostly women, do not have regular full-time jobs. Given such indications of the present situation, what is needed is surely neither utopian nor anti-utopian scenarios but all the social inventiveness Americans can muster.

WORLD BANK

The World Bank (Bank) or International Bank for Reconstruction and Development was created at a meeting of the forty-four World War II allied nations in Bretton Woods, New Hampshire, in 1944. Because of its promotion of economic development, the Bank is also an international institution involved to some extent with issues relevant to science, technology, and ethics.

Historical Emergence

At its inception, the Bank's mission was to make long term capital loans to countries harmed by World War II and, more generally, to undeveloped countries worldwide. Sister organizations founded at the same time, with overlapping missions, include the International Monetary Fund (IMF), the International Development Association, the International Finance Corporation, and the Multilateral Investment Guarantee Agency. Through an agreement signed in November 1948, the Bank acts as a specialized UN agency.

Surprisingly the Bank was largely irrelevant to the process of rebuilding Europe after World War II; the majority of the huge financial commitment came through the United States' Marshall Plan. In the first twenty-five years after its creation, the World Bank made only a handful of loans to European states (albeit large ones), including loans for the reconstruction of the steel industry in France, Belgium, and Luxembourg (McLellan 2003). With money in hand collected from its subscribing members, the Bank nevertheless felt an intense *pressure to lend,* and fell back to a secondary mission, that of lending to economically underdeveloped countries.

The Bank's charter contained language militating in favor of project-based lending, and in the early years most of its loans were for the finance of specific projects such as the development of mines or dams (Skogly 2001). The Bank, which experienced a failure rate of as much as 70 percent of its loans in the poorest countries (McLellan 2003), soon noticed that local conditions did not support the success of these projects. Among the factors cited by the Bank for project failure in poor countries are ineffective government, corruption, and *lack of transparency* (World Bank 1994).

To respond to these problems, the Bank began a program of so-called structural adjustment loans or SALs, which represented a movement away from its original project-based lending. SALs involve money advanced for a variety of projects and efforts, and are explicitly conditioned on the implementation of structural and economic changes by the borrowing country, including decentralization, privatization, cost-cutting, and discontinuance of tariffs and supports for its own currency.

In 2002 the Bank made $11.5 billion in loans in support of ninety-eight projects in forty countries. It currently has a total of about 1,800 projects in almost every developing country (McLellan 2003).

Evaluation

The main charge leveled against the Bank is that its ideological approach to lending actually creates the poverty it is intended to combat. Most critics focus on the SALs with their attendant mandatory conditions. Vikas Nath says that the Bank reduced many Third World nations to even greater poverty and dependence on Western aid. Countries often have to borrow from other sources to repay the Bank. Borrowing countries "gradually lost their ability to shape their own future. . . ." (McLellan 2003, p. 62). In the poorest countries, government employment arguably provides a social safety net when jobs in private industry are unavailable. Critics argue that, by forcing cuts in government employment, the Bank throws people into poverty, since the predicted growth in private employment does not materialize soon enough, or with salaries high enough, to pick up the slack.

For many years, the Bank rarely assessed the environmental or social impact of projects it funded. The Sardor Sarovar dam project in India, projected to displace 1 million people, was canceled because of local protests. The Bank admits that under its current portfolio of projects, some 26 million people have been evicted, lost land, or lost livelihoods. As a result, in the early-twenty-first century the Bank conducts environmental reviews of all projects, and lending for environmentally beneficial projects makes up 10 percent of its portfolio. (McLellan 2003).

Critics also question whether a for-profit institution can carry out a not-for-profit mission in the Third World. "The World Bank focuses on economic growth until it is distracted by other issues like hunger, women, health, the environment, etc. The World Bank tries to adapt itself to these considerations without giving up its basic goal" (Danaher 1994, p. ix).

Such critics contend that the SALs in particular lead to the repression of democratic rights in poor countries, without reducing poverty. "Structural adjustment is a policy to continue colonial trade and economic patterns developed during the colonial period.... [Third World countries] are more dependent on the ex-colonial countries than we ever were" (Danaher 2003, p. 4). Thirty out of forty-seven African governments have been in SALs for many years—yet by 1992, rather than being reduced, their external debt had more than doubled (to $290 billion) (Danaher 2003).

Shakrukh Rafi Kahn studied the impact of Bank lending in Pakistan over a twenty-year period. Though some initiatives, such as privatization of state-owned banks, were somewhat successful, he noted the greatly disproportionate impact of the Bank's SAL policies on the nation's poor: "They have been hurt many times over. Not only have they borne a disproportionate burden of the cuts in employment, cuts in subsidies and the rise in prices, but they also have started bearing more of the tax burden" (Kahn 1999, p. 120).

The Bank, in more guarded language, seems to be aware of the problems with its programs. In a publication on governance in developing countries, the Bank notes that the form of government (democratic or autocratic) is not one of its concerns. In reviewing its SALs around the world, the Bank concedes that things have not gone well in Africa: "Bank assistance to Africa is dominated by the collapse of public sector capacity in many countries, brought about by a combination of state over-extension, delayed adjustment to changed external economic circumstances, natural events, and poor governance" (World Bank 1994, p. 9). It recognizes that Western solutions to problems cannot always be transferred wholesale to countries with very different traditions. The Bank concludes "Performance in sub-Saharan Africa has been disappointing" (World Bank 1994, p. 11).

In a more overtly self-critical document, water expert George Keith Pitman (2002) argues that the Bank is poorly organized to implement its own water resources management strategy. Knowledge and leadership on water issues is seriously fragmented within the Bank's management structure, while budget cuts have eroded the knowledge function. Pitman also quotes certain nongovernmental organizations (NGOs) that believe "the pressure to lend ... has not been removed and continues to work against aspects of the water policy that recommend greater attention to smaller and cheaper alternatives" (Pitman 2002, p. 39).

The Poverty Action Lab, a Massachusetts Institute of Technology project, has begun randomized evaluations of the impact of Bank projects. Its researchers agree that success cannot be measured only by concrete achievements; assessments must include the impact of Bank projects on the lives of the poor (Dugger 2004). For example, hiring additional teachers for rural Indian schools did not improve test scores, but treating debilitating intestinal worms in Kenyan students raised attendance at a cost of only $3.50 per treated person per year.

Economists at the Poverty Action Lab say that the Bank's culture led to a certain complacency in the past, preventing the Bank from rigorously evaluating its own projects. The Bank is beginning to pay attention, organizing its own randomized studies.

Columbia professor Joseph Stiglitz believes that the Bank has been more successful than the international monetary fund in undertaking sweeping reforms of its own structure and approach: "the bank has always been less hierarchical than the IMF and more accepting of alternative views.... [by 1997] the bank had begun to seriously address the fundamental criticisms levied at it" (Stiglitz, p. 122).

Conclusion

The Bank is a well-funded, powerful Western institution with the mission of aiding developing countries. Many of its good intentions may be wasted due to its attempt to apply free market solutions in countries with very different traditions, or that are simply not ready for these approaches.

WORLD COMMISSION ON THE ETHICS OF SCIENTIFIC KNOWLEDGE AND TECHNOLOGY

The World Commission on the Ethics of Scientific Knowledge and Technology (COMEST) mirrors at the international level numerous national commissions on science, technology, and ethics. In the early 1990s, the General Conference of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) formally recognized that the changes wrought by science and technology raise questions that demand ethical reflection (Pompidou 2000). In 1997 it approved the creation of COMEST to institutionalize this growing awareness that ethical reflection must become an integral part of scientific research and its technological applications. COMEST and the Bioethics Programme at UNESCO comprise its Programme on the Ethics of Science and Technology, which is designed to further the mission of UNESCO to serve as the conscience of the United Nations.

In addition to advising UNESCO on its program concerning the ethics of scientific knowledge and technology, COMEST is mandated to: (a) be an intellectual forum for the exchange of ideas and experience; (b) identify the early signs of risk situations; (c) advise decision makers on such issues; and (d) promote dialogue between scientific communities, decision makers, and the general public. COMEST is composed of eighteen members and eleven ex-officio members diversified by expertise, nationality, and culture. The operating budget of COMEST for the 2002–2003 biennial was $3.8 million.

By mid-2004, COMEST had held three main sessions. The first was in Oslo in April 1999, which focused on analysis of the ethical aspects in the fields of energy and freshwater resources and the information society. The second, in Berlin in December 2001, was devoted to assessing the progress of COMEST and its influence. In addition, a youth forum on the ethics of science and technology was held and a statement about space policy developed. The third session was held in Rio de Janeiro in December 2003 with a significantly wider agenda incorporating the ethics of biotechnology and nanotechnology. In addition, the Rio de Janeiro Declaration on Ethics in Science and Technology, signed by representatives from Portugal and several countries in South America and Africa, committed the party nations to pursue ethical approaches to scientific and technological advance. The sessions were attended by policy makers, scientists, and representatives from various organizations and member nations.

Complementing these three sessions are various COMEST subcommissions and working groups. Four subcommissions have focused on the ethical aspects of freshwater resources, space policy, energy use, and the information society. These research topics were designed to follow up on the efforts of the World Conference on Science hosted by UNESCO and the International Council for Science (ICSU) held in Budapest in 1999. Working groups have addressed issues such as ethics education and ethics and responsibility in research training.

The principle outputs of the subcommissions and working groups have been a series of publications. Each report surveys an issue and highlights the ethical questions involved. The main focus is on recommendations to COMEST or other decision-making bodies regarding alternative courses of action. For example, the subcommission on the ethics of freshwater created the Research and Ethical Network Embracing Water (RENEW) to identify and endorse examples of best ethical practices of freshwater use. It also produced a report, "Some Examples of Best Ethical Practices in Water Use," that used five case studies to highlight fundamental ethical principles to guide water use policies. Other subcommissions have outlined considerations that could point the way toward more just and sustainable policies (for example Pompidou 2000, Kimmins 2001). The principle of precaution and the concepts of sustainable development and environmental responsibility underpin these recommendations.

COMEST has grown over its short history. Its budget increased 50 percent for the 2002–2003 sessions, and it has broadened its scope of topics. The global scale of COMEST provides its three main strengths. First the internationalization of ethical issues involving science and technology necessitate a global forum such as COMEST to foster communication and mediate conflicts. Its multicultural and interdisciplinary analyses have contributed to better identification of the ethical issues involved in areas such as freshwater, space, and energy. They have also detected early signs of possible risks to society and articulated guidelines for decision makers in the public and private sectors. Second its global reach allows COMEST to promote the development of ethical reflection on these issues in countries that do not have such institutions. Third the scope of COMEST allows it to formulate universal norms to guide the wise use of science and technology.

The global scale of COMEST is also a weakness because it can distance its analyses from the site-specific considerations necessary for formulating ethical policies. Invoking universal standards and ethical principles in concrete situations presents COMEST with its biggest challenge. Several subcommission reports recognize the need to tailor solutions to local conditions (Kimmins 2000). Yet this means that COMEST may be out of synch with its intended audiences and must strive to reconcile its global reach with local needs. Toward this end, COMEST must establish more objective assessments of its work in order to evaluate its efforts.

WORLD HEALTH ORGANIZATION

The World Health Organization (WHO) is one of the sixteen United Nations (UN) specialized agencies, with a mission to promote world health. The organization's broad conception of health as including politicized issues such as poverty, apartheid, and environmental quality has aroused controversy over the years.

Organization and History

The WHO was conceived at the 1945 San Francisco conference at which the United Nations was formed. It came into being on April 7, 1948, after its constitution was ratified by twenty-six of the original sixty-one members. WHO is based in Geneva and has six regional offices: Africa, Europe, Southeast Asia, Americas, Eastern Mediterranean, and Western Pacific. Governance is provided by the World Health Assembly, with representatives from (as of 2005) 192 member states. The assembly selects an executive board, which in turn nominates a director general, who is elected by the assembly for a five-year term.

The original top WHO priorities in 1948 were malaria, maternal and child health, tuberculosis, venereal disease, nutrition, and environmental sanitation.

Subsidiary concerns included public health administration, parasitic and viral diseases, and mental health.

WHO is the successor to a series of international Sanitary Commissions, beginning in the nineteenth century, that concentrated on the containment of infectious diseases. Whereas the philosophy of those earlier organizations was to keep infectious diseases out of nations or regions, the philosophy of WHO was to eradicate those diseases wherever they were found, a "total change of perspective" from that of its predecessors (Beigbeder 1998, p. 13).

In the early twenty-first century WHO fields emergency teams of medical professionals who respond to the outbreak of new infectious diseases such as severe acute respiratory syndrome (SARS) and avian flu. WHO also helps member countries create or improve medical schools and services.

Concept of Health

The WHO definition of health is very broad. According to the organization's constitution, health is "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity." WHO conceives of health as a fundamental human right and cornerstone of world peace.

In line with its broad definition of health, WHO has been a pioneer in environmental concerns. It was concerned as early as the 1950s about the effects of the eradication of insect species and the peaceful uses of nuclear power.

Although WHO has been most effective as a detail-oriented technical organization concentrating on medical and scientific problems such as smallpox eradication, its broad mandate has opened the door to numerous efforts to politicize it. From the beginning the WHO assembly has debated and voted on resolutions introduced by its members on political topics such as the effect on Palestinian physical and mental health of the Israeli occupation or on Nicaraguan health of U.S. sanctions. From the date Israel joined WHO the Eastern Mediterranean group always held its meetings in Arab capitals to which the Israeli delegates were not permitted to travel, effectively keeping Israel from playing a role in WHO regional activity. This situation was not resolved for more than thirty years, when Israel was invited to join the European region.

The U.S. ambassador William Scranton said in 1976 that "the absence of balance, the lack of perspective and the introduction by the World Health Organization of political issues irrelevant to the responsibilities of the World Health Organization do no credit to the United Nations" (Siddiqi 1995, p. 8).

Smallpox Eradication: A WHO Success

WHO played a lead role in one of the more dramatic medical victories of modern times: the worldwide elimination of smallpox. The organization announced its smallpox campaign in 1966 and was able to declare victory in 1979, at a cost of about $313 million. WHO acted as a clearinghouse for strategy, knowledge, and vaccine and coordinated a worldwide volunteer effort. To date smallpox is the only infectious disease that WHO or any other organization has succeeded in eradicating. Unlike malaria, one of the most visible failures of WHO, smallpox was an easier target because it is transmitted from human to human with no animal vectors, has a low rate of transmission and develops slowly, is easy to diagnose, and is easy to contain with small doses of vaccine.

Malaria: A WHO Failure

In 1955 WHO announced the ambitious goal of worldwide elimination of malaria; by 1960, sixty-five countries and territories had antimalarial programs. Those programs relied primarily on spraying the walls of houses with DDT. In 1966 WHO announced that 813 million people, 52 percent of the at-risk population, had been insulated from the disease. From 1959 to 1966 almost 11 percent of the organization's annual budget was devoted to the malaria campaign. However, things began to backslide soon afterward as malaria cases began to increase in some countries; for example, Pakistan, which had only 9,500 cases in 1968, had 10 million in 1974 (Siddiqi 1995).

By 1969 WHO recognized that the eradication program had failed. Many mosquitoes lived, bred, and bit their victims far away from the house walls that were being sprayed; some forms of shelter did not have walls; some species were becoming resistant to DDT or otherwise had changed their behavior; WHO had failed to account for population migratory patterns; and many countries did not have the infrastructure necessary to support the program. In 1969 WHO acknowledged that the eradication program did not "adequately take into account economic and social factors" in malaria-ridden countries (Siddiqi 1995, p. 163). Subsequently, WHO changed its focus from eradication to control of malaria. The disease continues to be the world's most lethal parasite-borne ailment and the second most important killer after tuberculosis in more than 190 countries inhabited by 40 percent of the world's population (Beigbeder 1998).

Despite its failure to conquer malaria, WHO has continued to attempt the worldwide eradication of infectious diseases. It vowed to eliminate polio by 2005. However, the September 11, 2001, attacks and the perceived intentions of al Qaeda to use any biological weapon available to attack the West led to renewed consideration of whether disease eradication will ever be possible (Roberts 2004).

Infant Formula: A Controversial Initiative

In December 1969 WHO began to focus on the decline in breast-feeding in Third World countries, which it believed might have been attributable to the aggressive promotion of formula substitutes. Many highly political nongovernmental organizations (NGOs) had seized on this issue as an important one, symbolic of the continuing fallout from colonialism and the exploitation of the Third World by multinational companies. In October 1979 WHO and the United Nations International Children's Emergency Fund (UNICEF) cosponsored a conference that was attended by NGOs and the formula industry. WHO, which had accepted a mandate to mediate between the opposing sides, adopted a working document that appeared to the companies to adopt many NGO grievances without citing supporting data. This led to collisions with "important commercial interests" (Beigbeder 1998, p. 76). The conference resulted in no compromises, and the NGO-industry dialogue was discontinued. WHO and UNICEF pressed on, in 1981 adopting nonbinding recommendations to member states relating to the marketing of substitutes for breast milk.

During the formula debate WHO was seen by critics as intervening in an ideological debate without citing firm scientific evidence for the proposition that babies were being harmed or killed by the use of formula instead of breast milk. WHO also was accused by the industry of disregarding social and even medical factors that contributed to the use of formula, such as its use by women with inadequate production of breast milk (Beigbeder 1998).

The Normative Role of WHO

WHO has three different modes of action under its constitution: It can adopt conventions, make regulations, or issue nonbinding recommendations. Whereas the first two actions bind its members to act, the third does not.

In practice most of the work done by WHO has been an exercise of its nonbinding recommendation power. The organization has been extremely reluctant to exercise its normative powers to make binding international law or rules. This is partly attributable to the initial reluctance of the United States to ratify the WHO charter, fearing that its actions would dictate the passage of domestic legislation: "Clearly, WHO's more influential member states have no intention to convert the Organization into a World Ministry of Health, no more than they wish to create a world government" (Beigbeder 1998, p. 15). WHO has proposed a single convention on tobacco that was never adopted. Even its nonbinding recommendations are a "starkly limited tool" (Koplow 2003, p. 143). Some commentators believe that WHO's reluctance to exercise its normative powers is a product of "organizational culture established by the conservative medical professional community that dominates the institution" (Taylor 1992, p. 303). David Koplow has noted that the WHO "has no power to enforce compliance, to mandate any particular resolution of a dispute, or to impose sanctions upon recalcitrant states" (Koplow 2003, p. 145).

Organizational Effectiveness

The organization's executive director Halfdan Mahler asked in 1987 whether WHO was to be "merely a congregation of romanticists talking big and acting small" (Beigbeder 1998, p. 191). His successor, Hiroshi Nahajima, appointed in 1988, said that "in the past, we have tended to be rigid and doctrinaire, when, in fact, the utmost flexibility is called for" (Beigbeder 1998, p. 28).

In a 1991 report the Danish government evaluated the effectiveness of WHO programs in Kenya, Nepal, Sudan, and Thailand and found "weak analytical capacity," a lack of prioritization, and failure to delegate authority (Beigbeder 1998, p. 191). Member nations often lack the resources to pay for the measures recommended by WHO or do not have the infrastructure or commitment necessary to implement them.

In the early years of the twenty-first century WHO, like other UN agencies, experienced a struggle for dominance between its First World and Third World members. While the United States continued to pay 25 percent of the organization's budget, the WHO executive board, only 42 percent of whose members came from Third World nations in 1950, by that time had an overwhelming majority of Third World representation (68 percent) (Siddiqi 1995). The United States and its allies frequently exercised behind-the-scenes influence on the outcome of WHO deliberations in a way that contradicted the apparently democratic and majoritarian structure of the organization. For example, the United States and Russia, the holders of the last publicly known smallpox stocks, were able to set WHO policy on the destruction of those stocks.

Evaluation

When it concentrates on technical cooperation, WHO sometimes has been extremely effective, as it was in eliminating smallpox from the world. However, like its sister UN agencies it has expended a large proportion of its resources and credibility in political and ideological disputes that have detracted from its technical mission.

WORLD TRADE ORGANIZATION

The World Trade Organization (WTO) is the largest, most powerful international organization dealing with global rules of trade among nations. It was formed in 1995 following the so-called Uruguay Round of negotiations under the General Agreement on Tariffs and Trade (GATT), the previous multilateral trading system established in 1948. Whereas GATT was primarily concerned with trade in goods, the WTO covers trade in goods and services, banking and finance, intellectual property, dispute settlement, and trade policy reviews. The purpose of the WTO is to provide a negotiating forum for nations to form agreements to lower trade barriers to ensure that trade flows as freely, fairly, and predictably as possible. The WTO regulates trade by administering and negotiating trade agreements, resolving trade disputes, reviewing national trade policies, providing technical assistance and training programs in developing nations, and cooperating with other international organizations. All WTO trade agreements are the result of a consensus among representatives of member governments, ratified by the parliaments of the participating nations. These binding agreements guarantee nations their trade rights and responsibilities. For the 147 member nations, the WTO is the most influential institution of international commerce.

WTO Agreements and Organization

Under WTO agreements, countries should neither discriminate among their trading partners nor should they discriminate between foreign and domestic products and services. Every government should be given "most-favored-nation" status whereby any favor granted to one nation must be granted to every other nation, thus ensuring that all trade partners be treated equally. The WTO aims to make trade more free and more fair by lowering trade barriers such as customs duties (tariffs), eliminating import bans or quotas, and limiting the nontariff trade barriers that nations may implement and enforce, such as domestic laws regulating product standards and liability, environmental protections, use of tax revenues for public services, and other domestic laws regulating investment and trade. The WTO limits the nature of tariffs a nation may impose, as well as what kind of nontariff barriers to trade nations may implement and enforce. Through the WTO Dispute Settlement Process, nations can challenge each other's laws on behalf of their commercial interests if they believe barriers to trade exist. If member nations do not conform to WTO regulations they face possible economic sanctions.

Six main agreements comprise the WTO: the umbrella agreement establishing the WTO, the General Agreement on Tariffs and Trade, the General Agreement on Trade in Services (GATS), and the agreements on Trade-Related Aspects of Intellectual Property (TRIPS), Dispute Settlement, and Trade Policy Reviews. The highest authority is the Ministerial Conference, where delegates from member nations meet every two years to reach consensus on multilateral agreements. The second level of authority, responsible for decisions between Ministerial Conferences, has three branches: the Dispute Settlement Body, the Trade Policy Review Body, and the General Council. The General Council is divided into three more councils, each handling a different area of trade: the Goods Council, the Services Council, and the TRIPS Council. Numerous specialized committees and working groups work on the details of individual agreements, as well as issues relating to the environment, development, finance, and regional trade agreements. The WTO Secretariat is based in Geneva, Switzerland, headed by a director-general with limited authority. The Secretariat's main duties include providing legal and technical support to the various councils and ministerial conferences, conducting research, and performing public affairs activities.

Relation to Science and Technology

Many WTO agreements affect the science and technology laws and practices of member nations. One example is the Sanitary and Phytosanitary Measures Agreement (SPS), which sets food safety and animal and plant health standards, including quarantine, inspection, and testing requirements. The aim of the SPS agreement is to establish standards based on accepted science to allow countries to set reasonable health and safety regulations but only to the extent necessary to protect human, plant, or animal life or health. The SPS agreement prevents countries from using higher sanitary and phytosanitary measures in order to protect domestic producers. WTO members can challenge each other's food health and plant and animal safety regulations if they exceed mandated limits.

The Agreement on Technical Barriers to Trade (TBT) ensures that product standards, regulations, testing, and certification for all goods, including industrial and agricultural products, do not become obstacles to trade. The TBT agreement sets limits on the standards governments may enforce to achieve social, environmental, consumer, or public health objectives. The aim is to prevent technical regulations and industrial standards from being used for protectionism. The WTO recognizes the rights of nations to protect the environment and public welfare but not if standards give domestically produced goods an unfair advantage or so far exceed the standards of other nations that they become an obstacle to trade. The TBT agreement subjects national product standards and regulations to scrutiny under WTO Trade Policy Reviews and challenges in Dispute Settlement Court.

The Agreement on Trade-Related Aspects of Intellectual Property establishes the levels of protection governments have to give the intellectual property rights of other governments. The agreement covers copyright (including computer programs, music recordings, and film), trademarks (signs and slogans), geographical indications (place-names that indicate where a product is from and what it is, such as champagne or tequila), industrial designs (for large-scale technologies), patents (protecting products and processes lasting for twenty years), trade secrets (and other undisclosed information with commercial value), and integrated circuit layout designs. TRIPS extends intellectual property rights to include pharmaceuticals, plant varieties, human and plant cell lines, microorganisms, and genes. The agreement defines what counts as intellectual property, how governments should enforce rights, and how to settle disputes over rights between member nations.

Criticisms of the WTO

The WTO has been dogged by controversy from its inception. It continues to be on the defensive against criticism that its agreements privilege corporate interest goals over public interest goals. Critics maintain that the WTO illegitimately dictates the policies of sovereign nations, promotes free trade at any cost, and gives commercial interests priority over development, the environment, health, safety, and worker rights. They further claim that it eliminates both job security and food security, favors developed nations over underdeveloped nations, and fosters a dispute resolution process that is undemocratic and unaccountable. The WTO maintains that through lowering import tariffs and "harmonizing" the international rules of commerce trade should become more predictable, more competitive, and more beneficial for all nations, especially less-developed nations.

Z

ZAMYATIN, YEVGENY IVANOVICH

Yevgeny Ivanovich Zamyatin (1884–1937), who was born in Lebedyan, Tamov district, Russia on February 1, is best known for having written *We* (1920), the archetypal anti-utopian novel. The son of a Russian Orthodox priest and a mother who had received a liberal education, he was a constant critic, siding with the Bolsheviks before the revolution and chiding the new government after their victory.

Zamyatin's critical posture was not limited to Russia. Although he was a naval architect by training, when he was in Great Britain (1916–1917) to supervise the building of Russian icebreakers, he published *The Islanders*, a satire of the English. Over the course of his career Zamyatin wrote about forty books, a few of which were quite influential in their time, but he is remembered primarily for one he could not publish. When the Soviets began to censor literature in 1922, the first manuscript banned was *We*, which then appeared in English in the United States (1924) and in Russian in Prague (1927). After 1929 Zamyatin could not publish at all at home. In 1931 at Zamyatin's request, Stalin allowed him to emigrate to Paris, where he lived, unsupported by the local Russian community, until his impoverished death on March 10.

We is the forty-record journal of D-503, an engineer supervising the building of *The Integral*, a spaceship intended to impose the philosophy of the totalitarian One State on other planets: "If they will not understand that we are bringing them a mathematically faultless happiness, our duty will be to force them to be happy" (p. 3). The fundamental contradiction between mechanism and individualism defines the novel. People are "Numbers": The higher the number, the higher the rank; there are vowels and even numbers for females, consonants and odd numbers for males. The "Lex Sexualis" states, "A Number may obtain a license to use any other Number as a sexual product" (p. 22)

Everyone lives according to a Table of Hours. All residences are made of glass. Curtains may be drawn only during Sexual Hours. Despite his role and self-conscious desire to be a good citizen, D-503 develops a soul. The first, unexamined symptom is his desire to express himself, to write the book that is before the reader. The second is a complex passion he feels for I-330, a bold woman revealed as a revolutionary who is trying to use D-503 to gain control of *The Integral* but also may have fallen in love with him.

The development of his soul subtly changes D-503's viewpoint: "As I crossed the avenue, I turned around. Here and there in the huge mass of glass penetrated by sunshine there were grayish-blue squares, opaque squares of lowered curtains, the squares of rhythmic, Taylorized happiness" (p. 41). The reference to Frederick Winslow Taylor (1856–1915), the inventor of time-motion studies and "industrial engineering," Zamyatin's high priest of dehumanizing technology, suggests why D-503 says, "Love = f(D), love is the function of death" (p. 127).

I-330 does seduce D-503, but an assistant prevents a takeover of the ship. I-330 is killed publicly, and D-503, like every other citizen of One State, undergoes a new procedure to remove the imagination, after which he concludes, with horrible happiness, "Reason must prevail" (p. 218).

Perhaps it must. In 1988, under glasnost, when the Soviet Union began to "rehabilitate" banned literature, *We* was on the very first list.

The fundamental contradiction between mechanism and individualism that Zamyatin explored has resonated ever since in discussions of science, technology, and ethics. As societies, by adopting modern science and technologies, have come to possess increasingly potent tools for individual action, those tools often have resulted in the conscious imposition or spontaneous emergence of machinelike social orders. For good and bad, after all, railroads make people run on time. This dilemma echoes through powerful and popular works ranging from Edgar Rice's play *The Adding Machine* (1923) to monitory novels such as Aldous Huxley's *Brave New World* (1932), Ayn Rand's *Anthem* (1938), George Orwell's *Nineteen Eighty-Four* (1948), and William Gibson's *Neuromancer* (1984) as well as potent sociological analyses such as Jacques Ellul's *The Technological Society* (1964) and touchstone movies such as *Blade Runner* (1982).

ZOOS

Evidence suggests that humans first domesticated animals beginning about 10,000 B.C.E., but collecting wild and exotic animals did not begin until about 3,000 B.C.E. During the next few millennia, gardens, animal collections, parks, and animal reserves grew in numbers and range. But it was not until the development of the nation-state in the sixteenth century that organized menageries, zoos, and aquaria emerged and proliferated (Kisling Jr. 2001). In the early twenty-first century visiting zoos is one of the most popular activities in many countries, yet keeping animals in zoos—particularly large mammals such as elephants and whales—raises important ethical questions that pit the interests of science and conservation against those of animal rights.

History

The first recorded examples of animal collections were found in the great civilizations of Mesopotamia, such as Assyria, Sumeria, and Babylon. Animal collections were the privilege of the wealthiest people, usually royalty, who could afford to capture or purchase, and maintain, exotic animals. Early collections often included falcons, deer, exotic birds, fish, gazelle, apes, monkeys, ostriches, lions, and elephants. Falcons and lions were often used in royal sport for hunting and fighting, and some parks and preserves were created for this very purpose (Kisling Jr. 2001). Animal collections, gardens and parks also existed in ancient Egypt, Asia, India, Greece, North and South America, and later in Europe, but continued to be a hobby enjoyed primarily by royalty.

In medieval Europe, animal collectors grew in number to include monasteries and municipalities, although collecting was still an expensive practice. As these collections grew in size during the Renaissance, particularly with the addition of exotic animals captured in the new world, they were referred to as menageries. With the onset of the industrial revolution, more people had extra spending money and leisure time in which to indulge in various interests, including the financial support of menageries. In the late-eighteenth and early-nineteenth centuries, private collections evolved into publicly supported menageries (Kisling Jr. 2001). The shift from menagerie to *zoological garden*, or simply zoo, also occurred in the early-nineteenth century. In 1825 the Zoological Society of London suggested creating a zoological garden in which living animals with "their nature, properties and habits may be studied" (Kisling Jr. 2001, p 37), indicating a shift to a more scientifically grounded purpose in collecting animals.

Human knowledge of animal husbandry has improved significantly since the mid-1800s. In early zoos it was not uncommon to see animals kept in small cages with dirt or concrete floors and in generally poor conditions. Twenty-first century zoos are more sensitive to the needs of the animals, and many animals are housed in naturalistic habitats that simulate the animal's original ecosystem. Zookeepers also recognize the importance of mentally stimulating larger mammals through various enrichment activities in order to keep them alert and healthy. Large animal parks in which animals roam freely have also become increasingly popular.

Ethical Issues

Proponents of keeping animals in zoos claim that there is much to be gained in terms of science, conservation, and even the long term welfare of the animals themselves. In some zoos, extensive research is undertaken in the fields of zoology, biology, animal behavior, and veterinary medicine, providing valuable information that is useful in a variety of milieus (Bostock 1993). Many endangered species are bred through intricately designed captive breeding programs, in accordance with species survival plans to ensure the genetic diversity, and thus survivability, of the species. The successful captive breeding program of the highly endangered California condor by the San Diego Zoo produced enough animals that many were released back into the wild. Some zoos have also evolved from simple purveyors of facts about individual animals into educators, describing the ecosystems, environmental concerns, and policy issues surrounding the animal, thus attempting to provide a more complete learning experience to the public. Indeed up until the recent proliferation of cable TV programs dedicated to animals, visiting the zoo was often the public's first exposure to, and education about, exotic animals and related conservation issues. Educating the public, many supporters believe, is crucial for raising awareness of critical conservation and preservation issues. Finally proponents point to the fact that many zoo animals live longer in captivity than their wild counterparts, suggesting that zoos are actually beneficial to the animals themselves (Bostock 1993).

Opponents of zoos contest the claims that the animals are well-treated. Despite significant improvements in zoo-keeping practices, many zoos around the world still display animals in small cages and in sterile environments. Even in the United States, many animals are not provided the minimum standards required by the American Zoo and Aquarium Association (AZA). According to the Humane Society of the United States, only about 10 percent of more than 2,000 animal exhibitors licensed by the U.S. Department of Agriculture (USDA) are approved by the AZA, which has high standards for animal care. Opponents also doubt the legitimacy of scientific research, suggesting that such research is in fact not that common, and that most is geared solely toward the management of captive animals and cannot be extrapolated to wild populations (Hancocks 2001). Questions also arise concerning conservation efforts in zoos. For example, is the purpose of conservation to preserve genes, individual animals, entire populations, or ecosystems? And which species should be selected for captive breeding programs? Still others argue that there is much to be done in terms of educating the public, in that zoos tend to perpetuate an overly simplistic, dominionistic, if not positivistic, view of the natural world. The result is that zoos tend to ignore smaller yet more populous animals in favor of charismatic megafauna that most visitors find more interesting (Hancocks 2001).

Philosopher Dale Jamieson, in his now famous, and controversial, essay, "Against Zoos," argues that even if there are some benefits to zoos, there is an overwhelming ethical reason for not having them, namely the rights inherent in each animal to live freely and to develop its own potential. Furthermore he contends that capturing wild animals for the hungry zoo market often leads to the death of many other animals, often the mothers or adult males who protect the young. While zoo supporter Stephen Bostock agrees that capturing wild animals is one of zoo keeping's weaknesses, even calling for a ban on the trading and capturing of wild animals, he disagrees with the notion that only wild animals can live freely. Freedom, he suggests, describes an environment in which most of the animals' needs are cared for, and well-managed zoos can do just that.

As a result of the continued professionalization of zoos and zoo keeping, several international associations have developed codes of ethics by which member zoos must abide. Ethical standards focus on everything from minimum standards of animal care, responsibility to the animals, species survival plans, commitment to biodiversity and conservation efforts, and professional conduct. Member zoos found in violation of ethical standards face sanctions or dismissal from the association. Many ethical discussions regarding zoos will likely continue, but some claim that debating whether or not zoos should exist at all is one that should end. David Hancocks explains that zoos are here to stay, and that human energy should focus on how to improve them, and to develop a new relationship with animals and nature (2001).

APPENDIX CONTENTS

The *Encyclopedia of Science, Technology, and Ethics* includes five appendices designed to provide supporting materials for individual articles and further resources for readers.

APPENDIX I

SELECTIVE, ANNOTATED, GENERAL BIBLIOGRAPHY ON SCIENCE, TECHNOLOGY, AND ETHICS

This selected bibliography emphasizes works in English and in print during the early 2000s that are also accessible to the generally educated reader. The goal is to provide an introduction to some of the most useful efforts to lay out arguments relevant to science, technology, and ethics. Arguments may focus on science and technology as a whole or on some specific aspect of the science, technology, and ethics interaction.

The bibliography is divided into six sections:

1. Reference Works
2. Monographs and Edited Volumes: General Implications
3. Monographs and Edited Volumes: Specialized Approaches
4. Textbooks
5. Twentieth and Twenty-First Century Ethics
6. Journals

Reference works are alphabetized by title, and include a few items of marginal value, if only to steer readers away from some materials that might otherwise attract attention. Monographs and edited volumes are divided into those of a general orientation and those focused more on specific sciences or technologies. Some specific approaches that nevertheless have broader implications as well as textbooks that transcend the genre are included in the section on general monographs. This section thus constitutes the core resources in the bibliography. Supplementing these core sections is another of selected works on ethics that indicate the background traditions of reflection brought to bear on science and technology from the early twentieth century.

Like reference works, journals are alphabetized by title. All other works are alphabetized by author or editor. Multiple works by the same author are arranged chronologically by date of publication.

1. Reference Works

Applied Ethics: Critical Concepts in Philosophy. Ruth Chadwick and Doris Schroeder, eds. 6 vols. London: Routledge, 2002. Vol. 1 deals with the nature and scope of applied ethics. Vols. 2 and 3 focus on ethical issues in medicine, technology, and the life sciences. Vol. 4 is dedicated to environmental issues. Vol. 5 is on business and economics. Vol. 6 is on politics. Collects and reprints a large number of influential articles from the last half of the twentieth century. Each volume includes an introduction summarizing the historical context and trends.

The Blackwell Guide to the Philosophy of Computing and Information. Luciano Floridi, ed. Malden, MA: Blackwell, 2004. Twenty-six articles. Most directly relevant are those on "Computer Ethics," "Computer-mediated Communication and Human-Computer Interaction," "Internet Culture," "The Philosophy of AI and Its Critique," "Virtual Reality," and "Philosophy of Information Technology."

A *Companion to Environmental Philosophy*. Dale Jamieson, ed. Oxford: Blackwell Publishers, 2003. Pp. xvi, 531. Collects a preface and thirty-six essays arranged in four parts: cultural traditions, contemporary environmental ethics, environmental philosophy and its neighbors (e.g., literature, aesthetics, history, ecology, politics, and law), and problems in environmental philosophy.

A Companion to Ethics. Peter Singer, ed. Cambridge, MA: Blackwell, 1991. Pp. xxii, 565. Forty-seven chapters highlighting origins of ethics, major traditions, the Western philosophical tradition, basic theories of obligation, applied ethics (poverty, environmentalism, euthanasia, abortion, sex, personal relationships, equality, animals, business, crime and punishment, politics, and war), arguments concerning the nature of ethics (realism, intuitionism, naturalism, etc.), and challenges (feminism, evolution, Marxism, etc.). Although neither "science" nor "technology" appear in either the table of contents or the index, this provides useful background material for discussions in science, technology, and ethics.

A Companion to Genethics. Justine Burley and John Harris, eds. Oxford: Blackwell, 2002. A comprehensive look at the philosophical, ethical, social and political dimensions of developments in human genetics.

The Concise Encyclopedia of the Ethics of New Technologies. Ruth Chadwick, ed. San Diego: Academic Press, 2001. A selective examination of several contemporary technologies and the ethical dilemmas they present along with examples of frameworks for their assessment like environmental impact statements and different ethical theories. Arranged as 37 articles each with an outline, glossary, defining statement, and bibliography. A repackaging of selected articles from the 4-vol. *Encyclopedia of Applied Ethics*.

Encyclopedia of Applied Ethics. Ruth Chadwick, ed. 4 vols. San Diego: Academic Press, 1998. A major synthetic and informative reference work. Two hundred eighty one articles (averaging 5000 to 10,000 words) covering theories, concepts, and ethics related to medicine, science, the environment, law, education, politics, business, the media, social services, and social interactions. Two relevant spin-off collections are *The Concise Encyclopedia of the Ethics of New Technologies* (2001) and *The Concise Encyclopedia of Ethics in Politics and the Media* (2001).

Encyclopedia of Bioethics. Warren Reich, ed. First edition, 4 vols. New York: Macmillan Reference, 1978. Second edition, 5 vols. New York: Macmillan Reference, 1995. Third edition, 5 vols., Stephen G. Post, ed. New York: Macmillan, 2004. A model of scholarship and influence.

Encyclopedia of Ethical, Legal, and Policy Issues in Biotechnology. Thomas H. Murray and Maxwell J. Mehlman, eds. 2 vols. New York: John Wiley, 2000.

Encyclopedia of Ethics in Science and Technology. Nigel Barber. New York: Facts on File, 2002. A one-person product. Slightly better than Newton's *Social Issues* volume below, but similar.

Encyclopedia of Twentieth-Century Technology. Colin A. Hempstead, ed. 2 vols. New York: Routledge. Approximately 400 articles by about 175 authors. The focus is on technical descriptions, but there are a few articles on "Technology and Ethics" and related topics.

The Facts on File Encyclopedia of Science, Technology, and Society. Rudi Volti, ed. 3 vols. New York: Facts on File, 1999. Approximately 900 well crafted articles by 95 contributors, the majority of whom are historians of science and technology. Although the preface describes the focus as society as much as science or technology, the work is better or technical than social dimensions. There are no articles, for instance, on ethics, which is not even an indexed term.

Handbook of Science and Technology Studies. Jasanoff, Sheila, Gerald E. Markle, James C. Petersen, and Trevor Pinch, eds. Thousand Oaks, CA: Sage, 2004.

Science, Technology, and Society: An Encyclopedia. Sal Restivo, ed. New York: Oxford University Press, 2005.

Social Issues in Science and Technology: An Encyclopedia. David E. Newton. Santa Barbara, CA: ABC-CLIO, 1999. Approximately 350 entries, mostly 500–1000 words each. A one-person product of relatively high quality. Paperback version titled *From Global Warming to Dolly the Sheep: An Encyclopedia of Social Issues in Science and Technology*.

2. Monographs and Edited Volumes: General

Alcon, Paul A. *Practical Ethics for a Technological World*. Upper Saddle River, NJ: Prentice Hall, 2001. Pp. xiv, 239. Aims to be a guide to ethical decision making in the technological world; works back and forth to explore ethics and technology and their mutual interactions. Naive and weakly spiritual in orientation.

Allen, Anita L. *The New Ethics: A Guided Tour of the Twenty-First Century Moral Landscape*. New York: Miramax Books, 2004. Pp. xxxviii, 322. Overviews the contemporary ethical landscape focusing on widespread unethical behavior (e.g., lying, cheating, and corruption), new moral challenges presented by science, technology, and medicine, and complacency and apathy. Discusses ways to improve ethical behavior at work and in education. Concludes with sections on choosing well (e.g., consumption, family, and dying) and justice in multi-cultural societies.

Barbour, Ian. *Ethics in an Age of Technology*. San Francisco: Harper, 1993. Pp. xix, 312. An extended analysis of divergent ethical views of technology focusing on the values of justice, participation, and development. Considers case studies in agriculture, energy, genetic engineering, and computers. Argues in defense of environmental sustainability, appropriate technologies, and personal responsibility for promoting progressive change through education, political action, and the pursuit of alternative visions of the good life.

Barbour, Ian. *Religion and Science: Historical and Contemporary Issues*. San Francisco: Harper, 1997. Pp. xv, 368. This is a revised and expanded edition of *Religion in an Age of Science* (1990). Gives a broad overview of historical interactions between religion and science, and develops a typology of four ways of interacting: conflict, independence, dialogue, and integration. Defends dialogue and integration in both method and substantive forms of knowledge.

Bird, Stephanie, J., and Raymond Spier, eds. "The Role of Scientific Societies in Promoting Research Integrity." Theme issue, *Science and Engineering Ethics*, vol. 9, no. 2, April 2003. Pp. 158. Fourteen papers on the role professional scientific societies in promoting and implementing guidelines for research ethics. Includes examples, recommendations for further work, and strategies for evaluating existing programs.

Borgmann, Albert. *Holding On to Reality: The Nature of Information at the Turn of the Millennium*. Chicago, IL: The University of Chicago Press, 1999. Pp. 274. Explores, philosophically and historically, the relationship between things and signs, or reality and information, especially the rise of information as reality. Articulates and advocates a theoretical and ethical balance of signs and things that holds onto reality by averting a slide into hyperreality.

Borgmann, Albert. *Technology and the Character of Contemporary Life: A Philosophical Inquiry*. Chicago: University of Chicago Press, 1984. Borgmann's most general argument for a distinction between technological devices and focal things, each of which influences the development of different patterns of human behavior.

Borgmann, Albert. *Crossing the Postmodern Divide*. Chicago: University of Chicago Press, 1992. Pp. 173. A lucid and concise description of deep contemporary cultural challenges that traces them back to foundational thinkers in modern Western philosophy (e.g., Descartes) and presents a way forward that avoids the dehumanizing extremes of "hyperreality."

Buchanan, Richard, and Margolin, Victor eds. *Discovering Design: Explorations in Design Studies*. Chicago: University of Chicago Press, 1995. Pp. xxvi, 254. Includes the article "Prometheus of the Everyday: The Ecology of the Artificial and the Designer's Responsibility" by Ezio Manzini.

Callahan, Daniel. *The Tyranny of Survival: And Other Pathologies of Civilized Life*. New York, NY: Macmillan, 1973. Pp. xv, 284. Reprinted, University Press of America, 1985. Argues for a more realistic and sustainable aspiration than the quest for endless technological progress and unbounded individual freedom. Uses population growth and genetic technologies to illuminate technological change and argue for limiting technological excess and cultural hubris.

Callahan, Daniel. *What Kind of Life: The Limits of Medical Progress*. New York: Simon and Schuster, 1990. Pp. 318. Takes a synoptic view and argues that deep premises about health, illness, and life are fundamentally flawed and lead to insatiable expectations for healthier, longer lives that cannot be satisfied and that drive under-performing and increasingly expensive health care systems. Offers a new way to think of health that could help devise a more reasonable and just health care system that balances worthy aspirations with necessary limits.

Callahan, Daniel. *Setting Limits: Medical Goals in an Aging Society*. Washington, D.C.: Georgetown University Press, 1995. Pp. 272. Explores the shadows of medical progress and the attendant new ways of thinking about health, life, and aging (e.g., old age is to be overcome with the use of science and technology). Addresses such questions as the proper ends of medicine, what the young owe the old, the allocation of resources to the elderly, and care of the elderly dying. Seeks to stimulate a discussion on the future of health care for the aged and proposes a different way of understanding this issue. Concludes with responses to critics.

Callahan, Daniel. *The Troubled Dream of Life: In Search of a Peaceful Death*. Washington, D.C.: Georgetown University Press, 2000. Pp. 255. Integrates legal and policy issues of death and dying with deep philosophical questions about the meaning of death and its relation to self. Argues that many problems in the care of the dying, both in public attitudes and medical progress stem from mistaken views of death. Seeks to foster a common view of death by treating foundational issues rather than specific law or policy questions.

Callahan, Daniel. *What Price Better Health? Hazards of the Research Imperative*. Berkeley: University of California Press, 2003. Pp. xii, 329. Centered on the concept of the research imperative in medicine, which is a complex topic that refers to the inherent momentum of research and the view that the importance of research could trump moral values. Argues it is primarily a cultural (as opposed to a property inherent in the research community) problem that fuels most of the "shadows" or hazards of medical research. Chapters consider several issues including research as a moral obligation, enhancement, risks and benefits, human subjects research, and a distinction between doing good and doing well.

Collins, Harry, and Trevor Pinch. *The Golem: What You Should Know about Science*. 2nd ed. New York: Cambridge University Press, 1998. Pp. xix, 192. Directed to a general audience. Argues that science is akin to a clumsy and dangerous yet potentially helpful creature. Presents the actual workings of science to show that the authorization of knowledge claims is a political, complex, and messy process of persuasion that produces many controversies. Includes a description of the "experimenter's regress." Collects an introduction, conclusion, and seven case studies on the production and negotiation of new scientific knowledge, including experiments on relativity, the chemical transfer of memory, and solar neutrinos.

Collins, Harry, and Trevor Pinch. *The Golem At Large: What You Should Know About Technology*. New York: Cambridge University Press. 1998. Pp. xi, 163. Continues the social constructivist argument applied to technology.

Committee on Science, Engineering, and Public Policy (US). Panel on Scientific Responsibility and the Conduct of Research. *Responsible Science: Ensuring the Integrity of the Research Process*. 2 vols. Washington D.C.: National Academy Press, 1992 and 1993. Pp. xxiii, 199 (each vol.). Authorized by the National Research Council (whose members are drawn from the councils of the National Academy of Sciences, the National Academy of Engineering, and the Institute of Medicine). Reviews factors affecting the integrity of science and the research process in the US and institutional mechanisms for addressing allegations of misconduct. Recommends steps for reinforcing responsible research practices.

Ellul, Jacques. *The Technological Society*. Trans. John Wilkinson. New York: Knopf, 1964. Pp. xxxvi, 449, xiv. A classic examination of the social and moral consequences of the domination of "technique," or the totality of methods driven by the urge to absolute efficiency. Provides an historical overview and analyses of technique and the economy and state. Features a chapter titled "The Characterology of Technique," which argues that modern technique is fundamentally new due to its pervasiveness, connection to modern science, large scale, "automatism," and "self-augmentation."

Federman, Daniel, Kathi E. Hanna, and Laura Lyman Rodriguez, eds. *Responsible Research: A Systems Approach to Protecting Research Participants*. Washington, DC: National Academies Press, 2002. Pp. xix, 290. An Institute of Medicine report commissioned by the Secretary of the Department of Health that offers a comprehensive review of the present system for protecting human participants and suggestions for strengthening it. Recommends gathering data and taking a diversity of approaches to maximize the protection of individuals participating in research. Emphasizes a systematic approach and the importance of institutional cultures, training, improved informed consent, and improved research review procedures.

Feenberg, Andrew. *Critical Theory of Technology*. New York: Oxford University Press, 1991. Pp. xi, 235. Updates critical social theory for a high-tech world.

Feenberg, Andrew. *Alternative Modernity: The Technical Turn in Philosophy and Social Theory*. Berkeley: University of California Press, 1995. Pp. xi, 251.

Feenberg, Andrew. *Questioning Technology*. New York, NY: Routledge, 1999. Pp. xvii, 243. A philosophy of technology that critiques essentialism and shows the centrality of technological design to modern society and democratic politics. Proceeds in three parts: the politicizing of technology, democratic rationalization, and technology and modernity.

Feenberg, Andrew, and Alastair Hannay, eds. *Technology and the Politics of Knowledge*. Bloomington: Indiana University Press, 1995. Collects 16 articles by Steven Vogel, Robert B. Pippin, Langdon Winner, Albert Borgmann, Hubert L. Dreyfus, Terry Winograd, Tom Rockmore, Don Ihde, Yaron Ezrahi, Donna Haraway, Helen Longino, Marcel Hénaff, Pieter Tijmes, Paul Dumouchel, and Bruno Latour.

Florman, Samuel C. *The Existential Pleasures of Engineering*. 2nd ed. New York, NY: St. Martin's Press, 1994 (1st edition, 1976). Pp. xviii, 205. Inquires into the nature of the contemporary engineering experience. Views it as vital and alive, something to be celebrated as a response to deep human impulses, and as a source of sensual and spiritual reward.

Fox, Warwick, ed. *Ethics and the Built Environment*. London: Routledge, 2000. Pp. xv, 240. Seeks a critical mass of ideas to initiate a field of study to rectify envir-

onmental ethics traditional disregard of the built environment. Collects seventeen essays arranged into three sections: the green imperative, building with greater sensitivity to people and places, and toward a theory of ethics of the built environment.

Fukuyama, Francis. *Our Posthuman Future: Consequences of the Biotechnology Revolution*. New York: Farrar, Straus, and Giroux, 2002. Pp. xiii, 256. Examines the some techniques and ethical issues, develops an understanding of natural human rights, and concludes with comments on the regulation of biotechnology and recommended policies for the future. Creates a taxonomy of concerns and argues that the greatest reasons to worry about biotechnology are not utilitarian but that the human essence will somehow be lost. Argues for greater political control over the uses of science and technology.

Fuller, Steve. *The Governance of Science: Ideology and the Future of the Open Society*. Buckingham, PA: Open University Press, 2000. Pp. xii, 167. Rejects communitarian and liberal ideologies of science in favor of a republican approach centered on the right to be wrong. Argues that the scaling up of science threatens this ideal and focuses on the challenges of multiculturalism and capitalism for the university as a republic of science. Proposes a new social contract for science.

Goujon, P., and Bertrand Heriard Dubreuil, eds. *Technology and Ethics: A European Quest for Responsible Engineering*. Leuven, Belgium: Peeters, 2001. Pp. xx, 616. Collects 37 essays in three sections as part of the core materials project for the development of courses in professional ethics, in order to serve as a European engineering ethics handbook. The three main sections consider the ethics of industrial engineers, institutional responsibility, and the social and political policy implications. Includes contributions by humanists, social scientists, and engineers.

Guston, David H. *Between Politics and Science: Assuring the Integrity and Productivity of Research*. New York, NY: Cambridge University Press, 2000. Pp. xvii, 213. Examines the deterioration of the post-World War II assumption in U.S. science policy that integrity and productivity were the automatic products of unfettered scientific inquiry. Shows how "boundary organizations" have developed since the 1980s to rebuild and maintain trust between politics and science. Shows the attention to detail necessary for designing such institutions to be effective.

Habermas, Jürgen. *Technik und Wissenschaft als ''Ideologie.''* [Technology and Science as "Ideology"]. Frankfurt am Main: Suhrkamp, 1968. Pp. 169.

Habermas, Jürgen. *The Future of Human Nature*. Oxford: Polity Press, 2003. Pp. 127, viii. Asks if there are post-metaphysical answers to the question: what is the good life? Expands this question beyond personal ethics to the questions of a species ethic posed by genetic technologies where a novel kind of self transformation poses the dilemma that the "ethical understanding of language-using agents is at stake *in its entirety*." Concludes with a postscript and a reflection on faith and knowledge.

Harris, Charles E., Michael S. Pritchard, and Michael J. Rabins. *Engineering Ethics: Concepts and Cases*. 3rd ed. Belmont, CA: Wadsworth, 2005. Pp. xvii, 390. (1st ed., 1995). Analyzes the field of engineering ethics through ethical problem-solving strategies, generic topics of concern such as responsibility, honesty, and risk, and special topics such as professional societies, the environment, and international engineering contexts. Designed for classroom use, it includes case studies and an interactive CD-ROM.

Heidegger, Martin. *The Question Concerning Technology and Other Essays*. Trans. William Lovitt. New York: Harper and Row, 1977. Pp. xi, 182. A classic work in the philosophy of technology, argues that modern technology is more than merely instrumental means to ends, but rather it is a "challenging revealing" that hides Being and presents the world as a standing reserve of objects ready to hand. An ontological account of technology's fundamental impact on human experience.

Hickman, Larry A. *Philosophical Tools for Technological Culture: Putting Pragmatism to Work*. Bloomington: Indiana University Press, 2001. Pp. xi, 215. Argues that philosophy has a productive role to play as reformer and critic of technological culture between post-modern decontstructionism and the ancient practice of grand system building. Draws inspiration from John Dewey to develop a kind of philosophy called "productive pragmatism." Takes up several issues including education, expertise, art, community, and responsibility.

Hughes, Thomas P. *Human-Built World: How to Think About Technology and Culture*. Chicago: University of Chicago Press, 2004. Pp. xii, 223. An extended bibliographic essay on the history of technology and its various interpretations across time. Draws primarily from literature, art, and architecture to trace the transformation in meanings of technology from the second creation to machine to systems, controls, and information, to culture. Concludes with comments on creating an ecotechnology.

Ihde, Don. *Technology and Lifeworld: From Garden to Earth*. A phenomenological analysis of human-technology relations that suggests the emergence of a new kind of ethical relationship between humans and the world.

Institute of Medicine National Research Council. *Integrity in Scientific Research: Creating an Environment that Promotes Responsible Conduct*. Washington, DC: The National Academies Press, 2002. Pp. xiv, 202. A report issued by the Institute of Medicine Committee on Assessing Integrity in Research Environments that defines the desired outcomes in research integrity and the teaching of research ethics and provides a set of initiatives to enhance integrity in research. Also considers methods for assessing those initiatives.

Johnson, Deborah G., ed. *Ethical Issues in Engineering*. Englewood Cliffs, NJ: Prentice Hall, 1991. Pp. viii, 392. Collects 32 articles providing historical and social context of engineering ethics, analyses of professional codes, and discussions of responsibilities to society, company loyalty, and obligations to clients.

Johnson, Deborah G. *Computer Ethics*. 3rd ed. Upper Saddle River, NJ: Prentice-Hall, 2001. Pp. xvi, 240. (1st ed. 1985; 2nd ed. 1994). Articulates the field of computer ethics with a focus on the core issues of professional ethics, privacy, property, accountability, and social implications and values. Includes two chapters on ethics and the internet. Each chapter includes short case studies, analysis, study questions, and suggested readings.

Jonas, Hans. *The Imperative of Responsibility: In Search of an Ethics for the Technological Age*. Trans. Hans Jonas and David Herr. Chicago: University of Chicago Press, 1984. Pp. xii, 255. (Originally published as *Das Prinzip Verantwortung: Versuch einer Ethik fuer die technologische Zivilisation*. Frankfurt am Main: Insel Verlag, 1979; and *Macht oder Ohnmacht der Subjektivitaet? Das Leib-Seele-Problem im Vorfeld des Prinzips Verantwortung*. Frankfurt am Main: Insel Verlag, 1981.) Rethinks the foundations of ethics in light of modern technology by developing a metaphysical theory of responsibility that takes account of the extended time and space horizons affected by technological action. Also introduces a philosophy of nature to bridge the chasm between "is" and "ought" and develops a "heuristics of fear" to counter the dangers of utopianism. Jonas' goal is to develop an ethics of responsibility capable of saving humanity from the excesses of its own Promethean power.

Jonas, Hans. *Mortality and Morality: A Search for the Good after Auschwitz*. Ed. Lawrence Vogel. Evanston, IL: Northwestern University Press, 1996. Pp. xi, 218. Considered the consummation of Jonas' quest to critique nihilism and develop an ethic capable of limiting the powers of modern technology. Jonas grounds an imperative of responsibility in the phenomenon of life and speculates on theology and faith after the Holocaust. Includes an introduction by Lawrence Vogel that provides philosophical and historical context.

Kass, Leon. *Life, Liberty, and the Defense of Dignity: The Challenge for Bioethics*. San Francisco: Encounter, 2002. Pp. 313. Argues that there is more to biotechnology than saving life and avoiding death, namely, the preservation of human dignity and human nature. Claims that this is a peculiar challenge for modern liberal democracies where the dangers lie close to cherished principles, especially individual freedom, equality, and social progress. Traces the root of the dangers to modern scientific, especially biological, thought.

Keulartz, Jozef, Michiel Korthals, Maartje Schermer, and Tsjalling Swierstra, eds. *Pragmatist Ethics for a Technological Culture*. Norwell, MA: Kluwer Academic Publishers, 2002. Pp. xxvi, 264. Argues that pragmatism can serve as a solid way to cope with questions of technology and human values. Includes twenty chapters arranged into prologue, epilogue, and sections on technology and ethics, the status of pragmatism, pragmatism and practices, and discourse ethics and deliberative democracy.

Kitcher, Philip. *Science, Truth, and Democracy*. Oxford: Oxford University Press, 2001. Pp. xiii, 219. Argues that epistemic values do not stand apart from or above other values and practical interests. This requires a new ideal of science beyond the neat separation of science from society. This ideal is labeled "well-ordered" science, which is set in a democratic framework that takes the proper notion of scientific significance to be that which would emerge from ideal deliberation among ideal agents. Then considers problems posed by lapses from the ideal and responsibilities of those who work on projects that conflict with the ideal.

Latour, Bruno. *Science in Action: How to Follow Scientists and Engineers through Society*. Cambridge, MA: Harvard University Press, 1987. Pp. 274. A classic anthropological study of the actual workings of science (rather than theoretical accounts of those workings or deference to a "black box" account) to understand how hypotheses become accepted facts. Emphasizes the importance of interpersonal interactions and rhetoric in both the literature and laboratory for the making of

science. Furthered the social construction of science movement begun by Thomas Kuhn.

Latour, Bruno. *Politics of Nature: How to Bring the Sciences into Democracy*. Cambridge, MA: Harvard University Press, 2004. Pp. x, 307. Argues for an end to the dichotomy between nature and society and offers a new conceptual context for understanding political ecology and its promise to advance democracy that accounts for humans and non-humans as citizens. Claims that our conception of science is important both for our understanding of nature and politics.

Lightman, Alan, Daniel Sarewitz, and Christina Desser, eds. *Living with the Genie: Essays on Technology and the Quest for Human Mastery*. Washington, DC: Island Press, 2003. Pp. viii, 347. Examines the contrast between the rapid pace of technological change and the enduring core of humanness within the overarching argument that science and technology are the result of decisions and are thus fundamentally about voice and the allocation of power in democratic societies and the global economy. Collects a general introduction and sixteen essays that address topics at the interface of values, science, and technology such as artificial intelligence, HVAC systems, disability, death, happiness, and property rights.

Lowrance, William W. *Modern Science and Human Values*. New York, NY: Oxford University Press, 1985. Pp. xiv, 250. Examines how technical progress and expertise influence and are influenced by other parts of society. Argues that a more nuanced understanding of science, technology, and values is necessary for more effectively putting science and technology into the service of society. Themes include facts and values, expertise, decision-making, and science and technology in the polis.

McKibben, Bill. *Enough: Staying Human in an Engineered Age*. New York: Times Books, 2003. Pp. xiii, 271. Argues that aggressively pursuing certain new technologies (genetic engineering, robotics, and nanotechnology) will lead to a post-human era that impoverishes the meaning of being human. Explores how the technologies work and how to control them. Asks the central questions of whether people in the West lead sufficiently comfortable lives with sufficient technology now and whether controlling technologies is possible at all.

Melzer, Arthur M., Jerry Weinberger, and M. Richard Zinman, eds. *Technology in the Western Political Tradition*. Ithaca, NY: Cornell University Press, 1993. Pp. xv, 333. Presents a preface, introduction, and twelve essays that address the political character and implications of technology from classical antiquity through the nineteenth century and the meanings of technology for contemporary political life. An introduction by Leon Kass establishes "the problem of technology" as it provokes questions of human happiness at the same time that it undercuts the validity of answers to those questions. This leads to a need to rediscover the nontechnological conception of liberty and dignity in liberal democracies.

Mitcham, Carl, and Robert Mackey, eds. *Philosophy and Technology: Readings in the Philosophical Problems of Technology*. New York: Free Press, 1972. Paperback edition, 1983. Pp. xii, 403. A collection of 26 articles, some originally translated, that has remained in print for more than 30 years. The sections on "Ethical and Political Critiques," "Religious Critiques," and "Two Existentialist Critiques" are the most relevant.

National Academy of Engineering. *Emerging Technologies and Ethical Issues in Engineering*. Washington, D.C.: The National Academies Press, 2004. Pp. x, 155. Result of an NAE conference. Includes a keynote address by William A. Wulf and nine essays in three sections: emerging technologies, state of the art in engineering ethics, and ethics in engineering education.

National Academy of Sciences, National Academy of Engineering, and Institute of Medicine. *Responsible Science: Ensuring the Integrity of the Research Process*. Vol 1. Washington, DC: National Academy Press, 1992. Pp. xxiii, 1999. Result of a panel discussion to review factors affecting the integrity of research and recommend steps for reinforcing responsible research practices. Also reviews institutional mechanisms for addressing allegations of misconduct and considers the advantages and disadvantages of formal guidelines for the conduct of research.

National Academy of Sciences, National Academy of Engineering, and Institute of Medicine. *Responsible Science: Ensuring the Integrity of the Research Process*. Vol 2. Washington, DC: National Academy Press, 1993. Pp. xi, 275. See above for background. This volume includes background papers, samples of guidelines for the conduct of research, scientific research policies and practices, and policies and procedures for handling allegations of misconduct.

Postman, Neil. *Technopoly: The Surrender of Culture to Technology*. New York: Knopf, 1992. Pp. xii, 222. A broad-brush criticism of technological culture that updates arguments from the 1960s and 1970s.

President's Council on Bioethics. *Beyond Therapy: Biotechnology and the Pursuit of Happiness, A Report of the*

President's Council on Bioethics. New York: Regan Books, 2003. Pp. xiii, 328. A report by the U.S. bioethics commission with a foreword by its Chair, Leon Kass. Explores the ethical and social implications of using biotechnology for purposes of enhancement beyond therapy even as it problematizes this distinction. Includes chapters on "Better Children," "Superior Performance," "Ageless Bodies," "Happy Souls," and a conclusion.

Resnik, David B. *The Ethics of Science: An Introduction*. London: Routledge, 1998. Pp. x, 221. Develops a conceptual framework for understanding the ethics of scientific research and applies it to ethical questions in science. Seeks to clarify the nature of research ethics and the meaning of ethical behavior in science. Draws from several case studies and includes an appendix with 50 hypothetical case studies.

Sarewitz, Daniel. *Frontiers of Illusion: Science, Technology, and the Politics of Progress*. Philadelphia: Temple University Press, 1996. Pp. xi, 235. Deconstructs several "myths" instantiated in post-World War II U.S. science politics in order to gain clarity on the central questions of how science can best serve society, what science to pursue, and the relationship between scientific progress and human welfare. Concludes with a chapter titled "Toward a New Mythology," which includes policy recommendations for more explicitly integrating other values with epistemic pursuits in a democratic fashion.

Sassower, Raphael. *Technoscientific Angst: Ethics and Responsibility*. Minneapolis, MN: University of Minnesota Press, 1997. Pp. xv, 140. Relates the lessons of Auschwitz and Hiroshima to contemporary decision making about technoscience and the responsibility of intellectuals in a way that borrows from Hannah Arendt and Hans Jonas. Examines the anguish and angst felt by scientists but rarely exposed and the ambiguity concerning the responsibility of the technoscientific community in the face of mass destruction.

Sclove, Richard. *Democracy and Technology*. New York: Guilford Press, 1995. Pp. xiv, 338. Argues for democratic participation in technology, and proposes criteria for assessing engineering design in terms of the promotion of democracy.

Shrader-Frenchette, K. S. *Risk and Rationality: Philosophical Foundations for Populist Reforms*. Los Angeles: University of California Press, 1991. Pp. x, 312. Sketches a middle ground between the dominant sides of industrial charges of scientific illiteracy and populist charges of technological oppression. Proposes a new paradigm for making decisions about when the acceptance of public hazards is rational that includes more trust in the judgments of non-experts. Proceeds through a general introduction to a discussion of problematic risk-evaluation strategies to proposed reform for risk evaluation.

Shrader-Frenchette, Kristin. *Ethics of Scientific Research*. Lanham, MD: Rowman & Littlefield, 1994. Pp. x, 243. Arranged in ten chapters: introduction to and history of research ethics, professional codes, objectivity, promoting the public good, handling conflicts, uncertainty, case study in conservation research, gender and racial biases, social responsibility of engineers, and public health research. Last three chapters are authored by Helen Longino, Carl Mitcham, and Carl Cranor respectively.

Shrader-Frechette, Kristin. *Environmental Justice: Creating Equality, Reclaiming Democracy*. Oxford: Oxford Press, 2002. Pp. xiii, 269. Argues not only for protecting nature but also for public-interest advocacy in the name of the people who are victimized by environmental injustices. Diagnoses, analyzes, and seeks to resolve environmental injustices. Chapters elucidate concepts of justice (e.g., distributive, participatory, and procedural) and focus on case studies such as future generations and nuclear waste disposal, poor peoples and land use decisions, and risky occupational environments. Concludes with steps to take action.

Spier, Raymond. *Ethics, Tools, and the Engineer*. New York, NY: CRC Press, 2001. Pp. xiv, 306. Employs an evolutionary biology framework to discuss ethics and engineering. Discusses the meaning of ethics, describes engineers as toolmakers and users, considers the control and proper use of tools, and speculates on the cloning of humans. Also discusses the hazard and operability (HAZOP) process as a gatekeeping operation.

Spier, Raymond, ed. *Science and Technology Ethics*. New York, NY: Routledge, 2002. Pp. viii, 247. Reexamines contemporary ethics, asking whether sufficient ethical guidelines exist to minimize the disruptions of science and technology and maximize their benefits. Proposes new approaches to science and engineering practices. Eleven essays examine science and engineering broadly, developments in biology and information technology, the military industry, and environmental responsibilities.

Stokes, Donald E. *Pasteur's Quadrant: Basic Science and Technological Innovation*. Washington, DC: Brookings Institution Press, 1997. Pp. xiv, 180. Examines and reconceptualizes the division between basic and applied research that is at the core of post-World War II U.S. science policy. Analyzes the ways in which understand-

ing and use are often tightly intertwined in use-inspired basic research, presents this in a quadrant, and uses this to offer recommendations for a new contract between government and science.

Suzuki, David, and Peter Knudtson. *Genethics: The Clash between the New Genetics and Human Values*. Cambridge, MA: Harvard University Press, 1989. Proposes a set of genetic principles that emphasize individual rights and confidentiality with regard to genetic screening, caution in violating boundaries across species, and a ban on biological weapon development and the genetic manipulation of human germ cells.

Tenner, Edward. *Why Things Bite Back: Technology and the Revenge of Unintended Consequences*. New York: Alfred A. Knopf, 1996. Pp. xiii, 346. Explores the way in which technology, no matter how well designed, demands more human work despite promises to the contrary and introduces more chronic and insidious problems as the acute ones are never wholly resolved. These occurrences are explained as "revenge effects" that emerge from the interplay of technology, laws, customs, and habits. This stems largely from the inability to foresee future consequences of action.

Tiles, Mary, and Hans Oberdiek. *Living in a Technological Culture: Human Tools and Human Values*. London: Routledge, 1995. Pp. xi, 212. A philosophical reflection on technology, its many meanings, and its manifold relationships to culture. Examines conflicting visions of technology, facts and values, efficiency, science and the authority of experts, the transition from applied science to techno-science, and politics and responsibility.

Wenk, Edward, *Tradeoffs: Imperatives of Choice in a High-Tech World*. Baltimore, MD: Johns Hopkins University Press, 1989. Pp. xii, 238. Explores the neglect by economic and political institutions of the social impacts of new technologies and seeks to provide the "attentive public" with knowledge on how to direct and control technological applications. Argues that technology is more than hardware, but is an entire social system, that always entails side effects and tradeoffs that demand close attention to risk and uncertainties in a process of "looking before we leap." Explores public policy, private sector policies, their relationship, and the relationship of technology to science.

Whitbeck, Caroline. *Ethics in Engineering Practice and Research*. New York: Cambridge University Press, 1998. Pp. xx, 330. Uses a collection of case studies to address the professional and research responsibilities of engineers. Designed for classroom use, it includes a general introduction to ethical concepts and offers interactive activities with Case Western Reserve University's Online Ethics Center for Engineering and Science at http://onlineethics.org/.

Wiener, Norbert. *The Human Use of Human Beings: Cybernetics and Society*. Boston, Houghton Mifflin, 1950. Gives an account of the purpose of a human life and four principles of justice. Offers a method of applied ethics and discusses questions and topics in computer ethics. Republished by Da Capo Press in 1988.

Winner, Langdon. *The Whale and the Reactor: A Search for Limits in an Age of High Technology*. Chicago: University of Chicago Press, 1986. Outlines a political philosophy of technology as a form of political action. Technologies are not just means but "forms of life." Includes the influential essay "Do Artifacts Have Politics?" (pp. 19-39), to which the answer is yes. Other chapters discuss failed attempts to introduce technological fixes into political life as well as the weakness of environmentalism, technology assessment, and appeals to values.

3. Monographs and Edited Volumes: Specialized

Abram, David. *The Spell of the Sensuous: Perception and Language in a More-than-Human World*. New York: Pantheon Books, 1996. A personal and phenomenological account of human being as fundamentally dependent on contact and conviviality with what is not human. Calls for a renewal of human relationships with the sensuous world in which technologies are rooted in order to reassess the human and technological relationship with natural places. Aimed at both environmental activists and scholars.

Adas, Michael. *Machines as the Measure of Men: Science, Technology and Ideologies of Western Dominance*. London: Cornell University Press, 1989.

Aman, Kenneth, ed. *Ethical Principles for Development: Needs, Capacities or Rights*. *Proceedings of the IDEA/Montclair Conference*. Upper Montclair, NJ: Institute for Critical Thinking, 1991.

Angell, Marcia. *Science on Trial: The Clash of Medical Evidence and the Law in the Breast Implant Case*. New York: W. W. Norton and Company, 1996. Pp. 268. Critical analysis of law's treatment of science in the case of breast implants by medical researcher and former journal editor. Inquires into the distinctions in the way science, the law, and the public regard evidence and weigh risk. Organized in ten chapters with a preface and

afterword. Includes history, analysis of litigation and regulation, and the effects of corruption.

Arnhart, Larry. *Darwinian Natural Right: The Biological Ethics of Human Nature*. Albany: State University of New York Press, 1998. Defends a contemporary version of Aristotelian ethics using evolutionary biology.

Attfield, Judy. *Utility Reassessed: The Role of Ethics in the Practice of Design*. Manchester: Manchester University Press, 1999.

Barry, Robert L. and Gerard V. Bradley, eds. *Set No Limits: A Rebuttal to Daniel Callahan's Proposal to Limit Health Care for the Elderly*. Urbana: University of Illinois Press, 1991. Collects eight essays (including a preface and prologue) that criticize age-based rationing schemes for the allocation of health care resources. Argues that health care reforms are necessary but that it is not legally or morally justifiable to deprive people of life-sustaining care solely on the basis of their age. Considers moral and ethical, legal and jurisprudential, and public policy and economic aspects of age-based rationing.

Bavertz, Kurt, ed. *Sanctity of Life and Human Dignity*. Dordrecht: Kluwer, 1996. Pp. xix, 318. Engendered by a 1992 conference, compiles a general introduction and eighteen essays including an annotated bibliography and literature review. Sections include the concepts of human dignity, sanctity of life, and person, problems of critical care, and the role of the state.

Bayertz, Kurt. *GenEthics*. Cambridge, UK: Cambridge University Press, 1995. Clarifies the ethical dimensions generated by new human reproductive and genetic advancements. Most emphasis is on reproductive assisting technologies.

Beatley, Timothy. *Ethical Land Use*. Baltimore, MD: John Hopkins University Press, 1994.

Beauchamp, Tom, and Veatch, Robert eds. *Ethical Issues in Death and Dying*. 2nd ed. New York: Prentice Hall, 1996. Pp. xiv, 458. Gathers nine chapters of diverse resources pertaining to death and dying including essays, case studies, and government publications. Chapters are: definitions of death, truth-telling with dying patients, suicide, physician assisted suicide and euthanasia, forgoing treatment and causing death, decisions to forgo treatment involving once competent persons, decisions to forgo treatment involving never-competent patients, futile treatment and terminal care, and social reasons for limiting terminal care.

Bell, Robert. *Impure Science: Fraud, Compromise, and Political Influence in Scientific Research*. New York, NY: John Wiley & Sons, Inc., 1992. Pp. xvi, 301. Explores how the pursuit of money and prestige have compromised and corrupted scientific research in the U.S. Uses many case studies (e.g., Breuning and Baltimore) to substantiate and illuminate argument. Concludes with recommendations.

Belsey, Andrew, and Ruth Chadwick, eds. *Ethical Issues in Journalism and the Media*. London: Routledge, 1992. Pp. xiii, 179. Eleven original essays on topics such as ethics and politics, owners, editors, and journalists, terrorism and reporting restrictions, objectivity, honesty, privacy, codes of conduct, and freedom of speech.

Benso, Silvia. *The Face of Things: A Different Side of Ethics*. Albany: State University of New York Press, 2000. Pp. xxxviii, 258. Tries to bridge Emmanuel Levinas' emphasis on "love without things" and Martin Heidegger's "things without love" by arguing for an ethics of festive things. Amazingly fails to reference the work of Albert Borgmann.

Berry, Wendell. *The Unsettling of America: Culture and Agriculture*. San Francisco: Sierra Club Books, 1977. Pp. ix, 228. A criticism of modern industrial agriculture and its ecological and cultural consequences. A third edition was published by University of California Press, 1996.

Bertrand, Claude-Jean, ed. *An Arsenal for Democracy: Media Accountability Systems*. Cresskill, NJ: Hampton Press, 2003. Pp. xi, 420. Provides information on a wide range of ways in which to democratize the news media and make it accountable to the public, primarily through media accountability systems. Posits these systems as intermediaries between total loss of social responsibility and strict legal regulation. Arranged in twenty-nine chapters including principles and rules, press councils, research, ombudsmen, and media accountability systems in seven countries.

Bertrand, Claude-Jean. *Media Ethics and Accountability Systems*. New Brunswick, NJ: Transaction, 2000.

Brody, Baruch. *The Ethics of Biomedical Research*. New York: Oxford, 1998. Pp. xiii, 386. Covers both animal and human subjects research including chapters on genetic research, research involving vulnerable subjects, drug/device approval process, and a concluding chapter with philosophical reflections. Features four appendices on international, European transnational, U.S., and other countries' research ethics policies.

Brunner, Ronald D., Christine H. Colburn, Christina M. Cromley, Roberta A. Klein, and Elizabeth A. Olson. *Finding Common Ground: Governance and Natural Resources in the American West*. New Haven: Yale University Press, 2002. Pp. xiii, 303. Designed to help broad audiences understand the potential of community-based initiatives for resolving public policy disputes in the name of the common interest. Organized into a general introduction, four case studies, and a conclusion that seeks to draw out the lessons learned from community-based initiatives of policy making.

Buchanan, Allen, Dan Brock, Norman Daniels, and Daniel Wikler. *From Choice to Chance: Genetics and Justice*. New York: Cambridge, 2000.

Bud, Robert. *The Uses of Life: A History of Biotechnology*. Cambridge: Cambridge University Press, 1993. Pp. xvii, 299. Explores the long history of biotechnology, emphasizing the past 100 years, from ancient conceptions to nineteenth century zymotechnology to human genome research. Also tracks the disparate meanings of the term over time and cultures.

Callicott, J. Baird. *In Defense of the Land Ethic: Essays in Environmental Philosophy*. Albany: State University of New York Press, 1989. Pp. x, 325. Takes the econcentrist standpoint, drawing from sociobiology and ecology, that modern values of Western civilization must be overhauled. Organized into five sections: animal liberation and environmental ethics, a holistic environmental ethic, a non-anthropocentric value theory for environmental ethics, American Indian environmental ethics, and environmental education, natural aesthetics, and E.T. The second section develops and defends Aldo Leopold's land ethic.

Casebeer, William D. *Natural Ethical Facts: Evolution, Connectionism, and Moral Cognition*. Cambridge, MA: MIT Press, 2003. Argues for a strong form of scientific ethics, recapitulating a neo-Aristotelian virtue theory using resources from evolutionary biology and cognitive neuroscience.

Chadwick, Ruth, Darren Shickle, Henk ten Have, and Urban Wiesing, eds. *The Ethics of Genetic Screening*. London: Kluwer, 1999. Pp. xvi, 255. Collects twenty-one essays resulting from a three-year multinational and multidisciplinary project known as Euroscreen. Opens with an overview of genetic screening and the ethical principles available for addressing developments in the field with special reference to the Wilson and Jungner principles on screening. Other topics include nation-specific perspectives on ethical debates, regulatory systems, and history.

Chiles, James R. *Inviting Disaster: An Inside Look at Catastrophes and Why They Happen*. New York, NY: HarperBusiness, 2002. Pp. xxx, 338. Compiles twelve chapters and an introduction that use major disasters to highlight how "smart," increasingly complex systems fail as the pace and scope of change overwhelms human capabilities of response and control.

Chubin, Daryl E and Ellen W. Chu, eds. *Science Off the Pedestal: Social Perspectives on Science and Technology*. Belmont, CA: Wadsworth Publishing Co., 1989. Pp. x, 196. Designed for classroom use. Presents a primarily U.S.-centered account of science as cultural force, way of knowing, and institutionalized activity to supplement more traditional science teaching. Collects fourteen chapters and a postscript in three parts: science, technology, and other social institutions, world views and politics of knowledge, and science and technology as public resources.

Cohen, Avner, and Steven P. Lee, eds. *Nuclear Weapons and the Future of Humanity: The Fundamental Questions*. Totowa, NJ: Rowman and Allanheld, 1986. Pp. xii, 496. The single best collection of articles on this topic. Collects twenty-five essays and an afterward by John Holdren. Topics include reflections on the present threat, the oddity of nuclear thinking, just war and morality, and reformations of social and political realities toward a non-nuclear future. NUC Ethics

Cook, Robert Lynn. *Code of Silence: Ethics of Disasters*. Jefferson City, MO: Trojan Publishing, 2003.

Council of Biology Editors, Inc. *Ethics and Policy in Scientific Publication*. Bethesda, MD: Council of Biology Editors, Inc., 1990. Pp. xiii, 290. Presents the results of a survey of Council members about nineteen scenarios to identify and define ethical issues in publishing research results. Also presents twenty-nine papers from a conference. Issues include misconduct, peer review, conflicts of interest, informed consent, and much more.

Crocker, David A., and Linden, Toby, eds. *Ethics of Consumption: The Good Life, Justice, and Global Stewardship*. Lanham, MD: Rowman and Littlefield, 1998. Pp. xviii, 585. Contains "The Road Not Taken: Friendship, Consumerism and Happiness" by Robert E. Lane, pp. 218-248.

Cutcliffe, Stephen H. *Ideas, Machines, and Values: An Introduction to Science, Technology, and Society Studies*. Lanham, MD: Rowman and Littlefield, 2000. Pp. xii, 179. A broad overview of STS as a field of study including its historical emergence, relationships to the philosophy, sociology, and history of science and technology, and programs, institutions, and journals in the field. Includes a chapter on interdisciplinarity and the current state of STS and comments on future directions for the field.

Cutcliffe, Stephen H., and Carl Mitcham, eds. *Visions of STS: Counterpoints in Science, Technology, and*

Society. Albany: State University of New York Press, 2001. Pp. vi, 170. Collects a general introduction on the historical background and challenges of STS and ten essays arranged in three sections: general perspectives, applications, and critiques. Aims to clarify the complexities and debates within STS that emerge from its interdisciplinary nature by presenting ten views of where STS is or where it should be heading.

Danielson, Peter. *Artificial Morality: Virtuous Robots for Virtual Games*. New York, NY: Routledge, 1992. Pp. xiv, 240. Engages in controversies about the adequacy of rational choice theories and builds moral robots to explore the role of artificial intelligence in the development of a claim that morality is person-made and rational. Shows that moral agents are rational in the sense that they successfully solve some social problems that amoral agents cannot solve.

Davis, Michael. *Ethics and the University*. New York, NY: Routledge, 1999. Pp. xii, 267. Organized in three parts: a broad introduction to ethics in the academy, research ethics, and teaching ethics.

Davis, Michael. *Profession, Code and Ethics*. Burlington, VT: Ashgate Publishing Co., 2002. Pp. ix, 256. Addressed at scholars, teachers, and students. Presents a definition of profession and argues that codes of ethics are inherent to the nature of professionalism. Collects fourteen chapters arranged in four parts: lawyers, engineers and scientists, police, and teaching ethics.

Davis, Michael. *Thinking Like an Engineer: Studies in the Ethics of a Profession*. New York, NY: Oxford University Press, 1998. Pp. xii, 240. Inquires into the nature of engineering and the ethical principles that guide it. Provides historical background, comments on codes of ethics and whistleblowing, and thoughts on protecting engineering judgment. Then supplies empirical work to support the philosophical account of engineering

Deane-Drummond, Celia, Bronislaw Szerszynski, and Robin Grove-White, eds. *Reordering Nature: Theology, Society, and the New Genetics*. London: T and T Clark, 2003.

De Waal, Frans. *Good Natured: The Origins of Right and Wrong in Humans and Other Animals*. Cambridge, MA: Harvard University Press, 1996.

Dreyfus, Hubert L. *On the Internet*. New York, NY: Routledge, 2001. Pp. ix, 127. Critiques certain aspects of the promise of the internet to extend and improve human interaction, especially distance learning. Grounds his critique in the history of Western philosophy and certain long-standing conceptions such as mind-body dualism. Looks to existentialism and its focus on embodiment as an important resource for theories of education. Argues distance education can work, but care must be made to implement it correctly.

Escobar, Arturo. *Encountering Development: The Making and Unmaking of the Third World*. New Jersey: Princeton University Press, 1995. Pp. ix, 290. A discursive poststructuralist critique of economics as the foundational structure of modernity. Argues that development and the "Third World" are being unmade due to repeated failures to achieve goals and aspires to imagine alternatives for a post-development era.

Evan, William M., and Mark Manion. *Minding the Machines: Preventing Technological Disasters*. Upper Saddle River, NJ: Prentice Hall, 2002. Pp. xxiv, 485. Offers explanations for why technological disasters occur and preventive measures to cover all areas of risk. Topics examined include: history and theories of disasters, strategic responses, design and organizational failures, sociocultural failures, responsibilities of institutions and individuals, and participatory technology and the role of the citizen. Also comments on legal system and private corporations and provides some case studies.

Farber, Paul Lawrence. *The Temptations of Evolutionary Ethics*. Berkeley: University of California Press, 1994.

Foster, Kenneth R., and Peter W. Huber. *Judging Science: Scientific Knowledge and the Federal Courts*. Cambridge, MA: MIT Press, 1997. Pp. 333. An extended commentary on scientific validity and the law's rules of evidence aimed at non-expert audiences. Explains the significance of the *Daubert* criteria and addresses the central question of when evidence presented as scientific should be considered reliable enough to be presented to a jury. Concludes with an attempt to reconcile the law's needs for workable rules of evidence with the views of scientific validity and reliability held in scientific disciplines.

Fukuyama, Francis. *Trust: The Social Virtues and the Creation of Prosperity*. New York: Free Press, 1995. A comparative historical study of high-trust and low-trust societies and their business and economic consequences.

Goldberg, Steven. *Culture Clash: Law and Science in America*. New York: New York University Press, 1994. Pp. xi, 255. Argues that law and culture are at the roots of the slippage between the promise of U.S. science and the reality of commercial technology. Organized into ten chapters including the constitutional status of and statutory framework for basic research, science and religion in the law, legal restrictions on new technology, the human genome, nuclear fusion, and artificial intelligence.

Goldschmidt, Walter. *As You Sow: Three Studies in the Social Consequences of Agribusiness*. New York: Universe Books, 1978. Pp. liv, 505. Examines the consequences of corporate agriculture for rural communities in the United States. Features an extended general introduction on "Agriculture and the Social Order" that traces the rise of agribusiness.

Gough, Michael, ed. *Politicizing Science: The Alchemy of Policymaking.* Stanford, CA: Hoover University Press, 2003. Pp. xxi, 313. Shows the ways in which the connections between politics and science can thwart the achievement of social goals. Collects a preface, introduction, and eleven essays written by scientists about specific cases of excessive politicization.

Gould, Stephen J. *Rocks of Ages: Science and Religion in the Fullness of Life*. New York: Ballantine Books, 2002. Pp. viii, 241. Discusses the relationship between religion and science, arguing that the two are non-overlapping magisteria (NOMA) that can work peacefully together but only if there is no attempt to synthesize them somehow or bring one under the domain of the other. Argues that science deals with facts and theories about nature, whereas religion deals with human values and ultimate meaning.

Graham, Gordon. *The Internet: A Philosophical Inquiry*. New York, NY: Routledge, 1999. Pp. ix, 179. Assesses the implications of the internet for concepts of identity, moral anarchy, censorship, community, democracy, virtual reality, and imagination. Opens by negotiating the extremes of luddism and technophilia.

Greenberg, Daniel S. *Science, Money, and Politics: Political Triumph and Ethical Erosion*. Chicago: University of Chicago Press, 2001. Pp. x, 530. Examines and seeks to explain the prosperity and autonomy of science in the United States from the end of World War II to the turn of the century. Argues that the scientific "metropolis" has successfully lobbied for political resources, especially money and independence, but in so doing it has eroded its ethical integrity through these strategies of acquiring support and in the conduct of research. Takes a thematic approach through twenty-eight chapters that take up beliefs, social characteristics, goals, and revealing episodes.

Greenberg, Daniel S. *The Politics of Pure Science*, 2nd edition. New York: New American Library, 1999 (1st edition, 1967). Pp. xxvii, 311. Draws from personal experience writing for the journal Science on the politics of science and focuses on basic research. Explains how this politics works without sliding into either reverence or cynicism. Divided into three sections that treat the scientific community, the shaping of science politics during and after World War II, and some more recent examples of science politics. Concludes with notes about the new politics of science that demands more accountability from the scientific community.

Hamelink, Cees J. *The Ethics of Cyberspace*. Thousand Oaks, CA: Sage, 2000.

Hargrove, Eugene. *Foundations of Environmental Ethics*. Englewood Cliffs, NJ: Prentice Hall, 1989. Pp. x, 229. Organized into three sections. "Traditional Positions" explores Greek and modern philosophy. "The Environmental Position" outlines aesthetic, scientific, and wildlife protection attitudes and treats the perennial issues of value such as instrumental versus intrinsic. "Philosophical and Ethical Implications" presents an ontological argument for environmental ethics and discusses "therapeutic nihilism" in the context of environmental management.

Harries, Karsten. *The Ethical Function of Architecture*. Cambridge, MA: MIT Press, 1997. Pp. xiii, 403. Argues that architecture faces a deep philosophical problem bound up with questions of interpretation, the good life, and genuine dwelling as technology transforms human experience away from a focus on place and community. Claims that architecture should help define a sense of place in a disorienting world by articulating a common ethos. Includes 123 illustrations.

Hayles, M. Katherine. *How We Became Posthuman*. Chicago: University of Chicago Press, 1999. Pp. xiv, 350. Drawing from the history of cybernetics and information theories, argues that the emergence of distributed cognition and the disembodiment of infromation both furthers and overturns the liberal humanist subject. "Posthuman" is used in multiple, sometimes ironic ways, but all of which connot some form of union of humans with intelligent machines. Argues that human identity is more than information, but relies also on its instantiation and seeks to foster a future that embraces information technology "without being seduced by fantasies of unlimited power and disembodied immortality, that recognizes and celebrates finitude [and material embeddedness] as a condition of human being" (p. 5).

Hefner, Philip. *Technology and Human Becoming*. Minneapolis: Fortress Press, 2003. Proposes a Christian theory of co-creation in the use of science and technology.

Heller, Agnes. *Beyond Justice*. Oxford, U.K.: Basil Blackwell, 1987. Pp. vi, 346. Critiques theoretical assumptions underlying traditional and modern notions of justice, argues that all claims to justice are rooted in other values such as freedom and life, and claims that, although justice may be a precondition of the good life, the good life is something beyond justice. Contains analytic, historical, and normative chapters.

Hendler, Sue, ed. *Planning Ethics: A Reader in Planning Theory, Practice and Education*. New Brunswick, NJ: Center for Urban Policy Research, 1995. Pp. xx, 374. Reflects and furthers the expansion of professional ethics to more public and global concerns. Collects fifteen essays in three parts, each of which is set in the context of ethical theory: planning theory, planning practice, and planning education. Intended for planners and philosophers.

Herkert, Joseph R., ed. *Social, Ethical, and Policy Implications of Engineering*. New York: Institute of Electrical and Electronics Engineers (IEEE) Press, 2000. Pp. xi, 339. Collects 35 articles arranged in three categories: the societal context of technology and engineering, ethical responsibilities of engineers, and engineering ethics and public policy. Emphasis is placed on the policy aspects of contemporary ethical issues. Aimed at engineering educators, students, and practitioners. All articles are reprinted from the *IEEE Technology and Society Magazine*.

Hess, David. *Science Studies: An Advanced Introduction*. New York: New York University Press, 1997. Pp. vii, 197. Focuses on U.S. topics and highlights cross-disciplinary misunderstandings in the field. Collects six chapters including a chapter that discuss the philosophy of science, sociology of science, social studies of knowledge, critical and cultural studies of science and technology, and a conclusion that primarily treats policy issues.

Heyd, David. *Genethics: Moral Issues in the Creation of People*. Berkeley: University of California Press, 1992. Attempts to resolve many ethical paradoxes in intergenerational justice raised by advances in medicine, genetic engineering, and demographic forecasting.

Higgs, Eric. *Nature by Design: People, Natural Process, and Ecological Restoration*. Cambridge, MA: MIT Press, 2003. Pp. xv, 341. Introduces concept and cases of ecological restoration. Focuses on the concern that restoration acts as an apology for technological excess and demonstrates a hubristic urge to manipulate nature to mirror cultural values. Proposes "focal restoration" as a preferred way of ensuring participation and engagement in restoration projects and highlighting the importance of responsible and intentional "wild" design.

Higgs, Eric, Andrew Light, and David Strong, eds. *Technology and the Good Life?* Chicago: University of Chicago Press, 2000. A collection of essays on the work of Albert Borgmann.

Hilgartner, Stephen. *Science on Stage: Expert Advice as Public Drama*. Stanford, CA: Stanford University Press, 2000. Pp. xvi, 214. Uses two National Academy of Science reports to examine the production and use of science advice in an age conflicted by a vision of expertise as both value-laden and objective. Employs the theoretical trope of the theater to investigate how advisory bodies produce credibility and authority by managing information and appearances in complex ways. Investigates the "boundary work" and rhetorical and narrative techniques at the borders of science and society and uses the idea of "stage management" to differentiate "back stage" from "front stage" elements of science advice.

Homan, Roger. *The Ethics of Social Research*. New York: Longman, 1991.

Howard, Ted, and Jeremy Rifkin. *Who Should Play God?: The Artificial Creation of Life and What It Means for the Future of the Human Race*. New York: Delacorte Press, 1977. Pp. 272. Introduces genetic engineering and its history, links it to the ideology of eugenics supporters, describes its likely forms of application, and concludes with recommendations. Staunchly opposes genetic engineering and reductionism, arguing that the choice is between preserving humans and other species as they are or launching a mass program of biological reengineering. Argues that genetic engineering is inherently anti-democratic and elitist and requires active public participation to prevent dehumanization.

Jasanoff, Sheila. *The Fifth Branch: Science Advisors as Policymakers*. Harvard University Press, 1990. Pp. xiii, 302. Draws from social studies of science, especially constructivist work, to present a conceptual framework and differentiated vocabulary for the dilemmas faced by science advisory committees. Argues for procedural reforms in the role of science advisors in public policy making. Addresses the question of the limits of participatory decision-making in an age of growing technological complexity and expert knowledge.

Jasanoff, Sheila. *Science at the Bar: Law, Science, and Technology in America*. Cambridge, MA: Harvard University Press, 1995. Pp. xvii, 285. A classic overview of law-science relationship from social studies of science perspective. Argues that the courts actively influence the production of science and technology and serve as democratizing agents, but are often constrained in this role by positivistic assumptions. Analyzes scientific and legal modes of reasoning and concludes with a prescriptive look ahead.

Kass, Leon. *Toward a More Natural Science: Biology and Human Affairs*. New York: Free Press, 1985. Pp. xiv, 370. An Aristotelian account that argues that science can go too far if it is not appropriately regulated by the wisdom contained in our emotional reactions to certain technological advances.

Kavka, Gregory S. *Moral Paradoxes of Nuclear Deterrence*. New York: Cambridge University Press, 1987. Pp. xii, 243. A tightly argued exploration of the major quandaries that defends nuclear deterrence, if subjected to proper restrictions, as morally justified. Highlights conflicts and dilemmas both within and between utilitarian and deontological ethics.

Kellert, Stephen R. *The Value of Life: Biological Diversity in Human Society*. Washington, DC: Island Press, 1996. A taxonomy of views of nature.

Kevles, Daniel J. *In the Name of Eugenics: Genetics and the Use of Human Heredity*. Berkeley: University of California Press, 1985. Seminal work on history of eugenics and the eugenic implications of new reproductive technologies. Reprinted by Harvard University Press, 1995.

Kimbell, Richard. *Assessing Technology: International Trends in Curriculum and Assessment*. Philadelphia, PA: Open University Press, 1997. Pp. xiv, 249. Explores the issues of assessment that have emerged with the technology curriculum in the U.K., especially the problems of process-centered assessment that involve evaluating students' capabilities in the process of design and development. Provides international comparisons to the U.S., Germany, Taiwan, and Australia. Concludes with general reflections.

Koehn, Daryl. *The Ground of Professional Ethics*. New York, NY: Routledge, 1994. Pp. x, 224. Confronts and rebuts the challenge to the authority and ethics of professionals by arguing that it rests on a secure and morally legitimating ground because and to the extent that these professions are structured to merit the trust of clients.

LaFollette, Marcel C. *Stealing into Print: Fraud, Plagiarism, and Misconduct in Scientific Publishing*. Berkeley: University of California Press, 1992. Pp. viii, 293. Focuses on how scientific misconduct affects communication practices and policies in the journals that disseminate the results of scientific research.

Layton, Edwin T. Jr. *The Revolt of the Engineers: Social Responsibility and the American Engineering Profession*. 2nd ed. Baltimore: Johns Hopkins University Press, 1986. Pp. xxii, 286. (First published 1971.) Classic examination of the professionalization of engineering in the U.S. from 1900-1945. Analyzes the tensions between business interests and technical expertise, and describes failed attempts during the first half of the 20th century to promote unity and autonomy (the "revolt") around an ideology of engineers as professional leaders of advanced civilization. A new preface comments briefly on post-World War II developments.

Levine, Robert. *Ethics and the Regulation of Clinical Research*. 2nd ed. New Haven: Yale, 1988.

Light, Andrew and Eric Katz, eds. *Environmental Pragmatism*. London: Routledge Press, 1998. Pp. xvi, 352. Presents environmental pragmatism as a way to direct the fruits of (open-ended, pluralistic, and context specific) philosophical inquiry toward practical resolution of environmental problems. Collects seventeen essays and a general introduction.

Marcus, Stephen J., ed. *Neuroethics: Mapping the Field: Conference Proceedings, May 13-14, 2002, San Francisco, California*. New York: Dana Press, 2002. Pp. vii, 367. Result of a conference composed of scientists, ethicists, humanists, and others on the personal and social implications of human brain research. Organized into five sections: notions of self, social policy, ethics, public discourse, and mapping the future. Also includes two speeches, one by Arthur Caplan that argues the main issue is equity rather than worries about enhancement, and an introduction mapping the new emerging field of neuroethics.

Margolin, Victor. *The Politics of the Artificial: Essays on Design and Design Studies*. Chicago: University of Chicago Press, 2002. Pp. 273.

Mason, Richard, Florence Mason, and Mary Culnan. *Ethics of Information Management*. Thousand Oaks, CA: Sage Publications, 1995.

McDonough, William, and Michael Braungart. *Cradle to Cradle: Remaking the Way We Make Things*. New York: North Point Press, 2002. Pp. 193.

McGee, Glenn. *The Perfect Baby: A Pragmatic Approach to Genetics*. New York: Rowman and Littlefield, 1997. Denies the necessity of a "genethics," arguing that the wisdom we need can be found in the everyday experience of parents.

Mehlman, Maxwell J., and Jeffrey R. Botkin. *Access to the Genome: The Challenge to Equality*. Washington, DC: Georgetown University Press, 1998. Summarizes the Human Genome Project and discuss its practical

health applications and ethical and policy challenges such as bans, equal access, genetic handicapping, and genetic lotteries.

Mendelsohn, Everett, Merritt Roe Smith, and Peter Weingar, eds. *Science, Technology and the Military*, 2 vols. Boston: Kluwer, 1988. Pp. xxix, vii, 288; 274. Collects papers presented at 1987 conference with an introductory overview. Topics include war and the restructuring of physics, the military and technological development, industry, medicine, academy, and nuclear weapons and power.

Mepham, Ben., ed. *Food Ethics*. London: Routledge, 1996. Pp. xiv, 178. Collects ten essays and a select bibliography on such issues as food aid and trade, biotechnology, global hunger, consumer sovereignty, research ethics, and nutrition and health. Features an essay that presents an evaluative framework for ethical analysis of food biotechnologies.

Mirowski, Philip and Esther-Mirjam Sent, eds. *Science Bought and Sold: Essays in the Economics of Science*. Chicago: University of Chicago Press, 2002. Pp. ix, 573. Presents science as a deeply economic activity of investment and profit and shows the changing relations between science and economics. Collects a general introduction and nineteen original and reprinted essays arranged in six parts including science as a production process, science as a problem of information processing, contours of the globalized privatization regime, and the future of scientific credit.

Molotch, Harvey. *Where Stuff Comes From: How Toasters, Toilets, Cars, Computers and Many Other Things Come to Be As They Are*. New York: Routledge, 2003. Pp. 324.

Moulakis, Athanasios. *Beyond Utility: Liberal Education for a Technological Age*. Columbia: University of Missouri Press, 1994. Pp. viii, 171. Generated from experiences teaching a Humanities for Engineers course. Considers the larger purposes of liberal arts education and how they relate to the education of professionals. Addresses the controversy in education circles about tradeoffs between narrow, professional and broad, humanistic education.

National Academy of Engineering. *The Engineer of 2020: Visions of Engineering in the New Century*. Washington, D.C.: The National Academies Press, 2004. Pp. xv, 101. Result of a forward-looking conference about what engineering will and should be like in the future and to what extent engineers can shape that future. Includes an appendix with possible future scenarios.

Paradis, James, and George C. Williams, eds. *Evolution and Ethics*. Princeton, NJ: Princeton University Press, 1989. Contains the essay "A Sociobiological Expansion of Evolution and Ethics" by George Williams.

Pattyn, Bart, ed. *Media Ethics: Opening Social Dialogue*, Leuven, Belgium: Peeters, 2000. Contains the important article "An Intellectual History of Media Ethics" by Clifford Christians.

Pelletier, Louise, and Alberto Pérez-Gómez, eds. *Architecture, Ethics, and Technology*. Montreal: McGill-Queen's University Press, 1994.

Perrow, Charles. *Normal Accidents: Living with High-Risk Technologies*. New York: Basic Books, 1984. (Revised 1999, Princeton, NJ: Princeton University Press). Pp. x, 386. Traces six examples of modern industrial systems to argue that tight coupling and interactive complexity inevitably produce accidents, and that these are more important concerns than operator error or the failure of parts. Offers an assessment of these systems and recommendations for future action. Concludes with a discussion of high-risk decision making.

Peters, Ted. *Playing God?: Genetic Determinism and Human Freedom*. 2nd ed. New York: Routledge, 2003. Pp. xvii, 260. Rejects genetic determinism and argues that human nature is the product of genes, environment, and free will. Defends a Christian understanding of humans as future-oriented and cocreative as an ethic for guiding genetic research. Takes up questions of genetic manipulation beyond therapy, ethics and science in the "gay gene" controversy, and such issues as patenting genes, cloning, stem cell research, and germline intervention.

Postrel, Virginia. *The Future and Its Enemies: The Growing Conflict over Creativity, Enterprise, and Progress*. New York: Free Press, 1998. Pp. xviii, 265. A libertarian defense of technological innovation as basis for human freedom that portrays two alternative futures: one that is diverse, dynamic, decentralized and choice-driven and the other that is static, centralized, and controlled. Explores the clash between dynamism and stasis and defends the former over the latter. Has a companion website at www.dynamist.com.

Proctor, Robert N. *Value-Free Science? Purity and Power in Modern Knowledge*. Cambridge, MA: Harvard University Press, 1991. Pp. xi, 331. Traces the origin of value neutrality in the separation of theory and practice, the isolation of moral knowledge from natural philosophy, and the mechanical conception of the universe. Explores the exclusion of morals and politics in the

social sciences, especially in Germany, and reviews more recent critiques of value-neutral science.

Reiss, Michael J., and Roger Straughan. *Improving Nature? The Science and Ethics of Genetic Engineering.* New York: Cambridge University Press, 1996. Covers a broad range of ethical and theological concerns in genetic engineering of microorganisms, plants, animals, and humans.

Resnik, David B. *Owning the Genome: A Moral Analysis of DNA Patenting.* Albany: State University of New York Press, 2004. Pp. xiii, 235. Examines the main arguments for and against different types and scopes of DNA patenting from both consequentialist and deontological perspectives. Argues that consequentialist arguments pertain to most issues, whereas deontological arguments have a more limited application. Claims that DNA patenting offers society many important benefits and poses a few important threats. Articulates and defends the precautionary principle in some areas and concludes with policy recommendations.

Rifkin, Jeremy. *Who Should Play God?: The Artificial Creation of Life and What It Means for the Future of the Human Race.* New York: Delacorte Press, 1977.

Rip, Arie, Thomas J. Misa, and Johan Schot, eds. *Managing Technology in Society: The approach of Constructive Technology Assessment.* London, England: Pinter, 1995. Pp. xii, 361. Explores the concept of critical technology assessment and the need for it in the goal of maximizing benefits and minimizing harms of technologies, uses case studies to argue that changing entrenched technologies and institutions is difficult but possible, discusses conditions for learning about experiences to try in other contexts, and argues that such policies will be context specific.

Roco, Mihail C., and William S. Bainbridge, eds. *Societal Implications of Nanoscience and Nanotechnology.* Dordrecht, The Netherlands: Kluwer, 2001. Pp. vii, 370. Collects articles from various contributors organized into five introductory chapters on nanotechnology goals and societal interactions, social science approaches to assessment, and recommendations. Chapter six provides topical considerations including education, medicine, environment, space, and security.

Rolston III, Holmes. *Conserving Natural Value.* New York: Columbia University Press, 1993. Pp. 259. A philosophical argument that seeks to balance natural and cultural values and considers the anthropocentric and intrinsic theories of value.

Sachs, Wolfgang ed. *The Development Dictionary: A Guide to Knowledge as Power.* London: Zed Books, 1992. Pp. 306. Compiles a general introduction and nineteen essays that deconstruct key terms in the modern development discourse such as needs, progress, science, technology, development, state, and environment. Argues that it is time to abandon the dominant development paradigm or "cast of mind."

Sarewitz, Daniel, Roger A. Pielke, Jr., and Radford Byerly, Jr, eds. *Prediction: Science, Decision Making, and the Future of Nature.* Washington, DC: Island Press, 2000. Pp. xv, 405. Addresses the application of scientific predictions to environmental problems, noting promises and limits, and pointing out that predictions are at once technical, political and social. Argues that the relationship of predictions to policy making is rocky due to the complexity of systems that generate uncertainty (and uncertainty about uncertainty) and the widely held and problematic assumption that predictions can simplify the decision-making process. Includes a general introduction and eighteen essays collected in six parts: prediction as a problem, natural hazards, politics, policy, prediction in perspective, and a conclusion.

Schlossberger, Eugene. *The Ethical Engineer.* Philadelphia, PA: Temple University Press, 1993. Pp. xii, 284. Addressed both to practicing professionals and engineering students. Uses illustrating cases to supplement the text. Includes an introduction to engineering ethics and ethical decision making, comments ethical theories and the sources of ethical decisions, issues such as honesty, good faith, employee-employer relations, and consulting.

Schmitz, David, and Elizabeth Willott. *Environmental Ethics: What Really Matters, What Really Works.* Oxford: Oxford University Press, 2002. Pp. xxi, 566. Collects classic essays in environmental ethics in fifteen topical areas, each introduced with questions for reflection and discussion.

Schumacher, E. F. *Small Is Beautiful: Economics as if People Mattered.* New York: Harper Perennial, 1989. (Originally published 1973, Harper & Row; reprint 1999, Hartley & Marks.) Pp. xxiii, 324. A critique of neo-classical economics, its conception of human nature and desires, natural resources, and its tendencies to globalize systems of production and distribution on massive scales. Defends small-scale, decentralized economies and includes the influential essay "Buddhist Economics," which challenges the goal displacement of growth-oriented economies that use technology to alienate human meaning by focusing on conceptions of "right livelihood" and celebrating the humanizing and liberating quality of work when scaled down and rooted in a community.

Schweber, S. S. *In the Shadow of the Bomb: Bethe, Oppenheimer, and the Moral Responsibility of the Scientist.* Princeton, NJ: Princeton University Press, 2000. Pp. xviii, 260. Examines the different reactions of two physicists to the moral dilemmas posed by the development and use of atomic weapons and questions of the professional responsibilities and public roles of scientists and engineers. Details the different roles played by Oppenheimer and Bethe, their foundations, and their consequences.

Sen, Amartya. *Development as Freedom.* New York: Anchor Books, 1999.

Sieber, Joan E., ed. *The Ethics of Social Research: Surveys and Experiments.* 2 vols. New York: Springer-Verlag, 1982. Pp. xii, 249 and x, 187. Designed to assist social scientists in preparing for and resolving ethical issues. Arranged as ten chapters in the first volume and seven in the second in four total sections: respect for the individual, protection of privacy and confidentiality, ethnographic fieldwork and beneficial reciprocity, and the roles of social scientists in research regulation and media relations.

Silver, Lee. *Remaking Eden: Cloning and Beyond in a Brave New World.* New York: Avon, 1998. Pp. viii, 317. Takes stock of the current state of reproduction and genetics (reprogenetics) technology to survey likely future scenarios. Argues that Huxley's dystopian vision of a "brave new world" is mistaken because individuals, not governments, will control reprogenetic technologies and that a society that values individual freedom above all else has difficulty justifying restrictions on the use of technologies by individuals. Surveys the changing meanings of parenthood, childhood, and the meaning of human life, dismisses many oppositions to reprogentic technologies, and concludes that such new technologies are inevitable as guaranteed by the global market.

Sismondo, Sergio. *An Introduction to Science and Technology Studies.* Malden, MA: Blackwell, 2004. Pp. vii, 202. Provides a clear overview of the field for readers unfamiliar with it. Intended for undergraduate or graduate classroom use. Organized into sixteen chapters that address historical and conceptual topics such as the Kuhnian revolution following the prehistory of STS, actor-network theory, social construction of knowledge, rhetoric and discourse, and expertise and the public understanding of science.

Sonnert, Gerhard. *Ivory Bridges: Connecting Science and Society.* Cambridge, MA: The MIT Press, 2002. Pp. x, 227. Scrutinizes the links between science and society beginning with a Jeffersonian concept of science policy, followed by a consideration of voluntary public interest associations of scientists, and concluding with questions of autonomy and responsibility.

Steinbock, Bonnie, ed. *Ethical and Legal Issues in Human Reproduction.* Hampshire, U.K.: Ashgate, 2002.

Stock, Greg. *Redesigning Humans.* New York: Houghton Mifflin, 2002. Strong defense of the genetic engineering of human beings.

Stone, Jeremy J. *"Every Man Should Try:" Adventures of a Public Interest Activist.* New York, NY: PublicAffairs, 1999. An autobiography that focuses on the development of the Federation of American Scientists. Provides an inside, personal look at some of the politics behind nuclear disarmament talks, reflections on why successes and failures occurred, and lessons about the complexities of public interest science.

Sutton, Victoria. *Law and Science: Cases and Materials.* Durham, NC: Carolina Academic Press, 2001. Pp. xxiv, 388. A legal casebook. Includes over sixty cases arranged into five chapters: an introduction, government, private sector, courts, and a future outlook.

Szerszynski, Bronislaw. *Nature, Technology, and the Sacred.* Malden, MA: Blackwell, 2005. Pp. xviii, 222. Uses the term "sacred" to understand the ways in which a range of religious framings are involved in ideas of and interactions with nature and technology. Argues that implicitly religious understandings of nature and technology are widespread in Western cultures. Begins with reflections on modernity and the disenchantment of the world, arguing against contemporary theorists who claim no such thing has occurred. Argues for a conscious reappropriation of sacral traditions and outlines the implications.

Thompson, Alison K., and Ruth F. Chadwick, eds. *Genetic Information: Acquisition, Access, and Control.* New York: Kluwer, 1999. Pp. xi, 335. Collects thirty essays arranged in five sections: eugenics, genetics and insurance, commercialization of genetic information, public awareness, and theoretical concerns.

Thompson, Paul B. *Agricultural Ethics: Research, Teaching, and Public Policy.* Ames: Iowa State University Press, 1998. Pp. xi, 239. Aims to provide an introduction to philosophical reflection on agriculture and food production by reflecting on food system issues with key concepts from ethics. Emphasizes the importance of technological change, ethical extensionism, and questions about the worth of the family farm. Organized in three sections: research, teaching, and public policy with a general introduction and conclusion.

Thompson, Paul B. *The Ethics of Aid and Trade: U.S. Food Policy, Foreign Competition, and the Social Contract*. New York: Cambridge University Press, 1992. Pp. x, 233. Explores the principles of U.S. agricultural policy and foreign aid, arguing that the traditional model of the nation-state should be replaced with the "trading state." Addresses protectionist challenges to foreign aid and development assistance in moral, economic, and political terms. Proposes a model of international relations with greater fluidity of material and intellectual exchange and creates a new interpretation of social contract theory that is geared to the goals of international trade and development policy.

Thomson, Norma, ed. *Instilling Ethics*. Lanham, MD: Rowman and Littlefield, 2000. Pp. xv, 239. Collects fourteen original articles arranged in three sections: sources of ethical reflection, modernity and the problems of ethical reflection, and instilling ethics today.

Valenstein, Elliot S. *Great and Desperate Cures: The Rise and Decline of Psychosurgery and Other Radical Treatments for Mental Illness*. New York: Basic Books, 1986. Pp. xiv, 338. Pursues the history of psychosurgery (e.g., lobotomy) as a cautionary tale, arguing that these procedures were very much a part of mainstream medicine and that the conditions that fostered their development are still active. Sets the tale in context with an opening chapter on the treatment of mental illness.

Verbeek, Peter-Paul. *What Things Do: Philosophical Reflections on Technology, Agency, and Design*. Robert P. Crease, trans. University Park: Pennsylvania State University Press, 2005. Pp. viii, 249. Develops an innovative approach to understanding the role of technological devices in lived experience and how they shape personality and society. Distinguishes analysis from classical philosophy of technology to develop an empirical, "postphenomenological" approach.

Wachs, Martin, ed. *Ethics in Planning*. New Brunswick, NJ: Center for Urban Policy Research, 1985. Pp., xxi, 372. The first compendium of works on ethics in planning. Collects a general introduction (with a fourfold taxonomy of ethical issues) and seventeen essays arranged in four sections: overview of ethical issues in urban planning and administration, corruption and whistle-blowing, ethical issues in policy making, and the emergence of an environmental ethics. Includes four appendices with relevant codes of ethics.

Walter, Jennifer K., and Eran P. Klein, eds. *The Story of Bioethics: From Seminal Works to Contemporary Explorations*. Washington, DC: Georgetown University Press, 2003. Pp. xv, 248.

Wilson, Edward O. *Consilience: The Unity of Knowledge*. New York: Alfred A. Knopf, 1998. Pp. 332. Seeks to develop a unification of knowledge according to the principles found in the natural sciences, especially sociobiology. Espouses a version of material reductionism and champions the Enlightenment ideals of objective knowledge, human progress, and the unity of truth.

Wilson, Edward O. *Sociobiology: The New Synthesis*. 25th Anniversary Edition. Cambridge, MA: Harvard University Press, 2000. Pp. xiii, 697. First published in 1975, established the field of sociobiology, also terms evolutionary psychology. For an overview of early controversies related to this topic, see Arthur L. Caplan, ed., *The Sociobiology Debate: Readings on the Ethical and Scientific Issues Concerning Sociobiology* (New York: Harper and Row, 1978).

4. Textbooks

Almond, Brenda, ed. *Introducing Applied Ethics*. Oxford: Blackwell, 1995. Includes more than twenty texts on family life, professional ethics, law, economics, and international relations. Little focus on science or technology.

Baum, Robert R., and Albert Flores, eds. *Ethical Problems in Engineering*. 2 vols. Troy, NY: Center for the Study of the Human Dimensions of Science and Technology, 1978. Although out of print, this remains a classic engineering ethics collection.

Beauchamp, Tom L., and James F. Childress. *Principles of Biomedical Ethics*. 5th ed. New York: Oxford University Press, 2001. Pp. xi, 454. One of the most influential textbooks in the bioethics field. The most developed use of principlism in bioethics, arranged in three parts that treat moral norms, character, and theories and outline the basic principles of respect for autonomy, nonmaleficence, beneficence, and justice as well as a chapter on professional-patient relationships.

Bowyer, Kevin W. *Ethics and Computing: Living Responsibly in a Computerized World*. Washington, DC: Institute of Electrical and Electronics Engineers (IEEE) Computer Society Press, 1996. Pp. xvi, 449. Examines issues central to computer ethics including hacking, privacy, computers in safety-critical systems, whistle blowing, intellectual property, environmental health, law, and equity. Includes case studies and exercises suitable for undergraduate courses.

Bulger, Ruth Ellen, Elizabeth Heitman, and Stanley Joel Reiser, eds. *The Ethical Dimensions of the Biological*

Sciences. New York: Cambridge University Press, 1993. Pp. xi, 294. Collects thirty-six articles including a general introduction addressed primarily to graduate students and faculty responsible for teaching ethics in science. Includes classic essays, seminal works, policy statements, and research guidelines that address such topics as the ethics of research and teaching, the qualifications for authorship, and the relationship of science, industry, and society. Each section includes questions for discussion.

Cheney, Darwin, ed. *Ethical Issues in Research*. Frederick, MD: University Publishing Group, 1993. Pp. xx, 237. Collects an overview and twenty-two chapters arranged in five parts: misrepresentation of data (U.S. and international perspectives), conflict of interest, research on human subjects, use of embryos and fetuses, and use of animals.

DesJardins, Joseph, eds. *Environmental Ethics: Concepts, Policy, and Theory*. London: Mayfield, 1999. Pp. xvi, 620. A broad overview with discussion and study questions following each of 18 chapters with classic essays arranged into four sections: context, basic concepts, policies and controversies, and philosophy and theory.

Edel, Abraham; Elizabeth Flower; and Finbarr W. O'Connor. *Critique of Applied Ethics: Reflections and Recommendations*. Philadelphia: Temple University Press, 1994. Pp. vi, 274. Surveys theories of applied ethics and argues that the stabilities of traditional morality must be combined with new knowledge to direct the rapid pace of techno-societal change. Divided into two sections: philosophical background and an analysis of practical problems. Conclusion emphasizes the importance of applying theories to complex and changing contexts.

Ermann, M. David, and Michele S. Shauf, eds. *Computers, Ethics, and Society*. 3rd ed. New York: Oxford University Press, 2003. Pp. vi, 249. Standard text covering ethical frameworks, personal decision making, politics, and professional responsibilities. First edition, 1990.

Erwin, Edward, Sidney Gendin, and Lowell Kleiman, eds. *Ethical Issues in Scientific Research: An Anthology*. New York, NY: Garland Publishing, 1994. Pp. xi, 413. Collects twenty-six essays in six sections: science and values, fraud and deception, human experimentation, animal research, genetics research, controversial research topics.

Elliott, Deni, and Judy E. Stern, eds. *Research Ethics: A Reader*. Hanover, NH: University Press of New England, 1997. Pp. xii, 319. A student reader with original and reprinted articles, essays, and case studies. Topics include teaching ethics, misconduct, conducting, reporting, and funding research, conflicts of interest, institutional responsibility, and animal and human experimentation.

Fleddermann, Charles B. *Engineering Ethics*. Upper Saddle River, NJ: Prentice Hall, 1999.

Gorman, Michael E., Matthew M. Mehallik, and Patricia Werhane. Ethical and Environmental Challenges to Engineering. Upper Saddle River, NJ: Prentice Hall, 2000.

Gunn, Alastair S., and P. Aarne Vesilind. *Hold Paramount: The Engineer's Responsibility to Society*. Pacific Grove, CA: Brooks/Cole, 2003. Pp. xiv, 160. Intended for use as a textbook. Includes cases studies, feature boxes, and discussion questions. Topics addressed include expertise and obligation, codes of ethics, terrorism, professional development, conflicts of interest, and much more.

Johnson, Deborah G., and Helen Nissenbaum, eds. *Computers, Ethics, and Social Values*. Upper Saddle River, NJ: Prentice Hall, 1995. Pp. vi, 714. Collects fifty-eight articles organized in seven chapters that seek to define and differentiate the field of computer ethics. Explores the significance of computers in terms of social values such as privacy, justice, democracy, and property. Examines computers in controversies involving traditional ethical notions such as crime, risk, and responsibility. Concludes with a look at the ethical issues of an increasingly networked information society.

Kaplan, David M., ed. *Readings in the Philosophy of Technology*. Lanham, MD: Rowman and Littlefield, 2004. Pp. xvi, 512Thirty-one readings, with sections on "Technology and Ethics," "Technology and Politics," and "Technology and Human Nature" most directly relevant.

Katz, Eric, Andrew Light, and William Thompson, eds. *Controlling Technology*. 2nd ed. Amherst, NY: Prometheus Books, 2003. Pp. 531. Thirty-four essays and a general introduction aimed at humanists, scientists, and engineers. Arranged to address fundamental issues at the intersection of technology and human values, especially democracy. Topics include human autonomy and freedom, the autonomy of technology, human equality, and respect for others. Arranged in eight parts including appropriate technology, technology, ethics, and politics, and computers, information, and virtual reality.

Light, Andrew, and Holmes Rolston III, eds. *Environmental Ethics: An Anthology*. Oxford: Blackwell Publishers, 2003. Pp. x, 554. Collects a general introduction and forty essays arranged in seven sections including definitions of environmental ethics, moral standing, the question of intrinsic value in nature, monism versus pluralism, and reframing environmental ethics. Includes a bibliographic essay by Clare Palmer that sketches the history and central issues of environmental ethics.

Loue, Sana. *Textbook of Research Ethics: Theory and Practice*. Dordrecht: Kluwer, 1999. Provides a brief history of human subjects research and reviews relevant ethical theories and principles. Refers to international documents and national policies and includes case studies and discussion exercises.

Macrina, Francis L. *Scientific Integrity: An Introductory Text with Cases*. Washington, DC: ASM Press, 1995. Pp. xxi, 283. Designed for students pursuing careers in biomedical research. Most chapters conclude with case studies and extended case studies are included in an appendix. Topics include use of animals, human experimentation, mentoring, authorship, ownership of data, and genetics.

Mappes, Thomas A., and David Degrazia. *Biomedical Ethics*. 5th ed. New York: McGraw Hill, 2000.

Martin, Mike W., and Roland Schinzinger. *Ethics in Engineering*. 4th ed. New York: McGraw-Hill, 2005. Pp. xi, 339. (1st ed., 1983.) This widely used text argues for conceiving of engineering as social experimentation and thus applies issues of informed consent to engineering practice. One of the earliest, most original, and widely used books in the field. See also Martin and Schinzinger's shorter version: *Introduction to Engineering Ethics* (Boston: McGraw-Hill, 2000).

Mitcham, Carl, and R. Shannon Duval. *Engineer's Toolkit: Engineering Ethics*. Upper Saddle River, NJ: Prentice Hall, 2000. Pp. x, 131. A short, elementary modular text.

Murphy, Timothy. *Case Studies in Biomedical Research Ethics*. Boston: MIT, 2004. Pp. xvii, 340. Intended as a text for instruction in biomedical research ethics. Collects over 100 case studies organized into nine topics including oversight and study design, informed consent, genetic research, and authorship and publication. Each topical area includes a general introduction and each case study includes study questions.

National Academy of Sciences, National Academy of Engineering, and Institute of Medicine. *On Being a Scientist: Responsible Conduct in Research*, 2nd ed. Washington, DC: National Academy Press, 1995. Pp. 27. Designed to stimulate group discussion, primarily in classrooms. Traces the history of thought about research ethics through brief considerations of several topics including the social foundations of science, data, values in science, conflicts of interest, openness, misconduct, and authorship.

Penslar, Robin Levin, ed. *Research Ethics: Cases and Materials*. Bloomington: Indiana University Press, 1995. Pp. xvi, 278. A collection of case studies designed to aid faculty in raising and discussing ethically problematic aspects of conducting research. Arranged in three main sections that cover cases in biology, psychology, and history. Includes a general introduction to research ethics and ethical theory.

Scharff, Robert C., and Val Dusek, eds. *Philosophy of Technology: The Technological Condition: An Anthology*. Malden, MA: Blackwell, 2003. Pp. xi, 686. Fifty-five readings. Parts V, Technology and Human Ends," and VI, "Technology as Social Practice," constitute half the volume.

Schinzinger, Roland, and Mike W. Martin. *Introduction to Engineering Ethics*. 3rd ed. Boston: McGraw Hill, 2000. Pp. xi, 260. (1st ed. : 2nd ed.) Clarifies key concepts and provides case studies in the basic issues of engineering ethics, with an emphasis on the moral problems faced by engineers in the corporate setting. Includes an appendix with codes of engineering ethics from seven professional societies.

Seebauer, Edmund G., and Robert L. Barry. *Fundamentals of Ethics for Scientists and Engineers*. New York, NY: Oxford University Press, 2001. Pp. xvi, 269. An approach to education in technical ethics that develops a progressive "ethical serial" case study approach and highlights virtue theory. The first half focuses on ethical reasoning and the second half on applications. Organized in four units: foundational principles, resolving ethical conflicts, justice, and advanced topics (e.g., risk, resource allocation, and habit and intuition).

Sherlock, Richard, and John D. Morrey, eds. *Ethical Issues in Biotechnology*. Lanham, MD: Rowman and Littlefield, 2002. Pp. xiii, 643. Intended for use as a text book. Collects thirty-four essays arranged in six sections: fundamental issues, agricultural biotechnology, food biotechnology, animal biotechnology, human genetic testing and therapy, and human cloning and stem cell research. Includes overviews of basic ethics and science and concludes with study cases designed to spark classroom discussion.

Stern, Judy E. and Deni Elliot. *The Ethics of Scientific Research: A Guidebook for Course Development*. Hanover, NH: University Press of New England, 1997. Pp. x, 116. Result of a three-year project to produce a graduate level course in research ethics. Outlines course goals

and plan and discusses how to train faculty to teach ethics and how to evaluate efforts. Concludes with a course reading list and extended case and topic bibliographies as well as a videography.

Tavani, Herman T. *Ethics and Technology: Ethical Issues in an Age of Information and Communication Technology*. New York: John Wiley and Sons, 2003. Pp. xxiv, 344. Introduces the relatively new field of Cyberethics. Discusses key concepts and terms, includes actual and hypothetical case studies, and provides review questions at the end of each chapter.

Unger, Stephen H. *Controlling Technology: Ethics and the Responsible Engineer*. 2nd ed. New York: John Wiley, 1994. Pp. xiv, 353. Argues that the democratic control of technology requires engineers to take responsibility for the consequences of their work. Includes case studies on successful and unsuccessful instances of engineering ethics, codes of ethics for engineers, the role of engineering societies in ethics, and engineering and law.

Veatch, Robert. *The Basics of Bioethics*. 2nd. ed. Upper Saddle River, NJ: Prentice Hall, 2003. Pp. xvii, 205. A brief survey that gives a broad introduction to the field. Covers the basics of ethics, Hippocratic oath, moral standing, patient rights, death and dying, social ethics (e.g., allocation of resources and human subjects research), human control of life and human nature, conflicts among principles, and a new chapter on the virtues (professional, secular, religious, and care) in bioethics.

Vesilind, P. Aarne, and Alastair S. Gunn. *Engineering, Ethics, and the Environment*. New York: Cambridge University Press, 1998.

Zimmerman, Michael E., J. Baird Callicot, George Sessions, Karen J. Warren, and John Clark, eds. *Environmental Philosophy: From Animal Rights to Radical Ecology*. 3rd edition. Upper Saddle River, NJ: Prentice-Hall, 2001. Pp. ix, 486. Collects thirty-two essays in four sections: environmental ethics, deep ecology, ecofeminism, and political ecology. Includes a brief general introduction that places environmental philosophy in historical and conceptual context. First edition, 1993.

5. Twentieth and Twenty-First Century Ethics

Baier, Kurt. *The Moral Point of View: A Rational Basis of Ethics*. Ithaca, NY: Cornell University Press, 1958. Pp. xii, 326. Argues that the distinctly moral perspective is the universalizability of rules and judgments.

Bauman, Zygmunt. *Postmodern Ethics*. Oxford: Blackwell, 1993. Pp. vi, 255. A sociologist's overview the postmodern rejection of the adequacy in ethics of rules, universality, and foundations, and the loss of the sense of self, with a brief statement of the positive possibilities opened by such a stance.

Broad, C.D. *Five Types of Ethical Theory*. London: Routledge and Kegan Paul, 1930. Pp. xxv, 288. An analytic assessment of the ethical theories of Spinoza, Joseph Butler, David Hume, Immanuel Kant, and Henry Sidgwick.

Dewey, John. *Human Nature and Conduct: An Introduction to Social Psychology*. New York: Henry Holt, 1922. Pp. vii, 336. Proposes a pragmatist ethics grounded in psychology. For two other statements of Dewey's pragmatist ethics, see *Ethics* (1908) with James Tufts and *Theory of Valuation* (1939).

Frankena, William K. *Ethics*. Second edition. Englewood Cliffs, NJ: Prentice Hall, 1973. Pp. xvi, 125. (First edition, 1963.) A widely used and influential textbook that defends a version of rule utilitarianism, that is, the moral theory that takes as foundational assessments of the consequences of rules for guiding human behavior. Gives fair consideration to both egoistic and deontological theories, but finds them wanting. No particular effort to consider science or technology, although rule utilitarianism is often the assumed justification for each.

Habermas, Jürgen. *The Theory of Communicative Action*. 2 vols. Trans. Thomas McCarthy. Boston: Beacon Press. 1984-1987.

Hare, R.M. *The Language of Morals*, 2nd ed. Oxford: Clarendon Press, 1961. Pp. viii, 2002. (First edition, 1952.) The single most influential book in meta-ethics. Concerned not with normative issues so much as the nature and function of moral discourse.

Jonsen, Albert R., and Stephen Toulmin. *The Abuse of Casuistry: A History of Moral Reasoning*. Berkeley: University of California Press, 1988. Pp. ix, 420. The title is misleading; this book is in fact a defense of casuistry against those who would too quickly abuse it in the name of principlist ethics. Grew out of the experience of the coauthors working with the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, 1974-1978.

Kohlberg, Lawrence. *Essays on Moral Development*, vol. 1: *The Philosophy of Moral Development: Moral Stages and the Idea of Justice*. New York: Harper and Row, 1981. Pp. xxxv, 441. Collected papers providing the most complete statement of Kohlberg's influential theory (building on the work of Jean Piaget but based as well on his own empirical observations). Continued with vol. 2, *The Psychology of Moral Development: Moral*

Stages and the Life Cycle, and vol. 3, *Education and Moral Development: Moral Stages and Practice*.

Levinas, Emmanuel. *Totality and Infinity*. Trans. Alphonso Lingis. The Hague: Martinus Nijhoff, 1969. Pp. 307. (French original, 1961.) See also Adriaan T. Peperzak, ed., *Ethics as First Philosophy: The Significance of Emmanuel Levinas for Philosophy, Literature, and Religion* (New York: Routledge, 1995), which collects 21 original essays on Levinas' thought.

MacIntyre, Alasdair. *After Virtue: A Study in Moral Theory*. Second ed. Notre Dame, IN: University of Notre Dame Press, 1984. Pp. xi, 286. (First edition, 1981.) Three subsequent books in which MacIntyre extends his argument: *Whose Justice? Which Rationality?* (Notre Dame, IN: University of Notre Dame Press, 1988), *Three Rival Versions of Moral Enquiry: Encyclopedia, Genealogy, and Tradition* (Notre Dame, IN: University of Notre Dame Press, 1990), and *Dependent Rational Animals: Why Human Beings Need the Virtues* (1999).

Maritain, Jacques. *Integral Humanism: Temporal and Spiritual Problems of a New Christendom*. Trans. Joseph W. Evans. New York: Scribners, 1968. Pp. xii, 308. (French original, 1936.) An effort by one of the founders of Neothomism to develop a humanistic ethics that engages the modern world and responds to both liberalism and Marxism. No direct discussion of science and technology. Subsequent related efforts to restate the Thomistic perspective can be found in Yves R. Simon, *The Definition of Moral Virtue*, ed. Vukan Kuic (New York: Fordham University Press, 1986); and Ralph McInerny, *Ethica Thomistica: The Moral Philosophy of Thomas Aquinas*, revised edition (Washington, DC: Catholic University of America Press, 1997).

Moore, G.E. *Principia Ethica*. Cambridge, UK: Cambridge University Press, 1903. Pp. xxvii, 232. Although published during the first decade of the 20th century this book has exercised a strong influence over Anglo-American analytic ethics (comparable to the influence of Nietzsche's *On the Genealogy of Morals* on continental European phenomenological ethics). Argues that good is a unique, indefinable property that is directly intuited and for which nothing else can be substituted. It formulates in precise terms the so-called "naturalistic fallacy" (of identifying the good with the natural) and argues against naturalistic ethics, hedonism (meaning consequentialism), and metaphysical ethics (meaning the philosophy of Immanuel Kant). The long chapter five, "Ethics in Relation to Conduct," sets forth a program in practical ethics that anticipates applied ethics. The final chapter six, "The Ideal," distinguishes intrinsic goods in themselves, which Moore argues are exemplified in aesthetic enjoyments and personal affection, from extrinsic goods. Moore restates his argument in more textbook form in *Ethics* (London: Oxford University Press, 1912).

Münch, Richard. *The Ethics of Modernity: Formation and Transformation in Britain, France, Germany and the United States*. Lanham, MD: Rowman & Littlefield Publishers, Inc., 2001. Pp. xii, 281. A comparative interpretation of the common impulse of the transformation to modernism and its different expressions in four Western countries. Begins with an assessment of the West compared to the East and traces the formation of ethics through modern secularized and globalizing culture. Describes modern ethics as "instrumental activism," or the refusal to take the world as it is but rather to plan and intervene in it according to ideals. This creates a second world that is unpredictable and often brings unintended side effects that in turn call for more instrumental activism, or control.

Nietzsche, Friedrich. *Zur Genealogie der Moral* [On the genealogy of morals]. 1887. Although published in the last third of the nineteenth century, this book has exercised a strong influence over continental European phenomenological ethics (comparable to the influence of Moore's *Principia Ethica* on Anglo-American analytic ethics). Aiming to clarify his previous book, *Beyond Good and Evil* (1886), this volume, subtitled "A Polemic," is composed of three essays. The first distinguishes between moralities that has their origins in ruling classes (and distinguish between good and bad) and those formulated by the oppressed (who oppose good and evil). The second focuses on explicating the origins of guilt and bad conscience. The third criticizes ascetic ideals.

Ross, W.D. *The Right and the Good*. Oxford: Clarendon Press, 1930. Pp. vii, 176. Attempts to bridge deontological theories of the right and utilitarian theories of the good. Prima facie rights can on occasion be outweighed by anticipated bad consequences.

Scheler, Max. *Formalism in Ethics and Non-Formal Ethics of Values: A New Attempt toward the Foundation of an Ethical Personalism*. Trans. Manfred S. Frings and Roger L. Funk. Evanston, IL: Northwestern University Press, 1973. (Original German, 1913-1916.) Influential approach to ethics in the continental European phenomenological tradition. Criticizes Kantian formalism and defends the person as a source of substantive values, which range from sensible through vital and spiritual to the holy. For one subsequent statement of this approach emphasizing compassion as foundational for ethics see Werner Marx, *Towards a Phenomenological Ethics: Ethos and the Life-World* (Albany: State University of New York Press, 1992).

Scott, Charles E. *The Question of Ethics: Nietzsche, Foucault, Heidegger*. Bloomington: Indiana University Press, 1990. Pp. xii, 225. Argues that Nietzsche's questioning of ethics as a pathology is a fundamental part of ethics, an argument that he deepens with interpretations of Foucault and the problem of Heidegger's Nazism. Scott's thesis is that strong ethical commitments can create their own unethical behaviors, and that the questioning of ethics can (and must) be done on ethical not rejection of ethical grounds. Modest mentions of both science and technology. The argument is extended in Scott's *On the Advantages and Disadvantages of Ethics and Politics* (Bloomington: Indiana University Press, 1996), which includes more extended discussions of the ethical challenge of technology.

Toulmin, Stephen. *An Examination of the Place of Reason in Ethics*. Cambridge, UK: Cambridge University Press, 1950. Pp. xiv, 228. An attempt to develop a theory of moral reasoning in the analytic tradition that is perhaps the first instance to take explicit account of engineering and technology; see section 12.5, "Ethics and Engineering." Toulmin subsequently argues that attention to practical issues actually rescued ethics from abstraction in such articles as "The Recovery of Practical Philosophy," *American Scholar* 57, no. 3 (Summer 1971), pp. 337-352; and "How Medicine Saved the Life of Ethics," *Perspectives in Biology and Medicine* 25, no. 4 (Summer 1982), pp. 736-750. See also Toulmin's criticism of Enlightenment ethical rationalism in *Cosmopolis: The Hidden Agenda of Modernity* (New York: Free Press, 1990).

Williams, Bernard. *Ethics and the Limits of Philosophy*. Cambridge, MA: Harvard University Press, 1985. Pp. xiv, 230. An extended assessment of the limitations of modern ethics as "too much and too unknowingly caught up in ... administrative ideas of rationality" (p. 197). Argues that ethics needs to recover some of the resources of classical Greek philosophy while taking into account scientific knowledge in order to respond to the Socratic question of how one should live by making possible the pursuit of a meaningful life.

6. Journals

Bioethics, Publication of the International Association of Bioethics.

Bulletin of Science, Technology, and Society. Has been associated with the National Association for Science, Technology, and Society.

Environmental Ethics. Publication of the International Society for Environmental Ethics (ISEE).

Environmental Philosophy. Publication of the International Association for Environmental Philosophy (IAEP), University of North Texas.

Environmental Science and Policy. Published by Elsevier.

Ethics and Information Technology. Published by Kluwer.

Hastings Center Report. Publication of the Hastings Center.

IEEE Technology and Society Magazine. Publication of the Society on Social Implications of Technology of the Institute of Electrical and Electronics Engineers.

Philosophy and Public Affairs. Published by Blackwell-Synergy.

Philosophy and Public Policy Quarterly. Publication of The Institute for Philosophy and Public Policy, University of Maryland.

Science and Engineering Ethics. Published by Opragen.

Science and Public Policy. Published by Beechtree.

Science, Technology, and Human Values. Publication of the Society for Social Studies of Science (4S).

Techne: Research in Philosophy and Technology. An electronic journal published by the Society for Philosophy and Technology (SPT).

Technology and Culture. Publication of the Society for the History of Technology (SHOT).

Technology in Society. Published by Elsevier.

The American Journal of Bioethics. Publication of The American Journal of Bioethics at bioethics.net.

The New Atlantis. Publication of The Ethics and Public Policy Center.

COMPILED BY ADAM BRIGGLE AND CARL MITCHAM

APPENDIX II

INTERNET RESOURCES ON SCIENCE, TECHNOLOGY, AND ETHICS

This listing of Internet Resources reflects the fact that science, technology, and ethics discussions tend to be divided according to scholarly communities, as summarized in the specialized introduction entries of the encyclopedia.

General

American Association for the Advancement of Science: http://www.aaas.org/. An international non-profit organization founded in 1848 to advance science and innovation, also publishes the journal Science. Site includes news, publications, career information, and statistics on indicators in research and development. It features several programs, including the "Dialogue on Science, Ethics and Religion" at http://www.aaas.org/spp/dser/.

Carnegie Council on Ethics and International Affairs: http://www.cceia.org/index.php. Contains publications and links. In-depth sections include environment, armed conflict, human rights, and global justice. Features an electronic forum for discussion.

Case Western Reserve Online Ethics Center for Engineering and Science: http://onlineethics.org/. Created with an NSF grant and geared to engineers, scientists, and students. Focuses on engineering and research ethics, diversity, and issues in computer and natural sciences. Features numerous case studies, original materials, links, and an extensive collection of codes of ethics.

European Group on Ethics in Science and New Technologies: http://europa.eu.int/comm/european_group_ethics/index_en.htm. Established in 1997 to advise the European Commission. Features its opinions on diverse subjects, publications, and links.

Institute for Global Ethics: http://www.globalethics.org/default.html. Promotes ethics at several levels through research, dialogue, and action. Provides educational program materials and organizational services. Features white papers and other publications.

Kurzweil AI: http://www.kurzweilai.net/index.html?flash=2. Non-flash version available at http://www.kurzweilai.net/index.html?flash=1. Investigates the accelerating growth of intelligence and knowledge and the growing intersection of various fields of research and technology and their impacts on society. Site includes news, publications, and editorials. Also features Ramona, a photorealistic avatar host, and an innovative networked presentation of information.

Loyola University Center for Ethics and Social Justice: http://www.luc.edu/ethics/. Founded in 1991, provides ethics education to individuals and organizations.

Sigma Xi, The Scientific Research Society: http://www.sigmaxi.org/. A chapter-based organization that promotes the health of the scientific enterprise, supports original research, honors scientific achievement, and publishes the journal *American Scientist*. Site features links to local chapters, information on meetings and events, publications, programs, and news, as well as the booklet "The Responsible Researcher," which supplements "Honor in Science."

UNESCO World Commission on the Ethics of Scientific Knowledge and Technology (COMEST): http://portal.unesco.org/shs/en/ev.php-URL_ID=6193&URL_DO=DO_TOPIC&URL_SECTION=201.html. Created in 1997 to mirror at the international level, national commissions on science, technology, and ethics. Site has information on its functions and full publications.

Agricultural Ethics

Food-Ethics.net: http://food-ethics.net/. A European Union project begun in 2003 that serves as a subject information gateway for professionals to facilitate access to high quality information on ethical principles of food and ethical traceability.

The Food Ethics Council: http://www.foodethics-council.org/index.html. Founded in 1998 to address a broad spectrum of issues from the use of antibiotics to intellectual property. Site includes publications, news, and project information.

Applied Ethics

Ethics Updates: http://ethics.acusd.edu/. Founded in 1994 and edited by Lawrence Hinman at University of San Diego. Site has diverse resources including videos, bibliographic essays, publications, and links arranged in three main groups; ethical theory, resources, and applied ethics.

EthicsWeb.ca: http://www.ethicsweb.ca/resources/. Developed as part of the W. Maurice Young Center. Includes information on topics, institutions, and publications in several areas including business, health care, research, and environmental ethics and resources on ethics in decision making.

Harvard Edmond J. Safra Foundation Center for Ethics: http://www.ethics.harvard.edu/. Features publications, information on ethics in the curriculum, and links to other institutions.

Santa Clara University Center for Applied Ethics: http://www.scu.edu/ethics/. Established in 1986 and has information on diverse subjects including biotechnology and healthcare ethics, business ethics, and government ethics. Also features perspectives on recent events, publications, and links.

University of British Columbia W. Maurice Young Center for Applied Ethics: http://www.ethics.ubc.ca/. Created in 1993 to study, train, and consult in a diverse range of applied ethics topics. Site includes working papers and other publications, information on trainings and courses, and news.

Bioethics

American Journal of Bioethics: http://www.bioethics.net/. Founded in 1993 and the most read source of information on bioethics. Site contains news, editorials, essays, and a discussion forum.

American Society for Bioethics and the Humanities: http://www.asbh.org/index.htm. A professional association founded in 1998 to provide research, teaching, and policy development in bioethics. Site features publications and links for members and non-members.

Bioethics: http://www.web-miner.com/bioethics.htm. A comprehensive site operated by Sharon Stoerger with annotated links to academic centers, government agencies, publications, and other resources.

Bioethics.com: http://bioethics.com/. Features news, commentaries, and links in nine categories including stem cell research, research ethics, and health care.

The Center for Bioethics and Human Dignity: http://www.cbhd.org/. A Christian organization founded in 1994. Site contains news, articles, and a topical listing of bioethics issues, each with a bibliography.

Council of Europe Bioethics Division: http://www.coe.int/T/E/Legal_affairs/Legal_co-operation/Bioethics/. Includes information on legal conventions and protocols as well as research projects.

The Hastings Center: http://www.thehastingscenter.org/. Research institute founded in 1969 to study issues in biotechnology, health care, and the environment. Site includes news, research projects, publications, and a library.

Human Genome Project Ethical, Legal, and, Social Issues (ELSI): http://www.ornl.gov/sci/techresources/Human_Genome/elsi/elsi.shtml. Contains information on societal implications of genetic research, including links and articles on gene testing, gene therapy, privacy, patenting, forensics, courts, and behavior.

International Association of Bioethics: http://www.bioethics-international.org/. Focuses on networking and cross-cultural issues in bioethics and publishes two journals.

International Society of Bioethics: http://www.sibi.org/ingles/home2.htm. Spanish organization founded in 1996. Site features links and a focus on Latin American bioethics.

President's Council on Bioethics: www.bioethics.gov. Homepage for the U.S. federal bioethics panel created by George W. Bush in 2001. Site contains numerous publications, full texts of transcripts and meetings, and several other resources and links arranged topically.

UNESCO Bioethics Programme: http://portal.unesco.org/shs/en/ev.php-URL_ID=1372&URL_DO=DO_TOPIC&URL_SECTION=201.html. Primarily responsible for the Secretariat of two advisory bodies: International Bioethics Committee and Intergovernmental Bioethics Committee. Site links to these bodies and contains general information.

Biotechethics

Biotechnology Watch: http://www.infoshop.org/biotechwatch.html. An activist organization skeptical of biotechnology applications that is part of the Alternative Media Project. Site contains news, links, and information on direct action campaigns.

Ethics for the Biotech Industry: http://www.biotechethics.ca/. A program of academic research that views biotechnology through business and professional ethics. Site contains resources and publications.

Ford Foundation Program on Biotechnology, Religion, and Ethics: http://cohesion.rice.edu/centersandinst/bioreliethics/fordgrant.cfm?doc_id=2378. An expired four-year project on religion and biotechnology. Site has contact information for researchers involved.

Transhuman.com: http://www.transhuman.com/. A pro-biotechnology group advocating for the use of biotechnology to overcome human limitations. Site contains a book store and resources on transhumanism.

Business Ethics

Better Business Bureau: http://www.bbb.org/. Founded in 1912 to solve marketplace problems through self-regulation and consumer education. Site contains news, resources, and connections to local BBB organizations.

Business and Human Rights Resource Centre: http://www.business-humanrights.org/Home. Promotes awareness and discussion on issues involving business and human rights, including resources, news, reports of corporate misconduct, and examples of best practice. Features an in-depth library arranged topically, including information on individual companies and laws.

Business Ethics: http://www.web-miner.com/busethics.htm. Site operated by Sharon Stoerger that contains annotated links to publications, professional societies, case studies, resources, centers, and more.

Business Ethics Magazine: http://www.business-ethics.com/. Homepage for the magazine. Site contains information on events and an extensive business ethics directory with contact information for various organizations.

Business for Social Responsibility: http://www.bsr.org/. Non-profit organization that provides information, tools, training and advisory services to make corporate social responsibility an integral part of business operations and strategies. Site contains information on advisory services, news, links, and reports.

European Business Ethics Network: http://www.eben.org/. An international collaboration dedicated to the promotion of business ethics. Site contains in-house information and external links.

Global Ethics: http://www.ethics.org/i_centers.html. Supports local groups in establishing ethics initiatives. Site features products, resources, and research on organizational ethics, character development, and ethics centers worldwide.

Institute of Business Ethics: http://www.ibe.org.uk/home.html. Founded in 1986 to promote ethical standards and share information. Site includes publications, events, training, news, information on how to create and implement codes of conduct, and resources on teaching business ethics.

International Business Ethics Institute: http://www.business-ethics.org/about.asp. Founded in 1994 to promote business ethics and corporate responsibility through public awareness, education, and fostering international business ethics organizations in companies. Site contains resources on education and professional services and publications.

Communication Ethics

Communication Ethics Limited: http://www.communication-ethics.com/. A consultancy-network and partner of the Institute of Communication Ethics. Site includes information on social justice, information integrity, and more.

Institute of Communication Ethics: http://www.communication-ethics.org.uk/. Offers education, research, and training in communication ethics. Site provides information for members, link to its journal *Ethical Space*, and information on events.

Computer Ethics

Computer Ethics: http://library.thinkquest.org/26658/. Provides basic understanding of ethical issues for internet users. Main portion has introduction to computer ethics, copyrights and licensing information, privacy issues, and censorship information. Users can submit content and create individual accounts. Has news, links, references, and information for teachers.

Ethics in Computing: http://ethics.csc.ncsu.edu/. Arranged topographically by speech issues, commerce, risks, privacy, computer abuse, social justice, intellectual property and basics. Each section has extensive information, links, references, and/or case studies.

The Research Center on Computing and Society: http://www.southernct.edu/organizations/rccs/index.html. Hosted by Southern Connecticut State University.

Features news, links, and resources for researchers, teachers, and students. Contains supplementary materials to be used with a computer ethics textbook.

Development Ethics

Development Studies Association: http://www.devstud.org.uk/studygroups/ethics.htm. Based in and Ireland and the U.K. to promote ethics and knowledge of international development. Site organized by working group topics including development ethics, women in development, sustainability, and information technology and development.

International Development Ethics Association: http://www.development-ethics.org/. Multi-disciplinary, cross-cultural group studying the ethics of global development. Site contains newsletter, links, and information on conferences and other events.

Engineering Ethics

Case Western Reserve Online Ethics Center for Engineering and Science: http://onlineethics.org/. Operating under an NSF grant and geared to engineers, scientists, and students. Focus on engineering and research ethics, diversity, and issues in computer and natural sciences. Features numerous case studies, original materials, links, and an extensive collection of codes of ethics.

National Institute for Engineering Ethics: http://www.niee.org/pd.cfm?pt=NIEE. Founded in 2001 as part of Texas Tech University. Site contains newsletter, links, educational resources, and products and services.

National Society of Professional Engineers: http://www.nspe.org/home.asp. Founded in 1934 and serves over 50,000 members. Site contains information on licensure, ethics, and law, products and services, educational materials, employment opportunities, a journal, links, information on events and conferences, and more.

Texas Tech University Engineering Ethics: http://www.niee.org/. Central hub that links three sites: Applied Ethics in Professional Practice (featuring the case of the month program), National Institute for Engineering Ethics, and the Murdough Center for Engineering Professionalism. Also features events, correspondence courses, videos and other resources, and ethics case studies.

University of Virginia Engineering Ethics: http://repo-nt.tcc.virginia.edu/ethics/. Disseminates engineering ethics cases studies and resources for students and faculties. Access to full case studies requires authorization from the University of Virginia.

Environmental Ethics

Environmental Protection Agency, Office of Environmental Justice: http://www.epa.gov/compliance/resources/ej.html. Features a frequently asked question section, newsletters and listservs, reports, publications, and information on policy and guiding documents.

Institute for Environment, Philosophy, and Public Policy: http://www.lancs.ac.uk/fss/ieppp/. Multi-disciplinary research group founded in 2000 at Lancaster University. Site contains news and events, information for current and prospective students, and research updates.

International Association for Environmental Philosophy: http://www.environmentalphilosophy.org/. Multi-disciplinary group studying broad range of topics in environmental philosophy. Site features news, newsletter, resources, links, and information on membership and events.

International Society for Environmental Ethics: http://www.cep.unt.edu/ISEE.html. Group founded in 1990 as the first major professional environmental ethics organization. Site features a listserv, newsletter, bibliography, selected books and articles, a syllabus project, and links.

University of North Texas Environmental Ethics: http://www.cep.unt.edu/. Features information on books, journals, educational and professional opportunities, links, news, and events.

Genethics

Genethics.ca: http://genethics.ca/index.html. A clearinghouse for social, ethical, and legal issues related to genomic knowledge and technology. Features topics (eugenics, patenting, DNA banking, gene therapy, GMOs, and many more), news, journals, conferences, and links to discussion forums.

Center for Economic and Social Aspects of Genomics: http://www.cesagen.lancs.ac.uk/. Based at the Universities of Lancaster and Cardiff to study the economic, social, and ethical implications of genomic research. Site features research projects, resources, newsletter, and events.

Information Ethics

Information Ethics, Inc.: http://www.info-ethics.com/. Contains resources, links, publications, and focuses on the ethics of software development. Links to a service branch that consults and trains clients.

International Center for Information Ethics: http://icie.zkm.de/. Platform for exchanging information on worldwide teaching and research. Features news, articles, links to institutions in the field, teaching resources, and publications.

Journalism Ethics

European Codes of Journalism Ethics: http://www.uta.fi/ethicnet/. A comprehensive databank offering resources for students, teachers, scholars, and practitioners. Arranged by links to thirty-five European countries (and the International Federation of Journalists) with contact information and codes of journalism ethics for each. Also features supplementary links.

Indiana University Journalism Ethics Cases Online: http://www.journalism.indiana.edu/Ethics/. Collects an extensive list of case studies in thirteen topical areas (including privacy, sensitive news topics, and workplace issues) to be used for students, teachers, practitioners, and media consumers.

Journalism Ethics: http://www.web-miner.com/journethics.htm. A comprehensive site operated by Sharon Stoerger with annotated links to articles, centers, and professional organizations. Many of the article links are broken.

Poynter Online Ethics: http://www.poynter.org/subject.asp?id=32. Includes columns, discussion, case studies and an extensive archive of ethics related stories. Also contains credibility and ethics bibliographies, codes of ethics, and ethics guidelines for publishing featuring seven core values.

Medical Ethics

American College of Physicians Center for Ethics and Professionalism: http://www.acponline.org/ethics/. Devoted to policy development and implementation. Features resources on end-of-life care, managed care ethics, and many other areas. Provides career related information, resources for students, advice for advocates, and services for various practitioners.

American Medical Association, Medical Ethics: http://www.ama-assn.org/ama/pub/category/2416.html. Arranged into eight areas that feature different aspects of AMA work in medical ethics. These include an interactive forum for analysis and discussion, an ethics working group, an effort to develop health care performance measures for ethics, and strategies for teaching and evaluating professionalism.

BMC Medical Ethics: http://www.biomedcentral.com/bmcmedethics/. An open access, peer-reviewed journal that considers articles on the ethics of medical research and practice.

Public Responsibility in Medicine and Research: http://www.primr.org/. Established in 1974 to implement ethical standards in research. Cite contains educational materials, resources, events, and information on certification of IRB professionals.

Stanford Center for Biomedical Ethics: http://scbe.stanford.edu/. Conducts interdisciplinary research and education in biomedical ethics and provides clinical and research ethics consultation. Site features news, events, job opportunities, newsletter, educational materials, and other resources.

Military Ethics

Joint Services Conference on Professional Ethics: http://www.usafa.af.mil/jscope/. An organization of military professionals, academics, and others formed to discuss ethical issues relevant to the military. Site made possible by the U.S. Air Force Academy and features general information, case studies, bibliography, core values of each military branch and links to past conferences.

Naval Academy Center for the Study of Professional Military Ethics: http://www.usna.edu/Ethics/. Formed in 1998 to promote ethical advancement of military leaders through research and education. Site contains events, publications, news, and links.

Nanoethics

Foresight Institute: http://www.foresight.org/. A member of the Foresight family of institutions formed to help society prepare for nanotechnology and other advanced technologies of the future. Site features news, events, quarterly newsletter, discussion, and information on research, public policy, and career opportunities.

Nanoscience and Technology Studies Societal and Ethical Implications: http://www.cla.sc.edu/cpecs/nirt/mission.html. Founded in 2001 at the University of South Carolina to research the ethical, legal, and social implications of nanotechnology. Site includes research, education, outreach, papers and other publications, links, and information on events and grants.

Nanotechnology Now: http://www.nanotech-now.com/. An up-to-the-minute news service on nanotechnology developments geared primarily for those in research and industry. Includes links to a consulting service and technology transfer and patenting service.

National Nanotechnology Initiative (NNI) Societal and Environmental Implications: http://www.nano.-gov/html/facts/society.html. A multi-agency U.S. federal research and development project, part of which is devoted to the ethical, social, environmental, and legal implications of nanotechnology. Site contains links on societal and environmental implications for researchers and educational resources.

Neuroethics

Center for Cognitive Liberty and Ethics: http://www.cognitiveliberty.org/mission.html. A network of scholars promoting freedom of thought through research and advocacy based on core principles of privacy, autonomy, and choice. Site contains news, publications, and resources arranged topically.

Nuclear Ethics

Alsos Digital Library for Nuclear Issues: http://alsos.wlu.edu/. Named after the original Alsos Missions (1944-1945) that followed in the wake of Allied Armies in Europe to investigate the extent to which Nazi Germany was working on developing at atomic bomb. Includes a broad range of annotated references for the study of nuclear issues. This searchable collection includes books, articles, films, CD-ROMs, and websites.

Bulletin of the Atomic Scientists: http://www.thebulletin.org/index.html. Founded in 1945 and educates citizens on national security issues, especially nuclear and other weapons of mass destruction. Site features extensive data on nuclear weapons capabilities around the globe, news, articles, links, current and past issues of the journal, and the doomsday clock.

Planning Ethics

American Planning Association: http://www.planning.org/. Includes information on ethics for professional planners including legislation and policy, careers, news, publications, research, conferences, consultant services, and information on creating local communities.

Professional Ethics

Illinois Institute of Technology Center for the Study of Ethics in the Professions: http://www.iit.edu/departments/csep/. Founded in 1976 to promote education and scholarship on professional ethics. Site features a library, codes of ethics, publications, and links.

Research Ethics

Central Office for Research Ethics Committees: http://www.corec.org.uk/. Organized for three main user groups: patients and the public, research ethics committee community, and applicants. Each section contains news, links, and information about and updates to relevant rules.

Office of Research Integrity: http://ori.dhhs.gov/. Oversees and directs Public Health Service (PHS) research integrity activities and promotes integrity in biomedical and behavioral research. Site contains information on policies, protocols for handling misconduct, links to related international organizations, educational materials, and conference and events announcements.

On Being a Scientist: Responsible Conduct in Research: http://www.nap.edu/readingroom/books/obas/. An on-line booklet published by the National Academy Press in 1994. Chapters span the spectrum from broad considerations such as "Values in Science" to narrower topics such as "The Allocation of Credit."

Plagiarism: http://www.web-miner.com/plagiarism.htm. A comprehensive site operated by Sharon Stoerger with annotated links to articles and resources for instructors and students.

Research Ethics: http://www.web-miner.com/researchethics.htm. A comprehensive site operated by Sharon Stoerger with annotated links to articles, case studies, policies and guidelines, and centers.

Rhetoric of Science and Technology

American Association for the Rhetoric of Science and Technology: http://aarst.jmccw.org/. Founded in 1992. Site features news, discussion forum, merchandise, pedagogical materials, links to similar organizations, and information on conferences and events.

Science and Technology Policy

American Association for the Advancement of Science: Science and Policy: http://www.aaas.org/programs/science_policy/. The Directorate of Science and Policy Programs operates eight programs at the interface of science, government, and society. Site links to these programs: ethics, and religion; fellowships; science, technology, and congress; research and development budget analysis; science, technology, and security policy; research competitiveness; scientific freedom and responsibility; and science and human rights.

Consortium for Science, Policy and Outcomes: http://www.cspo.org/. An intellectual network aimed at enhancing the contribution of science and technology to societal goals such as freedom, equality, and quality of life. Site features news, editorials, projects, education and outreach materials, and a library.

Ethics and Public Policy Center: http://www.eppc.org/about/. Established in 1976 to clarify and reinforce the bond between the Judeo-Christian moral tradition and the public debate over domestic and foreign policy issues. Site contains news, updates, publications, conferences, and events.

European Scientific and Technological Options Assessment: http://www.europarl.eu.int/stoa/default_en.htm. Provides independent assessments of the science and technology components of policy options faced by the European Parliament. Site contains newsletter, publication, work plans, workshops, and links to relevant network of experts.

Humanities/Policy: http://humanitiespolicy.unt.edu/. Network of scholars developing interdisciplinary approaches to integrating ethics and values with science to better meet societal goals. Site features information on policy, the humanities, projects, and resources for scientists and engineers.

New Directions in Science, Policy, and the Humanities: http://newdirections.unt.edu//. Fosters interdisciplinary networks including private sector and government to work toward solutions for environmental problems. Site features interdisciplinary resources, workshops, and project outcomes.

The National Academies Committee on Science, Engineering, and Public Policy (COSEPUP): http://www7.nationalacademies.org/cosepup/. Provides independent analyses of cross-cutting issues in science and technology policy, often for government agencies. Site includes publications, links, resources, and current and recent projects.

United States Office of Science and Technology Policy (OSTP): http://www.ostp.gov/. Established in 1976 to advise the President on science and technology aspects of public policy. Site contains news, outreach, projects, and information on science, technology, and government.

University of Colorado Center for Science and Technology Policy Research: http://sciencepolicy.colorado.edu/. Founded in 2001 to conduct research, education, and outreach to improve the relationship between societal needs and science and technology policies. Site features news, events, publications, educational materials, and several projects with various foci including water, climate, and carbon.

Science Fiction

Asimov's Science Fiction: http://www.asimovs.com/. Site features current and archived journals but also includes discussion forums, links, and other resources.

SciFi.com: http://www.scifi.com/. Site features listings on the television channel but also includes news, events, and pedagogical materials.

Science, Technology, and Art

Interdisciplinarity Resources: http://notes.utk.edu/bio/unistudy.nsf/0/5fd8d0b054118786852566fd008282be?OpenDocument. Maintained by the University of Tennessee, Knoxville, site links to several related projects and resources at the interface of science, technology, art, humanities, and culture.

Science, Technology, and Law

American Bar Association Section of Science and Technology Law: http://www.abanet.org/scitech/home.html. Provides updates, links, publications, and a search engine for documents related to science, technology, and law.

Cornell Law School Legal Ethics Library: http://www.law.cornell.edu/ethics/. A digital library that contains both the codes or rules setting standards for the professional conduct of lawyers and commentary on the law governing lawyers, organized by jurisdiction and topic. Also includes materials on multidisciplinary practice.

National Academies Science, Technology, and Law Program: http://www7.nationalacademies.org/stl/index.html. Established in 1992 to link the science and engineering communities with the law community. Site features links, events, contacts, and current studies.

Science, Technology, and Literature

Society for Literature and Science: http://sls.press.jhu.edu/. Site features a bulletin board, publication, links, educational materials, and a directory.

Science, Technology, and Society Studies

History of Science Society: http://www.hssonline.org/. HSS was founded in 1924 and is dedicated to understanding science, technology, medicine, and their interactions with society in historical context. The HSS site features publications, information on the profession, and educational and research materials.

Society for Philosophy and Technology: http://www.spt.org/ index.html. SPT was founded in 1980 to facilitate philosophically significant reflections on technology. The SPT site includes journal, newsletter, and links.

Society for Social Studies of Science: http://4sonline.org/. 4S grew out of a program on the public understanding of science at Harvard University in the 1960s. It is now an organization devoted to understanding science and technology. The 4S site features scholarly resources, information on the profession, conferences, and information for students.

COMPILED BY ADAM BRIGGLE AND CARL MITCHAM

APPENDIX III

GLOSSARY OF TERMS

The following selection of terms and definitions is based on one originally authored by Caroline Whitbeck at the Online Ethics Center for Engineering and Science (OECES) at Case Western Reserve University (onlineethics.org) with the help of advisors to the OECES and discussed at greater length in her book, Ethics in Engineering Practice. *Its aim is to introduce a number of concepts and terms that figure prominently in many discussions of science, technology, and ethics. Italicized terms within a glossary definition are defined in the glossary.*

Academic Honesty and Academic Integrity: The maintenance of truthfulness and proper crediting of sources of ideas and expressions. Behaviors such as cheating on examinations and lab reports, or plagiarism of course papers and homework assignments violate academic integrity. Violations of academic integrity by students have the same character as violations of research integrity by scholars and research investigators (see *Research Ethics*). Other matters of academic integrity include honesty in writing letters of recommendation and in reporting institutional statistics.

Accountable: To be accountable is to be answerable or required to answer for one's actions. Sometimes the term *accountable* is used with a moral connotation (*normatively*), meaning morally required to answer for one's actions without specifying to whom one is accountable. More often accountable is used to describe the sociological fact that a person or organization in question is required to answer to a particular party by some rules or organizational structure. For example, "the principal is accountable to the school board" gives a description of the social facts without suggesting anything about the ethical legitimacy of the organizational structure.

Confusion arises when "responsible" is used as a synonym for accountable, especially in discussions of official responsibilities. When responsible is used as a synonym for accountable the preposition "to" is also involved, as in "each staff employee is responsible/accountable to a supervisor" (see *Responsibility*). Being a responsible person, that is, the sort of person who fulfills one's moral responsibilities, is an ideal of character, a virtue. Being accountable is not a moral virtue but only a fact about one's social or organizational situation. Although it is often argued that people are more likely to behave responsibly if they are held accountable for their actions, there is no necessary link between being responsible and being accountable.

Administrative Law: *Administrative law* is constituted by that body of regulations, rules, orders, decisions, and policies that carry out the regulatory powers created of administrative agencies. In ordinary use, as contrasted with technical legal use, people often speak of administrative law as "regulation." For example, it is often pointed out that it is easier for regulatory agencies, such as U.S. Environmental Protection Agency or the U.S. Occupational Safety and Health Administration to update their regulations than it is to get Congress to pass new laws. In the technical legal sense, regulation is law has "the force of law." Administrative law, like all other forms of law, is subject to assessment and criticism in terms of ethics and justice. See also *Civil Law* and *Criminal Law*.

Affirmative Action: Positive steps to enhance the diversity of some group, often to remedy the cumulative effect of subtle as well as gross expressions of prejudice. In science and engineering affirmation actions often aim to enhance the participation of women and underrepresented minorities in these fields.

Applied versus Basic Research: Applied research is the investigation of phenomena to discover whether their properties are appropriate to a particular need or want, usually a human need or want. In contrast, basic research investigates phenomena without reference to particular needs and wants. Applied research is more closely associated with technology, engineering, invention, and development. Basic research is sometimes described as "pure research."

Assent: Assent is a variation of the concept of *Informed Consent* specifically used in reference to research subjects such as children or other persons without the full competence to provide informed consent. For instance, because children under 18 are below the legal age of consent, the U.S. Department of Health and Human Services (DHHS) requires additional protections when children are involved as subjects. Assent is defined as "a child's affirmative agreement to participate in research. Mere failure to object should not, absent affirmative agreement, be construed as assent" (45 CFR 46 Subpart D). In addition, the federal regulations require the permission of one or both parents or guardians of the child, depending on the nature of the research to be performed.

Authenticity: The character trait or virtue of being genuine and honest with oneself as well as others. Therefore, authenticity connotes not only candor, but an absence of hypocrisy or self-deception.

Autonomy: See *Right to Self-Determination*

Basic Research: See *Applied versus Basic Research*

Bias: An inclination that influences judgment is a bias. The term may be used in a merely descriptive way to mean an inclination, but more often it is used indicate an inclination that influences judgment but ought not to. *Prejudice* is a synonym for bias in this pejorative sense.

However, the bias that cannot be completely eliminated in the work of scientific investigators, in contrast to bias or prejudice that can and should be eliminated, is also an important topic in research ethics. For example, the way disciplinary training inclines people to interpret the results of an experiment in terms of the established categories of that discipline is a permanent feature of research, and one that must be taken into account in assessing responsible behavior in research. Of course, researchers may hold disciplinary biases and still be unbiased in other respects, that is, they may be impartial on the question of the truth or falsity of a particular research hypothesis.

Biotechnology: As defined by the U.S. government, biotechnology refers to any technique that uses living organisms (or parts of organisms) to make or modify products, to improve plants and animals, or to develop microorganisms for specific use. Biotechnology focuses on the practical applications of science (as opposed to doing basic research). Historically, biotechnology has had an impact in three main areas: health, food and agriculture, and environmental protection. Biotechnologists try to solve problems in these and other areas such as the need to cure or prevent illness, for clean water, and to preserve food.

Bribe: A bribe is something given or offered to a person or organization in a position of trust to induce such a person to behave in a way inconsistent with that trust. As C. E. Harris et al. (2000) point out, offering a bribe is not the same as capitulating to extortion (that is, capitulating to a demand under coercion or intimidation). It may be ethically justified to pay extortion in some circumstances, even though it would be wrong to offer a bribe. Bribes are paid to obtain something to which one does not have a right, such as a special advantage in awarding a contract. In contrast, extortion is paid to secure something to which one has a right, such as the return of expensive equipment one has legally brought into a country but which a corrupt customs official claims has been "lost."

Candor: Candor is the quality of being frank or open. The original, now obsolete sense of the term was of the virtue of purity or innocence. Although being open and unbiased is a positive quality, in some circumstances it is better to be discreet rather than candid with someone about a particular topic. Certainly, there are matters in which a person is morally required to keep something confidential, and therefore being candid with the wrong party about such a matter would be an ethical breach. See also *Authenticity*.

Challenge Study: A study in which researchers intentionally give subjects or patients pharmacological agents in order to induce and study psychiatric symptomology.

Civil Law: That body of law relating to contracts and suits, as contrasted with criminal law. Civil law covers suits of one party by another for such matters as breach of contract or negligence, and as such may have application in scientific and engineering contracts as well certain professional obligations. The standard of proof in civil cases is preponderance of evidence—a greater weight of evidence for than against. This is a weaker standard of proof than exists in criminal cases. Civil law, like all other forms of law, is subject to assessment and criticism in terms of ethics and justice. See also *Administrative Law* and *Criminal Law*.

Civil Rights: Rights associated with citizenship that one acquires simply by being a citizen. Not all of these are inalienable rights, however. See *Rights*. For example, according to the law in some states, a citizen may lose the right to vote if convicted of certain crimes.

Complainant: A person who raises concerns inside or outside her organizations about something she believes to be amiss. The term does not have the negative connotation of "complainer." The complainant is one who speaks up in some way about a problem. This speaking up may or may not include filing a formal charge. See also *Whistleblower*.

Confidential: That which is done or communicated in trust is confidential. Confidential information is information entrusted to another. The implication is that it is information that for some reason (from personal privacy to competitive advantage) the person entrusting the information does not wish some others to know. Thus confidential information is information to be shared only with a very limited group who are involved with furthering certain ends which the one entrusting the information wants served, such as treatment of a disease, or development and manufacture of a new product. Most professions recognize some duty to keep confidential a client's information, although such a duty has limits when the confidential information concerns a danger to others.

Conflict of Interest: Someone has a conflict of interest when that person is in a position of trust requiring the exercise judgment on behalf of others (people, institutions, etc.) and also has interests or obligations of the sort that might interfere with the exercise of such judgment, and which the person is morally required to either avoid or openly acknowledge.

The lesser requirement of open acknowledgment is usually adopted when it seems too burdensome to require that persons in positions of trust divest themselves of the interest that conflicts with a position of responsibility. For example, some journals require that authors disclose any substantial financial interests that might have biased their research assessment. Requiring investigators to divest themselves of investments that they may have made on the basis of their scientific judgment would be too burdensome, and might even suppress publication.

Dictionary definitions frequently apply the term only to conflicts between a person's private interests and those of a public office, and by extension with that person's professional obligations and responsibilities. However, there can also be conflicts of interest in which private interests do not enter. For example, the American Bar Association specifies as part of a general rule on conflict of interest that lawyers should not represent a client if such representation may be materially limited by the lawyer's responsibilities to another client or to a third party. There is no similar rule requiring engineers or engineering firms to avoid, say, building manufacturing facilities for, or supplying parts to, two companies that directly compete in the same market, although the engineering firm might need to be especially careful to avoid disclosing the proprietary information of one company to the other.

This example illustrates the point that one needs to look carefully at the nature of a professional's or public official's obligations and responsibilities in order to know when conflicting interests become a conflict of interest, that is, when a situation that requires discretion to handle the actual or potential conflict fairly is one that he is morally required to avoid altogether, or at least to disclose to all parties.

Policies requiring financial disclosure, that is disclosure of financial interests that might conflict with judgment as a researcher or as public official, are very commonly called a "conflict of interest policy," although such financial conflict of interest is only one specific type.

Contract: As used in ethics, the term contract means an explicit agreement that is freely entered into. Only a small number of these would qualify as legal contracts. A legal contract is a legally binding agreement among two or more parties. Breach of contract is the failure to fulfill a legal contract.

Copyright: A legal right (usually of the author or composer or publisher of a work) to exclusive publication production, sale, and/or distribution of some work for a specified period of time. What is protected by the copyright is the "expression," not the idea. Notice that taking another's idea without attribution may be plagiarism, so copyrights are not the equivalent of legal prohibition of plagiarism.

Cost-Benefit Analysis: To use cost-benefit analysis (also sometimes called risk-benefit or risk-cost-benefit analysis) requires that one consider only those consequences or the probability of consequences that can be quantified, such as number of deaths, days of illness, or monetary costs. Cost-benefit analysis is a technique taken from economics that weighs alternative actions in terms of such consequences. Its great strength is that it can introduce a measure of objectivity into sometimes complex or contentious decision-making. Its weakness is that it is not able to consider consequences such as the loss of moral integrity or human flourishing that do not lend themselves to quantification. See also *Risk*.

Criminal Law: That body of law relating to crimes (which can be classified as either felonies or misdemeanors). Crimes are offenses against the state; they are investigated by the police, prosecuted at public expense, and can be punished by incarceration as well as fines. The uses of science and technology to commit crimes are always subject to criminal prosecution and punishment. The standard of proof in criminal cases is stronger than the standard of proof in civil cases, which is preponderance of evidence and may extend to absence of reasonable doubt. Criminal law, like all other forms of law, is subject to ethical assessment and criticism. See also *Administrative Law* and *Civil Law*.

Data Selection: Involves emphasizing some data over other data or sometimes ignoring certain data. The term is primarily used when data selection is legitimate and clarifies research, as opposed to selection that falsifies the research. Selection of data for analysis or presentation is legitimate only when undertaken on the basis of clear criteria for thinking that in comparison with other related data it is less subject to confounding influences or "noise." Any selection must be disclosed in reporting the research.

Defendant: A party being sued in civil proceedings, or accused of a crime in criminal proceedings.

Dilemma: A dilemma involves a forced choice between courses of action (usually two) which are both unacceptable. Sometimes people will call any challenging moral problem a dilemma, but this is misleading. Only a few moral problems are dilemmas in the technical sense of the term. Calling moral problems "dilemmas" is confusing because it implies that the only possible responses are the two obvious (and unacceptable) ones; this tends to discourage real problem solving.

Discrimination: Discrimination in the common, morally relevant use of the term, is a failure to treat people fairly due to a bias against (or for), based on a characteristic such as race, religion, sex, national origin, sexual orientation, physical appearance, or disability that is irrelevant to the decision at hand (e.g., job skills or qualifications for public housing). Discrimination may be intentional or unintentional. Discrimination is a form of behavior that shows prejudice, but not the only form.

Due Process: That procedure or process required for a given judgment to be fair. Fairness here is specified in terms of the process rather than the outcome. For example, although it is desirable that those and only those who are guilty of a crime be punished for it, infallibility of judgment by the law courts cannot be guaranteed. The feasible goal is to try to ensure everyone a fair trial. Similarly, although it is hoped that important research does not go unrecognized, it is impossible to guarantee that the contributions of those who are "ahead of their time" will be recognized. The feasible goal is to ensure fair process in the reviewing of research proposals for funding or research results for publication.

Duty: See *Obligations*

Ethical Relativism: Ethical relativism or "relativism" may be used to indicate several different views. One view, which is also called "ethical subjectivism," is the view that the truth of some ethical judgment as applied to a person's behavior depends on whether the person believes the actions to be right or wrong. This view is commonly expressed as "there is no right or wrong, it's only a matter of opinion." Acceptance of this view undermines the claim of any ethical judgment to have validity. One who believes in ethical relativism in this sense would have to agree that there was nothing objectively wrong with a person torturing or killing another person, as long as the individual committing those actions sincerely believed it was not wrong to do so.

A second view, which is sometimes called "cultural relativism," is the view that ethical judgments and moral rules always reflect the cultural context from which they are derived and cannot be immediately applied to other cultural contexts. Some who hold this view are skeptical about even the possibility of saying that slavery is wrong in a slave-holding society and so are close to the ethical subjectivists. At the other extreme, some cultural relativists only put the burden of proof on those who think that they can generalize from one social context to another, but accept that the burden of proof is often met.

Many ethical philosophers, such as Alasdair MacIntyre (1988) and Annette Baier (1994), who do not consider themselves relativists, nevertheless argue that moralities are social products constructed by particular people in particular societal contexts and must be understood in relation to those societal contexts. For example, the Hippocratic oath specifies extensive duties toward those who have taught one medicine. In this oath physicians pledge to respect and care for their teachers as for their own parents. The societal context in which these duties of physicians were formulated was very different from what it is in industrialized nations today. It is implausible that the same duties should apply to physicians in all societies, but this does not mean that they did not have validity when the oath was first formulated. What makes the difference is not a person's or the group's opinion, but the social reality in which the person participated.

Ethics and Morals: The term *ethics* is used in several different ways. First, it may mean the study of morals, meaning individual or social forms of behavior. It is also the name for that branch of philosophy concerned with the nature of morals and moral evaluation: what is right and wrong, virtuous or vicious, good and bad, and beneficial or harmful (to oneself or others).

Second, ethics or morality may be used to mean the standards for ethical or moral behavior of a particular group, such as "Buddhist ethics" or "nursing ethics" or "Roman Catholic morality" or "the professional ethics of engineers in the United States." To give a description of such ethical codes and standards is "descriptive ethics." Descriptive ethics does not include a judgment as to whether the code or standards of behavior are ethically justified. The examination of the adequacy of moral or ethical values, standards, or judgments is *normative* ethics.

Third, some authors even use the terms *ethics* or *morality* more loosely to refer to any code of behavior, even one that no one regards as having any moral justification. For example, Robert Jackall (1988) describes what he calls the "ethics" or "morality" of a corporation and takes it to include such judgments as "What is right is what the guy above you wants from you." Such a judgment is about the most immediate way to survive in the organization, but does not pretend to be a statement about what is morally or ethically justified. It may be important to examine such codes of behavior and see how they affect the opportunities for moral action, but not every code of behavior has, or is even claimed to have, moral or ethical justification.

The term "moral" tends to be used for more practical elements, such as "moral problems" and "moral beliefs," and "ethical" tends to be used for more abstract and theoretical elements, such as "ethical principles," but the distinction is by no means hard and fast.

Evaluation: Evaluation can be either descriptive or normative. Descriptive evaluation may range from simple measurement to complex judgment about such things as the presence of mineral deposits. Normative evaluations involve judgments as to whether something is good or bad in some respects—a value judgment.

Explanation: Explanations of human actions typically make reference to the agent's reasons or motives for some action. For example, the student went to the bookstore to buy a text book. Causes are usually cited only for human actions that are not intentional, such as falling. A person's falling might be causally explained by the slipperiness of the road surface, the person having been pushed, or drugged, or having a heart attack. A person's falling with acceleration would be explained in terms of the gravitational field in which the person was falling. Notice that in certain contexts, notably ordinary life and law, it is often the unusual that is explained, whereas scientific explanation more commonly explains typical behavior.

Fabrication: In research ethics, fabrication means making up data, experiments, or other significant information in proposing, conducting, or reporting research. In engineering, fabrication has a benign connotation, meaning to make something. Sometimes the term is used to refer specifically to an intermediate stage between design and manufacture or construction.

Falsification: In research ethics falsification means changing or misrepresenting data or experiments, or misrepresenting other significant matters such as the credentials of an investigator in a research proposal. Unlike fabrication, the distinguishing of falsification data from legitimate data selection often requires judgment and an understanding of statistical methods.

Fraud: An intentional deception perpetrated to secure an unfair gain. Financial fraud, that is, a deception practiced on another party to cheat that party out of money, is the most commonly discussed type of fraud.

The terms "research fraud" or "scientific fraud" are used to mean an intentional deception about experiments or results, and is a type of research misconduct. In this case, the act may not include a financial transaction and there need not be an injured party or even anyone who was actually deceived. Therefore, so-called "research fraud" does not fit the legal criteria for a fraudulent act, which are discussed below.

In a civil law suit charging fraud there is a plaintiff who makes the charge against a defendant. To win a suit the plaintiff must prove five points, which are the five legal criteria for fraud: (1) the defendant made a false representation; (2) the defendant knew that the representation was false or at least recklessly disregarded whether it was true or false; (3) the defendant intended to induce belief in the misrepresentation; (4) the plaintiff had a reasonable belief in the misrepresentation; and (5) the plaintiff suffered damage as a result. As is illustrated in the case of "research fraud," the term "fraud" is often used informally to mean a misrepresentation but in which there may be no injured party who might become a plaintiff and so which satisfies only the first two criteria.

Glass Ceiling: The term *glass ceiling* indicates a barrier to advancement within an organization experienced by members of certain groups because of prejudice (including discomfort in their presence). This term is most often used when the organization recruits members of an affected group but then fails to promote them through the junior ranks on a comparable basis to other favored groups. If members of a group tend to leave the organization soon after entering, this is termed a "revolving door" rather than a "glass ceiling." The barrier in an organization may be different for different groups that are commonly victims of prejudice and usually is strongly influenced by so-called "corporate culture."

Good: The good is that which is rational to want or desire. A good knife is one that has characteristics it is rational to want in a device with one blade used for cutting. When considering what makes a good person, or good character, the matter becomes more complex, because it then becomes important to ask whether the traits under discussion are those that people would want in themselves, or those that they would want in others, and whether these are the same, or in what sort of society they might be the same.

Good Scientific Practice: See *Research Ethics or the Responsible Conduct of Research*

Human Rights: See *Rights*

Inherently Safe: The term *inherently safe* is applied to products, processes, and systems in which operational safety is independent of any user training or auxiliary devices. For instance, Elisha Otis's invention of the safety elevator in the 1850s was designed to function only when the lift cable disengaged a brake; if the cable failed, the brake was automatically engaged. Since the 1970s nuclear reactors that are designed to automatically shut down in the case of any malfunction are also described as inherently safe. With inherently safe technologies, any deviation from expected use or operation leads to a nonhazardous state.

Inherently safe manufacturing processes utilize machines that will not function unless workers have placed themselves in safe positions, as when for example both hands must be placed on two separate switches before a cutting operation can proceed. Another inherently safe process would minimize the use of hazardous materials or the time employed in their use, thus reducing the dependency of safety on worker training or protective equipment.

In contrast, the notion of inherently dangerous or unreasonably dangerous is a legal notion that applies to products, processes, and systems which, under normal operating conditions, entail some level of hazard. Inherently dangerous can entail strict liability in tort.

A related term "intrinsically safe" is applied to electrical or electronic equipment that is incapable of producing a dangerous spark or thermal effect under either normal or abnormal operating conditions.

Informed Consent: Describes the obligation of physicians or researchers to allow patients or subjects to be active participants in decision-making with regard their care or research in which they play a role. Informed consent is rooted in the concept of autonomous choice or the *Right of Self-Determination*, and requires five elements: (1) disclosure (of information to the patient/subject), (2) comprehension (by the patient/subject of the information being disclosed); (3) voluntariness (of the patient/subject in making his/her choice); (4) competence (of the patient/subject to make a decision); and (5) consent (by the patient/subject).

Legal Contract: See *Contract*

Legal Rights: See *Rights*

Liability: A person is liable when obligated by law to make satisfaction, compensation, or restitution for some act or injury. Liability is a legal notion indicating a legal debt or obligation. The liabilities most often at issues in discussions of science, technology, and ethics are those having to do with compensation for injury (to one's person, property, finances, or reputation) or to clean up toxic contamination. Legal liability to compensate for an injury or to clean up contamination does not necessarily require that one has caused the injury or contamination, or that one be guilty in a moral sense. Under the doctrine of strict liability a party may be liable without having been guilty of negligence.

Liberties: See *Rights*

Morals: See *Ethics and Morals*

Moral Agent: One whose actions are capable of moral evaluation. We may say that an avalanche killed three people, but the avalanche is not open to moral evaluation. The avalanche is an amoral force. A competent and reasonably mature human being is the most familiar example of a moral agent. In contrast, most so-called "lower" (that is, non-human) animals are generally understood to be amoral (although this is open to debate regarding species that have complex and flexible social relations, such as primates and dolphins).

Moral Integrity: *Moral integrity* is a complex and subtle ethical notion. As theologian Stanley Hauerwas (1981) has argued, it is central to all the other virtues but more fundamental than any single virtue. The root of the term integrity is wholeness. Moral wholeness rather than rigidity best captures the idea of moral integrity. For example, a person might discover that some long-held ethical belief, attitude, or rule of conduct was mistaken because the person came to see that it was incompatible with other, more fundamental ethical commitments. A person's moral integrity is central to a person's sense of meaning.

Philosophers such as John Ladd (1982) have argued that a person's moral integrity is a central aspect of that person's well-being. Therefore, leading another person to compromise moral integrity is a fundamental injury to that person. Concern for a person's moral integrity requires an understanding of the person's moral convictions and in this respect differs from merely respecting a person's *Right of Self-Determination*, which requires only that one refrain from restricting their actions.

Some professional codes of ethics uphold the right to refuse work that would compromise an individual professional's ethical commitments even when the act in question (say, performing an abortion or developing weapons systems) is something the profession as a whole has not ruled morally objectionable.

Moral Standing: A being's moral standing determines the extent to which its well-being must be ethically considered for its own sake. To say that some groups of beings have moral standing is to say that, as a moral matter, their well-being must be given some consideration. It does not decide the question of whether they have the same moral standing as people (and thus have "human" rights). The welfare of such beings as cattle, for example, might be considered for prudential reasons, but that would not require that they have moral standing. One might decide that it is important to feed one's cattle, just as one might decide it was stupid to throw one's stamp collection into the river, thinking of the cattle or stamps as investments, without believing that either deserves such or better treatment out of consideration for their own well-being.

Moral Values: See *Values*

Motive: That which moves a person to action. Typically these are emotions, desires, or concerns. Thus people say such things as, "The motive for the crime was revenge." However, it is often common to hear someone speak simply of the intended result as "the motive." For example, any of the following sentences might be used to convey the same thought: "Lee's motive in arising early was to avoid traffic." "Lee arose early to avoid traffic." "Lee arose early because he wanted to avoid traffic." In such cases we assume that a desire or concern to realize the intended state is the implied motive. The expression "mixed motives" is used most often to suggest, not just any combination off emotions, desires, and concerns, but more specifically a mixture of selfish and altruistic concerns.

Negligence: A failure to be sufficiently careful in relation to a matter about which one has a moral responsibility to exercise care. Some careless mistakes are negligent, as when a surgeon sews up a patient with surgical instruments inside. Others are not, as when one dribbles soup down the front of one's sweater. Negligence is a legal basis for the recovery of damages from a private or civil wrong or injury, what is called a tort. The failure to fulfill a recognized duty, or to act with less care than would a reasonably prudent person in the same circumstances is the mark of negligence.

Normative: Derived from the Latin *norma,* the name for a carpenter's square, and is a loose synonym for authoritative or required. It is sometimes used broadly to mean that which establishes or reflects any sort of standard, even a statistical one. But in ethics when a standard, judgment, or assessment is normative, it concerns respects in which something is right or wrong, good or bad. Value judgments are normative in the ethical sense, but the judgment that X is greener or heavier than Y is not. In the ethical sense normative is a close synonym for prescriptive, that which "makes or gives rules."

However, not all rules are ethically normative; they may simply establish order. For example, the statement "Put out your trash out for collection on Tuesdays" is a prescription about when to put out trash, but does not suggest or establish that there is anything in Tuesday trash collection that is superior to collection on some other day.

Obligations: Requirements arising from a person's situation or circumstances (e.g., relationships, knowledge, position) that specify what must or must not be done for some moral, legal, religious, or institutional reasons. For example, students may have an obligation see their advisor on or before registration day, simply because this is one of actions students in a particular institutional context are asked to perform. But it can also be argued that persons insofar as they are moral have an obligation to keep their promises, because this is one of things that being moral entails. Notice that usually statements of obligations specify what acts are required or forbidden without reference to the consequences of performing the act (except in so far as these consequences are a part of the characterization of the act itself).

Obligations can be more or less specific. That drivers are obligated to obey the traffic rules is much more specific than "Engineers have an obligation in their work to ensure the public safety." The second obligation names a responsibility that engineers have to achieve a certain end, namely safety of the public, but fails to specify what specific acts they should or should not perform in order to ensure safety.

A legal obligation is one that specifies what types of actions are permitted, forbidden, or required with certain state-enforced penalties attached for failures to comply.

Official Responsibility: See *Responsibility, Official*

Patents: A (special, alienable, prima facie) legal right granted by the government to use, or at least (in cases where other patents that such use would infringe) to bar others from using a device, design, or type of plant that one has created. In the United States restrictions last for 17 years for useful devices, and 14 years for designs. Specific provisions of U.S. patent law may soon change to bring it into conformity with the provisions of other techologically developed countries. To patent a device one must prove that it is useful, original, and not obvious. Patents are subject to challenge in court and may be upheld or overturned.

Paternalism: Derived from the Latin word for father (*pater*) and means acting as a parent toward someone who is not in fact one's child. Acting like a parent toward those who are not one's children may or may not be justified in particular circumstances. Parents need to make judgments about many areas of their young children's lives (with the particular areas depending on the age or maturity of the children), but adults assume the responsibility for making those decisions for themselves. Paternalism may be roughly defined (following Gert and Culver, 1976) as violating a moral rule of conduct toward someone or limiting that person's self-determination (and hence often infringing that person's rights) for what is perceived as being that person's own benefit.

Paternalism may be justified or unjustified, but the paternalistic treatment of adults always requires justification because of the infringement of the person's right that it entails. Paternalism in the treatment of clients most commonly arises in professional contexts where the professional has a face-to-face relationship with those whose well-being they seek to ensure, and in professions where practitioners are in positions of greater power than their clients.

The question of paternalism often arises in medicine and healthcare with respect to the treatment of patients. Because many engineers and scientists in industry must protect the safety and health of anonymous members of the public rather than identified clients, and usually do not occupy positions of greater power than their clients, paternalism is not a frequently discussed topic for engineers in industry. Nevertheless, issues of paternalism often do arise for engineers and scientists in relationships among co-workers and in educational contexts.

Plagiarism: Commonly defined as the unauthorized or unacknowledged appropriation of the words, graphics images, or ideas of another person. In some instances reference is also made to artistic creations such as music. Plagiarism is theft of credit and covers ideas as well as forms of expression and should be distinguished from copyright violation, which does not cover ideas and is a matter of intellectual property violation.

Plaintiff: An injured party suing someone (a defendant) in order to be compensated for an injury or loss.

Preferences: Statements about the person who has them. If statements of preference are false it is because they are not true about that person. Such statements of preferences should be distinguished from *Value Judgments*, which are statements about the thing being judged good or bad.

Economists often avoid getting into substantive value discussions by considering only what people want or prefer and how much they prefer some things over other things. What makes this confusing is that they sometimes speak about what people "value," but they mean only what people prefer, and not what people have reasons for thinking are good or bad in some respect. It is of course possible for someone to prefer something because they judge it to be good. However, many factors other than value judgments enter into people's preferences, such as their early conditioning, habits, and vivid personal experiences. (If this were not the case, there would not be such a large market for cigarettes, for example, since even most smokers do not judge smoking to be a good thing to do.)

Prejudice: Bias for or against someone or something that fails to take true account of their characteristics.

Principal: A principal in an engineering firm (or other company) is a co-owner, that is, a partner or stockholder.

Privacy: It is common to distinguish three species of privacy: physical, informational, and decisional. In addition, philosopher and legal theorist Anita Allen (2003) distinguishes dispositional privacy. Physical privacy is a restriction on the ability of others to experience a person through one or more of the five senses. Informational privacy is a restriction on facts about the person that are unknown or unknowable. Decisional privacy is the exclusion of others from decisions, such as healthcare decisions or marital decisions, made by the person and his group of intimates. Finally, dispositional privacy is a restriction on the ability of others to know a person's state of mind.

Claims to privacy find moral justification in a recognition that people need to have control over some matters that intimately relate to them in order to function as people and be responsible for their own actions. Foremost among these are rights to one's own body. If, for example, people were permitted to drug one another at will, that would effectively undercut the rest of moral life.

Just what a person is expected to do in order to respect another's privacy varies with culture. For example, expectations that people will knock on the door before entering certain areas assumes the existence of both doors and of expectations about the amount of so-called "private space" to which a person is entitled. In some contemporary cultures, parents oversee their children's affairs much more closely than in others. In traditional Chinese families, for example, it is expected that parents will do such things as read the mail addressed to their adolescent children as part of their responsible oversight of their children, whereas in Anglo-American culture such acts would be viewed as intrusions on the adolescent's privacy.

Questions of privacy have become particularly prominent as computers and other technological innovations have made it possible to collect, assemble, and transmit quantities of information in ways that previously were impossible. Once the questions of appropriate levels of privacy protection have been established, the question of how that level of privacy can be practically ensured is a matter of security.

Profession: An occupation, the practice of which directly influences human well-being, and requires mastery of a complex body of knowledge and specialized skills, requiring both formal education and practical experience.

Professional Engineering: In the United States a professional engineer (P.E.) is a person who is licensed to practice engineering in a particular state or U.S. territory after meeting all requirements of the law. To practice in multiple states or territories, the P.E. must be licensed in each state in which he or she wishes to practice.

Professional Responsibility: See *Responsibility, Professional*

Property: A property, from the Latin *proprius*, meaning "one's own" or "special," can refer to the key characteristic of a thing ("One property of water is to be a solvent") or that to which an individual has special rights. In this second sense, very different sorts of things may be regarded as property. Individual rights to property (other than clothing and other personal effects), especially the right to own land, is a major innovation in modern thought. Land was one important kind of property, physical objects that constitute "the fruit of one's labor" were another.

It was a short step from physical property to intellectual property, the fruit of one's intellectual labor, which was given some recognition in the U.S. Constitution (see *Copyright, Patent, Trademark, Trade Secret Patent*). (Notice that "ideas" cannot be owned by these means but only some "expression," design, or device.) The advent of electronic information has raised new issues and problems about intellectual property and rights to such property, because of the extreme ease with which electronic information can be copied and transmitted.

Proprietary/Property Rights: Proprietary rights, claims, etc. are the rights, claims, etc. of owners. Sorting out the rights that go with property ownership is complicated, both because of the variety of types of property, and because of the problem of sorting out conflicting claims regarding property and conflicts between property rights and other rights.

Prudence or Prudential Judgment: See *Values and Value Judgments*

Reparations: Benefits given to some person or group to make amends for damage done by previous injustice. For example, as a result of the "Civil Liberties Act of 1988," Japanese-Americans who were placed in internment camps during World War II were given a monetary payment (of about $20,000 each) as reparations. Because children may be damaged by injustice done to their forebears, e.g. because poverty undermines their health or limits their educational opportunities, arguments are made for reparations to descendants of those who were first injured, if the consequences of the injury are of the sort that pass from one generation to the next.

Research Ethics or the Responsible Conduct of Research: *Research ethics* or *responsible conduct of research* (RCR) are terms used broadly to refer to many ethically significant issues that arise in research, from fair apportionment of credit among members of a research team, to responsible behavior in submitting or reviewing grant applications and the responsible treatment of research subjects.

Since the U.S. government and institutional regulations regarding the treatment of human and animal research subjects predated the increased attention to and the regulation of matters of research integrity (including fair credit) that arose in the 1980s, some RCR resources address only issues of research integrity and not the treatment of research subjects. Similarly, laboratory safety has long been regulated by OSHA, and is not necessarily a matter of research integrity. Therefore, it too is often omitted from discussions of responsible behavior in research. For example, *On Being a Scientist: Responsible Conduct in Research* (1995), put out by the National Academy of Sciences, the National Academy of Engineering, and the Institute of Medicine, in both its first and second edition omitted any discussion of the treatment of research subjects or laboratory safety. The treatment of research subjects and laboratory safety are nevertheless reasonably classed as matters of research ethics, even if they are not always included under this designation.

In Europe the term "good scientific practice" (GSP) covers much of the same territory as research ethics and RCR.

Research Misconduct: *Research misconduct* is a term used rather narrowly. It does not include all violations of standards of research ethics. In particular, it is not applied to violations of the norms for the use of human or animal subjects.

In the United States the three actions that have been the focus of misconduct definitions are fabrication, falsification, and plagiarism (FFP). In 1995 the Congressionally-mandated Commission on Research Integrity issued a report, "Integrity and Misconduct in Research," arguing that FFP did not cover all serious deviations from accepted practices, and proposed a broader definition of research misconduct as misappropriation, interference, and misrepresentation, but this definition was not adopted. After extensive public debate the U.S. Office of Science and Technology Policy in 2000 issued the following common definition: "Research misconduct is defined as fabrication, falsification, or plagiarism in proposing, performing, or reviewing research, or in reporting research results." See the U.S. Federal Policy on Research Misconduct http://onlineethics.org/fedresmis.html.

Responsible Conduct of Research: See *Research Ethics and Responsible Conduct of Research*

Responsibility: *Responsibility* is a complex concept with both non-moral and moral meanings, and at least forward- and back-looking forms. The moral and forward-looking sense of responsibility is the sense in which one is responsible for achieving (or maintaining) a good result in some matter. The idea is that one is entrusted with achieving or maintaining this outcome, and expected both to have relevant knowledge and skills, and to make a conscientious effort. However, despite one's best efforts, the result may not be achieved. For example, patients of responsible physicians may die. The work of a responsible engineer may result in an accident because the accident was not foreseeable, it was not possible to compensate for the factors causing the accident, or because others were unwilling to heed the engineer's warnings. The moral and backward-looking sense of responsibility is that in which a person or group deserves ethical evaluation for some act or outcome, that is deserves moral praise for a good outcome or blame for a bad one.

The moral sense of responsibility should not be confused with the causal sense of responsibility for some existing or past state of affairs. For example, when we say "the storm was responsible for three deaths and heavy property damage," meaning that it caused these outcomes, we do not mean to attribute moral responsibility to the storm. Storms do not have moral responsibilities, and are neither responsible nor irresponsible in the moral sense. However, when a moral agent is causally responsible for some outcome, that is some reason to think that the agent is morally responsible for it. Causal responsibility is not conclusive evidence of moral responsibility, however. If one's actions cause a terrible outcome only because of bad moral luck, in the form of a freak accident, then one is not morally responsible for the outcome.

Responsibility, Official: The responsibility one is assigned as a result of some job or office. Unfortunately, official responsibilities may require one to behave unethically. But although "It was my job" might be a reason, it is not a valid excuse for immoral behavior. However, even when the requirements of an official responsibility are ethically acceptable, the concept of official responsibility functions differently from moral responsibility. Official responsibility resembles moral responsibility in generating prescriptions for conduct—duties or at least statements about what someone "ought" to do. As philosopher John Ladd points out, moral and official responsibility differ in at least two respects: First, official responsibilities are "exclusionary"—if one person has a particular official responsibility, another person does not (unless, of course, it was part of the job description of both). Second, official responsibilities, together with whatever rights, duties, and requirements for accountability attend them, are all "alienable" (see *Rights*)—they can be given to or taken over by someone else. In contrast, if one has a moral responsibility to inform the public about some matter, then even if one is in the position to delegate that responsibility to someone else, one still must see that the responsibility is fulfilled, because one does not get rid of a moral responsibility by giving it to someone else.

Responsibility, Professional: Professional responsibility is a paradigm case of the moral responsibility that arises from the special knowledge that one possesses. It is mastery of a special body of advanced knowledge, particularly knowledge that bears directly on the well-being of others, which demarcates a profession. As custodians of special knowledge that bears on human well-being, professionals are constrained by special moral responsibilities—that is, moral requirements to apply their knowledge in ways that benefit the rest of the society.

Right of Self-Determination: The right of self-determination equals the right to choose one's own actions or course of life, so long as doing so does not interfere unduly with the lives and actions of others.

Rights: Rights are claims that have some justification behind them. A moral right is a morally justified claim. A legal right is a legally justified claim. When we use the term "right" without specifying the nature of the justification, we usually mean a moral right.

Rights specify acts that are permitted, forbidden, or required. If they specify acts that the rights-holder may perform (such as vote, or drive a car), they are often called licenses. If they specify acts that others may not perform (as the right to life obliges others to refrain from killing the rights holder), they are called liberties or (in law) negative rights. If they specify what the rights-holder should receive, the law commonly calls them positive rights, although some philosophers call them claim rights.

Other major types of classifications of rights are:

- Alienable rights and inalienable rights. Alienable rights may be taken or given away. Inalienable rights cannot be taken or given away.
- Human rights and special rights. Human rights belong to all people, or all people who are competent to exercise them. (Another term that is a close synonym for human rights is "natural rights.") In contrast, a right that only belongs to some people is termed a "special" right.
- Absolute rights and prima facie rights. Absolute rights cannot be outweighed by other considerations; prima facie rights can be outweighed by other considerations. For example, many of those who oppose capital punishment say that the right to life is an absolute right, but those who believe that capital punishment is morally justified in some circumstances say it is only a prima facie right.

See also *Copyright* and *Propietary/Property Rights*.

Risk: *Risk* is used colloquially as a term for a danger that arises unpredictably, such as being struck by a car. Sometimes it is used for the likelihood of a particular danger or hazard, as when someone says, "You can reduce your risk of being hit by a car by crossing at the crosswalk."

When used in technical context, such as in the terms "risk assessment" or "risk management," the notion of risk is the probability or likelihood of some resulting harm (such as the likelihood of being killed by being struck by a car) multiplied by the magnitude of the harm. One can then compare, say, the average citizen's risk of death from crossing the street with such a person's risk of death from cancer in a given period. One could also compare the risk of harms of different magnitudes. For example, two monetary risks: the rather likely event of losing a quarter in a malfunctioning vending machine, and the comparatively unlikely loss of one's wallet due to robbery at gun point. It may turn out that there is a greater risk of monetary loss from malfunctioning vending machines than from robbery at gun point. Notice that use of the technical sense of risk requires that one be able to meaningfully quantify the resulting harms. For many harms this is difficult to do except in an arbitrary way.

Risk and Benefits: See *Costs and Benefits*

Safety: *Safety* involves freedom from danger. A property of a device or process is safe insofar as it limits the risk of accident below some specified acceptable level.

Scientific Misconduct: See *Falsification, Fraud, Plagiarism, Research Misconduct*.

Screening: Involves the testing of a large number of individuals in a way designed to identify those with a particular genetic trait, characteristic, or biological condition. Screening differs from other biological testing in that it is done without any indication that the condition tested for is one possessed by any particular individual who is screened.

Security: The security of a system is the extent of protection against some unwanted occurrence such as the invasion of privacy, theft, and the corruption of information or physical damage.

Self-Deception: A failure to make explicit, even to oneself, some truth about oneself (often one's behavior). It may take the form of making up some rationalization for a behavior that is inconsistent with one's sense of self, or it may take the form of failing to take notice of some of the features of the situation when it would be appropriate to do so. The latter phenomenon is one that psychologists call "denial." Self-deception is a barrier to *authenticity*.

Stakeholder: A person or group who can affect or be affected by an action. Responsible decision-making requires consideration of the effects on all stakeholders. Some stakeholders may not be morally entitled to consideration of the same aspects of their welfare, however. For example, a corporate decision may affect or be influenced by employees, stockholders, customers, suppliers, communities, some government agencies, and corporate competitors. Competitors are entitled to fairness in competition, but not to the same consideration as, say, employees.

Standard: An established basis of comparison in measuring or judging capacity, quantity, content, value, quality, etc. It may also be a specified set of safety or performance criteria that a device or process ought to possess. The meeting of safety or performance standards must generally be demonstrated by a series of tests conducted under predetermined conditions.

Standard of Care: The degree of care that a reasonably prudent person would exercise in some particular circumstances. In negligence law, if someone's conduct falls below such a standard, then the person may be liable in tort for injuries or damages resulting from his or her conduct. In professional malpractice cases, a standard of care is applied to measure the competence as well of the degree of care shown by a professional's actions.

Therapeutic Illusion: A condition under which research subjects falsely believe that taking part in a particular study will likely result in some direct therapeutic benefit for themselves.

Therapeutic Orphan: A term given to children to express the concern that a fear of harming individual children by exposing them to research results is harming children as a class by undermining efforts to gain knowledge about how to better treat them. The question of the best methods for determining safe and effective medications is a continuing problem for drug research.

Tort: A private or civil (as contrasted with criminal) wrong or injury. Sometimes "tort law" is used as a general designation to include provisions concerning breaches of contract as well as a failure in some duty. However, the term *tort* is commonly used more narrowly to refer only to specific failure in some recognized duty, or a failure to exercise reasonable prudence or care. In this narrower sense *tort* is contrasted with "breach of contract" (failure to fulfill a legal agreement).

Trademark: An officially registered and legally restricted name, symbol, or representation, the use of which is restricted to its owner.

Trade Secret: A device, method, or formula that gives one an advantage over the competition, and which must therefore be kept secret if it is to be of special value. It is legal to use reverse engineering to learn a competitor's trade secret. "Know how" concerning research procedures may function as something like a trade secret.

Trust: Confident reliance. We may have confidence in events, people, or circumstances, or at least in our beliefs and predictions about them, but if we do not in some way rely on them, our confidence alone does not amount to trust. Reliance is a source of risk, and risk differentiates trusting in something from merely being confident about it. When one is in full control of an outcome or otherwise immune from disappointment, trust is not necessary. Of course, it is possible to rely on other people or on circumstances simply because one lacks other options.

The bases for confidence in relying on some person may not be morally sound. Trust may be naive or otherwise ill-founded. In this case it is likely to be disappointed. Trust may also rest on a morally unsound foundation as when, for example, one party feigns *trustworthiness* or behaves reliably only because the other party dominates.

Trustworthiness: When *trust* is well-founded and if trust of another person or moral agent is morally sound, then it is based on trustworthiness. Put another way, that which deserves trust is trustworthy.

Values and Value Judgments: Value judgments judge things to be good or bad in some respect. Moral or ethical values are only one type of value, and moral evaluation is only one type of value judgment.

Consider the following nine value judgments:

1. This is a good (important, significant) hypothesis.
2. That is a good (insightful or informative) article.
3. This is a good (beautiful, masterfully executed) symphony.
4. That is a good (prudent or effective) strategy.
5. This is a bad (stupid, short-sighted) idea.
6. That is a good (virtuous, of high moral character) person.
7. This is a bad (evil, vicious) motive.
8. That is a good (kind, generous or right-minded) act or deed.
9. That is the right thing to do.

The first two are judgments of epistemic or knowledge value. The third is an aesthetic judgment. The fourth and fifth are prudential judgments. The sixth, seventh, and eighth are moral judgments. The ninth is also a moral judgment that is similar in some respects to the eighth, although the presence of "the" rather than "a" in the ninth suggests that the act in question is uniquely acceptable.

Assertions such as the ninth are usually justified by an appeal to moral rules, often to the exclusion of any mention of consequences. There are other types of value and value judgments that also come into play in ethics, such as those related to religious value. Religious terms of evaluation include "sacred" and "holy," as contrasted with "profane" and "mundane." In addition to purely religious judgments, the practice of most religions also involves making moral or ethical judgments.

Virtues and Vices: Virtues are positive traits of moral character such as honesty, kindness, or being a courageous or responsible person. Vices are negative traits of moral character such as dishonesty or cowardice. Notice that these terms of moral evaluation are applied to people, rather than to their actions (which may be assessed in terms of rights, obligations, and moral rules) or to the outcomes they seek to achieve (which may be assessed in terms of responsibilities).

Washout Study: A study in which patients or subjects are removed from all psychiatric medication to study baseline states or pure effects of new drug treatment.

Whistleblower: A whistleblower is a person who takes a concern (such as one about safety, financial fraud, or mistreatment of research animals) outside of the organization in which the abuse or suspected abuse is occurring and with which the whistleblower is affiliated. Not all whistleblowing is equally adversarial to the affected organization, even though it is at least an embarrassment for an organization to be exposed as one that cannot correct its own problems.

There are many regulatory agencies, such as the U.S. Occupational Safety and Health Administration, that exist to perform oversight and to which whistleblowers can go anonymously. Going to those charged with oversight, such as regulatory agencies, is usually seen as much less adversarial than, say, going to the media. Some people have used the term *whistlerblower* for those who raise an issue within their organization, but the more general term for a person who raises an issue inside or outside an organization is *complainant*.

APPENDIX IV

CHRONOLOGY OF HISTORICAL EVENTS RELATED TO SCIENCE, TECHNOLOGY, AND ETHICS

The purpose of this chronology is not to provide an all-inclusive history of science, technology, and ethics. Rather the aim is to highlight enough of the most important developments to capture a sense of the timing and pace of both macro-level (e.g., shifts from pre-modern to modern forms of science) and micro-level (e.g., the interplay of contemporary thinkers) changes and interactions. By organizing information in a historical manner, the chronology provides a supplementary perspective for thinking about science, technology, and ethics. It enables users of the encyclopedia to orient specific article topics within the larger sweep of time that conditions and is in turn conditioned by various persons, events, organizations, and ideas. The compilers of this chronology are grateful to Dr. David Lee for allowing the use of material from his website at http://www.sciencetimeline.net/.

The Ancient World: From the First Tools to 550 B.C.E.

Paleolithic (Old Stone Age) ca. 2 million B.C.E.–13000 B.C.E.

ca. 2 million–10000	Hunting and gathering were the main forms of human sustenance.
ca. 1 million	Chipped or patterned stone tools were first used.
ca. 125000	The control of fire by humans is widespread.
ca. 40000	Specialized instruments, such as needles and harpoons came into use.
ca. 30000	Cro–Magnon Man inhabited the valleys of France.

Mesolithic (Middle Stone Age) 13000 B.C.E.–6000 B.C.E.

ca. 11000	Bands of hunters in Europe depicted animals in cave paintings.
ca. 10000	Humans first began practicing agriculture.
ca. 10000	Wolves were first domesticated.
ca. 9000	Sheep were domesticated in the Middle East.
ca. 7700	Farming people settled in the Fertile Crescent.
ca. 7000	Wheat was domesticated in Mesopotamia.
ca. 6500	The wheel was invented in the Tigris–Euphrates basin by Sumerians.
ca. 6300	The earliest dug-out canoes were being made.

Neolithic (New Stone Age) 6000 B.C.E.–3000 B.C.E.

ca. 5000–3500	Villagers in Mesopotamia began practicing irrigation.
ca. 4800	Astronomical calendar stones were being used on the Nabta plateau.
ca. 4400	The first loom was used in Egypt.
ca. 4000	Light wooden plows were used in Mesopotamia.
ca. 4000–3500	Copper smelting in minute quantities was introduced in Mesopotamia.
ca. 3600	Southwestern Asians began using bronze, which unlike smelted copper, can hold an edge.
ca. 3500	The Sumerian civilization was born, which featured animal drawn vehicles, bronze, and the cuneiform alphabet.
ca. 3400	The first dynasty began in Egypt.
ca. 3000	The Sahara desert changed from a fertile area to an arid desert due to over use.
ca 3200	Wheeled vehicles were used in Uruk.
ca. 3200	The Egyptians were using sailboats with masts and broad, square sails.

	They also painted pictures of these boats.
ca. 3000	Cotton was being grown in India.
ca. 3000	The Egyptians used a writing material called papyrus, which was made from woven reeds.

Bronze and Iron Ages 3000 B.C.E. –550 B.C.E.

ca. 2900–2450	The Great Pyramid of Cheops was built at Giza, Egypt.
ca. 2850	The sphinx was built in Egypt.
ca. 2700	Cuneiform signs and numerals appeared on Sumerian tablets, with a slanted double wedge between number symbols to indicate the absence of a number, or zero.
ca. 2500	Bronze was used widely, enabling the dagger form to be stretched into swords.
ca. 2500	The Iron Age began in the Middle East.
ca. 2500–2000	The dome was first used in architecture.
ca. 2400	The short, composite bow was developed by mounted archers. Unstrung, it curved forward and could pierce armor at 100 yards.
2205	The Xia dynasty came to power in China.
ca. 2000	The Minoan civilization emerged on Crete.
ca. 2000	Chinese thinkers discovered magnetic attraction.
1792–1750	Hammurabi (d. 1750) was king of Mesopotamia and created his code of laws, including "eye for an eye."
ca. 1900–1600	Stonehenge was built in present day England.
ca. 1750	The Babylonians began to use advanced geometry to make astronomical studies.
ca. 1700	The Babylonians created the first windmills, which pumped water for irrigation.
ca. 1700	Judaism was founded by Abraham.
ca. 1650	The first use was made of phonetic signs, derived from Egyptian hieroglyphics, in the Serabit el Khadim inscriptions, in the Sinai peninsula.
ca. 1600	The Mycenaean civilization emerged on the Greek mainland. Rulers constructed hilltop fortresses and were buried with treasures acquired through trade.
ca. 1500	The Chinese began weaving with silk.
ca. 1450	The Egyptians invented the sundial.
ca. 1400	The Egyptians invented the water clock.
ca. 1380	The Egyptians built the first canal, merging the Nile and the Red Sea.
ca. 1200–1000	Iron smelting was introduced on an industrial scale in Armenia.
1193	Troy fell to the Greeks in the Trojan War.
ca. 1100	Modern alphabetic writing was prefigured in the Phoenician alphabet.
ca. 1000	The Olmec civilization flourished in Mesoamerica.
ca. 850	Homer wrote the *Iliad* and *Odyssey*.
ca. 630	Zarathustra (aka Zoroaster) (c. 630–c. 530), of present day Iran, founded the mystical religion of Zorastrianism, one of the first forms of monotheism.
ca. 600	Thales of Miletus (c. 624–c. 547) speculated that the basic stuff of nature is water. He also argued that logic should replace myth as the foundation of human understanding.
ca. 600	Anaximander of Miletus (611–547) discovered the ecliptic (the angle between the plane of the earth's rotation and the plane of the solar system).
597	Babylonian society, with the hanging gardens, reached its zenith.

The Classical World 550 B.C.E.–500C.E.

World Events

509 B.C.E.–476 C.E.	The Roman Empire.
492–400 B.C.E.	Classical Greece introduced the world to democracy and many of the great ideas of philosophy.

432–404 B.C.E. Athens and Sparta engaged each other in the Peloponnesian war. Athens lost, signaling the decline of Greek power and the rise of the Hellenistic age.

334 B.C.E. Alexander the Great (356–323) invaded Asia in the first of many victories that would eventually push his empire as far as India.

321–185 B.C.E. The Maurya Dynasty ruled in India.

221 B.C.E. China was unified under the "First Emperor," Qin Shi Huangdi (259–210). The Great Wall was built around this time.

49–44 B.C.E. Julius Caesar (100–44) was declared dictator for life, marking the transfer of Rome from Republic to Empire.

ca. 7 B.C.E.–ca 33 C.E. Jesus Christ lived in Palestine.

ca. 79 C.E. Domitian (51–96) dedicated the Roman Colosseum.

79 C.E. Mt. Vesuvius erupted, burying Hercaulenum and Pompeii.

313 C.E. Constantine (272–337) became Christian and issued the Edict of Milan, which granted freedom of worship to all inhabitants of the Roman Empire.

415 C.E. A mob of rioters burned down the Library of Alexandria, and much of the recorded knowledge of the western world was lost.

Technological Inventions

ca. 500 B.C.E. The Persians constructed the first highways.

ca. 400 B.C.E. An arrow–shooting catapult was developed at Syracuse. It deliberately and systematically utilized mechanical and physical principles to improve weaponry.

ca. 170 B.C.E. Parchment, superior to papyrus because it can be printed on both sides and folded, was invented in Pergamon.

ca. 150 B.C.E. Hipparchus of Nicaea (c. 190–c. 120) invented the astrolabe, which was widely used until the eighteenth century when the sextant was invented.

ca. 100 B.C.E. Paper was first used in China.

ca. 260 B.C.E. Archimedes of Syracuse (c. 287–212) invented many machines, including a pump, effective levers and compound pulleys, and a mechanical planetarium.

ca. 50 C.E. Hero of Alexandria (c. 10–c. 70) invented the first steam engine (the aeolipile), many feedback control devices, and the first type of analogue computer programming.

105 C.E. The Chinese court official Ts'ai Lun (d. 121) developed a method to make paper out of cotton rags.

271 C.E. Chinese mathematicians invented the magnetic compass.

Philosophy and Ethics

528 B.C.E. Buddhism was founded by Siddhartha (563–483), a former prince, in India.

ca. 500 B.C.E. Lao Tzu, of China, founded the naturalistic philosophy of Taoism.

ca 500 B.C.E. Heraclitus of Ephesus (540–475) maintained that permanence was an illusion and the only possible real state was the process of becoming.

ca. 450 B.C.E. Anaxagoras (500–428) proposed the first clearly materialist philosophy that the universe is made entirely of matter in motion.

ca. 440 B.C.E. Protagoras of Abdera (485–415) held that man is the measure of all things by which he meant that we only know what we perceive, not the thing perceived.

ca. 425 B.C.E. Herodotus of Halicarnassus (c. 485–c. 420) wrote the first scientific history by asking questions rather than just telling what he thinks he knows.

399 B.C.E. Socrates (469–399) drank hemlock as punishment for his subversive views. His fate demonstrated the conflict between the philosopher (knowledge) and the city and the paradox that a liberal education is at once radical (challenging conventions) and conservative (forming good citizens).

ca. 380 B.C.E.	At his Academy in Athens, Plato (420–340) expounded his metaphysics based upon the doctrine of forms, or eternal ideas.
ca. 335 B.C.E.	Aristotle (384–322) established the Lyceum in Athens and wrote on such varied topics as logic, ethics, physics, metaphysics, politics, epistemology, and biology.
ca. 300 B.C.E.	Epicurus (341–270) adopted and expanded the philosophy of atomism, in which all happens purely by chance, raising questions of determinism and freedom.
ca. 50 B.C.E.	Marcus Tullius Cicero (106–43) transformed Greek philosophy into a practical affair, suitable to Roman concerns about law, governance, and military strategy.
ca. 350 C.E.	Christianity began to fluorish and its doctrines became systematized during several ecumenical councils.
397 C.E.	Augustine (354–430) wrote *The Confessions*.

Scientific Discoveries

ca. 530 B.C.E.	Pythagoras (585–497) studied musical intervals and regarded mathematics as the study of ultimate, eternal reality, immanent in nature and the universe.
ca. 450 B.C.E.	Empedocles of Agrigento (d. 433) explained physical changes as movements of the basic particles of which things consisted, Fire, Earth, Air, and Water.
ca. 430 B.C.E.	Hippocrates of Chios (c. 460–c. 377) squared the lune, a major step toward squaring the circle.
ca. 420 B.C.E.	Democritus of Abdera (c. 460–c. 370) developed atomic theory, which held that haphazard collisions of atoms accounted for the formation and dissolution of objects.
ca. 300 B.C.E.	Epicurus (341–270) attempted to deal with the contradictions between constant atoms and the appearance of novel combinations.
ca. 300 B.C.E.	Euclid (365–300) wrote "Elements," a treatise on geometry. He offered an axiomatic system based on a few "common notions" and five basic postulates.
300 B.C.E.	The number of volumes in the Library of Alexandria reached 500,000.
ca. 260 B.C.E.	Archimedes of Syracuse (c. 287–212) formulated the principle that a body immersed in fluid is buoyed up by a force equal to the weight of the displaced fluid.
45 B.C.E.	Sosigenes of Alexandria designed a calendar of 365.25 days, which was introduced by Julius Caesar.
ca. 10 C.E.	Strabo (c. 63 B.C.E. –c. 24C.E.) published his *Geographia*, which served as an encyclopedia of geographical knowledge at that time.
ca. 50 C.E.	Hero of Alexandria explained that the four elements consist of atoms. He also observed that heated air expanded and made contributions to optics and geometry.
127–141 C.E.	Claudius Ptolemaeus (c. 85–c. 165), or Ptolemy, compiled a compendium of opinion and data on the stars. He rejected the Peripatetic physics of the heavens.
ca. 170 C.E.	Claudius Galen (131–201) used pulse taking as a diagnostic, performed animal dissections, and wrote treatises on anatomy.
190 C.E.	Chinese mathematicians calculated pi to five decimal places. Archimedes had previously done so in the third century B.C.E.

Age of Faith 500–1400

World Events

ca. 450–1200	Europe was in the Middle Ages.
ca. 500–900	The Mayan Civilization dominated much of Mesoamerica.
527–565	The Byzantium Empire spread under Justinian's rule.
541	The bubonic plague spread from Egypt throughout the Roman–Byzantine world.
581–907	The Sui and Tang Dynasties ruled in China.

610	Mohammed began to secretly preach at Mecca.
771	Charlemagne became the king of all Franks.
ca. 900–1000	The Vikings discovered Greenland.
960–1279	The Song Dynasty ruled in China.
1066	William of Normandy became the first king of England.
1095–1291	The Crusades.
1211–1223	Genghis Khan invaded China, Persia, and Russia.
1215	King John of England signed the Magna Carta, which limited the powers of the king and guaranteed certain political liberties.
1271	Marco Polo (1254-1324, Venetia) journeyed to China along the Silk Road.
1281–1919	The Ottoman Empire reached its zenith in the sixteenth century, but then declined until it was ultimately dissolved in the aftermath of World War I.
ca. 1300–1600	The Renaissance in Europe marked the end of the Middle Ages. It was a cultural movement that revived the works of ancient Greece and Rome.
1337–1453	France and England fought the Hundred Years' War.
1347–1351	The Black Death, bubonic plague, wiped out roughly a third of Europe's population.
1368–1644	The Ming Dynasty ruled in China.

Technological Inventions

700	Block printing was developed in Japan.
700	The Chinese invented porcelain.
ca. 770	Stirrups were introduced in Frankish lands, enabling the development of the armored knight and mounted shock combat, which vastly altered society.
ca. 770	Iron horseshoes were common.
ca. 850	The Moors in Spain prepared pure copper by reacting its salts with iron, a forerunner of electroplating.
867	Wang Jie printed the oldest book known, *The Diamond Sutra*, in China.
ca. 1045	The Chinese inventor Pi Sheng made moveable type of earthenware.
ca. 1100	The crossbow was developed in Europe and outlawed, in 1139, by the second Ecumenical Lateran Council, as one of the first formal attempts at arms control.
ca. 1250	Gunpowder became known in Europe, perhaps introduced from China through the Mongols.
ca. 1350	Cannons were used widely in European battles. Developments in gunpowder in helped speed the military adoption of cannons.

Philosophy and Ethics

ca. 1250	Albert of Bollstadt (c. 1200–1280, Bavaria), called Albertus Magnus, wrote commentaries on Aristotle and studied plant morphology and ecology.
1267–1268	Roger Bacon (1214–1294, England) championed empiricism and the modern scientific method, asserting that the only basis for certainty is experience, or verification.
1267–1273	Thomas Aquinas (1224–1274, born in Italy) composed a synthesis of Christianity and Aristotelian philosophy.

Scientific Discoveries

ca. 1000	Ibn Sina (980–1037, Persia), or Avicenna, studied medicine and geology and challenged Aristotelian conceptions of motion.
ca. 1000	Ibn al-Haitham (965–1038, Arabia), or al-Hazen, studied optics and challenged Ptolemy by insisting that the hypothetical spheres corresponded to real bodies.
ca. 1190	Moses ben Maimon (1135–1204, born in Spain), or Maimonides, studied astrological systems and maintained the separation of earthly and heavenly spheres.
ca. 1215	Robert Grosseteste (1168–1253, England) studied optics and analyzed the

	inductive and experimental procedures of science.
ca. 1323	William Ockham (1285–1349, England) introduced the distinction between dynamic motion and kinematic motion.
1337	William Merle of Oxford made regular records of the weather.

Age of Discovery 1400–1750

World Events

1418	Prince Henry the Navigator (1394–1460, Portugal) began exploring Africa.
1431	Joan of Arc (1412–1431, France) was burned at the stake.
1486	Bartolomeu Dias (1450–1500, Portugal) sailed around the Cape of Good Hope.
1492–1504	Christopher Columbus (1451–1506, Italy) discovered the Caribbean islands.
1497	Vasco da Gama (1469–1524, Portugal) sailed around Africa, discovering a sea route to India.
1509	Michelangelo (1475–1564, Italy) painted the ceiling of the Sistine Chapel.
1517	Martin Luther (1483–1546, Germany) posted his ninety–five theses in Wittenberg, initiating the Reformation.
1519–1521	Ferdinand Magellan (c. 1470–1521, Portugal) circumnavigated the globe.
1547	Ivan IV (1530–1584), or Ivan the Terrible, became the first ruler of Russia to claim the title of tsar.
1607	Jamestown, Virginia was established as the first English colony in the New World.
1618–1648	The Thirty Years' War raged between Protestants and Catholics.
1619	The first slaves were transported to America.
1620	Pilgrims landed at Plymouth Rock, Massachusetts.
1644	The Ming Dynasty ends in China and the Manchus come to power.
1661	Louis XIV (1638–1715) became absolute monarch of France.
1660	The Royal Society of London was founded.
1682	Peter the Great (1672–1725) became tsar of Russia. His efforts at westernization led to the development of Russia as a major European power.
1704	Johann Sebastian Bach (1685–1750, Germany) began composing music.

Technological Inventions

1437	Johann Gutenberg (c. 1390–1468, Germany) became the first in Europe to print with movable type cast in molds.
1475	The first muzzle-loaded rifles were developed in Italy and Germany.
1502	Peter Henlein of Nuremberg (c. 1480–1542, Germany) constructed the first watch.
1568	Concrete, which had been used in ancient times, was resuscitated by the architect Philibert de l'Orme (c. 1510–1570, France), who publicized its composition.
ca 1595	Spectacle maker Zacharias Janssen (1580–1638, Netherlands) invented the compound microscope.
1592	Galileo (1564–1642, Tuscany) invented a thermometer.
1594	Alexander Cummings (England) invented the flush toilet under English patent number 814. The ancient Cretans, however, used flush toilets as early as ca 2000 B.C.E.
1605	Hans Lippershey (c. 1570–1619, Netherlands) developed the telescope.
1621	Dud Dudley (1599–1684, England) invented the first blast furnace.
1625	William Oughtred (1575–1660, England) invented the slide rule.
1654	Otto von Guericke (1602–1686, Germany) invented the vacuum

pump and the Magdeburg hemispheres.

1707 Denis Papin (1647–c. 1712, France) invented the high–pressure boiler.

1718 James Puckle (1667–1724, England) invented the machine gun. The Puckle Gun was capable of firing nine rounds before being reloaded.

ca. 1730 Two different men, John Hadley (1682–1744, England) and Thomas Godfrey (1704–1749, American colonies) independently invent the Sextant.

Philosophy and Ethics

1503 Desiderius Erasmus (1466–1536, Netherlands) argued that the chief evil of the day was a blind respect for traditions without considering the true message of Christ.

1532 *The Prince* by Niccolò Machiavelli (1469–1527, Italy) was published. It presents an early form of utilitarianism and realpolitik, although Machiavelli was a Republican.

1583 Giordano Bruno (1548–1600, Italy) defended a decentralized, infinite universe, governed by the identity of fundamental laws, rather than two separate spheres.

1620 Francis Bacon (1561–1626, England) published *Novum Organum*, which modeled an early form of empiricism as superior to scholastic a priori methods.

1637 René Descartes (1596–1650, France) wrote *Discourse on Method*

1651 Thomas Hobbes (1588–1679, England), in *Leviathan*, argued that humans must surrender individual autonomy to the state in order to avoid constant war.

1690 John Locke (1632–1704, England) argued that the mind is a blank slate. He also defended a social contract theory of the state and individual property rights.

1710 George Berkeley (1685–1753, Ireland) developed idealism, which holds that qualities, not things, are perceived and that perception is relative to the perceiver.

1725 Giovanni Battista Vico (1668–1774, Italy) critiqued the methodology of the natural sciences and maintained that truth is an act made by humans.

1748 David Hume (1711–1776, Scotland) described the mind as a bundle of perceptions and argued that moral obligation is a function of human passion rather than reason.

Scientific Discoveries

ca. 1482 Leonardo da Vinci (1452–1519, Italy) studied the human body and improved and invented many instruments with a devotion to the Archimedean ideal of measurement.

1536 Philippus Aureolus Paracelsus (1493–1541, Switzerland) foreshadowed systematic, modern medicine by rejecting the bodily "humours" as explanatory terms in physiology.

1543 Nicolaus Copernicus (1473–1543, Poland) defended heliocentrism along NeoPlatonic lines.

1569 Gerard de Cremer (1512–1594, Flanders), or Gerardus Mercator, published the projection map of the world that bears his name.

1572 Tycho Brahe (1546–1601, Denmark) observed a supernova in the constellation *Cassiopeia*, now known as Tycho's star.

1583 Galileo Galilei (1564–1643, Tuscany) pioneered the scientific age due to his systematic, quantitative experiments and his mathematical analysis of their results.

1586 Simon Stevin (1548–1620, Denmark) maintained that perpetual motion was impossible and made contributions to physics and geometry.

1604 Johannes Kepler (1571–1630, Germany) held that the intensity of light varies inversely with the square of the distance from the source.

1619 Kepler stated the third law of planetary motion, argued that the planets' orbits were ellipses, and developed a universal law to explain both heavenly and earthly bodies.

1627 William Harvey (1578–1657, England) confirmed his observation that the blood circulates throughout the body, which he inferred from the structure of the venal valves.

ca. 1629 Pierre de Fermat (1601–1665, France) discovered the fundamental principle of analytic geometry and pioneered differential calculus.

1633 The Inquisition forced Galileo to recant his belief in Copernican theory.

1650 Archbishop Usher estimated by reading the Bible that the earth was created on October 23, 4004 B.C.E. at 9:00 am.

1654 Blaise Pascal (1623–1662, France) and Pierre de Fermat developed the foundation for the theory of probability.

1661 Robert Boyle (1627–1691, England) separated chemistry from alchemy, leading to the general abandonment of ancient concepts of matter.

1665 Robert Hooke (1635–1703, England) named and gave the first description of cells.

1665–1666 Newton (1643–1727, England) made discoveries in calculus, universal gravitation, and optics.

1674 Anton van Leeuwenhoek (1632–1723, Netherlands) reported his discovery of protozoa. He made contributions to the microscope and cell biology.

1675 Gottfried Wilhelm von Leibniz (1646–1716, Germany) developed differential calculus.

1684 Leibniz published his system of calculus, developed independently of Newton. It is Leibniz's notation that has been adopted.

1687 Newton argued that natural laws govern the behavior of earthly and heavenly bodies. These laws of motion the groundwork for classical mechanics.

1693 Edmund Halley (1656–1742, England) discovered the formula for the focus of a lens and suggested a measurement of the distance between the earth and the sun.

Age of Revolution 1750 - 1830

World Events

1756–1763 The Seven Years' War was the first "world war" involving most European countries and their colonies around the globe.

1762 Catherine the Great (1729–1796) ascended the Russian throne.

1775–1783 The American Revolution began with the battle of Lexington and Concord and ended with the Treaty of Paris.

1789–1799 The French Revolution began with the storming of the Bastille and culminated in a coup by Napoleon.

1796 Napoleon Bonaparte (1769–1821, France) defeated Austria in the first of a string of military victories in Europe.

1799 French troops under Bonaparte discovered the Rosetta Stone that permitted Thomas Young and Jean–François Champollian to decipher Egyptian hieroglyphs.

1800–1830 Several Latin American countries won their Independence. For example: Venezuela 1810, Argentina 1816, Peru 1821, Brazil 1822, and Bolivia 1825.

1803 The Louisiana Purchase ushered in an era of expansion in America.

1808 Johann Wolfgang von Goethe (1749–1832, Germany) wrote the first part of *Faust*, a cautionary tale about the corrupting force of the powers that knowledge can unlock.

Technological Inventions

1752 Benjamin Franklin (1706–1790, U.S.) invented a lightening conductor. He also invented the Franklin stove and bifocals.

1764 James Hargreaves (1720–1778, England) invented the spinning jenny.

1769 James Watt (1736–1819, Scotland) patented a new type of steam engine equipped with a simple centrifugal "governor" for safety.

1785 Edmund Cartwright (1743–1823, England) invented the power loom.

1794 Eli Whitney (1765–1825, U.S.) patented the cotton gin, which quickly and easily separated the fiber from the seeds and seedpods.

1796 Edward Jenner (1749–1823, England) developed the first system of vaccination, by infecting patients with cowpox in order to make them resistant to smallpox.

1800 Alessandro Volta (1745–1827, Italy) invented the electric battery, a device that stores energy and makes it available in an electric form.

1804 Richard Trevithick (1771–1833, England) built the first steam–powered locomotive.

1826 Samuel Morey (1762–1843, U.S.) invented the internal combustion engine.

Philosophy and Ethics

1762 Jean-Jacques Rousseau (1712–1778, Switzerland) argued that the only natural association for humans is the family and that society must form a social contract.

1776 Adam Smith (1723–1790, Scotland) advanced the idea that businesses survive through successful trading in pursuit of their self–interest.

1781 and 1787 Immanuel Kant (1724–1804, Prussia) wrote the *Critique of Pure Reason*, in which he distinguished sensory from a priori elements of reason.

1789 Jeremy Bentham (1748–1832, England) outlined an ethical system based on a hedonistic calculation of the utility of actions and the greatest happiness of all.

1807 Georg Wilhelm Friedrich Hegel (1770–1831, Germany) criticized the distinction of objective and subjective and developed a dialectical and comprehensive philosophy.

1819 Arthur Schopenhauer (1788–1860, Germany) developed a life philosophy centered on the concept of will.

Scientific Discoveries

1751 Benjamin Franklin published works on electricity and invented many terms still in use, including positive, negative, conductor, and battery.

1754 Jean Le Rond d'Alembert (1717–1783, France) formulated "D'Alembert's ratio."

1766 Henry Cavendish (1731–1810, England) isolated and described "inflammable air," later named hydrogen, and distinguished it from carbon dioxide.

1772 Daniel Rutherford (1749–1819, England) discovered nitrogen.

1774 Joseph Priestly (1733–1804, England) discovered sulphur dioxide, ammonia, and "dephlogisticated air," later named oxygen.

1780 Antoine Laurent Lavoisier (1743–1794, France) and Pierre-Simon Laplace (1749–1827, France) developed a theory of chemical and thermal phenomena based on the assumption that heat is a substance and held that respiration is a form of combustion.

1783 Lazare Nicolas Marguerite Carnot (1753–1823, France) specified the optimal and abstract conditions for the operation of machines.

1786 Kant suggested the doctrine of the unity and convertibility of forces.

1787 Lavoisier published a nomenclature of chemistry.

1791 Goethe began publishing works on optics and developed a holistic philosophy opposed to Newtonian reductionism's dependence on theoretical constructs.

1795 James Hutton (1726–1797, Scotland) wrote the earliest comprehensive treatise that is a geologic synthesis, featuring uniformitarianism as a guiding principle.

1801 John Dalton (1766–1844, England) formulated the law of gaseous expansion at constant pressure and the law of gaseous partial pressures.

1803 Dalton put forth his theory of the atom.

1808 Dalton published a periodic table based on atomic weights.

1809 Jean-Baptiste Monet de Lamarck (1744–1829, France) stated that acquired characteristics were heritable and was a proponent of evolution.

1811 Amedeo Avogadro (1776–1856, Italy) proposed that equal volumes of gases at the same temperature and pressure contain the same number of molecules.

1824 Sadi Carnot (1796–1832, France) established the fundamental theory of the internal combustion engine and initiated the modern theory of thermodynamics.

1829 Charles Lyell (1797–1875, England) expanded on the principle of uniformitarianism and constant change in geology, which was useful for developing theories of evolution.

The Age of Industry and Empire 1830–1910

World Events

1830 The first railroad came into operation, running between Liverpool and Manchester, England.

1839 China was defeated by Britain in the First Opium War.

1848 Europe was convulsed with political revolutions.

1848 Mexico ceded vast amounts of land to the U.S. at the end of the Mexican War.

1849 The California gold rush drew thousands of settlers out West.

1858 Britain imposed formal colonial rule on India.

1859 Edwin Drake (1819–1880, U.S.) discovers oil near Titusville, Pennsylvania, ushering in the massive exploitation of petroleum to fuel modern industrialization.

1869 The first transcontinental train route in U.S. was completed.

1869 A French company completed the Suez Canal, allowing water transport between Europe and Asia without circumnavigating Africa.

1871 Kaiser Wilhelm I was declared German Emperor and the North German Confederation was transformed into the German Empire (Deutsches Reich).

1861–1865 The American Civil War was fought between the Union and the Confederacy. Slavery was ended by the Thirteenth Amendment in 1865.

1880s The French began using the first pesticide.

1884–1885 The Berlin Conference regulated and formalized the colonization of Africa by European countries.

1887 The U.S. Congress founded the National Institutes of Health (NIH).

1898 The U.S. gained control of Cuba and the Philippines in the Spanish American War.

1904 The New York City subway opened.

Technological Inventions

1831 Michael Faraday (1791–1867, England) invented the electrical generator and the Bunsen burner and performed pioneering experiments in electromagnetism.

1834 Thomas Davenport (1802–1851, U.S.) is generally credited with inventing the electric motor.

1835 Charles Babbage (1791–1871, England) started work on the first "analytical engine," a precursor to the modern computer that used punch cards.

1835 Samuel Colt (1814–1862, U.S.) invented the revolver pistol.

1837 Samuel F. B. Morse (1791–1872, U.S.) invented the electrical telegraph and Morse code.

1838 John Deere (1804–1886, U.S.) invented the first cast-steel plow, a significant improvement over iron plows.

1853 Henry Bessemer (1813–1898, England) and William Kelly (1811–1888, U.S.) invented the Bessemer steel process.

1860 J.J.E. Lenoir (1822–1900, France) developed the first practical internal combustion engine. It relied upon coal gas and was double–acting.

1866 Alfred Nobel (1833–1896, Sweden) patented dynamite. It consisted of a mixture of nitroglycerine with inert, absorbent clay such as kieselguhr.

1866 Wilhelm (1855–1919, Germany) and Carl Friedrich von Siemens (1872–1941, Germany) invented the open–hearth furnace.

1866 Christopher Sholes (1819–1890, U.S.) invented the first modern, practical typewriter.

1876 Alexander Graham Bell (1847–1922, Scotland–Canada–U.S.) invented the telephone.

1876 Nikolas August Otto (1832–1891, Germany) designed the first four–stroke piston engine.

1877 Thomas A. Edison (1847–1931, U.S.) developed the phonograph, or gramophone, the first device for recording and replaying sound.

1879 Edison achieved his goal of making the burning time of the electric light bulb long enough to be commercially viable.

1882 Nikola Tesla (1856–1943, Serbia–U.S.) built the first induction motor, invented the Tesla coil (a type of transformer), and performed work on rotating magnetic fields.

1883 Sir Joseph Swann (1828–1914, England) invented the first synthetic fiber.

1885 Carl Friedrich Benz (1844–1929, Germany) invented the gasoline–powered automobile. The work of Gottlieb Daimler (1834–1900, Germany) was also important.

1885 George Eastman (1854–1932, U.S.) invented roll film, which brought photography into popular usage and was the basis for the later invention of motion picture film.

1898 Rudolf Diesel (1858–1913, France-Germany) received a patent for the diesel engine.

1903 Orville (1871–1948, U.S.) and Wilbur Wright (1867–1912, U.S.) achieved flight in a manned, gasoline power–driven, heavier–than–air flying machine.

1904 Building off the work of Heinrich Hertz (1857–1894, Germany) and James Clerk Maxwell (1831–1879, Scotland), Christian Huelsmeyer invented radar.

Philosophy and Ethics

1830 Auguste Comte (1798–1857, France) developed positivism, a belief that natural science comprises the whole of human knowledge.

1855 Herbert Spencer (1820–1903, England) attempted to generalize from Darwinian evolution a comprehensive account of human social and moral progress.

1861 John Stuart Mill (1806–1873, England) extended and refined Bentham's utilitarian moral theory.

1867 Karl Marx (1818–1883, Prussia) systematically critiqued capitalism and developed a philosophy of dialectical materialism to account for historical change.

1885 Friedrich Wilhelm Nietzsche (1844–1900, Germany) deconstructed all meta-narratives and advocated the transvaluation of values through the strength of will.

1890 William James (1842–1910, U.S.) developed psychological theory into a systematic science and advanced a philosophy of pragmatism.

1900 Sigmund Freud (1856–1939, Austria) developed a tripartite under-

	standing of human being and emphasized the importance of unconscious forces.
1903	G.E. Moore (1873–1958, England) rejected the "naturalistic fallacy" and developed analytic philosophy.

Scientific Discoveries

1820	Hans Christian Orsted (1777–1851, Denmark) discovered the relationship between electricity and magnetism.
1831	Faraday discovered electromagnetic induction.
1839	Charles Goodyear (1800–1860, U.S.) discovered the vulcanization process that creates rubber.
1840	William Whewell (1794–1866, England) introduced the word "scientist" to distinguish science or natural philosophy from a priori reasoning and moral science.
1840	Louis Agassiz (1807–1873, Switzerland-U.S.) published a demonstration of the existence of a glacial epoch in the temperate zones.
1847	Hermann Ludwig Ferdinand von Helmholtz (1821–1894, Germany) formulated the law of the conservation of energy.
1854	George Boole (1815–1864, England) invented Boolean algebra, the foundation of all modern computer arithmetic.
1857	Louis Pasteur (1822–1895, France) demonstrated that lactic acid fermentation is carried out by living bacteria and performed work with chiral molecules.
1858	Rudolf Virchow (1821–1902, Germany) stated that "every cell originates from another cell." He made contributions to pathology, medicine, and anthropology.
1859	Charles Darwin (1809–1882, England) presented his theory of biological evolution by natural selection.
1866	Gregor Mendel (1822–1884, Austria) interpreted heredity in terms of a pairing of unit characters that could in practice be treated as indivisible and independent particles.
1888	Hertz discovered radio waves, verifying Maxwell's prediction of electromagnetic waves.
1891	Marie Eugene Dubois (1858-1940, Netherlands) discovered Javaman, now known as *Homo erectus*.
1893	Émile Durkheim (1858–1917, France) and Max Weber (1864–1920, Germany) founded sociology and explained religion in terms of its social functions.
1895	Wilhelm Conrad Röntgen (1845–1923, Germany) observed a new form of penetrating radiation, which he named X–rays.
1896	J.J. Thompson (1856–1940, England) discovered the electron, which had been posited earlier by G. Johnstone Stoney as a unit of charge in electrochemistry.
1900	Max Planck (1858–1947, Germany) developed Planck's Law of Black Body Radiation, a pioneering works in the development of quantum mechanics.
1905	Albert Einstein (1879–1955, Germany–U.S.) demonstrated that the presence of atoms could be confirmed by observing objects influenced by their fluctuations.
1905	Einstein developed the Special Theory of relativity.

The Modern World 1910–2004

World Events

1914–1919	World War I began with the assassination of Archduke Franz Ferdinand and ended when a vanquished Germany signed the Treaty of Versailles.
1917	The Russian Revolution gave rise to the USSR. The Bolsheviks became the Communist party and held power for most of the twentieth century.
1925	The "Monkey Trial" of John T. Scopes (1900–1970, U.S.) occurred

	in Tennessee after he taught evolution in his classroom.
1927	Charles Lindbergh (1902–1974, U.S.) flew solo across the Atlantic Ocean.
1929	Inflated by speculation with borrowed money, the U.S. stock market crashed in October, initiating the slide into the Great Depression that would last through the 1930s.
1930	The U.S. Food and Drug Administration (FDA) was created.
1931	The International Council for Science (ICSU) was founded.
1932	Aldous Huxley (1894–1963, England) published *Brave New World*, the classical formulation of a techno-scientific dystopia.
1939	Leo Szilard (1898–1964, Hungary–U.S.) and Eugene Paul Wigner (1902–1995, Hungary–U.S.) visited Einstein to discuss methods of averting a German atomic bomb.
1939	Britain and France declared war on Germany, signaling the beginning of World War II.
1941	Pearl Harbor, a U.S. naval base in Hawaii, was attacked by the Japanese.
1944	The liberation of mainland Europe from Nazi occupation commenced with the Battle of Normandy, D–Day, on June 6.
1945	On July 16, a plutonium atomic bomb was detonated at the Trinity Site in the New Mexico desert.
1945	On August 6 and August 9, the U.S. dropped atomic bombs on Hiroshima and Nagasaki, respectively. Hundreds of thousands were killed.
1945	World War II ended with the surrender of Germany and Japan.
1945	The United Nations was founded in San Francisco.
1947	The General Agreement on Tariffs and Trade, later renamed the World Trade Organization, signaled the beginning of institutionalized economic globalization.
1948	The state of Israel was proclaimed.
1949	The North Atlantic Treaty Organization was established to counter Soviet aggression.
1950–1953	The Korean War occurred between the communist North and anti-communist South and was a proxy war between the U.S. and the Soviet Union.
1950	The U.S. Congress established the National Science Foundation (NSF).
1955	Bertrand Russell (1872–1970, England) and Albert Einstein issued the Russell-Einstein Manifesto, which called for international arms control and peace.
1957	The USSR launched Sputnik I, the first artificial satellite to orbit earth. Sputnik II was launched shortly thereafter and carried the first living passenger, a dog named Laika.
1958	The U.S. Congress established the National Aeronautics and Space Administration (NASA).
1959	Richard Feynman (1918–1988, U.S.) delivered his now famous speech "There's Plenty of Room at the Bottom" that foreshadowed later developments in nanotechnology.
1960	The U.S. FDA approved the birth control pill.
1961–1975	The Vietnam War occurred between communist North Korea and its allies and South Korea and its allies, primarily the United States.
1962	Rachel Carson (1907–1964, U.S.) wrote *Silent Spring*, which detailed the negative impact of pesticides on the environment.
1962	Trofim Denisovich Lysenko (1898–1976, U.S.S.R.) was removed from his position as head of the Academy of Agricultural Sciences of the Soviet Union.

1963 The United States, Great Britain, and the Soviet Union signed the Limited Test Ban Treaty.

1966–1976 Mao Zedong (1893–1976) and his wife Jiang Qing (1914–1991) carried out the Cultural Revolution in China.

1966–1979 Workers at the U.S. Center for Disease Control and the World Health Organization eradicated smallpox worldwide with vaccinations and containment.

1968 The Nuclear Non–Proliferation Treaty took effect, prohibiting non-nuclear weapon States from possessing, manufacturing, or acquiring nuclear weapons.

1969 Neil A. Armstrong (b.1930, U.S.) became the first man to walk on Moon. He was accompanied by Edwin E. Aldrin, Jr. (b.1930, U.S.).

1970 The U.S. Environmental Protection Agency (EPA) was created.

1975 The Asilomar Conference established guidelines for the physical and biological containment of recombinant DNA (rDNA).

1976 The two U.S. Viking probes landed on Mars.

1979 On March 28, a reactor at the Three Mile Island Nuclear Generating Station (Pennsylvania, U.S.) suffered a partial core meltdown.

1979 The U.S. spacecraft Voyager 1 photographed Jupiter's rings.

1979 The first "test tube baby," Louise Brown (U.K.), was born using the technique of in vitro fertilization (IVF).

1984 A Union Carbide pesticide plant in Bhopal, India accidentally released forty tons of methyl isocyanate (MIC) into the surrounding environment.

1986 On January 28, the space shuttle Challenger exploded just seventy–three seconds after launch. The accident was caused by the failure of an O–ring seal in the right solid rocket booster.

1986 On April 26, the Chernobyl nuclear power plant in Ukraine (then part of the Soviet Union) suffered a catastrophic nuclear meltdown.

1988 The Intergovernmental Panel on Climate Change (IPCC) was created to assess climate science and the impacts of climate change.

1988 James Watson unilaterally sets aside three to five percent of the budget of the Human Genome Project to study Ethical, Legal, and Social Issues (ELSI) of genomic research.

1989 On March 24, the Exxon Valdez oil tanker spilled eleven million gallons of crude oil into Prince William Sound, Alaska. It was the worst oil spill in United States history.

1989 The Berlin wall was torn down, signaling the end of the cold war. Germany began the process of reunification.

1992 The United States and thirty–four other industrial nations met in Rio de Janeiro, Brazil to discuss world environmental concerns.

1993 The U.S. Supreme Court articulated its set of criteria for the admissibility of scientific expert testimony in the case of Daubert v. Merrell Dow.

1996 The Comprehensive Nuclear Test Ban Treaty was signed by seventy–one nations, banning all nuclear explosions in all environments for military or civilian purposes.

1997 The World Commission on the Ethics of Scientific Knowledge and Technology (COMEST) was created as a U.N. body.

2001 The U.S. President's Council on Bioethics was created as part of a decision by President George W. Bush (b. 1946) to fund limited stem cell research.

2001 On September 11, the World Trade Center and Pentagon were attacked by terrorists who had hijacked commercial airplanes.

2003 The Space Shuttle Columbia was lost when it exploded upon reentry.

Technological Inventions

1913 Henry Ford (1863–1947, U.S.) added the assembly line to his automobile plant at Highland Park, Michigan.

1916 Paul Langevin (1872–1946, France) achieved the first successful use of sonar.

1924 Robert Goddard (1882–1945, U.S.) built and launched the first liquid–fueled rocket.

1927 Vannevar Bush (1890–1974, U.S.) developed the Differential Analyzer, an analog computer, which sped the solution of problems related to the electric power network.

1927 Vladimir Zworykin (1889–1982, Russia–U.S.), Paul Nipkow (1860–1940, Germany), Philo T. Farnsworth (1906–1971, U.S.), and John Baird (1888–1946, Scotland) all contributed to the invention of television.

1935 IBM introduced a punch card machine with an arithmetic unit based on relays that could perform multiplication.

1936 Alan M. Turing (1912–1954, England) conceived the Turing machine, the abstract precursor of the computer that gave a mathematically precise definition to algorithm.

1936 Felix Wankel (1902–1988, Germany) designed a motor (the Wankel engine) that revolved around a central shaft, using a rotary piston instead of reciprocating pistons.

1938 Roy Plunkett (1910–1994, U.S.) accidentally invented Polytetrafluorethylene, commonly known as Teflon, while working at DuPont.

1940 Igor Sikorsky (1889–1972, Russia–U.S.) invented the helicopter.

ca. 1942 John von Neumann (1903–1957, Hungary–U.S.) developed architecture for a computing machine that allows it to be reprogrammable.

1944 Howard W. Aiken (1900–1973, U.S.) and a team of engineers from IBM displayed the first widely known and influential large scale automatic digital computer.

1945 The atomic bomb was developed in Los Alamos as part of the top secret Manhattan Project by J. Robert Oppenheimer (1904–1967, U.S.), Hans Bethe (1906–2005, Germany–U.S.), Einstein, Enrico Fermi (1901–1954, Italy–U.S.), Richard Feynman (1918–1988, U.S.) and hundreds of other scientists.

1946 The Raytheon Corporation patented the microwave oven. It built the first commercial microwave in 1947, which measured six feet tall and weighed 750 pounds.

1947 Working at Bell Labs, John Bardeen (1908–1991, U.S.), Walter Brattain (1902–1987, U.S.), and William Shockley (1910–1989, England–U.S.) invented the transistor, a solid state semiconductor device used for amplification and switching.

1949 Francis Bacon (1904–1992, England) invented a fuel cell, an electrochemical device similar to a battery, employing only hydrogen and water.

1951 Carl Djerassi (b.1923, Austria), Gregory Pincus (1903–1967, U.S.), Min Church Chiang, and John Rock (1890–1984, U.S.) all contributed to the invention of the oral contraceptive pill. Margaret Sanger (1879–1976, U.S.) worked to educate women about different birth control methods.

1954 Joseph Murray (b.1919, U.S.) and J. Hartwell Harrison performed the first successful human organ transplant.

1955 The USS Nautilus (SSN–571), the first nuclear powered submarine, was launched.

1955 Enrico Fermi and Leo Szilard received a joint U.S. patent for the nuclear reactor. The first nuclear power plant began producing electricity in Obninsk, Russia, in 1954.

1958 Jack Kilby (b.1923, U.S.) (Texas Instruments) and Robert Noyce (1927–1990, U.S.) (Fairchild Semiconductor) developed the first integrated circuit, a microelectronic semiconductor device consisting of many interconnected transistors.

1960 Theodore Maiman (b.1927, U.S.) invented the first operable laser, a device that uses generates a very collimated, monochromatic, and coherent beam of light.

1969 Edward Hoff (b.1937, U.S.) and Intel Corp. developed the microprocessor, which is an electronic computer central processing unit (CPU) made from miniaturized transistors and other circuit elements on a single semiconductor intergrated circuit (chip).

1969 The Advanced Research Projects Agency Network (ARPANET) of the U.S. Department of Defense was the world's first operational packet switching network and the progenitor of the global Internet.

1970 The first useful optical fiber was invented by researchers at Corning Glass Works.

1971 Bowmar released the first pocket-sized calculator, the 901B, with four functions and an eight–digit red LED display.

1977 Steven Jobs (b.1955, U.S.) and Steven Wozniak (b.1950, U.S.) introduced the Apple II, initiating the widespread use of home computers.

1979 The first commercial cellular phone service is started in Japan. Researchers at Bell Labs had been working on the technology since the late 1940s.

1980 Heinrich Rohrer (b.1933, Switzerland) and Gerd Binnig (b. 1947, Germany) developed a "scanning tunneling microscope."

1981 NASA launched the first space shuttle, Columbia.

1981 Programmers at Microsoft Corporation developed a computer disk operating system, MS–DOS.

1982 The FDA approved the first recombinant pharmaceutical, insulin. This allowed insulin to be used on a wide scale and reduced reactions to impurities.

1982 Sony and Philips Corporations introduced the compact disc (CD) player.

1983 ARPANET changed its core networking protocols from NCP to TCP/IP, marking the start of the Internet.

1985 Kary Banks Mullis (b. 1944, U.S.) and co-workers invented the polymerase chain reaction (PCR) which multiplies DNA sequences *in vitro*.

1985 Alec Jeffreys (b. 1950, England) invented DNA fingerprinting, a technique to distinguish between two individuals using only samples of their DNA.

1988 Working at the Roussel Uclaf company, Etienne Baulieu (France) developed the RU–486 abortifacient or "abortion pill," Mifepristone.

1989 Charles Bennett and Gilles Brassard built a quantum computer, a device that computes using superpostions and entaglement of quantum states.

1989 The World Wide Web was developed by Tim Berners-Lee (b. 1955, England). The current web can be traced back to a project at CERN (the European Organization for Particles Physics Research) called ENQUIRE. The primary underlying concept of hypertext came from earlier efforts such as Vannevar Bush's memex and Ted Nelson's (b. 1937, U.S.) Project Xanadu.

1990 W. French Anderson (U.S.) performed the first gene transplant on a human being, injecting engineered genes into a four–year–old to repair her faulty immune system.

1990 Scientists at NASA and the European Space Agency (ESA) launched the Hubble Space Telescope.

1993 The work of Ivan Getting and Bradford Parkinson led to the invention of the Global Positioning System (GPS).

1997 The digital versatile disk (DVD) was introduced.

Philosophy and Ethics

1910 Alfred North Whitehead (1861–1947, England) and Bertrand Russell put forth the theory that there is a discontinuity between a class and its members and attempted to overcome certain logical paradoxes by the formal device of branding them meaningless.

1918 Ludwig Wittgenstein (1889–1951, Austria) put forth his theory of language as "picturing" reality, which he later abandoned for language as a system or a game played amongst a community.

1929 John Dewey (1859–1952, U.S.) argued that an experimental approach to moral decision making promised to solve the fact/value gap that had been championed by several analytic philosophers.

1934 Karl R. Popper (1902–1994, Austria)advanced the theory that the test of an empirical system, the demarcation of the limit of scientific knowledge, is its "falsifiability" and not its "verifiability."

1949 Simon de Beauvoir (1908–1986, France)traced the oppression of women through literary and historic sources and argued that the male is objectified as a positive norm.

1951 Willard Van Orman Quine (1908–2000, U.S.) argued against reductionism and the distinction between analytic and synthetic.

1953 Martin Heidegger (1889–1976, Germany) argued that modern technology reveals the world as an undifferentiated standing reserve (Bestand) of energy and resources subordinated to the will of humans, thus, the culmination of modern nihilism. He contrasted the way in which technology conceals Being to the way in which Being is revealed by the language of poetry.

1958 Hannah Arendt (1906–1975, Germany-U.S.) analyzed the modern human condition marked by the hegemony of laboring and making over action and the revolt against natural limits.

1962 Thomas S. Kuhn (1922–1996, U.S.) argued that new scientific paradigms are formed and retained because they are useful and conform to the standards of a community of practitioners, not because they approximate reality.

1971 John Rawls (1921–2002, U.S.) outlined the social arrangement of the "veil of ignorance" that guarantees no interests will be sacrificed arbitrarily to the interests of others. His concept of "justice as fairness" presented a non-historical variation of the social contract theory.

1974 Robert Nozick (1938–2002, U.S.) claimed that direct action by the state is rarely warranted, and that justice should be evaluated by reference to the means by which social policies are implemented, rather than their consequences.

1974 Thomas Nagel (b. 1937, U.S.) attempted to reconcile the subjective elements of human life with the urge for objective, value free truth.

1975 Peter Singer (b.1946, Australia) argued that, since a difference of species entails no moral distinction between sentient beings, it is wrong to mistreat non–human animals.

1978 Mary Daly (b. 1928, U.S.) argued that women must create a separate culture in order to fully effect their power outside of a patriarichal society.

1979 Hans Jonas (1903–1993, born in Germany) formulated a new ethics designed to save humanity from the excesses of its own technological powers.

1981 Jurgen Habermas (b. 1929, Germany) developed a theory of moral discourse and knowledge in society as part of a larger effort to develop a post–metaphysical normativity founded on interpersonal relationships.

1982 Richard Rorty (b. 1931, U.S.) distinguished between Platonic, Positivist, and Pragmatist notions of truth and the consequences for acting on each choice.

1986 Martha Nussbaum (b. 1947, U.S.) argued that the moral philosophy of Aristotle remains relevant in the examination of human emotions and decision making.

Scientific Discoveries

1910 Fritz Haber (1868–1934, Germany) and Carl Bosch (1874–1940, Germany) patented the Haber–Bosch process for producing ammonia from the nitrogen contained in air.

1911 Einstein made predictions about the influence of gravity on the propagation of light.

1913 Niels Bohr (1885–1962, Denmark) calculated closely the frequencies of the spectrum of atomic hydrogen, supporting his conception of electron orbitals and foreshadowing quantum mechanics.

1915 Einstein completed the mathematical generalization of the theory of relativity and attributed the magic of the theory to differential calculus. This theory replaced the Kepler–Newton theory of planetary motion.

1923 Sigmund Freud (1856–1939, Austria) argued that the functioning of the mental apparatus is best understood as being the result of the interaction among three agencies or structures, which he labeled id, ego, and superego.

1925 Werner Heisenberg (1901–1976, Germany) formulated matrix mechanics, the first formalization of quantum mechanics.

1926 Erwin Schrödinger (1887–1961, Austria) initiated the development of the final quantum theory by describing wave mechanics, which predicted the positions of the electrons.

1927 Heisenberg proposed the Uncertainty Principle, which states that one cannot simultaneously determine the position and momentum of a subatomic particle.

1929 Alexander Fleming (1881–1955, Scotland) discovered the antibiotic substance lysozyme and issued a publication about penicillin.

1937 Hans Adolf Krebs (1900–1981, Germany) discovered the citrus acid cycle, also known as the tricarboxylic acid cycle and the Krebs cycle.

1938 Otto Hahn (1879–1968, Germany), Lise Meitner (1878–1968, Austria-Germany), and co–workers discovered nuclear fission.

1942 Paul Herman Mueller discovered the insecticidal properties of DDT (Dichloro–diphenyl–trichloroethane). DDT was first synthesized in 1873.

1943 Selman Waksman (1888–1973, Russia-U.S.) discovered streptomycin, which was the first antibiotic remedy for tuberculosis. It was first isolated by Albert Schatz, Waksman's research student.

1944 Friedrich Hayek (1899–1992, Austria) argued that only the unorganized price system in a free market enables order to arise from the chaos of individual plans.

1945 Vannevar Bush presented his vision of the "memex," which foreshadowed personal computers and hypertext systems like the World Wide Web.

1947 Ilya Prigogine (1917–2003, Belgium) studied dissipative structures and the self-organization of open thermodynamic systems.

1947 Willard Libby (1908–1980, U.S.) and others develop radiocarbon dating.

1948 George Gamow (1904–1968, Russia–U.S.) and Ralph Alpher (b.1921, U.S.) published the big bang theory of how the universe began.

1950 Norbert Wiener (1894–1946, U.S.) popularized the social implications of the emerging field of cybernetics.

1953 Working with the x-ray research of Rosalind Franklin (1920–1958, England), James Watson (b.1928, U.S.-England) and Francis Crick (1916–2004, England) built a model of DNA showing that the structure was two paired, complementary strands, helical and anti-parallel, associated by secondary, noncovalent bonds.

1964 Louis Leaky (1903–1972, U.K.) identified and named *Homo habilis*.

1970 Stephen Hawking (b.1942, England) and Roger Penrose (b.1931, England) proved that the Universe must have had a beginning in time, on the basis of Einstein's theory of General Relativity.

1975 Edward O. Wilson (b.1929, U.S.) analyzed the social instincts of animals and humans, giving rise to sociobiology.

1976 Richard Dawkins (b.1941, England) argued that the gene (or the "meme" in cultural evolution) is the relevant unit of selection.

1984 Luc Montagnier (b.1932, France) and other scientists working at the Pasteur Institute isolated the human immunodeficiency virus, or HIV. Robert Gallo (b.1937, U.S.) published the discovery of the HIV virus in the same year.

1984 Joe Farman, Brian Gardiner, and Jonathan Shanklin (England) published their discovery of the ozone hole.

1996 At the Roslin Institute in Scotland, Ian Wilmut (b.1944, Scotland) and Keith Campbell (England) cloned a sheep, "Dolly" (1996–2003), from adult cells.

1997 The U.S. Pathfinder vehicle studied and photographed Mars.

1998 Robert Waterston, John E. Sulston, and numerous colleagues reported the mapping of the entire genome of *Caenorhabditis elegans*.

2000 Researchers at the Human Genome Project completed a rough draft of the nucleotide sequence of the human genome. The project was completed ahead of schedule due to advances in sequence analysis and computer technologies.

2000 Craig Venter (b.1946, U.S.) led a team which sequenced the genome of *Drosophila melanogaster*.

2004 Mars rovers Spirit and Opportunity sent back photos of the red planet and collected data that further supported the hypothesis that water was once prevalent on Mars.

2004 Researchers at Seoul National University in South Korea became the first to clone a human embryo and then cull master stem cells from it.

COMPILED BY ADAM BRIGGLE AND CARL MITCHAM

APPENDIX V

ETHICS CODES AND RELATED DOCUMENTS

This selective collection of professional ethics codes related to technology, engineering, and science, in both the professional and corporate contexts, along with a few declarations and manifestos, indicates the wide range of responses that exist in the technical and intellectual communities to some of the issues covered in the Encyclopedia of Science, Technology, and Ethics. *Most well developed are codes of conduct in the medical professional (which are well documented in the* Encyclopedia of Bioethics *and thus not duplicated here) and the engineering profession, as is indicated by the number of official documents from engineering societies throughout the world. Two other major resources for professional codes of this and related types can be found at the Case Western Reserve Online Ethics Center for Engineering and Science (onlineethics.org) and the Illinois Institute of Technology Center for the Study of Ethics in the Professions (ethics.iit.edu).*

Definition of Research Misconduct from the U.S. Federal Register

THE AMERICAN INSTITUTE OF ARCHITECTS (AIA): 2004 CODE OF ETHICS AND PROFESSIONAL CONDUCT

Preamble

Members of The American Institute of Architects are dedicated to the highest standards of professionalism, integrity, and competence. This **Code of Ethics and Professional Conduct** states guidelines for the conduct of Members in fulfilling those obligations. The **Code** is arranged in three tiers of statements:

- Canons, Ethical Standards, and Rules of Conduct:
- Canons are broad principles of conduct.
- Ethical Standards (E.S.) are more specific goals toward which Members should aspire in professional performance and behavior.
- Rules of Conduct (Rule) are mandatory; violation of a Rule is grounds for disciplinary action by the Institute.

Rules of Conduct, in some instances, implement more than one Canon or Ethical Standard. The **Code** applies to the professional activities of all classes of Members, wherever they occur. It addresses responsibilities to the public, which the profession serves and enriches; to the clients and users of architecture and in the building industries, who help to shape the built environment; and to the art and science of architecture, that continuum of knowledge and creation which is the heritage and legacy of the profession. Commentary is provided for some of the Rules of Conduct. That commentary is meant to clarify or elaborate the intent of the rule. The commentary is not part of the *Code*. Enforcement will be determined by application of the Rules of Conduct alone; the commentary will assist those seeking to conform their conduct to the **Code** and those charged with its enforcement.

Statement in Compliance with Antitrust Law

The following practices are not, in themselves, unethical, unprofessional, or contrary to any policy of The American Institute of Architects or any of its components:

1. submitting, at any time, competitive bids or price quotations, including in circumstances where price is the sole or principal consideration in the selection of an architect;
2. providing discounts; or
3. providing free services.

Individual architects or architecture firms, acting alone and not on behalf of the Institute or any of its components, are free to decide for themselves whether or not to engage in any of these practices. Antitrust law permits the Institute, its components, or Members to advocate legislative or other government policies or actions relating to these practices. Finally, architects should continue to consult with state laws or regulations governing the practice of architecture.

CANON I

General Obligations

Members should maintain and advance their knowledge of the art and science of architecture, respect the body of architectural accomplishment, contribute to its growth, thoughtfully consider the social and environmental impact of their professional activities, and exercise learned and uncompromised professional judgment.

E.S. 1.1 Knowledge and Skill: Members should strive to improve their professional knowledge and skill.

Rule In practicing architecture, **1.101** Members shall demonstrate a consistent pattern of reasonable care and competence, and shall apply the technical knowledge and skill which is ordinarily applied by architects of good standing practicing in the same locality.

Commentary: By requiring a ''consistent pattern'' of adherence to the common law standard of competence, this rule allows for discipline of a Member who more than infrequently does not achieve that standard. Isolated instances of minor lapses would not provide the basis for discipline.

E.S. 1.2 Standards of Excellence: Members should continually seek to raise the standards of aesthetic excellence, architectural education, research, training, and practice.

E.S. 1.3 Natural and Cultural Heritage: Members should respect and help conserve their natural and cultural heritage while striving to improve the environment and the quality of life within it.

E.S. 1.4 Human Rights: Members should uphold human rights in all their professional endeavors.

Rule 1.401 Members shall not discriminate in their professional activities on the basis of race, religion, gender, national origin, age, disability, or sexual orientation.

E.S. 1.5 Allied Arts & Industries: Members should promote allied arts and contribute to the knowledge and capability of the building industries as a whole.

CANON II

Obligations to the Public

Members should embrace the spirit and letter of the law governing their professional affairs and should promote and serve the public interest in their personal and professional activities.

E.S. 2.1 Conduct: Members should uphold the law in the conduct of their professional activities.

Rule 2.101 Members shall not, in the conduct of their professional practice, knowingly violate the law.

Commentary: The violation of any law, local, state or federal, occurring in the conduct of a Member's professional practice, is made the basis for discipline by this rule. This includes the federal Copyright Act, which prohibits copying architectural works without the permission of the copyright owner: Allegations of violations of this rule must be based on an independent finding of a violation of the law by a court of competent jurisdiction or an administrative or regulatory body.

Rule 2.102 Members shall neither offer nor make any payment or gift to a public official with the intent of influencing the official's judgment in connection with an existing or prospective project in which the Members are interested.

Commentary: This rule does not prohibit campaign contributions made in conformity with applicable campaign financing laws.

Rule 2.103 Members serving in a public capacity shall not accept payments or gifts which are intended to influence their judgment.

Rule 2.104 Members shall not engage in conduct involving fraud or wanton disregard of the rights of others.

Commentary: This rule addresses serious misconduct whether or not related to a Member's professional practice. When an alleged violation of this rule is based on a violation of a law, or of fraud, then its proof must be based on an independent finding of a violation of the law or a finding of fraud by a court of competent jurisdiction or an administrative or regulatory body.

Rule 2.105 If, in the course of their work on a project, the Members become aware of a decision taken by their employer or client which violates any law or regulation and which will, in the Members' judgment, materially affect adversely the safety to the public of the finished project, the Members shall:

a. advise their employer or client against the decision,
b. refuse to consent to the decision, and
c. report the decision to the local building inspector or other public official charged with the enforcement of the applicable laws and regulations, unless the Members are able to cause the matter to be satisfactorily resolved by other means.

Commentary: This rule extends only to violations of the building laws that threaten the public safety. The obligation under this rule applies only to the safety of the finished project, an obligation coextensive with the usual undertaking of an architect.

Rule 2.106 Members shall not counsel or assist a client in conduct that the architect knows, or reasonably should know, is fraudulent or illegal.

E.S. 2.2 Public Interest Services: Members should render public interest professional services and encourage their employees to render such services.

E.S. 2.3 Civic Responsibility: Members should be involved in civic activities as citizens and professionals, and should strive to improve public appreciation and understanding of architecture and the functions and responsibilities of architects.

Rule 2.301 Members making public statements on architectural issues shall disclose when they are being compensated for making such statements or when they have an economic interest in the issue.

CANON III

Obligations to the Client

Members should serve their clients competently and in a professional manner, and should exercise unprejudiced and unbiased judgment when performing all professional services.

E.S. 3.1 Competence: Members should serve their clients in a timely and competent manner.

Rule 3.101 In performing professional services, Members shall take into account applicable laws and regulations. Members may rely on the advice of other qualified persons as to the intent and meaning of such regulations.

Rule 3.102 Members shall undertake to perform professional services only when they, together with those whom they may engage as consultants, are qualified by education, training, or experience in the specific technical areas involved.

Commentary: This rule is meant to ensure that Members not undertake projects that are beyond their professional capacity. Members venturing into areas that require expertise they do not possess may obtain that expertise by additional education, training, or through the retention of consultants with the necessary expertise.

Rule 3.103 Members shall not materially alter the scope or objectives of a project without the client's consent.

E.S. 3.2 Conflict of Interest: Members should avoid conflicts of interest in their professional practices and fully disclose all unavoidable conflicts as they arise.

Rule 3.201 A Member shall not render professional services if the Member's professional judgment could be affected by responsibilities to another project or person, or by the Member's own interests, unless all those who rely on the Member's judgment consent after full disclosure.

Commentary: This rule is intended to embrace the full range of situations that may present a Member with a conflict between his interests or responsibilities and the interest of others. Those who are entitled to disclosure may include a client, owner, employer, contractor, or others who rely on or are affected by the Member's professional decisions. A Member who cannot appropriately communicate about a conflict directly with an affected person must take steps to ensure that disclosure is made by other means.

Rule 3.202 When acting by agreement of the parties as the independent interpreter of building contract documents and the judge of contract performance, Members shall render decisions impartially.

Commentary: This rule applies when the Member, though paid by the owner and owing the owner loyalty, is nonetheless required to act with impartiality in fulfilling the architect's professional responsibilities.

E.S. 3.3 Candor and Truthfulness: Members should be candid and truthful in their professional communications and keep their clients reasonably informed about the clients' projects.

Rule 3.301 Members shall not intentionally or recklessly mislead existing or prospective clients about the results that can be achieved through the use of the Members' services, nor shall the Members state that they can achieve results by means that violate applicable law or this **Code**.

Commentary: This rule is meant to preclude dishonest, reckless, or illegal representations by a Member either in the course of soliciting a client or during performance.

E.S. 3.4 Confidentiality: Members should safeguard the trust placed in them by their clients.

Rule 3.401 Members shall not knowingly disclose information that would adversely affect their client or that they have been asked to maintain in confidence, except as other wise allowed or required by this **Code** or applicable law.

Commentary: To encourage the full and open exchange of information necessary for a successful professional relationship, Members must recognize and respect the sensitive nature of confidential client communications. Because the law does not recognize an architect-client privilege, however, the rule permits a Member to reveal a confidence when a failure to do so would be unlawful or contrary to another ethical duty imposed by this **Code.**

CANON IV

Obligations to the Profession

Members should uphold the integrity and dignity of the profession.

E.S. 4.1 Honesty and Fairness: Members should pursue their professional activities with honesty and fairness.

Rule 4.101 Members having substantial information which leads to a reasonable belief that another Member has committed a violation of this **Code** which raises a serious question as to that Member's honesty, trustworthiness, or fitness as a Member, shall file a complaint with the National Ethics Council.

Commentary: Often, only an architect can recognize that the behavior of another architect poses a serious question as to that other's professional integrity. In those circumstances, the duty to the professional's calling requires that a complaint be filed. In most jurisdictions, a complaint that invokes professional standards is protected from a libel or slander action if the complaint was made in good faith. If in doubt, a Member should seek counsel before reporting on another under this rule.

Rule 4.102 Members shall not sign or seal drawings, specifications, reports, or other professional work for which they do not have responsible control.

Commentary: Responsible control means the degree of knowledge and supervision ordinarily required by the professional standard of care. With respect to the work of licensed consultants, Members may sign or seal such work if they have reviewed it, coordinated its preparation, or intend to be responsible for its adequacy.

Rule 4.103 Members speaking in their professional capacity shall not knowingly make false statements of material fact.

Commentary: This rule applies to statements in all professional contexts, including applications for licensure and AIA membership.

E.S. 4.2 Dignity and Integrity: Members should strive, through their actions, to promote the dignity and integrity of the profession, and to ensure that their representatives and employees conform their conduct to this **Code**.

Rule 4.201 Members shall not make misleading, deceptive, or false statements or claims about their professional qualifications, experience, or performance and shall accurately state the scope and nature of their responsibilities in connection with work for which they are claiming credit.

Commentary: This rule is meant to prevent Members from claiming or implying credit for work which they did not do, misleading others, and denying other participants in a project their proper share of credit.

Rule 4.202 Members shall make reasonable efforts to ensure that those over whom they have supervisory authority conform their conduct to this **Code.**

Commentary: What constitutes "reasonable efforts" under this rule is a common sense matter. As it makes sense to ensure that those over whom the architect exercises supervision be made generally aware of the **Code**, it can also make sense to bring a particular provision to the attention of a particular employee when a situation is present which might give rise to violation.

CANON V

Obligations to Colleagues

Members should respect the rights and acknowledge the professional aspirations and contributions of their colleagues.

E.S. 5.1 Professional Environment: Members should provide their associates and employees with a suitable working environment, compensate them fairly, and facilitate their professional development.

E.S. 5.2 Intern and Professional Development: Members should recognize and fulfill their obligation to nurture fellow professionals as they progress through all stages of their career, beginning with professional education in the academy, progressing through internship and continuing throughout their career.

E.S. 5.3 Professional Recognition: Members should build their professional reputation on the merits of their own service and performance and should recognize and give credit to others for the professional work they have performed.

Rule 5.301 Members shall recognize and respect the professional contributions of their employees, employers, professional colleagues, and business associates.

Rule 5.302 Members leaving a firm shall not, without the permission of their employer or partner, take designs, drawings, data, reports, notes, or other materials relating to the firm's work, whether or not performed by the Member.

Rule 5.303 A Member shall not unreasonably withhold permission from a departing employee or partner to take copies of designs, drawings, data, reports, notes, or other materials relating to work performed by the employee or partner that are not confidential.

Commentary: A Member may impose reasonable conditions, such as the payment of copying costs, on the right of departing persons to take copies of their work.

RULES OF APPLICATION, ENFORCEMENT, AND AMENDMENT

Application

The **Code of Ethics and Professional Conduct** applies to the professional activities of all members of the AIA.

Enforcement

The Bylaws of the Institute state procedures for the enforcement of the **Code of Ethics and Professional Conduct.** Such procedures provide that:

1. Enforcement of the **Code** is administered through a National Ethics Council, appointed by the AIA Board of Directors.
2. Formal charges are filed directly with the National Ethics Council by Members, components, or any-

one directly aggrieved by the conduct of the Members.

3. Penalties that may be imposed by the National Ethics Council are:

   (a) Admonition
   (b) Censure
   (c) Suspension of membership for a period of time
   (d) Termination of membership

4. Appeal procedures are available.
5. All proceedings are confidential, as is the imposition of an admonishment; however, all other penalties shall be made public.

Enforcement of Rules 4.101 and 4.202 refer to and support enforcement of other Rules. A violation of Rules 4.101 or 4.202 cannot be established without proof of a pertinent violation of at least one other Rule.

Amendment

The Code of Ethics and Professional Conduct may be amended by the convention of the Institute under the same procedures as are necessary to amend the Institute's Bylaws. The **Code** may also be amended by the AIA Board of Directors upon a two-thirds vote of the entire Board.

*2004 EDITION. *This copy of the* **Code of Ethics** *is current as of September 2004. Contact the General Counsel's Office for further information at (202) 626-7311.*

AMERICAN INSTITUTE OF GRAPHIC ARTS (AIGA) STANDARDS OF PROFESSIONAL PRACTICE

• • •

The purpose of the statement of policy on professional practice is to provide all AIGA members with a clear standard of professional conduct. AIGA encourages the highest level of professional conduct in design. The policy is not binding. Rather, it reflects the view AIGA on the kind of conduct that is in the best interest of the profession, clients, and the public.

For the purposes of this document the word "designer" means an individual, practicing design as a freelance or salaried graphic designer, or group of designers acting in partnership or other form of association.

The designer's professional responsibility

1.1 A designer shall at all times act in a way that supports the aims of the AIGA and its members, and encourages the highest standards of design and professionalism.

1.2 A designer shall not undertake, within the context of his or her professional practice, any activity that will compromise his or her status as a professional consultant.

The designer's responsibility to clients

2.1 A designer shall acquaint himself or herself with a client's business and design standards and shall act in the client's best interest within the limits of professional responsibility.

2.2 A designer shall not work simultaneously on assignments that create a conflict of interest without agreement of the clients or employers concerned, except in specific cases where it is the convention of a particular trade for a designer to work at the same time for various competitors.

2.3 A designer shall treat all work in progress prior to the completion of a project and all knowledge of a client's intentions, production methods, and business organization as confidential and shall not divulge such information in any manner whatsoever without the consent of the client. It is the designer's responsibility to ensure that all staff members act accordingly.

The designer's responsibility to other designers

3.1 Designers in pursuit of business opportunities should support fair and open competition based upon professional merit.

3.2 A designer shall not knowingly accept any professional assignment on which another designer has been or is working without notifying the other designer or until he or she is satisfied that any previous appointments have been properly terminated and that all materials relevant to the continuation of the project are the clear property of the client.

3.3 A designer must not attempt, directly or indirectly, to supplant another designer through unfair means; nor must he or she compete with another designer by means of unethical inducements.

3.4 A designer must be fair in criticism and shall not denigrate the work or reputation of a fellow designer.

3.5 A designer shall not accept instructions from a client that involve infringement of another person's property rights without permission, or consciously act in any manner involving any such infringement.

3.6 A designer working in a country other than his or her own shall observe the relevant Code of Conduct of the national society concerned.

Fees

4.1 A designer shall work only for a fee, a royalty, salary, or other agreed-upon form of compensation. A designer shall not retain any kickbacks, hidden discounts, commission, allowances, or payment in kind from contractors or suppliers.

4.2 A reasonable handling and administration charge may be added, with the knowledge and understanding of the client, as a percentage to all reimbursable items, billable to a client, that pass through the designer's account.

4.3 A designer who is financially concerned with any suppliers who may benefit from any recommendations made by the designer in the course of a project shall secure the approval of the client or employer of this fact in advance.

4.4 A designer who is asked to advise on the selection of designers or the consultants shall not base such advice in the receipt of payment from the designer or consultants recommended.

Publicity

5.1 Any self-promotion, advertising, or publicity must not contain deliberate misstatements of competence, experience, or professional capabilities. It must be fair both to clients and other designers.

5.2 A designer may allow a client to use his or her name for the promotion of work designed or services provided but only in a manner that is appropriate to the status of the profession.

Authorship

6.1 A designer shall not claim sole credit for a design on which other designers have collaborated.

6.2 When not the sole author of a design, it is incumbent upon a designer to clearly identify his or her specific responsibilities or involvement with the design. Examples of such work may not be used for publicity, display, or portfolio samples without clear identification of precise areas of authorship.

INDUSTRIAL DESIGNERS SOCIETY OF AMERICA (IDSA) CODE OF ETHICS

Recognizing that industrial designers affect the quality of life in our increasingly independent and complex society; that responsible ethical decision making often requires conviction, courage and ingenuity in today's competitive business context: We, the members of the Industrial Designers Society of America, will endeavor to meet the standards set forth in this code, and strive to support and defend one another in doing so.

Fundamental Ethical Principles

We will uphold and advance the integrity of our profession by:

1. Supporting one another in achieving our goals of maintaining high professional standards and levels of competence, and honoring commitments we make to others;
2. Being honest and fair in serving the public, our clients, employers, peers, employees and students regardless of gender, race, creed, ethnic origin, age, disability or sexual orientation;
3. Striving to maintain sufficient knowledge of relevant current events and trends so as to be able to assess the economic and environmental effects of our decisions;
4. Using our knowledge and skill for the enrichment of human well-being, present and future; and
5. Supporting equality of rights under the law and opposing any denial or abridgement of equal rights by the United States or by any individual state on account of gender, race, creed, ethnic origin, age, disability or sexual orientation.

Articles of Ethical Practice

The following articles provide an outline of ethical guidelines designed to advance the quality of our profession. They provide general principles in which the "Ethics Advisory Council" can resolve more specific questions that may arise.

Article I: We are responsible to the public for their safety, and their economic and general well-being is our foremost professional concern. We will participate only in projects we judge to be ethically sound and in conformance with pertinent legal regulations; we will advise our clients and employers when we have serious reservations concerning projects we have been assigned.

Article II: We will provide our employers and clients with original and innovative design service of high quality; by serving their interests as faithful agents; by treating privileged information with discretion; by communicating effectively with their appropriate staff members; by avoiding conflicts of interest; and by establishing clear contractual understandings regarding obligations of both parties. Only with agreement of all concerned will we work on competing product lines simultaneously.

Article III: We will compete fairly with our colleagues by building our professional reputation primarily on the quality of our work; by issuing only truthful, objective and non-misleading public statements and promotional materials; by respecting competitors' contractual relationships with their clients; and by commenting only with candor and fairness regarding the character of work of other industrial designers.

Article IV: We will be responsible to our employees by facilitating their professional development insofar as possible; by establishing clear contractual understandings; by maintaining safe and appropriate work environments; by properly crediting work accomplished; and by providing fair and adequate compensation for salary and overtime hours.

Article V: We will be responsible to design education by holding as one of our fundamental concerns the education of design students; by advocating implementation of sufficiently inclusive curricula and requiring satisfactory proficiency to enable students to enter the profession with adequate knowledge and skills; by providing opportunities for internships (and collaboratives) with and observation of practicing designers; by respecting students' rights to ownership of their designs; and by fairly crediting them for work accomplished.

Article VI: We will advance the interests of our profession by abiding by this code; by providing a forum within the Society for the ongoing review of ethical concerns; and by publishing, as appropriate, interpretations of this Code.

COMPUTERS

ASSOCIATION FOR COMPUTING MACHINERY (ACM) CODE OF ETHICS AND PROFESSIONAL CONDUCT

Adopted by ACM Council 10/16/92.

Preamble

Commitment to ethical professional conduct is expected of every member (voting members, associate members, and student members) of the Association for Computing Machinery (ACM).

This Code, consisting of 24 imperatives formulated as statements of personal responsibility, identifies the elements of such a commitment. It contains many, but not all, issues professionals are likely to face. *Section 1* outlines fundamental ethical considerations, while *Section 2* addresses additional, more specific considerations of professional conduct. Statements in *Section 3* pertain more specifically to individuals who have a leadership role, whether in the workplace or in a volunteer capacity such as with organizations like ACM. Principles involving compliance with this Code are given in *Section 4*.

The Code shall be supplemented by a set of Guidelines, which provide explanation to assist members in dealing with the various issues contained in the Code. It is expected that the Guidelines will be changed more frequently than the Code.

The Code and its supplemented Guidelines are intended to serve as a basis for ethical decision making in the conduct of professional work. Secondarily, they may serve as a basis for judging the merit of a formal complaint pertaining to violation of professional ethical standards.

It should be noted that although computing is not mentioned in the imperatives of *Section 1*, the Code is concerned with how these fundamental imperatives apply to one's conduct as a computing professional. These imperatives are expressed in a general form to emphasize that ethical principles which apply to computer ethics are derived from more general ethical principles.

It is understood that some words and phrases in a code of ethics are subject to varying interpretations, and that any ethical principle may conflict with other ethical principles in specific situations. Questions related to ethical conflicts can best be answered by thoughtful consideration of fundamental principles, rather than reliance on detailed regulations.

Contents and Guidelines

1. GENERAL MORAL IMPERATIVES.

As an ACM member I will . . .

1.1 Contribute to society and human well-being.

This principle concerning the quality of life of all people affirms an obligation to protect fundamental human rights and to respect the diversity of all cultures. An essential aim of computing professionals is to minimize negative consequences of computing systems, including threats to health and safety. When designing or implementing systems, computing professionals must attempt to ensure that the products of their efforts will be used in socially responsible ways, will meet social needs, and will avoid harmful effects to health and welfare.

In addition to a safe social environment, human well-being includes a safe natural environment. Therefore, computing professionals who design and develop systems must be alert to, and make others aware of, any potential damage to the local or global environment.

1.2 Avoid harm to others.

"Harm" means injury or negative consequences, such as undesirable loss of information, loss of property, property damage, or unwanted environmental impacts. This principle prohibits use of computing technology in ways that result in harm to any of the following: users, the general public, employees, employers. Harmful actions include intentional destruction or modification of files and programs leading to serious loss of resources or unnecessary expenditure of human resources such as the time and effort required to purge systems of "computer viruses."

Well-intended actions, including those that accomplish assigned duties, may lead to harm unexpectedly. In such an event the responsible person or persons are obligated to undo or mitigate the negative consequences as much as possible. One way to avoid unintentional harm is to carefully consider potential impacts on all those affected by decisions made during design and implementation.

To minimize the possibility of indirectly harming others, computing professionals must minimize malfunctions by following generally accepted standards for system design and testing. Furthermore, it is often necessary to assess the social consequences of systems to project the likelihood of any serious harm to others. If system features are misrepresented to users, coworkers, or supervisors, the individual computing professional is responsible for any resulting injury.

In the work environment the computing professional has the additional obligation to report any signs of system dangers that might result in serious personal or social damage. If one's superiors do not act to curtail or mitigate such dangers, it may be necessary to "blow the whistle" to help correct the problem or reduce the risk. However, capricious or misguided reporting of violations can, itself, be harmful. Before reporting violations, all relevant aspects of the incident must be thoroughly assessed. In particular, the assessment of risk and responsibility must be credible. It is suggested that advice be sought from other computing professionals. See *principle 2.5* regarding thorough evaluations.

1.3 Be honest and trustworthy.

Honesty is an essential component of trust. Without trust an organization cannot function effectively. The honest computing professional will not make deliberately false or deceptive claims about a system or system design, but will instead provide full disclosure of all pertinent system limitations and problems.

A computer professional has a duty to be honest about his or her own qualifications, and about any circumstances that might lead to conflicts of interest.

Membership in volunteer organizations such as ACM may at times place individuals in situations where their statements or actions could be interpreted as carrying the "weight" of a larger group of professionals. An ACM member will exercise care to not misrepresent ACM or positions and policies of ACM or any ACM units.

1.4 Be fair and take action not to discriminate.

The values of equality, tolerance, respect for others, and the principles of equal justice govern this imperative. Discrimination on the basis of race, sex, religion, age, disability, national origin, or other such factors is an explicit violation of ACM policy and will not be tolerated.

Inequities between different groups of people may result from the use or misuse of information and technology. In a fair society, all individuals would have equal opportunity to participate in, or benefit from, the use of computer resources regardless of race, sex, religion, age, disability, national origin or other such similar factors. However, these ideals do not justify unauthorized use of computer resources nor do they provide an adequate basis for violation of any other ethical imperatives of this code.

1.5 Honor property rights including copyrights and patent.

Violation of copyrights, patents, trade secrets and the terms of license agreements is prohibited by law in most circumstances. Even when software is not so protected, such violations are contrary to professional behavior. Copies of software should be made only with proper authorization. Unauthorized duplication of materials must not be condoned.

1.6 Give proper credit for intellectual property.

Computing professionals are obligated to protect the integrity of intellectual property. Specifically, one must not take credit for other's ideas or work, even in cases where the work has not been explicitly protected by copyright, patent, etc.

1.7 Respect the privacy of others.

Computing and communication technology enables the collection and exchange of personal information on a scale unprecedented in the history of civilization. Thus there is increased potential for violating the privacy of individuals and groups. It is the responsibility of professionals to maintain the privacy and integrity of data describing individuals. This includes taking precautions to ensure the accuracy of data, as well as protecting it from unauthorized access or accidental disclosure to inappropriate individuals. Furthermore, procedures must be established to allow individuals to review their records and correct inaccuracies.

This imperative implies that only the necessary amount of personal information be collected in a system, that retention and disposal periods for that information be clearly defined and enforced, and that personal information gathered for a specific purpose not be used for other purposes without consent of the individual(s).

These principles apply to electronic communications, including electronic mail, and prohibit procedures that capture or monitor electronic user data, including messages, without the permission of users or bona fide authorization related to system operation and maintenance. User data observed during the normal duties of system operation and maintenance must be treated with strictest confidentiality, except in cases where it is evidence for the violation of law, organizational regulations, or this Code. In these cases, the nature or contents of that information must be disclosed only to proper authorities.

1.8 Honor confidentiality.

The principle of honesty extends to issues of confidentiality of information whenever one has made an explicit promise to honor confidentiality or, implicitly, when private information not directly related to the performance of one's duties becomes available. The ethical concern is to respect all obligations of confidentiality to employers, clients, and users unless discharged from such obligations by requirements of the law or other principles of this Code.

2. MORE SPECIFIC PROFESSIONAL RESPONSIBILITIES.

As an ACM computing professional I will . . .

2.1 Strive to achieve the highest quality, effectiveness and dignity in both the process and products of professional work.

Excellence is perhaps the most important obligation of a professional. The computing professional must strive to achieve quality and to be cognizant of the serious negative consequences that may result from poor quality in a system.

2.2 Acquire and maintain professional competence.

Excellence depends on individuals who take responsibility for acquiring and maintaining professional competence. A professional must participate in setting standards for appropriate levels of competence, and strive to achieve those standards. Upgrading technical knowledge and competence can be achieved in several ways: doing independent study; attending seminars, conferences, or courses; and being involved in professional organizations.

2.3 Know and respect existing laws pertaining to professional work.

ACM members must obey existing local, state, province, national, and international laws unless there is a compelling ethical basis not to do so. Policies and procedures of the organizations in which one participates must also be obeyed. But compliance must be balanced with the recognition that sometimes existing laws and rules may be immoral or inappropriate and, therefore, must be challenged. Violation of a law or regulation may be ethical when that law or rule has inadequate moral basis or when it conflicts with another law judged to be more important. If one decides to violate a law or rule because it is viewed as unethical, or for any other reason, one must fully accept responsibility for one's actions and for the consequences.

2.4 Accept and provide appropriate professional review.

Quality professional work, especially in the computing profession, depends on professional reviewing and critiquing. Whenever appropriate, individual members should seek and utilize peer review as well as provide critical review of the work of others.

2.5 Give comprehensive and thorough evaluations of computer systems and their impacts, including analysis of possible risks.

Computer professionals must strive to be perceptive, thorough, and objective when evaluating, recommending, and presenting system descriptions and alternatives. Computer professionals are in a position of special trust, and therefore have a special responsibility to provide objective, credible evaluations to employers, clients, users, and the public. When providing evaluations the professional must also identify any relevant conflicts of interest, as stated in *imperative 1.3*.

As noted in the discussion of *principle 1.2* on avoiding harm, any signs of danger from systems must be reported to those who have opportunity and/or responsibility to resolve them. See the guidelines for *imperative 1.2* for more details concerning harm, including the reporting of professional violations.

2.6 Honor contracts, agreements, and assigned responsibilities.

Honoring one's commitments is a matter of integrity and honesty. For the computer professional this includes ensuring that system elements perform as intended. Also, when one contracts for work with another party, one has an obligation to keep that party properly informed about progress toward completing that work.

A computing professional has a responsibility to request a change in any assignment that he or she feels cannot be completed as defined. Only after serious consideration and with full disclosure of risks and concerns to the employer or client, should one accept the assignment. The major underlying principle here is the obligation to accept personal accountability for professional work. On some occasions other ethical principles may take greater priority.

A judgment that a specific assignment should not be performed may not be accepted. Having clearly identified one's concerns and reasons for that judgment, but failing to procure a change in that assignment, one may yet be obligated, by contract or by law, to proceed as directed. The computing professional's ethical judgment should be the final guide in deciding whether or not to proceed. Regardless of the decision, one must accept the responsibility for the consequences.

However, performing assignments "against one's own judgment" does not relieve the professional of responsibility for any negative consequences.

2.7 Improve public understanding of computing and its consequences.

Computing professionals have a responsibility to share technical knowledge with the public by encouraging understanding of computing, including the impacts of computer systems and their limitations. This imperative implies an obligation to counter any false views related to computing.

2.8 Access computing and communication resources only when authorized to do so.

Theft or destruction of tangible and electronic property is prohibited by *imperative 1.2*—"Avoid harm to others." Trespassing and unauthorized use of a computer or communication system is addressed by this imperative. Trespassing includes accessing communication networks and computer systems, or accounts and/or files associated with those systems, without explicit authorization to do so. Individuals and organizations have the right to restrict access to their systems so long as they do not violate the discrimination principle (see *1.4*). No one should enter or use another's computer system, software, or data files without permission. One must always have appropriate approval before using system resources, including communication ports, file space, other system peripherals, and computer time.

3. ORGANIZATIONAL LEADERSHIP IMPERATIVES.

• • •

As an ACM member and an organizational leader, I will . . .

BACKGROUND NOTE: This section draws extensively from the draft IFIP Code of Ethics, especially its sections on organizational ethics and international concerns. The ethical obligations of organizations tend to be neglected in most codes of professional conduct, perhaps because these codes are written from the perspective of the individual member. This dilemma is addressed by stating these imperatives from the perspective of the organizational leader. In this context "leader" is viewed as any organizational member who has leadership or educational responsibilities. These imperatives generally may apply to organizations as well as their leaders. In this context "organizations" are corporations, government agencies, and other "employers," as well as volunteer professional organizations.

3.1 Articulate social responsibilities of members of an organizational unit and encourage full acceptance of those responsibilities.

Because organizations of all kinds have impacts on the public, they must accept responsibilities to society. Organizational procedures and attitudes oriented toward quality and the welfare of society will reduce harm to members of the public, thereby serving public interest and fulfilling social responsibility. Therefore, organizational leaders must encourage full participation in meeting social responsibilities as well as quality performance.

3.2 Manage personnel and resources to design and build information systems that enhance the quality of working life.

Organizational leaders are responsible for ensuring that computer systems enhance, not degrade, the quality of working life. When implementing a computer system, organizations must consider the personal and professional development, physical safety, and human dignity of all workers. Appropriate human-computer ergonomic standards should be considered in system design and in the workplace.

3.3 Acknowledge and support proper and authorized uses of an organization's computing and communication resources.

Because computer systems can become tools to harm as well as to benefit an organization, the leadership has the responsibility to clearly define appropriate and inappropriate uses of organizational computing resources. While the number and scope of such rules should be minimal, they should be fully enforced when established.

3.4 Ensure that users and those who will be affected by a system have their needs clearly articulated during the assessment and design of requirements; later the system must be validated to meet requirements.

Current system users, potential users and other persons whose lives may be affected by a system must have their needs assessed and incorporated in the statement of requirements. System validation should ensure compliance with those requirements.

3.5 Articulate and support policies that protect the dignity of users and others affected by a computing system.

Designing or implementing systems that deliberately or inadvertently demean individuals or groups is ethically unacceptable. Computer professionals who are in decision-making positions should verify that systems are designed and implemented to protect personal privacy and enhance personal dignity.

3.6 Create opportunities for members of the organization to learn the principles and limitations of computer systems.

This complements the imperative on public understanding (*2.7*). Educational opportunities are essential to facilitate optimal participation of all organizational members. Opportunities must be available to all members to help them improve their knowledge and skills in computing, including courses that familiarize them with the consequences and limitations of particular types of systems. In particular, professionals must be made aware of the dangers of building systems around oversimplified models, the improbability of anticipating and designing for every possible operating condition, and other issues related to the complexity of this profession.

4. COMPLIANCE WITH THE CODE.

• • •

As an ACM member I will . . .

4.1 Uphold and promote the principles of this Code.

The future of the computing profession depends on both technical and ethical excellence. Not only is it important for ACM computing professionals to adhere to the principles expressed in this Code, each member should encourage and support adherence by other members.

4.2 Treat violations of this code as inconsistent with membership in the ACM.

Adherence of professionals to a code of ethics is largely a voluntary matter. However, if a member does not follow this code by engaging in gross misconduct, membership in ACM may be terminated.

This Code and the supplemental Guidelines were developed by the Task Force for the Revision of the ACM Code of Ethics and Professional Conduct: Ronald E. Anderson, Chair, Gerald Engel, Donald Gotterbarn, Grace C. Hertlein, Alex Hoffman, Bruce Jawer, Deborah G. Johnson, Doris K. Lidtke, Joyce Currie Little, Dianne Martin, Donn B. Parker, Judith A. Perrolle, and Richard S. Rosenberg. The Task Force was organized by ACM/SIGCAS and funding was provided by the ACM SIG Discretionary Fund. This Code and the supplemental Guidelines were adopted by the ACM Council on October 16, 1992.

SOFTWARE ENGINEERING CODE OF ETHICS AND PROFESSIONAL PRACTICE

• • •

IEEE-CS/ACM Joint Task Force on Software Engineering Ethics and Professional Practices

PREAMBLE

• • •

Computers have a central and growing role in commerce, industry, government, medicine, education, entertainment and society at large. Software engineers are those who contribute by direct participation or by teaching, to the analysis, specification, design, development, certification, maintenance and testing of software systems. Because of their roles in developing software systems, software engineers have significant opportunities to do good or cause harm, to enable others to do good or cause harm, or to influence others to do good or cause harm. To ensure, as much as possible, that their efforts will be used for good, software engineers must commit themselves to making software engineering a beneficial and respected profession. In accordance with that commitment, software engineers shall adhere to the following Code of Ethics and Professional Practice.

The Code contains eight Principles related to the behavior of and decisions made by professional software engineers, including practitioners, educators, managers, supervisors and policy makers, as well as trainees and students of the profession. The Principles identify the ethically responsible relationships in which individuals, groups, and organizations participate and the primary obligations within these relationships. The Clauses of each Principle are illustrations of some of the obligations included in these relationships. These obligations are founded in the software engineer's humanity, in special care owed to people affected by the work of software engineers, and in the unique elements of the practice of software engineering. The Code prescribes these as obligations of anyone claiming to be or aspiring to be a software engineer.

It is not intended that the individual parts of the Code be used in isolation to justify errors of omission or commission. The list of Principles and Clauses is not exhaustive. The Clauses should not be read as separating the acceptable from the unacceptable in professional conduct in all practical situations. The Code is not a simple ethical algorithm that generates ethical decisions. In some situations, standards may be in tension with each other or with standards from other sources. These situations require the software engineer to use ethical judgment to act in a manner which is most consistent with the spirit of the Code of Ethics and Professional Practice, given the circumstances.

Ethical tensions can best be addressed by thoughtful consideration of fundamental principles, rather than blind reliance on detailed regulations. These Principles should influence software engineers to consider broadly who is affected by their work; to examine if they and their colleagues are treating other human beings with due respect; to consider how the public, if reasonably well informed, would view their decisions; to analyze how the least empowered will be affected by their decisions; and to consider whether their acts would be judged worthy of the ideal professional working as a software engineer. In all these judgments concern for the health, safety and welfare of the public is primary; that is, the "Public Interest" is central to this Code.

The dynamic and demanding context of software engineering requires a code that is adaptable and relevant to new situations as they occur. However, even in this generality, the Code provides support for software engineers and managers of software engineers who need to take positive action in a specific case by documenting the ethical stance of the profession. The Code provides an ethical foundation to which individuals within teams and the team as a whole can appeal. The Code helps to define those actions that are ethically improper to request of a software engineer or teams of software engineers.

The Code is not simply for adjudicating the nature of questionable acts; it also has an important educational function. As this Code expresses the consensus of the profession on ethical issues, it is a means to educate both the public and aspiring professionals about the ethical obligations of all software engineers.

PRINCIPLES

Principle 1 PUBLIC: Software engineers shall act consistently with the public interest. In particular, software engineers shall, as appropriate:

1.01. Accept full responsibility for their own work.

1.02. Moderate the interests of the software engineer, the employer, the client and the users with the public good.

1.03. Approve software only if they have a well-founded belief that it is safe, meets specifications, passes appropriate tests, and does not diminish quality of life, diminish privacy or harm the environment. The ultimate effect of the work should be to the public good.

1.04. Disclose to appropriate persons or authorities any actual or potential danger to the user, the public, or the environment, that they reasonably believe to be associated with software or related documents.

1.05. Cooperate in efforts to address matters of grave public concern caused by software, its installation, maintenance, support or documentation.

1.06. Be fair and avoid deception in all statements, particularly public ones, concerning software or related documents, methods and tools.

1.07. Consider issues of physical disabilities, allocation of resources, economic disadvantage and other factors that can diminish access to the benefits of software.

1.08. Be encouraged to volunteer professional skills to good causes and to contribute to public education concerning the discipline.

Principle 2 CLIENT AND EMPLOYER: Software engineers shall act in a manner that is in the best interests of their client and employer, consistent with the public interest. In particular, software engineers shall, as appropriate:

2.01. Provide service in their areas of competence, being honest and forthright about any limitations of their experience and education.

2.02. Not knowingly use software that is obtained or retained either illegally or unethically.

2.03. Use the property of a client or employer only in ways properly authorized, and with the client's or employer's knowledge and consent.

2.04. Ensure that any document upon which they rely has been approved, when required, by someone authorized to approve it.

2.05. Keep private any confidential information gained in their professional work, where such confidentiality is consistent with the public interest and consistent with the law.

2.06. Identify, document, collect evidence and report to the client or the employer promptly if, in their opinion, a project is likely to fail, to prove too expensive, to violate intellectual property law, or otherwise to be problematic.

2.07. Identify, document, and report significant issues of social concern, of which they are aware, in software or related documents, to the employer or the client.

2.08. Accept no outside work detrimental to the work they perform for their primary employer.

2.09. Promote no interest adverse to their employer or client, unless a higher ethical concern is being compromised; in that case, inform the employer or another appropriate authority of the ethical concern.

Principle 3 PRODUCT: Software engineers shall ensure that their products and related modifications meet the highest professional standards possible. In particular, software engineers shall, as appropriate:

3.01. Strive for high quality, acceptable cost, and a reasonable schedule, ensuring significant tradeoffs are clear to and accepted by the employer and the client, and are available for consideration by the user and the public.

3.02. Ensure proper and achievable goals and objectives for any project on which they work or propose.

3.03. Identify, define and address ethical, economic, cultural, legal and environmental issues related to work projects.

3.04. Ensure that they are qualified for any project on which they work or propose to work, by an appropriate combination of education, training, and experience.

3.05. Ensure that an appropriate method is used for any project on which they work or propose to work.

3.06. Work to follow professional standards, when available, that are most appropriate for the task at hand, departing from these only when ethically or technically justified.

3.07. Strive to fully understand the specifications for software on which they work.

3.08. Ensure that specifications for software on which they work have been well documented, satisfy the users' requirements and have the appropriate approvals.

3.09. Ensure realistic quantitative estimates of cost, scheduling, personnel, quality and outcomes on any project on which they work or propose to work and provide an uncertainty assessment of these estimates.

3.10. Ensure adequate testing, debugging, and review of software and related documents on which they work.

3.11. Ensure adequate documentation, including significant problems discovered and solutions adopted, for any project on which they work.

3.12. Work to develop software and related documents that respect the privacy of those who will be affected by that software.

3.13. Be careful to use only accurate data derived by ethical and lawful means, and use it only in ways properly authorized.

3.14. Maintain the integrity of data, being sensitive to outdated or flawed occurrences.

3.15. Treat all forms of software maintenance with the same professionalism as new development.

Principle 4 JUDGMENT: Software engineers shall maintain integrity and independence in their professional judgment. In particular, software engineers shall, as appropriate:

4.01. Temper all technical judgments by the need to support and maintain human values.

4.02. Only endorse documents either prepared under their supervision or within their areas of competence and with which they are in agreement.

4.03. Maintain professional objectivity with respect to any software or related documents they are asked to evaluate.

4.04. Not engage in deceptive financial practices such as bribery, double billing, or other improper financial practices.,/item>

4.05. Disclose to all concerned parties those conflicts of interest that cannot reasonably be avoided or escaped.

4.06. Refuse to participate, as members or advisors, in a private, governmental or professional body concerned with software related issues, in which they, their employers or their clients have undisclosed potential conflicts of interest.

Principle 5 MANAGEMENT: Software engineering managers and leaders shall subscribe to and promote an ethical approach to the management of software development and maintenance. In particular, those managing or leading software engineers shall, as appropriate:

5.01 Ensure good management for any project on which they work, including effective procedures for promotion of quality and reduction of risk.

5.02. Ensure that software engineers are informed of standards before being held to them.

5.03. Ensure that software engineers know the employer's policies and procedures for protecting passwords, files and information that is confidential to the employer or confidential to others.

5.04. Assign work only after taking into account appropriate contributions of education and experience tempered with a desire to further that education and experience.

5.05. Ensure realistic quantitative estimates of cost, scheduling, personnel, quality and outcomes on any project on which they work or propose to work, and provide an uncertainty assessment of these estimates.

5.06. Attract potential software engineers only by full and accurate description of the conditions of employment.

5.07. Offer fair and just remuneration.

5.08. Not unjustly prevent someone from taking a position for which that person is suitably qualified.

5.09. Ensure that there is a fair agreement concerning ownership of any software, processes, research, writing, or other intellectual property to which a software engineer has contributed.

5.10. Provide for due process in hearing charges of violation of an employer's policy or of this Code.

5.11. Not ask a software engineer to do anything inconsistent with this Code.

5.12. Not punish anyone for expressing ethical concerns about a project.

Principle 6 PROFESSION: Software engineers shall advance the integrity and reputation of the profession consistent with the public interest. In particular, software engineers shall, as appropriate:

6.01. Help develop an organizational environment favorable to acting ethically.

6.02. Promote public knowledge of software engineering.

6.03. Extend software engineering knowledge by appropriate participation in professional organizations, meetings and publications.

6.04. Support, as members of a profession, other software engineers striving to follow this Code.

6.05. Not promote their own interest at the expense of the profession, client or employer.

6.06. Obey all laws governing their work, unless, in exceptional circumstances, such compliance is inconsistent with the public interest.

6.07. Be accurate in stating the characteristics of software on which they work, avoiding not only false claims but also claims that might reasonably be supposed to be speculative, vacuous, deceptive, misleading, or doubtful.

6.08. Take responsibility for detecting, correcting, and reporting errors in software and associated documents on which they work.

6.09. Ensure that clients, employers, and supervisors know of the software engineer's commitment to this Code of ethics, and the subsequent ramifications of such commitment.

6.10. Avoid associations with businesses and organizations which are in conflict with this code.

6.11. Recognize that violations of this Code are inconsistent with being a professional software engineer.

6.12. Express concerns to the people involved when significant violations of this Code are detected unless this is impossible, counter-productive, or dangerous.

6.13. Report significant violations of this Code to appropriate authorities when it is clear that consultation with people involved in these significant violations is impossible, counter-productive or dangerous.

Principle 7 COLLEAGUES: Software engineers shall be fair to and supportive of their colleagues. In particular, software engineers shall, as appropriate:

7.01. Encourage colleagues to adhere to this Code.

7.02. Assist colleagues in professional development.

7.03. Credit fully the work of others and refrain from taking undue credit.

7.04. Review the work of others in an objective, candid, and properly-documented way.

7.05. Give a fair hearing to the opinions, concerns, or complaints of a colleague.

7.06. Assist colleagues in being fully aware of current standard work practices including policies and procedures for protecting passwords, files and other confidential information, and security measures in general.

7.07. Not unfairly intervene in the career of any colleague; however, concern for the employer, the client or public interest may compel software engineers, in good faith, to question the competence of a colleague.

7.08. In situations outside of their own areas of competence, call upon the opinions of other professionals who have competence in that area.

Principle 8 SELF: Software engineers shall participate in lifelong learning regarding the practice of their profession and shall promote an ethical approach to the practice of the profession. In particular, software engineers shall continually endeavor to:

8.01. Further their knowledge of developments in the analysis, specification, design, development, maintenance and testing of software and related documents, together with the management of the development process.

8.02. Improve their ability to create safe, reliable, and useful quality software at reasonable cost and within a reasonable time.

8.03. Improve their ability to produce accurate, informative, and well-written documentation.

8.04. Improve their understanding of the software and related documents on which they work and of the environment in which they will be used.

8.05. Improve their knowledge of relevant standards and the law governing the software and related documents on which they work.

8.06. Improve their knowledge of this Code, its interpretation, and its application to their work.

8.07. Not give unfair treatment to anyone because of any irrelevant prejudices.

8.08. Not influence others to undertake any action that involves a breach of this Code.

8.09. Recognize that personal violations of this Code are inconsistent with being a professional software engineer.

This Code was developed by the IEEE-CS/ACM joint task force on Software Engineering Ethics and Professional Practices (SEEPP):

Executive Committee: Donald Gotterbarn (Chair), Keith Miller and Simon Rogerson;

Members: Steve Barber, Peter Barnes, Ilene Burnstein, Michael Davis, Amr El-Kadi, N. Ben Fairweather, Milton Fulghum, N. Jayaram, Tom Jewett, Mark Kanko, Ernie Kallman, Duncan Langford, Joyce Currie Little, Ed Mechler, Manuel J. Norman, Douglas Phillips, Peter Ron Prinzivalli, Patrick Sullivan, John Weckert, Vivian Weil, S. Weisband and Laurie Honour Werth.

TEN COMMANDMENTS OF COMPUTER ETHICS OF THE COMPUTER ETHICS INSTITUTE

1. Thou shalt not use a computer to harm other people.
2. Thou shalt not interfere with other people's computer work.
3. Thou shalt not snoop around in other people's computer files.
4. Thou shalt not use a computer to steal.
5. Thou shalt not use a computer to bear false witness.
6. Thou shalt not copy or use proprietary software for which you have not paid.
7. Thou shalt not use other people's computer resources without authorization or proper compensation.
8. Thou shalt not appropriate other people's intellectual output.
9. Thou shalt think about the social consequences of the program you are writing or the system you are designing.
10. Thou shalt always use a computer in ways that ensure consideration and respect for your fellow humans.

ENGINEERING

ETHICS CODES IN PROFESSIONAL ENGINEERING: OVERVIEW AND COMPARISONS

The development of ethics codes in professional engineering began in the late 1800s and continues into the present. It has been influenced by the development of ethics codes in other professions, especially medicine and law, but exhibits its own dynamics and characteristics. This historical dynamics is particularly apparent in the United States, in a movement toward responsibility for public safety, health, and welfare. Outside the United States the movement is not as well documented, but modest comparisons can be made between professional engineering codes in different countries.

Engineering Ethics Codes in General

A code of ethics—also known as a code of conduct—is the public expression of guidelines for behavior by a professional organization enforced in some manner by that organization. A professional code is, as it were, regionalized legislation. What law—as a set of rules for behavior articulated and enforced by the state—does for society as a whole, so codes of ethics do for what Alexis de Tocqueville referred to as public associations (*Democracy in America,* vol. II, book 2, chapter 5) and are now called non-governmental organizations (NGOs).

Thus in order for there to be engineering ethics codes there must first be organized associations of engineers. But as the comparison with law also suggests, this is a necessary but not sufficient condition for engineering ethics codes. There are states that are governed by custom or tradition rather than by law. Just as law is often preceded (and complemented) by more informal and even unconscious mores and social norms, so among engineers it might be that the general function served by a code of ethics could be met (as well as complemented) by more implicit social mores.

The comparison invites further consideration of the possibility of diverse forms of professional organization and diverse relationships between professional associations and ethics codes. Complementing comparative government is comparative professional ethics. One aspect of this comparison would have to include consideration of the relation between various engineering standards, "building codes" or "construction codes," and ethics. For instance, one can postulate an inverse relationship between construction and ethics codes. When construction codes are detailed and explicit, ethics codes can be correspondingly ambiguous, whereas when construction codes are loose or non-existent, the engineering would depend on a high degree of moral dedication not to cut corners.

ENGINEERING ASSOCIATIONS. Engineering associations arose during the eighteenth century in two distinct contexts. In the first they arose within the government as formal organizations of those military personnel especially trained to design and operate "engines of war" (hence the term "engineers") and fortifications. In 1716 in France state service took civilian form as the Corps des Ponts et Chaussées; three decades later, for the more effective training of manpower for this corps, there was established the famous Ecole des Ponts et Chaussées (1747). This was followed by the Ecole des Mines (1783) and the Ecole Polytechnique (1794), the latter founded to train officers for the French revolutionary army. (For a general assessment of the complexities of professional engineering in France, including reference to engineering ethics, see Didier 1999.)

In a second instance engineers came together in informal associations independent of government. In England in the late 1700s, John Smeaton, architect of the Eddystone Lighthouse, and colleagues "were accustomed to dine together every fortnight at the Crown and Anchor in the Strand, spending the evening in conversation on engineering subjects" (Smiles, 1861–1862, vol. 2, p. 474). This led to the informal formation of a club called The Society of Civil Engineers, the term "civil engineer" having been coined by Smeaton in 1768 to distinguish those engineers who were not soldiers. It was not until 1828 that this club was incorporated under Royal Charter as the Institute of Civil Engineers.

The implications of these two origins are quite different. In the French system the education or the school, established by the government, has been primary. One becomes an engineer by earning the special academic degree of engineer, and is then entitled to be called "engineer." The professional organization of such engineers is either the bureau or agency for which one works or some kind of alumni association. Under such circumstances a code of ethics stresses governmental or state service and can afford to be largely implicit.

In the British system the professional association is primary. One becomes an engineer not by earning a special academic degree but by meeting the standards for joining a professional organization. Indeed, academic courses of instruction in engineering are not set up in England until the early 1800s, and the engineering degree does not have its wholly unique curriculum but is simply specified as a kind of bachelor degree.

Under such circumstances it has been found more necessary to formulate an explicit code of ethics, which has tended to stress promotion of the profession over governmental service. For instance, the Royal Charter of the British Institution of Mechanical Engineers (founded 1847), gives the aims of the organization as "to encourage invention and research," "to hold meetings," "to print, publish and distribute the proceedings," and "to co-operate with universities" in "matters connected with mechanical engineering." According to the By-Laws of the Institution, members should conduct themselves "in order to facilitate the advancement of the science of mechanical engineering by preserving the respect in which the community holds persons who are engaged in the professional of mechanical engineering." In other words, the primary obligation of engineers is to the engineering profession rather than the state.

Engineering Ethics in the United States

Although the first institution of higher education in the to grant engineering degrees in the United States was the Military Academy at West Point (founded 1802), non-military engineering schools rapidly superseded it in influence, and the U.S. has largely followed the British model in its professional engineering organizations. The engineering degree is simply one type of the bachelor's degree, and to be a professional engineer is effectively constituted by membership in a professional engineering association such as the American Society for Civil Engineers (ASCE, founded 1852) or the American Society for Mechanical Engineers (ASME, founded 1880). (For background on the history of the engineering profession in the U.S., see Layton 1971.)

The professional codes of these associations initially highlighted professional loyalty and—no doubt reflecting a unique commitment to capitalistic enterprise—especially loyalty to a client or employer (and for most engineers, it was an employer). For instance, the 1914 code of the ASME listed the first duty of the engineer to be a "faithful agent or trustee" of some employing client or corporation. Although Michael Davis (2002) has contested a too literal reading of this requirement, the ASME Committee on Code of Ethics (1915) in a contemporaneous commentary emphasized "protection of a client's or employer's interests" as an engineer's "first obligation." At the same time, engineers should also "endeavor to assist the public to a fair and correct general understanding of engineering matters." But across the twentieth century engineering educators returned repeatedly to the difficulties of communicating to engineers a broad conception of their professional responsibilities.

Following World War II, and especially during the 1970s, engineering ethics codes in the United States were subject to considerable discussion and revision to reflect a new awareness of and commitment not just to public education but to public welfare. The background of this new ferment regarding engineering ethics was concern over the enormous powers engineers now exercised, and public concern about a number of specifically technical catastrophes as well as environmental degradation associated with technical engineering developments. Well-known examples were the DC-10 crashes and Ford Pinto car accidents caused by designs that companies refused to correct because of economic constraints, even though engineers called them to attention.

Such experiences led to the development of a new category of technical hero, the "whistle blower" who transgresses company loyalty and goes public with allegations of wrong doing. Here one influential example involved the case of three engineers—Holger Hjortsvang, Max Blankenzee, and Robert Bruder—who, while working on the San Francisco Bay Area Rapid Transit (BART) in 1972, came to the conclusion that the system was unsafe. When the contractor refused to heed their warnings, they appealed to an oversight board and were fired. But the California Society of Professional Engineers supported them, and indeed a few months later a train had an accident of exactly the kind they had predicted.

Subsequent examples included Richard Parks blowing of the whistle (in 1983) on unsafe practices in the clean-up of the Three Mile Island nuclear disaster, and Roger Boisjolay's exposure of the warnings given to Morton-Thiokol and NASA before the launch of the space shuttle Challenger (of 1986). During the 1980s the Accreditation Board for Engineering and Technology also began to require that engineering programs include engineering ethics in their curricula (Stephan

2002), perhaps in part as a result of such cases and the problems they created for practicing engineers.

Engineering Ethics Outside the United States

Although engineering ethics developments in the United States have taken place independent of contact with developments in other countries, the problems with which United States engineers have been trying to deal transcend national boundaries. Moreover, engineering ethics outside the United States can provide welcome new perspectives for U.S. engineers while profiting as well from U.S. achievements.

For example, ethics codes in Canada and in Australia provide other important variations on the British model that have nevertheless historically placed stronger weight on public responsibility. In Europe there exists a multinational and transdiciplinary to develop an approach to engineering ethics that offers an alternative to the standard U.S. case study, individual responsibility emphasis (see Goujon and Hériard Dubreuil 2001). It is also the case that various transnational professional engineering associations such as the Unión Panaméricana de Asociaciones de Ingenieros (UPADI or Pan American Union of Associations of Engineers) and the Européenne d'Associations Nationales d'Ingénieurs (FEANI or European Federation of National Engineering Associations) are making important contributions to engineering ethics. For present purposes, however, and as a general introduction to the collection of professional ethics codes that follow, it is sufficient to consider six national cases of some particular interest: Germany, Japan, Hong Kong, Sweden, the Dominican Republic, and Chile. (For more on code developments in other countries, see Davis1990, 1991, and 1992.)

Philosophical Engineering Ethics in Germany

The development of engineering ethics in Germany has a much more developed theoretical base than in the United States. Nineteenth and early twentieth century attitudes toward engineering were influenced by philosophers such as Immanuel Kant and G. W. F. Hegel, and by the German notion of education as *Bildung*, formation or growth, understood as the perfection of human nature through culture. Ernst Kapp and Friedrich Dessauer, for instance, argued that like the classics and the humanities, the experience of technological creativity could contribute to the development of a higher moral consciousness.

Immediately after World War II, however, because some of its members had been compromised by involvement with National Socialism, the Verein Deutscher Ingenieure (VDI or Association of German Engineers) developed its first explicit ethics code, the "Engineer's Confessions," which exhibited a distinctly religious character. It also undertook to promote a new philosophical reflection among engineers by establishing a *Mensch und Technik* [Humans and technology] committee, an initiative that has led to a more sustained dialogue between engineers and philosophers than in any other country.

During the 1960s and 1980s the discussion of technology and philosophy became a publicly debated issue. The role of the engineer and the impact on society was discussed during an international conference organized by the German Commission for UNESCO. The public became involved and concerns for the environment were brought up and discussed by committees and groups throughout the country. In 1980 the VDI wrote "Future Tasks" which discussed societal, political, and ethical goals such as improving the possibilities for life, as well as what was technically possible.

This work in turn led to replacement of what had become the dated "Engineer's Confessions" and to further interdisciplinary engineering-philosophy research, especially on the theoretical basis of technology assessment. With regard to professional ethics, one *Mensch und Technik* working committee report in 1980 proposed simply that "The aim of all engineers is the improvement of the possibilities of life for all humanity by the development and appropriate application of technical means." With regard to the foundations of technology assessment, a second working committee in 1986 identified eight fields of value (environmental quality, health, safety, functionality, economics, living standards, personal development, and social quality), mapped out their interrelations, and developed a draft set of recommendations for their implementation in the design of technical products and projects. (For a more extended discussion of these developments, see Huning and Mitcham 1993.)

In 2002, no doubt with influence from movements toward globalization, a new generation of philosophers and engineers simplified the VDI ethics code, and stressed raising ethics awareness and conflict resolution at the levels of both individual practice and oppositions between principles. "In the case of conflicting values," engineers are encouraged to give priority "to the values of humanity over the dynamics of nature, to issues of human rights over technology implementation and exploitation, to public welfare over private interests, and to safety and security over functionality and profitability."

Science and Engineering Ethics Combined in Japan

Engineering ethics codes in Japan, the second major World War II defeated power, exhibited a quite different genesis. To begin with, engineering became professionally organized only after World War II and did so in much closer association with science. In Japan science and engineering have not been treated as much as separate enterprises as they have been in Europe or the United States.

Moreover, the first and most influential code-like document is the "Statement on Atomic Research in Japan" issued by the Japanese Science Council (which includes both scientists and engineers) in 1954. This statement sets forth what have become known as "The Three Principles for the Peaceful Use of Atomic Energy": All research shall be conducted with full openness to the public, shall be democratically administered, and shall be carried out under the autonomous control of the Japanese themselves.

As is readily apparent, these principles reflect the desire of Japanese during the 1950s to distance themselves from United States interests (recall that the Allied occupation ended in 1952) and policy. Immediately after World War II, the U.S. prohibited all Japanese research in aviation, atomic energy, and any other war-related area. But by 1951, following the Communist victory in China and the outbreak of the Korean War, U.S. policy began to shift toward encouraging certain kinds of military-related science and engineering and the incorporation of Japan into the Western alliance.

Indeed, Japanese scientists and engineers recognized that the Three Principles were in opposition to, for example, the U.S. policy of secrecy in atomic research, and in order to avoid publicity and the possible development of opposition, the JSC statement was not initially translated into English. It is also a policy which, although formulated by scientists and engineers themselves, was readily adopted by the government, thus perhaps reflecting the greater social prestige and political influence of the Japanese technical community in comparison with that in the United States.

Beginning in the 1980s scientists and engineers developed a new interest in ethics reflective of but with continuing distinctions from interests in the United States. This is illustrated, for instance, by the JSC declarations on "The Basic Principles of International Scientific Exchange" (1988) and "The New Science Scheme: Science for Society and the Fusion of Humanity and Natural Sciences" (2003), both of which have emphasized a responsibility on the part of scientists and engineers to promote sound scientific development and to help educate the public about important issues related to scientific and technological development. In 1999 there was also established the Japan Accreditation Board for Engineering Education (JABEE), an agency that has given special attention to engineering ethics education.

Engineering Ethics as Institutional Protection in Hong Kong

Another special case in Asia that can be briefly mentioned is that of the Hong Kong Institution of Engineers (HKIE, founded 1947). As a British Crown Colony, the professional organization of engineers in Hong Kong originally developed not just on the British model but as a branch of British institutions. With the realization that Hong Kong would in the near future (in 1997) be returned to Chinese sovereignty, however, local engineers in the 1970s began to provide Hong Kong with a truly independent engineering association. Part of this activity involved some intensive discussion of professional ethics, with a special conference being organized in 1980 on "Professional Ethics in the Modern World."

In 1994 the HKIE formally adopted a set of "Rules of Conduct" that differed in a few key respects from the parent organization. Although the primary obligation remained the responsibility to the profession, this was modified by the following statement: "When working in a country other than Hong Kong [the Hong Kong engineer should] order his [or her] conduct according to the existing recognized standards of conduct in that country, except that he should abide by these rules as applicable in the absence of local standards."

The basis of this modification had been clearly spelled out in previous discussions. At an inter-professional symposium in December 1985, F.Y. Kan of the Hong Kong Institute of Surveyors identified the role of his professional association as the promotion of the status of surveyors and the usefulness of the profession. "So far," he is reported to have said,

> the role [has] not changed but, with the Sino-British agreement in operation [to return Hong Kong to Chinese sovereignty in 1992], there might be a tendency to a far-reaching effect on the professions. There was, therefore, a need to break away from U.K. qualifications. However, professional competence must be maintained and this could bring institutions into the political field. (Luscher, 1986, p. 39)

In a world in which engineering easily comes into contact with the political field—something that is increasingly likely to be the case not only in Hong

Kong—it is increasingly important for engineers to think about ethical issues, and to do with awareness of what is happening in their profession throughout the world.

Engineering Ethics as Social Reform in Sweden

In Europe there has also been some desire to establish professional engineering independence of various pressures from other nations. In this regard Sweden provides an instructive case study of a neutral country that used its engineering prowess to provide itself with a strong military by relying on a well-developed domestic weapons industry. One of the leading weapons producing corporations has been Bofors, a primary supplier of advanced field artillery, anti-aircraft artillery, and ship artillery to the Swedish armed forces. Known not only domestically but internationally for such technologies, in the 1960s Bofors increased its exports. In principle, exports of military weapons were prohibited. But the government can legally waive this restriction for special cases, which nevertheless became increasingly questionable.

An engineer named Ingvar Bratt began working for Bofors in 1969 and participated in projects including a missile and anti-aircraft gun which were delivered to Malaysia in 1977. During the 1970s and 1980s, however, Bratt became politically active, and by 1982 was publicly opposed all weapons exports, even approved ones.

Rumors arose that unapproved countries had acquired Bofors missile technology presumably through an approved third-party country. Bratt discovered evidence in a Bofors' office near his own that missiles had in fact been exported to Singapore. He shared this information with a journalist who that Singapore was an arms dealer. This suggested Singapore as a possible approved country through which the unapproved countries such as Dubai and Bahrain were receiving arms. In 1984 Bratt left Bofors and helped to pursue further evidence of these illegal activities.

This exposé contributed to development of a new code of engineering ethics, one that downplayed company loyalty, a focus of the previous code, and emphasized responsibility to "humanity, the environment, and society." In response to the view that engineers were often those who contributed to social or environmental problems, the new ethics codes stressed the social and ecological responsibility of engineers, promoting the idea that engineers might play a more positive role in society. (This section draws heavily on Welin 1991.)

Engineering Ethics to Resist Corruption in the Dominican Republic

Engineers ethics codes in developing countries provide still another point of comparison. Concern for engineering and ethics has emerged in the Dominican Republic in response to numerous engineering failures and catastrophes that have occurred there as a result of professional negligence.

Engineering, architecture, and surveying were first introduced to the Domincan Republic by Spanish conquistadores in the early 1500s. But engineering was not a formal course of study until the 1900s, and there was not much difference between engineers and architects until 1945 when the first engineering organization was formed.

During the 1980s many engineered structures failed, which led to increased calls for governmental regulation. But a civil engineer, Orlando Franco Batlle, also argued that part of the problem rested with a weak tradition in professional engineering ethics, and promoted new guidelines for the ethical and responsible exercise of the civil engineering profession. In this effort he was inspired by the code of the American Society of Civil Engineers.

The Colegio Dominicano de Ingenieros, Arquitectos y Agrimensores (CODIA or Dominican Association of Engineers, Architects, and Surveyors) had in the 1960s created a code of ethics to promote national interest and relationships within the profession and with clients. But there was no mention of public safety, health, or well-being. There was also no reference to responsibility or concern for the negative effects of engineering on society or the environment. Yet Franco Batlle's argument was unable to bring about a change in this code.

However, whether a reform of the professional ethics code would have any substantial impact on the problem of substandard work remained questionable. A survey in 1990 among CODIA members revealed that most had not even read the existing code, and if they had did not take it seriously. Engineering was thought to be simply the best paying job in the country, with medicine is the most prestigious. This implied that engineers had chosen their profession for economic benefit—and, in fact, two thirds of the engineering professors thought that societal interest was secondary to self-interest. (This section adapts research by César Cuello Nieto, 1992.)

Engineering Ethics as Alternative Development in Chile

A second comparison from the perspective of engineering ethics in a developing country is provided by Chile. In Chile, as in many countries other than the United States, professional codes such as the "Code of

Professional Ethics of the Engineers of the Colegio de Ingenieros de Chile [Association of Engineers of Chile]," actually have the force of law, as a result of having been formulated, in this case, in response to general legislation calling for such codes in all professional organizations. Although the Colegio was founded in 1958, its code was not formulated until it was required by the authoritarian regime of Augusto Pinochette (1973-1990). At the same time, as Marcos García de la Huerta (1991) has argued, Pinochette's two-decade dictatorship severely compromised almost all professional practices. This is a degradation that García de la Huerta has himself worked to overcome by publishing what is probably the first textbook on engineering ethics in Latin America (García de la Huerta and Mitcham 2001).

The Chilean code, like many others, includes little by way of positive guidance. There is, for instance, no mention of any responsibility to public safety, health, and welfare. Instead, the code consists primarily of an extended list of actions that are contrary to sound professional conduct, and that are thus punishable by professional censure. Among many unremarkable canons against conflict of interest, graft, and more, however, is one rejecting "actions or failures to act that favor or permit the unnecessary use of foreign engineering for objectives and work for which Chilean engineering is sufficient and adequate." Such a canon, emphasizing national interests, can also be found in other codes throughout Asia and Latin America, from India to Venezuela.

It is important to note that such a canon need not have simply nationalistic implications. Judith Sutz, for example, a computer scientist in Uruguay, in an essay raising important questions about the directions of information technology research in Latin America, argues that

> The basic question is, What do Latin American engineers want? Do they want to seek original solutions to indigenous problems? Or do they only want to identify with that which is more modern, more sophisticated, more powerful—disregarding real usefulness—in order to feel like they "live" in the developed world? (Sutz 1993, p. 304)

Many countries experience a serious difficulty in addressing their own real problems. Driven by what René Girard (1965) calls mimetic desire, engineers and scientists often devote themselves to high-tech research that brings international prestige rather than to less glamorous but more useful tasks. One serious challenge to professional engineering in the age of globalization will be the extent to which various national and cultural differences can be maintained in the face of such pressures.

Acknowledgments

This article has drawn heavily on a research grant from the National Science Foundation Grant (NSF #DIR 8721989), June 1988 to November 1990, with supplemental support from the Philosophy and Technology Studies Center at Polytechnic University, the Science, Technology, and Society Program of Pennsylvania State University. This research has been further extended by participation in the development of a Humanitarian Engineering Program at the Colorado School of Mines funded by a grant from the William and Flora Hewlett Foundation. Michelle DeBacker, a research assistant, has also made numerous contributions to the preparation of this introduction and the collection of codes.

ACCREDITATION BOARD FOR ENGINEERING AND TECHNOLOGY (ABET) CODE OF ETHICS

As approved by the Board of Directors on October 30, 1999

Preamble

The Accreditation Board for Engineering and Technology, Inc. (ABET) requires ethical conduct by each volunteer and staff member engaged in fulfilling the mission of ABET. The organization requires that every volunteer and staff member exhibit the highest standards of professionalism, honesty, and integrity. The services provided by ABET require impartiality, fairness, and equity. All persons involved with ABET activities must perform their duties under the highest standards of ethical behavior. It is the purpose of this document to detail the ethical standards under which we agree to operate.

The ABET Guidelines for Interpretation of the Canons

The ABET guidelines for interpretation of the Canons represent the objectives toward which its volunteers and staff members should strive. They are principles which those involved in accreditation activities can reference in specific situations. In addition, they provide interpretive guidance to the ABET Professional Development Committee.

1. ABET volunteers and staff members agree to accept responsibility in making accreditation decisions and credential evaluations consistent with approved criteria and the safety, health, and welfare of the public and to disclose promptly factors that may directly or indirectly conflict with these duties and/or may endanger the public. a). All those involved in ABET activities shall recognize that the lives, safety, health and welfare of the general public are dependent upon a pool of qualified graduate professionals to continue the work of their profession. b). Programs shall not receive accreditation that do not meet the criteria as set forth by the profession through ABET in the areas of engineering, technology, computing, and applied science. c). If ABET volunteers or staff members have knowledge of or reason to believe that an accredited program may be non-compliant with the appropriate criteria, they shall present such information to ABET in writing and shall cooperate with ABET in furnishing such further information or assistance as may be required. d). If credential evaluation staff members have reason to believe that the credentials submitted for evaluation are not authentic or information submitted in support of an evaluation is misleading, they shall cooperate with ABET or any other entities affected by this process to verify the validity of facts and proof the authenticity of the academic documents in question.

2. ABET volunteers and staff members agree to perform services only in areas of our competence. All those involved in ABET activities shall undertake accreditation assignments only when qualified by education and/or experience in the specific technical field involved.

3. ABET volunteers and staff members agree to act as faithful agents or trustees of ABET, avoiding conflicts of interest and disclosing them to affected parties when they exist. a). All those involved in ABET activities shall avoid all known conflicts of interest when representing ABET in any situation. b). They shall disclose all known or potential conflicts of interest that could influence or appear to influence their judgment or the quality of their services. c). They shall not serve as a consultant in accreditation matters to a program or institution while serving as a member or alternate of a commission or the Board of Directors. Program evaluators who have or will serve as consultants must disclose this to ABET per the ABET Conflict of Interest Policy and may not participate in any deliberations regarding ABET matters for that institution. d). They shall not undertake any assignments or take part in any discussions that would knowingly create a conflict of interest between them and ABET or between them and the institutions seeking programmatic accreditation. e). They shall not solicit

or accept gratuities, directly or indirectly, from programs under review for accreditation or from individuals/entities when credentials are under evaluation. f). They shall not solicit or accept any contribution, directly or indirectly, to influence the accreditation decision of programs or the outcome of credential evaluations.

4. ABET volunteers and staff members agree to keep confidential all matters relating to accreditation decisions and credential evaluations unless by doing so we endanger the public or are required by law to disclose information. a). All those involved in ABET activities shall treat information coming to them in the course of their assignments as confidential, and shall not use such information as a means of making personal profit under any circumstances. b). They shall not reveal confidential information or findings except as authorized or required by law or court order. c). They shall only reveal confidential information or findings in their entirety where required to do so and then only with the prior consent of ABET and the institution/programs involved.

5. ABET volunteers and staff members agree to issue either public or internal statements only in an objective and truthful manner. a). All those involved in ABET activities shall be objective and truthful in reports, statements or testimony. They shall include all relevant and pertinent information in such reports, statements, or testimony and shall avoid any act tending to promote their own interest at the expense of the integrity of the process. b). They shall issue no statements, criticisms, or arguments on accreditation matters which are inspired or paid for by an interested party, or parties, unless they preface their comments by identifying themselves, by disclosing the identities of the party or parties on whose behalf they are speaking, and by revealing the existence of any financial interest they may have in matters under discussion. c). They shall not use statements containing a misrepresentation of fact or omitting a material fact. d. They shall admit their own errors when proven wrong and refrain from distorting or altering the facts to justify their mistakes or decisions.

6. ABET volunteers and staff members agree to conduct ourselves honorably, responsibly, ethically, and lawfully so as to enhance the reputation, and usefulness of ABET. a). All those involved in accreditation activities and credential evaluations shall refrain from any conduct that deceives the public. b). They shall not falsify or permit misrepresentation of their, or their associates', academic or professional qualifications. c). They shall not maliciously or falsely, directly or indirectly, injure the professional reputation, prospects, practice or employment of another. If they believe others are guilty of unethical or illegal behavior, they shall present such information to the proper authority for action.

7. ABET volunteers and staff members agree to treat fairly all persons regardless of race, religion, gender, disability, age, national origin, marital status or political affiliation. All those involved in accreditation activities and credential evaluations shall act with fairness and justice to all parties.

8. ABET volunteers and staff members agree to assist colleagues and co-workers in their professional development and to support them in following this code of conduct. a). ABET will provide broad dissemination of these canons of conduct to its volunteers, staff, representative organizations, and other stakeholders impacted by accreditation and credential evaluations. b). ABET will provide training in the use and understanding of the Code of Conduct for all new volunteers and staff members. c). All those involved in accreditation matters and credential evaluations shall continue their professional development throughout their service with ABET and shall provide/participate in opportunities for the professional and ethical development of all stakeholders.

9. Through its Committee on Professional Development, ABET will provide a mechanism for the prompt and fair adjudication of alleged violations of the Code of Conduct. Persons found to be in violation of the ABET Code of Conduct may be subject to any of a number of sanctions including being declared ineligible for service in further activities on behalf of ABET.

Fundamental Canons

Now, therefore, as a volunteers and/or staff member of the Accreditation Board for Engineering and Technology, Inc., and/or its member societies and having read and understood the above stated Guidelines, I __________________________ do hereby commit myself to the highest ethical and professional conduct and agree:

1. to accept responsibility in making accreditation decisions and credential evaluations consistent with approved criteria and the safety, health, and welfare of the public and to disclose promptly, factors that may directly or indirectly conflict with these duites and/or may endanger the public;
2. to perform services only in areas of my competence;

3. to act as a faithful agent or trustee of ABET avoiding conflicts of interest and disclosing them to affected parties including but not limited to, ABET when they exist;
4. to keep confidential all matters relating to accreditation decisions and credential evaluations unless by doing so we harm the public or are required by law to disclose information;
5. to issue either public or internal statements only in an objective and truthful manner;
6. to conduct myself honorably, responsibly, ethically, and lawfully so as to enhance the reputation and effectiveness of ABET;
7. to treat fairly all persons regardless of race, religion, gender, disability, age, national origin, marital status, or political affiliation;
8. to assist colleagues and co-workers in their professional development and to support them in following this code of conduct;
9. to support a mechanism for the prompt and fair adjudication of alleged violations of these canons.

AMERICAN SOCIETY OF CIVIL ENGINEERS (ASCE) CODE OF ETHICS

Fundamental Principles

Engineers uphold and advance the integrity, honor and dignity of the engineering profession by:

(1) using their knowledge and skill for the enhancement of human welfare and the environment;

(2) being honest and impartial and serving with fidelity the public, their employers and clients;

(3) striving to increase the competence and prestige of the engineering profession; and

(4) supporting the professional and technical societies of their disciplines.

Fundamental Canons

(1) *Engineers shall* hold paramount the safety, health and welfare of the public and shall strive to comply with the principles of sustainable development3 in the performance of their professional duties.

(2) *Engineers shall* perform services only in areas of their competence.

(3) *Engineers shall* issue public statements only in an objective and truthful manner.

(4) *Engineers shall* act in professional matters for each employer or client as faithful agents or trustees, and shall avoid conflicts of interest.

(5) *Engineers shall* build their professional reputation on the merit of their services and shall not compete unfairly with others.

(6) *Engineers shall* act in such a manner as to uphold and enhance the honor, integrity, and dignity of the engineering profession.

(7) *Engineers shall* continue their professional development throughout their careers, and shall provide opportunities for the professional development of those engineers under their supervision.

Guidelines to Practice Under the Fundamental Canons of Ethics

CANON 1.

Engineers shall hold paramount the safety, health and welfare of the public and shall strive to comply with the principles of sustainable development in the performance of their professional duties.

(a) Engineers shall recognize that the lives, safety, health and welfare of the general public are dependent upon engineering judgments, decisions and practices incorporated into structures, machines, products, processes and devices.

(b) Engineers shall approve or seal only those design documents, reviewed or prepared by them, which are determined to be safe for public health and welfare in conformity with accepted engineering standards.

(c) Engineers whose professional judgment is overruled under circumstances where the safety, health and welfare of the public are endangered, or the principles of sustainable development ignored, shall inform their clients or employers of the possible consequences.

(d) Engineers who have knowledge or reason to believe that another person or firm may be in violation of any of the provisions of Canon 1 shall present such information to the proper authority in writing and shall cooperate with the proper authority in furnishing such further information or assistance as may be required.

(e) Engineers should seek opportunities to be of constructive service in civic affairs and work for the advancement of the safety, health and well-being of their communities, and the protection of the environment through the practice of sustainable development.

(f) Engineers should be committed to improving the environment by adherence to the principles of sustainable development so as to enhance the quality of life of the general public.

CANON 2.

Engineers shall perform services only in areas of their competence.

(a) Engineers shall undertake to perform engineering assignments only when qualified by education or experience in the technical field of engineering involved.

(b) Engineers may accept an assignment requiring education or experience outside of their own fields of competence, provided their services are restricted to those phases of the project in which they are qualified. All other phases of such project shall be performed by qualified associates, consultants, or employees.

(c) Engineers shall not affix their signatures or seals to any engineering plan or document dealing with subject matter in which they lack competence by virtue of education or experience or to any such plan or document not reviewed or prepared under their supervisory control.

CANON 3.

Engineers shall issue public statements only in an objective and truthful manner.

(a) Engineers should endeavor to extend the public knowledge of engineering and sustainable development, and shall not participate in the dissemination of untrue, unfair or exaggerated statements regarding engineering.

(b) Engineers shall be objective and truthful in professional reports, statements, or testimony. They shall include all relevant and pertinent information in such reports, statements, or testimony.

(c) Engineers, when serving as expert witnesses, shall express an engineering opinion only when it is founded upon adequate knowledge of the facts, upon a background of technical competence, and upon honest conviction.

(d) Engineers shall issue no statements, criticisms, or arguments on engineering matters which are inspired or paid for by interested parties, unless they indicate on whose behalf the statements are made.

(e) Engineers shall be dignified and modest in explaining their work and merit, and will avoid any act tending to promote their own interests at the expense of the integrity, honor and dignity of the profession.

CANON 4.

Engineers shall act in professional matters for each employer or client as faithful agents or trustees, and shall avoid conflicts of interest.

(a) Engineers shall avoid all known or potential conflicts of interest with their employers or clients and shall promptly inform their employers or clients of any business association, interests, or circumstances which could influence their judgment or the quality of their services.

(b) Engineers shall not accept compensation from more than one party for services on the same project, or for services pertaining to the same project, unless the circumstances are fully disclosed to and agreed to, by all interested parties.

(c) Engineers shall not solicit or accept gratuities, directly or indirectly, from contractors, their agents, or other parties dealing with their clients or employers in connection with work for which they are responsible.

(d) Engineers in public service as members, advisors, or employees of a governmental body or department shall not participate in considerations or actions with respect to services solicited or provided by them or their organization in private or public engineering practice.

(e) Engineers shall advise their employers or clients when, as a result of their studies, they believe a project will not be successful.

(f) Engineers shall not use confidential information coming to them in the course of their assignments as a means of making personal profit if such action is adverse to the interests of their clients, employers or the public.

(g) Engineers shall not accept professional employment outside of their regular work or interest without the knowledge of their employers.

CANON 5.

• • •

Engineers shall build their professional reputation on the merit of their services and shall not compete unfairly with others.

(a) Engineers shall not give, solicit or receive either directly or indirectly, any political contribution, gratuity, or unlawful consideration in order to secure work, exclusive of securing salaried positions through employment agencies.

(b) Engineers should negotiate contracts for professional services fairly and on the basis of demonstrated competence and qualifications for the type of professional service required.

(c) Engineers may request, propose or accept professional commissions on a contingent basis only under circumstances in which their professional judgments would not be compromised.

(d) Engineers shall not falsify or permit misrepresentation of their academic or professional qualifications or experience.

(e) Engineers shall give proper credit for engineering work to those to whom credit is due, and shall recognize the proprietary interests of others. Whenever possible, they shall name the person or persons who may be responsible for designs, inventions, writings or other accomplishments.

(f) Engineers may advertise professional services in a way that does not contain misleading language or is in any other manner derogatory to the dignity of the profession. Examples of permissible advertising are as follows:

Professional cards in recognized, dignified publications, and listings in rosters or directories published by responsible organizations, provided that the cards or listings are consistent in size and content and are in a section of the publication regularly devoted to such professional cards.

Brochures which factually describe experience, facilities, personnel and capacity to render service, providing they are not misleading with respect to the engineer's participation in projects described.

Display advertising in recognized dignified business and professional publications, providing it is factual and is not misleading with respect to the engineer's extent of participation in projects described.

A statement of the engineers' names or the name of the firm and statement of the type of service posted on projects for which they render services.

Preparation or authorization of descriptive articles for the lay or technical press, which are factual and dignified. Such articles shall not imply anything more than direct participation in the project described.

Permission by engineers for their names to be used in commercial advertisements, such as may be published by contractors, material suppliers, etc., only by means of a modest, dignified notation acknowledging the engineers' participation in the project described. Such permission shall not include public endorsement of proprietary products.

(g) Engineers shall not maliciously or falsely, directly or indirectly, injure the professional reputation, prospects, practice or employment of another engineer or indiscriminately criticize another's work.

(h) Engineers shall not use equipment, supplies, laboratory or office facilities of their employers to carry on outside private practice without the consent of their employers.

CANON 6.

• • •

Engineers shall act in such a manner as to uphold and enhance the honor, integrity, and dignity of the engineering profession.

Engineers shall not knowingly act in a manner which will be derogatory to the honor, integrity, or dignity of the engineering profession or knowingly engage in business or professional practices of a fraudulent, dishonest or unethical nature.

CANON 7.

• • •

Engineers shall continue their professional development throughout their careers, and shall provide opportunities for the professional development of those engineers under their supervision.

(a) Engineers should keep current in their specialty fields by engaging in professional practice, participating in continuing education courses, reading in the technical literature, and attending professional meetings and seminars.

(b) Engineers should encourage their engineering employees to become registered at the earliest possible date.

(c) Engineers should encourage engineering employees to attend and present papers at professional and technical society meetings.

(d) Engineers shall uphold the principle of mutually satisfying relationships between employers and employees with respect to terms of employment including professional grade descriptions, salary ranges, and fringe benefits.

As adopted September 2, 1914, and most recently amended November 10, 1996.

(1) The American Society of Civil Engineers adopted THE FUNDAMENTAL PRINCIPLES of the ABET Code of Ethics of Engineers as accepted by the Accreditation Board for Engineering and Technology, Inc. (ABET). (By ASCE Board of Direction action April 12-14, 1975)

(2) In November 1996, the ASCE Board of Direction adopted the following definition of Sustainable Development: "ustainable Development is the challenge of meeting human needs for natural resources, industrial products, energy, food, transportation, shelter, and effective waste management while conserving and protecting environmental quality and the natural resource base essential for future development."

AMERICAN SOCIETY OF MECHANICAL ENGINEERS (ASME) CODE OF ETHICS

• • •

ASME requires ethical practice by each of its members and has adopted the following Code of Ethics of Engineers as referenced in the ASME Constitution, Article C2.1.1.

Code of ethics of engineers

THE FUNDAMENTAL PRINCIPLES Engineers uphold and advance the integrity, honor and dignity of the engineering profession by:

(I) using their knowledge and skill for the enhancement of human welfare;

(II) being honest and impartial, and serving with fidelity the public, their employers and clients; and

(III) striving to increase the competence and prestige of the engineering profession.

THE FUNDAMENTAL CANONS

(1) Engineers shall hold paramount the safety, health and welfare of the public in the performance of their professional duties.

(2) Engineers shall perform services only in the areas of their competence.

(3) Engineers shall continue their professional development throughout their careers and shall provide opportunities for the professional and ethical development of those engineers under their supervision.

(4) Engineers shall act in professional matters for each employer or client as faithful agents or trustees, and shall avoid conflicts of interest or the appearance of conflicts of interest.

(5) Engineers shall build their professional reputation on the merit of their services and shall not compete unfairly with others.

(6) Engineers shall associate only with reputable persons or organizations.

(7) Engineers shall issue public statements only in an objective and truthful manner.

(8) Engineers shall consider environmental impact in the performance of their professional duties.

(9) Engineers shall consider sustainable development in the performance of their professional duties.

The Board on Professional Practice and Ethics maintains an archive of interpretations to the ASME Code of Ethics (P-15.7). These interpretations shall serve as guidance to the user of the ASME Code of Ethics and are available on the Board's website or upon request.
Responsibility: Council on Member Affairs/Board on Professional Practice and Ethics
Adopted: March 7, 1976
Revised several times

INSTITUTE OF ELECTRICAL AND ELECTRONIC ENGINEERS (IEEE) CODE OF ETHICS

• • •

We, the members of the IEEE, in recognition of the importance of our technologies in affecting the quality of life throughout the world, and in accepting a personal obligation to our profession, its members and the communities we serve, do hereby commit ourselves to the highest ethical and professional conduct and agree:

1. to accept responsibility in making engineering decisions consistent with the safety, health and welfare of the public, and to disclose promptly factors that might endanger the public or the environment;
2. to avoid real or perceived conflicts of interest whenever possible, and to disclose them to affected parties when they do exist;
3. to be honest and realistic in stating claims or estimates based on available data;
4. to reject bribery in all its forms;
5. to improve the understanding of technology, its appropriate application, and potential consequences;
6. to maintain and improve our technical competence and to undertake technological tasks for others only if qualified by training or experience, or after full disclosure of pertinent limitations;
7. to seek, accept, and offer honest criticism of technical work, to acknowledge and correct errors, and to credit properly the contributions of others;
8. to treat fairly all persons regardless of such factors as race, religion, gender, disability, age, or national origin;
9. to avoid injuring others, their property, reputation, or employment by false or malicious action;
10. to assist colleagues and co-workers in their professional development and to support them in following this code of ethics.

Approved by the IEEE Board of Directors
August 1990

NATIONAL SOCIETY OF PROFESSIONAL ENGINEERS (NSPE) CODE OF ETHICS

• • •

Preamble

Engineering is an important and learned profession. As members of this profession, engineers are expected to exhibit the highest standards of honesty and integrity. Engineering has a direct and vital impact on the quality of life for all people. Accordingly, the services provided by engineers require honesty, impartiality, fairness, and equity, and must be dedicated to the protection of the public health, safety, and welfare. Engineers must perform under a standard of professional behavior that requires adherence to the highest principles of ethical conduct.

I. Fundamental Canons

Engineers, in the fulfillment of their professional duties, shall:

1. Hold paramount the safety, health and welfare of the public.
2. Perform services only in areas of their competence.
3. Issue public statements only in an objective and truthful manner.
4. Act for each employer or client as faithful agents or trustees.
5. Avoid deceptive acts.
6. Conduct themselves honorably, responsibly, ethically, and lawfully so as to enhance the honor, reputation, and usefulness of the profession.

II. Rules of Practice

1. Engineers shall hold paramount the safety, health, and welfare of the public.

(a) If engineers' judgment is overruled under circumstances that endanger life or property, they shall notify their employer or client and such other authority as may be appropriate.

(b) Engineers shall approve only those engineering documents that are in conformity with applicable standards.

(c) Engineers shall not reveal facts, data, or information without the prior consent of the client or employer except as authorized or required by law or this Code.

(d) Engineers shall not permit the use of their name or associate in business ventures with any person or firm that they believe are engaged in fraudulent or dishonest enterprise.

(e) Engineers shall not aid or abet the unlawful practice of engineering by a person or firm.

(f) Engineers having knowledge of any alleged violation of this Code shall report thereon to appropriate professional bodies and, when relevant, also to public authorities, and cooperate with the proper authorities in furnishing such information or assistance as may be required.

(2) Engineers shall perform services only in the areas of their competence.

(a) Engineers shall undertake assignments only when qualified by education or experience in the specific technical fields involved.

(b) Engineers shall not affix their signatures to any plans or documents dealing with subject matter in which they lack competence, nor to any plan or document not prepared under their direction and control.

(c) Engineers may accept assignments and assume responsibility for coordination of an entire project and sign and seal the engineering documents for the entire project, provided that each technical segment is signed and sealed only by the qualified engineers who prepared the segment.

(3) Engineers shall issue public statements only in an objective and truthful manner.

(a) Engineers shall be objective and truthful in professional reports, statements, or testimony. They shall include all relevant and pertinent information in such reports, statements, or testimony, which should bear the date indicating when it was current.

(b) Engineers may express publicly technical opinions that are founded upon knowledge of the facts and competence in the subject matter.

(c) Engineers shall issue no statements, criticisms, or arguments on technical matters that are inspired or paid for by interested parties, unless they have prefaced their comments by explicitly identifying the interested parties on whose behalf they are speaking, and by revealing the existence of any interest the engineers may have in the matters.

(4) Engineers shall act for each employer or client as faithful agents or trustees.

(a) Engineers shall disclose all known or potential conflicts of interest that could influence or appear to influence their judgment or the quality of their services.

(b) Engineers shall not accept compensation, financial or otherwise, from more than one party for services on the same project, or for services pertaining to the same project, unless the circumstances are fully disclosed and agreed to by all interested parties.

(c) Engineers shall not solicit or accept financial or other valuable consideration, directly or indirectly, from outside agents in connection with the work for which they are responsible.

(d) Engineers in public service as members, advisors, or employees of a governmental or quasi-governmental body or department shall not participate in decisions with respect to services solicited or provided by them or their organizations in private or public engineering practice.

(e) Engineers shall not solicit or accept a contract from a governmental body on which a principal or officer of their organization serves as a member.

(5) Engineers shall avoid deceptive acts.

(a) Engineers shall not falsify their qualifications or permit misrepresentation of their or their associates' qualifications. They shall not misrepresent or exaggerate their responsibility in or for the subject matter of prior assignments. Brochures or other presentations incident to the solicitation of employment shall not misrepresent pertinent facts concerning employers, employees, associates, joint venturers, or past accomplishments.

(b) Engineers shall not offer, give, solicit or receive, either directly or indirectly, any contribution to influence the award of a contract by public authority, or which may be reasonably construed by the public as having the effect of intent to influencing the awarding of a contract. They shall not offer any gift or other valuable consideration in order to secure work. They shall not pay a commission, percentage, or brokerage fee in order to secure work, except to a bona fide employee or bona fide established commercial or marketing agencies retained by them.

III. Professional Obligations

(1) Engineers shall be guided in all their relations by the highest standards of honesty and integrity.

(a) Engineers shall acknowledge their errors and shall not distort or alter the facts.

(b) Engineers shall advise their clients or employers when they believe a project will not be successful.

(c) Engineers shall not accept outside employment to the detriment of their regular work or interest. Before accepting any outside engineering employment they will notify their employers.

(d) Engineers shall not attempt to attract an engineer from another employer by false or misleading pretenses.

(e) Engineers shall not promote their own interest at the expense of the dignity and integrity of the profession.

(2) Engineers shall at all times strive to serve the public interest.

(a) Engineers shall seek opportunities to participate in civic affairs; career guidance for youths; and work for the advancement of the safety, health, and well-being of their community.

(b) Engineers shall not complete, sign, or seal plans and/or specifications that are not in conformity with applicable engineering standards. If the client or employer insists on such unprofessional conduct, they shall notify the proper authorities and withdraw from further service on the project.

(c) Engineers shall endeavor to extend public knowledge and appreciation of engineering and its achievements.

(3) Engineers shall avoid all conduct or practice that deceives the public.

(a) Engineers shall avoid the use of statements containing a material misrepresentation of fact or omitting a material fact.

(b) Consistent with the foregoing, engineers may advertise for recruitment of personnel.

(c) Consistent with the foregoing, engineers may prepare articles for the lay or technical press, but such articles shall not imply credit to the author for work performed by others.

(4) Engineers shall not disclose, without consent, confidential information concerning the business affairs or technical processes of any present or former client or employer, or public body on which they serve.

(a) Engineers shall not, without the consent of all interested parties, promote or arrange for new employment or practice in connection with a specific project for which the engineer has gained particular and specialized knowledge.

(b) Engineers shall not, without the consent of all interested parties, participate in or represent an adversary interest in connection with a specific project or proceeding in which the engineer has gained particular specialized knowledge on behalf of a former client or employer.

(5) Engineers shall not be influenced in their professional duties by conflicting interests.

(a) Engineers shall not accept financial or other considerations, including free engineering designs, from material or equipment suppliers for specifying their product.

(b) Engineers shall not accept commissions or allowances, directly or indirectly, from contractors or other parties dealing with clients or employers of the engineer in connection with work for which the engineer is responsible.

(6) Engineers shall not attempt to obtain employment or advancement or professional engagements by untruthfully criticizing other engineers, or by other improper or questionable methods.

(a) Engineers shall not request, propose, or accept a commission on a contingent basis under circumstances in which their judgment may be compromised.

(b) Engineers in salaried positions shall accept part-time engineering work only to the extent consistent with policies of the employer and in accordance with ethical considerations.

(c) Engineers shall not, without consent, use equipment, supplies, laboratory, or office facilities of an employer to carry on outside private practice.

(7) Engineers shall not attempt to injure, maliciously or falsely, directly or indirectly, the professional reputation, prospects, practice, or employment of other engineers. Engineers who believe others are guilty of unethical or illegal practice shall present such information to the proper authority for action.

(a) Engineers in private practice shall not review the work of another engineer for the same client, except with the knowledge of such engineer, or unless the connection of such engineer with the work has been terminated.

(b) Engineers in governmental, industrial, or educational employ are entitled to review and evaluate the work of other engineers when so required by their employment duties.

(c) Engineers in sales or industrial employ are entitled to make engineering comparisons of represented products with products of other suppliers.

(8) Engineers shall accept personal responsibility for their professional activities, provided, however, that engineers may seek indemnification for services arising out of their practice for other than gross negligence, where the engineer's interests cannot otherwise be protected.

(a) Engineers shall conform with state registration laws in the practice of engineering.

(b) Engineers shall not use association with a nonengineer, a corporation, or partnership as a "cloak" for unethical acts.

(9) Engineers shall give credit for engineering work to those to whom credit is due, and will recognize the proprietary interests of others.

(a) Engineers shall, whenever possible, name the person or persons who may be individually responsible for designs, inventions, writings, or other accomplishments.

(b) Engineers using designs supplied by a client recognize that the designs remain the property of the client and may not be duplicated by the engineer for others without express permission.

(c) Engineers, before undertaking work for others in connection with which the engineer may make improvements, plans, designs, inventions, or other records that may justify copyrights or patents, should enter into a positive agreement regarding ownership.

(d) Engineers' designs, data, records, and notes referring exclusively to an employer's work are the employer's property. The employer should indemnify the engineer for use of the information for any purpose other than the original purpose.

(e) Engineers shall continue their professional development throughout their careers and should keep current in their specialty fields by engaging in professional practice, participating in continuing education courses, reading in the technical literature, and attending professional meetings and seminars.

—*As Revised January 2003*

"By order of the United States District Court for the District of Columbia, former Section 11(c) of the NSPE Code of Ethics prohibiting competitive bidding, and all policy statements, opinions, rulings or other guidelines interpreting its scope, have been rescinded as unlawfully interfering with the legal right of engineers, protected under the antitrust laws, to provide price information to prospective clients; accordingly, nothing contained in the NSPE Code of Ethics, policy statements, opinions, rulings or other guidelines prohibits the submission of price quotations or competitive bids for engineering services at any time or in any amount."

Statement by NSPE Executive Committee

In order to correct misunderstandings which have been indicated in some instances since the issuance of the Supreme Court decision and the entry of the Final Judgment, it is noted that in its decision of April 25, 1978, the Supreme Court of the United States declared: "The Sherman Act does not require competitive bidding."

It is further noted that as made clear in the Supreme Court decision:

(1) Engineers and firms may individually refuse to bid for engineering services.

(2) Clients are not required to seek bids for engineering services.

(3) Federal, state, and local laws governing procedures to procure engineering services are not affected, and remain in full force and effect.

(4) State societies and local chapters are free to actively and aggressively seek legislation for professional selection and negotiation procedures by public agencies.

(5) State registration board rules of professional conduct, including rules prohibiting competitive bidding for engineering services, are not affected and remain in full force and effect. State registration boards with authority to adopt rules of professional conduct may adopt rules governing procedures to obtain engineering services.

(6) As noted by the Supreme Court, "nothing in the judgment prevents NSPE and its members from attempting to influence governmental action ..."

NOTE: In regard to the question of application of the Code to corporations vis-à-vis real persons, business form or type should not negate nor influence conformance of individuals to the Code. The Code deals with professional services, which services must be performed by real persons. Real persons in turn establish and implement policies within business structures. The Code is clearly written to apply to the Engineer and items incumbent on members of NSPE to endeavor to live up to its provisions. This applies to all pertinent sections of the Code.

PUERTO RICO: ASSOCIATION OF ENGINEERS AND SURVEYORS OF PUERTO RICO CODE OF ETHICS

• • •

College of Engineers and Surveyors of Puerto Rico

RULES OF ETHICS

In order to maintain and extol the integrity, honor, and dignity of their professions, in accordance with the highest moral and ethical professional norms of conduct, the **Engineer** and the **Surveyor:**

1. Should consider their principal function as professionals as that of serving humanity. Their relation as professional and client, and as professional and patron, should be subject to their fundamental function of promoting the wellbeing of humanity and that of protecting the public interest.
2. They will be honest and impartial and will serve faithfully in the development of their professional functions, always maintaining their independence of criteria which constitutes the base of professionalism.
3. They will strive to improve the competence and the prestige of engineering and surveying.

RULES OF PROFESSIONAL ETHICS

The **Engineer** and the **Surveyor**, in fulfilling their professional duties, must:

RULE I: Protect, above all other consideration, the security, environment, health, and wellbeing of the community in the execution of their professional responsibilities.

RULE II: Provide services only in their areas of competence.

RULE III: Make public declarations only in a true and objective form.

RULE IV: Act in professional matters for each patron or client as faithful agents or fiduciaries, and avoid conflicts of interests or the mere appearance of these, always maintaining independence of criteria as the base of professionalism.

RULE V: Build their professional reputation on the merit of their services and not compete disloyally with others.

RULE VI: Not participate in deceitful acts in the pursuit of employment and in offering professional services.

RULE VII: Act with the decorum that sustains and enhances the honor, integrity, and dignity of their professions.

RULE VIII: Associate only with persons and organizations of good reputation.

RULE IX: Continue their professional development throughout their careers and promote opportunities for the professional and ethical development of the engineers and surveyors under their supervision.

RULE X: Strive to and accept to take professional actions only in conformity with the applicable laws and with these Rules.

NORMS OF PRACTICE RULE I: Protect, above all other consideration, the security, environment, health, and wellbeing of the community in the execution of their professional responsibilities.

The **Engineer** and the **Surveyor:**

a. Will recognize that the life, the security, the environment, the health, and the wellbeing of the community depend on the judgments, decisions, and professional practices incorporated in systems, structures, machines, processes, products, and artifacts.

b. Will approve, seal, stamp, or certify, when appropriate, only those documents revised or prepared by those who understand that they are safe for the environment, health, and wellbeing of the community in conformity with the accepted standards.

c. When their professional judgment might have been repealed in circumstances where the security, environment, health, or wellbeing of the community are put in danger, they will inform their clients or patrons of the possible consequences. If the threat to the security, environment, health, or wellbeing of the community continues, they will inform the concerned authorities about the matter.

d. When they have knowledge or sufficient reason to believe that another engineer or surveyor is violating the dispositions of this Code, or that a person or firm is putting in danger the security, environment, health, or wellbeing of the community, they will present such information in writing to the concerned authorities and will cooperate with said authorities by providing what information or assistance that might be required by them.

e. They will serve constructively in civic matters and will work for the advancement of the security, environment, health, and wellbeing of their communities.

f. They will promise to better the environment and do all that which might be within their reach to enhance the quality of life.

RULE II: Provide services only in their areas of competence.

The **Engineer** and the **Surveyor:**

a. Will only undertake those jobs for which they are qualified by education or experience in the specific technical fields which are being dealt with.

b. Will be able to accept a charge that requires education and experience outside of their fields of competence always and whenever their services are restricted to those phases of the project for which they are qualified. All the other phases of such a project will be executed by qualified associates, consultants, or employees who will approve, seal, stamp, or certify, where necessary, the concerned documents.

c. They will not approve, seal, stamp, or certify, where necessary, any plan or document that deals with some material en which they do not have competence by virtue of their education or experience.

RULE III: Make public declarations only in a true and objective form.

The **Engineer** and the Surveyor:

a. Will be objective and true in professional reports, declarations, or testimonies. They will include all relevant or pertinent information in said reports, declarations, or testimonies.

b. Will undertake to make public knowledge the reach and the practice of their professions and will not participate in the dissemination of false, unjust, or exaggerated declarations.

c. When they serve as technical witnesses, experts, or technicians in any forum, they will express a professional opinion only when it is founded in an adequate knowledge of the facts of the controversy, in a technical competence about the material in question, and in an honest conviction of the exactitude and propriety of their testimonies.

d. They will not make declarations, critiques, or arguments about materials of their respective professions that are motivated or paid by an interested party or parties, unless in these commentaries their author is identified, and the identity of the party or parties whose interest is being spoken about is revealed, as well as the existence of any pecuniary interest that they might have in the matters under discussion.

e. They will be serious and restrained in explaining their work and merits, and will avoid any act tending to promote their own interest at the expense of the integrity, honor, and dignity of their profession or of another individual.

f. They will express publicly a professional opinion about technical matters only when that opinion is founded upon an adequate knowledge of the facts, and competence in these matters.

RULE IV: Act in professional matters for each patron or client as faithful agents or fiduciaries, and avoid conflicts of interests or the mere appearance of these, always maintaining independence of criteria as the base of professionalism.

The **Engineer** and the **Surveyor:**

a. Will avoid all known or potential conflicts of interest with their patrons or clients and will inform in a prompt manner said patrons or clients about any business relation, interests, or circumstances that might influence their judgment or the quality of their services.

b. Will not undertake any charge that might, knowingly, create a potential conflict of interest among them and their clients or patrons.

c. Will not accept compensation from third parties for services rendered in a project, or for services pertaining to the same project, unless the circumstances are completely revealed, and agreed upon by all interested parties.

d. Will not solicit or accept significant gratuities, directly or indirectly, from contractors or their agents or other parties in relation to work that is realized for patrons or clients for which they are responsible.

e. Will not solicit or accept considerations or compensations of any kind for specifying products or materials or suppliers of equipment, without divulging it to their clients or patrons.

f. Those who are in public service as members, advisors, or employers of a governmental body or department will not participate in decisions related to professional services solicited or provided by them or by their organizations in professional practice, be it private or public.

g. Will not solicit or accept contracts for professional services from a governmental body en which an individual or official of their organizations serves as a member.

h. When, as a result of their studies, they understand that a project will not be successful, they will make such an opinion part of the report to their patron or client.

i. Will treat all information that arrives to them in the course of their professional duties as confidential and will not use such information as a means to achieve personal benefit if such an action is adverse to the interests of their clients, of their patrons, of the commissions or committees to which they belong, or of the public.

j. Will not reveal confidential information concerning business matters or technical processes of any patron or bidder, current or previous, under evaluation, without their consent, except when it might be required by law.

k. Will not duplicate designs that are supplied to them by their clients for others, without the express authorization of their client and of the designer, considering the relevant contracts and laws.

l. Before undertaking work for others, in which they can make renovations, plans, designs, inventions, or other registers, that can justify obtaining author's rights or patents, will arrive at an agreement in relation to the rights of the respective parts.

m. Will not participate in or represent an adversary interest without the consent of the interested parts, in relation to a specific project or matter in which they have gained a particular specialized knowledge in the name of a former patron or client.

RULE V: **Build their professional reputation on the merit of their services and not compete disloyally with others.**

The **Engineer** and the **Surveyor:**

a. Will not offer, give, solicit, or receive, directly or indirectly, any monetary contribution or contribution of any other type directed at influencing the granting of a contract by a public authority. They will not offer any gift or any other type of consideration of worth with the aim of obtaining work. They will not pay a commission, percent, or rights of brokerage with the aim of obtaining work except to a bonafide employee or to commercial agencies or to established marketing agencies, bonafide and contracted by them for this reason.

b. Will negotiate contracts for professional services on the base of professional competence and demonstrated qualifications for the type of professional service required and then for just and reasonable honorariums.

c. Will not solicit, propose, or accept professional commissions on a base contingent upon circumstances in which their professional judgment may be seen as compromised.

d. Will not attempt to recruit an employee from other patron by means of false or deceitful representations.

e. Will not maliciously or falsely damage, directly or indirectly, the professional reputation, the prospects, the practice, or the employment of another engineer or surveyor, nor will criticize indiscriminately the work of these people.

f. Will not use the equipment, supplies, laboratory, or office of their patrons in order to execute exterior private practice without their consent.

g. Will not take advantage of the advantages of a salaried position in order to disloyally compete with colleagues who exercise the profession privately.

h. Will not attempt to supplant, nor will supplant another engineer or surveyor, after a professional position has been offered to him or her, nor will compete unjustly with said person.

i. The professionals who act as subcontractors on a project or who in some capacity utilize the services of another professional will not be able to retain for themselves the professional honorariums charges without having attended to the payment of the honorariums of their collaborators at least in a form equitable or proportional to their own; or in any manner deprive or further that their professional companions do not receive just or equitable pay for their services.

j. Will not approve, seal, stamp, or certify, according to the case, nor authorize the presentation of plans, specifications, calculations, opinions, briefs, or reports that have not been elaborated by them or by others under their direct responsibility. Furthermore, they will give credit for the engineering, surveying, or architectural work to those who have done it.

RULE VI: **Not participate in deceitful acts in the pursuit of employment and in offering professional services.**

The **Engineer** and the **Surveyor:**

a. Will not falsify or permit the misrepresentation of their academic or professional qualifications, nor that of their associates or employees. They will not misrepresent or exaggerate the degree of their responsibility in previous positions or concerning the matters that these positions entailed. The folders or types of presentations created for the purpose of soliciting employment will not represent the pertinent facts concerning previous patrons, employees, associates, employers, or achievements.

b. Will announce their professional services without self-praise and without deceitful language, and in a manner in which the dignity of their professions is not diminished. Some examples of permissible announcements are as follows:

1. Professional announcements in recognized publications, and listings in registries or directories published by responsible organizations, as long as the announcements and registries are consequent in size and content and are in a section of the publication dedicated regularly to such professional announcements.

2. Brochures that in fact describe the experience, installations, personnel, and capacity to render services, as long as they are not deceitful with respect to the participation of the professionals in the projects described.

3. Announcements in recognized professional and business magazines, as long as they refer to facts, do not contain self-praising expressions or implications, and are not deceitful with respect to the degree of participation of the professionals in the projects described.

4. A declaration of the names of the professionals or the name of the firm and the type of service, announced in projects for which the professionals render service.

5. The preparation or authorization of descriptive articles for the press that refer to facts, are serious, and are free of implicated praise. Such articles will imply nothing more that the direct participation of the professionals in the project described.

6. The authorization of professionals so that their names may be used in commercial announcements, such as those that can be published by contractors, suppliers of materials, etc., only through a serious and restrained annotation, recognizing the participation of the professionals in the project described. Such authorization will not include the public endorsement of brand-name products.

RULE VII: **Act with the decorum that sustains and enhances the honor, integrity, and dignity of their professions.**

The **Engineer** and the **Surveyor:**

a. Will not act, knowingly, in such a manner that might be harmful to the honor, integrity, and dignity of their professions.

b. Will not associate with, employ, or in any other way utilize in practice any person to render professional services as an engineer, surveyor, or architect, unless that person is an engineer, a surveyor, or an architect recognized by valid authorities as being able to render such services.

c. Will not associate their name with the practice of their profession with non-professionals or with persons or entities that are not professionals legally authorized to exercise the professions of engineering, surveying, or architecture.

d. Will not share honorariums except with engineers, surveyors, or architects who have been their collaborators in works of engineering, surveying, and architecture.

e. Will admit and accept their own errors when they are demonstrated to them and will abstain from distorting or altering the facts with the purpose of justifying their decisions.

f. Will cooperate en extending the efficacy of their professions through the exchange of information and experience with other engineers, architects, and surveyors, and with students of these professions.

g. Will not compromise their professional criteria for any other particular interest.

RULE VIII: **Associate only with persons and organizations of good reputation.**

The **Engineer** and the **Surveyor:**

a. Will not associate with or permit the use of their names or that of their firms, knowingly, with businesses run by any other person or firm that they know or have sufficient reason to believe might be involved in professional or business practices of a fraudulent or dishonest nature.

b. Will not use the association with natural or juridical persons to hide unethical acts.

RULE IX: **Continue their professional development throughout their careers and promote opportunities for the professional and ethical development of the engineers and surveyors under their supervision.**

The **Engineer** and the **Surveyor:**

a. Will keep themselves up to date in their fields of specialty by exercising professional practice, participating in continuing education courses, reading technical literature, and attending professional meeting and seminars.

b. Will encourage the engineers and surveyors in their employ to further their education.

c. Will encourage their graduate employees in training in engineering and surveying to obtain their professional licenses as quickly as possible.

d. Will encourage the engineers and surveyors in their employ to attend and present papers in meetings or professional and technical societies.

e. Will support the principle of mutually satisfactory relations between patrons and employees with respect to the conditions of employment, including a description of professional degree, and scales of salary and benefits.

RULE X: **Strive to and accept to take professional actions only in conformity with the applicable laws and with these Rules.**

The **Engineer** and the Surveyor:

a. Will carry out what is laid out in the laws that govern the practice and direction of engineering and surveying, according to reforms, with the rule of the College of Engineers and Surveyors of Puerto Rico (CIAPR) and of the Examination Board of Engineers, Architects, and Surveyors, and with the agreements and directives legitimately adopted by the General Assembly and Governing Board of CIAPR.

b. Will appear at any interview, administrative investigation, viewing, or procedure, before the Tribunal of Discipline and Professional Ethics or the Commission of Defense of the Profession of CIAPR to which they have been duly cited by the College, be it as a witness, plaintiff, or defendant.

Approved at the Annual Ordinary Assembly celebrated Saturday, August 20, 1994, in the El Conquistador Hotel, Fajardo, Puerto Rico.

THE INSTITUTION OF ENGINEERS CODE OF ETHICS

National Headquarters
11 National Circuit
Barton, Australian Capital Territory
2600 Australia

Founded 1919
Members: 45,000

Code of Ethics

Preamble

The further development of civilization, the conservation and management of natural resources, and the improvement of the standards of living of mankind are greatly affected by the work of the Engineer. For that work to be fully effective it is necessary not only that Engineers strive constantly to widen their knowledge and improve their skill but also that the community be willing to recognize the integrity and trust the judgment of members of the Profession of Engineering.

For this to happen, the Profession must be recognized in the community for

its skill in using technical expertise for the enhancement of human welfare

its loyalty to the community, to employers and clients

its honesty and impartiality in professional practice

Engineers shall so order their lives and work as to merit this trust.

To this end all members of the Institution are required to comply with the Code of Ethics set out hereunder; to give active support to the proper regulation of the qualifications, employment and practice of the Profession; and to promote the development and application of technology in the public interest.

Members acting in accordance with this Code will have the support of the Institution.

CODE

(1) The responsibility of Engineers for the welfare, health and safety of the community shall at all times come before their responsibility to the Profession, to sectional or private interests, or to other Engineers.

(2) Engineers shall act so as to uphold and enhance the honor, integrity and dignity of the Profession.

(3) Engineers shall perform work only in their areas of competence.

(4) Engineers shall build their professional reputation on merit and shall not compete unfairly.

(5) Engineers shall apply their skill and knowledge in the interests of their employer or client for whom they shall act, in professional matters, as faithful agents or trustees.

(6) Engineers shall give evidence, express opinions or make statements in an objective and truthful manner and on the basis of adequate knowledge.

(7) Engineers shall continue their professional development throughout their careers and shall actively assist and encourage Engineers under their direction to advance their knowledge and experience.

INTERPRETATIONS

It has been found in the past that inquiries are often received by the Institution from Engineers seeking guidance on the way in which the Code of Ethics applies in particular situations. The following interpretations are for the guidance and information of individual members as to the Institution's attitudes toward the implementation of this Code.

Clause 1:

The responsibility of Engineers for the welfare, health and safety of the community shall at all times come before their responsibility to the Profession, to sectional or private interests, or to other Engineers.

The principle here is that the interests of the community have priority over the interests of others. It follows that a member:

(a) shall avoid assignments that may create a conflict between the interests of his client or employer and the public interest;

(b) shall work in conformity with acceptable engineering standards and not in such a manner as to jeopardize the public welfare, health or safety;

(c) shall endeavor at all times to maintain engineering services essential to public welfare;

(d) shall in the course of his professional life endeavor to promote the wellbeing of the community. If his judgment is over-ruled in this matter he should inform his client or employer of the possible consequences (and, if appropriate, notify the proper authority of the situation);

(e) shall, if he considers that by so doing he can constructively advance the wellbeing of the community, contribute to public discussion on engineering matters in his area of competence.

Clause 2:

Engineers shall act so as to uphold and enhance the honor, integrity and dignity of the Profession.

The principle here is that the Profession should endeavor by its behavior to merit the highest esteem of the community. It follows therefore that a member:

(a) Shall not involve himself with any business or professional practice which he knows to be of a fraudulent or dishonest nature;

(b) shall not use association with other persons, corporations or partnerships to conceal unethical acts;

(c) shall not continue in partnership with, nor act in professional matters with, any Engineer who has been removed from membership of the Institution because of unprofessional conduct.

Clause 3:

Engineers shall perform work only in their areas of competence.

To this end the Institution has determined that:

(a) a member shall inform his employer or client, and make appropriate recommendations on obtaining further advice, if an assignment requires qualifications and experience outside his field of competence; and

(b) in the practice of Consulting Engineering a member shall not describe himself, nor permit himself to be described, nor act as a Consulting Engineer unless he is a Corporate Member, occupies a position of professional independence, is prepared to design and supervise engineering work or act as an unbiased and independent adviser on engineering matters, and conduct his practice in strict compliance with the conditions approved by the Council of the Institution.

Clause 4:

Engineers shall build their professional reputation on merit and shall not compete unfairly.

The principle here is that Engineers shall not act improperly in a professional sense to gain a benefit. It follows that a member:

(a) shall only approach prospective clients or employers with due regard to his professional independence and to this Code of Ethics;

(b) shall neither pay nor offer directly or indirectly inducements to secure work;

(c) shall promote the principle of selection of consulting engineers by clients upon the basis of merit, and shall not compete with other consulting engineers on the basis of fees alone. It shall not be a breach of the Code of Ethics for a member, upon an inquiry made in that behalf by a client or prospective client, to provide information as to the basis upon which he usually charges fees for particular types of work. Also it shall not be a breach of the Code of Ethics for a member to submit a proposal for the carrying out of work which proposal includes, in addition to a technical proposal and an indication of the resources which the member can provide, information as to the basis upon which fees will be charged or as to the amount of the fees for the work which is proposed to be done. In this respect it is immaterial whether or not the member is aware that other engineers may have been requested to submit proposals, including fee proposals, for the same work;

(d) shall promote the principle of engagement of engineers upon the basis of merit. He shall uphold the principle of adequate and appropriate remuneration for professional engineering staff and shall give due consideration to terms of employment which have the approval of the profession's appropriate association;

(e) shall not attempt to supplant another Engineer, employed or consulting, who has been appointed;

(f) in the practice of Consulting Engineering, shall not undertake professional work on a basis which involves a speculative fee or remuneration which is conditional on implementation of the work. This does not preclude competitions conducted within Australia provided that such competitions are conducted in accordance with conditions approved by the Institution;

(g) shall neither falsify nor misrepresent his or his associate's qualifications, experience and prior responsibility;

(h) shall neither maliciously nor carelessly do anything to injure, directly or indirectly, the reputation, prospects or business of others;

(i) shall not use the advantages of a privileged position to compete unfairly with other Engineers;

(j) shall exercise due restraint in explaining his own work and shall refrain from unfair criticism of the work of another Engineer;

(k) shall give proper credit for professional work to those to whom credit is due and acknowledge the contribution of subordinates and others;

(l) may properly use circumspect advertising (which includes direct approaches to prospective clients by any means) to announce his practice and availability. The medium or other form of communication used and the content of the announcement shall be dignified, becoming to a professional engineer and free from any matter that could bring disrepute to the profession. Information given must be truthful, factual and free from ostentatious or laudatory expressions or implications.

Clause 5:

Engineers shall apply their skill and knowledge in the interests of their employer or client for whom they shall act, in professional matters, as faithful agents or trustees.

It follows that a member:

(a) shall at all times avoid all known or potential conflicts of interest. He should keep his employer or client fully informed on all matters, including financial interests, which could lead to such a conflict, in no circumstance should he participate in any decision which could involve him in conflict of interest;

(b) shall, when acting as administrator of a contract, be impartial as between the parties in the interpretation of the contract. This requirement of impartiality shall not diminish the duty of engineers to apply their skill and knowledge in the interests of the employer or client;

(c) shall not accept compensation, financial or otherwise, from more than one party for services on the same project, unless the circumstances are fully disclosed to, and agreed to, by all interested parties;

(d) shall neither solicit nor accept financial or other valuable considerations, including free engineering designs, from material or equipment suppliers for specifying their products;

(e) shall neither solicit nor accept gratuities, directly or indirectly, from contractors, their agents, or other parties dealing with his client or employer in connection with work for which he is responsible;

(f) shall advise his client or employer when as a result of his studies he believes that a project will not be viable;

(g) shall neither disclose nor use confidential information gained in the course of his employment without express permission.

Clause 6:

Engineers shall give evidence, express opinions or make statements in an objective and truthful manner and on the basis of adequate knowledge.

It follows that:

(a) a member's professional reports, statements or testimony before any tribunal shall be objective and accurate. He shall express an opinion only on the basis of adequate knowledge and technical competence in the area, but this shall not preclude a considered speculation based intuitively on experience and wide relevant knowledge;

(b) a member shall reveal the existence of any interest, pecuniary or otherwise, that could be taken to affect his judgment in a technical matter about which he is making a statement or giving evidence.

Clause 7:

Engineers shall continue their professional development throughout their careers and shall actively assist and encourage those under their direction to advance their knowledge and experience.

The principle here is that Engineers shall strive to widen their knowledge and improve their skill in order to achieve a continuing improvement of the Profession. It follows therefore that a member:

(a) shall encourage his professional employees and subordinates to further their education; and

(b) shall take a positive interest in, and encourage his fellow Engineers actively to support the Institution and other Professional Engineering organizations which further the general interests of the Profession. In this regard the Councils of The Institution of Engineers, Australia. The Association of Professional Engineers, Australia, and The Association of Consulting Engineers, Australia, have jointly advised and recommend to all Professional Engineers in Australia that the interests of the community and of their profession will be best served by full individual membership and active support for each of these respective organizations for which the member is eligible.

NOTES

This code is promulgated in a small blue four-page pamphlet. On the cover it states that the code was "Approved by the Council of The Institution of Engineers, Australia to be effective from 1 August 1981. Adopted by the Association of Consulting Engineers, Australia. Adopted by the Federal Council of the Association of Professional Engineers, Australia."

Professional Conduct and Code of Ethics

A. Professional Conducts:All Corporate Members as well as Associate Members, Students and Affiliates are required to order their conduct so as to uphold the reputation of the Institution and the dignity of the profession of Engineers and shall observe and be found by the Code of Ethics. Any alleged breach of this Code by a Corporate Member or an Associate Member or a Student or an Affiliate may be brought before the Council, which shall be investigated with the knowledge of the member. If the Council considers the charge proved, action will be taken by suspension from office, expulsion or admonition by a letter or posting his/her name with description of his/her offence.

B. Code of Ethics:

(1) A member's responsibility to his employer and to the profession shall have full regards to the public interest.

(2) A member shall order his conduct so as to uphold the dignity, standing and reputation of the profession.

(3) A member shall discharge his duties to his employer with complete fidelity. He shall not accept remuneration for services rendered other than from his employer or with his employer's permission.

(4) A member shall not maliciously or recklessly injure or attempt to injure, whether directly, or indirectly, the professional reputation, prospects, or business of another member.

(5) A member shall not improperly canvass or solicit professional employment nor offer to make by way of commission or otherwise payment for the introduction of such employment.

(6) A member shall not, in a self-laudatory language or in any manner derogatory to the dignity of the profession, or professional bodies, advertise or write articles for publication, nor shall he authorize such advertisements to be written or published by any other person.

(7) A member, without disclosing the fact to his employer in writing, shall not be a director of nor have a substantial financial interest in, nor be an agent for any company, firm or person carrying on any contracting, consulting or manufacturing business which is or may be involved in the work to which his employment relates, nor shall he receive directly or indirectly any royalty, gratuity or commission on any article or process used in or for the purposes of the work in respect of which he is employed unless or until such royalty, gratuity or commission has been authorized in writing by his employer.

(8) A member shall not use the advantages of a salaried position to compete unfairly with other engineers.

(9) A member in connection with work in a country other than his own shall order his conduct according to these Rules, so far as they are applicable, but where there are recognized standards of professional conduct, he shall adhere to them.

(10) A member who shall be convicted by a competent tribunal of a criminal offence which in the opinion of the Disciplinary Body renders him unfit to be a member shall be deemed to have been guilty of improper conduct.

(11) A member shall not, directly or indirectly, attempt to supplant another member, nor shall he intervene or attempt to intervene in or in connection with engineering work of any kind to which his knowledge has already been entrusted to another member.

(12) A member shall not be the medium of payments made on his employer's behalf unless so requested by his employer, nor shall he in connection with work on which he is employed place contracts or orders except with the authority of and on behalf of his employer.

(13) A member shall not knowingly compete on the basis of Professional charges with another member.

NOTES

Although the Institution of Engineers, Bangladesh, dates its founding from 1948, the country of Bangladesh did not come into existence until 1971 when East Pakistan declared its independence of West Pakistan. See also the notes for Institution of Engineers, Pakistan.

CANADA

CANADIAN COUNCIL OF PROFESSIONAL ENGINEERS CODE OF ETHICS

Suite 401, 116 Albert Street
Ottawa, Ontario
Canada K1P 5G3

Founded: 1936
Members: 12 consultant associations representing over 137,000 professional engineers

CODE OF ETHICS

Preamble

Provincial and territorial associations of Professional Engineers are responsible for the regulation of the practice of engineering in Canada. Each association has been established under a Professional Engineering Act of its provincial or territorial legislature and serves as the licensing authority for engineers practicing within its jurisdiction. The Canadian Council of Professional Engineers (CCPE) is the national federation of these associations. CCPE provides a coordinating function among the provincial and territorial associations, fostering mutual recognition among them and encouraging the greatest possible commonality of operation in their licensing functions.

CCPE issues national guidelines on various subjects as a means to achieve coordination among its constituent member associations. Such guidelines are an expression of general guiding principles which have a broad basis of consensus, while recognizing and supporting the autonomy of each constituent association to administer the Professional Engineering Act within its jurisdiction. CCPE guidelines enunciate the principles of an issue but leave the detailed applications, policies, practices and exceptions to the judgment of the constituent associations.

CODE OF ETHICS

Professional engineers shall conduct themselves in an honorable and ethical manner. Professional engineers shall uphold the values of truth, honesty and trustworthiness and safeguard human life and welfare and the environment. In keeping with these basic tenets, professional engineers shall:

(1) hold paramount the safety, health and welfare of the public and the protection of the environment and promote health and safety within the workplace;

(2) offer services, advise on or undertake engineering assignments only in areas of their competence and practice in a careful and diligent manner;

(3) act as faithful agents of their clients or employers, maintain confidentiality and avoid conflicts of interest;

(4) keep themselves informed in order to maintain their competence, strive to advance the body of knowledge within which they practice and provide opportunities for the professional development of their subordinates;

(5) conduct themselves with fairness, courtesy and good faith towards clients, colleagues and others, give credit where it is due and accept, as well as give, honest and fair professional criticism;

(6) present clearly to employers and clients the possible consequences if engineering decisions or judgments are overruled or disregarded;

(7) report to their association or other appropriate agencies any illegal or unethical engineering decisions or practices by engineers or others; and

(8) be aware of and ensure that clients and employers are made aware of societal and environmental consequences of actions or projects and endeavor to interpret engineering issues to the public in an objective and truthful manner.

NOTES

This code, adopted November 1991, is the outcome of a workshop on professional issues held in November 1989.

ASSOCIATION OF PROFESSIONAL ENGINEERS OF ONTARIO CODE OF ETHICS

Founded: 1922
Members: 61,000

(1) In this section, "negligence" means an act or an omission in the carrying out of the work of a practitioner that constitutes a failure to maintain the standards that a reasonable and prudent practitioner would maintain in the circumstances.

(2) For the purposes of the Act and this Regulation, "professional misconduct" means

(a) negligence;

(b) failure to make reasonable provision for the safeguarding of life, health or property of a person who may be affected by the work for which the practitioner is responsible;

(c) failure to act to correct or report a situation that the practitioner believes may endanger the safety or the welfare of the public;

(d) failure to make responsible provision for complying with applicable statutes, regulations, standards, codes, by-laws and rules in connection with work being undertaken by or under the responsibility of the practitioner;

(e) signing or sealing a final drawing, specification, plan, report or other document not actually prepared or checked by the practitioner;

(f) failure of a practitioner to present clearly to his employer the consequences to be expected from a deviation proposed in work, if the professional engineering judgment of the practitioner is overruled by non-technical authority in cases where the practitioner is responsible for the technical adequacy of professional engineering work;

(g) breach of the act or regulations, other than an action that is solely a breach of the code of ethics;

(h) undertaking work the practitioner is not competent to perform by virtue of his training and experience;

(i) failure to make prompt, voluntary and complete disclosure of an interest, direct or indirect that might in any way be, or be construed as, prejudicial to the professional judgment of the practitioner in rendering service to the public, to an employer or to a client, and in particular without limiting the generality of the foregoing, carrying out any of the following acts without making such a prior disclosure:

1. Accepting compensation in any form for a particular service from more than one party.
2. Submitting a tender or acting as a contractor in respect of work upon which the practitioner may be performing as a professional engineer.
3. Participating in the supply of material or equipment to be used by the employer or client of the practitioner.
4. Contracting in the practitioner's own right to perform professional engineering services for other than the practitioner's employer.
5. Expressing opinions or making statements concerning matters within the practice of professional engineering of public interest where the opinions or statements are inspired or paid for by other interests;

(j) conduct or an act relevant to the practice of professional engineering that, having regard to all the circumstances would reasonably be regarded by the engineering profession as disgraceful, dishonorable or unprofessional;

(k) failure by a practitioner to abide by the terms, conditions or limitations of the practitioner's license, limited license, temporary license or certificate;

(l) failure to supply documents or information requested by an investigator acting under section 34 of the Act;

(m) permitting, counseling or assisting a person who is not a practitioner to engage in the practice or professional engineering except as provided for in the Act or the regulations.

CODE OF ETHICS

• • •

The following is the Code of Ethics of the Association:

1. It is the duty of a practitioner to the public, to his employer, to his clients, to other members of his profession, and to himself to act at all times with,

i. fairness and loyalty to his associates, employers, clients, subordinates and employees.

ii. fidelity to public needs, and

iii. devotion to high ideals of personal honor and professional integrity.

2. A practitioner shall,

i. regard his duty to public welfare as paramount,

ii. endeavor at all times to enhance the public regard for his profession by extending the public knowledge thereof and discouraging untrue, unfair or exaggerated statements with respect to professional engineering,

iii. not express publicly, or while he is serving as a witness before a court, commission or other tribunal, opinions on professional engineering matters that are not founded on adequate knowledge and honest conviction,

iv. endeavor to keep his license, temporary license, limited license or certificate of authorization, as the case may be, permanently displayed in his place of business.

3. A practitioner shall act in professional engineering matters for each employer as a faithful agent or trustee and shall regard as confidential information obtained by him as to the business affairs, technical methods or processes of an employer and avoid or disclose a conflict of interest that might influence his actions or judgment.

4. A practitioner must disclose immediately to his client any interest, direct or indirect, that might be construed as prejudicial in any way to the professional judgment of the practitioner in rendering service to the client.

5. A practitioner who is an employee-engineer and is contracting in his own name to perform professional engineering work for other than his employer, must provide his client with a written statement of the nature of his status as an employee and the attendant limitations on his services to the client, must satisfy himself that the work will not conflict with his duty to his employer, and must inform his employer of the work.

6. A practitioner must cooperate in working with other professionals engaged on a project.

7. A practitioner shall,

i. conduct himself towards other practitioners with courtesy and good faith,

ii. not accept an engagement to review the work of another practitioner for the same employer except with the knowledge of the other practitioner or except where the connection of the other practitioner with the work has been terminated,

iii. not maliciously injure the reputation or business of another practitioner,

iv. not attempt to gain an advantage over the other practitioners by paying or accepting a commission in securing professional engineering work, and

v. give proper credit for engineering work, uphold the principle of adequate compensation for engineering work, provide opportunity for professional development and advancement of his associates and subordinates, and extend the effectiveness of the profession through the interchange of engineering information and experience.

8. A practitioner shall maintain the honor and integrity of his profession and without fear or favor expose before the proper tribunals unprofessional, dishonest or unethical conduct by any other practitioner.

NOTES

These two sections 86 and 91 are from Ontario Regulation 538/84 made under the Professional Engineers Act, 1984.

CANADIAN INFORMATION PROCESSING SOCIETY (CIPS) CODE OF ETHICS

CODE OF ETHICS AND STANDARDS OF CONDUCT

• • •

Foreword

The field of information processing has a large impact on society. In turn society has the right to demand that practitioners in this field act in a manner which recognizes their responsibilities toward society, to demand that the practitioners are of the highest caliber, and to demand that a mechanism exist to protect society from those practitioners who do not, or can not, live up to these responsibilities. The standards contained in this document, and our agreement to adhere to these standards, is the response of the Canadian Information Processing Society to these rightful demands.

Introduction

This document describes the code of Ethics and Standards of Conduct of the members of the Canadian Information Processing Society, with respect to their professional activities. It should not be construed to deny the existence of other ethical or legal obligations equally imperative, although not specifically mentioned.

First, the general standards and high ideals of the members of CIPS are described in the form of a Code of Ethics. Second, specific rules, the Standards of Conduct, elaborate each element of the Code in a manner which assists determination of whether or not specific activities of an individual violate the Code. They are intended to establish a minimum acceptable level of conduct, below which an individual may be said to be unethical. Third, there is a procedure which details the steps the society will follow in determining whether or not a violation of the rules has occurred, what disciplinary action is possible, and under what circumstances information will be released.

In total, this document describes the professional behavior that members of CIPS demand of themselves and their peers. All members agree to live up to these standards when the join the Society, and reaffirm this commitment each time they renew their membership.

The Code of Ethics and Standards of Conduct deal with matters that are subject to judgment and are difficult to state absolutely. They contain words such as "authority," "competence," and "faithful" which must be judged in light of the professional and moral standards in effect at a given time and place. The enforcement procedures require peers to interpret the areas requiring judgment at the specific time of the complaint using the guidelines contained in this document.

Code of Ethics

The following statements are agreed to by all members of CIPS as a condition of membership.

I acknowledge that my position as an information processing professional carries with it certain important obligations, and I will take diligent personal responsibility for their discharge.

P) To the public: I will endeavor to protect the public interest and strive to promote understanding of information processing and its application, but will not represent myself as an authority on topics in which I lack competence.

M) To myself and my profession: I will guard my competence and effectiveness as a valuable possession, and work at maintaining them despite changing circumstances and requirements. Furthermore, I will maintain high personal standards of moral responsibility, character, and integrity when acting in my professional capacity.

F) To my colleagues: I will treat my colleagues with integrity and respect, and hold their right to success to be as important as my own. I will contribute to the professional knowledge of information processing to the best of my ability.

E) To my employer and management: I will give faithful service to further my employer's legitimate best interests through management's direction.

C) To my clients: I will give frank and careful counsel on matters within my competence, and guard my client's confidential information and private matters absolutely. In my capacity of provider of product or serve, I will provide good value for my compensation, and will endeavor to protect the user of my product or service against consequential loss or harm.

S) To my students: I will provide scholarly education to my students in a sympathetic and helpful manner.

STANDARDS OF CONDUCT

• • •

The Code of Ethics is a set of ideals to which CIPS members aspire. The Standards of Conduct is intended to be more practicably enforceable.

The following statements are agreed to by all members of CIPS as a condition of membership.

Due to my obligation to the public:

P1) I will not unreasonably withhold information pertinent to a public issue relating to computing.

P2) I will not disseminate, nor allow to go unchallenged, false or misleading information that I believe may have significant consequence.

P3) I will not offer information or advice that I know to be false or misleading, of whose accuracy is beyond my competence to judge.

P4) I will not seek to acquire, through my position or special knowledge, for my own or other's use, information that is not rightly mine to possess.

P5) I will obey the laws of the country, and will not counsel, aid, or assist any person to act in any way contrary to these laws.

P6) I will endeavor to enhance public understanding of information processing, particularly its current capabilities and limitations, and the role of the computer as tool, not an authority.

Due to my obligation to myself and my profession:

M1) I will not knowingly allow my competence to fall short of that necessary for reasonable execution of my duties.

M2) I will conduct my professional affairs in such a manner as to cause no harm to the stature of the profession.

M3) I will take appropriate action on reasonably certain knowledge of unethical conduct on the part of a colleague.

Due to my obligation to my colleagues:

F1) I will not unreasonably withhold information pertinent to my work or profession.

F2) I will give full acknowledgement to the work of others.

Due to my obligation to my employer and to my management:

E1) I will accept responsibility for my work, and for informing others with a right and need to know of pertinent parts of my work.

E2) I will not accept work that I do not feel competent to perform to a reasonable level of management satisfaction.

E3) I will guard the legitimate confidentiality of my employer's private information.

E4) I will respect and guard my employer's (and his supplier's) proprietary interest, particularly with regards to data and software.

E5) I will respect the commercial aspect of my obligation to my employer.

Due to my obligation to my clients:

C1) I will be careful to ensure that proper expertise and current professional knowledge is made available.

C2) I will avoid conflicts of interest and give notice of potential conflicts of interest.

C3) I acknowledge that statements E1 to E5, cast in the employee/employer context, are also applicable in the consultant/client context.

Due to my obligation to my students:

S1) I will maintain my knowledge of information processing in those areas that I teach to a level exceeding curriculum requirements.

S2) I will treat my students respectfully as junior scholars, worthy of significant effort on my part.

Enforcement Procedures

It is essential that the Code of Ethics and Standards of Conduct be supported with clear, orderly, and reasonable enforcement procedures if the Society is to be able to discipline members who violate the Standards of Conduct. The enforcement procedures must be equitable to all parties, and must ensure that no actions are taken in an arbitrary or malicious manner. The following Enforcement Procedures have been designed with these points in mind.

The Complaint

The complaint must:

— be against a single individual, and

— be in writing, and

— cite the specific clause of the Standards of Conduct that is alleged to have been violated, and

— describe the specific action in question, and

— describe, in general terms, the substantial negative effect of that action upon the profession, the Society, a business, or an individual, and

— contain a statement that the specific action of the accused in question is or is not already or imminently [to the best knowledge of the complainant(s)] the subject of legal proceedings, and

— contain a signed statement that the facts are true to the best knowledge of the complainant(s).

This complaint must be sent to the National President of CIPS. The National President, or his delegate, will review the complaint to determine if it meets the above criteria. If it doesn't, it will be returned to the complainant(s) for possible change and re-submission. If the specific action of the accused is (imminently) the subject of legal proceedings, no further action will be taken unto those proceedings are concluded. If the complaint is not rejected then, subject to legal advice, the accused member will be notified (by Registered Mail to last known address), provided with a copy of the complaint, and allowed 30 days to prepare a written rebuttal of the complaint if so desired. The President of the Section the accused belongs to will be notified. The rebuttal should address the same points as the complaint, and must also include a statement that the facts contained in the rebuttal are true to the best knowledge of the accused.

The National President of CIPS or his delegate shall review the complaint and, if available, the rebuttal, to determine if there is sufficient evidence to hold a full hearing. If it is determined that a full hearing is warranted, the full information will be forwarded to a three member Hearing Committee appointed within 30 days of the receipt of the rebuttal or of the last date allowed for receipt of the rebuttal.

The Hearing Process

The Hearing Committee shall adhere to the following procedure:

— The Hearing Committee will attempt to interview, at the expense of CIPS, the complainant(s), and the accused, plus any other parties with relevant information. The number of people interviewed, and the extent of the effort to secure interviews, is a matter of judgment by the Hearing Committee. The Hearing Committee will decide if the accused may be present during the interviews. If the accused is not allowed to be present during the interviews, the accused shall be provided with notes documenting the substance of the interviews.

— The accused will be afforded the opportunity for a full hearing, with the complainant present if desired by the accused.

— The Hearing Committee shall have the services of legal counsel available as required. The accused, and the complainant, may obtain counsel, at their own expense, if either or both so desire.

— The Hearing Committee, after full and complete deliberation, will rule in writing as to the individual case.

Additional rules and procedures shall be established by the Hearing Committee as required in their judgment.

The Hearing Committee ruling may be:

1) a clearing of charges, or
2) a warning statement to the accused, or
3) suspension of national and local membership for a specified period of time, or
4) revocation of the current membership of the accused in the Society, and a statement of the accused's eligibility for other grades of membership.
5) Such other ruling as the Hearing Committee in its discretion sees fit (e.g.: change letterhead, business cards to delete reference to being a member of CIPS).

The Hearing Committee will prepare an opinion on the particular case that will cover the facts of the case, the action taken, and the reason for that action. This will be reviewed by the Executive Committee of the National Board of CIPS and by legal counsel at the discretion of the Executive Committee. When approved, this opinion will be sent to the accused, who may consider exercising the Appeal Process.

Due diligence should be used to provide this opinion to the accused within 120 days of the receipt of the complaint by the Hearing Committee. If this is not possible, a letter should be sent to the National President of CIPS, with copies to the accused and complainant(s), requesting an extension of this limit, and stating the reason for this request.

The Appeal Process

If not satisfied with the ruling of the Hearing Committee, the accused may appeal to the Executive Committee of the National Board of CIPS within 30 days of issuance of the Hearing Committee opinion. If appealed, the following procedure will be used.

— The Executive Committee, at its next scheduled meeting, or at a special session, shall review the opinion, and any other information available, and shall determine if:

1) a substantive procedural error has been committed by the Hearing Committee, or
2) substantial new evidence has been produced.

— The accused and the complainant are permitted legal counsel at the Executive Committee appeal session.

— The Executive Committee shall determine if, in its sole judgment, one of the two above noted criteria have been established, in which case the council shall refer the matter back to the previous or a new Hearing Committee for further proceedings.

— The decision of the Executive Committee shall be final: there shall be no further appeal.

Publication and Record Retention

After the Appeal Process and any further proceedings have been exhausted, or after completion of the time allowed to initiate an Appeal Process, the Opinion will be published in the appropriate CIPS publication if the ruling was a suspension or revocation of membership, and will be published at the request of the accused, if the ruling was a clearing of charges or issuing of warning statement.

The record of the Hearing Committee and all appropriate supporting documentation will be retained by National for five years. Response to queries may include statistical information that does not reveal detail about a specific complaint, such as the number of complaints processed, provided the approval of the Executive Committee is obtained, or responses may include copies of information previously published.

Any other information may be released only with the written permission of the Executive Committee, the accused, and the accuser(s).

NOTES

Dated January 1985.Published and promulgated on a two-sided letter-sized sheet.

Code of Professional Ethics of the Engineers of the Association of Engineers of Chile

Title I. On General Norms

1ST ARTICLE. The Code of Professional Ethics establishes the responsibilities and regulates the rights and obligations as well as the conduct of engineers.

2ND ARTICLE. It is the imperative obligation of the engineer to maintain a level of professional conduct raised to the highest moral level in defense of the prestige and prerogatives of his profession.

The norms of this Code apply to all engineering activities and professional specialization does not liberate from them.

The engineer enrolled in the Association of Engineers ought to accept, to know, and faithfully to fulfill this Code of Ethics.

Title II. On the Exercise of the Profession

3RD ARTICLE. Engineers are obligated to respect in their professional action, the dispositions of Law 12.851, the Professional Fee Schedule, and the dispositions of the present Code, and also, the agreements of the General Counsel and the appropriate Provincial Counsel.

4TH ARTICLE. Acts contrary to Professional Ethics are the following:

a) To act contrary to the decorum and prestige of the profession, contrary to the discipline of the Institution or contrary to the respect and solidarity that ought to be preserved among the members themselves.

b) To promote or to collaborate in the promulgation of laws or other norms of a legal character, resolutions, judgments or measures that infringe the rights of the engineering profession, of the Association of Engineers, or of one or more colleagues.

c) To concur with deliberate omissions that produce some of the effects indicated in the preceding letter.

d) To permit actions or omissions that favor or permit the unnecessary use of foreign engineering for objectives and work for which Chilean engineering is sufficient and adequate.

e) Engineers are obligated to denounce to the Association all persons who exercise engineering functions without the legal capacity for it, as well as to denounce all acts that indicate transgression of the norms of the Code.

f) To sign off on studies, projects, plans, specifications, reports, judgments or authorizations that have not been personally executed, studied or reviewed and to falsify consultations, the performance of jobs or the work of an organization, society or institution of any nature, in that which by law requires engagement of an association engineer.

g) To give or to receive commissions or other noncontractual benefits through managing, keeping, or granting appointments of any kind.

h) To participate directly or indirectly in the granting of professional titles that infringe or harm the prestige and professional quality of the engineer, of conformity with the principles of technology, of Engineering, laws or regulations in force.

i) To undertake some professional work, be it individually, associated with other colleagues or third parties, or as a member of a legal or def facto association, in return for the payment of a fee less than the minimum established by the Professional Fee Schedule, and to agree or to pay other colleagues, fees less than the minimum established in the Schedule of the Association.

j) To make use of or to utilize studies, projects, plans, reports or other documents related to engineering without the authorization of their authors or owners.

Title III. Relations with Colleagues and Other Professionals

5TH ARTICLE. Acts between engineers and other professionals considered contrary to professional ethics:

a) To publicize opinions that harm the prestige of a colleague.

b) To replace or try to replace a colleague, without his prior consent, in the rendering of previously engaged professional services.

c) To take undue advantage of performing a job to obtain particular clients.

d) To promote one's own appointment to a public or particular job that a colleague exercises, when this person has not manifested an intention to give it up.

e) In the formulation of proposals, public as well as private, the engineer is prohibited: to give or to solicit any information prior to the request for proposal, which would seem to leave the proposer in a favored situation with respect to others; to try to obtain a favorable decision for oneself, or for a third party, by discrediting other bidders on the proposal; or to find out about or to decide a proposal, outside established procedures on the principles or regulations that regulate such decision making.

Title IV. Relations with Directors and Clients

6TH ARTICLE. Acts considered contrary to professional ethics between engineers, directors or employers, are the following:

a) As an employee, functionary or executive of a business or organization, to accept for personal gain commissions, rebates, discounts or other benefits provided, from contractors or from persons interested in the sale of materials, equipment or services, or in the performance of work that has been entrusted to you.

b) To reveal proprietary data of a technical, financial, or personal character concerning interests confidential to your study or case.

c) To act with partiality in discharging the function of specialist, or arbiter, or to one who interpreters or awards contracts, grants, or jobs.

d) To divulge without proper authorization procedures, processes, or characteristics of equipment, that are protected by patents or contracts that establish the obligation to protect professional secrets.

TRANSLATED BY CARL MITCHAM

NOTES

This code is published and promulgated in a small pamphlet entitled *Estatutos y Códigos de Etica Profesional del Colegio de Ingenieros de Chile* A.G. [Statutes and codes of professional ethics of the Association of Engineers of Chile, Inc.] (Santiago, Chile: Colegio de Ingenieros de Chile A.G., n.d.). The pamphlet contains twenty unnumbered pages.

The first section of the pamphlet contains the statutes or by-laws of the Association (10 pages) followed by an official letter of recognition (dated 16 July 1981) from the Assistant Secretary of Economics, Development, and Reconstruction.

The second section contains the code of professional ethics of the Association of Engineers (Law 12.851—2 pages, translated here) along with a printing of the Code of Professional Ethics of the Pan American Union of Associations of Engineers (2 pages).

CHINA, PEOPLE'S REPUBLIC OF

CHINESE MECHANICAL ENGINEERING SOCIETY CODE OF ETHICS

Chapter 1. General Rules and Information

1. The Chinese Mechanical Engineering Society is a national mechanical scientists and technicians organization. It is part of the Chinese Science and Technology Society.

2. The Society is located in Peiking.
3. Our Society encourages dialectic materialism. Our goal is to unite the majority of mechanical technicians to promote mechanical industry, advance technological service, accelerate new technological research, produce more scientists, and speed up national modernization.
4. The duty of our Society is:

4.1 To open technology exchange, organize research and technical investigations and encourage the exploration and application of mechanical technology.

4.2 To offer scientific research such as proofing (theory, design), criticism and comments on equipment (machine and tools), information, etc., and to accept corporations, companies, and agencies' entrust, and to offer technology information service.

4.3 To expand technical training: offer higher education for professional technicians in order to raise the majority of technicians' knowledge levels and practice abilities.

4.4 To spread science and advance technology and science management.

4.5 To open a worldwide technology exchange and develop a good relationship with foreign technology organizations.

4.6 To control technology information: edit and publish scientific magazines and collect reports and technical documents.

4.7 To honor the scientists and technical reporters who contribute to society.

4.8 To deal with the activities and services for economical construction, and increase the majority of scientists', technical benefits and activities.

4.9 To protect the technician's right to express suggestions, ideas, and criticisms.

Chapter 2. Membership

5. Individual membership: anyone who recognizes our regulations, meets the following standards, and obtains our society's permission will become a member of our society. The individual also must:

5.1 Have been educated at a level equal to or above that of engineer, technician, professor, assistant professor, or other technical position.

5.2 Be a scientist or technician with an education level above a master's degree.

5.3 Be a college graduate with a mechanical major who has worked with related material for at least 3 years, has a certain technical knowledge level, and has the ability to work individually. However, if one does not have a college degree, an exception may be made if the individual has had many years worth of work experience which equals or surpasses our standard knowledge level.

5.4 Be a technician with extraordinary distribution.

5.5 Earnestly support the society, the chairman, the director, the manager who works with the mechanic technical organization, and the management.

6. The process for an individual to join the society is as follows: Send in the application, be introduced by other current members, and have recommendations from the company or from another technical society. After being approved, the individual will transport to our society and become a member. The individual will then be classified into whichever expert organization fits his/her work level.
7. Organizations as members: any organization, corporation or research center which earnestly support our society, and has employees who are experts in our field or related fields, can be accepted as a member.
8. Preparatory members and student members: Preparatory members: any mechanical science, technical, or managerial officers who are under 35 years of age and are college graduates or technology school graduates may commence work for a period. They may send in the application to our society, and after approval will become a member immediately.

   Student members are required to have: had a mechanical major in college, received good grades junior and senior years, graduated from college, the ability to transform from student membership to preparing membership.
9. Foreign membership:

   Any foreign mechanics and science technicians who are friendly to our country and want to communicate, exchange information, and participate, must send in our application, go through two members introductions or have a recommendation letter from a division of our society. The individual may also have membership in his/her own country's Mechanical Engineering Society which has participated with our society. After our approval, the individual may become a member immediately.

10. Our society may accept any well-known and respectable mechanical science technician, specialist, or scientist with great scientific accomplishment into our society.
11. The member must adhere to the rights and duties of the individual in his local technical organization.
    11.1 Members have the right to vote, and to be voted on.
    11.2 Members have the right to criticize and suggest new ideas to our society.
    11.3 Members have the right to join related technical activities.
    11.4 Members have the priority to obtain any related technical information date.
    11.5 Members must obey our society's regulation.
    11.6 Members must perform, follow and support our society's decisions and entrusted work.
    11.7 Members may join the society's different types of activities.
    11.8 Members must pay the membership fee according to regulations.
12. The Foreign Member's right and duty: The foreign member:
    12.1 May be invited to join our society and attend a science technology conference meeting, or other international technical activity, and have the meeting's registration fee reduced.
    12.2 Has the right to obtain our society's related technical information.
    12.3 Has the private right to publish and submit reports/articles in our society's magazine.
    12.4 May obtain the help of the society with the arrangement of technical visits.
    12.5 Must support our society's goals and accept the duties entrusted to him/her by our society.
    12.6 Must pay the membership fee according to the regulation.
13. Membership Card: You must get permission from the state engineering society to have a membership card. From this society, you can get Chinese Technical Engineer Prepared Membership card. The student membership card is issued by an organization member.
14. Individual and organization members have to pay annual membership fees. The payment methods and fee amounts are determined by negotiations between the society and local branches. If a member (including foreign members) does not pay the membership fee in the current year, he will be revoked of his membership rights. After failing to pay for two years the membership is automatically cancelled. Once the fee is paid we will reissue the membership card back to you.
15. Members have the right to withdraw from the society if leaving the university will cancel the student membership.

    Prepared members over the age of 35 years will also have their membership cancelled.
16. Any one who loses his/her political rights will naturally lose membership.
17. If a member's work address changes, s/he should connect with the local branch of the society.

Chapter 3. National Congress

18. The society's highest leading organization is national congress. Its jobs are:
    18.1 Checking and grading national council's work report.
    18.2 Deciding the next goal and plan of the society.
    18.3 Vote and select next direction of the council.
    18.4 Comment, check and discuss the society's regulations honoring the Scientists and societal members who have contributed to technological development.
19. National Congress is called by the national council.
20. National Representation Conference representatives are selected by National Council members and the experts in the society (people who work in the specific field).

Chapter 4. National Council

21. The National council is the leading organization after the National Congress. Its duties are:
    21.1 Execute nation congress's decision.
    21.2 Document a working report and record long term plans and work goals.
    21.3 Correct and review the society's regulations.
    21.4 Arrange the next date for the National Representative Conference.
22. The current national council members have been elected by previous council members and experts democratically; "absorb" new elected "members" and several national (or foreign) famous scientist,

expert. Then, through national representative conference's voting, produce new council members.

The total number of national council is around one hundred. They should have experience with technological research and science management. Have good moral standard, anxiously working, have good health, which can join the society's real practice wok. Any member can not been council member for over two terms.During the term, if council member can work due to accident or any other reason, after the board of national council's credential, the council member can be replaced.

23. Nation council select (vote) a director of the council, vice director, and a secretary. Board of national council. The director of the council can only work one term, then he will be one of the next term's board of national council.

24. The duty of the board of national council:

  24.1 Execute all jobs, work which given by national council.

  24.2 Make working plan and goal.

  24.3 Comment committees' working report.

  24.4 Hire people who are going work for the committee.

  24.5 Agreed, forbidden contract and negation.

  24.6 The board national council have conference every year.

25. According to the request of national council, setting several committee. Committee member works under national council's leading.

26. The national managing directors have the secretary department, the senior secretary will response for all regular works. All these senior secretary are given by the mechanical industry department.

Chapter 6. Society of Special Fields

27. We will set few major departments. These departments are responses in science study activity, engineer study or technical study activity. The national managing directors will decide how to set plan, how to regulate it and how to cancel it if it is needed.

28. The managing directors is a leader department its duty is:

  28.1 Perform the duty which is given by the national managing directors.

  28.2 Set the rule or major study activities and economic budget.

  28.3 Response in organization of different study activities.

  28.4 Give people some career advice thought state study society and city studysociety.

  28.5 Support the worker in this study society.

  28.6 The meeting of the board of directors of major study will has once a year.

29. Members in the board of directors of major study have to have the good health, and the honor technical degree. These members are introduced or elected by local departments. The board of directors should have no more than fifty people, and are elected every 4 years.

30. The board of directors has one president, three vise president, few secretaries and others. They will start their duty after the meeting of the meeting of the board of directors.

The president can not perform over one term.

31. The board of directors has two main parts: regular department (includes the secretary department, the accenting department and others beside research department) and the research department.

32. If it is necessary, the board of directors could be changed to few small boards. The small board of directors will be easy to manage and regulate.

33. The representative conference is the highest organization in state, city and local area. Any meeting, production and activity must follow the local rule.

34. According to research activity, we can set some direct and indirect relate departments to help our major study activity.

35. The duty of technical engineer study society is given by state, city or local department.

36. State, city or local department also advice the technical engineer study society to perform the job well.

Chapter 8. Relationship with Leader

37. This study society is lead by Chinese national science and mechanical systems.

Chapter 9. Fee

38. Our income comes from:

  38.1 The contribution of other co-level science research department (or companies).

  38.2 The mechanical industrial system and relate or dependent department.

  38.3 The income comes from the case research and activities.

38.4 The membership fee.

38.5 The national system, foreign system or personal contribution.

RETIRED ENGINEERS ASSOCIATION OF THE NANKING CHEMICAL-INDUSTRIAL CORPORATION CODE OF ETHICS

• • •

First Chapter: General Whole Principle

1. This Association is named "The Retired Engineers Association of The Nanking Chemical-Industrial Corporation." We simple call it "The Retired Association of Nanking Chemical."
2. "The Retired Association of Nanking Chemical" is a system which is consisted by retired engineers (include high technical workers) and under the leading of the communism party. This system will help the Corporation's development. It is a part of The Engineers Association of The Nanking Chemical-Industrial Corporation. Their action will open and develop the technology the technology. Making greater progress; take one more step forward.
3. The principle of this association is to combine and organize all retired engineers. Just as "The Older have some thing to feet; to learn and to practice". According to company's need, to do some Technical help and service.

Chapter 2: Duty

4. Must follow the policy that "Economic growth will dependent on the develop of technology. Technical work must face to economic growth." Manifest the point of "blooming in profusion; using all resources;" execute the democratize in this association. To have a good quality service.

5.1 Face to economical construction, explicate these retired engineers technical knowledge. Supply some suggestions to decisions of different departments improvement. To become a good helper.

5.2 For the company's business, They need to help this company to develop their own technology and learn some new knowledge from the advance countries.

5.3 For science developing, and helping those young engineers, We should offer some classes which can help younger to learn more experience.

5.5 Combine all strains; collect and exchange the sciences information; At some time, should learn English and translate them to Chinese (for us to learn to use).

5.6 Friendly to neighbor companies and related companies. This can help us to learn technology or exchange technology with them.

5.7 Tells the company what ideas do they suggest and what do they want. Study policy, technology, visit and help new members are very necessary.

5.8 Respect the older engineers emotion; respect their life, their health. Set up friendship.

CHAPTER 3: MEMBERSHIP

• • •

6. If you are a junior engineer or above, with a good health and must under 70 year old. And if you agree our associate principle you can fill a application form. Then we will give you a membership card after we discuss your case. For reach a good quality service, we will invite some special technical retired engineers to join with us.
7. The power of member:

7.1 Right for election; Right to be elected; Right to be cancelled.

7.2 Have the right to hear or get the new information and resources.

7.3 Have right to give the suggestion, to criticize the incorrect decision which made by association.

7.4 Have right to join the science, technical research; right to get pay.

7.5 Have right to though this association to tell self-request or other members request.

8. Responsibility of members.

8.1 Respect the principle of association, and execute the decision of association.

8.2 Join the active of association; hand the job that other associative ask for.

8.3 Keep professional morality. Maintain and protect the prefect and reputation. Never be allowed to damage the reputation of our association.

8.4 For some secret science information with a mark "Secret", no one be allowed to divulge a secret.

8.5 Must pay the membership fee on time.

9. Member has right to drop-out the membership. Member can fill out a application for drop-out. He (she) should return his (her) membership card after the association's agreement.
10. If member with no reason, and never perform any member's obligation in one year. He (she) will be cancelled from the membership and be requested to return membership card.
11. Any member who damage the principle of association, violate the benefit and reputation of our association, and also doesn't listen to advise, membership will be cancelled, or be punished.
12. Any member who performed illegal activity and be punished or get in jail, will be cancelled from membership.
13. Any decision of cancelling membership will notice to all members. This is the reference for some department in the future.

CHAPTER 4

• • •

14. Membership meeting is the most powerful in the association. This meeting has one in two years. Date of meeting can be changed if it is necessary.
15. Duty and responsibility of membership meeting:
    - 15.1 Decide the main working principle and duty.
    - 15.2 Listen and exam the working report and economic report of a aboard directors.
    - 15.3 Fix and declare the principle of association.
    - 15.4 Select the new director of board.
16. The board of directors will selected by members. The chairman of the board of directors will selected by the boards of director. The board of directors includes one chairman, one secretary and few wise-chairmen.
17. The chairman of board of directors has right to control the board and has right to use one wise-chairman work with him.
18. We will invest some consul for performing advises.
19. Set two people work in secretary apartment everyday. We will add more departments if we need.

CHAPTER 5

• • •

20. Our active fee from:
    - 20.1 National or some related departments' help
    - 20.2 Income of science resources and technology services
    - 20.3 Membership fee
    - 20.4 Receive subscribe money from corporation or personal.
    - 20.5 Other current income.
21. Active fee will use for:
    - 21.1 Perform the duty and develop activity
    - 21.2 For engineers' additional perform payment.
    - 21.3 Some request office supply expense.
    - 21.4 Expense of some professional (senior) engineers training younger and performing technical service.
    - 21.5 Other expenses.
22. Must set up a strong business rule and oversee the rule. The money will be controlled by the board of directors. Any one who want to use money should go to the board. Though wise-chairman, filled out a application. He (she) can use the money only if the application be agreed.

Code of Professional Ethics

The honor and dignity of the profession ought to be for the Engineer his or her major pride; as a result, in order to extol the profession, he should conform his conduct to the following norms that constitute his Code of Professional Ethics:

1. To exercise the profession as well as the activities derived from it with decorum, dignity, and integrity.
2. To always work under the assumption that the exercise of the profession constitutes not only a technical activity but also a social function.
3. To always act honorably and loyally with persons or entities to which services are offered.

4. To abstain from receiving gratuities and rewards other than the agreed upon salary or honorarium.
5. To not use with colleagues unfair methods of competition such as under bidding or offering professional services at a lower than standard price.
6. To try neither to supplant another engineer when a contract has already been awarded or a position determined nor to replace an honorable and competent employee.
7. To abstain from an intervention that would unfairly affect the professional reputation of a colleague.
8. To limit advertised services exclusively to those for which one is qualified by academic education or professional experience.
9. To not propose competitive bidding in which the value of the professional honorarium will be one of the factors that determines the selection of engineering consulting services, nor to participate in such competitive bidding.
10. Finally, to have due respect and consideration for all colleagues.

Code of Professional Ethics

The following acts are unethical:

A. In relation to the Profession:

a) To perform in bad faith acts that have been established as contrary to good techniques or to incur voluntary omissions even if it be in compliance with the orders of authorities or mandates.

b) To accept a job knowing that it may lend itself to malice or fraud or may be against the general interest;

c) To sign plans, specifications, recommendations, records or reports which have not been executed, studied, or seen personally, except those documents which, in themselves are objects of public faith and must be exercised personally. (As reformed in session 3-82 A.E.R.)

d) To associate one's name with propaganda or activities with persons who appear unqualified as professionals, to honor disproportionately persons or things to commercial or political ends.

e) To receive or give commissions or other benefits for promoting, obtaining or determining plans of any class or in the assignment of professional jobs.

f) To violate or comply with others in violating the laws of the Federated Association or the Codes, Norms, and Rules which are indicated here, in relation to the exercise of the profession.

B. In relation to Colleagues:

a) To utilize ideas, plans or technical documents without consent of the authors.

b) To participate in competitions of price or with a price that is less than that which is established as the minimum by the Federated Association to contract a professional job.

c) To attempt to injure, falsely or maliciously, directly or indirectly the professional reputation, situation or business of another member of the Federated Association.

d) To attempt to supplant fraudulently another engineer or architect after he has made definitive steps in his occupation.

e) To use favors or offer commissions in order to obtain professional work, directly or indirectly.

f) To nominate or intervene so that another should be nominated to be in charge of technical jobs that must be undertaken by a professional, when nominee does not have needed qualifications.

g) To compete unloyally with one's colleagues who work on contract by using the advantages of a position in a company.

h) To promote propaganda in language that is boastful or in any way that affects the dignity of the profession.

i) To establish or influence the establishment of honorariums or remunerations for engineering or architecture, when such honorariums or remunerations obviously present a compensation that is inadequate for the importance and responsibility of the services to be rendered.

j) To act in any manner or compromise oneself in any manner or practice which serves to discredit the honor and dignity of the profession of engineering and architecture.

C. In Relation to the Constituents or Employers:

a) To accept for one's own benefit commissions, discounts, or bonuses from materials providers, contractors or persons concerned in the execution of a job.

b) To reveal reserved technical, financial or personal data about the confidential interests in his study or his contract which is under his care for constituents or employers.

c) To act on behalf of his constituents or employers in a professional capacity or other manner which is not the manner of a loyal and non-prejudiced agent, as trustee, expert or arbiter in any contract or engineering or architectural job.

Code of Professional Ethics

It is considered contrary to ethics and incompatible with the dignified exercise of the profession for a member of the Dominican Association of Engineers, Architects, and Surveyors:

1st To act in any way that tends to diminish the honor, dignity, respect, honesty, ability and other attributes that support the full exercise of the profession.

2nd To violate, to permit the violation of, or to influence the violation of the laws and regulations related to the exercise of the profession.

3rd To utilize positions in official, semi-official, autonomous or private organizations or institutions to act with disloyalty contrary to the genuine national interests or that would have consequences contrary to the good involvement of professionals.

4th To receive, offer, or confer improper commissions, or to utilize influences in conflict with legitimate competence in order to secure the conference of contracts, works, or the execution of projects as a special favor, or as a favor to ones associates or partners.

5th To offer oneself for the performance of functions or specialties for which one does not have reasonable capacity and experience.

6th To present or talk about oneself in laudatory terms or in any form that acts against the dignity and seriousness of the profession.

7th To exempt oneself by convenience, collusion, or ties of friendship or family from fulfilling the duties that his position or job requires him to do or to respect.

8th To offer, solicit, or render professional services for remunerations below those established as a minimum in Professional Fee Schedule of the Dominican Association of Engineers, Architects, and Surveyors.

9th To sign without permission surveys, calculations, designs or any other intellectual work that is the fruit of the labor of other professionals.

10th To make oneself responsible for works or projects which are not under one's immediate direction, revision, or supervision.

11th To take charge of a work without having completed all technical studies necessary for its correct execution, or when for the realization of such a work there have been appointed terms, prices, or any other conditions in conflict with the good practice of the profession.

12th To use the inherent advantages of a remunerated position in order to compete with the practicing professional independently of other professionals.

13th To act against the reputation and/or legitimate rights and interests of other professionals.

14th To acquire interests that directly or indirectly collide with those of the interests of the company or clients that employ one's services, or to take charge without the knowledge of interested parties of works in which there exist antagonistic interests.

15th To contravene deliberately the principles of justice and loyalty in one's relations with clients, personnel subordinates, and workers; in relation to the last, in a special manner in that relevant to maintaining equitable work conditions and to their just participation in profits.

16th To supplant or intend to supplant a colleague in a particular contract after a definitive decision has been made to employ him for this contract, and to substitute through political or ideological arrangements of a discriminatory or arbitrary character a professional colleague who has been terminated or suspended from his functions.

17th To propitiate, serve as instrument for, or support with one's name the unjust replacement of Dominican professionals by foreign companies or persons settled in the country, or to do the same if living abroad.

18th To intend by any means to undermine and/or slight the prestige of the Dominican Association of Engineers, Architects, and Surveyors, and in any form to contribute, support, or encourage that there be abolished or eliminated the laws, rules, principles, ends, and purposes of the Association without the consent of its competent organs, or to provoke in any way the disintegration or weakening of the instituted organs of the Association.

19th To intend to pervert the principles, ends, and purposes of the Dominican Association of Engineers, Architects, and Surveyors, and in any form to contribute, support, or encourage the abolition of the laws and rules of the Association without the consent of its competent organs or in any way to support the disintegration or weakening of the instituted organs of the Association.

Code of Honor

In full knowledge of my rights and duties as a graduate engineer or architect, I will, in all my acts and deeds, obey the rules of life contained in this code of honor.

In my profession, I will not accept bribes. I will be tolerant. I know my duty to be the service of both my country and mankind as a whole.

In the recognition that my own knowledge and skills are inherited from the efforts of individuals over millennia, it is my desire to develop technology and engineering further, and especially to strive to teach the younger generation of engineers and architects the skills and traditions of my profession.

In addition to the development of technology, I will also be responsible for its right application and use, so that its consequences cause damage neither to society nor the individual.

I will participate only in honorable enterprises and deeds and will not take part in activities detrimental to the reputation or honor of engineers and architects.

I will respect the right of another to his ideas, publications and other results of his creativity.

I will strive to protect the interests and good name of every honorable engineer and architect, but if duty demands, I will not shrink from declaring the truth about anyone who has forfeited his right to this profession.

In my activities and strivings for position, I will use only loyal measures and will not attempt to damage my colleagues by unjustified criticism, and if I observe such an attempt, I will do my best to defeat it.

The employer or client for whom I am working can be assured that I will faithfully serve his best interests.

I will do my work well in order to justify honorable payment and will promote the development of my subordinates, as well as the quality of their working conditions and their remuneration.

I regard the participation of engineers and architects in public life, at local and national levels, to be an important factor in the development of our society.

I will continually cultivate my professional knowledge and competence and develop my personality by all means available; and I will remember that in my life and work I also represent the whole professional body of architects and graduate engineers.

NOTES

This code is promulgated in English as a one-page document with decorative border suitable for framing.

At the bottom it states that the code was "adopted in the meeting of the Council of The Engineering Society of Finland—STS, 16th December, 1966."

Charter of Ethics of the Engineer

Preamble

As they become more and more powerful, technologies promote major changes in everyday life, in the transformation of our society and its environment, while they also bring with them risks of serious harms. Additionally, while their complexity makes them difficult to comprehend, and the force of information increases, misinformation can introduce in public opinion exaggerated worries about security, with baseless psychoses and irrational fears.

Consequently engineers must assume an essential double role in society, first as those who control these technologies in service of the human community, and second as those who diffuse information about the real possibilities and limitations and assessments of the benefits and the risks they generate.

Because of the special characteristics of the exercise of their profession, engineers must conduct themselves with a certain rigor; it becomes more and more imperative that they explicitly clarify the reference points used and reasons for their conduct. This is why the National Council of the Engineers and the Scientists of France has produced a Charter of Ethics. This Charter must be considered as the profession of faith of all those who are listed in the Registry of French Engineers created by the CNISF.

As a reference for engineers, the Charter will help engineering students prepare for the exercise of their profession. It will enable the values that guide engineers to be better comprehended by everyone.

The Charter annuls and replaces the old CNISF "code of ethics."

The term "code of ethics" will henceforth be reserved for documents that define the correct professional conduct in each of the fields of engineering and whose non-observance could entail the application of sanctions.

The CNISF thanks in advance all those who, through their contributions, help the Charter become known, appreciated, enduring, and improved.

Engineers in Society

- Engineers are responsible citizens establish the link between science, technology, and the human community; they are involved in civic action for the common good.
- Engineers spread their knowledge and pass on their experience to serve society.
- Engineers are conscious and make society aware of the impact of technological achievements on the environment.
- Engineers act to ensure the "sustainable development" of resources.

Engineers and Their Abilities

- Engineers are a source of innovation and the engine of progress.
- Engineers are objective and methodical in their procedures and judgments. They attempt to explain the foundations of their decisions.
- Engineers regularly update their knowledge and their abilities according to the evolution of science and technology.
- Engineers listen to their peers; they are open to all other disciplines.
- Engineers know how to admit their mistakes, take them into account, and learn lessons for the future.

Engineers and Their Profession

- Engineers fully use their abilities, while being conscious of their limitations.
- Engineers loyally respect the culture and values of their companies and those of their peers and clients. They would not act contrary to their professional conscience. If need be, they accept the consequences of any contradictions that may arise.
- Engineers respect the opinions of their professional peers. They listen and are open in discussions.
- Engineers behave toward their collaborators with loyalty and equality without any discrimination. They encourage them to develop their abilities and help them to fully realize the potential in their professions.

Engineers and Their Assignments

- Engineers try to attain the best result in utilizing the best means available and in the integration of human, economic, financial, social, and environmental dimensions.
- Engineers take into account all the constraints that their assignments impose, especially with respect to health, safety, and the environment.
- Engineers integrate in their analyses and decisions the ensemble of legitimate interests of their assignments, as well as consequences of any kind on other persons and their welfare. They anticipate risks and the probabilities; they work hard to take advantage of them and to eliminate negative effects.
- Engineers are rigorous in analysis, methods, and in making decision and solution choices.
- Faced with unexpected situations, engineers immediately take permitted initiatives to create better conditions, and directly inform the appropriate persons.

ENGINEER'S CONFESSIONS

• • •

The *ENGINEER* should pursue his profession with respect for values beyond science and knowledge and with humbleness toward the Almighty who governs his earthly existence.

The *ENGINEER* should place professional work at the service of humanity and maintain the profession in those same principles of honesty, justice, and impartiality that are the law for all people.

The *ENGINEER* should work with respect for the dignity of human life and so as to fulfill his service to his fellowmen without regard for distinctions of origin, social rank, and worldview.

The *ENGINEER* should not bow down to those who disregard human rights and misuse the essence of technology; he should be a loyal co-worker for human morality and culture.

The *ENGINEER* should always work together with his professional colleagues for a sensible development of technology; he should respect their activity just as he expects them to rightly value his own creativity.

The *ENGINEER* should place the honor of his whole profession above economic advantage; he should behave so that his profession is accorded in all public arenas with as much respect and recognition as it deserves.

Düsseldorf, May 12th 1950

TRANSLATED BY CARL MITCHAM

FUNDAMENTALS OF ENGINEERING ETHICS

• • •

Preface

Natural sciences and engineering are important forces shaping our future. They exert both positive and negative influences upon our world. We all contribute to these changes. The engineering professions, however, have a particular responsibility in structuring these processes. Hence in 1950, the Association of Engineers VDI in Germany presented a document on the specific professional responsibilities of engineers.

Recently the VDI Executive Board passed the new document "Fundamentals of Engineering Ethics." They are intended to offer to all engineers, as creators of technology, orientation and support as they face conflicting professional responsibilities.

These fundamentals have been proposed by the "VDI philosophers" together with representatives of other disciplines within the VDI Committee on People and Technology.

I hope that this document may strengthen awareness and commitment in dealing with ethical issues of the engineering professions.

Dusseldorf, March 2002

Prof. Dr.-Ing. Hubertus Christ, President of the VDI

0. PREAMBLE

• • •

Engineers recognize natural sciences and engineering as important powers shaping society and human life today and tomorrow. Therefore engineers are aware of their specific responsibility. They orient their professional actions towards fundamentals and criteria of ethics and implement them into practice. The fundamentals suggested here offer such orientation and support for engineers as they are confronted with conflicting professional responsibilities.

The Association of Engineers in Germany (VDI)

- contributes to raising awareness about engineering ethics,
- offers consultancy and conflict resolution, and
- assists in all controversies related to issues of responsibility in engineering.

1. *Responsibilities*

1.1 Engineers are responsible for their professional actions and the resulting outcomes. According to professional standards, they fulfill their tasks as they correspond to their competencies and qualifications. Engineers perform these tasks and actions carrying both individual and shared responsibilities.

1.2 Engineers are responsible for their actions to the engineering community, to political and societal institutions as well as to their employers, customers, and technology users.

1.3 Engineers know the relevant laws and regulations of their countries. They honor them insofar as they do not contradict universal ethical principles. They are committed to applying them in their professional environment. Beyond such application they invest their professional and critical competencies into improving and developing further these laws and regulations.

1.4 Engineers are committed to developing sensible technology and technical solutions. They accept responsibility for quality, reliability, and safety of new technical products and processes. Their responsibilities include technical documentation as well as informing customers about both appropriate use and possible dangers of misuse of new technical solutions.

They furthermore include:

- defining the technical characteristics of such products and processes,
- suggesting alternative technical solutions and approaches, and

- taking into consideration the possibilities of unwanted technological developments and deliberate misuse of products and processes.

2. Orientation

2.1 Engineers are aware of the embeddedness of technical systems into their societal, economic and ecological context. Therefore they design technology corresponding to the criteria and values implied: the societal, economic and ecological feasibility of technical systems; their usability and safety; their contribution to health, personal development and welfare of the citizens; their impact on the lives of future generations (as previously outlined in the VDI Document 3780).

2.2 The fundamental orientation in designing new technological solutions is to maintain today and for future generations, the options of acting in freedom and responsibility.

Engineers thus avoid actions which may compel them to accept given constraints (e.g. the arbitrary pressures of crises or the forces of short-term profitability). On the contrary, engineers consider the values of individual freedom and their corresponding societal, economic, and ecological conditions the main prerequisites to the welfare of all citizens within modern society—excluding extrinsic or dogmatic control.

2.3 Engineers orient their professional responsibility on the same fundamentals of ethics as everybody else within society. Therefore engineers should not create products which are obviously to be used in unethical ways (e.g., products banned by international agreement). Furthermore they may not accept far-reaching dangers or uncontrollable risks caused by their technical solutions.

2.4 In cases of conflicting values, engineers give priority:

- to the values of humanity over the dynamics of nature,
- to issues of human rights over technology implementation and exploitation,
- to public welfare over private interests, and
- to safety and security over functionality and profitability of their technical solutions.

Engineers, however, are careful not to adopt such criteria or indicators in any dogmatic manner. They seek public dialogue in order to find acceptable balance and consensus concerning these conflicting values.

3. Implementation

3.1 Engineers are committed to keeping up and continually developing further their professional skills and competencies.

3.2 In cases of conflicting values, they are expected to analyze and weigh controversial views through discussions that cross borders of disciplines and cultures. In this way they acquire and strengthen their ability to play an active part in such technology assessment.

3.3 In all countries, national laws and regulations exist which concern technology use, working conditions, and the natural environment. Engineers are aware of the relevance of engineering ethics for these laws and regulations.

Many of these laws today take up controversial issues related to open questions in engineering sciences and ethics. Engineers are challenged to invest their professional judgment into substantiating such questions.

Concerning national laws, the sequence of priorities is as follows: national laws have priority over professional regulations, such professional regulations have priority over individual contracts.

3.4 There may be cases when engineers are involved into professional conflicts which they cannot resolve co-operatively with their employers or customers. These engineers may apply to the appropriate professional institutions which are prepared to follow up such ethical conflicts. As a last resort, engineers may consider to directly inform the public about such conflicts or to refuse co-operation altogether. To prevent such escalating developments from taking place, engineers support the founding of these supporting professional institutions, in particular within the VDI.

3.5 Engineers are committed to educational activities in schools, universities, enterprises and professional institutions with the aims of promoting and structuring technology education, and enhancing ethical reflection on technology.

3.6 Engineers contribute to developing further and continually adapting these fundamentals of engineering ethics, and they participate in the discussions corresponding.

Fundamentals of Engineering Ethics Summary

- Engineers are responsible for their professional actions and tasks corresponding to their competencies and qualifications while carrying both individual and shared responsibilities.
- Engineers are committed to developing sensible and sustainable technological systems.
- Engineers are aware of the embeddedness of technical systems into their societal, economic and ecological context, and their impact on the lives of future generations.

- Engineers avoid actions which may compel them to accept given constraints and thus lead to reducing their individual responsibility.
- Engineers base their actions on the same ethical principles as everybody else within society. They honor national laws and regulations concerning technology use, working conditions, and the natural environment.
- Engineers discuss controversial views and values across the borders of disciplines and cultures.
- Engineers apply to their professional institutions in cases of conflicts concerning engineering ethics.
- Engineers contribute to defining and developing further relevant laws and regulations as well as political concepts in their countries.
- Engineers are committed to keeping up and continually developing further their professional skills and competencies.
- Engineers are committed to enhancing critical reflection on technology within schools, universities, enterprises, and professional institutions.

HONDURAS

• • •

ASSOCIATION OF CIVIL ENGINEERS OF HONDURAS CODE OF ETHICS

• • •

CONSIDERING:

That it is urgent that the Code of Professional Ethics be put into practice to guard and sanction the professional conduct of the members of the association;

CONSIDERING:

That the standards that regulate the subject as established by the Organic Law contain guidelines that are general and not concrete ones dealing with particulars;

CONSIDERING:

That it is the obligation of the Directing Council to propose to the General Assembly Regulations of the Association that conform to the Organic Law and to promulgate resolutions that will insure compliance with these Regulations;

CONSIDERING:

That it is necessary to have a Code of Professional Ethics that meets the needs of the growing Association of Civil Engineers of Honduras (CICH);

THEREFORE:

The 38th Regular General Assembly of the Association of Civil Engineers of Honduras (CICH), using the power conferred by Article 16, section (c) of the Organic Law,

AGREES

To the following:

CODE OF PROFESSIONAL ETHICS

• • •

Chapter I

FUNDAMENTAL PRINCIPLES

Engineers ought to maintain and respect the integrity, honor, and dignity of the engineering profession:

I. Utilizing their knowledge and ability to improve human welfare.

II. Being honest and impartial and faithfully serving the public, their employees, and clients.

III. Striving to improve the capability and the prestige of the profession.

IV. Supporting technical and professional societies within their disciplines.

Chapter II

STANDARDS OF ETHICS

Article 1.

—Any colleague who transgresses from one or more of the duties or obligations stipulated by the present code in either his personal character or his engineering firm is considered in contempt of the ethics.

Article 2.

—The ethical misdeeds may be considered "slight," "serious," "grave," or "very grave."

Article 3.

It is the responsibility of the Honor Tribunal of the Association of Civil Engineers of Honduras to determine the qualification that corresponds to a transgression or a group of transgressions incurred by a colleague.

If more than one transgression is committed by the same student it cannot be qualified as "slight" even though each error considered individually may merit such qualification.

Article 4.

—Ethical transgressions are:

A) Toward the Profession:

a) To act in any way that serves to diminish the honor, respectability, and the virtues of honesty, integrity, and truthfulness that should serve as the basis for a full and complete exercise of the profession;

b) To exercise bad faith, engage in acts contrary to good technique, or to be involved in culpable omissions, even if it is done in order to comply with orders from superiors or to comply with commands;

c) To accept a job knowing that it is may lend itself to an evil deceit or be against the general good;

d) To sign as author any title for free or purchased plans, specifications, judgments, accounts, or any other professional information laid out by others;

e) To take charge of projects or works which are not under his immediate direction, review or supervision;

f) To associate with or to have his name linked with propaganda or activities involving people or entities who exercise or practice the engineering profession illegally;

g) To put himself forward for employment in specializations and operations for which he has no capacity, preparation, and reasonable experience;

Rules of Conduct

Introduction

The Ordinance and Constitution make it clear that members are required to conduct themselves in a manner which is becoming to professional engineers, as may be seen from the following general statement from clause (1) of Article 12 of the Constitution:

> "Every member shall at all times so order his conduct as to uphold the dignity and reputation of the Institution and act with fairness and integrity towards all persons with whom his work is connected and towards other members."

The Council, in clause (3) of Article 12 of the Constitution, is required to make specific rules which are to be observed by members, and such rules have been drawn up and approved by the Council. These rules, given below, set the standard for the conduct of all Institution members, though they are not wholly relevant to Students.

If members have any comments to make on the application of these rules to the real life situation it would be appreciated if they would send their contributions to the Secretary, preferably before the end of August, for the consideration of the Rules of Conduct Working Party.

Rules of Conduct

Rule 1: Responsibility to the Profession. A member of the Institution shall order his conduct so as to uphold the dignity, standing and reputation of the profession. In pursuance of which a member shall, inter alia:

1.1 discharge his professional responsibilities with integrity, dignity, fairness and courtesy;

1.2 not allow himself to be advertised in self-laudatory language nor in any manner derogatory to the dignity of his profession, nor improperly solicit professional work for himself or others;

1.3 give opinions in his professional capacity that are, to the best of his ability, objective, reliable and honest;

1.4 take reasonable steps to avoid damage to the environment and the waste of natural resources or the products of human skill and industry;

1.5 ensure adequate development of his professional competence;

1.6 accept responsibility for his actions and ensure that persons to whom he delegates authority are sufficiently competent to carry the associated responsibility;

1.7 not undertake responsibility which he himself is not qualified and competent to discharge;

1.8 treat colleagues and co-workers fairly and not misuse the advantage of position;

1.9 when working in a country other than Hong Kong order his conduct according to the existing recognized standards of conduct in that country, except that he should abide by these rules as applicable in the absence of local standards.

1.10 when working within the field of another profession pay due attention to the ethics of that profession.

Rule 2. Responsibility to Colleagues. A member of the Institution shall not maliciously or recklessly injure nor attempt to injure whether directly or indirectly the professional reputation of another engineer, and shall foster the mutual advancement of the profession. In pursuance of which a member shall, inter alia:

2.1 where appropriate seek, accept and offer honest criticism of work and properly credit the contributions of others;

2.2 seek to further the interchange of information and experience with other engineers;

2.3 assist and support colleagues and engineering trainees in their professional development;

2.4 not abuse his connection with the Institution to further his business interest;

2.5 not maliciously or falsely injure the professional reputation, prospects or practice of another member provided however that he shall bring to the notice of the Institution any evidence of unethical, illegal or unfair professional practice;

2.6 support the aims and activities of the Institution.

Rule 3. Responsibility to Employers or Clients. A member of the Institution shall discharge his duties to his employer or client with integrity. In pursuance of which a member shall, inter alia:

3.1 offer complete loyalty to his employer or client, past and present, in all matters concerning remuneration and in all business affairs and at the same time act with fairness between his employer or client and any other part concerned;

3.2 inform his employer or client in writing of any conflict between his personal or financial interest and faithful service to his employer or client;

3.3 not accept any financial or contractual obligation on behalf of his employer or client without their authority;

3.4 where possible advise those concerned of the consequences to be expected if his engineering judgment, in areas of his responsibility, is overruled by non-technical authority;

3.5 advise his employer or client in anticipating the possible consequences of relevant developments that come to his knowledge;

3.6 neither give nor accept any gift, payment or service of more than nominal value to or from those having business relationships with his employer or client without consent of the latter;

3.7 where necessary co-operate with, or arrange for the services of, other experts wherever an employer's or client's interest might best be served thereby.

Rule 4. Responsibility to the Public. A member of the Institution in discharging his responsibilities to his employer and the profession shall at all times be governed by the overriding interest of the general public, in particular their welfare, health and safety. In pursuance of which a member shall, inter alia:

4.1 seek to protect the safety, health and welfare of the public;

4.2 when making a public statement professionally, try to ensure that both his qualification to make the statement and his association with a benefiting party are made known to the recipients of the statement;

4.3 seek to extend public understanding of the engineering profession.

CODE OF ETHICS FOR MEMBERS

• • •

INDIAN INSTITUTE OF CHEMICAL ENGINEERS EXPECTS ALL ITS INDIVIDUAL MEMBERS TO BE GUIDED IN THEIR PROFESSIONAL LIFE AND CONDUCT BY THE FOLLOWING CODE OF ETHICS

1. Members shall be guided by the highest standards of integrity in all their professional dealings.
2. The members shall uphold the dignity of the profession and the reputation of the Institute.
3. The members shall avoid sensationalism and misleading claims and statements. In making first publication concerning inventions, discoveries or improvements in their fields, the members shall use the channels of recognized scientific societies or standard technical publications or periodicals.
4. The members shall endeavor at all times to give credit for work to those who, as far as their knowledge goes, are the real authors of such work.
5. The members shall provide sufficient opportunity and take responsibility for the training and development of other engineers under their change.
6. If a member considers another member guilty of unethical practice, he shall present the information to the Council of the Institute. He shall endeavor to avoid, under all circumstances, injuring the reputation of any member directly or indirectly.
7. The members shall not misrepresent their qualifications to clients, employers or others with whom they come in contact in their profession.
8. The members shall not divulge or make use of any confidential information or findings of clients, employers, or professional committees/commissions to which they are appointed as members for their personal gain without prior consent of the concerned authority.
9. The members shall uphold the principle that unreasonably low professional charges encourage inferior and unreliable work. This does not, however, preclude them from honorary work for professional/national advancement.
10. The members should inform their clients or employers of any interest in a business which may compete with or affect the interest of their clients or employers.
11. The members shall refuse to undertake for compensation work which they believe will be unprofitable to clients, without first advising the clients as to the improbability of successful results.
12. When called upon to undertake the use of inventions, equipment, processes and products in which a member has a financial interest, he shall make his status clear before engagement.
13. The members shall always give complete and accurate reports for promotion of business/enterprises and avoid unnecessary claims.
14. The members shall not indulge in any occupation which is contrary to law or public welfare.

Obligation

As a Fellow of the Indian National Academy of Engineering, I shall follow the code of ethics, maintain integrity in research and publications, uphold the cause of Engineering and the dignity of the Academy, endeavor to be objective in judgment, and strive for the enrichment of human values and thoughts.

Signature

Name in full

NOTES

This code is in the form of an obligation which has to be signed by every Fellow upon admission to the Academy. S.N. Mitra, Honorary Secretary of the Academy, explains the undefined reference to "the code of ethics" by simply noting (in a letter dated October 19, 1990) that "We do not have any elaborate Code of

Ethics for the Fellows of our Academy. We have only the Obligation Form, which, in a sense, is a summarized version of the Code of Ethics."

Code of Ethics for Members of Indian Society of Engineers

The most important rules for a Corporate Member in a Professional sphere to follow, in India or abroad, is the code of practice for the society of which he is a member. This is the following:

i) A Corporate Member should observe the principles of honesty, justice, and courtesy in his profession. His personal conduct should uphold his Professional reputation, he should avoid adverse Questions affecting brother associations/Professionals, and he should uphold the dignity and honor of the Society.

ii) A Corporate Member will co-operate with others in his profession by fair interchange of information and experience and endeavor to protect the profession from misrepresentation and misunderstanding, and will not divulge any confidential finding or actions of an engineering commission or committee, as a Member without obtaining permission from the Authority.

iii) A Corporate Member will not directly or indirectly make damage to the reputation or practice of another Corporate Member or criticize technically without proper forum of Engineering Society or Engineering Press.

iv) A Corporate Member will neither misrepresent his Qualification and misguide his employer or client or to the profession, nor disclose trade secrets or technical affairs of his client or employer without proper Authority.

v) A Corporate Member will not review works of another Corporate Member at the same time for the same client, except with the consent of the other Member.

vi) A Corporate Member will, if he considers another Corporate Member is guilty of unethical, illegal or unfair practices, inform the Council of the Society in writing with necessary documents for action.

vii) A Corporate Member shall always confirm the National Interest in his own Professional Engineering areas.

CODE OF ETHICS FOR CORPORATE MEMBERS

• • •

Foreword

"The task of ethics," said Jacques Maritain, "is a humble one but it is also magnanimous in carrying the mutable application of immutable moral principles even in the midst of agonies of an unhappy world as far as there is in it a gleam of humanity."To uphold the concept of professional conduct amongst Corporate Members, the Institution introduced the professional Conduct Rules for Corporate Members on August 30 th, 1944. They were replaced by the Code of Ethics for Corporate Members on October 15th, 1954. The Code was revised consistent with the changing needs of the profession on August 12th, 1962.

A Corporate Member should allow the principles of honesty, justice and courtesy to guide him in the practice of his profession and in his personal conduct. He should not merely observe them passively, but should apply them dynamically in the discharge of his duties to the public and the profession.

He should scrupulously guard his professional reputation and avoid association with any enterprise of questionable character. He should uphold the dignity and honor of the Institution.

The Code

1. A Corporate Member will cooperate with others in his profession by the free interchange of informa-

tion and experience and will contribute to the work of engineering institutions to the maximum effectiveness he is capable of.

2. A Corporate Member will endeavor to protect the engineering profession from misrepresentation and misunderstanding.
3. A Corporate Member will refrain from expressing publicly an opinion on an engineering subject unless he is informed of the facts relating to that subject.
4. A Corporate Member will express an opinion only when it is founded on adequate knowledge and honest conviction if he is serving as a witness before a court or commission.
5. A Corporate Member will not divulge any confidential findings or actions of an engineering commission or committee, of which he is a member, without obtaining official consent.
6. A Corporate Member will take care that credit for engineering work is given to those to whom credit is properly due.
7. A Corporate Member will not offer his professional services by advertisement or through any commercial advertising media, or solicit professional work either directly, or through an agent or in any other manner derogatory to the dignity of the profession.
8. A Corporate Member will not directly or indirectly injure the professional reputation or practice of another Corporate Member.
9. A Corporate Member will exercise due restraint in criticizing the work of another Corporate Member and remember that the proper forum for technical criticism is an engineering society or the engineering press.
10. A Corporate Member will not try to supplant another Corporate Member in a particular employment.
11. A Corporate Member will not compete unfairly with another Corporate Member by charging fees below those customary for others in his profession practicing in the same field and in the same area.
12. A Corporate Member will not associate in work with an engineer who does not conform to ethical practices.
13. A Corporate Member will act in professional matters for his client or employer as faithful agent or trustee.
14. A Corporate Member will not misrepresent his qualifications to a client or employer or to the profession.
15. A Corporate Member will not disclose information concerning the business or technical affairs of his client or employer without his consent.
16. A Corporate Member will present clearly the consequences to be expected if his professional judgment is overruled by the non-professional authority where he is responsible for the professional adequacy of work.
17. A Corporate Member will act with fairness and justice between his client or employer and the contractor when dealing with contracts.
18. A Corporate Member will not be financially interested in the bids of a contractor on competitive work for which he is employed as an engineer unless he has the written consent of his client or employer.
19. A Corporate Member will not resolve any commission, discount, or other indirect profit in connection with any work with which he is entrusted.
20. A Corporate Member will make his status clear to his client or employer before undertaking an engagement if he may be called upon to decide on the use of inventions or equipment or any other thing in which he may have a financial interest.
21. A Corporate Member will immediately inform his client or employer of any interest in a business which may compete with or affect the business of his client or employer.
22. A Corporate Member will not allow an interest in any business to affect the engineering work for which he is employed or may be called upon to perform.
23. A Corporate Member will engage, or advise engaging, engineering experts and specialists when in his judgment such services are in the interests of his client or employer.
24. A Corporate Member will not review the work of another Corporate Member for the same client except with the knowledge of the second Corporate Member, unless such engineering engagement or the work which is subject to review is terminated.
25. A Corporate Member will not accept financial or other compensation from more than one interested party for the same service, or for services pertaining to the same work, without the consent of all interested parties.
26. A Corporate Member will subscribe to the principles of appropriate and adequate compensation for those engaged in engineering work, including those in subordinate positions.
28. A Corporate Member will endeavor to provide opportunity for the professional development and advancement of engineers in his employ.
29. A Corporate Member will, if he considers that another Corporate Member is guilty of unethical,

illegal or unfair practice, present the information to the Council of the Institution for action.

30. A Corporate Member who is engaged in engineering work in a country abroad will order his conduct according to the professional standards and customs of that country, adhering as closely as is practicable to the principles of this Code.

NOTES

This code is published and promulgated in a pocket-sized pamphlet.

IRELAND

THE INSTITUTION OF ENGINEERS OF IRELAND CODE OF ETHICS

22 Clyde Road, Ballsbridge
Dublin 4, Ireland

Founded: 1835
Members: 5,900

STANDARDS OF PROFESSIONAL CONDUCT

Part I: FUNDAMENTAL PRINCIPLES

1. Every corporate member of the Institution shall order his conduct so as to serve the public interest and uphold the honor and standing of The Institution and of the Engineering Profession.
2. *In his relations with his employers, clients, professional colleagues, subordinates and others with whom he works, and with the public*, he shall maintain high standards of conduct and integrity.
3. *In his relations with an employer or client* he shall act at all times as a faithful agent or trustee, using all his professional skill and experience and making freely available his sincere opinion and advice in the proper interest of his employer or client. He shall do nothing directly or indirectly which might conflict or appear to conflict with those interests or might influence or appear to influence his opinion or advice.
4. *In his relations with another engineer* he shall respect his dignity and professional standing and shall do nothing directly or indirectly to injure maliciously his reputation, practice, employment or livelihood or to lessen the satisfaction that he obtains from his work. He shall never compete unfairly for any engagement or appointment. He shall ensure, so far as he is able, that an engineer receives credit for his professional achievements and the financial and other rewards to which he is entitled, and that a subordinate is provided with opportunities to develop his talents and exercise his skill.
5. *In his relations with all others with whom he works* he shall act with justice and impartiality and with respect for their rights and dignity as citizens and human beings.
6. *In his relations with the public* he shall apply his skill and experience to the common good and the advancement of human welfare and shall perform his professional duties and express his professional opinions with proper regard for true economy and for the safety, health and welfare of the public. Should he come to the conclusion after full consultation with his employer or client that any work required of him by them is likely to be seriously injurious to the public welfare or to create a hazard to the health or safety of the community he has a duty to put his opinion on record and to inform The Institution of this action.
7. *As an independent expert or arbitrator* he shall act with complete impartiality, uninfluenced by any personal consideration.
8. He has a duty to maintain his knowledge up-to-date in relation to that branch of engineering in which he practices.

Part II: GUIDE TO PROFESSIONAL CONDUCT

1. He shall not divulge any confidential information regarding the business affairs, technical processes or financial standing of his clients or employers without their consent. He shall not use information obtained in the course of his assignment for the purpose of making personal profit if such action is contrary to the best interest of his client, his employer or the public. He shall not divulge without authoritative permission any unpublished information obtained by him as a member of an investigating commission or advisory board.
2. His remuneration shall be restricted to his fee, commission or salary (including bonuses, etc.). Where his remuneration is by fee it shall be in accordance with the Conditions of Engagement and Scale of Fees published jointly with the Association of Consulting Engineers of Ireland as in force from time to time. He

shall not knowingly compete with another Chartered Engineer on the basis of professional charges.

3. He shall not receive any royalty or commission on any article or process used on his recommendation on work for which he is responsible unless such payment has the full consent of his client or employer.
4. He shall not while acting in a professional capacity be at the same time a director or substantial shareholder in any contracting, manufacturing or distributing business with which he may have dealings on behalf of his client or employer without divulging the full facts in writing to his client or employer, and obtaining his written agreement thereto.
5. He shall not advertise his practice or his availability except in accordance with such Code of Practice as may be in force from time to time. Under no circumstances shall he pay an agent to introduce clients to him.
6. He shall not practice as a consultant in the following circumstances:
   (a) in partnership with one who is not professionally qualified in engineering or an allied profession;
   (b) as Principal or one of the major shareholders of a limited liability Company unless the Company has the prior approval of the Council of The Institution.
7. A member shall not use the advantage of a salaried position to compete unfairly with other engineers. His outside activities in the engineering field should normally be confined to branches of engineering for which he has special qualifications. He shall not undertake as a part-time consultant any work which he might subsequently have to review in the course of his salaried employment.
8. When acting as a Consultant a member shall not attempt to supplant another Chartered Engineer nor shall he take over or review the work of another Chartered Engineer acting as a Consultant, without either having the written consent of such Engineer or having fully satisfied himself that such Engineer's association with the work has been terminated and his account fully discharged.

NOTES

Approved by the Council of The Institution of Engineers of Ireland at its Meeting of 15th October, 1971.

Published and promulgated as a four-page pamphlet.

Under revision as of November 1991.

CODE OF ETHICS

• • •

A Professional Engineer

1. owes certain duties to the public, to his employers, to other members of his profession and to himself and shall act at all times with:
   (a) fidelity to public needs;
   (b) fairness and loyalty to his associates, employers, clients, subordinates and employees: and
   (c) devotion to high ideals of personal honor and professional integrity.
2. shall express opinions on engineering matters only on the basis of adequate knowledge and honest conviction.
3. shall have proper regard for the safety health and welfare of the public in the performance of his professional duties.
4. shall endeavor to extend public understanding of engineering and its place in society.
5. shall not be associated with enterprises contrary to the public interest or sponsored by persons of questionable integrity, or which does not conform to the basic principles of the code.
6. shall sign and/or seal only those plans, specifications and reports actually prepared by him or under his direct professional supervision.
7. shall act for his client or employer as a faithful agent or trustee.
8. shall not disclose confidential information pertaining to the interests of his clients or employers without their consent.
9. shall present clearly to his clients or employers the consequences to be expected if his professional judgment is over-ruled by non-technical authority in matters pertaining to work for which he is professionally responsible.

10. shall not undertake any assignment which may create a conflict of interest with his clients or employers without the full knowledge of his clients or employers.
11. shall not accept remuneration for services rendered other than from his client or employer.
12. shall conduct himself towards other professional engineers with courtesy, fairness and good faith.
13. shall not compete unfairly with another engineer by attempting to obtain employment, advancement or professional engagements by competitive bidding, by taking advantage of a salaried position or by criticizing other engineers.
14. shall undertake only such work as he is competent to perform by virtue of his training and experience.
15. shall not advertise his work or merit in a self-laudatory manner and shall avoid all conduct or practice likely to discredit or unfavorably reflect upon the dignity or honor of the profession.
16. shall advise his Association or Institution or the Council of any practice by another Professional Engineer which he believes to be contrary to the Code of Ethics.

GUIDE TO PRACTICE UNDER THE CODE OF ETHICS

• • •

GENERAL:

ARTICLE 1. A Professional Engineer owes certain duties to thepublic, to his employers, to other members of his profession and to himself and shall act at all times with:

(a) fidelity to public needs;

(b) fairness and loyalty to his associates, employers, clients, subordinates and employees; and

(c) devotion to high ideals of personal honor and professional integrity.

DUTIES OF THE PROFESSIONAL ENGINEER TO THE PUBLIC

• • •

A Professional Engineer

ARTICLE 2. shall express opinions on engineering matters onlyon the basis of adequate knowledge and honest conviction.

(a) He shall ensure, to the best of his ability, the statements on engineering matters attributed to him are not misleading and properly reflect his professional opinion;

(b) He shall not express publicly or while he is serving as a witness before a court, commission or other tribunal opinions on professional engineering matters that are not founded on adequate knowledge and honest conviction.

ARTICLE 3. shall have proper regard for the safety health andwelfare of the public in the performance of his professional duties.

(a) He shall notify the proper authorities of any situation which he considers, on the basis of his professional knowledge, to be a danger to public safety or health.

(b) He shall complete, sign, or seal only those plans and/or specifications which reflect proper regard for the safety and health of the public.

ARTICLE 4. shall endeavor to extend public understanding of engineering and its place in society.

(a) He shall endeavor at all times to enhance the public regard for, and its understanding of, his profession by extending the public knowledge thereof and discouraging untrue, unfair or exaggerated statements with respect to professional engineering.

(b) He shall not give opinions or make statements on professional engineering projects connected with public policy where such statements are inspired or paid for by private interests unless he clearly discloses on whose behalf he is giving the opinions or making the statements.

ARTICLE 5. shall not be associated with enterprises contrary to the public interest or sponsored by persons of questionable integrity, or persons who do not conform to the basic principles of the code.

(a) He shall conform with registration laws in his practice of engineering.

(b) He shall not sanction the publication of his reports in part or in whole in a manner calculated to mislead and if it comes to his knowledge that they are so published, he shall take immediate steps to correct any false impressions given by them.

ARTICLE 6. shall sign and/or seal only those plans, specification and reports actually prepared by him or under his direct professional supervision.

DUTIES OF THE PROFESSIONAL ENGINEER TO HIS CLIENT OR EMPLOYER:
A Professional Engineer

ARTICLE 7. shall act for his client or employer as a faithful agent or trustee.

(a) He shall be realistic and honest in all estimates, reports, statements, and testimony.

(b) He shall admit and accept his own errors when proven obviously wrong and refrain from distorting or altering the facts in an attempt to justify his decision.

(c) He shall advise his client or employer when he believes a project will not be successful.

(d) He shall not accept outside employment to the detriment of his regular work or interest, or without the consent of his employer.

(e) He shall not attempt to attract an engineer from another employer by unfair methods.

(f) He shall engage, or advise engaging, experts and specialists when such services are in his clients or employer's best interests.

ARTICLE 8. shall not disclose confidential information pertaining to the interests of his clients or employers without their consent.

(a) He shall not use information coming to him confidentially in the course of his assignment as a means of making personal gain except with the knowledge and consent of his client or employer.

(b) He shall not divulge, without official consent, any confidential findings resulting from studies or actions of any commission or board of which he is a member or for which he is acting.

ARTICLE 9. shall present clearly to his clients or employers the consequences to be expected if his professional judgment is over-ruled by non-technical authority in matters pertaining to work for which he is professionally responsible.

ARTICLE 10. shall not undertake any assignment which may create a conflict of interest with his clients or employers without the full knowledge of his clients or employers.

ARTICLE 11. shall not undertake any assignment which may create a conflict of interest with his clients or employers without the full knowledge of his clients or employers.

(a) He shall inform his client or employer of any business connections, interests, or circumstances which may be deemed as influencing his judgment or the quality of his services to his client or employer.

(b) When in public service as a member, advisor or employee of a governmental body or department, he shall not participate in considerations or actions with respect to services provided by him or his organization in private engineering practice.

(c) He shall not solicit or accept an engineering contract from a governmental body on which a principal or officer of his organization serves as a member.

ARTICLE 11. shall not accept remuneration for services renderedother than from his client or employer.

(a) He shall not accept compensation from more than one interest party for the same service or for services pertaining to the same work, under circumstances that may involve a conflict of interest, without the consent of all interested parties.

(b) He shall not accept any royalty or commission on any article or process used on the work for which he is responsible without the consent of his client or employer.

(c) He shall not undertake work at a fee or salary below the accepted standards of the profession in the area.

(d) He shall not tender on competitive work upon which he may be acting as a consulting engineer.

(e) He shall not act as consulting engineer in respect of any work upon which he may be the contractor.

DUTIES OF THE PROFESSIONAL ENGINEER TO THE PROFESSION

• • •

A Professional Engineer

ARTICLE 12. shall conduct himself towards other professional engineers with courtesy, fairness and good faith.

(a) He shall not accept any engagement to review the work of another professional engineer for the same employer or client except with the knowledge of such engineer, unless such engineer's engagement on the work has been terminated.

(b) He shall not maliciously injure the reputation or business of another professional engineer.

ARTICLE 13. shall not compete unfairly with another engineer by attempting to obtain employment, advancement or professional engagements by competitive bidding, by taking advantage of a salaried position, or by criticizing other engineers.

(a) He shall not attempt to supplant another engineer in a particular employment after becoming aware that definite steps have been taken toward the other's employment.

(b) He shall not offer to pay, either directly or indirectly, any commission, political contribution, or a gift or other consideration in order to secure professional engineering work.

(c) He shall not solicit or submit engineering proposals on the basis of competitive bidding.

(d) He shall not use equipment, supplies, laboratory, or office facilities of his employer to carry on outside private practice without consent.

ARTICLE 14. shall undertake only such work as he is competent to perform by virtue of his training and experience.

(a) He shall not misrepresent his qualifications.

ARTICLE 15. shall not advertise his work or merit in a self-laudatory manner, and shall avoid all conduct or practice likely to discredit or unfavorably reflect upon the dignity or honor of the profession.

(a) Circumspect advertising may be properly employed by the Engineer to announce his practice and availability. Only those media shall be used as are necessary to reach directly an interested and potential client or employer, and such media shall in themselves be dignified, reputable and characteristically free of any factor or circumstance that would bring disrepute to the profession or to the professional using them. The substance of such advertising shall be limited to fact and shall contain no statement or offer intended to discredit or displace another engineer, either specifically or by implication.

ARTICLE 16. shall advise his Association or Institution or the Council of any practice by another Professional Engineer which he believes to be contrary to the Code of Ethics.

NOTES

Adopted by the Jamaica Institution of Engineers September 1986.

The JIE is a non-profit professional organization, comprised of members who are Engineers from all the various disciplines of Engineering, including Civil, Electrical, Mechanical, Chemical, Industrial and Agricultural.

The Institution is currently involved in a six-year program of technical co-operation (concluding in 1993) with the Canadian Society for Civil Engineering (CSCE), and funded by the Canadian International Development Agency (CIDA). The main objective being the improvement of technical expertise within the JIE community as regards to Civil Engineering aspects of transportation infrastructure and other topics.

Statement on "Charter for Scientific Researchers"

PREAMBLE

• • •

In order to promote the sound development of scientific research in Japan, the Science Council of Japan (JSC) recommended twice, in 1962 and in 1976, that the government prepare for the enactment of a Basic Act on Scientific Research to define its responsibility and urged the government to enact such a law. The Council has prepared and hereby issues a "Charter for Scientific Researchers" to complement the proposed Basic Act on Scientific Research, and itself resolves to abide by this "Charter." The Council thus makes public the responsibility of scientific researchers themselves, and expects the researchers of Japan to accomplish their tasks in accordance with the spirit of the "Charter."

CHARTER FOR SCIENTIFIC RESEARCHERS

• • •

Science enriches human life by the rational search for truth with actual evidence and also by applying the results in practical use. The search for truth in scientific research and the application of its results belong to the highest intellectual activities of human beings. Scientific researchers who are engaged in these activities are required to be sincere toward reality, exclude arbitrary decisions and keep their minds pure and strict toward truth.

It is not only the demand of human society but also the duty of scientific researchers to promote the sound development of science and the beneficial application of its results. To fulfill their duty, scientific researchers are required to act upon the following five points:

1. To be conscious of the significance and aim of his or her own research and to contribute to the welfare of mankind and world peace.
2. To defend the freedom of scientific research and to respect originality in research and development.
3. To attach importance to the harmonious development between various fields of science and to propagate the scientific attitude and knowledge among the general public.
4. To guard against disregard and abuse of scientific research and to strive to eliminate such dangers.
5. To place great value on the international nature of scientific research and to endeavor to promote interchanges with the scientific community of the world.

Purport and Process Leading to Adoption of "Charter for Scientific Researchers"

Explanatory note by Special Committee for Promotion of Science

In January 1975, at the opening of the tenth term of the Science Council of Japan, it was decided to take up for examination a proposal for formulation of a Charter for Scientists. Deliberations on this question have continued until now.

From the time of its establishment in 1949, JSC has constantly kept the rights and responsibilities of scientists under consideration, and pledged that it will strive to contribute to world peace and the welfare of mankind, based on the conviction that science provides the foundation for a cultured and peaceful nation.

The Council has continued to deliberate important questions relating to the sciences, and has made many recommendations and issued a wide range of statements. In 1962 and again in 1976 it recommended that preparations be made for legislation of a Basic Act for Scientific Research. The purpose of such an Act would be to define the responsibility of the State for the development of scientific research in Japan, and as complementary to this, the Science Council of Japan declared by resolution, as a representative body of scientific researchers, that it would adopt a "Charter for Scientific Researchers" (provisional name) setting out the responsibility of scientists toward the general public. The "Charter" would declare that scientific researchers must be conscious of the purposes of scientific research and their own social responsibilities, and devote themselves to the sound development of scientific research such as will meet the expectations of the people; that they accept it as their responsibility to protest against any oppression of freedom of scientific research, and make clear the damage which disregard and/or abuse of science and technology would cause to human society, thus to protect the welfare of the nation and the people.

The 18th session of the UNESCO General Conference in October, 1974 adopted a Recommendation on the Status of Scientific Researchers concerned mainly with the rights and status of scientific researchers, and the 70th session of the JSC General Meeting followed this up with its renewed recommendation to the Japanese government for a Basic Act for Scientific Research, in the desire to carry into effect in this country the spirit and contents of the UNESCO Recommendation as soon as possible.

In the hope that the proposed Charter could be drafted during the Council's 10th term, discussions were taken up among the Members, and a subcommittee on a "Charter for Scientific Researchers" was established in the Special Committee for Man and Science, which also had the responsibilities of scientific researchers under consideration. First, second and third drafts of the "Charter" were submitted to scientific researchers all over Japan through the members of JCS and through various academic societies and associations, seeking their comments.

The draft of an "Appeal to Examine the Responsibilities of Scientific Researchers" was presented to the 73rd session of the General Meeting in October, 1977 during the last session of the 10th term. The need for further examination was acknowledged, and it was agreed that the drafting of the "Charter for Scientific Researchers" should be completed as soon as possible in the 11th term.

Basic deliberations during the 11th term (1978-1981) highlighted the following three targets:

(1) high evaluation of creativity, originality and foresightedness in scientific researchers

(2) respect for human dignity and awareness of social responsibility among scientific researchers

(3) emphasis on global concept and on scientific cooperation with developing countries.

On points (1) and (2), it was decided that the Special Committee for Promotion of Science should bear the main responsibility for examining basic policy, and that the draft of the "Charter for Scientific Researchers" should be prepared by the newly appointed Subcommittee within the Special Committee.

Accordingly, the Subcommittee took up the results from considerations in the Council's previous term, and examined also documents from overseas relating to charters for scientists, and literature on the status and responsibility of scientists. Further comments from Members of JSC were received through questionnaires on the requirements, character and content of the "Charter." Based on these, the first draft was completed in February, 1979 and a consensus sought among scientific researchers. The first draft was deliberated at each Division of JSC meeting in that month. Based on these investigations, the Subcommittee presented the second draft of the "Charter" to the 77th session of the general meeting held in May. After receiving opinions on the second draft and making several amendments, the Special Committee for Promotion of Science submitted a draft of the Charter for Scientific Researchers on the second day of meeting of the 79th session of the General Meeting on 24 April, 1980. Seven Members spoke in approval of the draft, which, with minor verbal modification, was then adopted unanimously.

The Science Council of Japan hereby presents the "Charter for Scientific Researchers," with its resolution to abide by it, setting out the responsibilities of scientists toward the general public, and expresses the hope that scientific researchers will carry on their tasks in the spirit of this "Charter."

NOTES

Was founded as the governmental organization representative of all Japanese scientists to promote and reflect scientific development throughout national life, industry and administration, to co-ordinate scientific research and to link scientific organizations abroad.

MEXICO

MEXICAN UNION OF ASSOCIATIONS OF ENGINEERS CODE OF ETHICS

• • •

Code of Ethics of the Mexican Engineer (UMAI)

Contributed by Araceli Solano

The Code of Mexican Professional Engineering Ethics was published July 1, 1983, and signed by the witness, the Certified Licensed Miguel de la Madrid Hurtado, Constitutional President of the United Mexican States, which is transcribed below.

CONSIDERING THAT:

1. Mexican engineers sustain their conduct with the respect and love for the fatherland.
2. Engineers in our country have achieved the practice of their profession thanks to the opportunity that the Mexican nation affords them.
3. For their preparation they have a great obligation to contribute to the satisfaction of the needs and improvement of the quality of life of the Mexican people, with the moral conviction and responsibility of sustaining a development in accordance with social justice.
4. It is a duty to foster a favorable atmosphere for the development of activity in accordance with the Code of Ethics that specifies social obligations that make possible the respect of each professional for the rest, in search of a just and harmonious human conviviality within each nation and among nations.
5. Universal principles and our greatest traditions consider as a solemn duty both international solidarity and respect for the moral values of other peoples, in particular in those places where engineers forward their education or eventually exercises their profession.
6. The diverse codes of professional ethics of colleges and associations of engineers come together on one and the same conception.
7. The Union of Mexican Engineers has acknowledged principles and norms of conduct.

The Ordinary General Assembly of UMAI adopts the following Code of Professional Ethics of the Mexican Engineer:

Engineers recognize that the greatest merit is work, for which reason they will exercise their profession committed to service to Mexican society, caring for the wellbeing and progress of the majority. When transforming nature for the benefit of humanity, engineers should augment their awareness that the world is the living space of man and that their interest in the universe is a guarantee of the triumph of the spirit and of the knowledge of reality in order to make it more just and happy. Engineers should refuse work that has as its goal a crime against the general interest; in this way they will avoid situations which implicate dangers or constitute a threat to the environment, to life, health, or other rights of the human being. It is an inescapable duty of the engineer to sustain the prestige of the profession and strive for its proper exercise; likewise, to maintain a professional conduct cemented in capability, honor, strength, moderation, magnanimity, modesty, forthrightness, and justice, with consciousness of subordinating the wellbeing of the individual to the wellbeing of society. Engineers should procure the constant perfection of their knowledge, in particular that of their profession, divulge their wisdom, share their experience, provide opportunities for the education and enablement of workers, bestow recognition, moral and material support to the educational institution where they realized their studies; in this way they will return to society the opportunities that they have received. It is the responsibility of engineers that their work be realized with efficiency and aid to legal dispositions. In particular, they will ensure the fulfillment of the norms of protection of workers established in Mexican labor legislation. In the exercise of their profession, engineers must fulfill with diligence the commitments that they have assumed and will develop with dedication and loyalty the jobs assigned to them, avoiding putting personal interests first in the attention to the matters that are entrusted to them, or colluding in order to exercise disloyal competition to the detriment of those who received their services. They will observe decorous conduct, treating with respect, diligence, impartiality, and rectitude the persons with whom they have a relation, particularly their collaborators, abstaining from deviance and abuses of authority and from disposing or authorizing a subordinate to illicit conduct, such as unduly favoring third parties. Engineers must safeguard the interests of the institution or person for whom they are working and make good use of the resources that have been assigned to them for the undertaking of their work. They will fulfill the orders that in the exercise of their powers their superiors dictate to them, will respect and make respected their position and work; if they disagree with their superiors they will have the obligation to manifest before them the reasons for their disagreement. Engineers will have as a norm the creation and promotion of national technology; they will take special care to ensure that the transfer of technology adapted to our conditions conforms to the established legal framework. It is obligatory to keep as a professional secret the confidential data that they learn in the exercise of their profession, except when they might be required by a competent authority.

Code of Ethics

Protection of Life and Safeguarding People: Members have a duty of care to protect life and to safeguard people.

Guidelines

To satisfy this clause you need to:

1.1 Give priority to the safety and well-being of the community and have regard to this principle in assessing duty to clients and colleagues.

1.2 Be responsible for ensuring that reasonable steps are taken to minimize the risk of loss of life, injury or suffering which may result from the work or the effects of your work.

1.3 Draw the attention of those affected to the level and significance of risk associated with the work.

1.4 Assess and minimize potential dangers involved in the construction, manufacture and use of your products or projects.

Professionalism and Integrity

Members shall undertake their duties with professionalism and integrity and shall work within their levels of competence.

Guidelines

To satisfy this clause you need to:

2.1 Exercise initiative, skill and judgment to the best of your ability for the benefit of your employer or client.

2.2 Give engineering decisions, recommendations or opinions that are honest, objective and factual. If these are ignored or rejected you should ensure that those affected are made aware of the possible consequences.

In particular, where vested with the power to make decisions binding on both parties under a contract between principal and contractor, act fairly and impartially as between the parties and (after any appropriate consultation with the parties) make such decisions independently of either party in accordance with your own professional judgment.

2.3 Accept personal responsibility for work done by you or under your supervision or direction and take reasonable steps to ensure that anyone working under your authority is both competent to carry out the assigned tasks and accepts a like personal responsibility.

2.4 Ensure you do not misrepresent your areas or levels of experience or competence.

2.5 Take care not to disclose confidential information relating to your work or knowledge of your employer or client without the agreement of those parties.

2.6 Disclose any financial or other interest that may, or may be seen to, impair your professional judgment.

2.7 Ensure that you do not promise to, give to, or accept from any third party anything of substantial value by way of inducement.

2.8 First inform another member before reviewing their work and refrain from criticizing the work of other professionals without due cause.

2.9 Uphold the reputation of the Institution and its members, and support other members as they seek to comply with the Code of Ethics.

2.10 Follow a recognized professional practice (Model Conditions of Engagement are available) in communicating with your client on commercial matters.

Society and Community Well-Being

Members shall actively contribute to the well-being of society and, when involved in any engineering project or application of technology, shall, where appropriate, recognize the need to identify, inform and consult affected parties.

Guidelines

To satisfy this clause you need to:

3.1 Apply skill, judgment and initiative to contribute positively to the well-being of society.

3.2 Recognize in all your work your obligation to anticipate possible conflicts and endeavor to resolve them responsibly, and where necessary utilize the experience of the Institution and colleagues for guidance.

3.3 Treat people with dignity and have consideration for the values and cultural sensitivities of all groups within the community affected by your work.

3.4 Endeavour to be fully informed about relevant public policies, community needs, and perceptions, which affect your work.

3.5 As a citizen, use your knowledge and experience to contribute helpfully to public debate and to community affairs except where constrained by contractual or employment obligations.

Sustainable Management and Care of the Environment

Members shall be committed to the need for sustainable management of the planet's resources and seek to minimize adverse environmental impacts of their engineering works or applications of technology for both present and future generations.

Guidelines

To satisfy this clause you need to:

4.1 Be committed to the efficient use of resources.

4.2 Minimize the generation of waste and encourage environmentally sound reuse, recycling and disposal.

4.3 Recognize adverse impacts of your work on the environment and seek to avoid or mitigate them.

4.4 Recognize the long-term imperative of sustainable management throughout your work. (Sustainable Management is often defined as meeting the needs of the present without compromising the ability of future generations to meet their own needs).

Promotion of Engineering Knowledge

Members shall continue the development of their own and the profession's knowledge, skill and expertise in the art and science of engineering and technology, and shall share and exchange advances for the benefit of society.

Guidelines

To satisfy this clause you need to:

5.1 Seek and encourage excellence in your own and others' practice of the art and science of engineering and technology.

5.2 Contribute to the collective wisdom of the profession and art of engineering and technology in which you practice.

5.3 Improve and update your understanding of the science and art of engineering and technology and encourage the exchange of knowledge with your professional colleagues.

5.4 Wherever possible share information about your experiences and in particular about successes and failures.

NOTES

Approved by Council 5 July 1996.

NORWAY

• • •

ASSOCIATION OF NORWEGIAN CIVIL ENGINEERS CODE OF ETHICS

• • •

RELATION OF THE CIVIL ENGINEER TO SOCIETY

• • •

1. In their professional work, the members shall promote a community-oriented and harmonious technical and industrial development.
2. The members shall execute their work according to sound technical principles. Proper consideration must be given to economic and human factors, to the influence of the work on the environment and the community, and to other demands dictated by circumstances.
3. Professional (technical) questions must be dealt with in a factual and objective manner. The members must attempt to give the public a correct understanding of technical matters and to counteract erroneous conceptions.

RELATION OF CIVIL ENGINEER TO EMPLOYER AND CLIENT

• • •

1. The members shall protect the interests of their employers and clients in matters which have been entrusted to them, as long as this does not contradict general ethical fundamental principles.
2. The members are not allowed to receive compensation from anypartner in a group-deal unless all other partners are also aware of this. The members must not use their professional position to obtain personal advantages.

RELATION OF CIVIL ENGINEER TO COLLEAGUES AND CO-WORKERS

• • •

1. The members shall protect the professional reputation of their colleagues and co-workers against unfair criticism, slander, or false accusations. They should contribute to the fact that whosoever has executed a technical assignment should also receive the acknowledgement and compensation for this.
2. The members should not engage in disloyal competition. The rightful ownership of others with regard to plans, drawings, ideas, inventions, etc., should be respected.
3. A member is not allowed to take over a position after a colleague if there is reason to believe that the latter was unfairly dismissed or in some other manner deprived of his work for reasons which contradict the general ethical fundamental principles.
4. A member is not allowed to take over an assignment which has been entrusted to a colleague without first informing the latter and without ascertaining that there are reasonable grounds for the client's solicitation.
5. Members are not allowed to advertise their activities or to offer their services in an unworthy or misleading manner or to attempt to obtain assignments with improper methods.

TRANSLATED BY BIRGITTA D. KNUTTGEN

NOTES

This code is promulgated by means of a one-page typewritten and photocopied document.

An introductory note states that the code was "passed by the Board of Governors of the NIF [Norwegian Civil Engineers Association] on June 26, 1970, as a supplement to paragraph 8, point 1, of the statutes."

PAKISTAN

• • •

THE INSTITUTION OF ENGINEERS CODE OF ETHICS

• • •

Engineering Centre
Gulberg - III
Lahore, Pakistan

Founded: 1948

Professional Ethics and Code of Conduct

ARTICLE 1

To maintain, uphold and advance the honor and dignity of the engineering profession in accordance with this Code, a member shall:

(a) uphold the Ideology of Pakistan;

(b) be honest, impartial and serve the country, his employer, clients and the public at large with devotion;

(c) strive to increase the competence and prestige of the engineering profession;

(d) use his knowledge and skill for the advancement and welfare of mankind;

(e) promote and ensure the maximum utilization of human and material resources of Pakistan for achieving self-reliance; and

(f) not sacrifice the national interest for any personal gain.

ARTICLE 2

(1) A member shall be guided in all professional matters by the highest standards of integrity and act as a faithful agent or a trustee for each of his client and employer.

(2) A member shall:

(a) be realistic and honest in all estimates, reports, statements, and testimony and shall carry out his professional duties without fear or favor;

(b) admit and accept his own errors when proved and shall refrain from distorting or altering the facts justifying his decision or action;

(c) advise his client or employer honestly about the viability of the project entrusted to him;

(d) not accept any other employment to the detriment of his regular work or interest without the consent of his employer;

(e) not attempt to attract an engineer from another employer by false or misleading pretenses;

(f) not restrain an employee from obtaining a better position with another employer; and

(g) not endeavor to promote his personal interest at the expense of the dignity and integrity of the profession.

ARTICLE 3

A member shall have utmost regard for the safety, health, and welfare of the public in the performance of his professional duties and for that purpose he shall:

(a) regard his duty to the public welfare as paramount;

(b) seek opportunities to be of service in civic affairs and work for the advancement of the safety, health, and well-being of the community;

(c) not undertake, prepare, sign, approve, or authenticate any plan, design or specifications which are not safe for the safety, health, and welfare of a person or persons, or are not in conformity with the accepted engineering standards and if any client or an employer insists on such unprofessional conduct, he shall notify the authorities concerned and withdraw from further service on the project; and

(d) point out the consequences to his client or the employer if his engineering judgment is overruled by any non-technical person.

ARTICLE 4

(1) A member shall avoid all acts or practices likely to discredit the dignity or honor of the profession and for that purpose he shall not advertise his professional services in a manner derogatory to the dignity of the profession. He may, however, utilize the following means of identification:

(i) professional cards and listing in recognized and dignified publications and classified section of the telephone directories;

(ii) sign boards at the site of his office or projects for which he renders services; and

(iii) brochures, business cards, letterheads, and other factual representations of experience, facilities, personnel and capacity to render services.

(2) A member shall write articles for recognized publications but such articles should be dignified, free from ostentations or laudatory implications, based on factual conclusions and should not imply other than his direct participation in the work described unless credit is given to others for their share of the work.

(3) A member shall not allow himself to be listed for employment using exaggerated statements of his qualifications.

ARTICLE 5

(1) A member shall endeavor to extend public knowledge and appreciation of the engineering profession, propagate the achievements of the profession and protect it from misrepresentation and misunderstanding.

ARTICLE 6

(1) A member shall express an opinion of an engineering subject only when founded on adequate knowledge, experience, and honest conviction.

ARTICLE 7

(1) A member shall undertake engineering assignments only when he possesses adequate qualifications,

training, and experience. He shall engage or advise for engaging of the experts and specialists whenever the client's or employer's interests are best served by the service.

(2) A member shall not discourage the necessity of other appropriate engineering services, designs, plans, or specifications or limit-free competition by specifying materials of particular make or model.

ARTICLE 8

(1) A member shall not disclose confidential information concerning the business affairs or technical processes of any present or former client or employer without his consent.

ARTICLE 9

(1) A member shall uphold the principles of appropriate and adequate compensation for those engaged in engineering work and for that purpose he shall not:

(a) undertake or agree to perform any engineering service free except for civic, charitable, religious, or non-profit organizations or institutions;

(b) undertake professional engineering work at a remuneration below the accepted standards of the profession in the discipline; and

(c) accept remuneration from either an employee or employment agency for giving employment.

(2) A member shall offer remuneration in accordance with the qualifications and experience of an engineer employed by him.

(3) A member working in any sales section or department shall not offer or give engineering consultation, designs, or advice, other than specifically applying to the equipment being sold in that section or department.

ARTICLE 10

(1) A member shall not accept compensation, financial, or otherwise, from more than one party for the same service, or for services pertaining to the same work unless all interested parties give their consent to such compensation.

(2) A member shall not accept:

(a) financial or other considerations, including free engineering design, from material or equipment suppliers for specifying their products; and

(b) commissions or allowances, directly or indirectly from contractors or other parties dealing with his clients or employer in connection with work for which he is professionally responsible.

ARTICLE 11

(1) A member shall not compete unfairly with another member or engineer by attempting to obtain employment, professional engagements or personal gains by taking advantage of his superior position or by criticizing other engineers or by any other improper means or methods.

(2) An engineer shall not attempt to supplant another engineer in a particular employment after becoming aware that definite steps have been taken towards other's employment.

(3) A member shall not accept part-time engineering work at a fee or remuneration less than that of the recognized standard for a similar work and without the consent of his employer if he is already in another employment.

(4) A member shall not utilize equipment, supplies, laboratory, or office facilities of his employer or client for the purpose of private practice without his consent.

ARTICLE 12

(1) A member shall not attempt to injure, maliciously or falsely, directly or indirectly, the professional reputation, prospects, practices, or employment of another engineer or member.

(2) A member engaged in private practice shall not review the work of another engineer for the same client, except with knowledge of such engineer or, unless the connection of such engineer with the work has been terminated; provided that a member shall be entitled to review and evaluate the work of other engineers when so required by his employment duties.

(3) A member employed in any sales or industrial concern shall be entitled to make engineering comparisons of his products with products of other suppliers.

ARTICLE 13

(1) A member shall not associate with or allow the use of his name by an enterprise of questionable character; nor will he become professionally associated with engineers who do not conform to ethical practices or with persons not legally qualified to render the professional services for which the association is intended.

(2) A member shall strictly comply with the bye-laws, orders, and instructions issued by the Institution of Engineers (Pakistan) from time to time in professional practice and shall not use the association with a non-engineering corporation, or partnership as a cloak for any unethical act or acts.

ARTICLE 14

(1) A member shall give credit for engineering work to those to whom credit is due, recognize the proprietary interests of others and disclose the name of a person or persons who may be responsible for his designs, inventions, specifications, writings, or other accomplishments.

(2) When a member uses designs, plans, specifications, data, and notes supplied to him by a client or an employer or are prepared by him in reference to such client or the employer's work such designs, plans, specifications, data, and notes shall remain the property of the client and shall not be duplicated by a member for any use without the express permission of the client.

(3) Before undertaking any work on behalf of a person or persons for making improvements, plans, designs, inventions, or specifications which may justify copyright or patent, a member shall get ownership of such improvements, plans, designs, inventions, or specifications determined for the purpose of registration under the relevant copyright and patent laws.

ARTICLE 15

(1) A member shall disseminate professional knowledge by interchanging information and experience with other members or engineers and students to provide them opportunity for the professional development and advancement of engineers under his supervision.

(2) A member shall encourage his engineering employees to improve their knowledge, attend and present papers at professional meetings, and provide a prospective engineering employee with complete information on working conditions and his proposed status of employment and after employment keep him informed of any change in such conditions.

ARTICLE 16

A member employed abroad shall order his conduct according to this Code, so far as this is applicable, and the laws and regulations of the country of his employment.

ARTICLE 17

A member shall report unethical professional practices of an engineer or a member with substantiating data to the Institution of Engineers (Pakistan) as a witness, if required.

NOTES

This code is published in a booklet entitled The Institution of Engineers, Pakistan: Revised Constitution and By-Laws (Lahore, Pakistan: The Institution of Engineers, Pakistan, 1981). The booklet contains 88 numbered pages.

Part I, "Constitution," covers pp. 1-24. Part II, "By-Laws," as amended by the 174th Central Council Meeting held at Karachi 28-29 August 1980, covers pp. 28-81. This second part includes, as chapter II, "Membership," section 17 (last section), the "Professional Ethics and Code of Conduct" (pp. 35-42).

The code itself is prefaced with the statement that "The following Code of Conduct has been approved by the Central Council which shall apply to all members of the Institution of Engineers (Pakistan). This Code of Conduct is identical to the Code of Conduct approved by the Pakistan Engineering Council for its members."

The Institution of Engineers, Pakistan, is the successor to The Institution of Engineers, India, as a result of the independence and partition of these two countries. In the words of the "Preamble" of the Constitution: "whereas the Institution of Engineers (India) registered under the Indian Companies Act 1913 and incorporated by the Royal Charter 1935 existing immediately before the 14th of August, 1947 had its jurisdiction throughout India, has now its jurisdiction limited within the territory under the sovereignty of the Government of the Republic of India and had/has no successor other than 'The Institute of Engineers, Pakistan' anywhere within the territory forming Pakistan . . . 'The Institute of Engineers, Pakistan' is and shall be entitled to all rights or interests as might have accrued to or as might have deemed to accrue to the same as duly and legally constituted successor of 'The Institution of Engineers, India' in Pakistan" (pp. 1-2).

As the "Preface" notes, there was a further reorganization of the Institution of Engineers, Pakistan, in 1973 as a result of "the separation of East Pakistan" (p. vii).

SINGAPORE

• • •

THE INSTITUTION OF ENGINEERS, SINGAPORE CODE OF ETHICS

• • •

Rules for Professional Conduct

These rules shall apply to all forms of engineering employment, and for the purpose of these Rules the term "Employer" shall include the term "Client".

All members of the Institution are enjoined to conform with the letter and the spirit of the Rules set out hereunder.

(1) A member, in his responsibility to his Employer and to the profession, shall have full regard to the public interest.

(2) A member shall order his conduct so as to uphold the dignity, standing, and reputation of the profession.

(3) A member shall discharge his duties to his Employer with complete fidelity.

In whatever capacity he is engaged, he shall assiduously apply this skill and knowledge in the interests of his Employer. If he is confronted by a problem which calls for knowledge and experience which he does not possess, he shall not hesitate to inform his Employer of the fact, and shall make an appropriate recommendation as to the desirability of obtaining further advice. He shall not accept remuneration for services rendered other than from his Employer or with his Employer's permission.

(4) If called upon to give evidence or otherwise to speak on a matter of fact, he shall speak what he believes to be the truth, irrespective of its effect on his own interest, the interests of other Engineers, or other sectional interest.

(5) A member shall not maliciously or recklessly injure or attempt to injure, whether directly or indirectly, the professional reputation, prospects, or business of another Engineer.

Unless he is convinced that his duty to the public or his employer compels him to do so, he shall not express opinions which reflect on the ability or integrity of another Engineer.

(6) A member shall not improperly canvass or solicit professional employment nor offer to make by way of commission or otherwise payment for the introduction of such employment.

(7) A member shall not, in self-laudatory language in any manner derogatory to the dignity of the profession, advertise or write articles for publication, nor shall he authorize such advertisements to be written or published by any other person.

(8) A member, without disclosing the fact to his Employer in writing, shall not be a director of nor have substantial financial interest in, nor be agent for any company, firm or person carrying on any contracting, consulting or manufacturing business which is or may be involved in the work to which his employment relates; nor shall he receive directly or indirectly any royalty, gratuity or commission on any article or process used in or for the purpose of the work in respect of which he is employed unless or until such royalty, gratuity, or commission has been authorized in writing by his Employer.

He shall not report upon or make recommendation on any tender from a company or firm in which he has any substantial interest or on tenders which include such a tender unless specifically requested to do so in writing by his Employer. In this case, he shall maintain an attitude of complete impartiality.

(9) A member shall not use the advantages of a salaried position to compete unfairly with Engineers in private practice to the detriment of salaried engineers.

(10) A member who shall be convicted by a competent tribunal of a criminal offence which in the opinion of the disciplinary body renders him unfit to be a member shall be guilty of improper conduct.

(11) A member shall not, directly or indirectly, attempt to supplant another Engineer; nor shall he intervene or attempt to intervene in or in connection with engineering work of any kind which to his knowledge has been entrusted to another Engineer.

(12) A member shall not be the medium of payments made on his Employer's behalf unless so requested by his Employer; nor shall he in connection with work on which he is employed place contracts or orders except with the authority of and on behalf of his Employer.

(13) When in a position of authority over other Engineers, he shall take every care to afford to those under his direction every reasonable opportunity to advance their knowledge and experience.

He shall ensure that proper credit is given to any subordinate who has contributed in any material way to work for which he is responsible.

(14) A member shall not use for his personal gain or advantage, nor shall he disclose, any confidential information which he may acquire as a result of special opportunities arising out of work for his employer.

(15) In the preparation of plans, specification and contract documents, and on the supervision of construction work, a member shall assiduously watch and conserve the interests of his employer. However, in the interpretation of contract documents, he shall maintain an attitude of scrupulous impartiality as between his employer on the one hand, and the contractor on the other, and shall, as far as he can, ensure that each party in the contract shall discharge his respective duties and enjoy his respective rights as set down in the contract agreement.

SRI LANKA THE INSTITUTION OF ENGINEERS CODE OF ETHICS

• • •

120/15 Wijerama Mawatha
Colombo 7, Sri Lanka

BY-LAWS–APPENDIX I

• • •

1989

• • •

FORWARD

The need for professional ethics is recognized in most professions and the by-laws of the Institution of Engineers, Sri Lanka, require its members to observe certain rules of conduct.

This Code was approved by the General Membership at the Annual General Meeting held on 31st October, 1989.

For society to recognize the integrity and to trust the judgment of engineers they are required to comply with the Code of Ethics set out in this booklet.

Members acting in accordance with this Code would create an image that would stand out as a beacon of competence as well as of uprightness and integrity.

D.G. SENADHIPATHY, PRESIDENT 1990/91
1st March, 1991

CODE OF ETHICS

• • •

Clause 1. Engineers shall hold paramount the safety, health and welfare of the public and proper utilization of funds in the performance of their professional duties. It shall take precedence over their responsibility to the profession, to sectional or private interests, to employers or to other Engineers.

Clause 2. Engineers shall always act in such a manner as to uphold and enhance the honor, integrity and dignity of the profession while safeguarding public interest at all times.

Clause 3. Engineers shall build their reputation on merit and shall not compete unfairly.

Clause 4. Engineers shall perform professional services only in the areas of their competence.

Clause 5. Engineers shall apply their skills and knowledge in the interest of their employer or client for whom they shall act, in professional matters, as faithful agents or trustees, so far as they do not conflict with the other requirements listed here and the general public interest.

Clause 6. Engineers shall give evidence, express opinions or make statements in an objective and truthful manner.

Clause 7. Engineers shall continue their professional development throughout their careers and shall actively assist and encourage engineers under their direction to advance their knowledge and experience.

RULES

• • •

Clause 1

Engineers shall hold paramount the safety, health and welfare of the public and proper utilization of the funds in the performance of their professional duties. It shall take precedence over their responsibility to the profession, sectional or private interests, to employers or to other engineers.

As the first requirement places the interests of the community above all other, Engineers—

Rule 1.1 shall be objective and truthful in professional reports, statements or testimony. They shall include all relevant and pertinent information in such reports, statements or testimony.

Rule 1.2 shall endeavor at all times to maintain engineering services essential to public welfare.

Rule 1.3 shall work in conformity with recognized engineering standards so as not to jeopardize the public welfare, health or safety.

Rule 1.4 shall not participate in assignments that would create conflict of interest between their clients or employers, and the public.

Rule 1.5 shall, in the event of their judgment being overruled in matters pertaining to welfare, health or safety of the community, inform their clients or employers of the possible consequences and bring to their notice their (Engineers') obligations as professionals to inform the relevant authority.

Rule 1.6 Shall contribute to public discussion on engineering matters in their areas of competence if they consider that by so doing they can constructively advance the well-being of the community.

Rule 1.7 having knowledge of any alleged violation of this Code shall co-operate with the proper authorities in furnishing such information or assistance as may be required.

Rule 1.8 shall not knowingly participate in any act which will result in waste or misappropriation of public funds.

Clause 2

Engineers shall always act in such a manner as to uphold and enhance the honor, integrity and dignity of the profession while safeguarding public interest at all times.

This requires that the profession should endeavor by its behavior to merit the highest esteem of the community. It follows therefore that engineers—

Rule 2.1 shall not involve themselves with any business or professional practice which they know to be fraudulent or dishonest in nature.

Rule 2.2 shall not use association with other persons, corporations or partnerships to conceal unethical acts.

Rule 2.3 shall not continue in partnership with, or act in professional matters with any engineer who has been removed from membership of this Institution because of improper conduct.

Clause 3

Engineers shall build their reputation on merit and shall not compete unfairly.

This requirement is to ensure that engineers shall not seek to gain a benefit by improper means. It follows that engineers—

Rule 3.1 shall neither pay nor offer, directly or indirectly, inducements including political contribution.

Rule 3.2 shall promote the principle of engagement of engineers upon the basis of merit. They shall uphold the principle of adequate and appropriate remuneration for professional engineering staff and shall give due consideration to terms of engagement which have the approval of the Professional's appropriate association.

Rule 3.3 shall not attempt to supplant another engineer, employed or consulting, who has been appointed.

Rule 3.4 shall neither falsify nor misrepresent their own or their associate's qualifications, experience and prior responsibilities.

Rule 3.5 shall not maliciously do anything to injure, directly, or indirectly, the reputation, prospects or business of other.

Rule 3.6 shall not use the advantage of a privileged position to compete unfairly with other engineers.

Rule 3.7 shall exercise due restraint in explaining their own work and shall refrain from unfair criticism of the work of other engineers.

Rule 3.8 shall give proper credit for professional work to those to whom credit is due and acknowledge the contribution of subordinates and others.

Clause 4

Engineers shall perform professional services only in the areas of their competence.

To this end engineers—

Rule 4.1 shall undertake assignments only when qualified by education and experience in the specific technical fields involved. If an assignment requires qualification and experience outside their fields of competence they shall engage competent professionals with necessary qualifications and experience and keep the employers and clients informed of such arrangements.

Rule 4.2 shall not affix their signature to any plans or documents dealing with subject matter in which they lack competence, or to any plan or document not prepared under their direction or control.

Clause 5

Engineers shall apply their skills and knowledge in the interest of their employer or client for whom they shall act, in professional matters, as faithful agents or trustees, so far as they do not conflict with other requirements listed here and the general public interest.

It follows that engineers—

Rule 5.1 shall at all times avoid all known or potential conflicts of interest. They should keep their employees or clients dully informed on all matters, including financial interests, which could lead to such a conflict, and in no circumstances should they participate in any decision which could involve them in conflict of interest.

Rule 5.2 shall when acting as administrators of a contract be impartial as between the parties in the interpretation of the contract.

Rule 5.3 shall not accept compensation, financial or otherwise from more than one party for services on the same project, unless the circumstances are fully disclosed and agreed to, by all interested parties.

Rule 5.4 shall neither solicit nor accept financial or other valuable consideration, including free engineering designs, from material or equipment suppliers for specifying their products (except such designs obtained with the knowledge and consent of the employer or client).

Rule 5.5 shall neither solicit nor accept gratuities, directly or indirectly from contractors or their agents, or other parties dealing with their clients or employers in connection with work for which they are responsible.

Rule 5.6 Shall advise their clients or employers when as a result of their studies they believe that a project will not be viable.

Rule 5.7 Shall neither disclose nor use confidential information gained in the course of their employment without express permission (except where public interest and safety are involved).

Rule 5.8 shall not complete, sign, or seal plans and/or specifications that are not of a design safe to the public health and welfare and in conformity with accepted engineering standards. If the client or employer insists on such unprofessional conduct, they shall notify the proper authorities and withdraw from further service on the project.

Clause 6

Engineers shall give evidence, express opinion or make statements in an objective and truthful manner.

It follows that—

Rule 6.1 engineers' professional reports, statements or testimony before any tribunal shall be objective and such opinions shall be expressed only on the basis of adequate knowledge and technical competence in the area, but this does not preclude a considered speculation based intuitively on experience and wide relevant knowledge.

Rule 6.2 engineers shall reveal the existence of any interest, pecuniary or otherwise that could be taken to effect their judgment in a technical matter about which they are making a statement or giving evidence.

Clause 7

Engineers shall continue their professional development throughout their careers and shall actively assist and encourage engineers under their direction to advance their knowledge and experience.

The requirement here is that engineers shall strive to widen their knowledge and improve their skill in order to achieve a continuing improvement of the profession. It follows therefore that engineers—

Rule 7.1 shall encourage their professional employees and subordinates to further their education, and

Rule 7.2 shall take a positive interest in and encourage their fellow engineers actively to support the Institution and other professional engineering bodies which further the general interest of the profession.

GUIDE LINES FOR PROFESSIONAL CONDUCT

• • •

1. Engineers shall be guided in all their professional relations by the highest standards of integrity.

   a. Engineers shall admit and accept their own errors when proven wrong and refrain from distorting or altering the facts in an attempt to justify their decision.

   b. Engineers shall advise their clients or employers when they believe a project will not be successful

   c. Engineers shall not accept assignments outside their employment to the detriment of their regular work or interest. Before accepting any assignments outside their employment they will notify their employers and obtain their prior permission.

2. Engineers shall at all times strive to serve the public interest.

   a. Engineers shall seek opportunities to be of constructive service in civil affairs and work for the advancement of the safety, health and well being of their community.

   b. In public or private sector employment engineers shall refrain from participating knowingly in any act that will result in waste or misappropriation of employers funds.

   3. Engineers shall refrain from all conduct or practice which is likely to discredit the profession or deceive the public.

   a. Engineers shall refrain from using statements containing material misrepresentation of fact, or omitting material fact.

   b. Engineers shall refrain from showmanship, or self-laudation or from attempting to attract clients thereby and making derogatory statements about others. Consistent with the foregoing Engineers may advertise for recruitment of personnel.

   c. Consistent with the foregoing: Engineers may publish articles in the press or in technical journals but such articles shall not imply credit to the author for work performed by other.

4. Engineers shall not disclose confidential information concerning the business affairs or technical processes of employers without their consent.

5. Engineers shall not be influenced in their professional duties by conflicting interests.

   a. Engineers shall not accept financial or other consideration, from material or equipment suppliers for specifying their product.

   b. Engineers shall not accept commissions or allowances, directly or indirectly from contractors or other parties in connection with work for which the Engineer is responsible.

   c. Consistent with the foregoing Engineers may publish articles in the press on in technical journals but such articles shall not imply credit to the author for work performed by other.

6. Engineers shall uphold the principle of appropriate and adequate compensation for those engaged in engineering work.

   a. Engineers shall not accept remuneration from either an employee or employment agency for giving employment.

   b. Engineers, when employing other engineers, shall offer a salary according to professional qualifications, experience and recognized standards.

7. Engineers shall not compete unfairly with other engineers to obtain employment or advancement in employment or in seeking professional engagements by taking advantage of their position, by criticizing other engineers, or by other improper or questionable means.

   a. Engineers shall not request, propose, or accept a professional commission under circumstances in which their professional judgment may be compromised.

   b. Engineers in salaried position shall accept part-time engineering work only with the expressed permission of the employer and at recognized rates for such work.

   c. Engineers shall not use equipment, supplies, laboratory, or office facilities of an employer to carry out outside private work without the consent of the employer.

8. Engineers shall not attempt to injure, maliciously or falsely, (directly or indirectly) the professional reputation, prospects practice or employment of other engineers, nor indiscriminately criticize other engineers' work. Engineers who believe others are guilty of unethical or illegal practice shall present such information to the proper authority for action.

   a. Engineers in private practice shall not review the work of another engineer for the same client, except with the knowledge of such engineer, or unless the connection of such engineer with the work has been terminated for un-ethical practices.

   b. Engineers in governmental, industrial or educational employ are entitled to review and evaluate the work of other engineers when so required by their employers.

   c. Engineers in sales or industrial employ shall not criticize products of other manufactures which are similar to their own.

9. Engineers shall accept personal responsibility for their professional activities.

   a. Engineers shall conform with state registration laws in the practice of engineering.

   b. Engineers shall not use association with a non-engineer, a corporation, or partnership, as a "cloak" for unethical acts, but must accept personal responsibility for their own professional acts.

10. Engineers shall give credit for engineering work of other engineers to whom credit is due, and will recognize the proprietary interests of others.

    a. Engineers shall, when possible, name the person or persons who may be individually responsible for designs, inventions, writings, or other accomplishments.

    b. Engineers using designs supplied by client shall recognize that the designs remain the property of the client and shall not be duplicated by the Engineer for others without expressed permission.

    c. Engineers, before undertaking work for others which may result in the engineers producing inventions, plans, designs, improvements or other such, which may justify copyrights or patents, should enter into a position agreement regarding ownership.

    d. Engineers' designs, data, records, and notes referring exclusively to an employer's work shall not be sued for another client unless with the expressed permission of the employer for whom such work was carried out.

11. Engineers shall cooperate in extending the effectiveness of the profession by interchanging information and experience with other Engineers and Students, and will endeavor to provide opportunity for the professional development and advancement of engineers under their supervision.

    a. Engineers shall encourage Engineer employees' efforts to improve their education.

    b. Engineers shall encourage Engineer employees to attend and present papers at professional and technical society meetings.

    c. Engineers shall urge Engineer employees to become registered engineers at the earliest possible date.

    d. Engineers shall assign a professional engineer duties of a nature to utilize his full training and experience, in so far as is possible, and delegate lesser functions to sub-professionals or to technicians.

    e. Engineers shall provide a prospective employee with complete information on working conditions and proposed status of employment, and after engaging will keep such employees informed of any proposed changes.

SWEDEN

SWEDISH FEDERATION OF CIVIL ENGINEERS CODE OF ETHICS

• • •

Code of Honor for Civil Engineers

1. The civil engineer should feel, while practicing his profession, a personal responsibility that technology will be utilized in a fashion which benefits humanity, the environment, and society.
2. The civil engineer should strive to improve technology and technical expertise in the direction of a more efficient utilization of resources without detrimental side effects.
3. The civil engineer should be prepared to share his knowledge in public and private contexts in order to reach the best possible basis for a decision and to illustrate the capacities and the risks of technology.
4. The civil engineer should not work within or collaborate with corporations or organizations of a questionable character or ones whose goals are in conflict with the civil engineer's personal convictions.
5. The civil engineer should show complete loyalty to employers and co-workers. Any difficulties in this respect should be dealt with in an open discussion and, first of all, at the place of work.
6. The civil engineer is not permitted to use improper methods in the competition for employments, assignments, or commissions and, furthermore, must not attempt to damage the reputation of colleagues through unjustified accusations.
7. The civil engineer should respect the confidential nature of especially entrusted information, as well as the rights of others with regard to ideas, inventions, research, plans, and designs.
8. The civil engineer is not allowed to favor unauthorized interests and should openly account for financial and other interests that could affect the trust in his impartiality and judgment.
9. The civil engineer should, privately and in public, in speech and in writing, strive for an objective mode of presentation and avoid incorrect, misleading, or exaggerated statements.
10. The civil engineer should actively support colleagues who find themselves in trouble because of actions of the kind described in these rules and should prevent any violations against the rules, according to his best judgment.

TRANSLATED BY BIRGITTA D. KNUTTGEN

NOTES

This code is promulgated by means of a one-page document with a simple double-line border suitable for framing. As a kind of preface to the code it includes the following statement:

Technology and the natural sciences are powerful tools in the service of humankind, for better and for worse. They have thoroughly transformed society and will continue to have a profound effect on humankind also in the future.

The civil engineers are the bearers and managers of technical knowledge. Therefore, they are also given the special responsibility of ensuring that technology will be used in the best interests of society and humankind and that it will be transferred to future generations in an improved state.

In 1929, the Swedish Technological Association established a Code of Honor. The developments in society and technology have warranted a revision of the code. To provide support for the personal decision-making of a civil engineer with regard to ethical considerations, The Swedish Federation of Civil Engineers, on the 15th of November, 1988, established the following.

SWITZERLAND

SWISS TECHNICAL ASSOCIATION CODE OF ETHICS

Swiss Technical Association Honor Code

With reference to your inquiry of 10 April 1990, we regret to inform you that our association has not adopted an actual honor code. On the other hand, we have a so-called Chamber of Experts (architects, engineers), whose members can be consulted for expert opinions of all kinds. The members of this chapter are subject to an honor code. We have enclosed the version currently in force.

HONOR CODE FOR STV EXPERTS

The STV Expert is committed to uphold and apply the following principles:

1. With his specialized knowledge and competence as his guide, the STV Expert safeguards the legitimate concern of his employers. He does not overestimate his own abilities.
2. The STV Expert, in fulfilling his assignments, bears in mind the dignity of his profession. He does not participate in any procedure that could be injurious to this dignity.
3. The STV Expert is committed to maintaining professional secrecy in all aspects of his assignments.
4. The STV Expert, in his capacity as expert or arbitrator, is committed to being strictly objective. Should the danger of a conflict of interest arise, he is obliged to refuse or give up his position.
5. The STV Expert accepts no remunerations or personal privileges from any third party. As the representative or advisor to an employer, he acts with complete independence.
6. The STV Expert observes the appropriate technical standards. He is obliged to constantly further his studies in order to remain at the level of expertise required by his profession.
7. The STV Expert charges the customary fee for his area of expertise.14 March 1990.

UNITED KINGDOM

INSTITUTION OF CIVIL ENGINEERS CODE OF ETHICS

1-7 Great George Street, Westminster
London SW1P 3AA, England

Founded: 1818
Royal Charter: 1828
Members: 4,500

Rules for Professional Conduct

Made by the Council on 19 March 1963, and modified in 1971, 1973 and 1982 in accordance with By-law 32.

Expressions used in these Rules shall have the meaning if any assigned to them by the By-laws, Regulations, and Rules of the Institution. These Rules apply to all forms of engineering employment, and for the purpose of these Rules the term "Employer" shall include the term "Client."

1. A member, in his responsibility to his Employer and to the profession, shall have full regard to the public interest, particularly in matters of health and safety.
2. A member shall discharge his professional responsibilities with integrity.
3. A member shall discharge his duties to his Employer with complete fidelity. He shall not accept remuneration for services rendered other than from his Employer or with his Employer's permission.
4. A member shall not maliciously or recklessly injure or attempt to injure, whether directly or indirectly, the professional reputation, prospects or business of another Engineer.
5. A member shall not improperly canvass or solicit professional employment nor offer to make by way of commission or otherwise payment for the introduction of such employment.
6. A member shall not, in self-laudatory language or in any manner derogatory to the dignity of the profession, advertise or write articles for publication, nor shall he authorize such advertisements to be written or published by any person.
7. A member, without disclosing the fact to his Employer in writing, shall not be a director of nor have a substantial financial interest in, nor be agent for any company, firm or person carrying on any contracting, consulting or manufacturing business which is or may be involved in the work to which his employment relates; nor shall he receive directly or indirectly any royalty, gratuity or commission on any article or process used in or for the purposes of the work in respect of which he is employed unless or until such royalty, gratuity or commission has been authorized in writing by his Employer.
8. A member shall not use the advantages of a salaried position to compete unfairly with other engineers.
9. A member in connection with work in a country other than his own shall order his conduct according to these Rules, so far as they are applicable; but where there are recognized standards of professional conduct, he shall adhere to them.
10. A member who shall be convicted by a competent tribunal of a criminal offence which in the opinion of the disciplinary body renders him unfit to be a member shall be deemed to have been guilty of improper conduct.
11. A member shall not, directly or indirectly, attempt to supplant another Engineer, nor shall he intervene or attempt to intervene in or in connection with engineering work of any kind which to his knowledge has already been entrusted to another Engineer.
12. A member shall not be the medium of payments made on his Employer's behalf unless so requested by his Employer, nor shall he in connection with work on which he is employed place contracts or orders except with the authority of and on behalf of his Employer.
13. A member shall afford such assistance as he may reasonably be able to give to further the Education and Training of candidates for the Profession.

NOTES

This code is promulgated in the last page of a 28-page yellow pamphlet (1985) that includes its Royal Charter, By-laws, Regulations, and Rules.

By-law 32, to which reference is made in the preliminary indication of adoption dates, reads as follows: "Without prejudice to the generality of the last preceding By-law the Council may, for the purpose of ensuring the fulfillment of this requirement, make, amend, and rescind Rules to be observed by Corporate and Non-Corporate Members, with regard to their conduct in any respect which may be relevant to their position or intended position as members of the Institution and may publish directions or pronouncements as to specific conduct which is to be regarded as proper or as improper (as the case may be)."

The current SCET (Institution of Civil Engineers and Technicians) code is a result of past mergers with other professional organizations, i.e. in 1984 with The Institution of Municipal Engineers and again in 1989 with The Society of Civil Engineering Technicians and the Board of Incorporated Engineers and Technicians.

INSTITUTION OF MECHANICAL ENGINEERS CODE OF ETHICS

• • •

1 Birdcage Walk, Westminster
London SW1H 9JJ, England

Founded: 1847
Members: 78,000

PROFESSIONAL CODE OF CONDUCT

• • •

1. INTRODUCTION

The Institution of Mechanical Engineering as a learned body has three main functions: to promote the development of mechanical engineer, to govern the qualifications of its members, and to control their professional conduct. This leaflet, issued by the Professional Affairs Board of the Institution is concerned with the third of these functions and its surrounding circumstances. In this connection members are also referred to other relevant guides issued by the Institution, viz: Health & Safety at Work, Professional Engineers and Trade Unions (PAB 2/83) Guide for Consultancy and Product Liability.

2. CLASSES OF MEMBERSHIP

Under By-Law 2, the membership is divided into Corporate Members, (those entitled to be heard and vote at annual, ordinary, and special meetings) and Non-Corporate Members (with no such privileges except at ordinary meetings where they may be heard on mechanical engineering or allied subjects). The former group consists of three classes of persons viz:

Fellows

Members

The latter group (Non-Corporate Members) consists of six classes of persons viz:

Honorary Fellows who when elected Honorary Fellows were not already Corporate Members.

Companions

Associates

Associate Members

Graduates

Students

3. ABBREVIATED TITLES AND DESCRIPTION OF MEMBERSHIP (BY-LAW 6)

Corporate members may abbreviate their titles to Hon-FIMechE, FIMechE, or MIMechE as applicable, while Non-Corporate members may not use abbreviated titles except Honorary Fellows (Hon FIMechE) and Associate Members (AMIMechE) and, in certain cases of long-standing membership, Companions (CIMechE). By-LAW 6 (iii) states "a member shall not use or permit to be used any of the said titles or abbreviations in letters larger or bolder than those used in the name of the member which they follow."

4. CONDUCT OF MEMBERS (BY-LAW 32)

4.1 The Professional Conduct of all members is governed by By-Law 32 and its associated Rules of Conduct. Extracts are given below.

> 32. (i) In order to facilitate the advancement of the science of mechanical engineering by preserving the respect in which the community holds persons who are engaged in the profession of mechanical engineering, every member of any class shall at all times so order his conduct as to uphold the dignity and reputation of the Institution and act with fairness and integrity towards all persons with whom his work is connected and towards other members.
>
> (ii) Every Corporate Member shall at all times so order his conduct as to uphold the dignity and reputation of his profession, and to safeguard the public interest in matters of safety and health and otherwise. He shall exercise his professional skill and judgment to the best of his ability and discharge his professional responsibilities with integrity.

4.2 By-Law 32 (iii) allows the Council of the Institution to make, vary, or rescind Rules of Conduct for any class of member provided approval is received at a Special Meeting of Corporate members.

The only Rules of Conduct so approved are repeated below:

Pursuant to By-Law 32.

In these Rules, 'member' means a member of any class referred to in By-Law 2, and 'employer' includes 'client'.

1. A member whose professional advice is not accepted shall take all reasonable steps to ensure that the person overruling or neglecting his advice is aware of any danger which the member believes may result from such overruling or neglect.
2. A member shall not recklessly or maliciously injure or attempt to injure whether directly or indirectly the professional reputation, prospects, or business of another.
3. A member shall inform his employer in writing of any conflict between his personal interest and faithful service to his employer.
4. A member shall not improperly disclose any information concerning the business of his employer or any past employer.

5. A member shall not solicit or accept remuneration in connection with professional services rendered to his employer other than from his employer or with his employer's consent; nor shall he receive directly or indirectly any royalty, gratuity, or commission on any article or process used in or for the purpose of the work in respect of which he is employed unless or until such royalty, gratuity, or commission has been authorized in writing by his employer.
6. Where a member of any class has been (a) adjudicated bankrupt or (b) convicted of an offense, he shall be deemed to have been guilty of improper conduct if the circumstances of the offense are such as to constitute a breach of the By-Laws or of these Rules.

4.3 Members frequently seek guidance from the Institution over Rule 1. In considering this question of engineer should have a clear understanding of what he is accountable for. This is best achieved by reference to agreed written terms of reference. If an engineer, in the course of his duties makes a decision which is overruled by his employer and this, in his view, would be detrimental to public health and safety, then his obligation to his Institution will be discharged by issuing a written statement to his employer setting out the reasons why he believes public health and safety will be affected. As an employee, an engineer has no authority to direct his employer, therefore he cannot be held responsible for his employer's conduct. If the employer's action should prove to be detrimental to public health and safety, then this would be a matter for adjudication by the Courts.

Employed engineers finding themselves in such a situation are advised, in the first instance, to seek the view of fellow members of the Institution with whom they work. If further guidance is required, then the Professional Services Manager should be approached at Institution H.Q. Self-employed consulting engineers are able to resolve their own conflicts with professional obligations by being able to choose assignments and methods of working.

4.4 The obligations arising from the Institution's Codes and Rules of Conduct may be interpreted as requiring each member to behave so as:

to maintain and develop his Professional competence in the engineering field in which he practices;

to accept personal responsibility for his work and for those for whom he is accountable;

to give objective and reliable advice on matters within his field of practice when called upon to do so;

to avoid giving professional advice in engineering matters outside his competence;

to avoid malicious injury to the reputation, prospects, or business of others;

to avoid self-laudatory language in advertising his services or in published articles.

5. HEALTH AND SAFETY AT WORK ACT 1974

The 1974 Act imposes statutory duties on all persons at work and failure to comply with these may lead to criminal proceedings against them. All members are therefore expected to be familiar with the provisions of the Act and to read the guidance Booklet published by the Institution. Membership of a Professional body imposes on members the additional obligation of bringing the attention of their colleagues to the requirements of the 1974 Act.

6. PROFESSIONAL NEGLIGENCE

Professional negligence is discussed in the IMechE Booklet "Product Liability". A court judgment going against a member accused of professional negligence may under By-Law 33 (Disciplinary action), be taken as prima facie evidence of improper conduct. However, this is not necessarily so and will always depend upon all the circumstances of the case.

7. THE ENGINEER AS AN EXPERT WITNESS

A member called upon to testify as an Expert Witness should remember that he has a professional obligation to assist the court in reaching an equitable verdict and not to act as an advocate for whoever pays his fee. Guidance on this subject is provided in the IMechE Booklet "Guide for Consultancy".

8. TRADE UNION AND INDUSTRIAL ACTION

The act of joining a Trade Union is not contrary to the Institution's Rules of Professional Conduct. Any member of the Institution is free to join or not to join a Trade Union and if he so wishes to join, then the choice of a Union lies with him, but he is advised, where possible, to join one which supports his professional obligations and status.

Members are not forbidden to engage in industrial action provided such action does not conflict with their professional obligations as set out in the By-Laws. It is also important to exhaust the negotiating procedures before considering action. The Employment Act 1982 makes special provision to protect professional employees from dismissal arising from a conflict between professional obligation and obligations to a Trade Union. Guidance on all aspects of Union membership is given in IMechE leaflet reference PAB 2/83.

9. ADVERTISING AND USE OF SITE BOARDS

Advice on advertising and use of site boards is provided in the IMechE Booklet "Guide for Consultancy".

10. EXPULSION AND OTHER DISCIPLINARY ACTION (BY-LAW 33)

By-Law 33 provides the Council of the Institution with powers to investigate allegations of improper conduct lodged against any member and allows disciplinary action to be taken where a member is found guilty.

By-Law 33(i) is reproduced below:

33. (i) For the purposes of this By-Law improper conduct shall mean:

(a) the making of any false representation in applying for election or transfer to any class of membership of the Institution, or

(b) any breach of these By-Laws or of any Regulation or Rule or direction made or given thereunder, or

(c) any conduct injurious to the Institution.

Under the Disciplinary Regulations pursuant to By-Law 33, two Committees are appointed to investigate and adjudicate upon allegations of improper conduct: they are the Investigating Panel and the Disciplinary Board. Where the Investigating Panel finds that there is a prima facie case to answer, the accused member will be invited to put forward his observations in writing to the Panel for further consideration. If a prima facie case is still evident and the matter is not trivial, then the case goes to the Disciplinary Board for a full hearing. The accused member will be given a full and fair opportunity of being heard, of calling witnesses, and of cross-examining any witnesses testifying before the Board. He will be given the opportunity of being represented by a lawyer or by any other member of the Institution of his own choice. The full procedure covering disciplinary action is set out in the Institution's Disciplinary Rules.

For convenience the use of the words "he" or "his" in the text of this leaflet is to be read as being applicable to both sexes.

November, 1983

NOTES

Promulgation is by means of a two-sided yellow leaflet. At the top in a bold box is the statement: "Members should keep this leaflet for future reference."

Code of Professional Ethics

It is considered contrary to ethics and incompatible with the dignified exercise of the profession for a member of the Academy of Engineers of Venezuela:

1. To act in any way that serves to diminish the honor, respectability, and the virtues of honesty, integrity, and truthfulness that should serve as the base for a full and complete exercise of the profession.
2. To violate or to permit the violation of laws, ordinances, and regulations related to professional activity.
3. To neglect the maintenance and improvement of his technical knowledge thus becoming unworthy of the trust society places in the professional activity.
4. To put himself forward for employment in specializations and operations for which the applicant has no capacity, preparation, and reasonable experience, so as to describe or advertise himself in laudatory terms or in any manner which goes against the dignity and seriousness of the profession.
5. To neglect because of friendship, convenience, or coercion the fulfillment of contractual obligations when it is his job to respect and to fulfill them.

6. To offer, solicit, or borrow professional services by means of payments below those established as the minimum by the Academy of Engineers of Venezuela.
7. To lay out projects or prepare reports with negligence or inattention or with overly optimistic criteria.
8. To sign plans laid out by others and to take responsibility for projects or works that are not under his immediate direction, review, or supervision.
9. To take charge of works without having undertaken all of the necessary technical studies for their correct execution, when for their realization schedules incompatible with good professional practice have been set up.
10. To concur deliberately or to invite competitive bidding.
11. To offer, to give, or to receive commissions or loans and to solicit influences or to use them for obtaining or securing professional work or for creating privileged positions in their performance.
12. To use the advantages inherent in a job to compete with the independent practice of other professionals.
13. To act against the reputation or the legitimate interests of other professionals.
14. To acquire interests which directly or indirectly clash with the interests of the company or client that employs his services, or to take charge without knowledge about those parties interested in works in which conflicting interests exist.
15. To act deliberately against the principles of justice and loyalty in his relations with clients, subordinate personnel, and workers, especially in relation to the last, in reference to the maintenance of fair working conditions and their just participation in profits.
16. To intervene directly or indirectly to the destruction of natural resources, or to neglect the corresponding action to avoid the production of products that contribute to environmental deterioration.
17. To act in any way that would permit or facilitate contracting with foreign companies for studies or projects, construction or inspection of works, when in the judgment of the Academy of Engineers there exists in Venezuela the capacity to perform these tasks.

TRANSLATED BY ANNA H. LYNCH AND CARL MITCHAM

NOTES

This code is promulgated in two forms:

(1) It is included in a booklet entitled Reglamento interno [Internal regulation] (Caracas: Colegio de Ingenieros de Venezuela, 1988). This is a booklet of 137 numbered pages.

Following a prefatory note and table of contents, the first major part of this booklet prints decree 444 (24 November 1958), "Ley de Ejercicio de la Ingenieria, la Arquitectura y Profesiones Afines" [Law on the practice of engineering, architecture and related professions], pp. 3-12. This is followed by a commentary which includes both general considerations on the history and development of the Association and remarks on each article in the decree (pp. 15-27), with a one page summary of "Conclusions from the First Interamerican Workshop of University Professionals," Montevideo, November 1957.

Then comes the code of ethics (pp. 29-30). This printing of the code notes that point 15 was adopted on June 27, 1957; point 16 on October 4, 1976; and point 17 on June 27, 1980.

The second major of the booklet contains, in accord with article 21 of the law of 1958, the by-laws of the Association (pp. 31-132) as of August 13, 1984.

(2) The code is also printed as a separate, one-page document suitable for framing.

FÉDÉRATION EUROPÉENNE D'ASSOCIATIONS NATIONALES D'INGÉNIEURS (FEANI, EUROPEAN FEDERATION OF NATIONAL ENGINEERING ASSOCIATIONS) CODE OF ETHICS

The FEANI Code of Conduct is additional to and does not take the place of any Code of Ethics to which the registrant might be subject in his own country.

All persons listed in the FEANI Register have the obligation to be conscious of the importance of science and technology for mankind and of their own social responsibilities when engaged in their professional activities.

They exercise their profession in accordance with the normal rules of good conduct of European societies, respecting particularly the professional rights and the dignity of all those with whom they work.

They thereby undertake to comply with and maintain the following code of ethics.

1. Personal Ethics

The Engineer shall maintain his competence at the highest level, with a view to providing excellence of services in accordance with what is regarded as good practice in his profession and having regard to the laws of the country in which he is working.

His professional integrity and intellectual honesty shall be the guarantees of his impartiality of analysis, judgment and consequent decision. He shall consider himself bound in conscience by any business confidentiality agreement into which he has freely entered.

He shall not accept any payment except those agreed with his relevant employer.

He shall display his commitment to the engineering profession by taking part in the activities of its Associations, notably those which promote the profession and contribute to the continuing training of their members.

He shall use only titles to which he has a right.

2. Professional Ethics

The Engineer shall accept assignments only within the area of his competence.

Beyond this limit, he shall seek the collaboration of appropriate experts.

He is responsible for organizing and executing his assignments.

He must obtain a clear definition of the services required of him. Executing his assignments, he shall take all necessary steps to overcome any difficulties encountered whilst ensuring the safety of persons and property.

He shall take remuneration corresponding to the service rendered and the responsibilities assumed.

He shall try to ensure that the remuneration of each be consonant with the service rendered and the responsibilities assumed.

He strives for a high level of technical achievement which will also contribute to and promote a healthy and agreeable environment for his fellowmen.

3. Social Responsibility

The Engineer shall

- respect the personal rights of his superiors, colleagues and subordinates by taking due account of their requirements and aspirations, provided they conform to the laws and ethics of their professions,
- be conscious of nature, environment, safety and health and work to the benefit and welfare of mankind,
- provide the general public with clear information, only in his field of competence, to enable a proper understanding of technical matters of public interest,

- treat with the utmost respect the traditional and cultural values of the countries in which he exercises his profession.

N.B. : In this text, "he" and "his" are taken respectively for "he/she" and "his/her."

FOUNDING STATEMENT OF THE INTERNATIONAL NETWORK OF ENGINEERS AND SCIENTISTS FOR GLOBAL RESPONSIBILITY (INES)

• • •

November 29, 1991

Rapid changes in our environment and our societies are forcing us to become more conscious of our role in the world. Science and technology are employed in a worldwide competition for military and economic power. The impacts of this competition have global implications. We have entered a phase in which global developments are in conflict with basic requirements for human survival. Large stocks of weapons for mass destruction, the over-exploitation of common limited resources, and a heavily unbalanced world economy provide fundamental challenges to human civilization and may even threaten its further existence. The end of the cold war and the progress towards democracy and national self-determination in many regions provide important opportunities to resolve long-standing threats to international security. Dismantling the vast nuclear and conventional arsenals and demilitarizing international relations remains a high priority. However, after the decline of international bipolar divisions, many major problems remain. Regional and intercommunal conflicts, together with the proliferation of weapons technologies, threaten local and global security. Newly recognized problems such as climate change, ozone depletion and loss of species diversity raise new challenges regarding energy use, population growth and other aspects of development. Gross inequalities and injustice between and within industrialized and developing countries undermine military, economic, social and environmental security.

Developments in science and technology have helped to create global interdependence and to make us more profoundly aware of the planet's condition. Many engineers and scientists play a key role in both the processes that threaten international security and those that provide hope for the future. International organizations and norms are being developed to tackle common problems, and many structures for regional cooperation are emerging to overcome national divisions.

The engineering and scientific community is intrinsically international, with informal networks and channels of communication. However most existing professional organizations are highly specialized. It is now time to establish a multidisciplinary international network of engineers and scientists for global responsibility to promote the following aims:

- to encourage and facilitate international communication among engineers and scientists seeking to promote international peace and security, justice and sustainable development, and working for a responsible use of science and technology. This includes:
- to work for the reduction of military spending and for the transfer of resources thus liberated to the satisfaction of basic needs,
- to promote environmentally sound technologies, taking into account long-term effects,
- to enhance the awareness of ethical principles among engineers and scientists, and to support those who have been victimized for acting upon such principles.

In order to accomplish these aims, members and bodies of the network will

Promote collaborative and interdisciplinary research relating to such issues,

Publicize relevant research, contribute to education and scientific training and inform the public and professional colleagues,

Facilitate and undertake expert and responsible contributions to relevant policy debates, and advocate changes in national and international policies pertinent to the above aims.

We are convinced that it is our continuous task to reflect on values and standards of behavior which take into account basic human needs and our interrelationship with the biosphere. Membership of the network is open to non-governmental organizations and individual engineers and scientists. It will be a network seeking to provide a central resource for, and to promote coordination among, its members. We hope that the synergy of different approaches will facilitate steps from vision toward action.

UNIÓN PANAMERICANA DE ASOCIACIONES DE INGENIEROS

• • •

(UPADI, PANAMERICAN UNION OF ASSOCIATIONS OF ENGINEERS)

• • •

CODE OF PROFESSIONAL ETHICAL CONDUCT

• • •

I. The Fundamentals

1. The Code of Professional Ethics adopted by UPADI member organizations is intended to establish the responsibilities, to regulate rights, and to fix norms of conduct that should be observed by all engineers, both within their professional circles as well as within the larger society, nationally as well as internationally.
2. It is the imperative duty of the Pan-American engineers to maintain their professional and moral conduct at the highest level, in defense of the prestige and rights of the profession, and to be vigilant regarding the correct and proper practice and observation at all times of the dignity, integrity, and respect and loyal adherence to this code.
3. The UPADI engineers shall constantly seek to improve their knowledge and their profession, communicating and sharing their knowledge and experience, in an attempt to provide opportunities for the professional development of their colleagues.

II. Professional Practices

1. The practice of the engineering profession shall be understood exclusively in terms of engineers who hold university titles qualifying them in diverse specialties, in accordance with the current legislation in each country.
2. The practice of engineering shall be considered first and foremost a social function. Projects which might be used against the public interest should be refused, thus avoiding situations which involve danger and constitute a threat to life, health and the environment, or affect property and other human rights.
3. Professional practice implies obligatory service in whatever form the professional assumes: Individual, in society or in a dependent relationship.
4. The formation of professional prestige of engineers shall be based on ability and honesty.

III. Acts Contrary to Ethics

To be considered unethical and incompatible with the dignity of the profession:

1. To act against the honor decorum and prestige of the profession and against the dignity and solidarity which the engineers should guard within their professional circles.
2. To intervene directly or indirectly in the destruction of natural resources or to fail to engage in activity corresponding to the avoidance of the production of anything that contributes to the deterioration of the environment.
3. To permit or contribute to the committing of injustices against engineers.
4. To falsely attribute errors to other engineers.
5. To attempt to substitute of replace other engineers in the offering of professional services.
6. To authorize with one's firm, studies, projects, plans, specifications, reports, or professional opinions that have not been personally developed, executed, controlled or authenticated.
7. To offer or lend professional services for remuneration below the standards already established in the respective tariffs.
8. To utilize studies, projects, plans, reports or other documents that are not subject to public domain, without authorization from its authors or owners.
9. To reveal information reserved of a technical, financial or professional nature, as well as divulge, without proper authorization, procedures, processes or group characteristics that are protected by patents or contracts which establish obligations of professional secrecy.
10. To commit deliberate omissions or negligence in professional activities.
11. To fail to respect the norms established by the authorities and institutions of engineering of the country in which one is executing work.

IV. Organization and Control

1. The offering of professional service involves security and the well-being of the community and is of the character of public service. Thus said, it is necessary that the engineers of each country are matriculated in colleges, counsels or associations is obligatory.
2. The integration and government of these organizations shall be exercised by those same who are matriculated in these organizations and who should fulfill and follow this Code of Professional Ethics.

THE WORLD FEDERATION OF ENGINEERING SOCIETIES MODEL CODE OF ETHICS

• • •

Final version adopted in 2001

I. BROAD PRINCIPLES

Ethics is generally understood as the discipline or field of study dealing with moral duty or obligation. This typically gives rise to a set of governing principles or values which in turn are used to judge the appropriateness of particular conducts or behaviors. These principles are usually presented either as broad guiding principles of an idealistic or inspirational nature, or, alternatively, as a detailed and specific set of rules couched in legalistic or imperative terms to make them more enforceable. Professions that have been given the privilege and responsibility of self regulation, including the engineering profession, have tended to opt for the first alternative, espousing sets of underlying principles as codes of professional ethics which form the basis and framework for responsible professional practice. Arising from this context, professional codes of ethics have sometimes been incorrectly interpreted as a set of "rules" of conduct intended for passive observance. A more appropriate use by practicing professionals is to interpret the essence of the underlying principles within their daily decision-making situations in a dynamic manner, responsive to the need of the situation. As a consequence, a code of professional ethics is more than a minimum standard of conduct; rather, it is a set of principles which should guide professionals in their daily work.

In summary, the model Code presented herein expresses the expectations of engineers and society in discriminating engineers' professional responsibilities. The Code is based on broad principles of truth, honesty and trustworthiness, respect for human life and welfare, fairness, openness, competence and accountability. Some of these broader ethical principles or issues deemed more universally applicable are not specifically defined in the Code although they are understood to be applicable as well. Only those tenets deemed to be particularly applicable to the practice of professional engineering are specified. Nevertheless, certain ethical principles or issues not commonly considered to be part of professional ethics should be implicitly accepted to judge the engineer's professional performance.

Issues regarding the environment and sustainable development know no geographical boundaries. The engineers and citizens of all nations should know and respect the environmental ethic. It is desirable, therefore, that engineers in each nation continue to observe the philosophy of the Principles of Environmental Ethics delineated in Section III of this code.

II. PRACTICE PROVISION ETHICS.

Professional engineers shall:

- hold paramount the safety, health and welfare of the public and the protection of both the natural and the built environment in accordance with the Principles of Sustainable Development;
- promote health and safety within the workplace;
- offer services, advise on or undertake engineering assignments only in areas of their competence and practice in a careful and diligent manner;
- act as faithful agents of their clients or employers, maintain confidentially and disclose conflicts of interest;
- keep themselves informed in order to maintain their competence, strive to advance the body of knowledge within which they practice and provide opportunities for the professional development of their subordinates and fellow practitioners;
- conduct themselves with fairness, and good faith towards clients, colleagues and others, give credit where it is due and accept, as well as give, honest and fair professional criticism;
- be aware of and ensure that clients and employers are made aware of societal and environmental consequences of actions or projects and endeavor to interpret engineering issues to the public in an objective and truthful manner;
- present clearly to employers and clients the possible consequences of overruling or disregarding of engineering decisions or judgment;
- report to their association and/or appropriate agencies any illegal or unethical engineering decisions or practices of engineers or others.

III. ENVIRONMENTAL ENGINEERING ETHICS

Engineers, as they develop any professional activity, shall:

- try with the best of their ability, courage, enthusiasm and dedication, to obtain a superior technical achievement, which will contribute to and promote a healthy and agreeable surrounding for all people, in open spaces as well as indoors;
- strive to accomplish the beneficial objectives of their work with the lowest possible consumption of raw materials and energy and the lowest production of wastes and any kind of pollution;

- discuss in particular the consequences of their proposals and actions, direct or indirect, immediate or long term, upon the health of people, social equity and the local system of values;
- study thoroughly the environment that will be affected, assess all the impacts that might arise in the structure, dynamics and aesthetics of the ecosystems involved, urbanized or natural, as well as in the pertinent socioeconomic systems, and select the best alternative for development that is both environmentally sound and sustainable;
- promote a clear understanding of the actions required to restore and, if possible, to improve the environment that may be disturbed, and include them in their proposals;
- reject any kind of commitment that involves unfair damages for human surroundings and nature, and aim for the best possible technical, social, and political solution;
- be aware that the principles of eco-systemic interdependence, diversity maintenance, resource recovery and inter-relational harmony form the basis of humankind's continued existence and that each of these bases poses a threshold of sustainability that should not be exceeded.

IV. CONCLUSION

Always remember that war, greed, misery and ignorance, plus natural disasters and human induced pollution and destruction of resources, are the main causes of the progressive impairment of the environment and that engineers, as an active member of society, deeply involved in the promotion of development, must use our talent, knowledge and imagination to assist society in removing those evils and improving the quality of life for all people.

INTERPRETATION OF THE CODE OF ETHICS

• • •

The interpretive articles which follow expand on and discuss some of the more difficult and interrelated components of the Code especially related to the Practice Provisions. No attempt is made to expand on all clauses of the Code, nor is the elaboration presented on a clause-by-clause basis. The objective of this approach is to broaden the interpretation, rather than narrow its focus. The ethics of professional engineering is an integrated whole and cannot be reduced to fixed "rules". Therefore, the issues and questions arising from the Code are discussed in a general framework, drawing on any and all portions of the Code to demonstrate their interrelationship and to expand on the basic intent of the Code.

Sustainable Development and Environment

Engineers shall strive to enhance the quality of the biophysical and socioeconomic urban environment and the one of buildings and spaces and to promote the principles of sustainable development.

Engineers shall seek opportunities to work for the enhancement of safety, health, and the social welfare of both their local community and the global community through the practice of sustainable development.

Engineers whose recommendations are overruled or ignored on issues of safety, health, welfare, or sustainable development shall inform their contractor or employer of the possible consequences.

Protection of the Public and the Environment

Professional Engineers shall hold paramount the safety, health and welfare of the public and the protection of the environment. This obligation to the safety, health and welfare of the general public, which includes one's own work environment, is often dependent upon engineering judgments, risk assessments, decisions and practices incorporated into structures, machines, products, processes and devices. Therefore, engineers must control and ensure that what they are involved with is in conformity with accepted engineering practice, standards and applicable codes, and would be considered safe based on peer adjudication. This responsibility extends to include all and any situations which an engineer encounters and includes an obligation to advise the appropriate authority if there is reason to believe that any engineering activity, or its products, processes, etc. do not confirm with the above stated conditions.

The meaning of paramount in this basic tenet is that all other requirements of the Code are subordinate if protection of public safety, the environment or other substantive public interests are involved.

Faithful Agent of Clients and Employers

Engineers shall act as faithful agents or trustees of their clients and employers with objectivity, fairness and justice to all parties. With respect to the handling of confidential or proprietary information, the concept of ownership of the information and protecting that party's rights is appropriate. Engineers shall not reveal facts, data or information obtained in a professional capacity without the prior consent of its owner. The only exception to respecting confidentially and maintaining a trustee's position is in instances where the public interest or the environment is at risk as discussed in the preceding section; but even in these circumstances, the engineer should endeavor to have the client and/or employer appropriately redress the situation, or at least, in the absence of a compelling reason to the contrary, should make every reasonable effort to contact them and explain clearly the potential risks, prior to informing the appropriate authority.

Professional Engineers shall avoid conflict of interest situations with employers and clients but, should such conflict arise, it is the engineer's responsibility to fully disclose, without delay, the nature of the conflict to the party(ies) with whom the conflict exists. In these circumstances where full disclosure is insufficient, or seen to be insufficient, to protect all parties' interests, as well as the public, the engineer shall withdraw totally from the issue or use extraordinary means, involving independent parties if possible, to monitor the situation. For example, it is inappropriate to act simultaneously as agent for both the provider and the recipient of professional services. If client's and employer's interests are at odds, the engineer shall attempt to deal fairly with both. If the conflict of interest is between the intent of a corporate employer and a regulatory standard, the engineer must attempt to reconcile the difference, and if that is unsuccessful, it may become necessary to inform.

Being a faithful agent or trustee includes the obligation of engaging, or advising to engage, experts or specialists when such services are deemed to be in the client's or employer's best interests. It also means being accurate, objective and truthful in making public statements on behalf of the client or employer when required to do so, while respecting the client's and employer's rights of confidentiality and proprietary information.

Being a faithful agent includes not using a previous employer's or client's specific privileged or proprietary information and trade practices or process information, without the owner's knowledge and consent. However, general technical knowledge, experience and expertise gained by the engineer through involvement with the previous work may be freely used without consent or subsequent undertakings.

Competence and Knowledge

Professional Engineers shall offer services, advise on or undertake engineering assignments only in areas of their competence by virtue of their training and experience. This includes exercising care and communicating clearly in accepting or interpreting assignments, and in setting expected outcomes. It also includes the responsibility to obtain the services of an expert if required or, if the knowledge is unknown, to proceed only with full disclosure of the circumstances and, if necessary, of the experimental nature of the activity to all parties involved. Hence, this requirement is more than simply duty to a standard of care, it also involves acting with honesty and integrity with one's client or employer and one's self. Professional Engineers have the responsibility to remain abreast of developments and knowledge in their area of expertise, that is, to maintain their own competence. Should there be a technologically driven or individually motivated shift in the area of technical activity, it is the engineer's duty to attain and maintain competence in all areas of involvement including being knowledgeable with the, technical and legal framework and regulations governing their work. In effect, it requires a personal commitment to ongoing professional development, continuing education and self-testing.

In addition to maintaining their own competence, Professional Engineers have an obligation to strive to contribute to the advancement of the body of knowledge within which they practice, and to the profession in general. Moreover, within the framework of the practice of their profession, they are expected to participate in providing opportunities to further the professional development of their colleagues.

This competence requirement of the Code extends to include an obligation to the public, the profession and one's peers, that opinions on engineering issues are expressed honestly and only in areas of one's competence. It applies equally to reporting or advising on professional matters and to issuing public statements. This requires honesty with one's self to present issues fairly, accurately and with appropriate qualifiers and disclaimers, and to avoid personal, political and other nontechnical biases. The latter is particularly important for public statements or when involved in a technical forum.

Fairness and Integrity in the Workplace

Honesty, integrity, continuously updated competence, devotion to service and dedication to enhancing the life quality of society are cornerstones of professional responsibility. Within this framework, engineers shall be objective and truthful and include all known and pertinent information on professional reports, statements and testimony. They shall accurately and objectively represent their clients, employers, associates and themselves consistent with their academic, experience and professional qualifications. This tenet is more than 'not misrepresenting'; it also implies disclosure of all relevant information and issues, especially when serving in an advisory capacity or as an expert witness. Similarly, fairness, honesty and accuracy in advertising are expected.

If called upon to verify another engineer's work, there is an obligation to inform (or make every effort to inform) the other engineer, whether the other engineer is still actively involved or not. In this situation, and in any circumstance, engineers shall give proper recognition and credit where credit is due and accept, as well as give, honest and fair criticism on professional matters, all the while maintaining dignity and respect for everyone involved.

Engineers shall not accept nor offer covert payment or other considerations for the purpose of securing, or as remuneration for engineering assignments. Engineers should prevent their personal or political involvement from influencing or compromising their professional role or responsibility.

Consistent with the Code, and having attempted to remedy any situation within their organization, engineers are obligated to report to their association or other appropriate agency any illegal or unethical engineering decisions by engineers or others. Care must be taken not to enter into legal arrangements which compromise this obligation.

Professional Accountability and Leadership

Engineers have a duty to practice in a careful and diligent manner and accept responsibility, and be accountable for their actions. This duty is not limited to design, or its supervision and management, but applies to all areas of practice. For example, it includes construction supervision and management, preparation of shop drawings, engineering reports, feasibility studies, environmental impact assessments, engineering developmental work, etc.

The signing and sealing of engineering documents indicates the taking of responsibility for the work. This practice is required for all types of engineering endeavor, regardless where or for whom the work is done, including but not limited to, privately and publicly owned firms, crown corporations, and government agencies/departments. There are no exceptions; signing and sealing documents is appropriate whenever engineering principles have been used and public welfare may be at risk.

Taking responsibility for engineering activity includes being accountable for one's own work and, in the case of a senior engineer, accepting responsibility for the work of a team. The latter implies responsible supervision where the engineer is actually in a position to review, modify and direct the entirety of the engineering work. This concept requires setting reasonable limits on the extent of activities, and the number of engineers and others, whose work can be supervised by the responsible engineer. The practice of a "symbolic" responsibility or supervision is the situation where an engineer, say with the title of "chief engineer", takes full responsibility for all engineering on behalf of a large corporation, utility or government agency/department, even though the engineer may not be aware of many of the engineering activities or decisions being made daily throughout the firm or department. The essence of this approach is that the firm is taking the responsibility of default, whether engineering supervision or direction is applied or not.

Engineers have a duty to advise their employer and, if necessary, their clients and even their professional association, in that order, in situations when the overturning of an engineering decision may result in breaching their duty to safeguard the public. The initial action is to discuss the problem with the supervisor/employer. If the employer does not adequately respond to the engineer's concern, then the client must be advised in the case of a consultancy situation, or the most senior officer should be informed in the case of a manufacturing process plant or government agency. Failing this attempt to rectify the situation the engineer must advise in confidence his professional association of his concerns.

In the same order as mentioned above, the engineer must report unethical engineering activity undertaken by other engineers or by non-engineers. This extends to include for example, situations in which senior officials of a firm make "executive" decisions which clearly and substantially alter the engineering aspects of the work, or protection of the public welfare or the environment arising from the work.

Because of the rapid advancements in technology and the increasing ability of engineering activities to impact on the environment, engineers have an obligation to be mindful of the effect that their decisions will have on the environment and the well-being of society, and to report any concerns of this nature in the same manner as previously mentioned. Further to the above, with the rapid advancement of technology in today's world and the possible social impacts on large populations of people, engineers must endeavor to foster the public's understanding of technical issues and the role of Engineering more than ever before.

Sustainable development is the challenge of meeting current human needs for natural resources, industrial products, energy, food, transportation, shelter, and effective waste management while conserving and, if possible, enhancing the Earth's environmental quality, natural resources, ethical, intellectual, working and affectionate capabilities of people and socioeconomic bases, essential for the human needs of future generations. The proper observance to these principles will considerably help to the eradication of the world poverty.

CORPORATIONS AND OTHER NGOs

CODE OF CONDUCT FOR NGOs

Preamble

(1) The following represents the work of several non-governmental organizations (NGOs) working from late 1991 through the NGO Conference in Paris, the outcomes of the Agenda Ya Wananchi, from meeting during the New York PrepCom and in the intervening months up to and including the Global Forum in Rio de Janeiro in June, 1992.

(2) The goal of this NGO Code of Conduct process is to eventually have a Code that NGOs can sign on to.

(3) We pledge to continue to engage in the process to analyze and deepen this activity and make recommendations that groups may adopt.

(4) There has been a dramatic growth of community groups and NGOs during the past 10 years. The work of community and citizen groups and organisations and NGOs now constitutes the best option for citizen action to change the forces against a sustainable future.

(5) In order to build up our constituency base, to truly serve the people within our community/organization, certain ethical and accountable agreements need to be acknowledged.

Principles

(6) An NGO Code of Conduct could contain the following principles:

(7) National and local NGOs (in North and South) should:

(a) be rooted in issues at home

(b) have some definable constituency or membership

(c) have open democratic working systems, gender parity, consultative problem-solving, non-discriminatory practices

(d) have clear conflict of interest guidelines

(e) have a code of ethics for staff

(f) publish an annual report and audited financial statements

(g) be non-profit, non-party political

(h) foster justice and equity, alleviate poverty and preserve cultural integrity

(i) endeavor to enhance the total environment - physical, biological and human

(j) have a fair wage structure, with a credible scale between highest and lowest paid worker

(k) be truly with people and not impose their agendas on them

(l) base all their work on the resources available to the people, their expertise, existing institutions, culture and religions; be self-sufficient while remaining open to the assistance offered by their various partners

(m) avoid being corrupted both materially and spiritually

(n) facilitate people's efforts

(o) share information with all members; set up necessary mechanisms to gather and exchange experiences; and get actively involved in environmental education (awareness-building) and training

(p) articulate a broad political framework and code of ethics to guide their internal operations and their work with community groups and people's organisations, as well as their relations with the South, NGOs and the North

(q) ensure the highest levels of accountability, starting with their own constituencies - the people. This includes uncompromising evaluations involving the participation of the local populations. Campaigns

(8) Northern and Southern NGOs often have non-project or non-funding based relationships. Generally, these relationships are the basis for campaigns to protest certain social or environmental problems in a Northern or Southern country; or the campaigns may be on international issues, like the World Bank's Global Environmental Facility (GEF).

(9) This treaty should be designed to make clear the process of consultation and decision-making

among all the participants to facilitate a process of dialogue between Northern and Southern NGOs on campaigns. At this point, we have only questions, not answers:

(a) The overriding principle this treaty seeks to ensure is consultation among NGOs before anyone takes a position that might affect another. But that is not as easy as it seems.

(b) If a group in one country sends out an international action alert about a problem in its country, what obligation does it have to first assure that there is a consensus among the NGOs in that country about that problem? Conversely, what obligation has a group that receives an action alert to first assure that the alert is the result of a consensus position in the country of origin before responding to the action alert?

(c) Who has the obligation to compile a reasonable list of NGOs in each country (without a list it is not possible for groups elsewhere to consult with NGOs in one country before taking positions on issues that might affect that country)?

(d) What constitutes reasonable consultation? How many groups is "enough"?

(e) How long should the consultation process be allowed to take? Can deadlines be set for responses if there is a hearing or legislative action coming up? What if there is no response - is that consultation?

(f) Can a contact person be chosen in each region or country to facilitate communications and consultation? How would that person be chosen? In a crisis, may that person speak for their constituency without consultation?

(g) What if groups within a region disagree? Who gets listened to? What if regions disagree? Declaration of Solidarity

(10) Before making public expression of solidarity for NGOs and individuals a proper consultation process should be undertaken to ensure the safety of the affected parties.

Regarding NGOs working outside their country

(11) Northern and Southern NGOs should collaborate on the basis of:

(a) equitable and genuine partnership

(b) two-way flow of all information, ideas and experiences

(c) financial transparency.

(12) Southern NGOs not Northern NGOs have the major responsibility for activities within their own countries.

(13) Northern NGOs when working in the South must have transparent advisory systems within the country of operation; there must be transparent criteria for selection of working partners.

(14) Northern NGOs should monitor Northern government/corporate activity in their host country.

(15) Northern NGOs in their host country should live in an appropriate comparative level as counterpart NGOs, not in expatriate style.

(16) Northern NGOs should develop effective policy on international issues.

(17) Because development groups get most of their funding from their national governments, most Northern NGOs hardly question the policies and activities of their governments in the South. On the contrary, they have become accessories to the hidden agendas pursued by their governments and transnational corporations in gaining control over the resources of the South. In order for Northern NGOs to be able to forge genuine people-to-people solidarity, they should:

(a) build a relationship that is based on mutual respect and collaboration as equal partners, and that fosters self-determination and self-reliance

(b) use their comparative advantage of easy access to information and pass it on to their partners in the South

(c) challenge their governments and educate the public in order to change the prevailing inequitable international economic order and development paradigms which have been largely responsible for the deteriorating global environment

(d) campaign for genuine grassroots democracy in their own countries

(e) campaign for sustainable life-styles based on their own local resources as much as possible, and paying fair (ecological) prices for imported products. Action Plan for Follow-Up

(18) Regional focal points to publicize and maximize NGO input

(19) Broad correspondence

(20) 1993 meeting to prepare final copy for widespread adoption.

DOW CORNING ETHICAL BUSINESS CONDUCT

• • •

Dow Corning's Responsibilities to Employees:

All relations with employees will be guided by our belief that the dignity of the individual is primary.

Opportunity without bias will be afforded each employee in relation to demonstrated ability, initiative and potential.

Management practices will be consistent with our intent to provide continuing employment for all productive employees.

Qualified citizens of countries where we do business will be hired and trained for available positions consistent with their capabilities.

We will strive to create and maintain a work environment that fosters honesty, personal growth, teamwork, open communications and dedication to our vision and values.

We will provide a safe, clean and pleasant work environment that at minimum meets all applicable laws and regulations.

The privacy of an individual's records will be respected. Employees may review their own records upon request.

Management will provide, communicate and implement a Problem Resolution Process for use by all employees to identify and resolve business ethics and employee conduct problems and other disagreements between employees.

Our Responsibilities as Dow Corning Employees:

Employees will treat Dow Corning proprietary information as a valued asset and diligently protect it from loss or negligent disclosure.

Employees will respect our commitment to protect the confidentiality of information entrusted to us by customers, suppliers and others in our business dealings.

The proprietary information of others will be obtained only through the use of legal and ethical methods.

Employees will not engage in activities that either jeopardize or conflict with the company's interests. Recognizing and avoiding conflicts of interest is the responsibility of each employee.

When a potential conflict of interest exists, the employee is obligated to bring the situation to the attention of Dow Corning management for resolution.

Employees will use or authorize company resources only for legitimate business purposes.

The cost of goods or services purchased for Dow Corning must be reasonable and in line with competitive standards.

Employees will not engage in bribery, price fixing, kickbacks, collusion or any related practice that might be, or give the appearance of being, illegal or unethical.

Employees will avoid contacts with competitors, suppliers, government agencies and other parties that are, or appear to be, engaging in unfair competition or the restriction of free trade.

Business interactions with our competitors will be limited to those necessary for buyer-seller agreements, licensing agreements or matters of general interest to industry or society. All such interactions will be documented.

Relations with Customers, Distributors, Suppliers

We are committed to providing products and services that meet the requirements of our customers. We will provide information and support necessary to effectively use our products.

Business integrity is a criterion for selecting and retaining those who represent Dow Corning.

Dow Corning will regularly encourage its distributors, agents and other representatives to conduct their business on our behalf in a legal and ethical manner.

The purchase of goods and services will be based on quality, price, service, ability to supply and the supplier's adherence to legal and ethical business practices.

Environmental, Product Stewardship and Social Responsibility

- We are committed to the responsible management of chemicals through our support and practice of the principles of Responsible Care.
- Environmental consideration will be integrated into all appropriate business decisions and will be guided

by Dow Corning's Principles of Environmental Management.

- We will continually strive to assure that our products and services are safe, efficacious and accurately represented for their intended uses. We will fully represent the nature and characteristics of our raw materials, intermediates and products—including toxicity and other potential hazards—to our employees, suppliers, transporters and customers.
- We will build and maintain positive relationships with communities where we have a presence. Our efforts will focus on education, civic, cultural, environmental, and health and safety programs.

*A registered trademark of the Chemical Manufacturers Association.

International Business Guidelines

Dow Corning will be a responsible corporate citizen wherever we do business. We recognize that laws, business practices and customs differ from country to country. If legal conflicts arise in or between locations where we do business, or if conflicts with this Code present themselves, we will seek reasonable ways to resolve the differences. Failing timely resolution, we will remove ourselves from the particular business situation. Dow Corning employees will not authorize or give payments or gifts to government employees or their beneficiaries or anyone else in order to obtain or retain business. Facilitating payments to expedite the performance of routine services are strongly discouraged. In countries where local business practice dictates such payments and there is no alternative, facilitating payments are to be for the minimum amount necessary and must be accurately documented and recorded. No contributions to political parties or candidates will be given by Dow Corning, even in countries where such contributions are legal. Dow Corning considers its technology and know-how to be valuable assets and encourages their inter-company and transborder transfer to achieve its overall business objectives. Dow Corning, its subsidiaries and its majority-owned joint ventures expect to pay or receive fair compensation for the value provided or received for the technology or know-how transferred.

Financial Responsibilities

Dow Corning funds will be used only for purposes that arc legal and ethical and all transactions will be properly and accurately recorded.

We will maintain a system of internal accounting controls for Dow Corning and assure that all involved employees are fully apprised of that system.

Dow Corning encourages the free flow of funds for investment, borrowing, dividending and the return of capital throughout the world.

Dow Corning Corporation, its subsidiaries and its majority-owned joint venture companies will strive to establish and maintain inter-company prices and fees for goods and services comparable to those which would prevail in open-market transactions between unrelated parties. Within this context, the goal is to have inter-company prices and fees for goods and services that meet all applicable laws and are mutually agreed upon by the Dow Corning entities involved.

We will not participate in any financial arrangement where the perceived intent of the transaction would be a violation of this Code of Conduct.

Dow Corning Values

Integrity: Our integrity is demonstrated in our ethical conduct and in our respect for the values cherished by the society of which we are a part.

Employees: Our employees are the source from which our ideas, actions and performance flow. The full potential of our people is best realized in an environment that breeds fairness, self-fulfillment, teamwork and dedication to excellence.

Customers: Our relationship with each customer is entered in the spirit of a long-term partnership and is predicated on making the customer's interests our interests.

Quality: Our never-ending quest for quality performance is based on our understanding of our customers' needs and our willingness and capability to fulfill those needs.

Technology: Our advancement of chemistry and related sciences in our chosen fields is the Value that most differentiates Dow Corning.

Environment: Our commitment to the safekeeping of the natural environment is founded on our appreciation of it as the basis for the existence of life.

Safety: Our attention to safety is based on our full-time commitment to injury-free work, individual self-worth and a consideration for the well being of others.

Profit. Our long-term profit growth is essential to our long-term existence. How our profits are derived, and the purposes for which they are used, are influenced by our Values and our shareholders.

EATON ETHICAL BUSINESS CONDUCT

• • •

Eaton Corporation's commitment to the highest degree of integrity and honesty in the conduct of its business affairs is stated in the following letter. This letters, and prior versions of it, have been distributed periodically to Eaton employees since 1976.

Eaton Corporation
Eaton Center
Cleveland, OH 44114-2584
September 1, 1996

Dear Fellow Employee:

Eaton has always had a well-deserved reputation for honesty and integrity—a reputation which we have all helped build and maintain. My purpose in writing is to reaffirm Eaton's commitment to the highest standards of ethical behavior. I particularly want to emphasize that our standards remain constant even as Eaton experiences new international growth and evolution into a truly global company.

If you're concerned about any particular situation involving ethics, please don't hesitate to contact your supervisor or another member of management.

Here are the broad concepts that we regard as fundamental principles of ethical business behavior.

Obeying the Law—We respect and obey the laws of the cities, states and countries where we operate.

Competition—We respect the rights of competitors, customers and suppliers. The only competitive advantages we seek are those gained through superior research, engineering, manufacturing and marketing. We do not engage in unfair or illegal trade practices.

Conflicts of Interest—We expect Eaton employees to avoid any association which might conflict with their loyalty to the company or compromise their judgment. Under this guideline, it would be a conflict of interest for an Eaton employee to work simultaneously for a competitor, supplier or a customer.

Government Contracts—Eaton's customers include national, state and local governments. We take care to comply with the special laws, rules and regulations which govern these contracts.

Payments to Government Personnel—We do not make illegal payments to government officials of any country. In the case of U.S. federal government employees, we must comply with the stringent rules on business gratuities that they are permitted to accept.

Kickbacks and Gratuities—We do not offer or accept kickbacks or bribes, or gifts of substantial value.

Political Contributions—Our policy prohibits company contributions to political candidates or parties even where such contributions are lawful. We encourage individual employees to be involved in the political process and make personal contributions as they see fit.

It is important that the policies and principles set forth in this letter be understood and followed on a consistent basis by each of us. Our reputation for integrity is an important corporate asset. The principles as outlined are designed to help us protect that asset. Anyone violating these principles will face appropriate disciplinary action. Your commitment to ethical behavior is essential if Eaton is to maintain the highest degree of honesty and integrity in its business activities.

LOCKHEED MARTIN CORP. CODE OF ETHICS AND BUSINESS CONDUCT

• • •

Introduction

Dear Colleague:

This booklet, Setting the Standard, has been adopted by the Lockheed Martin Board of Directors as our Company's Code of Ethics and Business Conduct. It summarizes the virtues and principles that are to guide our actions in business. We expect our agents, consultants, contractors, representatives, and suppliers to be guided by them as well.

There are numerous resources available to assist you in meeting the challenge of performing your duties and responsibilities. There can be no better course of action for you than to apply common sense and sound judgment to the manner in which you conduct yourself. However, do not hesitate to use the resources that are available whenever it is necessary to seek clarification.

Lockheed Martin aims to "set the standard" for ethical business conduct. We will achieve this through six virtues: Honesty, Integrity, Respect, Trust, Responsibility, and Citizenship.

Honesty: to be truthful in all our endeavors; to be honest and forthright with one another and with our customers, communities, suppliers, and shareholders.

Integrity: to say what we mean, to deliver what we promise, and to stand for what is right.

Respect: to treat one another with dignity and fairness, appreciating the diversity of our workforce and the uniqueness of each employee.

Trust: to build confidence through teamwork and open, candid communication.

Responsibility: to speak up - without fear of retribution - and report concerns in the work place, including violations of laws, regulations and company policies, and seek clarification and guidance whenever there is doubt.

Citizenship: : to obey all the laws of the United States and the other countries in which we do business and to do our part to make the communities in which we live better.

You can count on us to do everything in our power to meet Lockheed Martin's standards. We are counting on you to do the same. We are confident that our trust in you is well placed and we are determined to be worthy of your trust.

Daniel M. Tellep
Norman R. Augustine
Bernard L. Schwartz

June 1996

Treat in an Ethical Manner Those to Whom Lockheed Martin Has an Obligation

We are committed to the ethical treatment of those to whom we have an obligation.

For our employees we are committed to honesty, just management, and fairness, providing a safe and healthy environment, and respecting the dignity due everyone.

For our customers we are committed to produce reliable products and services, delivered on time, at a fair price.

For the communities in which we live and work we are committed to acting as concerned and responsible neighbors, reflecting all aspects of good citizenship.

For our shareholders we are committed to pursuing sound growth and earnings objectives and to exercising prudence in the use of our assets and resources.

For our suppliers we are committed to fair competition and the sense of responsibility required of a good customer.

Obey the Law

We will conduct our business in accordance with all applicable laws and regulations. The laws and regulations related to contracting with the United States government are far reaching and complex, thus placing burdens on Lockheed Martin that are in addition to those faced by companies without extensive government contracts. Compliance with the law does not comprise our entire ethical responsibility. Rather, it is a minimum, absolutely essential condition for performance of our duties.

Promote a Positive Work Environment

All employees want and deserve a work place where they feel respected, satisfied, and appreciated. Harassment or discrimination of any kind and especially involving race, color, religion, gender, age, national origin, disability, and veteran or marital status is unacceptable in our work place environment.

Providing an environment that supports the honesty, integrity, respect, trust, responsibility, and citizenship of every employee permits us the opportunity to achieve excellence in our work place. While everyone who works for the Company must contribute to the creation and maintenance of such an environment, our executives and management personnel assume special responsibility for fostering a context for work that will bring out the best in all of us.

Work Safely: Protect Yourself and Your Fellow Employees

We are committed to providing a drug-free, safe, and healthy work environment. Each of us is responsible for compliance with environmental, health, and safety laws and regulations. Observe posted warnings and regulations. Report immediately to the appropriate management any accident or injury sustained on the job, or any environmental or safety concern you may have.

Keep Accurate and Complete Records

We must maintain accurate and complete Company records. Transactions between the Company and outside individuals and organizations must be promptly and accurately entered in our books in accordance with generally accepted accounting practices and principles. No one should rationalize or even consider misrepresenting facts or falsifying records. It is illegal, will not be tolerated, and will result in disciplinary action.

Record Costs Properly

Employees and their supervisors are responsible for ensuring that labor and material costs are accurately recorded and charged on the Company's records. These costs include, but are not limited to, normal contract work, work related to independent research and development, and bid and proposal activities.

Strictly Adhere to All Antitrust Laws

Antitrust is a blanket term for strict federal and state laws that protect the free enterprise system. The laws deal with agreements and practices "in restraint of trade" such as price fixing and boycotting suppliers or customers, for example. They also bar pricing intended to run a competitor out of business; disparaging, misrepresenting, or harassing a competitor; stealing trade secrets; bribery, and kickbacks.

Antitrust laws are vigorously enforced. Violations may result in severe penalties such as forced sales of parts of businesses and significant fines for the Company. There may also be sanctions against individual employees including substantial fines and prison sentences. These laws also apply to international operations and transactions related to imports into and exports from the United States. Employees involved in any dealings with competitors are expected to know that U.S. and foreign antitrust laws may apply to their activities and to consult with the Legal Department prior to negotiating with or entering into any arrangement with a competitor.

Know and Follow the Law When Involved in International Business

The Foreign Corrupt Practices Act (FCPA), a federal statute, prohibits offering anything of value to foreign officials for the purpose of improperly influencing an official decision. It also prohibits unlawful political contributions to obtain or retain business. Finally, it prohibits the use of false records or accounts in the conduct of foreign business. Employees involved in international operations must be familiar with the FCPA. You must also be familiar with the terms and conditions of 1976 Securities and Exchange Commission and Federal Trade Commission consent decrees resulting from past issues. The FCPA and the consent decrees govern the conduct of all Lockheed Martin employees throughout the world.

If you are not familiar with documents or laws, consult with the Legal Department prior to negotiating any foreign transaction.

International transfers of equipment or technology are subject to other U.S. Government regulations like the International Traffic and Arms Regulations (ITAR), which may contain prior approval and reporting requirements. If you participate in this business activity, you should know, understand, and strictly comply with these regulations.

It may be illegal to enter into an agreement to refuse to deal with potential or actual customers or suppliers, or otherwise to engage in or support restrictive international trade practices or boycotts.

It is also important that employees doing business in foreign countries know and abide by the laws of those countries.

Follow the Rules in Using or Working with Former Government Personnel

U.S. government laws and regulations governing the employment or services from former military and civilian government personnel prohibit conflicts of interest ("working both sides of the street"). These laws and rules must be faithfully and fully observed.

Follow the Law and Use Common Sense in Political Contributions and Activities

Federal law prohibits corporations from donating corporate funds, goods, or services—directly or indirectly—to candidates for federal offices. This includes employees' work time. As a matter of policy we will not make political contributions in foreign countries.

Carefully Bid, Negotiate, and Perform Contracts

We must comply with the laws and regulations that govern the acquisition of goods and services by our customers. We will compete fairly and ethically for all business opportunities. In circumstances where there is reason to believe that the release or receipt of non- public information is unauthorized, do not attempt to obtain and do not accept such information from any source.

Appropriate steps should be taken to recognize and avoid organizational conflicts in which one business unit's activities may preclude the pursuit of a related activity by another Company business unit.

If you are involved in proposals, bid preparations, or contract negotiations, you must be certain that all statements, communications, and representations to prospective customers are accurate and truthful. Once awarded, all contracts must be performed in compliance with specifications, requirements, and clauses.

Avoid Illegal and Questionable Gifts or Favors

To Government Personnel:

Federal, state and local government departments and agencies are governed by laws and regulations concerning acceptance by their employees of entertainment, meals, gifts, gratuities, and other things of value from firms and persons with whom those departments and agencies do business or over whom they have regulatory authority. It is the general policy of Lockheed Martin to strictly comply with those laws and regulations. With regard to all federal Executive Branch employees and any other government employees who work for customers or potential customers of the Corporation, it is the policy of Lockheed Martin to prohibit its employees from giving them things of value. Permissible exceptions are offering Lockheed Martin advertising or promotional items of *nominal value* such as a coffee mug, calendar, or similar item displaying the *Company logo*, and providing modest refreshments such as soft drinks, coffee, and donuts on an occasional basis in connection with business activities. "Nominal value" is $10.00 or less. (Note: Even though this policy may be more restrictive than the U.S. Government's own policy with regard to federal Executive Branch employees, this policy shall govern the conduct of all Lockheed Martin employees.) Legislative, judicial, and state and local government personnel are subject to different restrictions; both the regulations and Corporate Policies pertaining to them must be consulted before courtesies are offered.

To Non-Government Personnel:

As long as it doesn't violate the standards of conduct of the recipient's organization, it's an acceptable practice to provide meals, refreshments, and entertainment of reasonable value in conjunction with business discussions with non-government personnel. Gifts, other than those of nominal value ($50.00 or less), to private individuals or companies are prohibited unless specifically approved by the appropriate Ethics Officer or Corporate Office of Ethics and Business Conduct.

To Foreign Government Personnel and Public Officials:

The Company may be restricted from giving meals, gifts, gratuities, entertainment, or other things of value to personnel of foreign governments and foreign public officials by the Foreign Corrupt Practices Act and by laws of foreign countries. Employees must discuss such situations with the Legal Counsel and consult the Hospitality Guidelines (maintained by the Legal Department) prior to making any gifts or providing any gratuities other than advertising items.

To Lockheed Martin Personnel:

Lockheed Martin employees may accept meals, refreshments, or entertainment of nominal value in connection with business discussions. While it is difficult to define "nominal" by means of a specific dollar amount, a common sense determination should dictate what would be considered lavish, extravagant, or frequent. It is the personal responsibility of each employee to ensure that his or her acceptance of such meals, refreshments, or entertainment is proper and could not reasonably be construed in any way as an attempt by the offering party to secure favorable treatment.

Lockheed Martin employees are not permitted to accept funds in any form or amount, or any gift that has a retail or exchange value of $20 or more from individuals, companies, or representatives of companies having or seeking business relationships with Lockheed Martin. If you have any questions about the propriety of a gift, gratuity, or item of value, contact your Ethics Officer or the Corporate Office of Ethics and Business Conduct for guidance.

If you buy goods or services for Lockheed Martin, or are involved in the procurement process, you must treat all suppliers uniformly and fairly. In deciding among competing suppliers, you must objectively and impartially weigh all facts and avoid even the appearance of favoritism. Established routines and procedures should be followed in the procurement of all goods and services.

Steer Clear of Conflicts of Interest

Playing favorites or having conflicts of interest—in practice or in appearance—runs counter to the fair treatment to which we are all entitled. Avoid any relationship, influence, or activity that might impair, or even appear to impair, your ability to make objective and fair decisions when performing your job. When in doubt, share the facts of the situation with your supervisor, Legal Department, or Ethics Officer.

Here are some ways a conflict of interest could arise:

- Employment by a competitor or potential competitor, regardless of the nature of the employment, while employed by Lockheed Martin.
- Acceptance of gifts, payment, or services from those seeking to do business with Lockheed Martin.
- Placement of business with a firm owned or controlled by an employee or his/her family.
- Ownership of, or substantial interest in, a company which is a competitor or a supplier.
- Acting as a consultant to a Lockheed Martin customer or supplier.

Maintain the Integrity of Consultants, Agents, and Representatives

Business integrity is a key standard for the selection and retention of those who represent Lockheed Martin. Agents, representatives, or consultants must certify their willingness to comply with the Company's policies and procedures and must never be retained to circumvent our values and principles. Paying bribes or kickbacks, engaging in industrial espionage, obtaining the proprietary data of a third party, or gaining inside information or influence are just a few examples of what could give us an unfair competitive advantage in a government procurement and could result in violations of law.

Protect Proprietary Information

Proprietary company information may not be disclosed to anyone without proper authorization. Keep proprietary documents protected and secure. In the course of normal business activities, suppliers, customers, and competitors may sometimes divulge to you information that is proprietary to their business. Respect these confidences.

Obtain and Use Company and Customer Assets Wisely

Proper use of company and customer property, facilities, and equipment is your responsibility. Use and maintain these assets with the utmost care and respect, guarding against waste and abuse. Be cost-conscious and alert to opportunities for improving performance while reducing costs. The use of company time, material, or facilities for purposes not directly related to company business, or the removal or borrowing of company property without permission, is prohibited.

All employees are responsible for complying with requirements of software copyright licenses related to software packages used in fulfilling job requirements.

Do Not Engage in Speculative or Insider Trading

In our role as a U.S. corporation and a major government contractor, we must always be alert to and comply with the security laws and regulations of the United States.

It is against the law for employees to buy or sell Lockheed Martin stock based on "insider" information about or involving the Company. Play it safe: don't speculate in the securities of Lockheed Martin when you are aware of information affecting the company's business that has not been publicly released or in situations where trading would call your judgment into question. This includes all varieties of stock trading such as options, puts and calls, straddles, selling short, etc. Two simple rules can help protect you in this area: (1) Don't use non-public information for personal gain. (2) Don't pass along such information to someone else who has no need to know.

This guidance also applies to the securities of other companies (suppliers, vendors, subcontractors, etc.) for which you receive information in the course of your employment at Lockheed Martin.

For More Information:

In order to support a comprehensive Ethics and Business Conduct Program, Lockheed Martin has developed education and communication programs in many subject areas.

These programs have been developed to provide employees with job-specific information to raise their level of awareness and sensitivity to key issues.

Interactive video training modules and related brochures are planned to be available on the following topics:

Antitrust ComplianceLabor Charging

Domestic Consultants Leveraging Differences

Kickbacks re On Thin Ethical Ice When You Hear . . .

"Well, maybe just this once . . ."

"No one will ever know . . ."

"It doesn't matter how it gets done as long as it gets done."

You can probably think of many more phrases that raise warning flags. If you find yourself using any of these expressions, take the Quick Quiz on the following page and make sure you are on solid ethical ground.

Quick Quiz—When In Doubt, Ask Yourself . . .

Are my actions legal?

Am I being fair and honest?

Will my action stand the test of time?

How will I feel about myself afterwards?

How will it look in the newspaper?

Will I sleep soundly tonight?

What would I tell my child to do?

If you are still not sure what to do, ask . . . and keep asking until you are certain you are doing the right thing.

Our Goal: An Ethical Work Environment

We have established the Office of Vice President - Ethics and Business Conduct to underscore our commitment to ethical conduct throughout our Company.

This office reports directly to the Office of the Chairman and the Audit and Ethics Committee of the Board of Directors, and oversees a vigorous corporate-wide effort to promote a positive, ethical work environment for all employees.

Our Ethics Officers operate confidential ethics helplines at each operating company, as well as at the corporate level. You are urged to use these resources whenever you have a question or concern that cannot be readily addressed within your work group or through your supervisor.

In addition, if you need information on how to contact your local Ethics Officer - or wish to discuss a matter of concern with the corporate Office of Ethics and Business Conduct - you are encouraged to use one of the following confidential means of communication:

Call: 1-800-LM ETHIC (1-800-563-8442)

For the Hearing or Speech Impaired: (1-800-441- 7457)

Write: Office of Ethics and Business Conduct

Office of Ethics and Business Conduct

Lockheed Martin Corporation

P.O. Box 34143 Bethesda, MD 20827-0143

Fax: 818-876-2082

Internet E-Mail:Corporate.Ethics@den.mmc.com

When you contact your Company Ethics Officer or the Corporate Office of Ethics and Business Conduct:

- You will be treated with dignity and respect.
- Your communication will be protected to the greatest extent possible.
- Your concerns will be seriously addressed and, if not resolved at the time you call, you will be informed of the outcome.
- You need not identify yourself.
- Remember, there's never a penalty for using the HelpLine. People in a position of authority can't stop you; if they try, they're subject to disciplinary action up to and including dismissal.

RESPONSIBLE CARE GUIDING PRINCIPLES (CHEMICAL INDUSTRY)

Our industry creates products and services that make life better for people around the world - both today and in the future. The benefits of our industry are accompanied by enduring commitments to Responsible Care in the management of chemicals worldwide. We will make continuous progress toward the vision of no accidents, injuries, or harm to the environment and will publicly report our global health, safety, and environmental performance. We will lead our companies in ethical ways that increasingly benefit society, the economy and the environment while adhering to the following principles:

1. To seek and incorporate public input regarding our products and operations.
2. To provide chemicals that can be manufactured, transported, used and disposed of safely.
3. To make health, safety, the environment and resource conservation critical considerations for all new and existing products and processes.
4. To provide information on health or environmental risks and pursue protective measures for employees, the public and other key stakeholders.

5. To work with customers, carriers, suppliers, distributors and contractors to foster the safe use, transport and disposal of chemicals.
6. To operate our facilities in a manner that protects the environment and the health and safety of our employees and the public.
7. To support education and research on the health, safety and environmental effects of our products and processes.
8. To work with others to resolve problems associated with past handling and disposal practices.
9. To lead in the development of responsible laws, regulations, and standards that safeguard the community, workplace and environment.
10. To practice Responsible Care by encouraging and assisting others to adhere to these principles and practices.

EINSTEIN-RUSSELL MANIFESTO (1955)

In the tragic situation which confronts humanity, we feel that scientists should assemble in conference to appraise the perils that have arisen as a result of the development of weapons of mass destruction, and to discuss a resolution in the spirit of the appended draft.

We are speaking on this occasion, not as members of this or that nation, continent, or creed, but as human beings, members of the species Man, whose continued existence is in doubt. The world is full of conflicts; and, overshadowing all minor conflicts, the titanic struggle between Communism and anti-Communism.

Almost everybody who is politically conscious has strong feelings about one or more of these issues; but we want you, if you can, to set aside such feelings and consider yourselves only as members of a biological species which has had a remarkable history, and whose disappearance none of us can desire.

We shall try to say no single word which should appeal to one group rather than to another. All, equally, are in peril, and, if the peril is understood, there is hope that they may collectively avert it.

We have to learn to think in a new way. We have to learn to ask ourselves, not what steps can be taken to give military victory to whatever group we prefer, for there no longer are such steps; the question we have to ask ourselves is: what steps can be taken to prevent a military contest of which the issue must be disastrous to all parties?

The general public, and even many men in positions of authority, have not realized what would be involved in a war with nuclear bombs. The general public still thinks in terms of the obliteration of cities. It is understood that the new bombs are more powerful than the old, and that, while one A-bomb could obliterate Hiroshima, one H-bomb could obliterate the largest cities, such as London, New York, and Moscow.

No doubt in an H-bomb war great cities would be obliterated. But this is one of the minor disasters that would have to be faced. If everybody in London, New York, and Moscow were exterminated, the world might, in the course of a few centuries, recover from the blow. But we now know, especially since the Bikini test, that nuclear bombs can gradually spread destruction over a very much wider area than had been supposed.

It is stated on very good authority that a bomb can now be manufactured which will be 2,500 times as powerful as that which destroyed Hiroshima. Such a bomb, if exploded near the ground or under water, sends radio-active particles into the upper air. They sink gradually and reach the surface of the earth in the form of a deadly dust or rain. It was this dust which infected the Japanese fishermen and their catch of fish.

No one knows how widely such lethal radioactive particles might be diffused, but the best authorities are unanimous in saying that a war with H-bombs might possibly put an end to the human race. It is feared that if many H-bombs are used there will be universal death, sudden only for a minority, but for the majority a slow torture of disease and disintegration.

Many warnings have been uttered by eminent men of science and by authorities in military strategy. None of them will say that the worst results are certain. What they do say is that these results are possible, and no one can be sure that they will not be realized. We have not yet found that the views of experts on this question depend in any degree upon their politics or prejudices. They depend only, so far as our researches have revealed, upon the extent of the particular expert's knowledge. We have found that the men who know most are the most gloomy.

Here, then, is the problem which we present to you, stark and dreadful and inescapable: Shall we put an end to the human race; or shall mankind renounce war? People will not face this alternative because it is so difficult to abolish war.

The abolition of war will demand distasteful limitations of national sovereignty. But what perhaps impedes understanding of the situation more than anything else is that the term “mankind” feels vague and abstract. People scarcely realize in imagination that the danger is to themselves and their children and their grandchildren, and not only to a dimly apprehended humanity. They can scarcely bring themselves to grasp that they, individually, and those whom they love are in imminent danger of perishing agonizingly. And so they hope that perhaps war may be allowed to continue provided modern weapons are prohibited.

This hope is illusory. Whatever agreements not to use H-bombs had been reached in time of peace, they would no longer be considered binding in time of war, and both sides would set to work to manufacture H-bombs as soon as war broke out, for, if one side manufactured the bombs and the other did not, the side that manufactured them would inevitably be victorious.

Although an agreement to renounce nuclear weapons as part of a general reduction of armaments would not afford an ultimate solution, it would serve certain important purposes. First: any agreement between East and West is to the good in so far as it tends to diminish tension. Second: the abolition of thermo-nuclear weapons, if each side believed that the other had carried it out sincerely, would lessen the fear of a sudden attack in the style of Pearl Harbor, which at present keeps both sides in a state of nervous apprehension. We should, therefore, welcome such an agreement though only as a first step. Most of us are not neutral in feeling, but, as human beings, we have to remember that, if the issues between East and West are to be decided in any manner that can give any possible satisfaction to anybody, whether Communist or anti-Communist, whether Asian or European or American, whether White or Black, then these issues must not be decided by war. We should wish this to be understood, both in the East and in the West. There lies before us, if we choose, continual progress in happiness, knowledge, and wisdom. Shall we, instead, choose death, because we cannot forget our quarrels? We appeal, as human beings, to human beings: Remember your humanity, and forget the rest. If you can do so, the way lies open to a new Paradise; if you cannot, there lies before you the risk of universal death.

Resolution

We invite this Congress, and through it the scientists of the world and the general public, to subscribe to the following resolution:

> "In view of the fact that in any future world war nuclear weapons will certainly be employed, and that such weapons threaten the continued existence of mankind, we urge the Governments of the world to realize, and to acknowledge publicly, that their purpose cannot be furthered by a world war, and we urge them, consequently, to find peaceful means for the settlement of all matters of dispute between them."

MOUNT CARMEL DECLARATION ON TECHNOLOGY AND MORAL RESPONSIBILITY (1974)

We, meeting at Haifa to celebrate the fiftieth anniversary of the Technion-Israel Institute of Technology, deeply troubled by the threats to the welfare and survival of the human species that are increasingly posed by improvident uses of applied science and technology, offer the following Declaration for consideration and adoption. It is addressed, most urgently, to all whom it concerns, to governments and other political agencies, to administrators and managers, experts and laymen, educators and students, to all who have the power to influence decisions or the right to be consulted about them.

1. We recognize the great contributions of technology to the improvement of the human condition. Yet continued intensification and extension of technology has unprecedented potentialities for evil as well as good. Technological consequences are now so ramified and interconnected, so sweeping in unforeseen results, so grave in magnitude of the irreversible changes they induce, as to constitute a threat to the very survival of the species.
2. While actions at the level of community and state are urgently needed, legitimate local interests must not take precedence over the common interest of *all* human beings in justice, happiness, and peace. Responsible control of technology by social systems and institutions is an urgent *global* concern, overriding all conflicts of interest and all divergencies in religion, race or political allegiance. Ultimately all must benefit from the promise of technology, or all must suffer—even perish—together.
3. Technological applications and innovations result from human actions. As such, they demand politi-

cal, social, economic, ecological and above all *moral* evaluation. No technology is morally "neutral."

4. Human beings, both as individuals and as members or agents of social institutions, bear the sole responsibility for abuses of technology. Invocation of supposedly inflexible laws of technological inertia and technological transformation is an evasion of moral and political responsibility.

5. Creeds and moral philosophies that teach respect for human dignity can, in spite of all differences, unite in actions to cope with the problems posed by new technologies. It is an urgent task to work toward new codes for guidance in an age of pervasive technology.

6. Every technological undertaking must respect basic human rights and cherish human dignity. We must not gamble with human survival. We must not degrade people into *things* used by machines: every technological innovation must be judged by its contributions to the development of genuinely free and creative *persons*.

7. The "developed" and the "developing" nations have different priorities but an ultimate convergence of shared interests:

   For the developed nations: rejection of expansion at all costs and the selfish satisfaction of ever-multiplying desires–and adoption of policies of *principled restraint*—with unstinting assistance to the unfortunate and the underprivileged.

   For the developing nations: complementary but appropriately modified policies of principled restraint, especially in population growth, and a determination to avoid repeating the excesses and follies of the more "developed" economies.

   Absolute priority should be given to the relief of human misery, the eradication of hunger and disease, the abolition of social injustice and the achievement of lasting peace.

8. These problems and their implications need to be discussed and investigated by all educational institutions and all media of communication. They call for intense and imaginative research enlisting the cooperation of humanists and social scientists, as well as natural scientists and technologists. Better technology is needed, but will not suffice to solve the problems caused by intensive uses of technology. We need guardian *disciplines* to monitor and assess technological innovations, with especial attention to their moral implications.

9. Implementation of these purposes will demand improved social institutions through the active participation of statesmen and their expert advisers, and the informed understanding and consent of those most directly affected—especially the young, who have the greatest stake in the future.

10. This agenda calls for sustained work on three distinct but connected tasks: the development of "guardian disciplines" for watching, modifying, improving, and restraining the human consequences of technology (a special but not exclusive responsibility of the scientists and technologists who originate technological innovations); the confluence of varying moral codes in common action; and the creation of improved educational and social institutions.

Without minimizing the prevalence of human irrationality and the potency of envy and hate, we have sufficient faith in ourselves and our fellows to hope for a future in which all can have a chance to close the gap between aspiration and reality—a chance to become at last truly human.

No agenda is more urgent for human welfare and survival. This declaration, henceforth to be called the Mount Carmel Declaration on Technology and Moral Responsibility, is proclaimed in Jerusalem on this day, Wednesday, the twenty-fifth of December, 1974, in the Residence of the President of the State of Israel.

RIO DECLARATION ON ENVIRONMENT AND DEVELOPMENT (1992)

• • •

The United Nations Conference on Environment and Development,

Having met at Rio de Janeiro from 3 to 14 June 1992,

Reaffirming the Declaration of the United Nations Conference on the Human Environment, adopted at Stockholm on 16 June 1972, and seeking to build upon it,

With the goal of establishing a new and equitable global partnership through the creation of new levels of cooperation among States, key sectors of societies and people,

Working towards international agreements which respect the interests of all and protect the integrity of the global environmental and developmental system,

Recognizing the integral and interdependent nature of the Earth, our home,

Proclaims that:

Principle 1

Human beings are at the centre of concerns for sustainable development. They are entitled to a healthy and productive life in harmony with nature.

Principle 2

States have, in accordance with the Charter of the United Nations and the principles of international law, the sovereign right to exploit their own resources pursuant to their own environmental and developmental policies, and the responsibility to ensure that activities within their jurisdiction or control do not cause damage to the environment of other States or of areas beyond the limits of national jurisdiction.

Principle 3

The right to development must be fulfilled so as to equitably meet developmental and environmental needs of present and future generations.

Principle 4

In order to achieve sustainable development, environmental protection shall constitute an integral part of the development process and cannot be considered in isolation from it.

Principle 5

All States and all people shall cooperate in the essential task of eradicating poverty as an indispensable requirement for sustainable development, in order to decrease the disparities in standards of living and better meet the needs of the majority of the people of the world.

Principle 6

The special situation and needs of developing countries, particularly the least developed and those most environmentally vulnerable, shall be given special priority. International actions in the field of environment and development should also address the interests and needs of all countries.

Principle 7

States shall cooperate in a spirit of global partnership to conserve, protect and restore the health and integrity of the Earth's ecosystem. In view of the different contributions to global environmental degradation, States have common but differentiated responsibilities. The developed countries acknowledge the responsibility that they bear in the international pursuit of sustainable development in view of the pressures their societies place on the global environment and of the technologies and financial resources they command.

Principle 8

To achieve sustainable development and a higher quality of life for all people, States should reduce and eliminate unsustainable patterns of production and consumption and promote appropriate demographic policies.

Principle 9

States should cooperate to strengthen endogenous capacity-building for sustainable development by improving scientific understanding through exchanges of scientific and technological knowledge, and by enhancing the development, adaptation, diffusion and transfer of technologies, including new and innovative technologies.

Principle 10

Environmental issues are best handled with the participation of all concerned citizens, at the relevant level. At the national level, each individual shall have appropriate access to information concerning the environment that is held by public authorities, including information on hazardous materials and activities in their communities, and the opportunity to participate in decision-making processes. States shall facilitate and encourage public awareness and participation by making information widely available. Effective access to judicial and administrative proceedings, including redress and remedy, shall be provided.

Principle 11

States shall enact effective environmental legislation. Environmental standards, management objectives and priorities should reflect the environmental and developmental context to which they apply. Standards applied by some countries may be inappropriate and of unwarranted economic and social cost to other countries, in particular developing countries.

Principle 12

States should cooperate to promote a supportive and open international economic system that would lead to economic growth and sustainable development in all countries, to better address the problems of environmental degradation. Trade policy measures for environmental purposes should not constitute a means of arbitrary or unjustifiable discrimination or a disguised restriction on international trade. Unilateral actions to deal with environmental challenges outside the jurisdiction of the importing country should be avoided. Environmental measures addressing transboundary or global environmental problems should, as far as possible, be based on an international consensus.

Principle 13

States shall develop national law regarding liability and compensation for the victims of pollution and other environmental damage. States shall also cooperate in an expeditious and more determined manner to develop further international law regarding liability and compensation for adverse effects of environmental damage caused by activities within their jurisdiction or control to areas beyond their jurisdiction.

Principle 14

States should effectively cooperate to discourage or prevent the relocation and transfer to other States of any activities and substances that cause severe environmental degradation or are found to be harmful to human health.

Principle 15

In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.

Principle 16

National authorities should endeavour to promote the internalization of environmental costs and the use of economic instruments, taking into account the approach that the polluter should, in principle, bear the cost of pollution, with due regard to the public interest and without distorting international trade and investment.

Principle 17

Environmental impact assessment, as a national instrument, shall be undertaken for proposed activities that are likely to have a significant adverse impact on the environment and are subject to a decision of a competent national authority.

Principle 18

States shall immediately notify other States of any natural disasters or other emergencies that are likely to produce sudden harmful effects on the environment of those States. Every effort shall be made by the international community to help States so afflicted.

Principle 19

States shall provide prior and timely notification and relevant information to potentially affected States on activities that may have a significant adverse transboundary environmental effect and shall consult with those States at an early stage and in good faith.

Principle 20

Women have a vital role in environmental management and development. Their full participation is therefore essential to achieve sustainable development.

Principle 21

The creativity, ideals and courage of the youth of the world should be mobilized to forge a global partnership in order to achieve sustainable development and ensure a better future for all.

Principle 22

Indigenous people and their communities and other local communities have a vital role in environmental management and development because of their knowledge and traditional practices. States should recognize and duly support their identity, culture and interests and enable their effective participation in the achievement of sustainable development.

Principle 23

The environment and natural resources of people under oppression, domination and occupation shall be protected.

Principle 24

Warfare is inherently destructive of sustainable development. States shall therefore respect international law providing protection for the environment in times of armed conflict and cooperate in its further development, as necessary.

Principle 25

Peace, development and environmental protection are interdependent and indivisible.

Principle 26

States shall resolve all their environmental disputes peacefully and by appropriate means in accordance with the Charter of the United Nations.

Principle 27

States and people shall cooperate in good faith and in a spirit of partnership in the fulfillment of the principles embodied in this Declaration and in the further development of international law in the field of sustainable development.

TECHNOREALISM MANIFESTO (1998)

• • •

1. Technologies are not neutral.

A great misconception of our time is the idea that technologies are completely free of bias—that because they are inanimate artifacts, they don't promote certain kinds of behaviors over others. In truth, technologies come loaded with both intended and unintended social, political, and economic leanings. Every tool provides its users with a particular manner of seeing the world and specific ways of interacting with others. It is important for each of us to consider the biases of various technologies and to seek out those that reflect our values and aspirations.

2. The Internet is revolutionary, but not Utopian.

The Net is an extraordinary communications tool that provides a range of new opportunities for people, communities, businesses, and government. Yet as cyberspace becomes more populated, it increasingly resembles society at large, in all its complexity. For every empowering or enlightening aspect of the wired life, there will also be dimensions that are malicious, perverse, or rather ordinary.

3. Government has an important role to play on the electronic frontier.

Contrary to some claims, cyberspace is not formally a place or jurisdiction separate from Earth. While governments should respect the rules and customs that have arisen in cyberspace, and should not stifle this new world with inefficient regulation or censorship, it is foolish to say that the public has no sovereignty over what an errant citizen or fraudulent corporation does online. As the representative of the people and the guardian of democratic values, the state has the right and responsibility to help integrate cyberspace and conventional society.

Technology standards and privacy issues, for example, are too important to be entrusted to the marketplace alone. Competing software firms have little interest in preserving the open standards that are essential to a fully functioning interactive network. Markets encourage innovation, but they do not necessarily insure the public interest.

4. Information is not knowledge.

All around us, information is moving faster and becoming cheaper to acquire, and the benefits are manifest. That said, the proliferation of data is also a serious challenge, requiring new measures of human discipline and skepticism. We must not confuse the thrill of acquiring or distributing information quickly with the more daunting task of converting it into knowledge and wisdom. Regardless of how advanced our computers become, we should never use them as a substitute for our own basic cognitive skills of awareness, perception, reasoning, and judgment.

5. Wiring the schools will not save them.

The problems with America's public schools—disparate funding, social promotion, bloated class size, crumbling infrastructure, lack of standards—have almost nothing to do with technology. Consequently, no amount of technology will lead to the educational revolution prophesied by President Clinton and others. The art of teaching cannot be replicated by computers, the Net, or by "distance learning." These tools can, of course, augment an already high-quality educational experience. But to rely on them as any sort of panacea would be a costly mistake.

6. Information wants to be protected.

It's true that cyberspace and other recent developments are challenging our copyright laws and frameworks for protecting intellectual property. The answer, though, is not to scrap existing statutes and principles. Instead, we must update old laws and interpretations so that information receives roughly the same protection it did in the context of old media. The goal is the same: to give authors sufficient control over their work so that they have an incentive to create, while maintaining the right of the public to make fair use of that information. In neither context does information want "to be free." Rather, it needs to be protected.

7. The public owns the airwaves; the public should benefit from their use.

The recent digital spectrum giveaway to broadcasters underscores the corrupt and inefficient misuse of public resources in the arena of technology. The citizenry should benefit and profit from the use of public frequencies, and should retain a portion of the spectrum for educational, cultural, and public access uses. We should demand more for private use of public property.

8. Understanding technology should be an essential component of global citizenship.

In a world driven by the flow of information, the interfaces—and the underlying code—that make information visible are becoming enormously powerful social forces. Understanding their strengths and limitations, and even participating in the creation of better tools, should be an important part of being an involved citizen. These tools affect our lives as much as laws do, and we should subject them to a similar democratic scrutiny.

DECLARATION ON SCIENCE AND THE USE OF SCIENTIFIC KNOWLEDGE (1999)

• • •

Preamble

1. We all live on the same planet and are part of the biosphere. We have come to recognize that we are in a situation of increasing interdependence, and that our future is intrinsically linked to the preservation of the global life-support systems and to the survival of all forms of life. The nations and the scientists of the world are called upon to acknowledge the urgency of using knowledge from all fields of science in a responsible manner to address human needs and aspirations without misusing this knowledge. We seek active collaboration across all the fields of scientific endeavor, that is the natural sciences such as the physical, earth and biological sciences, the biomedical and engineering sciences, and the social and human sciences. While the *Framework for Action* emphasizes the promise and the dynamism of the natural sciences but also their potential adverse effects, and the need to understand their impact on and relations with society, the commitment to science, as well as the challenges and the responsibilities set out in this Declaration, pertain to all fields of the sciences. All cultures can contribute scientific knowledge of universal value. The sciences should be at the service of humanity as a whole, and should contribute to providing everyone with a deeper understanding of nature and society, a better quality of life and a sustainable and healthy environment for present and future generations.
2. Scientific knowledge has led to remarkable innovations that have been of great benefit to humankind. Life expectancy has increased strikingly, and cures have been discovered for many diseases. Agricultural output has risen significantly in many parts of the world to meet growing population needs. Technological developments and the use of new energy sources have created the opportunity to free humankind from arduous labour. They have also enabled the generation of an expanding and complex range of industrial products and processes. Technologies based on new methods of communication, information handling and computation have brought unprecedented opportunities and challenges for the scientific endeavor as well as for society at large. Steadily improving scientific knowledge on the origin, functions and evolution of the universe and of life provides humankind with conceptual and practical approaches that profoundly influence its conduct and prospects.
3. In addition to their demonstrable benefits the applications of scientific advances and the development and expansion of human activity have also led to environmental degradation and technological disasters, and have contributed to social imbalance or exclusion. As one example, scientific progress has made it possible to manufacture sophisticated weapons, including conventional weapons and weapons of mass destruction. There is now an opportunity to call for a reduction in the resources allocated to the development and manufacture of new weapons and to encourage the conversion, at least partially, of military production and research facilities to civilian use. The United Nations General Assembly has proclaimed the year 2000 as International Year for the Culture of Peace and the year 2001 as United Nations Year of Dialogue among Civilizations as steps towards a lasting peace; the scientific community, together with

other sectors of society, can and should play an essential role in this process.

4. Today, whilst unprecedented advances in the sciences are foreseen, there is a need for a vigorous and informed democratic debate on the production and use of scientific knowledge. The scientific community and decision-makers should seek the strengthening of public trust and support for science through such a debate. Greater interdisciplinary efforts, involving both natural and social sciences, are a prerequisite for dealing with ethical, social, cultural, environmental, gender, economic and health issues. Enhancing the role of science for a more equitable, prosperous and sustainable world requires the long-term commitment of all stakeholders, public and private, through greater investment, the appropriate review of investment priorities, and the sharing of scientific knowledge.

5. Most of the benefits of science are unevenly distributed, as a result of structural asymmetries among countries, regions and social groups, and between the sexes. As scientific knowledge has become a crucial factor in the production of wealth, so its distribution has become more inequitable. What distinguishes the poor (be it people or countries) from the rich is not only that they have fewer assets, but also that they are largely excluded from the creation and the benefits of scientific knowledge.

6. We, participants in the *World Conference on Science for the Twenty-first Century:A New Commitment*, assembled in Budapest, Hungary, from 26June to 1 July 1999 under the aegis of the United Nations Educational, Scientific and Cultural Organization (UNESCO) and the International Council for Science (ICSU):

Considering:

7. where the natural sciences stand today and where they are heading, what their social impact has been and what society expects from them,

8. that in the twenty-first century science must become a shared asset benefiting all peoples on a basis of solidarity, that science is a powerful resource for understanding natural and social phenomena, and that its role promises to be even greater in the future as the growing complexity of the relationship between society and the environment is better understood,

9. the ever-increasing need for scientific knowledge in public and private decision-making, including notably the influential role to be played by science in the formulation of policy and regulatory decisions,

10. that access to scientific knowledge for peaceful purposes from a very early age is part of the right to education belonging to all men and women, and that science education is essential for human development, for creating endogenous scientific capacity and for having active and informed citizens,

11. that scientific research and its applications may yield significant returns towards economic growth and sustainable human development, including poverty alleviation, and that the future of humankind will become more dependent on the equitable production, distribution and use of knowledge than ever before,

12. that scientific research is a major driving force in the field of health and social care and that greater use of scientific knowledge would considerably improve human health,

13. the current process of globalization and the strategic role of scientific and technological knowledge within it,

14. the urgent need to reduce the gap between the developing and developed countries by improving scientific capacity and infrastructure in developing countries,

15. that the information and communication revolution offers new and more effective means of exchanging scientific knowledge and advancing education and research,

16. the importance for scientific research and education of full and open access to information and data belonging to the public domain,

17. the role played by the social sciences in the analysis of social transformations related to scientific and technological developments and the search for solutions to the problems generated in the process,

18. the recommendations of major conferences convened by the organizations of the United Nations system and others, and of the meetings associated with the World Conference on Science,

19. that scientific research and the use of scientific knowledge should respect human rights and the dignity of human beings, in accordance with the Universal Declaration of Human Rights and in the light of the Universal Declaration on the Human Genome and Human Rights,

20. that some applications of science can be detrimental to individuals and society, the environment and human health, possibly even threatening the continuing existence of the human species, and that the contribution of science is indispensable to the cause of peace and development, and to global safety and security,
21. that scientists with other major actors have a special responsibility for seeking to avert applications of science which are ethically wrong or have an adverse impact,
22. the need to practice and apply the sciences in line with appropriate ethical requirements developed on the basis of an enhanced public debate,
23. that the pursuit of science and the use of scientific knowledge should respect and maintain life in all its diversity, as well as the life-support systems of our planet,
24. that there is a historical imbalance in the participation of men and women in all science-related activities,
25. that there are barriers which have precluded the full participation of other groups, of both sexes, including disabled people, indigenous peoples and ethnic minorities, hereafter referred to as disadvantaged groups,
26. that traditional and local knowledge systems, as dynamic expressions of perceiving and understanding the world, can make, and historically have made, a valuable contribution to science and technology, and that there is a need to preserve, protect, research and promote this cultural heritage and empirical knowledge,
27. that a new relationship between science and society is necessary to cope with such pressing global problems as poverty, environmental degradation, inadequate public health, and food and water security, in particular those associated with population growth,
28. the need for a strong commitment to science on the part of governments, civil society and the productive sector, as well as an equally strong commitment of scientists to the well-being of society,

Proclaim the following:

1. Science for knowledge; knowledge for progress

29. The inherent function of the scientific endeavor is to carry out a comprehensive and thorough inquiry into nature and society, leading to new knowledge. This new knowledge provides educational, cultural and intellectual enrichment and leads to technological advances and economic benefits. Promoting fundamental and problem-oriented research is essential for achieving endogenous development and progress.
30. Governments, through national science policies and in acting as catalysts to facilitate interaction and communication between stakeholders, should give recognition to the key role of scientific research in the acquisition of knowledge, in the training of scientists and in the education of the public. Scientific research funded by the private sector has become a crucial factor for socio-economic development, but this cannot exclude the need for publicly-funded research. Both sectors should work in close collaboration and in a complementary manner in the financing of scientific research for long-term goals.

2. Science for peace

31. The essence of scientific thinking is the ability to examine problems from different perspectives and seek explanations of natural and social phenomena, constantly submitted to critical analysis. Science thus relies on critical and free thinking, which is essential in a democratic world. The scientific community, sharing a long-standing tradition that transcends nations, religions and ethnicity, should promote, as stated in the Constitution of UNESCO, the "intellectual and moral solidarity of mankind", which is the basis of a culture of peace. Worldwide cooperation among scientists makes a valuable and constructive contribution to global security and to the development of peaceful interactions between different nations, societies and cultures, and could give encouragement to further steps in disarmament, including nuclear disarmament.
32. Governments and society at large should be aware of the need to use natural and social sciences and technology as tools to address the root causes and impacts of conflict. Investment in scientific research which addresses them should be increased.

3. Science for development

33. Today, more than ever, science and its applications are indispensable for development. All levels of government and the private sector should provide

enhanced support for building up an adequate and evenly distributed scientific and technological capacity through appropriate education and research programs as an indispensable foundation for economic, social, cultural and environmentally sound development. This is particularly urgent for developing countries. Technological development requires a solid scientific basis and needs to be resolutely directed towards safe and clean production processes, greater efficiency in resource use and more environmentally friendly products. Science and technology should also be resolutely directed towards prospects for better employment, improving competitiveness and social justice. Investment in science and technology aimed both at these objectives and at a better understanding and safeguarding of the planet's natural resource base, biodiversity and life-support systems must be increased. The objective should be a move towards sustainable development strategies through the integration of economic, social, cultural and environmental dimensions.

34. Science education, in the broad sense, without discrimination and encompassing all levels and modalities, is a fundamental prerequisite for democracy and for ensuring sustainable development. In recent years, worldwide measures have been undertaken to promote basic education for all. It is essential that the fundamental role played by women in the application of scientific development to food production and health care be fully recognized, and efforts made to strengthen their understanding of scientific advances in these areas. It is on this platform that science education, communication and popularization need to be built. Special attention still needs to be given to marginalized groups. It is more than ever necessary to develop and expand science literacy in all cultures and all sectors of society as well as reasoning ability and skills and an appreciation of ethical values, so as to improve public participation in decision-making related to the application of new knowledge. Progress in science makes the role of universities particularly important in the promotion and modernization of science teaching and its coordination at all levels of education. In all countries, and in particular the developing countries, there is a need to strengthen scientific research in higher education, including postgraduate programs, taking into account national priorities.

35. The building of scientific capacity should be supported by regional and international cooperation, to ensure both equitable development and the spread and utilization of human creativity without discrimination of any kind against countries, groups or individuals. Cooperation between developed and developing countries should be carried out in conformity with the principles of full and open access to information, equity and mutual benefit. In all efforts of cooperation, diversity of traditions and cultures should be given due consideration. The developed world has a responsibility to enhance partnership activities in science with developing countries and countries in transition. Helping to create a critical mass of national research in the sciences through regional and international cooperation is especially important for small States and least developed countries. Scientific structures, such as universities, are essential for personnel to be trained in their own country with a view to a subsequent career in that country. Through these and other efforts conditions conducive to reducing or reversing the brain drain should be created. However, no measures adopted should restrict the free circulation of scientists.

36. Progress in science requires various types of cooperation at and between the intergovernmental, governmental and non-governmental levels, such as: multilateral projects; research networks, including South-South networking; partnerships involving scientific communities of developed and developing countries to meet the needs of all countries and facilitate their progress; fellowships and grants and promotion of joint research; programs to facilitate the exchange of knowledge; the development of internationally recognized scientific research centers, particularly in developing countries; international agreements for the joint promotion, evaluation and funding of mega-projects and broad access to them; international panels for the scientific assessment of complex issues; and international arrangements for the promotion of postgraduate training. New initiatives are required for interdisciplinary collaboration. The international character of fundamental research should be strengthened by significantly increasing support for long-term research projects and for international collaborative projects, especially those of global interest. In this respect particular attention should be given to the need for continuity of support for research. Access to these facilities for scientists from developing countries should be actively supported and open to all on the basis of scientific merit. The use of information

and communication technology, particularly through networking, should be expanded as a means of promoting the free flow of knowledge. At the same time, care must be taken to ensure that the use of these technologies does not lead to a denial or restriction of the richness of the various cultures and means of expression.

37. For all countries to respond to the objectives set out in this Declaration, in parallel with international approaches, in the first place national strategies and institutional arrangements and financing systems need to be set up or revised to enhance the role of sciences in sustainable development within the new context. In particular they should include: a long-term national policy on science to be developed together with the major public and private actors; support to science education and scientific research; the development of cooperation between R&D institutions, universities and industry as part of national innovation systems; the creation and maintenance of national institutions for risk assessment and management, vulnerability reduction, safety and health; and incentives for investment, research and innovation. Parliaments and governments should be invited to provide a legal, institutional and economic basis for enhancing scientific and technological capacity in the public and private sectors and facilitate their interaction. Science decision-making and priority-setting should be made an integral part of overall development planning and the formulation of sustainable development strategies. In this context, the recent initiative by the major G-8 creditor countries to embark on the process of reducing the debt of certain developing countries will be conducive to a joint effort by the developing and developed countries towards establishing appropriate mechanisms for the funding of science in order to strengthen national and regional scientific and technological research systems.

38. Intellectual property rights need to be appropriately protected on a global basis, and access to data and information is essential for undertaking scientific work and for translating the results of scientific research into tangible benefits for society. Measures should be taken to enhance those relationships between the protection of intellectual property rights and the dissemination of scientific knowledge that are mutually supportive. There is a need to consider the scope, extent and application of intellectual property rights in relation to the equitable production, distribution and use of knowledge. There is also a need to further develop appropriate national legal frameworks to accommodate the specific requirements of developing countries and traditional knowledge and its sources and products, to ensure their recognition and adequate protection on the basis of the informed consent of the customary or traditional owners of this knowledge.

4. Science in society and science for society

39. The practice of scientific research and the use of knowledge from that research should always aim at the welfare of humankind, including the reduction of poverty, be respectful of the dignity and rights of human beings, and of the global environment, and take fully into account our responsibility towards present and future generations. There should be a new commitment to these important principles by all parties concerned.

40. A free flow of information on all possible uses and consequences of new discoveries and newly developed technologies should be secured, so that ethical issues can be debated in an appropriate way. Each country should establish suitable measures to address the ethics of the practice of science and of the use of scientific knowledge and its applications. These should include due process procedures for dealing with dissent and dissenters in a fair and responsive manner. The World Commission on the Ethics of Scientific Knowledge and Technology of UNESCO could provide a means of interaction in this respect.

41. All scientists should commit themselves to high ethical standards, and a code of ethics based on relevant norms enshrined in international human rights instruments should be established for scientific professions. The social responsibility of scientists requires that they maintain high standards of scientific integrity and quality control, share their knowledge, communicate with the public and educate the younger generation. Political authorities should respect such action by scientists. Science curricula should include science ethics, as well as training in the history and philosophy of science and its cultural impact.

42. Equal access to science is not only a social and ethical requirement for human development, but also essential for realizing the full potential of scientific communities worldwide and for orienting scientific progress towards meeting the needs of humankind.

The difficulties encountered by women, constituting over half of the world's population, in entering, pursuing and advancing in a career in the sciences and in participating in decision-making in science and technology should be addressed urgently. There is an equally urgent need to address the difficulties faced by disadvantaged groups which preclude their full and effective participation.

43. Governments and scientists of the world should address the complex problems of poor health and increasing inequalities in health between different countries and between different communities within the same country with the objective of achieving an enhanced, equitable standard of health and improved provision of quality health care for all. This should be undertaken through education, by using scientific and technological advances, by developing robust long-term partnerships between all stakeholders and by harnessing programs to the task.

• • •

44. We, participants in the *World Conference on Science for the Twenty-first Century: A New Commitment*, commit ourselves to making every effort to promote dialogue between the scientific community and society, to remove all discrimination with respect to education for and the benefits of science, to act ethically and cooperatively within our own spheres of responsibility, to strengthen scientific culture and its peaceful application throughout the world, and to promote the use of scientific knowledge for the well-being of populations and for sustainable peace and development, taking into account the social and ethical principles illustrated above.

45. We consider that the Conference document *Science Agenda—Framework for Action* gives practical expression to a new commitment to science, and can serve as a strategic guide for partnership within the United Nations system and between all stakeholders in the scientific endeavor in the years to come.

46. We therefore adopt this *Declaration on Science and the Use of Scientific Knowledge* and agree upon the *Science Agenda—Framework for Action* as a means of achieving the goals set forth in the Declaration, and call upon UNESCO and ICSU to submit both documents to the General Conference of UNESCO and to the General Assembly of ICSU. The United Nations General Assembly will also be seized of these documents. The purpose is to enable both UNESCO and ICSU to identify and implement follow-up action in their respective programs, and to mobilize the support of all partners, particularly those in the United Nations system, in order to reinforce international coordination and cooperation in science.

DECLARATION OF SANTO DOMINGO (1999)

• • •

We, the Heads of State and/or Government of the States, Countries and Territories of the Association of Caribbean States (ACS), meeting in the City of Santo Domingo de Guzmán, Dominican Republic, on 16 and 17 April 1999;

Committed to the principles and objectives enshrined in the Convention Establishing the ACS, and recognizing the validity of the Declaration of Principles and Plan of Action on Tourism, Trade and Transport resulting from the historic First Summit held in Port of Spain, Trinidad and Tobago, in August 1995 and the priorities identified for promoting regional integration, functional co-operation and co-ordination among the Member States and Associate Members of the ACS;

Have decided to analyze the progress made by the ACS from Port-of-Spain 1995 to Santo Domingo 1999 and determine the projection of the Caribbean Region into the 21st Century; and therefore:

1. We identify tourism as the activity where the Association has achieved the most significant progress. We recognize that sustainable tourism constitutes an adequate response to the challenges of increasing rates of growth in employment and foreign exchange earnings, protecting and preserving the environment and natural resources, protecting cultural patrimony and values. We support community participation, as well as the involvement of local interests in aspects of the tourism development process, such as policy making, planning, management, ownership and the sharing of benefits generated by this activity. In this respect, we adopt the Declaration on the Sustainable Tourism Zone of the Caribbean (STZC).
2. We reiterate our commitment to work jointly for the consolidation of an enhanced economic space

for trade and investment, based on the principles of the World Trade Organization (WTO), for which we shall continue to encourage integration and co-operation measures that permit the strengthening of intra-regional trade and investment.

3. We note with satisfaction the progress yielded in the area of trade liberalization and economic integration in the sub-regional and bilateral spheres among the Member States and Associate Members of the ACS. Within the framework of Article XX of the Convention Establishing the ACS, the interested countries will continue to encourage according to their priorities, trade agreements and tariff preferences, as identified in the initiative to establish the Caribbean Preferential Tariff (CPT).

4. We reiterate that the rationalization and definition of regional transport policies are among the highest priorities of the ACS Plan of Action. We consider that transport must be the fundamental instrument for the development of tourism and trade in the region. In this respect, we emphasize our commitment to the objectives of the program "Uniting the Caribbean by Air and Sea".

5. Based on the fulfillment of commitments made in Agenda 21, we support the activities for the protection and conservation of the environment and natural resources. In addition, we support the effort of CARICOM to have the Caribbean Sea declared a Special Area in the context of Sustainable Development, and instruct that this subject be included in the Caribbean Environmental Strategy. For this purpose, a high level meeting of experts will be convened to study this topic. Participation in this meeting will be open to all members of the Association.

6. We consider the Caribbean Sea an invaluable asset and agree to give special priority to its preservation. We therefore deplore its ecological degradation and reject its continuous use for the transport of nuclear and toxic waste that may in any way cause a greater degradation of the Caribbean Sea.

7. We express our deepest solidarity with the countries and territories of the ACS affected by natural disasters in recent years, as well as by the extensive losses of lives and material resources, caused by these phenomena, which have increased their difficulties in implementing their programs of economic and social development.

8. We instruct the national authorities responsible for the prevention, mitigation and preparation for disasters, to put into practice, as soon as possible, the implementation mechanisms of the Regional Co-operation Agreement in the Area of Natural Disasters, signed by the Ministers of Foreign Affairs. In this respect, special focus will be placed on strengthening co-operation with the Caribbean Disaster and Emergency Response Agency (CDERA) and the Central American Co-ordination Centre for the Prevention of Natural Disasters (CEPREDENAC).

9. We emphasize the importance of co-operation in science and technology as the basis for the promotion of sustainable development of the region and in this respect, we observe with satisfaction the progress made in the development of the Co-operation Mechanism in the area of Science and Technology.

10. We recognize the efforts to widen regional collaboration and co-operation with respect to the linguistic integration program, the promotion of the teaching of the official languages of the ACS and the development of programs of integration, co-operation and exchanges in the areas of education and culture. Similarly, we express our support for the activities being developed in the region with regard to the preservation of the cultural patrimony, and the promotion and defense of our cultural values.

11. We appreciate the importance of international co-operation for the development of the peoples and economies of the region, and we take note of the renewed effort by the ACS Special Fund to work in this direction.

12. We are aware that globalization constitutes for the region an enormous challenge, that entails risks and opportunities. We therefore reiterate our interest in strengthening consultation and co-ordination of our positions in all those issues of mutual interest in the international agenda.

13. We agree that, faced with the rapid globalization process, multilateralism is the indispensable response for dealing with its challenges and utilizing its advantages, and in particular, for ensuring the effective exercise of the juridical equality of the States. We are aware moreover that the transparent and democratic functioning of multilateral bodies should be based on international law.

14. We reiterate our categorical rejection of all unilateral coercive measures, as well as the extraterritorial application of national laws by any State, since this is contrary to International Law, and more-

over threatens the sovereignty of States and international co-existence. In this context, we reiterate our exhortation to the Government of the United States of America to put an end to the application of the Helms-Burton Law, in accordance with the Resolutions approved by the United Nations General Assembly.

15. We reaffirm our commitment to the preservation, consolidation and strengthening of democracy, political pluralism and the Rule of Law, as an ideal framework that allows respect for the defense and promotion of all human rights, including the right to development and basic liberties. In this respect, we reiterate that civic participation is an indispensable element in the creation of a new political culture. We also reiterate respect for the principles of sovereignty and non-intervention, in addition to the right of all peoples to build their own political system in peace, stability and justice.

16. We reiterate moreover the need to implement social and economic measures aimed at achieving integrated and harmonious development, based on equity, social justice, the raising of the standards of living of the population, and the eradication of poverty, with the human being as the fundamental focus of development plans.

17. We renew our commitment to work for the sustainable development of the Caribbean through co-operation and integration.

18. We recognize the differences in the size and levels of development of the economies of the countries of the ACS and attach special significance to the vulnerability of the small economies of our region. We will take into consideration these differences in the treatment of the countries in the activities being developed within the framework of the ACS. We will search for means, complementary with suitable internal policies that would afford opportunities to encourage participation and further the level of development of the small and less developed economies.

19. We urge the international community to strengthen programs of technical and financial assistance, human resource training, and the transfer of technology, in order to improve the opportunities for the small and less developed economies to prosper in the international system.

20. In this context, we agree that there is a need to promote co-operation and concerted action among the Member States and Associate Members of the ACS, so as to increase the negotiating capability of our region in international fora.

21. We reaffirm the principles adopted at the First ACS Summit, with regard to the international problem of the illicit traffic of drugs and related crimes, which represents a serious threat to tourism, trade and transport, and indeed, endangers the sovereignty and security of each State.

22. We reiterate the principles governing international co-operation for dealing with the international problem of the illicit traffic of drugs and related crimes, including shared responsibility, the global, integrated and balanced approach, unrestricted respect for the principles of International Law, in particular those of sovereignty and territorial integrity. We therefore strongly reject every type of intervention in the internal matters of States and the extraterritorial application of domestic laws and unilateral measures. In this respect, we agree that programs, actions and results must be considered within an agreed intergovernmental framework.

23. We are aware of the great wealth of the cultural diversity in the Caribbean region and as a result, we agree to increase efforts in defense of our cultural identity, to protect and promote its expressions, given that culture is one of the fundamental bases for the integration of the Caribbean peoples.

24. We reiterate the commitment of our governments to work in close collaboration in order to contribute to the success of the European Union/Latin America and the Caribbean Summit, which constitutes an exceptional opportunity for promoting concerted action among ACS Members, increasing co-operation and enhancing existing dialogues and agreements between the two regions. To this end, we will promote the Latin American and Caribbean proposal, adopted in Mexico City, in December 1998, aimed at identifying inter-regional co-operation activities that contribute to enhancing relations with the countries of the European Union.

25. This Summit will also be a special occasion to establish a direct and frank dialogue with the leaders of the European Union, in order to advance in a decisive manner economic relations between both regions, especially in the areas of trade and investment, as well as to promote the convergence of efforts to restore international financial stability

and to redress the continued imbalances that might provoke a global recession.

26. We call for the optimization of the potential and opportunities provided by the sectoral links among the programs of the ACS and collaboration with relevant regional and national organizations, in order to ensure increasing complementarity among the activities of Member States and Associate Members.
27. We express our deep gratitude to the President of the Dominican Republic, His Excellency Leonel Fernández, and to the Government and people of the Dominican Republic, for the warmth, friendliness and lavish hospitality accorded to us throughout the Second Summit.

To give impetus to the goals and objectives outlined in this Declaration, we agree to adopt and execute the attached Plan of Action.

RIO DE JANEIRO DECLARATION ON ETHICS IN SCIENCE AND TECHNOLOGY (2003)

• • •

We, the Ministers and Higher Authorities of Science and Technology of South America, gathered in Rio de Janeiro on this 4th day of December, 2003, to reflect upon the limits that ethics impose on the production and use of scientific knowledge,

Considering:

the Declaration on the Use of Scientific Knowledge, signed in Budapest in 1999, that placed science in its social and international context as an instrument for the well being of all peoples, and called upon all countries to work for the good of humanity;

the overwhelming process of economic globalization and the growing impact of scientific development and technological innovations on our societies;

that the South American countries represented at this meeting recognize the need in the elaboration of their management policies for scientific and technological development to pay special attention to the ethical implications, so that principles founded upon such policies may serve as guidance for efforts to achieve the well-being of their peoples and their autonomy as nations;

that a more democratic and far-reaching application of this knowledge requires national and regional development projects that include society as a whole;

that such projects must be viewed from the harmonic perspective of our peoples' common international interests, in order to confront the current trends of globalization in the realm of science, technology, economics, politics, and culture;

that the ethical and human conscience that grows at the heart of our societies impels us to prioritize, in the distribution of the benefits of knowledge to all, especially to women and children as well as all facets of excluded and marginalized segments of society, and the production of knowledge by women;

that the principles of democracy and social justice should govern international relations, serving as a reference for fraternity among countries, nations, and peoples;

that democracy, independence, and respect not only for individual and regional differences but also for the right and the struggle for peace, must reflect, within our countries, the same struggle for liberty, respect for human rights and, fundamentally, access for all to the intangible and practical benefits of human knowledge in culture, the arts, science and technology, through education and democratization of the results of economic development;

that we must defend an international system that elects to combat hunger and exclusion, especially exclusion from all forms of knowledge, as the highest priority, promoting universal quality education and that assures the right of all to healthcare, education, and housing while at the same time hinders abuses of power, condemns discrimination, and denounces intolerance and all other conditions or interests that may lead to war and the breakdown of democratic structures;

that free access to scientific knowledge and to effective participation in its creation, as well as the technological development and innovation, allowing the integration of our efforts, especially with respect to the establishment of an effective network of scientific and technological cooperation;

recognizing that the scientific and technological component forms the basis of the so-called "knowledge economy" - the economy of the third millennium - and that improved scientific and technological capacity will allow the participation in this economy and therefore in development; and

Facing limits imposed by international trade rules which, most of the time, do not consider the interests of the developing countries and their populations, and that our countries will also face competition from those countries possessing technology, as well as their transnational companies, the main beneficiaries of so-called "globalization".

Do recommend:

that the foundational activities for science and technology, such as education, scientific research, culture and technological development, be recognized and treated as public goods, and that an effort be made to diffuse knowledge, placing it at the disposal of humanity, especially the communities of the Third World;

that the governments of the Region support UNESCO in its efforts to allow the sectors and activities which constitute the "knowledge economy" (education, science, and culture) to contribute to socio-economic development in order to ensure the effective democratization of the components of knowledge generated by the digital industry and to render more flexible trade practices in the international regime of intellectual property, particularly in public health;

that the governments devote greater attention to the treatment given to science and technology in the context of the international trade rules and negotiations, adopting new critical approaches to the rules in effect and generating innovative proposals that increase access for the countries in the Region to knowledge and its benefits;

that our governments promote and stimulate the dissemination of information and knowledge through significant investments in R&D, information technology, robotics and computer science, software and hardware, popularizing the sources and the means of information as well as promoting universal access for all citizens;

that our governments support the increase in the use and production of software, seeking autonomy and cost reductions for the countries of the region;

that national and regional research groups be established with the objective of studying alternatives for the production of low-cost personal computers, aimed at universalizing usage of such computers, as well as implementing projects for regional cooperation in this field;

Do further recommend:

that attention be given to non-proprietary treatment of software, transmissions, and other digital technologies essential to ensuring the linguistic-cultural diversity of countries with relatively low representation on the Internet as well as in the use of electronic databases;

that an international network of scientific and technological knowledge be created, public in nature and freely accessible, also linked to databases on patents and inventions;

that a fund be established for the promotion of education, science, and culture in cyberspace, in support of networks of public schools, universities and research institutes in the countries of the Region, whose objective would be to promote science in the classroom and its popularization;

that the protection of individual rights and freedoms be promoted in measures relating to the fight against terrorism and to the promotion of a culture of cybersecurity;

that nations work together for the creation of an international consensus for the conversion of a portion of the payment of the external debt of developing countries into national investments in science and technology;

that our governments consider, the development of capacities which allow people to have access to new knowledge that make possible their productive participation in new sectors, if technological change so demands;

that the commitment to create spaces of cooperation in science and technology among our countries be reiterated, in both the public and private sectors, taking into account the ethical, political, social, and economic challenges they face;

that the essential role of the United Nations System's specialized agencies, particularly UNESCO, be recognized in supporting the elaboration of effective policies and guidelines in the field of ethics of Science and Technology and in technical cooperation through the exchange of international specialists, resource mobilization programs for the promotion of integrated interdisciplinary approaches to cooperation for development in science and technology and for the transfer of technological knowledge;

that UNESCO's work in the field of Ethics of Science and Technology and its role as focal point and legitimate participant in the world-wide debate over this issue be recognized and supported;

that the establishment, by UNESCO, of a mechanism that integrates and proposes dialogue on issues related to the Ethics of Science and Technology among our Governments be supported in order to promote the creation of programs for the teaching of ethics in basic, secondary and higher education and teacher training programs in this area; and the establishment of a network of governmental and non-governmental institutions in this area be supported;

that the work of COMEST as an independent advisory body of UNESCO regarding issues of Ethics in Science and Technology be recognized and that participation in this Commission be improved by the continued inclusion of representatives from all continents;

that the recommendations set forth by COMEST in such areas as the teaching of ethics, outer space, energy, and water be examined, in order to reinforce and to incorporate where necessary this ethical reflection in national and regional policies, in strategies, and in projects;

that States, organizations and other institutions interested in promoting and deepening reflection on the ethics of science be encouraged to create national and institutional commissions on scientific ethics;

that States be urged to implement, within the shortest time possible, the Universal Declaration on the Human Genome and Human Rights, approved in 1997 at the United Nations General Assembly;

and that the International Declaration on Human Genetic Data, approved at the 32nd UNESCO General Conference, be supported.

Thus, the Ministers and Higher Authorities of Science and Technology of South America, gathered in Rio de Janeiro, request the Heads of State and Government to confirm the growing importance of the ethical dimension of Science and Technology for the promotion of sustainable and equitable development, supporting the strengthening of cooperation in Science and Technology, above all with respect to their ethical implications, among the countries of South America, under the terms of the present Declaration.

The signatories hereby agree to transmit this Declaration to the Secretary General of the United Nations, as well as to the Director-General of UNESCO.

Rio de Janeiro, December 4, 2003

Signatories:

ROBERTO AMARAL—Minister of Science and Technology of Brazil

TULIO DEL BONO—Secretary of Science and Technology of Argentina

LUIS ALBERTO LIMA—President of the National Council of Science and Technology (CONCYT) of Paraguay

MARIA DEL ROSÁRIO GUERRA—Director of the Colombian Institute for Development of Science and Technology (CONCIENCIAS)

BENJAMIN MARTICORENA—President of the National Council of Science and Technology (CONCYTEC) of Peru

CPLP Authorities:

JOÃO BATISTA NGANDAJINA—Minister of Science and Technology of Angola

MARIA DE FÁTIMA SILVA BARBOSA—Minister of National Education of Guinea-Bissau

LÍDIA MARIA ARTHUR BRITO—Minister of Higher Education, Science and Technology of Mozambique

MARIA DA GRAÇA CARVALHO—Minister of Science and Higher Education of Portugal

MARIA DE FÁTIMA SILVA BARBOSA—Minister of National Education of Guinea-Bissau

AHMEDABAD DECLARATION (2005)

• • •

This Declaration was made on January 20th, 2005, by more than 800 learners, thinkers and practitioners from over 40 countries, engaged in education for sustainable development, at the *Education for a Sustainable Future* conference held at Centre for Environment Education, Ahmedabad, India.

As the first international gathering of the United Nations Decade of Education for Sustainable Development (DESD), we warmly welcome this Decade that highlights the potential of action education to move people towards sustainable lifestyles and policies.

If the world's peoples are to enjoy a high quality of life, we must move quickly toward a sustainable future. Although most indicators point away from sustainability, growing grassroots efforts worldwide are taking on the enormous task of changing this trend.

We accept our responsibility and we urge all people to join us in doing all we can to pursue the principles of the Decade with humility, inclusivity, and a strong sense of humanity. We invite wide participation through networks, partnerships, and institutions.

As we gather in the city where Mahatma Gandhi lived and worked, we remember his words: "Education for life; education through life; education throughout life". These words underscore our commitment to the ideal of education that is participatory and lifelong.

We firmly believe that a key to sustainable development is the empowerment of all people, according to the principles of equity and social justice, and that a key to such empowerment is action-oriented education.

ESD implies a shift from viewing education as a delivery mechanism, to the recognition that we are all learners as well as teachers. ESD must happen in villages and cities, schools and universities, corporate offices and assembly lines, and in the offices of ministers and civil servants. All must struggle with how to live and work in a way that protects the environment, advances social justice, and promotes economic fairness for present and future generations. We must learn how to resolve conflicts, create a caring society, and live in peace.

ESD must start with examining our own lifestyles and our willingness to model and advance sustainability in our communities. We pledge to share our diverse experiences and collective knowledge to refine the vision of sustainability while continually expanding its practice. Through our actions we will add substance and vigor to the UNDESD processes.

We are optimistic that the objectives of the Decade will be realized and move forward from Ahmedabad in a spirit of urgency, commitment, hope, and enthusiasm.

CHEMIST'S CODE OF CONDUCT OF THE AMERICAN CHEMICAL SOCIETY

The American Chemical Society expects its members to adhere to the highest ethical standards. Indeed, the federal Charter of the Society (1937) explicitly lists among its objectives **"the improvement of the qualifications and usefulness of chemists through high standards of professional ethics, education and attainments"**

Chemists have professional obligations to the public, to colleagues, and to science. One expression of these obligations is embodied in "The Chemist's Creed," approved by the ACS Council in 1965. The principles of conduct enumerated below are intended to replace "The Chemist's Creed". They were prepared by the Council Committee on Professional Relations, approved by the Council (March 16, 1994), and adopted by the Board of Directors (June 3, 1994) for the guidance of society members in various professional dealings, especially those involving conflicts of interest.

Chemists Acknowledge Responsibilities To:

- The Public: Chemists have a professional responsibly to serve the public interest and welfare and to further knowledge of science. Chemists should actively be concerned with the health and welfare of co-workers, consumer and the community. Public comments on scientific matters should be made with care and precision, without unsubstantiated, exaggerated, or premature statements.
- The Science of Chemistry: Chemists should seek to advance chemical science, understand the limitations of their knowledge, and respect the truth. Chemists should ensure that their scientific contributions, and those of the collaborators, are thorough, accurate, and a unbiased in design, implementation, and presentation.
- The Profession: Chemists should remain current with developments in their field, share ideas and information, keep accurate and complete laboratory records, maintain integrity in all conduct and publications, and give due credit to the contributions of others. Conflicts of interest and scientific misconduct, such as fabrication, falsification, and plagiarism, are incompatible with this Code.
- The Employer: Chemists should promote and protect the legitimate interests of their employers, perform work honestly and competently, fulfill obligations, and safeguard proprietary information.
- Employees: Chemists, as employers, should treat subordinates with respect for their professionalism and concern for their well-being, and provide them with a safe, congenial working environment, fair compensation, and proper acknowledgment of their scientific contributions.
- Students: Chemists should regard the tutelage of students as a trust conferred by society for the promotion of the student's learning and professional development. Each student should be treated respectfully and without exploitation.
- Associates: Chemists should treat associates with respect, regardless of the level of their formal education, encourage them, learn with them, share ideas honestly, and give credit for their contributions.
- Clients: Chemists should serve clients faithfully and incorruptibly, respect confidentiality, advise honestly, and charge fairly.
- The Environment: Chemists should understand and anticipate the environmental consequences of their work. Chemists have responsibility to avoid pollution and to protect the environment.

CODE OF ETHICS OF THE AMERICAN ANTHROPOLOGICAL ASSOCIATION

I. Preamble

Anthropological researchers, teachers and practitioners are members of many different communities, each with its own moral rules or codes of ethics. Anthropologists have moral obligations as members of other groups, such as the family, religion, and community, as well as the profession. They also have obligations to the scholarly discipline, to the wider society and culture, and to the human species, other species, and the environment. Furthermore, fieldworkers may develop close relationships with persons or animals with whom they work, generating an additional level of ethical considerations.

In a field of such complex involvements and obligations, it is inevitable that misunderstandings, conflicts, and the need to make choices among apparently incompatible values will arise. Anthropologists are responsible for grappling with such difficulties and struggling to resolve them in ways compatible with the principles stated here. The purpose of this Code is to foster discussion and education. The American Anthropological Association (AAA) does not adjudicate claims for unethical behavior.

The principles and guidelines in this Code provide the anthropologist with tools to engage in developing and maintaining an ethical framework for all anthropological work.

II. Introduction

Anthropology is a multidisciplinary field of science and scholarship, which includes the study of all aspects of humankind—archaeological, biological, linguistic and sociocultural. Anthropology has roots in the natural and social sciences and in the humanities, ranging in approach from basic to applied research and to scholarly interpretation.

As the principal organization representing the breadth of anthropology, the American Anthropological Association (AAA) starts from the position that generating and appropriately utilizing knowledge (i.e., publishing, teaching, developing programs, and informing policy) of the peoples of the world, past and present, is a worthy goal; that the generation of anthropological knowledge is a dynamic process using many different and ever-evolving approaches; and that for moral and practical reasons, the generation and utilization of knowledge should be achieved in an ethical manner.

The mission of American Anthropological Association is to advance all aspects of anthropological research and to foster dissemination of anthropological knowledge through publications, teaching, public education, and application. An important part of that mission is to help educate AAA members about ethical obligations and challenges involved in the generation, dissemination, and utilization of anthropological knowledge.

The purpose of this Code is to provide AAA members and other interested persons with guidelines for making ethical choices in the conduct of their anthropological work. Because anthropologists can find themselves in complex situations and subject to more than one code of ethics, the AAA Code of Ethics provides a framework, not an ironclad formula, for making decisions.

Persons using the Code as a guideline for making ethical choices or for teaching are encouraged to seek out illustrative examples and appropriate case studies to enrich their knowledge base.

Anthropologists have a duty to be informed about ethical codes relating to their work, and ought periodically to receive training on current research activities and ethical issues. In addition, departments offering anthropology degrees should include and require ethical training in their curriculums.

No code or set of guidelines can anticipate unique circumstances or direct actions in specific situations. The individual anthropologist must be willing to make carefully considered ethical choices and be prepared to make clear the assumptions, facts and issues on which those choices are based. These guidelines therefore address *general* contexts, priorities and relationships which should be considered in ethical decision making in anthropological work.

III. Research

In both proposing and carrying out research, anthropological researchers must be open about the purpose(s), potential impacts, and source(s) of support for research projects with funders, colleagues, persons studied or providing information, and with relevant parties affected by the research. Researchers must expect to utilize the results of their work in an appropriate fashion and disseminate the results through appropriate and timely activities. Research fulfilling these expectations is ethical, regardless of the source of funding (public or private) or purpose (i.e., "applied," "basic," "pure," or "proprietary").

Anthropological researchers should be alert to the danger of compromising anthropological ethics as a condition to engage in research, yet also be alert to proper demands of good citizenship or host-guest relations. Active contribution and leadership in seeking to shape public or private sector actions and policies may be as ethically justifiable as inaction, detachment, or noncooperation, depending on circumstances. Similar principles hold for anthropological researchers employed or otherwise affiliated with nonanthropological institutions, public institutions, or private enterprises.

A. Responsibility to people and animals with whom anthropological researchers work and whose lives and cultures they study.

1. Anthropological researchers have primary ethical obligations to the people, species, and materials they study and to the people with whom they work. These obligations can supersede the goal of seeking new knowledge, and can lead to decisions not to undertake or to discontinue a research project when the primary obligation conflicts with other responsibilities, such as those owed to sponsors or clients. These ethical obligations include:

- To avoid harm or wrong, understanding that the development of knowledge can lead to change which may be positive or negative for the people or animals worked with or studied
- To respect the well-being of humans and nonhuman primates
- To work for the long-term conservation of the archaeological, fossil, and historical records
- To consult actively with the affected individuals or group(s), with the goal of establishing a working relationship that can be beneficial to all parties involved

2. Anthropological researchers must do everything in their power to ensure that their research does not harm the safety, dignity, or privacy of the people with whom they work, conduct research, or perform other professional activities. Anthropological researchers working with animals must do everything in their power to ensure that the research does not harm the safety, psychological well-being or survival of the animals or species with which they work.

3. Anthropological researchers must determine in advance whether their hosts/providers of information wish to remain anonymous or receive recognition, and make every effort to comply with those wishes. Researchers must present to their research participants the possible impacts of the choices, and make clear that despite their best efforts, anonymity may be compromised or recognition fail to materialize.

4. Anthropological researchers should obtain in advance the informed consent of persons being studied, providing information, owning or controlling access to material being studied, or otherwise identified as having interests which might be impacted by the research. It is understood that the degree and breadth of informed consent required will depend on the nature of the project and may be affected by requirements of other codes, laws, and ethics of the country or community in which the research is pursued. Further, it is understood that the informed consent process is dynamic and continuous; the process should be initiated in the project design and continue through implementation by way of dialogue and negotiation with those studied. Researchers are responsible for identifying and complying with the various informed consent codes, laws and regulations affecting their projects. Informed consent, for the purposes of this code, does not necessarily imply or require a particular written or signed form. It is the quality of the consent, not the format, that is relevant.

5. Anthropological researchers who have developed close and enduring relationships (i.e., covenantal relationships) with either individual persons providing information or with hosts must adhere to the obligations of openness and informed consent, while carefully and respectfully negotiating the limits of the relationship.

6. While anthropologists may gain personally from their work, they must not exploit individuals, groups, animals, or cultural or biological materials. They should recognize their debt to the societies in which they work and their obligation to reciprocate with people studied in appropriate ways.

B. Responsibility to scholarship and science

1. Anthropological researchers must expect to encounter ethical dilemmas at every stage of their work, and must make good-faith efforts to identify potential ethical claims and conflicts in advance when preparing proposals and as projects proceed. A section raising and responding to potential ethical issues should be part of every research proposal.

2. Anthropological researchers bear responsibility for the integrity and reputation of their discipline, of scholarship, and of science. Thus, anthropological researchers are subject to the general moral rules of scientific and scholarly conduct: they should not deceive or knowingly misrepresent (i.e., fabricate evidence, falsify, plagiarize), or attempt to prevent reporting of misconduct, or obstruct the scientific/scholarly research of others.

3. Anthropological researchers should do all they can to preserve opportunities for future fieldworkers to follow them to the field.

4. Anthropological researchers should utilize the results of their work in an appropriate fashion, and

whenever possible disseminate their findings to the scientific and scholarly community.

5. Anthropological researchers should seriously consider all reasonable requests for access to their data and other research materials for purposes of research. They should also make every effort to insure preservation of their fieldwork data for use by posterity.

C. Responsibility to the public

1. Anthropological researchers should make the results of their research appropriately available to sponsors, students, decision makers, and other nonanthropologists. In so doing, they must be truthful; they are not only responsible for the factual content of their statements but also must consider carefully the social and political implications of the information they disseminate. They must do everything in their power to insure that such information is well understood, properly contextualized, and responsibly utilized. They should make clear the empirical bases upon which their reports stand, be candid about their qualifications and philosophical or political biases, and recognize and make clear the limits of anthropological expertise. At the same time, they must be alert to possible harm their information may cause people with whom they work or colleagues.

2. Anthropologists may choose to move beyond disseminating research results to a position of advocacy. This is an individual decision, but not an ethical responsibility.

IV. Teaching

Responsibility to students and trainees

While adhering to ethical and legal codes governing relations between teachers/mentors and students/ trainees at their educational institutions or as members of wider organizations, anthropological teachers should be particularly sensitive to the ways such codes apply in their discipline (for example, when teaching involves close contact with students/trainees in field situations). Among the widely recognized precepts which anthropological teachers, like other teachers/mentors, should follow are:

1. Teachers/mentors should conduct their programs in ways that preclude discrimination on the basis of sex, marital status, "race," social class, political convictions, disability, religion, ethnic background, national origin, sexual orientation, age, or other criteria irrelevant to academic performance.

2. Teachers'/mentors' duties include continually striving to improve their teaching/training techniques; being available and responsive to student/trainee interests; counseling students/ trainees realistically regarding career opportunities; conscientiously supervising, encouraging, and supporting students'/trainees' studies; being fair, prompt, and reliable in communicating evaluations; assisting students/ trainees in securing research support; and helping students/ trainees when they seek professional placement.

3. Teachers/mentors should impress upon students/ trainees the ethical challenges involved in every phase of anthropological work; encourage them to reflect upon this and other codes; encourage dialogue with colleagues on ethical issues; and discourage participation in ethically questionable projects.

4. Teachers/mentors should publicly acknowledge student/trainee assistance in research and preparation of their work; give appropriate credit for coauthorship to students/trainees; encourage publication of worthy student/trainee papers; and compensate students/trainees justly for their participation in all professional activities.

5. Teachers/mentors should beware of the exploitation and serious conflicts of interest which may result if they engage in sexual relations with students/trainees. They must avoid sexual liaisons with students/trainees for whose education and professional training they are in any way responsible.

V. Application

1. The same ethical guidelines apply to all anthropological work. That is, in both proposing and carrying out research, anthropologists must be open with funders, colleagues, persons studied or providing information, and relevant parties affected by the work about the purpose(s), potential impacts, and source(s) of support for the work. Applied anthropologists must intend and expect to utilize the results of their work appropriately (i.e., publication, teaching, program and policy development) within a reasonable time. In situations in which anthropological knowledge is applied, anthropologists bear the same responsibility to be open and candid about their skills and intentions, and monitor the effects of their work on all persons affected. Anthropologists may be involved in many types of work, frequently affecting individuals and groups with diverse and sometimes conflicting interests. The individual anthropologist must make carefully considered ethical choices and be prepared to make clear the assumptions, facts and issues on which those choices are based.

2. In all dealings with employers, persons hired to pursue anthropological research or apply anthropological knowledge should be honest about their qualifications, capabilities, and aims. Prior to making any professional commitments, they must review the purposes of prospective employers, taking into consideration the employer's past activities and future goals. In working for governmental agencies or private businesses, they should be especially careful not to promise or imply acceptance of conditions contrary to professional ethics or competing commitments.

3. Applied anthropologists, as any anthropologist, should be alert to the danger of compromising anthropological ethics as a condition for engaging in research or practice. They should also be alert to proper demands of hospitality, good citizenship and guest status. Proactive contribution and leadership in shaping public or private sector actions and policies may be as ethically justifiable as inaction, detachment, or noncooperation, depending on circumstances.

VI. Epilogue

Anthropological research, teaching, and application, like any human actions, pose choices for which anthropologists individually and collectively bear ethical responsibility. Since anthropologists are members of a variety of groups and subject to a variety of ethical codes, choices must sometimes be made not only between the varied obligations presented in this code but also between those of this code and those incurred in other statuses or roles. This statement does not dictate choice or propose sanctions. Rather, it is designed to promote discussion and provide general guidelines for ethically responsible decisions.

HIPPOCRATIC OATH FOR SCIENTISTS (U.S. STUDENT PUGWASH GROUP VERSION)

"I promise to work for a better world, where science and technology are used in socially responsible ways.

I will not use my education for any purpose intended to harm human beings or the environment. Throughout my career, I will consider the ethical implications of my work before I take action. While the demands placed upon me may be great, I sign this declaration because I recognize that individual responsibility is the first step on the path to peace."

INTERNATIONAL NETWORK OF ENGINEERS AND SCIENTISTS FOR GLOBAL RESPONSIBILITY (INES)

Appeal to Engineers and Scientists (1995)

APPEAL Science and technology influence the social, economic and political development of civilization throughout the world. In many ways science and technology have made our life easier, richer and safer. However, science and technology can be used for destructive purposes and are key factors in the current growth economy that is threatening the viability of the biosphere and of human societies.

In its origins, science is a search for truth about our world. Its results can be used for good and misused for evil. Technological consequences are now so powerful and interconnected, so sweeping in unforeseen results, that they endanger basic requirements for sustaining life on earth. Without adherence to generally accepted ethical standards, science and technology can damage the future of society and life itself.

The greatest challenge of our time is to enable to all members of the world population to live in dignity in a manner that is sustainable for humankind and nature. In meeting this challenge science and technology—if used in the right way—play a decisive role by providing the necessary means or by analyzing the various consequences of human activities.

The web of humanity and life as a whole must not be endangered by vested interests. Knowledge gives power, and power may corrupt and be used for destructive purposes. Therefore, social structures and institutions on local, national, regional and global levels are urgently needed to promote responsible uses of science and technology. We appeal to engineers and scientists to respect human rights and human dignity unconditionally.

Secrecy of scientific and technological research allows its misuse. Our vision is a science which seeks truth in open discourse.

In the last decades several initiatives promoting ethical pledges of scientists have been launched. The values underlying these pledges can form the foundation of a worldwide community of responsibility among scientists and engineers. In adherence to the UNESCO Declaration for Scientific Professionals of November 1974, we have attempted to harmonize existing pledges into the following code of ethics:

PLEDGE 1. I acknowledge as a scientist or engineer that I have a special responsibility for the future of humankind. I share a duty to sustain life as a whole. I therefore pledge to reflect upon my scientific work and its possible consequences in advance and to judge it according to ethical standards. I will do this even though it is not possible to foresee all possible consequences and even if I have no direct influence on them.

2. I pledge to use my knowledge and abilities for the protection and enrichment of life. I will respect human rights, and the dignity and importance of all forms of life in their interconnectedness. I am aware that curiosity and pressure to succeed may lead me into conflict with that objective. If there are indications that my work could pose severe threats to human life or to the environment, I will abstain until appropriate assessment and precautionary actions have been taken. If necessary and appropriate, I will inform the public.

3. I pledge not to take part in the development and production of weapons of mass destruction and of weapons that are banned by international conventions. Aware that even conventional arms can contribute to mass destruction, I will support political efforts to bring arms production, arms trade, and the transfer of military technology under strict international control.

4. I pledge to be truthful and to subject the assumptions, methods, findings and goals of my work, including possible impacts on humanity and on the environment, to open and critical discussion. To the best of my ability I shall contribute to public understanding of science. I shall support public participation in a critical discussion of the funding priorities and uses of science and technology. I will carefully consider the arguments from such discussions which question my work or its impact.

5. I pledge to support the open publication and discussion of scientific research. Since the results of science ultimately belong to humankind, I will conscientiously consider my participation in secret research projects that serve military or economic interests. I will not participate in secret research projects if I conclude that society will be injured thereby. Should I decide to participate in any secret research, I will continuously reflect upon its implications for society and the environment.

6. I pledge to enhance the awareness of ethical principles and the resulting obligations among scientists and engineers. I will join fellow scientists and others willing to take responsibility. I will support those who might experience professional disadvantages in attempting to live up to the principles of this pledge. I will support the establishment and the work of institutions that enable scientists to exercise their responsibilities more effectively according to this pledge.

7. I pledge to support research projects, whether in basic or applied science, that contribute to the solution of vital problems of humankind, including poverty, violations of human rights, armed conflicts and environmental degradation.

8. I acknowledge my duty to present and future generations, and pledge that the fulfillment of this duty will not be influenced by material advantages or political, national or economic loyalties.

The above text incorporates material and ideas from the following declarations:

- The Mount Carmel Declaration on Technology and Moral Responsibility (Haifa, 1974)
- The Biologists Pledge (MIT, 1987)
- Hippocratic Oath for Scientists (Nuclear Age Peace Foundation, (1987)
- The Buenos Aires Oath (Buenos Aires, 1988)
- The Uppsala Code of Ethics for Scientists (Uppsala, 1984)
- Hippocratic Oath for Scientists, Engineers and Executives (Inst. for Social Inventions, 1987)
- Scientists Pledge Not to Take Part in Military-Directed Research (SANA, London, 1991)
- Appeal to Scientists (Wittenberg, 1989)
- A Pledge for Scientists (Berlin, 1984)
- The Toronto Resolution (Toronto, 1991)

We see these declarations as a part of a wider movement which has expressed itself in particular in the Declaration of a Global Ethic of the Parliament of the World's Religions (Chicago, 1993) and in the Trieste Declaration of Human Duties (Trieste, 1994).

7. GOVERNMENT

DEFINITION OF RESEARCH MISCONDUCT FROM THE U.S. FEDERAL REGISTER

Research misconduct is defined as fabrication, falsification, or plagiarism in proposing, performing, or reviewing research, or in reporting research results.

1. No rights, privileges, benefits or obligations are created or abridged by issuance of this policy alone. The creation or abridgment of rights, privileges, benefits or obligations, if any, shall occur only upon implementation of this policy by the Federal agencies.

2. Research, as used herein, includes all basic, applied, and demonstration research in all fields of science, engineering, and mathematics. This includes, but is not limited to, research in economics, education, linguistics, medicine, psychology, social sciences, statistics, and research involving human subjects or animals.

Fabrication is making up data or results and recording or reporting them.

Falsification is manipulating research materials, equipment, or processes, or changing or omitting data or results such that the research is not accurately represented in the research record.

3. The research record is the record of data or results that embody the facts resulting from scientific inquiry, and includes, but is not limited to, research proposals, laboratory records, both physical and electronic, progress reports, abstracts, theses, oral presentations, internal reports, and journal articles.

Plagiarism is the appropriation of another person's ideas, processes, results, or words without giving appropriate credit.

Research misconduct does not include honest error or differences of opinion.
