Joy, Bill. (2000). "Why The Future Doesn't Need Us." *Wired* 8(4): April. Available from http://www.wired.com/wired/archive/8.04/joy.html. Argues that research in biotechnology, artificial intelligence, robotics and nanotechnology should be regulated, and in some instances prohibited, because they pose a threat to human survival.

HISTORICAL TRADITIONS

The relation between science, technology, and Christianity has been subjected to varying interpretations. A popular impression inherited from the Enlightenment of the eighteenth century is that the relationship is one of perpetual conflict. Science is opposed to religious belief and, by focusing on material phenomena, diverts attention from spiritual concerns. In reaction, some scholars contend that Christian theology provided the intellectual foundations for modern science and technology. Because nature was not sacred it was open to investigation and manipulation, activities that improved the human condition and were therefore compatible with Christian convictions. In distinction from both these analyses, other theologians contend that the relationship is characterized by neither hostility nor affinity. Science and religion represent two different forms of inquiry and discourse, and technology consists of neutral instruments that can be used for either good or evil purposes. These varying interpretations are reflected in the historical development of this relationship, which in turn informs contemporary assessments.

Premodern Christian Attitudes toward Nature, Science, and Technology

Early Christian interpretation of Scripture reflects ambiguous appraisals of activities associated with science and technology. Work, for example, is both extolled as a sacred vocation and portrayed as punishment for Adam's original sin. The grandeur and beauty of creation that humans cannot fully understand and master is juxtaposed with a dominion that they are called by God to exert over a world that is often inimical to their welfare, a mandate that can be accomplished only with the aid of tools and artifacts. There is, in short, no obvious endorsement or condemnation of what is now called science (*episteme* and *logos*) and technology (*techne*) in the Bible.

As recorded in the Gospels, Jesus of Nazareth often alluded to nature in his parables and, except for the last week in Jerusalem before his crucifixion, confined his ministry largely to the countryside. Care should be taken, however, not to read too much into such general observations. It is not clear if these allusions imply a positive view of nature or if Jesus employed familiar scenes for his predominantly rural audience; nor should his death be construed as a blanket condemnation of urban life. Jesus, after all, was also a carpenter (*tekton*).

In contrast, Paul makes few references to nature, and spent his ministry almost entirely in cities along the Mediterranean. Moreover, he thanked God for the mobility and safety afforded by Roman roads and ships that assisted his missionary work. Caution dictates, however, against concluding that Paul valued human artifacts more highly than nature. Although he appreciates the ability to transform natural resources into useful tools, Paul also offers the enigmatic vision of creation groaning in futility awaiting its salvation, implying that nature has an intrinsic value and will be included in God's final redemptive act (*Romans* 8:18–25).

This ambiguity extends into the patristic period (the first few centuries C.E.). Although Tertullian (c. 155 or 160–after 220 C.E.), for instance, admits that natural philosophy may disclose some of the workings of creation, he insists that the knowledge revealed in Scripture is of far greater importance. The former deals only with temporal matters, whereas the latter is focused on eternity. The science of Athens has nothing significant to add to the faith of Jerusalem. Gregory of Nazianzus (c. 330–c. 389) was more open to what Athens offered, using the science of his day to expound the creation stories found in Genesis. But he too concludes that mystical experience is superior to natural knowledge.

Augustine of Hippo (354–430) likewise insisted that revelation was superior to unaided reason, but he exhibited, to a greater extent than previous theologians, an appreciation of natural philosophy. He rebuked fellow Christians who were uninformed about the natural workings of the world that were well known to educated unbelievers, complaining that their ignorance brought the faith into disrepute. Moreover, Augustine argued that because the world is God's good creation, the material aspects of life should not be despised. In contrast to Greek philosophy, the physical world is not a place of vulgar necessity in which the craft of artisans is inherently inferior to contemplative pursuits. Augustine praised human intellect and ingenuity, singling out achievements in such areas as agriculture, architecture, navigation, communication, medicine, military weaponry, and the arts (*City of God*, Book XXII, Chapter 24).

Interest in science and technology waxed and waned among subsequent generations of theologians. It was with the recovery of Aristotle (384–322 B.C.E.) by scholastic theologians that attention gathered momentum. This is particularly the case in the synthesis of Augustinian and Aristotelian themes by Thomas Aquinas (1225–1274). Thomas argued that reason and revelation do not contradict each other, and grace perfects rather than negates nature. Knowledge about the world complements and amplifies religious belief.

The recovery of Aristotle also transformed the medieval university. Alongside the faculties of theology, law, and medicine, the arts and sciences grew in prestige and intellectual rigor. Inevitable tensions arose as rediscovered texts in Greek mathematics, physics, and astronomy were refined and elaborated upon, but a great deal of latitude was given to scientific inquiry so long as it did not challenge directly the church's core theological teachings.

Modern Christian Attitudes toward Science and Technology

Tension nevertheless grew more intense as scientists gained greater confidence in their methods of investigation. Galileo Galilei (1564–1642), for example, was tried and convicted of heresy because his defense of a heliocentric universe displaced the earth from its central position. More importantly, this shift from the center to the periphery implied that humankind could no longer regard itself as the apex of creation. The case of Galileo, however, is not representative of the relation between Catholicism and science throughout the sixteenth and seventeenth centuries. Many Catholics, such as Marin Mersenne (1588–1648), René Descartes (1596–1650), and Pierre Gassendi (1592–1655), made important contributions to science during this period.

Protestants, however, tended to view science and technology in a more accommodating manner. The ordering of creation was subject to God's providential governance, which though at times inscrutable was ultimately intelligible. Scientific inquiry could disclose the workings of divine providence, and scientists were thereby encouraged to explore the created order. Many Protestants, for example, were influential members of the Royal Society. This framework led scientists such as Johannes Kepler (1571–1630), Isaac Newton (1642–1727), and Robert Boyle (1627–1691) to investigate nature with relative freedom, leading to numerous important discoveries. More significantly, many discoveries contributed to inventive developments in commerce and industry.

The Enlightenment and its aftermath placed severe strains on this Protestant framework. The problem was primarily philosophical. A number of philosophers claimed that the physical world could be described in naturalistic terms independently from theistic beliefs. Initially, many theologians invoked science as an ally in defending traditional doctrines against deist and atheist attacks. Natural theology in particular drew heavily upon science to argue that nature had been designed by a creator. The image of a watch and watchmaker was often used as a popular analogy. Yet the analogy required appeal to consistent laws of nature rather than an inscrutable divine providence to account for the rational ordering of the universe. Significantly, scientists could appeal to these same laws without attributing their legislation to the God of the Bible and Christian dogma.

Both theologians and scientists referred to nature in increasingly mechanistic terms. This in part reflected the rapid proliferation of inventions and other technological innovations associated with scientific discoveries. A growing knowledge of natural laws could be applied to improving the quality of human life by constructing more effective tools and artifacts. Progress thus displaced providence as the dominant conceptual framework for charting the course and destiny of human history. This progressive ideology introduced a tacit division of labor in which nature was a realm studied by science, whereas spiritual and moral concerns fell within ecclesiastical purview. Conflict was avoided so long as neither party crossed these jurisdictional boundaries.

In the nineteenth century this tacit division began to unravel. Charles Darwin's *The Descent of Man* (1871) implied that even human nature could be explicated in naturalistic categories. Natural selection and not the presence of a soul shaped human behavior. In short, there was no longer a unique sphere that Christianity could claim as its own. It should not be assumed, however, that the ensuing battle lines were drawn evenly or predictably. Darwin had both his scientific critics and religious defenders, and it is arguable that new forms of biblical criticism (before Darwin) and Freudian psychology (after him) presented more severe challenges to traditional Christian beliefs than evolution.

Christianity in the Industrial Revolution

Nevertheless, Darwinian evolution influenced later developments in ethics and social theory related to the rapid industrialization of the late nineteenth and early twentieth centuries. The image of nature red in tooth and claw captured both public and intellectual attention. Social Darwinists, such as Herbert Spencer (1820–1903) and William Graham Sumner (1840–1910), contended that what was true in nature was also true in society, namely, that competition over scarce resources promoted a strong and vibrant human race. Moreover, science and technology were key factors in ensuring the survival of the fittest. This was readily apparent in the economic realm, where the rapid development of new industrial, transportation, and communication technologies offered competitive advantages.

Although the Industrial Revolution generated unprecedented wealth and created new markets and employment opportunities, the ensuing economic benefits were unevenly distributed. Factory workers were usually underpaid and overworked, and endured dangerous working conditions. Rapidly growing cities suffered from overcrowded tenements, inadequate sanitation, stifling pollution, widespread poverty, and violent crime. These deplorable conditions inspired mounting social unrest. In defense of industrialization it was often argued that these conditions were regrettable but necessary in the short term, and would eventually be remedied through greater economic growth driven by technological innovation. Workers must be patient, for any attempt to redistribute wealth along socialistic lines would serve only to derail the necessary competition that would eventually provide greater material comfort to a wider range of people, especially those devoted to thrift and hard work.

Religious responses to industrialization and its accompanying ethical issues were far from uniform. Proponents of the gospel of wealth maintained that economic competition was not incompatible with biblical and Christian teaching. Indeed, the accumulation of wealth promoted a philanthropic spirit as demonstrated in the largesse of such industrialists as Andrew Carnegie (1835–1919) and John D. Rockefeller (1839–1937). Critics countered that the plight of workers was patently unjust and dehumanizing. Laborers were little more than commodities exploited by owners driven by monopolistic greed instead of genuine competition. In response, the Social Gospel movement, drawing especially on the works of Walter Rauschenbusch (1861–1918), advocated workers' rights, the formation of labor unions, large public expenditures to improve urban life, antitrust legislation, and at times more radical proposals for public ownership of various industries.

What was at stake in these disputes was purportedly the progressive trajectory and destiny of history. Although various protagonists tried to wrap themselves in the mantel of progress, the perception of science and technology as the twin engines driving the steady improvement of human life made a powerful public impression. This impression was reinforced by the publication of John William Draper's *The History of the Conflict between Religion and Science* (1874) and Andrew Dickson White's *A History of the Warfare of Science with Theology in Christendom* (1896), both of which portrayed a perpetual battle between science and religion. The popularity of these books helped create a public perception that the progressive forces of science and technology were once again struggling against their old foes of religion and superstition. Although the myth of perpetual warfare is a modern invention, it continues to influence popular perceptions. As other entries demonstrate, however, contemporary Christian assessments of science and technology are more varied and nuanced than the myth admits.

CICERO'S CREED

Lawyer, author, statesman, and scholar Marcus Tullius Cicero (106–43 B.C.E.) is considered Rome's greatest orator. His philosophical writings are impressive. In vocabulary alone, Cicero gave Rome the words *quality*, *individual*, *moral*, *definition*, *comprehension*, and *infinity* (Everitt 2001). Also attributed to him is Cicero's Creed, called the oldest statement of engineering ethics specifically, "Salus populi suprema est lex," or "the safety of the public shall be the[ir] highest law" (Broome 1986), which is comparable in stature to medicine's "primum non nocere" ("first, do no harm," attributed to Hippocrates, but found in his *Epidemics* rather than his *Oath*). Varying versions of Cicero's Creed have been incorporated into each of the major engineering professional organizations' codes (Martin and Schinzinger 2005). As such, it has served as a common reference point for contemporary engineers navigating the moral boundaries of their work.

As with "first, do no harm," however, the practicality of applying Cicero's Creed came into question during the 1980s. Just as the new field of bioethics scrutinized how physicians made ethical decisions and asked what role (if any) the public had in this process (Veatch 1981), three contending criticisms challenged Cicero's Creed. The contractarian code denied any implied or explicit contract between engineers and the public and posited that social contracts were "abstract, arbitrary, and absent of authority." The only operative contract was one between professional engineers and their employers. The personal-judgment imperative maintained that the interests of business and government never conflict with the interests of the public. Engineers, de facto, then represent the public in their safety decisions. The third criticism defined engineering as consisting of "theories for changing the physical world before all relevant scientific facts are in." Hence, engineering could never be totally risk-free or absolutely safe (Broome 1986).

Rosa Pinkus, et al. (1997) incorporated these disparate views into a framework for gauging the ethical practice of both the individual and the organization. It consists of three principles: competence, responsibility, and Cicero's Creed II. Adding specificity to the historic code, Cicero's Creed II suggests that the "ethical engineer should be cognizant of, sensitive to, and strive to avoid the potential for harm and opt for doing good." Operationalizing this implies understanding the risk and failure characteristics of the product or process at hand. Further, "the ethical organization manages technology so as not to betray the public trust," thus introducing the concept of stewardship for public resources that embodied the intent of Cicero's original ethic. Hence, the ethical engineer must have the "competence" to assess risk and should exercise the "responsibility" to communicate it when it is known.

The longevity of Cicero's Creed is a tribute to the rhetorical power and wisdom of its originator. When Cicero coined the phrase, "the safety of the people shall be their highest law," rather than engineers, he was referring to newly appointed "praetors, judges, and consuls" who were, in turn, directed to decide civil cases in the Roman Empire. However, as noted by Harris, Pritchard, and Rabins (2004, p. 12), it was not until 1947, when the engineers' council for professional development issued the first major code proclaiming that engineers "will have due regard for the safety and health of the public." Until then, engineers were to consider the protection of their clients or employers interests as their highest professional obligation.

Hence one can conjecture that around this time some engineers began to refer to the safety of the public as "Cicero's Creed." Perhaps it was first used in a popular speech or article and caught on as a professional ethic. Mistaken context aside, when balanced within the cost and schedule of completing a project, Cicero's Creed can provide direction for weighing the competing ethical demands that are built into the profession of engineering.

CITIZENSHIP

Citizenship is the status of being a legally recognized member of a nation-state or other political community, possessing rights such as voting and owing duties such as jury service. In democratic thought, citizens generally are expected to be more actively involved and influential than citizens of authoritarian political systems. By joining environmental organizations, writing letters to government officials, working as volunteers, and otherwise affecting civic life, millions of citizens have helped bring about improvements in environmental policy, AIDS-HIV treatment, civilian nuclear power, genetically modified foods, and other technological endeavors.

In the city-state of ancient Athens, members of the *demos* participated directly in public debates and governmental choices, a time-consuming responsibility and honor—but only for the minority of the adult population who were not females, slaves, or otherwise excluded. When democracy was reinvented on the scale of the nation-state in Western Europe and the United States, citizenship extended only to property-owning males. Although such legal constraints have been abolished, the affluent and well educated continue to participate at higher rates, donate more money to candidates, and speak and write more persuasively. Women are underrepresented in political life due to the legacy of being hindered in "their access to full citizenship (including their capacity to speak and write freely, to acquire education, or to run for political office)" (Kessler-Harris 2001, p. 3–4). Ethnic minorities are disadvantaged almost everywhere.

New Citizenship Problematics

Challenges for citizenship now arise from globalization and the erosion of national sovereignty. The governmental unit one should identify with—the city of Paris, the nation of France, the European Union, or humanity most generally—is no longer clear (Balibar 2004). Because technological innovation emerges primarily in the affluent nations, moreover, those who reside elsewhere—a majority of humanity—in some respects are not citizens of the technological world order. Transnational citizenship seems increasingly sensible, therefore, yet institutions for it are weak.

Citizenship also becomes less salient when technological choices occur via the economy more than via government. Business executives exercise primary discretion over job creation, quality of work life, and new technological products, and computerized transactions in a few financial centers such as London affect monetary matters worldwide (Dean 2003). The privileged position of business extends to ordinary politics, where industry executives marshal unrivaled expertise, enjoy easy access to public officials, and have ample funds for lobbying and for legal challenges to government regulations (Lindblom and Woodhouse 1993).

In contrast, most adults work in semiauthoritarian organizations and exert little influence over whether technological innovations are used to make jobs more interesting, or to displace and down-skill those affected. Workers may learn a more general lesson: Don't expect to be full citizens whose opinions are valued and influential. Industrial democracy in the former Yugoslavia, codetermination laws in Scandinavia, and other experiments in economic democracy have not been widely emulated (Dahl 1985).

To the extent that ordinary people do participate in economic-technological choices, it is via consumer purchasing or *market voting*. Thus new homes in the United States grew from 800 to 2,300 square feet from 1950 to 2000, affecting energy usage, environmental despoliation, and even the level of envy. Consumer-citizens catalyzed global proliferation of a high-consumption lifestyle including air conditioning, television, and leisure travel—thereby distributing endocrine-disrupting chemicals throughout the biosphere, causing the extinction of several thousand languages and traditional cultures, endangering myriad species, and increasing rates of psychological depression.

The Challenge of Technoscientific Expertise

Another difficulty confronting citizenship is that technical knowledge increasingly required for informed discussion. When a U.S. congressional committee considered tax credits to help professional cleaners switch away from the dangerous solvent perchloroethylene in 1999, not a single citizen or public interest group wrote, phoned, or visited: Hardly anyone understood the problem of toxic air pollution from professional cleaning. Technologists do not themselves control governments, but expertise complexifies and effectively restricts participation in governance (Laird 1993).

A subtle way this occurs is that technoscientists accelerate innovation to a pace that government regulators, interest groups, and the attentive public cannot match. Roboticists, developers of esoteric weapons, biomedical researchers, nanotechnologists, and others ride a juggernaut fundamentally altering everyday life worldwide. If representative processes do not apply to technologists—most of whom are upper-middle-class males from the European Union, Japan, and the United States—and if there is insufficient time for deliberation, what meaning does citizenship have?

For all the shortcomings of traditional democratic procedures, that realm at least has competing parties, electoral campaigns, interest groups, and other forms of public inquiry, advocacy, deliberation, and dissent. Consumer-citizens enjoy none of these advantages—for example, shoppers rarely hear informed, conflicting views about environmental and other public consequences of products they purchase. Should citizenship be extended to the technological-economic sphere? To do so might require a set of citizen rights and obligations to "reconcile democracy . . . with the right of innovators to innovate . . . (and) to reconcile technology's unlimited potentials for human benefit and ennoblement with its unlimited potentials for human injury, tyrannization, and degradation" (Frankenfeld 1992, p. 462). Citizens arguably deserve relevant information, informed consent, and a limit on endangerment; and they presumably should embrace a corresponding duty to learn enough to exercise informed judgment.

In the early twenty-first century, technoscientists often proceed without obtaining informed consent, publics are mostly quiescent, and decision-making processes are not designed for timely deliberation. Extensive political research and development would be required to develop new mechanisms for holding technoscientific-economic *representatives* accountable, while organizing intermediary institutions to assist citizens in gaining requisite knowledge and shouldering other burdens of responsible participation.

There are a few encouraging signs: Some European political parties now require that women occupy 50 percent of elected offices, international norms and governance mechanisms may be emerging, and small-scale experiments with consensus conferences and other participatory innovations are gaining credibility. Nevertheless *no innovation without representation* is a long way from becoming the twenty-first-century equivalent of American colonists' cries against taxation without representation; there are formidable obstacles to an ethically defensible citizenship for wisely governing technoscientific trajectories and for fairly distributing rights and duties in a technological civilization.

CIVIL SOCIETY

Civil society refers to the sphere of human activity outside government, the market economy, and the family. It includes communities, churches, voluntary associations, philanthropic organizations, and social movements. Civil society potentially constitutes a venue for reasoned discussion that bridges social differences, empowers participation in public life, and encourages deliberation concerning ethical issues pertaining to science and technology.

Development and Problems

Derived from Aristotle and applied to the modern nation-state by eighteenth-century liberal reformers, the concept of civil society came to be so closely associated with bourgeois economic and political life that Karl Marx distrusted the idea. Neo-Marxists came to endorse a public arena independent of state- or party-controlled communication, however, and contemporary social scientists generally view intermediary associations as conducive to stable democracy. As civic disengagement became widespread in the 1970s and thereafter, coupled with globalization, deregulation of industry, and the rise of new social movements, the idea of *building social capital* by strengthening nongovernmental organizations (NGOs) and other social institutions that *make democ-*

racy work seemed attractive to many social thinkers and activists, especially in the former Soviet sphere and in Latin America.

Defining the boundaries of civil society proves difficult, however. Publicly funded educational institutions catalyze research and discussion, yet are part of government. Most mass media are profit-making businesses; yet civic life depends on these institutions for informed inquiry. Conversely, some not-for-profit organizations such as hospitals are hard to distinguish from private businesses. Quakers and Unitarians may think deeply about social justice, but other religious groups turn away from social problems. So where exactly *is* civil society?

Also problematic is the idea of a venue/network where people with public-regarding values interact to produce outcomes endorsed by progressive social forces—saving the Mediterranean, stopping abusive labor practices, bringing AIDS drugs to Africa. However the Heritage Foundation and the Hoover Institution helped conservative Republicans create reform agendas that progressives perceive as exacerbating social differences and disempowering non-elites. Yet those research institutions clearly belong to the system of organized social inquiry and discourse. Perhaps, then, civil society belongs to no particular ideological camp, but can be mobilized by one's allies or opponents in the service of both good and ill.

A third difficulty is that most nongovernmental organizations are not altogether *public*. The American Association for the Advancement of Science (AAAS) lobbies government for taxpayer subsidies for well-paid scientists, with much research arguably serving scientists' hobbies more than the public good. Auto and chemical workers' unions focus on higher wages for current members rather than on fairer income distribution or on innovating technologically to improve the quality of work life for all. And if admission to a not-for-profit science museum costs more than seeing a Hollywood film, in what sense is the museum a *public* institution?

Fourth, governments and corporations dominate technological decisions, relegating civil society to the periphery of innovations in robotics, nanotechnology, weaponry, computers, pharmaceuticals, electronics, transport, chemicals, and agriculture. There are too many businesses for the few NGOs to watch, and government officials usually side with business. Thus, although Consumers Union and Mothers Against Drunk Driving (MADD) make modest contributions to transportation safety, they are no match for investment tax credits to industry, trust funds for building highways, and billions spent marketing new cars.

Achievements and Limitations

Nevertheless, NGOs have been influential on aspects of environmental policy, including technological changes such as catalytic converters on cars, scrubbers on electric power plants, and support for renewable energy. The environmental movement has enrolled millions of people in opposing hazardous waste dumping, fighting installation of polluting facilities, and lobbying for tighter regulations. Health social movements have tilted medical care toward AIDS prevention and treatment. Although quite important, these are exceptions to the rule, and the rule is that civil society organizations participate in only a small fraction of technoscientific choices, rarely winning a large fraction of what they seek.

Such inherent disadvantages are magnified by elite dominance over fundamental ideas circulating within civil society. From clergy and nobles of centuries past to contemporary scientific spokespersons, government officials, and business executives, elites sometimes reinforce myths that limit critical inquiry and thoughtful deliberation concerning science, technology, and ethics. Such myths include, among many others:

- That technoscience benefits all more or less equally, even though poorer persons and countries obviously are less able to purchase innovations;
- That research and development should proceed quite rapidly, despite the fact that humans learn and react rather slowly to the many unintended consequences of technology;
- That inherited economic and political institutions need not be fundamentally reconsidered, despite new organizational challenges involved in governing technological civilization.

It is of course rare to find societies where the dominant myths do not serve the interests of powerful organizations, affluent people, and experts themselves (Lindblom and Woodhouse 1993).

Perhaps the clearest connection between technological innovation and civil society is that television has displaced political conversation and other leisure activities, because "more television watching means less of virtually every form of civic participation and social involvement" (Putnam 2000, p. 228). Television maximalists lack time for civic engagement; the medium encourages individuation—as epitomized by the ubiquity of television sets in children's bedrooms; and an emphasis on individual rather than collective failings discourages viewers from trying to ameliorate social problems. Cell phones and email have been used in organizing public protests and even toppling a few governments, but cyberspace generally has not lived up to the hopes of early advocates as a space for public inquiry.

Capacities for public thought and action would be stronger in a commendable technological civilization, where civil society might function closer to the *ideal speech situation* envisioned by Jürgen Habermas. One of the most important changes would be to reduce the domination of public discourse by those with governmental, business, media, religious, and scientific authority; this would allow organizations and spokespersons to champion many more facets of many more issues than now occurs. Another important change, now partially under way, would be the evolution of an international civil society capable of reining in the worst practices of national governments, multinational corporations, and the global communities of technoscientists. Third, civil society participants would need to pay far more attention to ethical and policy issues pertaining to science and technology.

Overall, then, civil society advocates from Alexis de Toqueville to Michael Walzer surely are correct in recognizing that *social capital* plays an important role in building a society worth living in. Civil society plays an indispensable role in focusing, channeling, and helping to improve the quality of public thought: When anti-environmentalists win public office, for example, they cannot reverse most policies because pro-environmental discourse has become so widespread. Advocacy organizations play important roles in raising questions about the conduct of science and technology, and strengthening civil society probably is a necessary condition for a wiser, fairer technological civilization. However a balanced understanding of civil society must include recognition that it is difficult to conceptualize, is relatively weak compared with market and state, and possibly has been undermined as much as strengthened by the rise of global science and by recent technological developments.

CLASS

Social inequalities are ancient, but the concept of class evolved only in the nineteenth century with the increasing division of labor accompanying industrialization. Karl Marx (1818–1883) sometimes wrote as if there were just two distinct, inherently antagonistic classes—the bourgeoisie owning the means of production, and the proletariat working for them. Class structures actually were more complex than that even in prerevolutionary Europe, and are all the more so in a global technological civilization. Class is thus a special form of inequality tied to the development of modern science and technology; it is of ethical significance because the costs and benefits of innovation tend to be distributed along class lines.

Sociology of Class

Sociologists studying class tend to categorize households by the male breadwinner's occupation. John H. Goldthorpe (1987) uses eleven categories ranging from professionals, administrators, and corporate managers at the top, to small proprietors, farmers, and personal service workers in the middle, to unskilled manual and agricultural workers near the bottom. Using this and other measures, it becomes apparent that there is substantial variation in distribution of what Max Weber called life chances: The United States has much greater income inequality than most other affluent nations, and low-income American families have worse access to health care, education, and other desired social outcomes (Lareau 2003, Hofrichter 2003). Intergenerational social mobility turns out to be poor just about everywhere, however, with the odds of a middle-class child remaining in that class as an adult about fifteen times greater than the chances of a working-class child moving into the middle class (Marshall et al. 1997).

Increasing participation of women in the workforce means that spouses may work in different job categories, which makes the above classification scheme harder to apply. Two-income households can afford different lifestyles than single-income households, moreover, so categorizing by occupation has become less meaningful. Parents' education may matter more than their occupations in determining a family's Internet usage, leisure activities, nutrition and health, and aspirations for children's futures. More fundamentally, conventional depictions of social class capture rather poorly the creative destruction that technological innovation brings, creating new types of careers while undermining older occupations. The winners celebrate, but several hundred million worldwide have been displaced from farms, factories, and other workplaces in the past generation at considerable personal and social cost.

Likewise being reconstructed over time are the everyday lives of various social strata. At the beginning of the twenty-first century, the affluent enjoy transportation, communication, medical care, food, and leisure opportunities superior to what has previously been available to anyone. Even persons of comparatively modest means have access to television, refrigeration, T-shirts, plastic bags, and other manufactured artifacts. Their shared participation in a *consumer class* may be a more salient social fact than their occupational or even income differences. Because people's realities are substantially structured in relationship with material things, class warfare arguably has become less a conflict among classes than one between the consumer class and the planet.

International Dimensions

Older understandings of class are challenged as well by international stratification. Most of the affluent live in the northern hemisphere, and a *working-class* household in Europe or Japan is well above average for the world as a whole—and may include a comfortable dwelling, reliable electricity, convenient mass transit or automobile, and government-funded medical care. Peasant farmers and stably employed urban dwellers in poor countries have far less access to technological benefits, and yet they are well above the billion or more persons living in absolute poverty.

Possibly on the lowest rung of the ladder are those who speak one of the 3,000 languages likely to become extinct in the twenty-first century. For example, in 2003 the Danish Supreme Court turned down the final appeal of 150,000 indigenous peoples forcibly expelled from their ancestral lands in northern Greenland during the Cold War to make way for a U.S. missile base. "The Inuit will, in all likelihood, join other indigenous peoples globally whose language, culture, and presence are no longer with us" (Lynge 2002, p. 103).

Thus conventional depictions of social class are too *nice*, and fail to convey the raw power and powerlessness that often accompany technologies deployed in contexts of socioeconomic inequality. Large dams that flooded villages while failing to deliver the promised irrigation benefits displaced millions. Millions more have been dislocated, maimed, or killed in civil wars fought with helicopter gun ships and automatic weapons. Subsistence farming was undermined by the imposition of export-oriented monocultures and European and North American *scientific* agricultural methods. International financial markets enabled by computerized data processing have caused ruinous fluctuations in local currencies. Toxic wastes and environmentally hazardous manufacturing processes have been transferred to poor countries (Clapp 2001).

Even within affluent societies, technological bads tend to follow class lines. As environmental justice advocates point out, those with less capacity to buy their way out or to organize politically often get stuck living near noisy factories, polluted waterways, traffic noise and exhaust fumes, hazardous waste dumps, landfills, and other noxious facilities (Bullard 2000). Those with less power in the labor market often find themselves disadvantaged by technological changes in the workplace (Wyatt et al. 2000)

The Future of Class

In sum, an adequate understanding of social class requires dealing with the ugly realities of power, gross international inequalities, post-industrial socioeconomic issues going well beyond occupational stratification, consumers as a new kind of class, and upheavals in work roles and lifestyles associated with technological innovation. The technoscientists' predicament is that their findings and innovations enter a highly stratified world; although few technologists might be comfortable acknowledging it, in effect they work for some social classes much more than for others. Class consciousness has long been weak in the United States, and has diminished even in European social democracies; many social observers speak as if inequality were unimportant. Yet the pervasive, harmful effects of inequalities are well documented, and one need not return to simplistic notions of a ruling class in order to think that ethically charged questions about who gets what deserve the same careful attention accorded to technical aspects of innovation.

CLINICAL TRIALS

Clinical trials are systematic investigations on human subjects testing the safety and efficacy of novel medical interventions, including drug, surgical, or behavioral treatments. Conventionally clinical trials are divided into four types or *phases*. In a phase I clinical trial, typically involving tens of subjects, a novel procedure is tested for the first time in human beings and data is collected on safety. In a phase II trial, which may involve hundreds of patients, evidence is sought that a novel intervention has a therapeutic effect on the disease of interest. In a phase III clinical trial, often involving thousands of patients, the novel intervention is compared to a standard intervention or placebo. In a phase IV trial, called a post-marketing study, information is collected on the long-term safety and efficacy of the intervention from patients receiving the intervention in clinical practice and measured against a control treatment. The rigorous evaluation of novel medical interventions in clinical trials is a foundation of evidence-based medicine.

Historical Development

The randomized clinical trial is one of the most important advances in medicine in the twentieth century. Prior to its development, treatments were adopted on the basis of the publication of a series of cases in which their use had proved helpful. Due to numerous sources of potential bias, including variation in expertise from one clinician to the next, and the selection of patients more likely to recover for inclusion in the study, case series often led to misleading results. Clinicians were faced with numerous treatments from which to choose, and little evidentiary basis upon which to ground a choice. For example, Richard Doll, a well-known British clinical trialist, described how at the start of his research into the treatment of peptic ulcer in 1948, he was able to list purported treatments beginning with each letter of the alphabet.

In clinical trials until mid-twentieth century, two treatments for comparison were allocated to alternating patients. This method was flawed by the fact that physicians could anticipate the treatment assignment, and thereby select which treatment a particular patient would receive by changing the patient's position in the queue. It was not until mid-century that R.A. Fisher's allocation strategy using random numbers, developed in 1926 for agricultural experiments, was used in clinical trials. Allocation using random numbers countered bias in selection and provided statisticians with an estimate of random error, a key component of modern statistical analysis. The first clinical trial to randomly allocate treatments to patients using random numbers was the United Kingdom Medical Research Council (MRC) whooping cough immunization trial initiated in 1946. The better-known MRC streptomycin trial in tuberculosis started a few months later, but published its results before the whooping cough trial in 1948.

Since the mid-twentieth century, the clinical trial has undergone a dramatic increase in use for the evaluation of the safety and efficacy of novel medical interventions. A variety of social and political factors supported this trend. The period following the Second World War witnessed an unprecedented public investment in health research. In 1945, the United States National Institutes of Health budgetary appropriation was $700,000; in 1970 its appropriation was $1.5 billion. Drugs regulation underwent significant changes in this period as well. From 1938 to 1962, the U.S. Food and Drug Administration (FDA) was only empowered to require that new drugs be tested for safety. Following on the heels of the thalidomide tragedy, in which hundreds of infants were born with congenital malformations after exposure to thalidomide in utero, legislative reform dramatically increased the FDA's power. The 1962 Kefauver-Harris Act expanded the FDA's mandate to test new drugs for both safety and efficacy.

The testing of new drugs for safety and efficacy in clinical trials occurs in an increasingly international environment. Cooperation among drugs regulators and manufacturers seeks to standardize the conduct of clinical trials and their review by drugs regulators. The International Conference on Harmonization *Good Clinical Practice* guidelines are a key instantiation of this effort. The protection of human subjects in research is similarly seen as a matter of global concern. Perhaps the most influential ethics document in the international forum is the World Medical Association's *Declaration of Helsinki*. The declaration requires that clinical trials be reviewed by appropriately constituted research ethics committees; research be free of misconduct; the consent of human subjects be obtained; study participation pose a favorable balance of benefits to harms; and subjects be selected equitably.

Ethical Issues

Some of the most important ethical challenges of clinical trials stem from conflicting duties of the physician-researcher. Physicians have fiduciary obligations to patients, including a duty to provide competent personal care. Researchers, by contrast, have obligations to science and society, including duties to provide treatment as prescribed in the trial protocol, ensure that patients comply with treatment, and encourage them to stay in the study. Given that these duties may conflict, the central moral question of the clinical trial is: When may physicians legitimately offer patients enrollment in a clinical trial? While a variety of answers have been provided to this question, the most widely accepted is that of clinical equipoise. According to clinical equipoise, physicians may legitimately offer patients enrollment in a clinical trial only if the medical interventions within the study are consistent with competent medical care. More formally, it requires that at the start of the study there exists a state of honest, professional disagreement as to the preferred treatment. The consequences of clinical equipoise for the design of clinical trials are far reaching.

Two issues in respect to the design of clinical trials have dominated research ethics literature since the 1990s. The first is the proper role of placebo controls in the new drug approval process in developed countries. Drug regulatory agencies in developed countries, such as the FDA, have long required that new drugs prove superior to placebos in at least two clinical trials before licensure. The practice in the United States is rooted in legislation that requires the FDA to ensure new drugs are efficacious, that is, that they have some effect in treating the condition of interest, but generally restricts its ability to demand evidence of comparative effectiveness. According to clinical equipoise, placebo-controlled clinical trials are unproblematic when there is no proven treatment for the condition of interest.

Criticism has focused on the use of placebo controls in clinical trials testing novel interventions for treatable medical conditions, such as severe depression and schizophrenia. The use of placebos in these cases is impermissible, because no competent physician would fail to offer a patient treatment and, accordingly, clinical equipoise is violated.

The 2002 revision of the Declaration of Helsinki sets aside this fundamental moral requirement, and for the first time permits the use of a placebo control when "compelling and scientifically sound methodological reasons" exist. This change seems to violate a core provision of the declaration requiring that "[i]n medical research on human subjects, considerations related to the well-being of the human subject should take precedence over the interests of science and society." Whether there are in fact *scientifically sound methodological reasons* to prefer a placebo control over a standard treatment control remains an open question.

The second clinical trial design issue to receive considerable attention in the literature is the choice of control treatment in clinical trials of new and affordable treatments for developing countries. Disagreement was originally sparked by clinical trials testing the efficacy of short-course zidovudine against placebos for the prevention of transmission of HIV from mother to child. Critics of the clinical trials pointed to the existence of an effective prevention regimen called ACTG 076 used in developed countries. Denying subjects in the clinical trials conducted in developing countries access to this prevention regimen, they claimed, constitutes an ethical double standard between developed and developing countries.

Proponents of the clinical trials countered that the ACTG 076 regimen is not suited to administration in many developing countries and the cost is prohibitive. Changes in international regulation have tended to entrench rather than resolve the dispute. The Declaration of Helsinki proscribes placebo controlled trials in developing countries when effective treatment exists in developed countries saying that "[t]he benefits, risks, burdens and effectiveness of a new method should be tested against those of the best current prophylactic, diagnostic, and therapeutic methods." Yet the "International Ethical Guidelines for Biomedical Research Involving Human Subjects" permit placebo controlled trials under these circumstances provided the clinical trial is "responsive to the health needs of the population from which the research subjects are recruited and there [is] assurance that, if it proves to be safe and effective, it will be made reasonably available to that population."

OPEN QUESTIONS. The interface between the ethics and science of clinical trials is replete with challenging questions yet to be addressed adequately. What ought the role be for adaptive designs, for instance, clinical trials in which the probability of being assigned to one treatment or another is dynamic in an attempt to minimize the number of subjects who receive the treatment that turns out to be inferior? Can alternative medical treatments be evaluated rigorously in clinical trials? Alternative practitioners may claim that alternative treatments cannot be removed from a holistic treatment context, a substantial obstacle to the rigorous assessment of the treatment's efficacy. How will pharmacogenetic testing impact the conduct of clinical trials? Proponents of pharmacogenetics suggest that identification by genetic testing of those likely to respond to treatments and those likely to suffer adverse events would increase the efficiency and safety of clinical trials. Critics wonder if the gains from such testing will be as large as promised and what impact it will have on the generalizability of clinical trial results.

While ethical issues in the design of clinical trials are the subject of ongoing scholarship, ethical aspects of the conduct and reporting of clinical trials are relatively ignored. As clinical trials accumulate data on outcomes, disparities may emerge between the treatments in the clinical trial raising questions as to whether the trial ought to be stopped early. It is generally agreed that when clinical trials use outcome measures of mortality or serious morbidity an independent data monitoring committee should be established to periodically review accumulating data. A satisfactory moral framework to guide the decisions of data monitoring committees has yet to be developed.

Ethical issues in the reporting of clinical trial results also deserve attention. If researchers fail to report the results of a negative clinical trial, subjects in the trial were exposed to risk for naught and the problem of publication bias is compounded. While this seems problematic intuitively, a moral basis for an obligation to publicize clinical trial results has yet to be articulated.

CODES OF ETHICS

A code of ethics may appear in disciplines such as engineering, science, and technology under several other names: professional principles, rules of conduct, ethical guidelines, and so on. However denominated, a code of ethics can be placed in one of three categories: (1) *professional*, such as the Chemist's Code of Conduct of the American Chemical Society, applying to all the members of a certain profession (chemists) and only to them; (2) *organizational*, such as the Code of Ethics of the Institute of Electrical and Electronic Engineers, applying to members of the technical or scientific society that has enacted it and only to them or, in the case of the code of ethics of a university or industrial laboratory, only to a certain class of the enacting organization's employees; (3) *institutional*, such as the Computer Ethics Institute's Ten Commandments of Computer Ethics, applying to anyone involved in a certain activity (in this case, using a computer).

Codes of ethics may include ordinary moral rules ("Do not steal" or "Treat others fairly"). Codes of ethics may be enacted into law. For example, some codes (such as the engineer's code of ethics in Chile) have the status of domestic administrative law. Other codes, such as the "Nuremberg Code" on human experimentation, have become part of both international law and the general domestic law of many countries. Nonetheless, a code of ethics is never simply a matter of law or ordinary morality. To call a document a code of *ethics* is to make a claim for it one does not make when one claims that the document in question is a statute or statement of ordinary morality.

The Meaning of Codes

The word *code* comes from Latin. Originally it referred to any wooden board, then to boards covered with wax that were used to write on, and then to any book (*codex*). That was the sense it had when first applied to the book-length systemization of Roman statutes that the Emperor Justinian enacted in 529 C.E. Justinian's *Code* differed from an ordinary compilation of law in one important respect: He had the legal authority to make his compilation law, replacing all that preceded it.

Since that time, any document similar to Justinian's *Code* could be called a code. Sometimes the analogy with Justinian's *Code* is quite close (as it is, for example, for the *Code Napoleon*). Sometimes it is not. For example, computer code is code in a rather distant sense: Although the rules are presented systematically, computer code is written for machines, not for humans.

An important feature of Justinian's compilation is that it was written. Could a code be *unwritten*? Certainly there are unwritten laws. However, because the point of codification is to give law (and by analogy any similar system of guidance) an explicit and authoritative formulation, an unwritten code would seem not to be a code at all. There are nonetheless at least two ways in which codes can be unwritten. First, a code that is not in writing may have an authoritative *oral* formulation. Second, an unformulated code may be so obvious to those familiar with the practice that the code need only be formulated to be accepted. Although some parts of engineering or science may have a few rules unwritten in one or both of these senses, no large discipline or organization seems to have enough of those rules to constitute an unwritten code. In a world in which so much changes so quickly, how can individuals separated by education, experience, and distance reach agreement on much without putting that agreement in writing?

The Meaning of Ethics

The term *ethics* has at least four senses. In one, it is a synonym for ordinary morality, the universal standards of conduct that apply to moral agents simply because they are moral agents. Etymology justifies this sense. The root of the word *ethics* (*ēthos*) is the Greek word for "habit" (or "character"), just as the root of the word *morality* (*mores*) is the Latin word for that concept. Etymologically, *ethics* and *morality* are twins (as are *ethic* and *morale*). In this sense of the term, codes of ethics are systematic statements of ordinary morality; there is no point in speaking of ethics rather than morality.

In at least three other senses, however, ethics differs from morality. In one, ethics consists of the standards of conduct that moral agents *should* follow (*critical morality*); morality, in contrast, consists of the standards that moral agents generally do follow (*positive morality*). Ethics in this sense is very close to its root *mores*; it can refer to unethical acts in the first sense of *ethics*. What some believe is morally right (slavery, forced female circumcision, and the like) can be morally wrong. Morality in this sense has a plural: There can be as many moral*ities* as there are moral agents. Nonetheless, ethics in this sense can be a standard that is common to everyone. This second sense of ethics is, then, as irrelevant to the purposes here as is the first. Codes of ethics generally contain some rules ordinary morality does not.

Sometimes ethics is contrasted with morality in another way: Morality consists of the standards that every moral agent should follow. Morality is a universal minimum, the standard of moral right and wrong. Ethics, in contrast, is concerned with moral good, with whatever is beyond the moral minimum. This is another sense that seems not to fit codes of ethics. First, this ethics of the good is still universal, applying outside professions, technical societies, and institutions as well as within them. Second, codes of ethics in fact consist largely of *requirements*, the right way to conduct oneself rather than just a good way. Any sense of ethics that excludes requirements cannot be the sense relevant to codes of ethics.

The term *ethics* can be used in a fourth sense to refer to the morally permissible standards of conduct that govern the members of a group simply because they are members of that group. In this sense, research ethics is for people in research and no one else, engineering ethics is for engineers and no one else, and so on. Ethics in this sense is relative even though morality is not; like law and custom, it can vary from place to place, group to group, and time to time.

Though relative, ethics (in this sense) is not mere mores. It must (by definition) set a standard that is at least morally permissible. There can be no thieves' ethics or Nazi ethics, except with quotes around the word to signal an analogical or perverted use. Because ethics in this fourth sense must both be morally permissible and apply to members of a group simply because of their membership, it must demand more than law, market, and ordinary morality otherwise would. It must set a "higher" or "special" standard.

The Meaning of Codes of Ethics

A code of ethics, though not a mere restatement or application of ordinary morality, can be morally binding on those to whom it applies; that is, it can impose new moral obligations or requirements. How is this possible? Some codes of ethics are morally binding in part because they require an oath, a promise, or other "external sanction" (for example, one's signature on a contract that makes accepting an employer's code of ethics a condition of one's employment). In general, though, codes of ethics are binding in the way the rules of a morally permissible game are binding on those who voluntarily participate. The sanction is "internal" to the practice. When a person voluntarily claims the benefits of a code of ethics—for example, the special trust others place in those whom the code binds—by claiming to be a member of the relevant group ("I am an engineer"), that person has a moral obligation, an obligation of fairness, to do what the code says. Because law applies to its subjects whether they wish it to or not, law cannot bind in the way a code of ethics (a voluntary practice) can. Because a code of ethics applies only to voluntary participants in a special practice, not everyone, a code, if it is generally followed, can create trust beyond what ordinary moral conduct can. It can create a special moral environment. So, for example, if engineers generally "issue public statements only in an objective and truthful manner [including] all relevant and pertinent information" (as the Code of Ethics of the National Society of Professional Engineers requires), their public statements will generally (and justifiably) be trusted in a way those of politicians, lobbyists, and even ordinary private citizens would not be. Engineers will therefore have a moral obligation to do as required to preserve that trust. They will have a special moral obligation to provide all relevant and pertinent information even when others do not have such an obligation.

Attempts have been made to distinguish between short, general, or uncontroversial codes (code of ethics) and longer, more detailed, or more controversial ones (code of conduct, guidelines, and the like). Although this type of distinction may occasionally be useful in practice, it is hard to defend in theory. A typical code of conduct is as much a special standard as a typical code of ethics is, except when the code of ethics, being a mere restatement of morality, is just a moral code. Codes of conduct are also generally as morally binding as other codes of ethics. Sometimes, as in the Code of Ethics and Professional Conduct of the Association of Computing Machinery, the code does not even distinguish between the two.

Attempts have also been made to distinguish between (hard and fast) "rules" and mere "guidelines". Rules are then said to be typical of law, to allow only for submission or defiance, and therefore to interfere with moral autonomy. Guidelines, in contrast, are said to be typical of ethics, to require interpretation rather than "mindless submission", and therefore to preserve moral autonomy. In fact, all rules, including statutes, require interpretation (rather than mindless submission). In this respect, all rules are mere guidelines. There is, then, no reason why a code of ethics, understood as rules, should interfere with moral autonomy—or, at least, no reason why it should interfere any more than a promise or obligation of fairness does. On the other hand, "guidelines" such as those in ACM's Code often have the same mandatory form as other rules. They function as a commentary on the code rather than as a distinct document.

Uses and Design of Codes of Ethics

Codes of ethics have at least five uses: First and most important, a code of ethics can establish special standards of conduct in cases in which experience has shown that common sense is not adequate. Second, a code of ethics, being an authoritative formulation of the rules that govern a practice, can help those new to the practice learn how to act. Third, a code can remind those with considerable experience of what they might otherwise forget. Fourth, a code can provide a framework for settling disputes even among persons with considerable experience. Fifth, a code can help those outside the group ("the public") understand what they may justifiably expect of those in the group.

A code of ethics can also be used to justify discipline, legal liability, or other forms of external accountability, but such uses threaten to turn the code into something like law. Even when a code of ethics has been enacted into law, obedience to it must rely in large part on conscience or there is no point in describing it as a code of *ethics* (rather than just another legal requirement).Therefore, to object to a code of ethics that it cannot be enforced in the way laws generally are is to confuse ethics with law.

Some writers have claimed that a code of ethics must have a certain content (something more specific than "a higher standard"), for example, that any "true professional code" must have a provision giving special prominence to the public interest. For some professions, such as engineering, the claim is plausible. Engineers have long agreed that the public health, safety, and welfare should be "paramount" in their professional work. But for other professions, such as mathematics, the claim is much less plausible. The Ethical Guidelines of the American Mathematical Society commit mathematicians to mathematical truth, whether in the public interest or not. Many other scientific professions have a similar commitment to truth rather than the public interest as such. There can be no moral objection to such a failure to emphasize the public interest so long as the code does not require or allow anything ordinary morality forbids.

Because codes of ethics have no necessary content, they have no necessary structure or design. So, for example, the Software Engineering Code of Ethics divides its requirements into eight major categories (Public, Client and Employer, Product, Judgment, Management, Profession, Colleagues, and Self); the Codes of Ethics of the Australian Computer Society divides its requirements into six (Priorities, Competence, Honesty, Social Implications, Professional Development, and Computing Profession); and other codes have adopted other divisions, some similar to these and some quite different. About all that can usefully be said about the structure of codes of ethics generally, is that the structure should help ordinary users understand the code as a whole and to find what in particular they need.

In *Technology and Ethics: A European Quest for Responsible Engineering,* ed. Philippe Goujon and Bertrand Hériard Dubreuil. Leuven, Belgium: Peeters. Describes the failure of a major international organization to adopt a code of ethics, apparently because of worries about enforceability.

Coady, Margaret, and Sidney Block, eds. (1996). *Codes of Ethics in the Professions.* Carlton South, Victoria, Australia: Melbourne University Press. A good collection of essays providing a benchmark for current philosophical understanding of codes of ethics in professions.

Davis, Michael. (2002). *Profession, Code, and Ethics.* Aldershot, UK: Ashgate. A major challenge to the current philosophical (and sociological) understanding of professions, with engineering (along with law and police) as one of the three major professions studied.

Ladd, John. (1980). "The Quest for a Code of Professional Ethics: An Intellectual and Moral Confusion." In *AAAS Professional Ethics Project: Professional Ethics Activities in the Scientific and Engineering Societies,* ed. Rosemary Chalk, Mark S. Frankel, and Sallie B. Chafer. Washington, DC: American Association for the Advancement of Science. A classic challenge to the very idea of a code of ethics.

Luegenbiehl, Heinz. (1983). "Codes of Ethics and the Moral Education of Engineers." *Business and Professional Ethics Journal* 2: 41–61. An important work on the educational uses of codes of ethics, as well as the classic statement of the distinction between rules and guidelines.

INTERNET RESOURCE

Center for the Study of Ethics in the Professions, Illinois Institute of Technology. "Codes of Ethics Online." Available at http://www.iit.edu/departments/csep/PublicWWW/codes. An enormous collection of codes of ethics, by far the largest available online. All codes cited here can be found at this site.

COLONIALISM AND POSTCOLONIALISM

Colonialism, understood provisionally as the European annexation and administration of lands and populations in the Americas, Africa, and Asia, has been intertwined with science, technology, and ethics since the Renaissance. Certainly one prelude to colonial expansion was the European acquisition of military and navigational technologies superior to those found in other continents. But the colonial experience also had a formative impact on the nascent European science, because it permitted the region's scholars to come into contact with new environments and data and provided access to alternative systems of knowledge developed by other cultures. In fact, the requirement of controlling and cataloging colonial populations and resources led to the creation of new disciplines in the social sciences, such as ethnography, linguistics, and archaeology. Moreover, this impact has continued to the early twenty-first century, as a new scientific discipline, ecology, has found inspiration in the practices of non-western precolonial cultures and on the nineteenth century British and French "colonial conservationism" that attempted to deal with the degradation caused by the exploitation of recently acquired environments was "able to foresee, with remarkable precision, the apparently unmanageable environmental problems of today"(Grove 1995, p. 12).

Indeed, colonialism had an indirect, though profound, impact on European culture. In reaction to the frequently genocidal military tactics used by Europeans and the exploitation of indigenous populations that characterized the administration of colonies, few, if any, other historical events did more to promote the extension of ethics into the political, social, and legal spheres. In politics, such central contemporary concepts as human rights, representative democracy, and socialism developed, at least in part, as reactions to the brutality of the process of colonization and to the contact with non-European cultures and their political systems. Moreover, colonialism, by transferring enormous amounts of gold and silver from the Americas to Europe during the sixteenth and seventeenth centuries, thereby permitting the development of a money economy, may be seen as a factor that contributed to the development of capitalism, and the science that studies it, economics. The European colonization of Africa, the Americas, and Asia is thus one of the founding experiences of modernity, its impact felt on every aspect of contemporary life, even in countries that did not embark on colonial adventures.

Conceptual Issues

Despite its importance, however, any attempt to define colonialism in a manner that goes beyond the mere recounting of a set of historical facts runs into a series of conceptual problems. The difficulty in defining colonialism and related concepts—such as imperialism, anticolonialism, neocolonialism, or even postcolonialism—is that they can be interpreted as linked to social phenomena existing since antiquity throughout the world. Yet, it is customary to see colonialism as bounded, on the one hand, by a European expansion that began in the fifteenth century with the Portuguese and Spanish forays into Africa and the Americas, and, on the other, by the decolonization of Asia and Africa, a process that concluded in 1975 with the independence of the last Portuguese dominions, Mozambique and Angola. Although the United Nations reported that, as of 2003, there were still sixteen "non-self-governing territories," colonialism, as customarily defined, is no longer at the core of the world economy, and the impetus for self-governance, while not fully realized, concerns smaller populations and areas.

These temporal boundaries are justified by a central difference between classical and modern empires. In the latter, colonization was characterized not only by the conquest of a territory and its population, or by the extraction of monetary, human, or material resources, as was the case in antiquity, but also by a thorough restructuring of the colonial economy for the benefit of the economic interests of the metropolis. The securing of raw materials to be used exclusively by imperial industries or the restrictions placed on the production of goods in the colonies in order to transform them into exclusive markets for metropolitan products are examples of such restructuring.

In addition to reshaping economic structures, modern colonialism also attempted to change the cultures of the populations conquered. The successful catechization of Latin America in the sixteenth century, despite the frequently syncretic character of the resulting religion (that is, its being a combination of originally Amerindian and European beliefs), is a case in point. In fact, this cultural change was often a prerequisite for the economic exploitation of the acquired territories, because traditional labor patterns and economic structures had to be transformed according to the economic requirements of European industries and settlers. Colonialism's practical emphasis on the modification of the cultures of the conquered populations and the concomitant resistance of the latter, as well as the unavoidable hybrid identities generated by this encounter, have become key objects of study for contemporary theorists.

But the difficulties to be found in conceptually delimiting colonialism remain implicit in such a description. The most obvious problem is that processes of colonization and decolonization are not discrete and chronological. In fact, the first postcolonial societies in the Americas arose before the second wave of European imperialist expansion crested in the nineteenth century. Furthermore, as José Carlos Mariátegui (1894–1930) noted in the 1920s, colonial practices, institutions, and ideologies did not disappear with formal independence, but frequently constituted the bases on which the new nations were built. Thus it becomes possible to talk of an internal colonialism present in politically independent nations in which cultural, racial, ethnic, religious, linguistic, or caste differences form the basis for the institutionalized economic exploitation of one group by another. Then, moreover, there is the unique case of the United States: a postcolonial society that itself became a full-fledged colonial power in the second half of the nineteenth century through the annexation of Puerto Rico, the Philippines, and Hawaii, and that in the twentieth century helped establish new patterns of international domination and unequal resource flows. Given this inequality, it is possible to argue that current international economic structures and relationships among different national and regional economies constitute a continuation and development of colonialism rather than its abolition.

Imperial Differences

Critics have questioned the validity of the chronology proposed above by distinguishing Spanish and Portuguese colonialism, on one side, and the later French and British empires, on another. Unlike the more fully capitalist British or French colonial regimes, the earlier Iberian empires were frequently mercantilist and precapitalist, even medieval. While the former restructured the new colonies' economies so as to propel metropolitan capitalist growth, the latter colonial enterprises were based mainly on the acquisition or extraction of directly marketable resources, such as gold or spices, and on the taxation of native and settler populations as direct sources of income. From this perspective, colonialism as a fully modern capitalist undertaking must be differentiated from earlier Iberian empire building. In fact, critics have argued that terms such as colonialism, imperialism, or postcolonial "evince the history of British colonial/imperial involvement with Ireland, India, and South Africa" and that their use leads to the "(mis)-understanding and (mis)labeling of the so-called colonial American situation" (Klor de Alva 1995, p. 264). Thus mainstream analyses of colonialism would be applicable only to the European empires built in Asia and Africa during the eighteenth and particularly the nineteenth centuries.

A concept frequently used to separate earlier Iberian and later colonialisms is that of imperialism. In 1917 V. I. Lenin (1870–1924), arguably the most influential critic of imperialism, claimed that it constituted "the monopoly stage of capitalism." For him, colonial expansion responded to the needs of monopolistic finance capital, which he believed to be the hegemonic sector in a modern economy, to find a "guarantee against all contingencies in the struggle against competitors" by ensuring access to markets and resources (Lenin 1977, p. 260). Because Lenin saw finance capital as firmly national, imperialism necessarily led to war as the colonial powers attempted to acquire "precapitalist" areas, to forcibly take over each other's colonies, or even to try to gain access to the natural resources located in Europe. (World War I was Lenin's prime example of how the hegemony of financial monopoly capital invariably led to war.)

Critics have noted, however, that one can free Lenin's arguments from his national, political, and military framework. In this way it becomes possible to speak of a U.S. imperialism that is no longer based on the formal possession of colonies, as Harry Magdoff (1969) first argued; or of a neocolonialism in which "First World" nations use international economic, political, and cultural structures and institutions to maintain their political and economic control over nominally independent nations, as the Ghanaian independence leader Kwame Nkrumah (1909–1972) proposed in 1965. In their 2000 book, *Empire,* Michael Hardt and Antonio Negri have taken this loosening of the ties between economic relations and the national sphere to its ultimate conclusion. For them, globalization has led to the creation of a true empire of capital in which unequal flows of resources are organized by means of a "decentered and deterritorializing apparatus of rule" that no longer has a geographically defined direction (Hardt and Negri 2000, p. xii). While inequality is seen as probably growing, the concept of imperialism, based on notions of metropolises and colonies, and its dependency theory derivation of center and periphery, is, therefore, obsolete.

Paradoxically, this postmodern interpretation of empire has been proposed at precisely the moment when the United States has acquired unparalleled economic, military, and technological superiority, and has claimed the right to use military force to achieve its goals, exercising this "right" first in Afghanistan (2001) and then in Iraq (2003). Indeed, critics as well as supporters of contemporary U.S. foreign policy frequently describe it as imperial. Thus current discussions of imperialism and empire frequently attempt to elucidate the role played by the United States in international economic inequalities. For instance, Aijaz Ahmad argues "what we actually have is, finally, for the first time in history, a globalised empire of capital itself, in all its nakedness, in which the United States *imperium* plays the dominant role, financially, militarily, institutionally, ideologically" (Ahmad 2000, Internet page). Whether this new globalized capitalism is a dramatically new stage in capitalism that invalidates earlier analyses whether Marxist or not, as Hardt and Negri argue, or simply an intensification and elaboration of the basic traits of capitalism and imperialism, as analyzed by Marx and Lenin, as Ahmad and others propose, is a matter of disagreement.

The standard chronology of colonialism has also been put into question by arguments that in order to understand European colonization it is necessary to analyze its underlying discursive and ideological underpinnings. Thus in his 1978 book, *Orientalism,* arguably the foundational text of postcolonial studies, Edward Said (1935–2003) traces the construction of the "Orient" back to early modern and even Greek sources, analyzes its influence on the self-construction of the "West," and notes how this European production of knowledge affected colonialist practice in the region. From a related perspective, Nelson Manrique (1993) has emphasized the manner in which the mind-set formed by 700 years of contradictory interaction among Christians, Muslims, and Jews was transplanted by the Spanish conquistadors to very different American realities. According to these and related studies, the conventional chronology of European colonialism leads only to the distortion, even the mutilation, of history.

Given these difficulties in establishing a clearly bounded definition of colonialism and related terms, these must be seen as constituting a semantic field in which conceptual boundaries blur into one other, and in which historical frameworks, though necessary, necessarily break down.. But underlying the semantic field there exists a continuum of unequal and exploitative economic, social, and political phenomena that impacts directly on the relationships among science and technology, and has ethical consequences that have yet to be fully explored.

Colonialism as Turning Point

Iberian colonialism nevertheless signaled a turning point in world history. Not only did European power and culture begin its process of expansion and imposition throughout lands and populations unknown by the West, but also new unequal flows of resources favoring colonial powers were for the first time established on a planetary scale. British and French colonialism, even contemporary international trade relations, are subsequent, capitalist developments within this unequal planetary framework. Furthermore, the pivotal role played by the Iberian empires is evidenced by the way they developed two of the central institutions characteristic of eighteenth- and nineteenth-century colonialism and beyond, slavery and the plantation system, as well as the ultimate ideological basis on which colonialism would be built: racism. As the Spanish philosopher Juan Ginés de Sepúlveda (1490?–1572 or 1573) argued, the colonization of the Americas and the exploitation of the Amerindians was justified by the fact that these were "as inferior to Spaniards as children are to adults and women to men ... and there being between them [Amerindians and Spaniards] as much difference as there is between ... monkeys and men" (Sepúlveda 1951 [1547], p. 33). Although miscegenation (the mixing of races) was more frequent in Iberian colonies than in those of France or England, it was the product of necessity, given the limited number of women who traveled with the conquistadors, and was not incompatible with the development of intricate racial hierarchies that became legacies of the Spanish and Portuguese empires. Indeed, the scientific racialism of the nineteenth century would ground a similar discourse, not on philosophical and religious reasons, as Sepúlveda did, but on (pseudo)scientific ones.

Colonialism is thus more than a set of institutions or practices that permit the establishment and maintenance of unequal economic exchanges among regions or countries. Underlying colonial economic relations and institutions are evolving beliefs or ideologies that make possible the permanence and reproduction of colonialism. For instance, the Spanish conquistadors saw even their most brutal actions justified by their role in spreading the Catholic religion. It is reported that Hernán Cortés (1485–1547), the conqueror of Mexico, claimed that "the main reason why we came ... is to praise and preach the faith of Christ, even if together with this we can achieve honor and profit" (Zavala 1972, p. 25). In a similar vein, the British and French empires found their justification in supposedly bringing civilization to "primitive" regions of the world.

Western culture is thus permeated by pseudo-rational justifications of racial hierarchies, which would seem to ground colonialism on nature. Even the usually skeptical David Hume (1711–1776) accepts colonial racial hierarchies when he states "the Negroes and in general all other species of men (for there are four or five different kinds) to be naturally inferior to the whites. There never was a civilized nation of any other complexion than white, nor even any individual eminent either in action or speculation" ("Of National Characters," *Philosophical Works III*, p. 228). Writing about "Locke, Hume, and empiricism," Said has argued "that there is an explicit connection in these classic writers between their philosophic doctrines [and] racial theory, justifications of slavery [and] arguments for colonial exploitation" (Said 1978, p. 13). Other canonic names are easily added to that of Hume, and many other disciplines to that of philosophy, from evolutionary biology—which, despite the misgivings of Charles Darwin (1809–1882), ended up applying its notions of competition to humanity—to historical linguistics, which helped provide a pseudoscientific basis for racist celebration of the so-called Aryan race.

Anticolonialism

Yet just as colonialism found occasional supporters among its subjects in the Americas, Africa, and Asia, European reaction to colonialism was not homogeneous. There was an important streak of anticolonial thought and action in Europe as long as colonies existed, and this too left an imprint on Western thought. Indeed, colonialism not only permeated Western culture, it also established the framework within which anticolonialist thought and action frequently developed. Because of the central role played by Catholicism in the justification of Spanish expansion, the anticolonialist reaction in sixteenth-century Spain used the intellectual tools provided by the church. Thus Bartolomé de Las Casas (1474–1566), the greatest critic of the Spanish conquest, used Biblical exegesis, scholastic philosophy, canonic law, historiography, and his own and others' eyewitness accounts to convince the Spanish court and the church of the humanity of the Native American populations and to achieve partial recognition of their rights. In fact, the arguments of Las Casas and other like-minded contemporary critics of colonialism, such as Francisco de Vitoria (c. 1486–1546), are the seeds from which contemporary notions of human rights and international law have sprung. But Las Casas did not deny the need to evangelize Native Americans or fail to acknowledge the sovereignty of the Spanish monarchy over them, even as he vindicated their right to self-government and to be treated as human beings.

Even texts produced in the Americas that are generally taken to be expressions of indigenous cultures, such as the anonymous seventeenth-century compilation of Meso-American myths, the *Popol Vuh,* or the Andean chronicler Felipe Guaman Poma de Ayala's *El primer nueva corónica y buen gobierno* (The first new chronicle and good government), also finished in the early seventeenth century, were intellectually framed by Catholicism. While the *Popol Vuh* uses Latin script to reconstruct the Mayan hieroglyphic books destroyed during the Spanish catechization, and can, therefore, be considered an act of absolute resistance to the Spanish conquest, its anonymous author describes the text as written "in Christendom." Although Guaman Poma de Ayala's very title implies criticism of Spanish rule, it is a hybrid text in which traditional Andean structures, such as the *hanan/hurin* (upper/masculine–lower/feminine) binary, are maintained while acknowledging Catholicism and incorporating into its narrative idiosyncratic versions of biblical stories.

This dependence on European thought, even on some of the basic presuppositions of colonialism itself, will be continued by most oppositional movements and texts produced after the first moment of resistance to European invasion. For instance, while for Lenin imperialism is rooted in the nation and in national capital, anti-imperial movements will likewise be national movements struggling to achieve independence. If the spread of "civilization" is seen in the nineteenth century as validating colonial expansion, the Cuban anticolonial activist, revolutionary, and scholar José Martí (1853–1895), in his classic essay, "Our America," proposed the establishment of the "American University," in which a decolonized curriculum would, for example, privilege the Incas and not the Greeks as the foundation of culture. Even the appeal of Mahatma Gandhi (1869–1948) to nonviolence as the basis of the struggle against colonial oppression, while rooted in his reading of the *Bhagavad Gita,* is also a reinterpretation of principles first proposed by David Henry Thoreau (1817–1862) and developed by Leo Tolstoy (1828–1910), with whom the great Indian leader corresponded.

A similar appropriation and modification of Western discourse can be found in twentieth-century anticolonialism's relationship with Marxism, even if in this case, as in that of nonviolence, it is an oppositional rather than a hegemonic one that is being used. Thus Mariátegui argued: "[Socialism] must be a heroic creation. We must give life to an Indo-American socialism reflecting our own reality and in our own language" (Mariátegui 1996, p. 89). And this attempt at translating Marxism into local cultural traditions was replicated throughout most of the colonial and neocolonial world, as authors as diverse as Ernesto "Che" Guevara (1928–1967), Amilcar Cabral (1921–1973), and Mao Zedong (1893–1976) attempted to create "socialisms" not only compatible with the social and cultural conditions of Latin America, Lusophone (Portuguese-speaking) Africa, and China, but also rooted in them. Precisely because of the importance given to local conditions, this anticolonial and nationalist Marxism was characterized by an emphasis on the cultural effects of political actions, and vice versa. Although not completely ignored, culture and nation did not play prominent positive roles in classic European revolutionary authors such as Karl Marx (1818–1883), Friedrich Engels (1820–1895), and Lenin. The subsequent preoccupation with culture is a link between anticolonial Marxism and postcolonialism, understood as a cultural and political critique of the surviving colonial and developing neocolonial structures and discourses.

Postcolonialism

But questions remain regarding postcolonialism. Is the *post* in *postcolonialism* merely a temporal marker? If so, all postindependence literary and critical production in all former colonies, regardless of whether they deal with or promote cultural and structural decolonization, would be postcolonial. Or is it a reference to those writings that attempt to deal with the aftermath of colonialism, with the social and cultural restructuring and healing necessary after the expulsion of the European colonists? In this case the novels of James Fenimore Cooper (1789–1851) and even those of Henry James (1843–1916), all of which, in one way or another, deal with the problem of establishing a U.S. identity distinct from those of England and Europe, could be classified as "postcolonial." In Latin America, several figures would qualify as postcolonial thinkers: the nineteenth-century polymath Andrés Bello (1781–1865), with his didactic poetry praising and, therefore, promoting "tropical agriculture," and his attempt at modifying Spanish orthography so as to reflect Spanish-American pronunciation; the Cuban scholar Fernando Ortiz (1881–1969), producer of pioneering studies of the cultural hybridity characteristic of the colonial and postcolonial experiences for which he coined the term *transculturation;* and, as well, the aforementioned Martí and Mariátegui, who among others, initiated in the region the systematic criticism of neocolonialism, internal colonialism, racism, and cultural dependence.

Or is the *post* in the term a not-so-implicit alignment with poststructuralism and postmodernism, that is with the antifoundational philosophies developed by, among others, Jacques Derrida (1930–2004), Gilles Deleuze (1925–1995) and Félix Guatari (1930–1992) and Michel Foucault (1926–1984)? If so, despite the existence of transitional figures such as Frantz Fanon, whose writings combine anti-colonial agitation, Marxism, French philosophy and psychoanalysis, postcolonialism could be seen as opposed to Marxist and non-Marxist anticolonialism and to mainstream attempts at understanding and undermining neocolonialism. From this antifoundational perspective, if the stress on cultural topics characteristic of anticolonial and postindependence fictional and theoretical texts establishes a connection with postcolonialism, their frequent essentialism, occasional blindness toward gender hierarchies, emphasis on politics and economics over constructions of subjectivity, make them at best flawed precursors. And from the point of view of scholars who claim to be developing the perspectives proposed by anticolonial theorists—Marxist or otherwise—postcolonialism can be interpreted as the direct application of theories developed in Europe and the United States that disregard earlier local theorizations and mediations.

Regardless of how one understands its relationship with anticolonial thought, this postcolonialism as exemplified by the works of Said, Homi K. Bhabha, and Gayatri Chakravorty Spivak, among others, has generated challenging analyses of the role of gender within colonial and postcolonial institutions, of the political implications of hybridity and diaspora, of racism, and of the importance of constructions of identity within colonial, neocolonial, and postcolonial situations. Moreover, it has permitted the extension of its analyses of subjectivity and of heterogeneous social groupings to the colonial archive, permitting the elaboration of innovative historical reconstructions that go beyond the obsession with facts and events of conventional historiography, or the frequently exclusive preoccupation with classes and economic structures characteristic of Marxism.

Assessment

The importance of the study of colonial and postcolonial structures and ideologies resides in the fact that contemporary international economic and cultural relations and realities, rather than being their negation, can be read as their continuation. In fact, contemporary American, African, and Asian national boundaries are part of the colonial inheritance. These borders, drawn according to purely administrative and political criteria by the imperial powers without taking into account cultural, ethnic, linguistic, or historical differences among the diverse populations thus brought together, have been a contributing factor to the ethnic and national violence that have plagued postcolonial areas.

But international economic inequality is the most egregious legacy of empire. The depth of this continuing disparity is such that, according to the Food and Agriculture Organization (FAO) of the United Nations, of the 842 million people classified as undernourished between 1999 and 2001, 798 million lived in postcolonial areas (FAO 2003). A similar inequality, though undeniably less dramatic in its immediate consequences, is present in the field of science and technology. For instance, Latin America holds only 0.2 percent of all patents (Castro Díaz-Balart and Rojas Pérez 2002, p. 331). While this is the direct result of the countries of the so-called developing world investing only 0.3 to 0.5 percent of their gross domestic product in the fields of science and technology—in contrast, "First World" countries set aside 2 to 5 percent for the same purpose (Castro Díaz-Balart and Rojas Pérez 2002)—it is also a consequence of the unequal manner in which the contemporary global economy is structured, which transforms scientific and technological research into a luxury. Moreover, this low investment in science and technology constitutes a contributing factor to the perpetuation of this international inequality (Castro Díaz-Balart and Rojas Pérez 2002). Furthermore, colonialism and the continuing global inequality it created can be seen as determining patterns of consumption of natural resources that have played a central role in past and current exploitation and destruction of colonial and postcolonial environments. For instance, Richard Tucker (2000) has noted that the United States, as a neocolonial power, has come "to be inseparably linked to the worldwide degradation of the biosphere" (p. 2). Thus the inheritance of colonialism, described by the constellation of heterogeneous terms postcolonialism, neocolonialism, or imperialism—in both its territorialized and deterritorialized conceptualizations—not only constitutes a central problematic in the fields of science and technology but also is at the core of the major ethical dilemmas faced by humanity in the early twenty-first century.

COMMON HERITAGE OF MANKIND PRINCIPLE

The Common Heritage of Mankind Principle (CHP) as it was presented to the United Nations General Assembly in various declarations and treaties, and as it is understood in the early-twenty-first century, affirms that the natural resources of the deep seabed and of outer space are held in common by all nations, and should be distributed equitably for the benefit of all humankind. Specifically the CHP of the 1979 Treaty Governing the Activities of States on the Moon and Other Celestial Bodies (The Moon Treaty), refers to: the equitable sharing of outer space resources; the nonappropriation of *in-place* resources particularly with regard to outer space mining activities; and the institution of an *international regime* to supervise commercial activities in space.

The CHP was presented with the understanding that it was crucial to plan for future exploration and uses of these important regions in order to insure not only an equitable distribution of their natural resources, but to prevent conflicts among nations as have occurred during earlier eras of exploration. Proponents of the CHP believe the principle confers on a region the designation of *domino util* or beneficial domain that should be legally defined as *res communis humanitatis,* a common heritage that is not owned by any nation, but from which all nations may garner profits and benefits.

Early Usage

Notions designating global resources as the common property of humankind (*res communis*) are not new, particularly in relation to the oceans, but date back more than 400 years. During the great age of discovery in the fifteenth century, Spain and Portugal claimed sovereignty over the high seas in accordance with the Papal Bull of 1493. This Bull established the border between Portuguese and Spanish waters "by a meridian line running 100 leagues west of the Azores, through both poles." In the late 1500s, however, the Protestant, seafaring nations of England and Holland challenged these claims of exclusive sovereignty over the oceans. Elizabeth I, in 1577, specifically dismissed Spanish claims of sovereignty over the high seas by "declaring that the sea, like the air, was common to all mankind and that no nation could have title to it" (Schachter 1959, p. 10). This began the establishment of the principle of *freedom of the seas,* or open access and nonappropriation in maritime law, which later was seen as a positive-sum game that encourages the usage and development of ocean resources as well as international trade for the common interest of nations (DeSaussure 1989, p. 29).

Modern Applications

The International Geophysical Year (IGY) was a main motivating factor behind the development of contemporary legal notions concerning open access and common property as applied to new territories such as Antarctica, the deep seabed, and outer space. The international scientific investigations conducted during 1957 and 1958 were enormously successful, and created a new paradigm for international prestige through cooperation in quality scientific research. In fact, the collaborations forged during the IGY fostered the formation of a number of new international committees and agreements including the 1958 United Nations General Assembly Conference in Geneva on the Law of the Sea, which reaffirmed the freedom of the high seas and began negotiations concerning the natural resources of the continental shelf and deep seabed; the 1959 Antarctic Treaty; the United Nations Committee on the Peaceful Uses of Outer Space (COPUOS); and ultimately the 1967 Outer Space Treaty containing the Common Benefit Principle (a modified *res communis*), which mandates that space exploration and the utilization of its resources be "for the benefit and in the interests of all countries."

The Law of the Sea and the Moon Treaty

During the late 1960s, the development of new technologies capable of taking commercial advantage of natural resources in the deep seabed and outer space, rendered the common benefit and nonappropriation clauses of earlier treaties obsolete. Ambassador Arvid Pardo of Malta introduced to the United Nations in 1967 a declaration related to the peaceful uses of the seabed and ocean floor that referred to these areas as a common heritage of humankind (Gorove 1972). According to Pardo, the CHP would establish "an administrative process whereby benefits derived from the resources of the [ocean] would be used for the common advantage of all peoples without regard to conditions of poverty or of wealth"; require supplementary programs of environmental protection to insure that the ocean's resources would be "passed on to succeeding generations"; and imply that the ocean and its resources "will be used exclusively for peaceful purposes" (Christol 1976, p. 44.) This declaration was accepted by the United Nations General Assembly without major criticism, and work began on the Declaration of Principles Governing the Sea-bed, the Ocean Floor, and the Subsoil Thereof, Beyond the Limits of National Jurisdiction, which was presented to the General Assembly in 1970.

The opening of outer space territories and resources to the possibility of commercial ventures also raised new questions with regard to the activities of states and private entities in outer space. The Common Benefit Principle of the 1967 Outer Space Treaty in combination with its nonappropriation clause in Article 2 left open certain questions concerning sovereignty and property rights in relation to permanent space stations, lunar stations, and astral and lunar mineral resources. The CHP was offered as a complementary principle that would fill these legal gaps by defining the nature and use status of outer space and its resources; clarifying the rights and obligations of states and private entities in relation to these resources; and providing regulatory guidelines that would reduce the monetary risks of commercial space ventures. In 1972 the United States made a formal presentation to the COPUOS committee working on the Moon Treaty draft advocating inclusion of the CHP into the treaty text.

Implications for Science and Technology

The possible implications of the CHP for advancement of science and technology can be found in the debate between First and Third World nations as to the effects the implementation of this principle might have on the commercial development of space resources and the technologies that access them.

As committee work on the Moon Treaty continued, controversy grew in the United States concerning the CHP and its implications for the development, use, and allocation of outer space resources. There was considerable debate on both the definition of what the equitable sharing of resources meant under the CHP, and whether or not that sharing included access to space technology. In particular, a swarm of small but powerful U.S. space interests, especially the L-5 Society, began to publicly protest against the treaty, and managed to challenge the original U.S. position in several important areas.

Consequently U.S. representatives began arguing that the implementation of the CHP, with its mandate for profit sharing through an international regime, would be a disincentive to capital investment by private enterprise in the development of space resources and technologies. In addition, the principle's affirmation of equitable sharing and open access to space resources and technologies would bring about static inefficiency in the development of these resources, resulting in fewer benefits being produced for all concerned. Finally the equitable sharing of space technologies would be a threat to national security, both undermining the economic base of the United States and supplying potentially unstable nations with technology that had possible dual-use military applications.

Third World nations argued that the CHP did not constitute a disincentive to space resource development because its provisions were designed to grant positive rights that would allow humankind to exploit the benefits of space resources for the first time (Cocca 1973). This was a clear improvement to the 1967 Outer Space Treaty that specifically excluded the possibility of appropriating these resources. In addition, the CHP authorizes an equitable, not an equal, sharing of profits, and contains a compromise clause that balances the distribution of benefits by taking into consideration both the needs of Third World countries, and the efforts put forth by the nations or entities developing these specific resources.

Third World nations also argued that the international regime, rather than obstructing the development of space resources, actually furnishes a system capable of facilitating cooperative space ventures between nations for the accessing of space resources. Moreover the mitigation of Third World underdevelopment and external dependency on the First World through the equitable sharing of outer space resources would in reality further international cooperation and reap greater economic benefits for all nations. In fact, economic research studies have recommended that "for the sake of American commercial competitiveness in space," the United States should maintain lenient policies in relation to international technology transfers and encourage the cooperative exchange of information among scientists from all nations as a means of accelerating technological innovation (Corson 1982, pp. 59–61).

Status and Assessment

The Moon Treaty, with its common heritage language, spent seven years in the COPUOS working committee before it was finally passed by consensus and sent to the UN General Assembly in 1979 for a vote, where it was adopted by all 152 member nations. However the Moon Treaty was subsequently ratified by only thirteen nations, and while it is technically in force in 2004, the lack of support by First World, spacefaring nations has undermined the treaty's inherent authority, and ultimately created a large and growing gap between the uses of space resources and technologies and the adequacy of the laws regulating them.

In the absence of an accepted system of international space law, nations have been turning to the formation of their own domestic law to furnish at least some legal guidance and security for the conduct of space activities (Goldman 1988, p. 85). Domestic space law, however, generates even more complex issues of compliance, particularly given the international nature of outer space and space activities. Questions regarding whose law will apply for joint space ventures such as the international space station, or in areas of liability for space accidents occurring between states, will be extremely troublesome to answer.

Yet the compromises that occurred during the laborious process of consensus in developing the Moon Treaty and the CHP were made to "assure developed and developing nations the opportunity to benefit from space activities" taking place within a commonly held region beyond national territorial boundaries (Jasentuliyana 1984, p. 4). The Moon Treaty offered an indispensable legal framework for maintaining international stability and clarifying the expectations of the international community, thereby reducing the potential for conflict, creating a safer investment climate for both government and private entities, and furnishing an organizational mechanism for cooperative commercial ventures in outer space (Jasentuliyana 1980, pp. 6–7; Goldman 1985, p. 85).

Consequently First World suspicions regarding the CHP and its mandate for the equitable sharing of space resources and technologies, along with the belief that open access, and/or cooperative ventures with *less qualified* Third World nations would lead to the inefficient development of these resources, ended an unprecedented era of international collaboration in scientific exploration, technological advancement, and the development of positive international law.

COMMUNICATION ETHICS

Communication ethics is concerned primarily with human communication mediated by communications technologies, from print to radio, television, and other advanced electronic media. As such it assumes the importance of ethical responsibilities in direct or immediate communication, such as the obligation to speak truthfully, and seeks to reflect on how these carry over into the complex circumstances that arise with the development of communications science and technology. Because of the historical role played by reflection on ethics in relation to mass circulation print technologies in the form of newspapers during the first half of the twentieth century, communication ethics has its roots in journalism ethics. Because of the multiplicity of communications media during the last half of the twentieth century, the term *media ethics* is sometimes used as a synonym for communication ethics.

Contemporary Context

The communication technologies that produce and distribute information are an economic paradise. Massive multimedia conglomerates are at war for the trillions of dollars at stake—Pearson PLC in England, Bertlesmann in Germany, Microsoft and Disney in the United States, the Rupert Murdoch empire, and Sony of Japan. The business tycoons of these global companies do not specialize in hard goods, but control images, data, software, and ideas. Clusters of high-tech communication firms are re-mapping the planet. Previous geographical alignments organized by political power are being reordered in terms of electronic megasystems.

The revolution is not taking place in abstraction, outside of everyday affairs. Banking, the stock market, entertainment media, and the military represent the most advanced electronic communication systems. However the menagerie of fiber optics, supercomputer data, and satellite technology, although inescapably global, is local and personal as well. Television, CDs and CD-ROMs, DVDs and VCRs, online databases, rock music channels, PCs, video games, cellular telephones, and virtual reality—the electronic highway has become the everyday world of advanced industrial societies

Public life in the twenty-first century is being altered in complex ways through ubiquitous multimedia technologies, and ethics is essential for coming to grips with them. Language is indispensable to humanness and to the social order; therefore when human communication capacity is mediated in fundamentally different ways than before, the impact is substantial and far-reaching. Accounting for the social influence of media technologies is an historical and empirical task, but clearly the domain of communication ethics as well.

Communication as Symbol Making

The mainstream view in communication studies has been a mechanistic stimulus-response model rooted in empiricist science. However since the 1990s, communication theory has been complemented with an interpretive turn. From this perspective, human discourse and culture become fundamental, and language is the public agent through which identity is realized. Individuals are integrated into social units through symbol, myth, and metaphor. Communication is the creative process of building and reaffirming through symbols, with cultures the constructions that result. In a symbolic approach to communications, concepts are not isolated from their representations. The social and individual dimensions of language are a unified whole. Through the social nature of language, human beings integrate specific messages with the larger project of cultural formation.

Although not identical to that which they symbolize, symbols participate in their meaning. They share the significance of that to which they point. Symbols create what human beings call reality. Human identity embedded in representations matters to people. Thus worries about racism, sexism, and age discrimination in language are not marginal but central to socially responsible communication. The manner in which race, age, gender, class, disabilities, economic status, and ethnicity are represented symbolically influences the possibilities for a just sociopolitical order.

From a symbolic perspective, when symbols are mediated technologically, the changes in human life and culture must be understood historically and evaluated morally. Walter Ong (2002) calls this *technologizing the word*. Symbolic theory presumes that the history of communications is central to the history of civilization, that social change results from media transformations, that changes in symbolic forms alter the structure of consciousness.

The Canadian scholar Harold Innis (1951), for instance, studied the introduction of papyrus, the printing press, radio, and the telegraph—and documented a bias regarding space and time. Oral communication systems, he argued, are biased toward time, making time continuous while rendering space discontinuous. Print systems, by contrast, are biased toward space, making geography continuous and breaking time into distinct units.

Thus from the introduction of cuneiform writing to contemporary communication satellites and fiber optics, media technologies have attracted considerable attention—scholars in the symbolic tradition examining all significant shifts in technological form, associating with them alternations in culture and in perception. Within this paradigm of bias in communication systems, the intellectual challenge is to identify the distinguishing properties of particular media technologies such as books, cinema, and the Internet. As the physicist steps inside the world of atoms to understand them from the inside, so communications scholars, regarding television or magazines or billboards, must delve into their aesthetic properties in order to know them fundamentally and distinctively (McLuhan 1966).

As a minor premise, Innis (1952) argued that one form of communication tends to monopolize human knowledge and render other forms residual. Communications media never exist innocently and equally alongside one another. Elizabeth Eisenstein (1979), for example, documents the overriding significance of symbolic formation in her definitive work on the invention of printing. The printing press reformulated symbols at a historical watershed, fostering prescriptive truth and decentering papal authority by empowering the home and countryside with vernacular Bibles and Martin Luther's pamphlets. The ninth-century Carolingian and twelfth-century Gothic renascences were limited and transitory. The preservative power of Johannes Gutenberg's invention made the Renaissance permanent and total.

If oral cultures make time stand still, and print cultures foster empire and objectivism, the ongoing shift, from invention of the telegraph to early-twenty-first-century electronic culture, dislocates individuals from both space and history. It ruptures historical consciousness and pushes people into world citizenship, ill-equipped as they may be to accept that role. Without specific anchors in time and space, humans are ripe for electronic picking. Linear rationality facilitated by print is co-opted by mass media images. In sociological terms, the large-scale electronic media radically disconnect human beings from the mediating structures that serve as their everyday habitat—family, school, church, neighborhoods, and voluntary associations. Such primary groups lose their resonance.

The development of Internet technology marks another era of rapid growth and change in the media. Mass media technologies are converging into digital formats. Internet chat rooms, e-mail, multi-user domains (MUD), web-based publications, and the ability to hyperlink are producing new forms of human interaction. The 3-D virtual world is the innovative edge of these online technologies. In principle, interactive Internet technology gives people a voice and connects users directly without professionals or gatekeepers in between. Internet technologies can be democratic tools that serve people's everyday needs rather than those of special interest groups or the market.

Jacques Ellul developed the argument that technology is decisive in defining contemporary culture. Indeed not only productivity, but also economics, politics, and symbolic formations are dominated by the technological. In Ellul's (1969) framework, communications media represent the world of meaning in the technological system at large, the arena where the latter's character is most clearly exposed. Though exhibiting the structural elements of all technical artifacts, their particular identity as a technology inheres in their function as bearers of symbols. Information technologies thus incarnate the properties of technology while serving as agents for interpreting the meaning of the very phenomenon they embody.

Ellul calls communication systems the "innermost, and most elusive manifestation" of human technological activity (Ellul 1978, p. 216). All artifacts communicate meaning in some sense, but media instruments play this role exclusively. As the media sketch out the world, organize conversations, influence decisions, and impact self-identity, they do so with a technological cadence, massaging a technological rhythm and disposition into the human soul. With moral and social values disrupted and reoriented in the process, the ethics of communications technologies are an important arena for examining life in technological societies at present.

History of Communication Ethics

Historically communication ethics arose in conjunction with concerns related to print media, so that it requires work to extend the original developments to the more prominent digital technologies. Print news and the ethical standards for newspaper reporters were the first concerns of anything that could be called communication ethics. The harm that an unregulated press could do to society was first explicitly linked to ethical principles in North America and Europe during the 1890s, when critics began assessing journalism philosophically. These initial forays blossomed into the first systematic work in communication ethics during the 1920s in the United States. Four major books emerged from

America's heartland during that decade, their authors among a *Who's Who* of journalism luminaries: Nelson Crawford's *Ethics of Journalism* (1924), Leon Flint's *The Conscience of the Newspaper* (1925), William Gibbons's *Newspaper Ethics* (1926), and Albert Henning's *Ethics and Practices in Journalism* (1932). These authors understood ethics as a scholarly enterprise and left a permanent legacy. In Europe also several ethical issues emerged during the early-twentieth-century. Sensationalism was considered contrary to the public service role of the newspaper. Freebies and junkets, scourged by media critics as early as 1870, were treated more systematically in the context of rising business competition. Truthfulness as a moral principle was abstracted for the first time from the practice of accurately reporting facts. During this period, a platform for the free press/fair trial debate was created, though it was one-sided in promoting the rights of the press. Together they carved out much of the structure that dominates journalism ethics across Europe and North America in the early-twenty-first century, and with some nuances, in various regions around the world.

The intellectual roots of the democratic press were formed when print technology was the exclusive option. Most of the heavyweights in communication ethics in industrialized democracies demonstrate like predilections for news, and news in its literary rather than electronic broadcast form. Yet extensive research remains to be done on various aspects of the news business: declining readership among youth and in urban cultures, production practices, multiculturalism, the problematic status of objectivity, technological innovation, newspaper credibility, hiring practices, and others. Most of the perpetual issues in media ethics—invasion of privacy, conflict of interest, sensationalism, confidentiality of sources, and stereotyping—get their sharpest focus in a print context. Meanwhile newspapers outside the mainstream have scarcely been considered.

But the context has changed. Television is the primary source of news for most people and information radio remains vital. Even research that emphasizes the news function tackles cases and problems from broadcasting, the wire service agencies, and documentaries, in addition to everyday reporting. And beyond the daily paper, magazines and instant books are increasingly prominent. In a more dramatic trend, reporting is being removed from its pedestal and treated in the same way as other mass media functions. News is now being integrated with other aspects of the information system, that is, to persuade, to entertain, and to serve bureaucracy. In fact, practitioners of journalism, advertising, entertainment, and data management are often part of the same institutions and encounter other media functions directly in their work.

Arguably heads of media corporations should ideally come from a news background, and clearly the demands on news operations have never been more intense. But it is empirically true that the media's role in persuasion, entertainment, and digital transmission has also become pervasive, socially significant, and ethically charged—thus the burgeoning research in the ethics of public relations, organizations, face-to-face encounters, the music business and cinema, libraries, book publishing, confidentiality in computer storage, fiction, new media technologies, the mass-mediated sports industry, and more.

The dark side of ethical research into this expanding field is faddishness and fragmentation. However there is hope that the widening spectrum will open new insights and fresh approaches to the substantive issues. Deception and economic temptation are common in all mass-mediated communication. Sexism and racism are deep-seated everywhere. Reporters often fail to recognize sensationalism in the news until they confront the difference between gratuitous violence and realism in entertainment media. Invasion of privacy, easily excused in news, becomes an insufferable evil when government agencies access confidential information from data banks without permission. The challenge is to demonstrate how ongoing ethical quandaries can be fruitfully examined across a diverse range of media technologies and functions.

Ethical Issues

In outlining an agenda for communication ethics in terms of global media technologies rather than print journalism alone, several issues emerge as primary. Each can profit from the past, though several are new or have such dramatic intensity in the early twenty-first century that thinking rooted in the communication ethics of the first half of the twentieth century is no longer directly relevant. Meanwhile the electronic media have achieved some important successes. The Internet makes it possible for people who disagree with government policies to unite and protest against them. The Montreal Protocol and the Landmine Ban Treaty, for example, could not have happened without new media technologies. Television was the stimulus for humanitarian intervention in Somalia and prison reform in the U.S. military. Strengthening the media's role in democracy is important for communication ethics, while identifying the negative dimensions that are already obvious.

DISTRIBUTIVE JUSTICE. An ethics of distributive or social justice is mandatory for understanding the communications revolution. The mainstream view of social justice centers on fairness. As a formal concept, justice means "the consistent application of the same norms and rules to each and every member of the social cluster to which the norms and rules apply" (Heller 1987, p. 6). But in the more dynamic and multidimensional terms of distributive justice, the overriding question is accessibility. Just distribution of products and services means that media access ought to be allocated to everyone according to essential needs, regardless of income or geographical location. Comprehensive information ought to be ensured to all parties without discrimination.

In contrast, the standard conception among privately owned media is allocating to each according to ability to pay. The open marketplace of supply and demand determines who obtains the service. Consumers are considered at liberty to express their preferences and to select freely from a variety of competing goods and services. The assumption is that decisions about allocating the consumer's money belong to the consumer alone as a logical consequence of the right to exercise social values and property rights without coercion from others.

An ethics of justice where distribution is based on need offers a radical alternative to the conventional view. Fundamental human needs are related to survival or subsistence. They are not frivolous wants or individual whims or deserts. Agreement is rather uniform on a list of most human necessities: food, housing, clothing, safety, and medical care. Everyone is entitled without regard for individual success to that which permits them to live humanely.

The electronic superhighway is swiftly becoming indispensable. Communications networks make the global economy run, they provide access to agricultural and health care information, they organize world trade, they are the channels through which international and domestic political discussions flow, and through them people monitor war and peace. Therefore as a necessity of life in a global order, communication systems ought to be distributed impartially, regardless of income, race, religion, or merit.

What is most important about Internet technology is not so much the availability of the computing device or the Internet line, but rather the ability to make use of the device and conduit for meaningful social practices. Those who cannot read, who have never learned to use a computer, and who do not know the major languages of software and Internet content will have difficulty getting online, much less using the Internet productively.

There is no reasonable likelihood that need-based distribution will ever be fulfilled by the marketplace itself. Technological societies have high levels of computer penetration, and nonindustrial societies do not. Digital technology is disproportionately concentrated in the developed world, and under the principle of supply and demand there are no structural reasons for changing those disproportions. Even in wired societies, the existence of Internet technology does not guarantee it will reach its potential as a democratic medium. There is a direct correlation between per capita gross domestic product (GDP) and Internet distribution. The geography of the digital world is not fundamentally different from that of the off-line world. The history of the communications media indicates that existing political and economic patterns will prevail; inequities in society lead to inequities in technology.

In the digital age—rooted in computers, the Internet, fiber optics, and communication satellites—ideally all types of persons will use all types of media services for all types of audiences. Therefore the normative guideline ought to be universal access, based on need. And universal service is the Achilles' heel of new technologies driven by engineering and markets. As the economic disparity between rich and poor countries grows, an information underclass exacerbates the problem because information is an important pathway to equality. An ethics of justice requires that the approach to media institutions should be modeled after schools, which citizens in democracies accept as their common responsibility. Without intervention into the commercial system on behalf of distributive justice, the world will continue to be divided into the technologically elite and those without adequate means to participate.

CULTURAL DIVERSITY. Indigenous languages and ethnicity have come into their own in the early-twenty-first century. Sects and religious fundamentalists insist on recognition. Culture is more salient at present than countries. Muslim immigrants are the fastest-growing segment of the population in France and longstanding policies of assimilation are no longer credible. Thirty thousand Navajos live in Los Angeles isolated from their native nation and culture. The nomadic Fulani, searching for good pasture throughout sub-Saharan West Africa, are held together by clan fidelity, but their political future hangs in the balance. More than 30 percent of the information technicians working for the Microsoft Corporation in the United States come from India. In the early 1900s, 80 percent of immigrants to the United States were from Europe. Since the 1960s, the majority has come from Asia, Latin America, and developing countries in Africa. Rather than the melting pot of the last century, immigrants to the United States in the early-twenty-first century insist on maintaining their own cultures, religions, and languages. Identity politics has become dominant in world affairs since the Cold War, and ethnic self-consciousness is now considered essential to cultural vitality. As a result, social institutions such as the mass media are challenged to develop a healthy cultural pluralism instead of strident tribalism.

In order to integrate the new demands of cultural diversity into media practices and policies, an individualistic morality of rights must be modified by a social ethics of the common good. A commitment to cultural pluralism makes sense when the community is understood to be axiologically and ontologically superior to the individual. Human beings in this communitarian perspective do not disappear into the tribe, but their identity is constituted organically. Persons depend on and live through the social realm. Human beings are born into a sociocultural universe where values, moral commitments, and existential meanings are both presumed and negotiated. Thus in communitarian ethics, morally appropriate action intends community. Unless a person's freedom is used to help others flourish, that individual's well being is itself diminished.

Communitarianism as the basis for ethnic plurality moves media programming and organizations away from melting pot homogeneity and replaces it with the politics of recognition. The basic issue is whether democracies discriminate against their citizens in an unethical manner when major institutions fail to account for the identities of their members (Taylor et al. 1994). In what sense should the specific cultural and social features of African Americans, Asian Americans, Native Americans, Buddhists, Jews, the physically disabled, or children publicly matter? Should not public institutions insure only that democratic citizens share an equal right to political liberties and due process without regard to race, gender, or religion? Charles Taylor considers the issue of recognizing multicultural groups politically as among the most urgent and vexing on the democratic agenda. Beneath the rhetoric is a fundamental philosophical dispute that Taylor calls the *politics of recognition*. As he puts it, "Nonrecognition or miscrecognition can inflict harm, can be a form of oppression, imprisoning someone in a false, distorted, and reduced mode of being. Due recognition is not just a courtesy we own people. It is a vital human need" (Taylor et al. 1994, p. 26). This foundational issue regarding the character of cultural identity needs resolution for cultural pluralism to come into its own.

As one illustration of this framework, Robert Entman and Andrew Rojecki (2000) indicate how the race dimension of cultural pluralism ought to move forward in the media. Race in the early-twenty-first-century United States remains a preeminent issue, and Entman and Rojeck's research indicates a broad array of white racial sentiments toward African Americans as a group. They emphasize not the minority of outright racists but the perplexed majority. On a continuum from comity (acceptance) to ambivalence to animosity and finally racism, a complex ambivalence most frequently characterizes the majority. "Whites bring complicated combinations of assumptions, misinformation, emotional needs, experiences, and personality traits to their thinking about race" (Entman and Rojecki 2000, p. 21). They may believe, for example, that blacks face discrimination and merit aid, but argue against welfare spending out of a suspicion of government programs. Ambivalence means that the majority of whites do not necessarily harbor deep-seated fears or resentment, but become conflicted about the best strategies to follow and sometimes lose their patience with the slow progress of change.

Correcting white ignorance and dealing with ambiguities hold the most promise for the media. The reality is, however, that the media serve as resources for shading ambivalence off into animosity. There is little evidence that television or other popular media pull their viewers toward comity. The white majority mostly experiences "media images of Blacks on welfare, of Black violence on local news, and of crude behavior—open sexuality and insolence—in entertainment television.... The habits of local news—for example, the rituals in covering urban crime—facilitate the construction of menacing imagery" (Entmann and Rojecki 2000, p. 34). Thus the media do little to enhance racial understanding among the ambivalent majority most open to it. Unfortunately the media do not provide the information that this important swing group needs to move policy and institutions toward cultural pluralism.

VIOLENCE. Violence in television and film has been a major ethical issue for decades. Internet technology has complicated the problem with hate speech and cyberterrorism.

In the United States, for example, studies have shown that by high school graduation the average seventeen-year-old will have seen 18,000 murders in the movies and on television. From the horrific shootings at Columbine High School in 1999 to similar tragedies in other states and countries before and since, teenagers who slaughter their classmates and teachers, and then kill themselves, are linked by debate or research to the culture of violence in which they live. While the United States leads the world in the amount of violence on television, television programming in all parts of the globe contains a great deal of violence, including a high percentage of guns as weapons and indifference to brutality, with the terrible consequences only hinted at or not depicted at all (Potter 1999). Gun-related deaths in the United States have reached the level of a public health epidemic.

Meanwhile media industries and civil libertarians opposed to censorship claim that no direct effects from violent programming have been documented or proved. In fact, this argument against curtailing violence in the media has long been the most persistent and persuasive. However the no-effects conclusion is no longer credible. Evidence of a positive association between media violence and real violence has been accumulating for at least forty years. Analyses during the 1990s of literally hundreds of studies on media violence verify a causal link between televised violence and real-life aggression with some of the strongest effects among young children. Research conducted for the American Medical Association (AMA) and the National Centers for Disease Control and Prevention, and the results of the exhaustive National Television Violence Study (1994–1998) support the same conclusion (Wilson et al. 2002).

Based on a review of the research, James Potter (1999) concludes that there exist both immediate and extended consequences from televised violence—with the caveat that the effects process is highly complex. In the short term, fear and habituation occur, but increased aggressiveness toward others is strongly supported also. The same is true for effects over a longer period: Research shows that exposure to violence in the media is linked to long-term negative effects such as increased aggression, a worldview based on fear, and desensitization to violence.

Violence is a serious ethical issue because it violates the persons-as-ends principle. In Immanuel Kant's standard formulation, people must treat all other people as ends-in-themselves and never as means only. In Judeo-Christian agape and feminist relational ethics, violence contradicts Other-regarding care. On multiple grounds, the gratuitous cheapening of human life to expand ratings is a reprehensible mistreatment of human beings. From the persons-as-ends perspective, there is a special interest in the sexual violence so common in music video, horror movies (especially slasher films), pornographic literature, and video games. Sadistic, bloodthirsty torture in a sexual context is a particularly offensive form of dehumanization.

A new dimension of violence has emerged with hate speech on the Internet. In 1995, former Ku Klux Klan (KKK) leader Don Black established Stormfront, the first white supremacist Internet site. As access to the Internet became less expensive and creating web pages much simpler, the number of Internet sites and people visiting them grew exponentially. Mirroring this growth, Internet sites espousing various kinds of bigotry have multiplied dramatically, now numbering in the thousands. In the past, hate was promoted through crude graffiti and low quality pamphlets. Bulk mailings to even a few hundred people were difficult. But with the Internet, slick web sites devoted to hate are available to a potential audience of millions.

In the early-twenty-first century, though the KKK is more fragmented than at any time since World War II, its factions are using the Internet to revitalize the organization. The KKK sites maintain and defend the superiority of the white race, and warn against interracial marriage. Jews are vilified as Satan's people, and immigration is condemned as an uncontrolled plague. In addition, the number of Internet sites for the National Association for the Advancement of White People, founded by former KKK leader David Duke, has mushroomed and energized the so-called *Klan without robes*.

Numerous neo-Nazi Internet sites promote the anti-Semitic racism of Adolf Hitler, with the National Alliance being the most prominent Hitlerian organization in the United States. Jews are blamed for inflation, media brainwashing, and government corruption, with blacks depicted as criminals and rioters. A host of sites are devoted to Holocaust revisionism, denying the murder of Jews in World War II.

Internet sites of hate groups that claim religious legitimacy are flourishing as well. The Christian Identity site is virulently racist and anti-Semitic. The World Church of the Creator calls nonwhites physiologically subhuman. The site for White Aryan Resistance rails against the nonwhite birthrate. Other sites are anti-Catholic and anti-Muslim, or militantly anti-abortion.

Most organizations that monitor Internet hate activity do not advocate censorship. Education is seen as more effective than trying to silence bigots. With many moral problems in the media, some ethical theories are more appropriate than others, but hate speech on the Internet is contradicted by all major theories without exception. This across-the-board condemnation suggests that all personal, educational, and policy efforts to combat Internet hate speech are permissible, even mandatory, but obviously without the revenge and aggressiveness that contradict good ends.

Another kind of violence made possible by digital technology is cyberterrorism, that is, attacks on human targets abetted by machines and direct attacks on the telecommunications infrastructure. Financial transaction systems, electrical supply networks, military operations, police and emergency electronic devices, water purity management, air traffic control, and other essential services are vulnerable to computerized sabotage. All attempts at protecting societies through cybersecurity have tended to lead to increased surveillance, intrusions upon private data, and centralized government authority. High-level encryption technology is essential for protecting civil liberties and societies from terrorist attacks. Many security issues in advanced societies are still unclear and their resolution ill-defined. Should diagrams of nuclear power plants or city water systems, for example, be easily available to the public as they were before September 11, 2001? Resolving the conundrums requires as much open communication as possible, but the profusion of communication itself is sometimes counterproductive. In all aspects of cyberterrorism, a proactive citizenry and enlightened legislation are indispensable.

INVASION OF PRIVACY. Public opinion polls indicate that privacy is the premier issue in media ethics, at least in European and North American cultures. Intruding on privacy creates resentment and damages the credibility of the news media. But for all of the advances in privacy and tort law, ethicists consider legal definitions an inadequate foundation. How can the legally crucial difference between newsworthy material and gossip or voyeurism be reasonably determined?

Therefore while acknowledging legal distinctions and boundaries, the ethics of privacy is constructed from such moral principles as the dignity of persons and the redeeming social value of the information disclosed. Privacy is a moral good because it is a condition for developing a healthy sense of personhood. Violating it, therefore, violates human dignity. But privacy cannot be made absolute because people are cultural beings with responsibility in the social and political arena. People are individuals and therefore need privacy; people are social beings and therefore need public information about others. Because people are individuals, eliminating privacy would eliminate human existence as they know it; because people are social, elevating privacy to absolute status would likewise render human existence impossible. These considerations lead to the formal criterion that the intimate life space of individuals cannot be invaded without permission unless the revelation averts a public crisis or is of overriding public significance and all other means to deal with the issue have been exhausted.

From an ethical perspective, legal definitions of privacy beg several questions about the relationship between self and society. A legal right to privacy presumes a sharp line dividing an individual from the collective. An ethics of privacy prefers the richer connections between public and private advocated by social theorists since Alexis de Tocqueville, who have centered their analysis on a viable public life. While participating in theoretical debates over the nature of community, media ethicists have been applying moral principles to three areas: (a) the reporting of personal data on various social groups from innocent victims of tragedy to public officials to criminals; (b) protecting confidential information stored in computer data banks—medical, financial, library, educational, and personal records, for example, and (c) ubiquitous advertising that intrudes on our everyday activities.

Conclusion

The cosmopolitan reach of high-speed electronic technologies has made communication systems and institutions of global scope possible. Dealing with these new entities requires a technologically sophisticated, cross-cultural ethics commensurate with the worldwide reach of the media. In the process of identifying and responding to specific issues, communication and media ethics must make the questions raised by technology the central focus while repositioning them internationally. As true of professional ethics generally, communication ethics ought to become comparative in character. In place of its largely European and North American, gender-biased, and monocultural canon, media ethics of the future must be ecumenical, gender-inclusive, and multicultural.

A diversified comparative ethics, with a level playing field rooted in equal respect for all cultures, is by no means unproblematic and involves an act of faith. The claim that all cultures have something important to say to all human beings is an hypothesis that cannot be validated concretely. Yet it serves as an open horizon for moving comparative, transnational study forward in an interactive mode. Of the various types of applied and professional ethics, communication ethics has its roots most deeply in language, culture, and dialogue. In that sense, a multicultural style is required for its own authenticity.

COMMUNICATIONS REGULATORY AGENCIES

Human beings are animals that communicate intensively, and all communication systems, beginning with spoken and written languages, are regulated in at least informal ways. Most people feel that there are certain things that should not be said or written and that certain forms of speech and writing are appropriate for different contexts. However, with the development of physical communication systems such as the postal system and even more with that of the telegraph, telephone, radio, and television, regulation guided by ethical principles has become an increasingly prominent feature of those technologies. Ethical principles concerning content and access have created the foundation for regulation of communication systems. Concerns about content include privacy and anonymity, copyright, defamation, censorship, and profanity. Ethical issues relating to access include concerns about the availability of communication systems and control of content production.

Speech and Postal Systems

Law has been used to regulate the content of speech and writing since at least Roman jurisprudence, in which speakers were held liable for defamatory communication that caused injury to another party. The United Kingdom began regulation of defamation during the sixteenth and seventeenth centuries; this area of law was established in the United States after independence and is mirrored in other countries. Defamation law protects individuals from falsehoods that may cause economic or emotional harm and covers utterances in both speech (slander) and writing (libel). This principle of constrained communication extends to all media and their respective systems and has a lengthy judicial history in the United States and the United Kingdom (Jones 2003).

A number of ancient civilizations created courier services to deliver official documents and messages, with the earliest evidence of an organized infrastructure appearing in Egypt in 2000 B.C.E. From initially serving the government, a number of those systems were expanded to include public and private correspondence; that led to the almost complete control of postal services by nations by 1875. Regulation of those entities focused primarily on efficient administration.

However, by the middle of the twentieth century an expectation of privacy had made its way into many legal systems, including the Mexican constitution, U.S. and British law, and the European Convention on Human Rights. This principle restricts readership of mail to the addressee but generally is qualified to give states the ability to censor materials in the name of security; this explains the still widespread censorship of mail within military forces (Scheele 1970).

Toward the end of the twentieth century government-run monopolies on postal services began to compete again with private courier services. In response a number of government services, including the U.S. Postal Service, began to operate with more independence from the government. Ensuring complete access to the global postal network remains a key factor supporting government-run services as many small or hard to reach communities fear complete isolation in an entirely privately run system.

Telegraph and Telephone

The wire telegraph was invented by Samuel F. B. Morse (1791–1872) in 1835 and saw widespread deployment within ten years of its invention. Alexander Graham Bell (1847–1922) was granted a patent on the telephone in 1876, but that technology grew somewhat more slowly than did the telegraph, with the first transcontinental line in North America not being finished until 1915. In 1865 the International Telegraph Union was founded to support international interoperability of the telegraph system. That union was the first international body to regulate communications and attempted to allow easier communication across national boundaries. The union has expanded to include all telecommunications activities but does not address ethical issues involving content or access directly.

The telegraph initially was regulated in the United States through the Post Roads Act of 1866, which gave authority to the postmaster general to fix rates for telegrams sent by the government. Greater government involvement in the industry did not come until twenty-one years later, when the U.S. Congress passed the Interstate Commerce Act of 1887 to regulate railroads and laid the foundation for the regulation of common carriers within the United States. A common carrier is any transporter that offers services to the general public to transport goods. Court interpretation of common carriers to include communication services provided the legal authority for government to become more actively involved in the communications industry. The 1887 act was amended explicitly to include that extension of government jurisdiction to regulate telephone and telegraph companies by the Mann-Elkins Act of 1910. Regulation of telephone and telegraph was taken over by the Federal Communications Commission (FCC) at its inception in 1934.

Although some nations tried to regulate privately owned telephone and telegraph companies as the United States did, a number of others followed a model closer to that of the postal service and created nationalized phone utilities. In many countries, including the United States, regulators oversaw private companies with full or partial monopolies. Regardless of the details of the regulatory structure or the preference for government involvement or free market competition, each nation faced similar ethical questions.

Early regulation of the telegraph and telephone industries focused on improving interoperability between competing networks, allowing consumers to send messages to any recipient regardless of the network to which they subscribed. Regulators also attempted to ensure that telephone and telegraph companies charged consumers equally for the same service, thus supporting equal access to the system. Each regulatory regime also grappled with questions concerning the privacy and content of those transmissions. When can the state or an individual record or intercept those messages? In the United States third-party taping of conversations requires a court order, whereas rules for recording by parties to a conversation vary from state to state. As with the postal service, most nations have formulated some expectation for the privacy of telephone and telegraph messages.

Radio and Television

Concurrent with the initial development of the telephone and telegraph, research into wireless communications systems led to the creation of the first wireless telegraph by Guglielmo Marconi (1874–1937) in 1895. Maritime adoption of that technology for ship-to-ship and ship-to-shore communication spread rapidly and led to the Berlin International Radiotelegraphic Convention, a series of international conferences in Berlin in 1903 and 1906 and in London in 1912 to discuss radio telegraphy. Beyond determining SOS as the standard distress signal, the 1912 conference led directly to the U.S. Radio Act of 1912, which, along with the Mann-Elkins Act, became the foundation for the regulation of communication systems by the U.S. government.

Radio transmission of voice developed slowly during that period and remained closely tied to telephony. However, by 1920 radio broadcasting had begun in earnest with the November 2 broadcast of election returns by the Pittsburgh station KDKA. The early years of broadcast radio were marked by turmoil. Stations went on and off air, using a frequency and power of their choosing, resulting in widespread interference and confusion. The Radio Act of 1912 required stations to obtain a license from the U.S. Department of Commerce, although the department had no enforcement authority and issued licenses with little oversight. As a result Congress passed the Dill-White Radio Act of 1927, which established the Federal Radio Commission and granted it authority to assign and revoke broadcast licenses at particular powers and frequencies. The act also included provisions for the regulation of programs that exploited or misled the public; that allowed the commission to end broadcasts of fraudulent drug claims or religious scams.

Faced with a growing number of regulatory bodies responsible for communication, Congress created the Federal Communications Commission in the Communications Act of 1934 to take over all communication regulatory activities of the U.S. government. The U.S. regulatory structure stayed largely unchanged until the passage of the Telecommunications Act of 1996.

By the time of the creation of the FCC the television pioneers Vladimir Zworykin (1889–1982) and Philo Taylor Farnsworth (1906–1971) had succeeded in designing and producing all-electronic televisions and television broadcasting was beginning. By the mid-1930s over a dozen stations were broadcasting within the United States. As with radio, the FCC regulated the licensing, power, and frequency of new broadcasters to limit or eliminate interference and ensure that airways were used in the public interest. Television began to grow rapidly in the 1950s and 1960s, quickly reaching a large majority of the public. In the United States satellite and cable television entered the market in the late1970s, but its development was largely unregulated after the Cable Communications Act of 1984 removed much of FCC jurisdiction over those industries.

Although the telegraph and the telephone were accessible by a wide range of the public, broadcast radio and television were limited to a few stations that could broadcast without interference. As a result of the limited nature of broadcasting, governments created various methods to ensure programming in the public interest. In the United Kingdom owners of television sets are required to pay a license fee for partial funding of the government-sponsored British Broadcasting Corporation. In the United States the FCC requires broadcast stations to meet public interest requirements as terms for receiving a broadcasting license. In 1967 the Public Broadcasting Act created public television and radio stations in the United States and partially excluded them from FCC regulation. However, the FCC did act to revoke the license of the Alabama Educational Television network in 1975 because of its racist programming and hiring practices.

From the creation of the Federal Radio Commission to 1987 the FCC enforced a regulatory principal known as the Fairness Doctrine, which holds that stations are obligated to seek out issues of public importance and present contrasting points of view. During the presidency of Ronald Reagan (1980–1988) the FCC began to deregulate all the industries in its jurisdiction. Court cases in 1987 held that the Fairness Doctrine was not required by an act of Congress, allowing the FCC to rescind the policy. Two related rules requiring equal time for targets of personal attacks or political editorials to respond were removed in 2000. Advocates of the change argued that the growth in media outlets negated the need for the doctrine; opponents argued that broadcasters would attempt to further specific political and/or economic agendas to the detriment of the public at large. The Fairness Doctrine was a prime example of regulation of communication that was intended to benefit the public by influencing the content of broadcasts.

Regulators also grappled with control of the limited means of production in the broadcast industry. In light of the limited number of voices that can be brought to air, the distribution of those voices is an important ethical question. A poignant example of the perceived power of broadcasting was the capitulation of broadcasting companies in 1950s to the blacklisting of performers, writers, and directors for alleged leftist political leanings by the organization aware. In that case regulators at the FCC took no action, as they would later do in cases of race or gender discrimination.

Regulators often have attempted to limit ownership of multiple media outlets by single companies to maintain diversity, seeking a balance between preserving independent ownership and allowing free competition. Advances in technology also have changed the availability of the broadcast spectrum by decreasing the amount of interference between nearby stations. At the beginning of the twenty-first century the FCC examined the viability of low-power television and radio stations that would serve small areas and determined that those neighborhood broadcasters did not pose a significant risk of interference with established stations. However, legislation to grant the FCC authority to license those stations has not gotten support from the U.S. Congress.

Internet, Convergence, and the Information Society

The last two decades of the twentieth century saw tremendous growth in a number of new telecommunications fields, especially the worldwide network of computers now known as the Internet. The potential movement of traditional telephone, radio, and television communication to the Internet is known as convergence. The technological underpinning of the Internet makes no distinction between data as the data travel. E-mail, pirated video, and Internet telephony all move equally and without distinction. Data can be identified only by destination or origin. The transformation of all types of data (writing, speech and audio, pictures and video) to computer-based digital data has profound implications for all previous systems: Anyone with access to the Internet can transfer text, audio, or video around the globe and can compete with or avoid traditional communication systems.

Regulation in the new media has been minimal for the most part, with China being a striking exception. The easy accessibility of information on the Internet has led to concerns about the content being provided. The Chinese government regularly blocks content from outside the country and exerts strong control of the information posted within the country. In the United States some have found the availability of pornography to be repugnant and have pushed for greater control over content. In 1996 that desire led to the Communications Decency Act, which created stiff penalties for the distribution of pornographic works to minors; however, the act was struck down by courts as a violation of First Amendment freedom of speech rights.

In light of the growing importance of the Internet, access has become a vitally important question. Disparities between rich and poor individuals and nations in computer access have created a digital divide that has implications for the future growth and equality of those groups.

Assessment

Communication regulation helps define the limits of freedom of speech. Regulators set limits on the content of communication for a variety of reasons, including the protection of personal or secret information, a desire to limit false and misleading claims, and the encouragement of debate. Communication may have negative consequences for individuals, groups, or entire societies. Lessening these harms, however, can require sacrifices in terms of the privacy, anonymity, and freedom of individuals. Modern regulatory agencies must balance the rights of the individual broadcaster with the interests of society as a whole.

Coupled with the regulation of communication content, regulatory agencies also try to control access to communication technologies. Some technologies have a limited capacity for public use, such as radio and over-the-air television. Thus, access to those means of communication is a unique benefit that government has seen fit to control. Other technologies may have limited access because of economic inequities or limits to the physical interconnection of communication networks. Here too regulatory agencies have interfered with the market to promote access to the widest possible set of consumers.

The great power of communications systems as a persuasive force makes these determinations of appropriate content and access disputed issues. Changes in these systems affect millions of consumers and billions of dollars of economic activity. Regulatory agencies sit at the center of political and ethical debate over the appropriate use of these rapidly evolving technologies.

COMMUNISM

The word Communism has been used in different senses by different authors, but from 1917 onward it was most readily associated with the type of political and economic system established in Russia and the other lands that became the Union of Soviet Socialist Republics (USSR). By the 1970s Communism in this sense of the term prevailed in Latvia, Lithuania, Estonia, and parts of Bessarabia, all of which were incorporated directly into the USSR, as well as in Mongolia, Poland, Hungary, Czechoslovakia, Bulgaria, Romania, Yugoslavia, Albania, East Germany, North Korea, China, Tibet, Cuba, Vietnam, Laos, and Cambodia. A number of other states, including Nicaragua, Granada, Afghanistan, Angola, Mozambique, and Ethiopia, were ruled by parties closely allied with the USSR, but whether they were full-fledged Communist states is open to debate. In addition, parties advocating the Soviet model of government formed in most other countries. These states and parties, although they used various names—workers, people's, democratic—were commonly referred to as Communist.

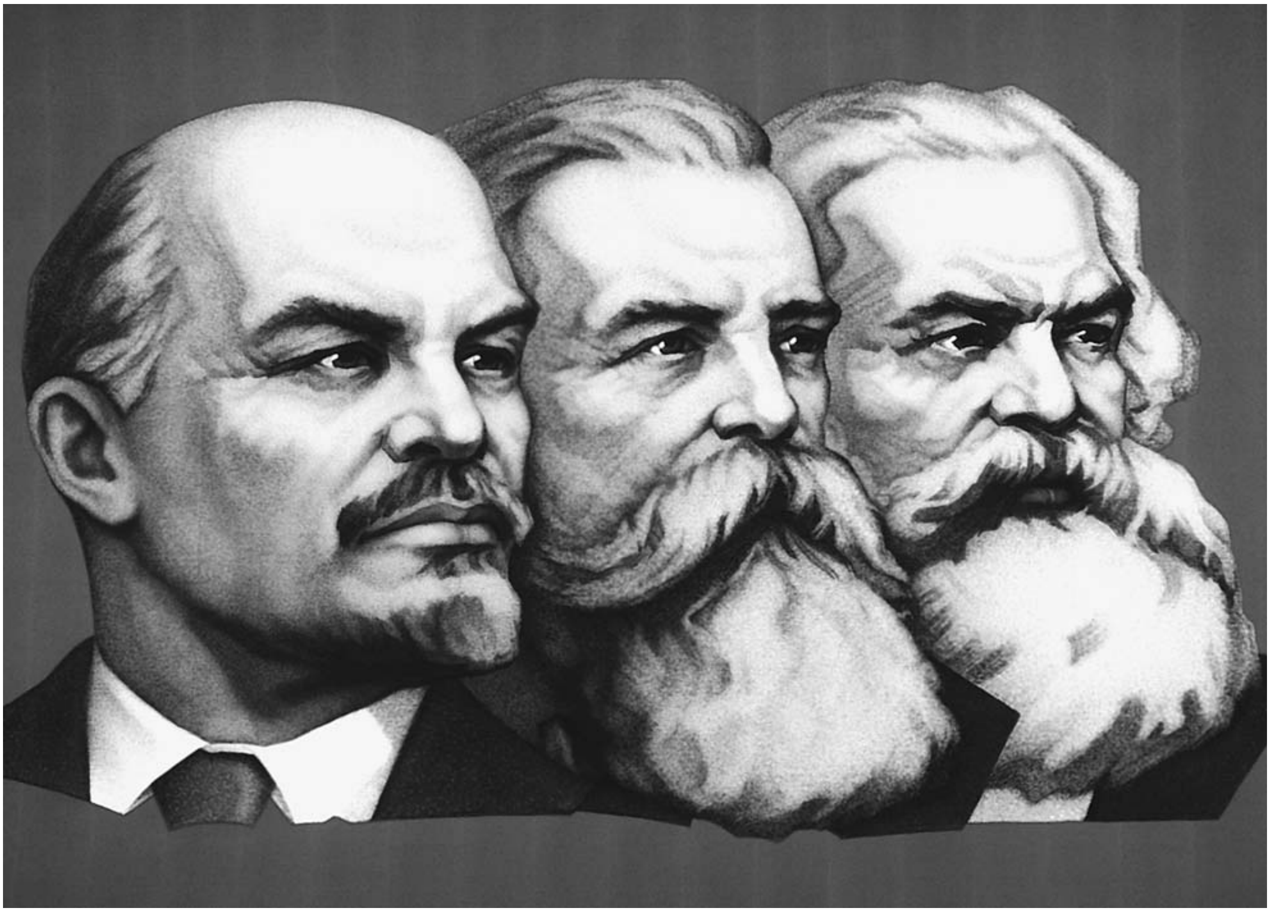
From its earliest period of development Communism made two important claims about its relation to science. The first was that it was itself a scientific theory. The second was that it put science and technology to greater benefit than any competitor political practice. Both claims were disputed by non-Communists.

Marxism-Leninism as Science

Although Communism was not alone among the various schools of socialism in tracing its roots to Marxism, Communists were the most emphatic in asserting the absolute validity of that doctrine. Under Vladimir I. Lenin (1870–1924), the founder of Communism, the scientific claims of Marxism were treated as undeniable dogma. Lenin wrote, "From the philosophy of Marxism, cast of one piece of steel, it is impossible to expunge a single basic premise, a single essential part, without deviating from objective truth, without falling into the arms of bourgeois-reactionary falsehood" (Lenin 1977, p. 326).

Lenin wrote these words years before he came to rule Russia. Once he took power, the dogmatic spirit they reflect was reinforced by the exigencies of revolutionary government. Lenin's party, first called Bolshevik and later Communist, was a small, elite group. In order to hold onto power its members saw they would have to suppress the opposition, and Lenin made no bones about this. Since he was confident that his party was the authentic representative of the proletariat, any opposition would inevitably reflect hostile class interests that deserved to be suppressed for the sake of human progress.

Thus did Lenin introduce the practice of silencing criticism or dissent. Under his heir, Joseph Stalin (1879–1953), and their disciples in other countries, such as China's Mao Zedong (1893–1976), Communism assiduously policed the expression of opinion, exacting draconian penalties against any deviation from party policy. All of this was accompanied by sweeping assertions of the scientific character of Marxist and Commu-



Banner depicting (left to right) Vladimir Lenin, Karl Marx, and Friedrich Engels. The three men can be thought of as the "fathers" of Communism. *(© Brian A. Vikander/Corbis.)*

nist doctrine, evidenced by the fact that almost any speech, book, essay, or paper required numerous citations from the texts of Marx, Engels, and Lenin. This semblance of scientific procedure was topped off by the claim that Communism was possessed of a unique form of philosophical reasoning called *dialectic* or *dialectical materialism* that somehow offered more penetrating insights than did conventional logic.

In the usage of Lenin and subsequent Communists, calling something science or scientific meant that something was true. To real scientists, the term has nearly the opposite meaning, connoting a search for truth in which all conclusions are provisional.

In the end even Communist leaders themselves acknowledged that the legacy they inherited was less one of science than dogma. In the USSR Mikhail Gorbachev, under the rubric *glasnost,* reversed the tradition initiated by Lenin and opened the way to freedom of speech. And in China Deng Xiaoping (1904–1997) sought to undo Mao's worship of doctrine, coining the slogan: "It does not matter if a cat is black or white as long as it catches mice."

If free inquiry and acceptance of the notion that all conclusions are subject to revision in the face of new evidence are the touchstones of science, then Communism presented an environment that was inimical to science. This went even a step further in China, where for a time Mao actively discouraged the reading of books and education other than practical training. Peasants, although harshly exploited in collective farms, were nonetheless held by Mao to be the repositories of revolutionary virtue, and urbanites that fell afoul of the regime were often exiled to the countryside to "learn from the peasants." During the Great Proletarian Cultural Revolution (1966–1977), schools were closed for years as teenagers were mobilized into perpetual street mobs in byzantine power struggles between rival party factions. All of this fierce anti-intellectualism, so at odds with traditional Chinese reverence for education, was justified as being egalitarian and antielitist. But such contempt for formal learning was also antiscientific.

Communist Achievements in Science and Technology

This is not to say that Communist societies were without their accomplishments in scientific fields. There were some, particularly in engineering and applied research. Great investments were made in military equipment and in other technologies such as space exploration that were part of a symbolic competition with the capitalist world. Moreover Communist regimes were disdainful or indifferent to *soft* fields of scholarship—the arts, humanities, and social sciences—so that the finest minds of these societies almost necessarily found their outlets in hard science or engineering.

In addition to discouraging free inquiry, Communist regimes sometimes intervened directly in scientific questions, most famously when Stalin directed Soviet biology to embrace the tenets of Trofim Denisovich Lysenko (1898–1976). Ironically, in light of Marx and Engels's belief that their theories were analogs to Darwin's, Lysenko was a Soviet scientist who dissented from a key tenet of Darwin's principle of natural selection. Lysenko believed that acquired, as opposed to inherited, traits could be passed on genetically. Because Stalin had a deep fondness for great projects of social engineering, the idea that one might alter life itself in this manner appealed greatly. For some years genetic research in the USSR was forced to devote itself to Lysenko's eventually discredited theories.

Through the concentration of material and human capital, Communist regimes competed effectively, albeit usually coming in second, in the fields of weaponry and space exploration. Sometimes what these endeavors lacked in fine-tuning they made up for in size—for example, less accurate missiles armed with larger warheads. Usually they competed a lot less well in technologies devoted to consumer goods. The lack of marketplace incentives to maintain or improve the quality of products, combined with the general dampening of innovation and the low priority given to economic planning involving consumer goods, resulted in a generally shoddy quality of merchandise. Popular discontent on this score was an important factor that eventually resulted in pressure for political change in China and the USSR.

The most singular episode in the history of technology under Communism was the Great Leap Forward (1957–1960), a program guided by Mao's conviction that a collective farm could produce industrial as well as agricultural goods and thereby become completely self-sufficient. In a fervent national campaign from which dissent was not tolerated, collectives began trying to produce industrial goods including that sine quo non of industry, steel. Mao announced that small *backyard* smelters could replace large steel mills. One of the many flaws in this theory was the absence of thought given to the question of material inputs for these smelters. Egged on and intimidated, peasants felt compelled to contribute not only scrap but whatever was available in existing tools and utensils, so that these might be melted down to make new steel. Little real steel was produced by this method, but many small tools and even cooking woks were sacrificed. Add to this the sacrifice of peasant labor diverted from the fields, and the result was a mass famine during the years 1959–1962 that most sinologists estimate took some 30 million or more lives.

Ethics: New Ends Justify Any Means

The large-scale loss of life under Communism in China, the USSR, and a few other places, notably Cambodia and North Korea, highlights the ethical issues raised by Communism. Although the facts of these cases were once hotly disputed, for the most part disputes ended when successor Communist rulers acknowledged the respective tragedies. That is, the deaths caused by Stalin's regime in the USSR were decried first by Nikita Khrushchev (1894–1971), then more fully by Gorbachev. The depredations of Pol Pot (1926–1998) were roundly denounced by the Communists who threw him out of power in Cambodia. And some of the carnage caused by Mao—that associated with the Great Proletarian Cultural Revolution—was recognized at least implicitly after Deng Xiaoping took the helm in China in 1978, although Mao was not directly blamed.

The needless deaths of large numbers of human beings would in itself seem to constitute a moral transgression of the highest order. And yet under Communism this was not deemed axiomatic. Communists asserted the moral standards that were traditional to Christianity (and in the East to Confucianism or other longstanding codes) were themselves expressive of the domination of the wealthy classes. As Lenin put it: "People always have been the foolish victims of deception and self-deception in politics, and they always will be until they have learned to seek out the *interests* of some class or other behind all moral, religious, political and social phrases, declarations and promises." (Lenin 1969).

Mao Zedong waves to the cheering crowd at Tiananmen Square in Beijing as they celebrate May Day, 1967. Mao was influenced by the writings of Marx and Lenin, but was also inescapably a Chinese nationalist. He believed that the communist revolution in China was distinct from all others because of the weight of its history and culture. *(Getty Images.)*

Therefore the proletariat would embody its own ethical standards. And these would be closely tied to the fulfillment of its mission to overthrow capitalism and usher in a new historical age. Communism would provide a fulfilling life for all people, and since society would no longer be divided by classes, it would make possible for the first time the emergence of truly universal moral principles.

Since so much is at stake in the triumph of the socialist revolution—nothing short of the achievement of humankind's ultimate destiny—everything must be put at the service of this goal. As Lenin wrote:

> "Our morality is entirely subordinated to the interests of the proletariat's class struggle. When people tell us about morality, we say: to a Communist all morality lies in conscious mass struggle against the exploiters. We do not believe in an eternal morality Communist morality is based on the struggle for the consolidation and completion of communism." (Lenin 1968).

In taking this approach, Lenin rested on a strong but nonetheless ambiguous tenet in Marxist theory. Marx and Engels asserted that all ideas spring from class roots, which suggests that no objective ethical standards exist. Yet their condemnation of capitalism drew its power from its implied moral terms. Marx and Engels often claimed that they had done no more than lay bare the laws of history, showing that capitalism was destined to be replaced by socialism. But if so, there was no reason to work for the advancement of socialism. In practice Marx and Engels worked with all the energy they could muster. They were as much activists as philosophers, and the only explanation for this, even if implicit, was that socialism was not only inevitable but also highly desirable—which implies some standard of good and bad.

At the same time, Marx also proclaimed that "Communism is the riddle of history solved." If indeed this is the case, then it is hard to take exception to Lenin's very instrumental approach to ethics, for nothing else could possibly take priority. The achievement of Communism would be the measure of all things.

A companion aspect of the view that all else must be subordinated to the fulfillment of the destiny of humankind as a whole is that any given individual's well being might be subordinated to this higher, collective good. As explained by Aleksandr F. Shishkin, author of the leading Soviet text on ethics, Communist morality teaches the individual "not to look upon himself as an end in himself." Rather "the new society cultivates the individual in such fashion as to cause him to see the fullness of human existence to lie in struggle for a common cause and to be able to resolve in favor of society any contradiction arising between the needs of society and his personal ambition" (Shishkin 1978, p. 88).

COMMUNITARIANISM

Communitarianism is part of the neo romantic reaction to rationalism. It emphasizes moral and social values and the societal institutions that support them, especially community and its traditions, passions and beliefs, religion, and the habits of the heart. Communitarianism is not blind to facts and logic, the cool calculations of the rational mind, or the importance of science, technology, and economic progress. Nevertheless, it is concerned that such perspectives may override, if not ignore, other *human* considerations, to which communitarianism is attentive. For the same reasons, communitarianism seeks to balance concern for individual rights and liberty with concerns for the common good and community.

Definition and History

The term *communitarian* was first introduced in 1841, to mean "of, pertaining to, or characteristic of a community or communistic system; communitive." It was infrequently employed from then until the mid-twentieth century.

Several critics have argued that the concept of the community is of questionable value because it is so ill-defined. In *The Myth of Community Studies*, Margaret Stacey (1974) argues that the solution to this problem is to avoid the term altogether. In the same publication, Colin Bell and Howard Newby similarly point out, "There has never been a theory of community, nor even a satisfactory definition of what community is" (p. xliii).

Amitai Etzioni (1996) has nevertheless argued that community can be defined with reasonable precision. Community has two characteristics: first, a web of affect-laden relationships among a group of individuals, relationships that often crisscross and reinforce one another (as opposed to one-on-one relationships); and second, a measure of commitment to a set of shared history and identity—in short, a particular culture. David E. Pearson stated, "To earn the appellation 'community,' it seems to me, groups must be able to exert moral suasion and extract a measure of compliance from their members. That is, communities are necessarily, indeed by definition, coercive as well as moral, threatening their members with the stick of sanctions if they stray, offering them the carrot of certainty and stability if they don't" (Pearson 1995, p. 47)

Among early sociologists whose work is focused on communitarian issues (though they did not draw on the term) are Ferdinand Tönnies (1855–1936), especially his comparison of the *Gemeinschaft* and *Gessellschaft*; Emile Durkheim (1858–1917), particularly his studies of the socially integrating role of values and the relations between the society and the person; and George Herbert Mead (1863–1931) in his work on the self. Other early relevant sociological works are those of Robert E. Park, William Kornhauser, and Robert Nisbet.

While the term *communitarian* was coined in the mid-nineteenth century, ideas that are essentially communitarian appear much earlier. They are found in the Old and New Testaments, Catholic theology (for example, the emphasis on the Church as a community), more recently in socialist doctrine (for example, writing about early communes and workers' solidarity), and finally *subsidiarity*—the principle that the lowest level of authority capable of addressing an issue is the one best able to handle it. In essence, moral judgments are best made at the community level rather than from the higher governing bodies.

Balancing Liberty with the Common Good

In the 1980s, communitarianism was largely advanced by political theorists Charles Taylor, Michael Sandel, and Michael Walzer. They criticized liberalism for overlooking that people can have a strong attachment to their societies. They lamented liberalism's focus on individualistic self-interest.

Since that time, two main forms of communitarianism have emerged. Authoritarian communitarians, who typically concern themselves with Asian culture, argue that to maintain social harmony, individual rights and political liberties must be curtailed. Some emphasize the importance of the state to maintain social order (for instance, leaders and champions of the regimes in Singapore and Malaysia), and some focus on strong social bonds, morality, and traditional culture (as in Japan). Some Asian communitarians also hold that the West's notion of liberty actually amounts to anarchy, that strong economic growth requires limiting freedoms, and that the West uses its idea of legal and political rights to chastise other cultures.

In 1990 a new school of communitarianism developed. Among its leading scholars are political theorist William A. Galston, legal scholar Mary Ann Glendon, political scientist Thomas Spragens, Jr., writer Alan Ehrenhalt, and sociologists Philip Selznick, Robert Bellah and his associates, and Amitai Etzioni. The work of these authors laid the foundations in 1990 for the second form of communitarianism: responsive (democratic) communitarianism.

Responsive communitarianism assumes that societies have multiple and not wholly compatible needs, in contrast to philosophies built on one core principle, such as liberty. In communities, there is an irrepressible tension between exclusion and inclusion, and between civility and piety. Thus community is not a restful idea, a realm of peace and harmony. On the contrary, community members must recognize and deal with competing principles. Responsive communitarianism assumes that a good society is based on a balance between liberty and social order, and between particularistic (communal) and society-wide values and bonds. This school stresses the responsibilities that people have to their families, kin, communities, and societies. These exist above and beyond the universal rights that all individuals command, which is the main focus of liberalism.

While a carefully crafted balance between liberty and social order defines a generic concept of the good society, communitarians point out that the historical-social conditions of specific societies determine the rather different ways that a given society in a given era may need to change to attain the same balance. Thus, contemporary Japan requires much greater tolerance for individual rights, while in the American society excessive individualism needs to be curbed.

To achieve this balance, unlike laissez faire conservatives and welfare liberals who differ mainly with regard to the respective roles of the private sector and that of the state, communitarians are especially concerned with the third sector, that of civil society. They pay special attention to the ways that informal communal processes of persuasion and peer pressure foster social responsibilities for the common good.

Communitarians are also concerned with the relationship between the self and the community. Political theorists depict the self as "embedded," implying that the self is constrained by the community. Responsive communitarians stress that individuals who are well integrated into communities are better able to reason and act in responsible ways than are isolated individuals, but if social pressure to conform rises to high levels, it will undermine the individual self and therefore disrupt the balance.

This issue is reflected in questions that arise when associations of scientists and professions such as engineering address ethical and policy issues relevant to their work. Should the decisions involved, say whether or not to proceed with human cloning, be made by each scientist or by their informal communities or associations? And what role, if any, should the public and its elected representatives have in making these decisions? Closely related are similar questions such as to how to deal—and above all, who should deal—with instances of fraud in research, misappropriation of funds, and violations of security.

Communitarianism's Critics

Critics generally suggest that those who long for communities ignore the darker side of traditional communities. "In the new communitarian appeal to tradition, communities of 'mutual aid and memory,'" writes Linda McClain (1994), "there is a problematic inattention to the less attractive, unjust features of tradition" (p. 1029). Amy Gutmann (1985) pointedly remarks that communitarians "want us to live in Salem" (p. 319), a community of strong shared values that went so far as to accuse nonconformist members of witchcraft during the seventeenth century.

Communitarians counter that behind many of these criticisms lies an image of old, or total, communities, that are neither typical of modern society nor necessary for, or even compatible with, a communitarian society. Old communities (traditional villages) were geographically bounded and the only communities of which people were members. In effect, other than escaping into no-man's-land, often bandit territories, individuals had few opportunities for choosing their social attachments. In short, old communities had monopolistic power over their members.

New communities are often limited in scope and reach. Members of one residential community are often also members of other communities, for example work, ethnic, or religious ones. As a result, community members have multiple sources of attachments; if one community threatens to become overwhelming, individuals will tend to pull back and turn to another for their attachments. Thus, for example, if a person finds herself under high moral pressure at work to contribute to the United Way, to give blood, or to serve at a soup kitchen for the homeless, and these are lines of action she is not keen to follow, she may end up investing more of her energy in other communities—her writers' group, for instance, or her church. This multi-community membership protects the individuals from both moral oppression and ostracism.

Another criticism is that communities are authoritarian. Derek Phillips (1993), for instance, remarks, "[C]ommunitarian thinking … obliterates individual autonomy entirely and dissolves the self into whatever roles are imposed by one's position in society" (p. 183). As the political scientist Robert Booth Fowler (1991) puts it, critics "see talk of community as interfering with the necessary breaking down of dominant forces and cultures" (p. 142). Some critics mean by this that communities are totalistic, a point already covered. Others mean that they are dominated by power elites or have one group that forces others to abide by the values of those in power.

Communitarians find that this criticism has merit but is misdirected. There are communities both past and present that have been or still are authoritarian. The medieval phrase *Stadt Luft macht frei* ("the air of the cities frees") captures what the farmers of traditional villages must have felt when they first moved into cities at the beginning of the industrial era. (Poor working conditions and slums aside, being away from the stricter social codes of their families and villages seems to have given them a sense of freedom, which in some cases led to anarchic behavior.) Totalitarian communities exist in contemporary societies, such as North Korea. However, most contemporary communities, especially in communitarian societies, are not authoritarian even when they are defined by geography. Also, the relative ease of mobility means that people often choose which community to join and within which to live. Agnostics will not move into a Hasidic community in Brooklyn, and prejudiced whites will not move into a neighborhood dominated by the Nation of Islam.

Science and technology help open up societies and they promote relatively empirical, rational approaches to the world. New communications technologies, such as the Internet and satellite dishes, help undermine authoritarian regimes. However, no one should assume that on their own, these devices are capable of delivering a truly democratic state—especially when such technological advances are not accompanied by a proper change in values, as has been seen in Russia, Singapore, and China in the early twenty-first century.

Contemporary Issues

Communitarians have developed several specific concepts and policies that draw on their philosophy. They favor shoring up families, not traditional-authoritarian ones but peer marriages (in which mothers and fathers have equal rights and responsibilities). They fostered schools that provide character education rather than merely teach, but avoid religious indoctrinization. They developed notions of community justice, in which offenders, victims, and members of the community work together to find appropriate punishments and meaningful reconciliation. Communitarians favored devolution of state power, and the formation of communities of communities (within national societies and among nations), among many other policies.

Following the growing popularity of the concept of civic society, Etzioni (1999) argues that contemporary civic society is insufficient because it tends to be morally neutral on all matters other than the attributes that citizens need to make themselves into effective members of a civic society, for instance, the ability to think critically. In contrast, a good society seeks to promote a core of substantive values, and thus views some voluntary associations and social activities as more virtuous than others.

In the same vein, communitarians argue that while everyone's right to free speech should be respected, some speech—seen from the community's viewpoint is morally highly offensive and when children are exposed, damaging. For instance, the (legal) right to speak does not render verbal expressions of hate (morally) right.

Science has long been associated with rational thinking and in turn with secularism. Indeed, historically, science has often been considered antithetical to religion. However, communitarians are concerned with the moral fabric of society and they find religion one source of moral values. A communitarian may prefer to divide the issues people face among those that are subject to rational or scientific analysis and those that belong to a different sphere, reserved for belief. These include questions such as is there a god, why people are cast in this world born to die, what people owe their children and members of their community, among others.

Closely related is the question of a proper balance between the two *sectors*. Since the enlightenment, the sector of rationality (and within it science and technology) has increased dramatically in western societies. Communitarians ask whether in the process resources and time dedicated to the family, social and public life, culture, and spiritual and religious activities have been neglected.

While sociologists made numerous contributions to altered communitarian thinking, in turn communitarian philosophy has challenged sociology to face issues raised by cross-cultural moral judgments. Sociologists tend to treat all values as conceptually equal; thus, sociologists refer to racist Nazi beliefs and those of free societies by the same "neutral" term, calling both *values*. Communitarians instead use the term *virtue* to indicate that some values have a high moral standing because they are compatible with the good society, while other values are not and hence they are "aberrant" rather than virtuous.

COMMUNITY

Community is a term with widely varying historical and current meanings in both specialized and everyday discourse. It also possesses several dimensions—ethical, political, social, ontological, psychological, and epistemological—many of which are relevant to discussions of science and technology.

Theorists generally consider community to be a good that, carried too far, may undermine its own moral and political values for those both within and outside it. Community is an important source of meaning in human lives, and it encompasses the sets of values, beliefs, and interpretative frameworks by which the world takes on meaning. Indeed, the scientific and technological enterprise is often described as dependent on the special values of a scientific or technical community (Merton 1942). Community, however, may also manifest itself in oppressive political forms that defy universal values, shared rights, or basic forms of well-being of certain members of a society in the name of community. Political forms of community such as nationalism or populist fascism, or Thomas Hobbes's or Jean-Jacques Rousseau's different versions of collective identity, may belie other human values such as individual liberty. Members of the scientific community have also sometimes ignored the rights of nonscientists or the larger social orders of which science is a part.

At a minimum, community is a set of shared goals or values perceived as good by those who participate in their formation or by those who belong to the heritage these shared values define. A qualitative sense of belonging therefore attends community, and a broader notion of community also includes common language, rituals, geographical territory, religion, historical memory, and ethnic identification.

Community versus Society

In 1887 the German sociologist Ferdinand Tönnies developed the distinction between community and society in terms of the informal, moral, familial bonds of traditional communal life and the formalized and impersonal, amoral, juridical, and administrative relations of industrial society. "Community" was taken to have an organic quality, whereas society was mechanistic in nature. The importance of this distinction relates to the sense of belonging in social relations and has applications for notions of citizenship, the legitimacy of political representation, ideas of the common good, and the meaning of public participation. "Society" corresponds to the "neutral" structural conditions of modern life. For better or worse, Tönnies's distinction has served to circumscribe much of the sociological, political, and moral meaning of community to this day. In contemporary political thought, for example, the distinction is manifested in terms of holistic communitarianism versus individualistic liberalism. While complex, these latter terms highlight the relative importance of participation in political life, whether the good is best articulated collectively or individually, and the extent to which institutions should choose between a fully embodied moral community and a minimally protective framework for individual liberties.

If one assumes that shared values and frameworks of belief are paramount in the legitimate governance of societies, Tönnies's distinction between community and society has also influenced modern science and technology in important ways. Twentieth-century critics of technology as varied as Martin Heidegger, Herbert Marcuse, Jacques Ellul, Ivan Illich, and early Jürgen Habermas maintain that the intrinsic qualities of communal life were slowly eroded by a postindustrial society of "technoscientific," instrumental emphasis on values of use and efficiency. Langdon Winner (1986) further argues that technological choices determine broader social and administrative structures and reframe the conditions of moral and political life, even though these choices remain beyond the scope of communities. In such views, modern society is an "organizational" society in which rationalizing "technoscientific" approaches to social organization root out the affective (emotional) characteristics of sociality and the bonds of community that Tönnies and others ascribe to community. Expert management replaces participation and communal frameworks of value as the main force of modern social and value formation. If moral value is rooted in community, then technical social management entails institutions that express a small set of values disguised as socially neutral instruments. Others argue, more specifically, that the global spread of modern technologies has served to destroy traditional cultures, communities, and economies and to undermine modern values such as sustainability (see, for example, Helena Norberg-Hodge's studies of Ladakh [1991]).

Scientific and Democratic Community

In contrast, John Dewey (1954 [1927]) and others argue that technological society, especially through new communications technologies, harbors the potential to revive local community. Similarly, Thomas C. Hilde (2004) suggests that the integration of modern technologies and science into the global formation of norms presents not only risks to traditional notions of community but also new possibilities. For Hilde this framework constitutes an "epistemic cosmopolitanism" capable of facilitating new forms of community.

The scientific sense of communal inquiry and of the production of knowledge is further developed by Peter M. Haas (1990) and others as "epistemic community." Epistemic communities are, according to Haas, scientists and others united by both causal explanations (of, for example, ecological damage) and shared values regarding which policies should emerge from scientific evidence.

If scientific inquiry always harbors the preferences of a broader community and social organization in which scientists work (Kuhn 1962, Longino 2002, Harding 1998), then the currently dominant utilitarian values enframe the broader technological/scientific project. This, in turn, constricts the range of values embodied in technical decisions that influence the shape of society and its future policy outcomes. If this basic thesis regarding the importation of value is correct, then both community and scientific inquiry merit further discernment of beneficial preferences from damaging ones, and in such cases deliberation may be better sought through the broader community. Scientific inquiry might then better serve to advance not only the knowledge of the broader community, but also its methods of inquiry.

COMPLEMENTARY AND ALTERNATIVE MEDICINE

The term *alternative medicine* refers to therapies and diagnostic procedures that are used instead of those of conventional medicine, whereas *complementary medicine* refers to therapies and diagnostic procedures that are used in addition to those of conventional medicine. The same therapy can be alternative or complementary, depending on its use. For example, a dietary program for treating cancer sometimes is used as a complement to surgery but also may be employed as an alternative to chemotherapy. The term *complementary and alternative medicine* (CAM) is a standard way of referring to both, whereas *integrative medicine* refers to medical practices that bring together conventional medicine and CAM. *Experimental medicine* refers to therapies, usually drugs, that are undergoing testing for regulatory approval.

Classification of CAM

The National Center for Complementary and Alternative Medicine (2003) of the U.S. National Institutes of Health classifies CAM into the following subcategories: alternative medical systems such as Chinese medicine and naturopathic (a type of nutritional and dietary) medicine; mind-body interventions that are not mainstream, such as prayer, meditation, and mental healing; biologically based therapies such as dietary supplements and herbs (one also would include here immunological therapies that are not in clinical trials); manipulative therapies such as chiropractic; and therapies based on electromagnetic energy or forms of energy that are not accepted by contemporary science.

Applying Bioethics Principles

Most of the literature on medical ethics and CAM is based on the mainstream bioethical principles of beneficence (guiding and helping a patient), nonmaleficence (avoiding harmful and futile treatments), autonomy (protecting a patient's informed consent to choose treatments), and justice (fairness in terms of the right of access). There have been attempts to introduce other principles that are relevant to CAM (Guinn 2001), but the vast majority of the discussions take place in the context of conventional bioethical principles (Sugarman and Burk 1998). Furthermore, most ethics discussions related to CAM focus on the relationship between the health-care provider and the patient. The principle of justice gets much less attention.

Patients' use of CAM therapies has grown since the 1980s, and in the United States CAM increasingly is offered through licensed alternative professions such as naturopathy, chiropractic, and acupuncture/Chinese medicine. Other countries also provide legal recognition of various types of CAM providers. In the United States the Federation of State Medical Boards (2002) developed guidelines for physicians who use CAM or work with licensed CAM providers. The statement outlines three types of possible harm from CAM: economic harm from spending money on futile therapies, indirect harm caused by avoiding efficacious conventional therapies or having hopes raised falsely, and direct harm caused by negative side effects of CAM therapies. The statement also specifies four ethically relevant categories of CAM: documented as effective and safe, documented as effective but with side effects and risk, inadequately studied but safe, and ineffective and dangerous. The federation suggests that physicians recommend CAM treatment when there is a favorable risk-benefit ratio, a favorable expected outcome, and a greater benefit with CAM than with no treatment. Under those conditions physicians should not lose their licenses for recommending CAM and should respect a patient's right to choose CAM (the principle of autonomy).

The guidelines provide some help in answering two of the most frequently discussed ethical issues regarding CAM: obligation to inform and obligation to treat. Is a physician obligated to inform a patient of an available CAM option? Failure to do so for conventional therapies generally is considered a violation of informed consent, and this principle is being extended to CAM therapies, but only if they meet fairly high standards for efficacy and/or safety. Is a physician obligated to treat a patient if the patient has full informed consent with regard to the risk-benefit ratio yet opts instead for a CAM therapy that the physician considers dangerous? Here there is a conflict between the principles of beneficence (the physician's assumed superior knowledge) and maleficence (the purported danger of the CAM therapy) and the principle of autonomy (the patient's right to choose). Frequently in this situation physicians will refuse additional treatment or comanagement of the case. In addition to their ethical defense based on concern for the patient's well-being physicians may cite their personal risk of malpractice litigation or loss of license (Studdert et al. 1998).

The guidelines represent a significant shift from older medical approaches to CAM, which dismissed it as quackery and considered recommendations to consider CAM therapies to be unethical. However, ethical ambiguities and questions remain.

First, frequently patients opt to receive a CAM therapy from a nonlicensed provider, such as a noninvasive spiritual or mind-body therapy that often is associated with a patient's religious belief in shamanism, spiritualism, or evangelical faith healing. How should physicians or CAM professionals answer questions about healing services offered by religious groups or other nonlicensed providers? Should absence of indirect and direct harm suffice to warrant discussions or even referrals?

A second ambiguity is the question of what constitutes adequate evidence for evaluations of safety and efficacy. In contemporary medical science evidence usually is organized in a hierarchy of credibility. At the top is the gold standard: the controlled clinical trial. In this form of research patients are divided on a random basis into two or more groups, one with the test therapy (in this case a CAM therapy) and others with placebos or conventional therapies. The following alternative methods often are viewed in a descending order of evidential value: a retrospective form of data analysis that takes existing cases, such as patients who used a CAM therapy, and compares them with a control group; the best case series, which shows promising results in a series of patients but lacks a statistical analysis with a comparison group; subclinical research such as experiments that test CAM substances on animals or cell cultures; and a lower level of subclinical research that provides biochemical analyses of a CAM substance (such as an herb) to determine if it has any known pharmacologically active agents. A significant debate has emerged regarding the value of clinical trials versus other methods for the evaluation of CAM (Hess 1999).

Most CAM therapies lack a body of consistent clinical trials with supporting evidence at the other levels. If the evidence were complete, consistent, and highly positive, the therapy probably would be considered conventional, not CAM. As a result both conventional and CAM providers face the dilemma of making recommendations in the absence of complete evidence. In many cases there is only some, often mixed, evidence for efficacy, but there is a long record of use with few or no risks, side effects, or negative interactions with other therapies. In such cases physicians who practice integrative medicine sometimes will add CAM therapies, but only as a complementary modality.

To understand some of the complexities one can consider the case of a patient whose tumor has metastasized, or spread, to other organs. Surgery was only partially successful, and the oncologist recommends additional chemotherapy. The chemotherapy for this tumor type has serious side effects and is not curative; it prolongs life for a few weeks or months at the cost of highly reduced quality of life. There are some CAM treatments with claims of long-term survival, but those treatments are expensive. There have not been clinical trials yet, but there are a few case study series that show impressive remissions, and there is a good biological rationale with some supportive subclinical data. If the patient opts for the alternative therapy instead of chemotherapy, is the oncologist's decision to abandon the patient ethically justified?

Justice Issues

A broader set of ethical issues involves the principle of justice. Conventional providers often place the responsibility for gathering evidence with CAM providers. They argue that it is unethical for CAM providers to offer therapies to patients without providing adequate evidence in support of their claims of therapeutic benefit; that CAM providers should enroll patients in clinical trials or other forms of clinical evaluation; that by failing to do so those providers put personal gain ahead of potential economic, indirect, or direct harm to patients; and that it would be legitimate for the government and medical associations to close down such providers.

From the CAM perspective the same argument applies in reverse. CAM practitioners charge that the pharmaceutical industry and the members of many medical specialties are economically threatened by the potential of alternative (rather than complementary) therapies. For example, if chelation therapy (the use of mineral ions to remove cardiovascular blockages) and dietary/lifestyle programs were to replace bypass surgery, hospitals and surgeons would lose revenue. Similarly, if dietary programs were to replace chemotherapy as follow-up to surgery for solid tumors, oncologists and pharmaceutical companies also would lose money. Consequently, by failing to investigate promising CAM therapies developed by credentialed researchers or clinicians, the medical profession and affiliated industries put their own financial gain ahead of potential benefits to patients.

CAM advocates argue that the lack of ethics lies not in their failure to provide extensive positive evidence but in the long history of suppression of CAM research and therapies. They argue that clinical trials are very expensive and that their applications for research support go unfunded. Even worse, applications for research support often trigger investigations that lead to the loss of licenses or clinic closures. CAM advocates further argue that in the few cases in which public pressure has led to government-supported clinical trials (e.g., laetrile, hydrazine sulfate, and vitamin C) studies of CAM by conventional researchers have been weakened by exclusion of CAM advocates from research teams, protocol modifications that introduce biases against CAM, biased interpretation of equivocal data, and follow-up media campaigns intended to discredit CAM.

Historical research has documented suppression of CAM research and therapies (Hess 1997, Moss 1996, Richards 1981). Researchers and clinicians who have attempted to investigate CAM have faced denial of

U.S. Food and Drug Administration (FDA) investigational drug permits, dismissal from universities or other organizations, bias and blockage of publication in peer-reviewed journals, media campaigns against CAM, and loss of funding. Clinicians who use alternative therapies, particularly for cancer, have faced restraining orders, raids on clinics, warnings and denial of drug permits from the FDA, hostile tax audits, revocation of licenses and hospital privileges, and criminal charges (fraud, manslaughter, etc.) and civil lawsuits by CAM opponents.

Where cases have ended up in court, in some cases the rulings have favored CAM practitioners and in other cases the medical profession and state. Whether the historical cases represent unethical suppression of potentially beneficial therapies or an ethically legitimate watchdog function of the medical profession and state depends on one's assessment of the potential of CAM. If CAM is viewed as largely the product of quacks who want to make money from suffering patients, an ethical public policy would emphasize paternalism (protection from maleficence), suppress those alternatives, and limit the range of therapeutic options available to patients. If the promise of CAM is viewed in a more favorable light, an ethical public policy would emphasize autonomy, favor a more tolerant approach to alternatives, and increase both research funding and clinical access for CAM.

To some extent the older patterns of suppression have subsided as the medical profession has called for limited acceptance of CAM on the basis of evidence. However, although surveys continue to document high levels of patient utilization, federal government funding for CAM research amounts to less than 1 percent of funding for conventional medicine. Furthermore, the pattern of integration tends to favor complementary usage of CAM over alternative usage (Hess 2002). For example, in cancer research nutritional programs are being incorporated as complements to conventional therapies rather than as alternatives to them.

Does CAM offer the possibility of more than complementary, palliative care for chronic disease? Does it offer the potential for less toxic, less expensive, and more efficacious alternative therapies for a significant range of chronic diseases? Although the framework of evidence-based medicine can answer those questions, the lack of funding and the channeling of existing funding toward complementary therapies suggest that the answer will be deferred for many years.

COMPLEXITY AND CHAOS

Complexity and chaos are intuitive notions not easily rendered into formal definitions, and yet they have become increasingly important to both science and technology—and thereby to ethics. One useful way to approach complexity is through the analysis of dynamic systems.

Dynamic or changing systems are of two types: those in which knowledge of current states enables the prediction of future states, and those in which knowledge of current states does not enable the prediction of future states. In general ethics has attributed the first type of system to the world (because this appears to reflect a large part of reality, and in the absence of such a system it would be hard to hold human beings responsible for the consequences of their actions), and the second type to human beings (again because this appears confirmed by some aspects of human behavior, and without it humans could not be held accountable for voluntarily choosing to perform one action rather than another). Only since the last third of the twentieth century has scientific understanding of dynamic systems been advanced enough to explain the intellectual framework behind these two attributions.

Linear Dynamics and Its Limits

In the wake of the scientific revolution of the sixteenth and seventeenth centuries, science projected that all natural phenomena, including human actions, could be fully explained with the same logic used to predict planetary motion. According to this view, events are fully explained only when their occurrence is inferred from a covering law together with initial condition statements. The following assumptions framed this approach to explanation: (a) All phenomena are essentially atemporal or, in the case of near-equilibrium thermodynamics, independent of their history; that is, only the future, not the past, is packed into the present; (b) All phenomena are linear, that is, similar causes, under similar conditions, always produce similar results; and (c) Wholes are epiphenomenal by-products no different from aggregates and can therefore be functionally decomposed into their component parts. Insofar as these assumptions hold, all phenomena were taken to be reducible and decomposable in a way that made them tractable to deductive explanation, and thus predictable. For many centuries, in short, a deterministic, clockwork universe served as the ontological underpinning for Western epistemology and ethics.

Because free will is commonly viewed as a precondition of normative behavior (if everything is fully determined and predictable, responsibility and agency go by the board), a mechanistic worldview makes it necessary either to conclude that human beings are as determined as the rest of the universe (which yielded Calvinist ethics as its axiological counterpart), or to imagine free will as a nonnatural faculty itself uncaused but with the ability to exercise causal power (a view espoused by Immanuel Kant). For ascriptions of moral responsibility to be possible, behavior must be voluntary and caused or controlled by a *meaningful* intention, reason, or purpose (and not just triggered by a forceful Newtonian cause). Postulating free will as a nonnatural trait in human beings allowed theorists to account for the philosophical concepts of moral value and responsibility. Grounding moral responsibility on an uncaused act of will is, however, as problematic a tactic for ethical theory as the determinism it was supposed to correct: If intentions are caused by external events, then they are not freely formed; if intentions just pop into existence for no reason whatsoever, ascriptions of moral responsibility are as arbitrary as their causal origins. In any case, according to the received worldview (and paralleling the received logic of explanation), moral education consists in learning a set of universal moral principles and then exercising free will to implement the specific normative prescriptions that follow from those principles in particular circumstances.

In the nineteenth century, the mechanistic framework was challenged by the appearance of two new scientific theories: thermodynamics and evolution. Unlike the time-reversible equations of Newtonian mechanics, the second law of thermodynamics postulates an arrow of time. For near-equilibrium thermodynamics, usable energy decreases inexorably over time, a death march that will ultimately end in a state characterized by a complete lack of energy potential. Since usable energy is associated with order, and unusable energy is associated with disorder, Victorians worried about the ethical implications of thermodynamics.

Charles Darwin's theory of evolution, by contrast, appeared to identify the mechanism responsible for the increasing complexity and order characteristic of ontogeny and phylogeny. Nineteenth-century moralists did not quite know what to make of Darwin's ideas. On one hand, they were welcomed because the sequence of creation described by Genesis—from simple organisms to the most complex human beings—seemed to find support in the trajectory of evolution. On the other, his ideas were uncomfortable insofar as evolution suggested that nature was *red in tooth and claw,* removed altruism and agape from the natural realm, and called into question the origin and ontological status of the human mind and soul. Finally, because of the role of random mutations in evolution, its trajectory was shown not to be predictable and determinable, even in principle, an obstacle that made Darwin (who subscribed to the deductive logic of explanation) doubt that evolution was even explicable.

Attempts to force evolution (and biology in general) to fit the mechanistic view met with failure time and again; it became clear that organisms are not clockwork-like. Because complex systems (including biological organisms) are described by second order, nonlinear differential equations that are not formally solvable, they were for centuries considered intractable.

Nonlinear Dynamics and Its Achievements

The advent of computer simulation changed all this. Computer simulation research during the last quarter of the twentieth century demonstrated that turbulent flow and other seemingly *chaotic* processes in fact exhibit a very sophisticated form of order that is nevertheless unpredictable in detail. In the early 1960s, Edward Lorenz of the Massachusetts Institute of Technology (MIT) discovered the underlying mechanism responsible for deterministic chaos. Working with meteorological models, Lorenz showed that systems with only a few variables, even though deterministic, display highly complex behavior that is unpredictable in fact because slight differences in one variable produce dramatic effects on the overall system. This feature of complex and chaotic systems has come to be called *sensitivity to initial conditions*.

In 1977 the Russian-born Belgian scientist Ilya Prigogine received the Nobel Prize in chemistry for his formulation of the theory of *dissipative structures*, whose fundamental insight is that nonequilibrium is a source of order and complexity. Prigogine demonstrated that open systems (which include organisms) that exchange matter and energy with their environments can show a reduction of local or internal entropy; that is, they are able to self-organize and complexify. Complex systems are dynamical systems whose cooperating and interacting parts display spontaneous, self-organized pattern formation with emergent properties that are not reducible to the sum of their constituent parts. Early-twenty-first-century proponents of a complex dynamical systems approach to the mind (Scott Kelso, Francisco Varela) maintain that mental and axiological properties are high-level dynamical neurological patterns.

For a dynamical system to show structure formation, the process must take place far from equilibrium; it must be nonlinear; and the system must be open to exchanges with its environment. Nonlinearity appears whenever there is interaction among components, whenever the *organizational relationships* among parts determine the overall systemic behavior. Such nonlinear dynamical systems are typically characterized by feedback loops that embed the systems in their environment and history in such a way that their trajectory history is inscribed in their very structure. Thus the dynamical systems become deeply contextual and extremely sensitive to initial conditions. After a few iterations, the trajectory of two initially close nonlinear dynamical systems will diverge exponentially, and long-term predictions become impossible.

Phenomenologically, however, it was evident that some systems eventually settle down to an oscillatory pattern. Others, such as the Belousov-Zhabotinsky reaction (B-Z reaction), trace complexly patterned trajectories. Yet others, such as turbulent flow, become chaotic, displaying (not no order at all, as had initially been thought) a highly complex form of order. These complex and chaotic systems are described by second order nonlinear differential equations and, as noted, had previously been considered intractable.

The B-Z reaction sequence is an illustration of the abrupt self-organization of hidden order that occurs in open systems far from equilibrium. It shows what can happen when potassium bromate, malonic acid, and manganese sulfate are heated in a bath of sulfuric acid. The first three reactions of the sequence are not remarkable, but the fourth has the unusual feature of being autocatalytic: The product of the process is necessary for the activation of the process itself. Instead of damping oscillations, positive feedback loops around autocatalytic cycles increase system fluctuations around a reference value.

With the system driven far from equilibrium by this runaway process, at a certain critical distance an instability occurs: a threshold point at which small, randomly occurring fluctuations can no longer be damped. Instead the internal dynamics of the autocatalytic cycle amplify a fluctuation, driving the reaction to a new mode of organization. The new system is characterized by the *coherent behavior* of an amazingly large number of molecules that synchronize to form a chemical wave that oscillates from blue to red. A colorful macroscopic structure (the visible evidence of a phase change) appears. True self-organization has taken place because the internally driven dynamics of autocatalysis precipitate the sudden change.

Biological complex systems are adaptive: As a result of feedback, they change their internal structure to respond to a changing environment. Virus mutations are a good illustration. Fundamentally rooted in their environment and history through context-dependent constraints, complex adaptive systems are thus deeply enmeshed in their surroundings. Nor do they start from scratch; they are fundamentally historical entities that embody in their structure the very conditions under which they were created and the trajectory they followed. Snowflakes are examples of such systems. Not only is each unique; its very structure *carries its history on its back* by embodying the pressure and temperature conditions in which it formed. At the same time, self-organizing systems such as slime molds display an autonomy that effectively decouples them from their environment.

Such complex adaptive systems, a category that includes people and their actions, are not isolated atoms. They are always already networked and entangled in both time and space. Their relationships create an interdependent whole that is ontologically new. Thus the environment coevolves with human beings; niches change in response to the organisms that occupy them, every bit as much as the organisms are selected by the niches. And both ontogenetically and phylogenetically, they become increasingly individuated over time.

Ethics in and of Nonlinear Dynamics

The dynamical systems approach suggests an interesting new ethical discussion (Dupre 1993, Juarrero 1999). From the perspective of this new science, the prerequisite for moral action known as free will is not the absence of external determining (Newtonian) causes, but the human capacity to impose order on a progressively disordered world. Because all self-organizing systems select the stimuli to which they respond, their behavior is constrained top-down and becomes increasingly autonomous from environmental impact. More complex systems are more autonomous. Self-organized processes, in other words, act from their own point of view. Furthermore the more complexly structured the entity, the more varied its organization and its behavior, and the more decoupled from and independent of its environment—the more autonomous and authentic, in short.

In another sense, the more complex a nonlinear dynamical system is, the freer it is because increasing complexity corresponds to an increase in state space: The system has new, different, and more varied states to access. Intentional human action is free to the degree and extent that the behavior is controlled by higher-level neurological contextual constraints, those with the emergent properties of meaning, value, and even awareness to a certain degree. Insofar as a wink is an action for which an agent can be held morally responsible precisely because the behavior is caused and controlled by a meaningful intention, and the agent is aware of so acting, a wink is freer than a blink because the latter originates in less complex neurological structures that do not embody meaning and value, and may occur as a reflex reaction.

The atoms of a Newtonian universe are independent of one another. So too are moral agents in a Kantian world. Because they are essentially relational entities, however, complex adaptive systems show how interdependence can create an ontologically distinct phenomenon, an organic whole greater than its parts. This is a fundamental axiological lesson of nonlinear dynamics.

Beginning with Plato's utopia, *The Republic,* Western philosophers have attempted to design fail-safe social systems (whether legal, educational, penal, or other) that are perfect and so never go wrong, morally or otherwise. Complex systems theory shows this is a hopeless task. First, since people carry their history on their backs, they can never begin from scratch, either personally or as societies. Second, perfection allows no room for improvement. Plato was one of the few thinkers who understood that if a utopia were ever successfully established, the only way it could change would be for the worse. Stasis and isolation are therefore essential to maintaining the alleged perfection, not only of Plato's *Republic,* but of most other utopias as well. The noumenal self that Kant postulates as the seat of moral choice and free will is likewise not part of this world. The possibility of perfection requires isolation.

The only choice, from an evolutionary perspective, is to cobble together safe-fail family and social organizations, structures flexible and resilient enough to minimize damage when things go wrong as they inevitably will. But to do so, human beings must recognize the potential of interdependence to create an ontologically distinct, metastable entity. Society needs to reintegrate those pieces torn apart by the old Newtonian framework, whether personally or socially, in both its means of communication and its advocacy of public policy. "Personal ethics must now be augmented by policy making" (Mitcham 2003, p. 159).

The downside of historical and environmental embeddedness is that, as members of a community, human beings do lose some of their freedom. Living in society can and often does cramp one's style. By contrast, components in a system acquire characteristics and identities they previously lacked (and could never acquire on their own): They become nodes in a network of relationships that permits new forms of life and act-types unavailable either to the hermit or to Kant's noumenal self: Only as members of complex social systems can humans be citizens and senators, teachers and wives, scientists and philosophers. The more complex the entity, the more meaningful the choices as well: As citizens and teachers, senators and wives, whatever roles they choose, people can be responsible or irresponsible, conscientious or careless, virtuous or not.

Because of their sensitivity to initial conditions, complex dynamical systems are not only unpredictable, they also become increasingly individuated over time making each developmental or ontogenetic trajectory unique. In contrast to the science of both Aristotle and Newton, non-linear dynamical systems theory incorporates individuation and concreteness into its conceptual framework. Knowing that each complex system's trajectory is unique raises questions about the universality at the heart of Kant's famous moral command, the categorical imperative. Human individuality, historicity, and contextuality are forced into a one-size-fits-all mold. Unacknowledged recognition of the inevitable interdependence and entanglement highlighted by both complexity and quantum theories might well be behind the more recent emphasis on Kant's second formulation of the categorical imperative: Always treat people as ends, never merely as means.

In a world with room enough for both societies and unique individuals, and the creativity and novelty they promote, precise prediction is impossible. Accordingly, dynamical systems theory calls into question the morality of consequentialism, whether in the utilitarianism of John Stuart Mill or elsewhere. In a world where precise consequences cannot be predicted, and where phenomena are intertwined and entangled in their own histories, basing morality on the *actual* outcome of individual behavior is a poor foundation for moral decisions and judgments.

Both consequentialism and Kantian formalism reduce morality and ethics to a set of formal rules. The highly contextual nature of complex systems suggests, in contrast, a different approach to moral education, one that references the virtue ethics of Aristotle and the ancients. Instead of memorizing a set of moral principles, which the agent is then suppose to implement moral education would consist of a gradual shaping of character through feedback and habituation. Moral education under this approach is the process of molding certain desires and character traits that are activated in appropriate contexts.

Nonlinear dynamical systems theory also calls for an ethics appropriate to a universe of interdependence and uncertainty. The recent renewal of interest in virtue ethics seems to implicitly recognize this. By contrast, as Carl Rubino notes, because of the ruling mechanistic paradigm's continuing influence on axiology, uncertainty still carries negative connotations. It should not. Complex dynamical systems teach that "change, novelty, creativity and spontaneity are the real laws of nature, which makes up the rules as it goes along. This is good news, cause for rejoicing; we should lift up our voices, as the prophet says, and not be afraid" (Rubino 1990, p. 210).

COMPUTER ETHICS

The field of study referred to as *computer ethics* addresses ethical issues arising around the development and use of computers and related technology. Computer ethics can be thought of as the field of study that examines ethical issues distinctive to an *information society*. Information society is the term often used (especially by economists and sociologists) to characterize societies in which human activity and social institutions have been significantly transformed by computer and information technology (Webster 2002). The focus of attention in this field has varied over its twenty-five- to thirty-year history as the technology has evolved. Because the field is relatively new and computer technology is continually changing and being used in new domains, computer ethics overlaps with other fields of study such as information ethics, media ethics, and communication ethics, as well as domain-specific ethics such as medical ethics, business ethics, environmental ethics, and legal ethics. Computer ethics is centrally focused on understanding the interactions among science, technology, and ethics and, arguably, it is one of the most developed fields with such a focus.

A Short History of Computer Ethics

From the moment of their invention, computers raised complex social, ethical, and value concerns. While computers are not the first technology to raise ethical issues, they have been especially fascinating to scholars, science fiction writers, and the public. The origin of this fascination may well be related to computers having been initially perceived and characterized as *thinking machines*. As such, they were thought to challenge the distinguishing feature of humankind. For centuries, human beings had been thought of as unique because they were able to *reason* and had the capacity for *rational thinking*. When computers were first developed and used, they seemed capable of being programmed to think in some of the ways that humans think; some believed they had the potential to become even more sophisticated and eventually reach or even surpass human intelligence. In that context, it was thought that computers would revolutionize the way humans think about themselves and what it means to be human. While many of the original hopes and promises of artificial intelligence (AI) researchers have not come to fruition, computers have changed the way scientists think about human cognition and brain functions. Computer technology continues to be a fascination for scientists, science fiction writers, and humanities and social science scholars as well as ethicists.

From a historical perspective, the ethical issues identified in relation to computers seem to follow the sequence of development of the technology. In addition to the threat to notions of what it means to be human, in the very early days of computing the first ethical issues arose in relation to the enormous power that computers might give to government and large bureaucratic organizations. By the late 1970s, the first books on this topic were published. Joseph Weizenbaum's *Computer Power and Human Reason* (1976) and Abbe Mowshowitz's *Conquest of Will* (1976) were, perhaps, the most notable. In this period, the record-keeping capabilities of computers were a key focus, especially the privacy issues raised by this record keeping. Several major government reports were issued including: in 1972, *Databanks in a Free Society: Computers, Record-Keeping and Privacy* by Alan F. Westin and Michael A. Baker, a report of the National Academy of Sciences; in 1973, *Records, Computers, and the Rights of Citizens*, a report of the U.S. Department of Health, Education, and Welfare from the Secretary's Advisory Committee on Automated Personal Data Systems; and in 1977, *Personal Privacy in an Information Society: The Report of the Privacy Protection Study Commission*. The issues that took shape in this period were largely issues of privacy and the power of centralized government was often characterized as the threat of Big Brother. In the aftermath of World War II and the fight against totalitarianism, it was feared that computers would give government unprecedented power and reach.

In hindsight this concern was the result in part of the size of computers. At that time, they were huge mainframe systems that cost a lot, took up a lot of space, and were labor-intensive; hence large organizations were the only viable users. Moreover, in those early days of computing, mainframes were used for large-scale calculations and to create and maintain huge databases. Such calculations made weapons development, space travel, and census tracking possible on a broader scale than ever before. The databases mostly contained personal information. In any event, large organizations were the likely users and hence the concerns about centralization of power and privacy.

The next major technological shift was the development of small computers referred to initially as *microcomputers* and later *personal computers*. Public interest, for a time at least, turned to the democratizing aspects of computers. Computer enthusiasts saw in these small machines the potential for a major social revolution. With visions of computers in every home and shifts in power from large organizations to small businesses and individuals, the fear of Big Brother dissipated somewhat.

As microcomputers were being developed and taking hold in the marketplace, remote access became possible, first to contact large mainframes and later as a component of a network of telecommunications connections between large and small computers. That network eventually became the Internet. However, long before the advent of the Internet, attention turned to software. Microcomputers were less expensive and easier to use; this meant a much broader range of users and, in turn, a broad range of uses. During this phase in the development of computers, software became extremely important both for the development of the technology but also, in parallel, for computer ethics.

To make computers effective tools for the wide range of activities that seemed possible, user-friendly software was critical. Companies and individuals began developing software with a fury, and with that development came a new set of ethical issues. Issues having to do with property rights and platform dominance in software were particularly important in this era. Software was recognized as something with enormous market value; hence, the questions: Should software be owned? If so, how? Would existing intellectual property law—copyright, patents, trade secrecy—be adequate protection for software developers? Ownership rights in programs used to create computer or video games were the first kinds of software cases brought before the courts; the market value of owning these programs was significant.

Along with property rights issues came issues of liability and responsibility. Consumers who buy and use computers and software want to be able to rely on these tools, and when something goes wrong, they want to know whom to blame or they want to be compensated for their losses. Computer ethicists as well as lawyers and computing professionals rose to the challenge and questions of property rights and liability were debated in print as well as in courts.

In the 1980s, more attention began to focus on hackers. Hackers did not like the idea of property rights in software. However those who were acquiring such property rights or making a business of computing were threatened by hackers not only because the latter were breaking into systems but also because they had a different vision of how the system of computers, software, and telecommunications connections should be set up and how software should be distributed. At that time, there were no laws against breaking into computer systems or duplicating software. Hackers argued for open systems with fewer controls on access to information. Perhaps the best illustration of this movement is Richard Stallman's work and the development of the Free Software Association (Stallman 1995).

By the 1990s, the development of the Internet was well underway and seen as a revolutionary event. The coming together of computers, telecommunications, and media and the global scale of the Internet produced a seemingly endless array of ethical issues. The

Internet was being used in many different ways, in many different domains of life. In effect the Internet recreated much of the world in a new medium. Property rights, freedom of speech, trust, liability, and privacy had to be rethought for a medium in which instantaneous communication was the norm; the reproduction of information, documents, or programs was almost effortless; and anonymity was favored. Moreover the new medium facilitated interaction on a global scale, raising issues regarding what laws and conventions applied in *cyberspace*.

During the 1980s and 1990s, computer technology also began to be used for a wide variety of visualization activities. Computer graphics and gaming were part of this, but equally if not more important was the development of many simulation applications including medical imagining and graphical dynamic models of the natural world. The power and reliability of these technologies raised ethical concern. An offshoot of these developments was a focus on *virtual reality* and what it might mean to human experience. Would human beings become addicted to living in fantasy worlds? Would experiences in violent, virtual computer games make individuals more violent than they would otherwise be? These concerns continue in the early-twenty-first century as new applications are developed. For example, important ethical issues are being raised about *tele-medicine*. Computing together with the Internet makes it possible for many aspects of medical treatment to be performed electronically. Issues of responsibility and liability are diffused when doctors do surgery remotely. A doctor in one location can manipulate machines that are electronically connected to machines in a second location where the surgical procedure actually occurs. Should doctors be allowed to do this? That is, is it appropriate? Is it safe? Who is responsible if something goes wrong?

Ethical issues surrounding computer technology continue to arise as new developments in the technology occur. Many of these involve computing applications. For example, new areas of concern include surveillance technologies that result from using geographic information systems and digital imagining to keep track of individuals via digital cameras and satellites. There are projections about the use of tiny, biological computers that might be deployed in human bodies to seek out poorly functioning cells and fix them. Computer technology makes possible human behavior and social arrangements that have a moral character. Hence activities involving computers will continue to be a focus for computer ethics.

Persistent Issues

As computer technology evolves and is deployed in new ways, ethical issues proliferate. To illustrate the kinds of concerns that arise, issues of professional ethics, privacy, hacking and cracking, and the Internet will be briefly described.

PROFESSIONAL ETHICS. In an information society, a large number of individuals are educated for, and employed in, jobs that involve development, maintenance, buying and selling, and use of computer and information technology. Indeed an information society is dependent on such individuals—dependent on their special knowledge and expertise and on them fulfilling social and professional responsibilities. Expertise in computing can be used recklessly or cautiously, for good or ill, and the organization of information technology experts into occupations and professions is an important social means of ensuring that the expertise is used in ways that serve human well-being.

The social responsibilities of computer experts are connected to more general notions of duty and responsibility and computer ethicists have drawn on a variety of traditional philosophical concepts and theories to understand them. Computing professional associations have developed codes of ethical and professional conduct that represent what computer professionals believe to be their duties and the ideals to which they should aspire. However it is important to note that computing is not a single, homogenous profession. The responsibilities and likely areas of ethical concern vary widely with the computer professional's particular job and employment context. Consider, for example, the differences between academic computer scientists, software engineers working in industry, programmers, managers of information technology units in organizations, and computer and software marketers.

The largest and most visible organization of computer professionals is the Association for Computer Machinery (ACM). The ACM has a code of ethics and professional conduct and, with the Institute for Electrical and Electronic Engineers (IEEE), also has developed a code for software engineers, the ACM/IEEE Code of Ethics for Software Engineers. The key elements in both codes are very general edicts to contribute to society and human well-being; avoid harm; be honest and trustworthy; and act in a manner that is consistent with the interests of client, employer, and public. Yet both codes go beyond these general principles and give content and meaning to the principles. While one can argue that codes of conduct are not a very effective mechanism for regulating behavior, they are an important component in constituting a responsible profession. The codes are statements to the public as to what to expect; they articulate standards for the field and make clear that members are professionals. Codes can be used in relation to employers and others to emphasize that computer professionals must adhere to standards independent of the orders they receive at work.

PRIVACY. In an information society, privacy is a major concern in that much (though by no means all) of the information gathered and processed is information about individuals. Computer technology makes possible a magnitude of data collection, storage, retention, and exchange unimaginable before computers. Indeed computer technology has made information collection a built-in feature of many activities, for example, using a credit card, making a phone call, and browsing the Worldwide Web (WWW). Such information is often referred to as transaction-generated information (TGI).

Computer ethicists often draw on prior philosophical and legal analyses of privacy and focus on two fundamental questions, What is privacy? and Why is it of value? These questions have been contentious and privacy often appears to be an elusive concept. Some argue that privacy can be reduced to other concepts such as property or liberty; some argue that privacy is something in its own right and that it is intrinsically valuable; yet others argue that while not intrinsically valuable, privacy is instrumental to other values such as friendship, intimacy, and democracy.

Computer ethicists have taken up privacy issues in parallel with more popular public concerns about the social effects of so much personal information being gathered and exchanged. The fear is that an information society can easily become a *surveillance society*. Computer ethicists have drawn on the work of Jeremy Bentham and Michel Foucault suggesting that all the data being gathered about individuals may create a world in which people effectively live their daily lives in a *panopticon* (Reiman 1995). Panopticon is a term that describes the shape of a structure that Bentham designed for prisons. In a panopticon, prison cells are arranged in a circle with the inside wall of each cell made of glass so that a guard, sitting in a guard tower situated in the center of the circle, can see everything that happens in every cell. The effect is not two-way; that is, the prisoners cannot see the guard in the tower. In fact, a prison guard need not be in the guard tower for the panopticon to have its effect; it is enough that prisoners believe they are being watched. When individuals believe they are being watched, they adjust their behavior accordingly; they take into account how the watcher will perceive their behavior. This influences individual behavior and how individuals see themselves.

While computerized information gathering does not physically create the structure of a panopticon, it does something similar insofar as it makes much individual behavior available for observation. Thus the data collection activities of an information society could have a panoptic effect. Individuals know that most of what they do can be observed and that knowledge could influence how they behave. When human behavior is monitored, recorded, and tracked, individuals may become intent on conforming to norms for fear of negative consequences. If this were to happen to a significant extent, the ability of individuals to act freely and think critically—capacities necessary to realize democracy—may be compromised. In this respect, the privacy issues around computer technology go to the heart of freedom and democracy.

A good illustration of the panoptic environment is the use of cookies at web sites. A cookie is a file placed on a user's computer when the user visits a web site. The file allows the web site to keep track of subsequent visits by the user. Thus, the web site maintains a record of the user's visits. While this can help the web site provide better service to the user—based on information about use—users are being watched, records are being created and the panoptic effect may occur. Moreover, the records created can be matched with information from other web sites and domains.

It might be argued that the panoptic effect will not occur in information societies because data collection is invisible; individuals are unaware they are being watched. This is a possibility, but it is also possible that as individuals become more and more accustomed to information societies, they will become more aware of the extent to which they are being watched. They will see how information gathered in various places is put together and used to make decisions that affect their interactions with government agencies, credit bureaus, insurance companies, educational institutions, and employers, among others.

Concerns about privacy have been taken up in the policy arena with the passage of legislation to control and limit the collection and use of personal data. An important focus is comparative analyses of policies in different countries. The U.S. approach has been piecemeal with separate legislation for different kinds of records, for instance, medical records, employment histories, and credit records. By contrast, several European countries have comprehensive policies that specify what kind of information can be collected under what conditions in *all* domains. The growing importance of global business influences policy debates. Information-gathering organizations promise that they will use information only in certain ways; yet, in a global economy, data collected in one country—with a certain kind of data protection—can flow to another country where there is no protection, or where such protection differs from that of the original country. To assure that this does not happen, a good deal of attention is focused on working out international arrangements and agreements to protect data internationally.

HACKERS AND CRACKERS. While the threats to privacy described above arise from *uses* of computer and information technology, other threats arise from *abuses*. As individuals and companies do more and more electronically, their privacy and property rights become increasingly important. Individuals who defy the law or test its limits can threaten these rights. Such individuals, often called *hackers* or *crackers*, may seek personal gain or may just enjoy the challenge of figuring out how to *crack* security mechanisms. The term hacker originally referred to individuals who simply loved the challenge of working on programs and figuring out how to do complex things with computers, but who did not necessarily break the law. Crackers referred to individuals who did. However, in the early-twenty-first century, the terms are used somewhat interchangeably to refer to those who engage in criminal activity.

Distinguishing the terms, however, reveals two streams of development in computing and two streams of analysis in computer ethics. Hackers are not only individuals who love computing and are very knowledgeable about it, but in particular are those who advocate an alternative vision of how computer technology might be developed and used. Hackers are interested in a computing environment that has more sharing and less ownership. For many hackers, this is not just talk. They are involved in what is sometimes called the open source movement, which involves the development of software that is available for free and can be modified by the user. Over the years, through various organizations, a good deal of open source software has been developed including, notably, the Linux operating system.

Because hackers represent an alternative vision of software, they are seen as part of a social and political movement, a kind of counterculture. A strand of this movement goes beyond the development of open source software and engages in political activism, using computing expertise to make political statements. The term *hacktivism* refers to on-line political activism. Whether such behavior is legal or illegal remains ambiguous.

Another stream of analysis centers around crackers. Cracker refers, simply, to an online criminal. Crackers break into systems or disrupt activities on the Internet by launching viruses or worms or by engaging in a host of other kinds of disruptive behavior, including pinging, and taking control of websites. The ethical issues are not particularly deep. Cracking behavior interferes with innocent users who are trying to do what they have legal rights to do; the behavior of crackers may violate property rights or privacy, involve harassment, and more. Computer ethics literature examines this behavior for its ethical content but also to try to understand whether there is anything unique or special about cracking behavior and computer crime.

Law often lags behind technology and, in the early days of computing, there were no prohibitions against the disruptive behavior of crackers. In the early-twenty-first century, however, there are many laws regulating behavior on the Internet. Yet issues and problems persist. New technologies facilitate crackers and there are serious questions regarding harmonization of laws globally. Anonymity makes it difficult to catch computer criminals.

INTERNET ISSUES. Arguably the Internet is the most powerful technological development of the late-twentieth century. The Internet brings together many industries but especially the computer, telecommunications, and media enterprises. It provides a forum for millions of individuals and businesses around the world. It is not surprising, then, that the Internet is a major focus of attention for computer ethicists. The development of the Internet has involved moving many basic social institutions from a paper and ink environment to an electronic environment. The change in environment changes the features of activities. Thus a number of ethical issues arise as regards the behavior of individuals and organizations on the Internet.

The Internet has at least three features that make it unique. First, it has unusual scope in that it provides many-to-many communication on a global scale. Of course, television and radio, as well as the telephone, are global in scale, but television and radio are one-to-many forms of communication, and the telephone, which is many-to-many, is expensive and more difficult to use. Individuals and companies can communicate with one another on the Internet frequently, in real time, at relatively low cost, with ease, and with visual as well as sound components. Second, the Internet facilitates a certain kind of anonymity. One can communicate with individuals across the globe (with ease and minimal cost), using pseudonyms or real identities, and yet never actually meet those people. This type of anonymity affects the content and nature of the communication. The third special feature of the Internet is its reproducibility. Text, software programs, music, and video on the Internet can be duplicated ad infinitum and altered with ease. The reproducibility of the medium means that all activity on the Internet is recorded and can be traced.

These three features—global, many-to-many scope; anonymity; and reproducibility—have enormous positive, as well as negative, potential. The global, many-to-many capacity can bring people closer together, relegating geographic distance to insignificance. This feature is especially liberating to those for whom travel is physically challenging or prohibitively expensive. However these benefits come with drawbacks; one is that such capabilities are also available to those who use them for heinous purposes. Individuals can—while sitting anywhere in the world, with very little effort—launch viruses and disrupt communication. They can misrepresent themselves and dupe others on a much larger scale than was possible before the Internet.

Similarly anonymity has both benefits and dangers. The kind of anonymity available on the Internet frees some individuals by removing barriers based on physical appearance. For example, in contexts in which race and gender may get in the way of fair treatment, the anonymity provided by the Internet can eliminate bias (for example, in online education, race, gender, and physical appearance are removed as factors affecting student-to-student interactions as well as teacher evaluations of students). Anonymity may also facilitate participation in beneficial activities such as discussions among rape victims, battered wives, or criminal offenders, in which individuals might be reluctant to participate unless they had anonymity.

Nevertheless anonymity leads to serious problems of accountability and integrity of information. Perhaps the best illustration of this is information acquired in chat rooms on the Internet. It is difficult (though not impossible) to be certain of the identities of people with whom one is chatting. One person may participate under multiple identities; a number of individuals may use the same identity; or participants may have vested interests in the information being discussed (for instance, a participant may be an employee of the company or product being discussed). When one cannot determine the true source of information or develop a history of experiences with a particular source, it is impossible to gauge the reliability of the information.

Like global scope and anonymity, reproducibility also has benefits and dangers. Reproducibility facilitates access to information and communication; it allows words and documents to be forwarded (and downloaded) to an almost infinite number of sites. It also helps in tracing cybercriminals. At the same time, however, reproducibility threatens privacy and property rights. It adds to problems of accountability and integrity of information arising from anonymity. For example, students can send their assignments to teachers electronically. This saves time, is convenient, and saves paper. However the reproducibility of the medium raises questions about the integrity of the students' product. How can a teacher be sure a student actually wrote the submitted paper and did not download it from a web site?

As the daily activities of individuals and businesses have moved online, distinctive ethical questions and issues have been identified; some of these issues have been addressed by adopting or modifying relevant laws; others have been addressed by new technology; yet others persist as nagging problems without solution or only with solutions that are worse than the problem. Plagiarism is an example of a problem that can be at least partially addressed via new technology; that is, there are tools available for teachers and professors to use to detect student work that has been copied from the Internet or copied from other students. On the other hand, pornography is an example of an issue that defies solution. An incredibly large proportion of the traffic on the internet involves distributing, advertising, and accessing pornography. This seems an unworthy use of one of the most important, if not the most important, inventions of the twentieth century. Yet, eliminating or reducing pornography on the Internet would seem to require censorship and policing of a kind that would undermine the freedom of expression that is the bedrock of democratic societies. Hence, pornography on the internet persists.

Conclusion

Perhaps the deepest philosophical thinking on computer-ethical issues has been reflection on the field itself—its appropriate subject matter, its relationship to other fields, and its methodology. In a seminal piece titled "What is Computer Ethics?" James Moor (1985) recognized that when computers are first introduced into an environment, they make it possible for human beings (as individuals and through institutions) to do things they could not do before and that this creates *policy* *vacuums*. People do not have rules, policies, and conventions on how to behave with regard to the new possibilities. Should employers monitor employees with computer software? Should doctors perform surgery remotely? Is there any harm in taking on a pseudoidentity in an on-line chat room? Should companies doing business online be allowed to sell the TGI they collect? These are examples of policy vacuums created by computer technology.

Moor's account of computer ethics has shaped the field. Many computer ethicists see their role as that of filling policy vacuums. Indeed one topic of interest in computer ethics is defining the activity of filling policy vacuums.

Because computers and information technology will continue to evolve and become further integrated into human life, new ethical issues will certainly arise. However, as human beings become more and more accustomed to interacting with and through computer technology, the difference between ethics and computer ethics may well disappear.

COMPUTER VIRUSES/ INFECTIONS

A computer virus is a piece of software that "invades" a computer. As such, a computer virus is one of several kinds of infections, including Trojan horses and worms. Infections are themselves a subset of possible attacks on computers and networks; other attacks include probes, unauthorized access, denial of service, Internet sniffers, and large-scale scanning. This entry focuses on viruses, worms, and Trojan horses—collectively termed *electronics infections*—the three most common kinds of attacks and the ones best known by the public (Carnegie Mellon University Internet site). All such infections constitute multiple ethical and political issues: the responsibilities to protect against them, determining consequences for those responsible for attacks, and how to educate users about their vulnerabilities.

Technical Features

A virus is a piece of software that is hidden inside a larger program. When the larger program is executed, the virus is executed as well. During that execution, the virus can try to fulfill its purpose, often to replicate (that is, copy) itself in other programs on its host machine or (via the Internet) to new host machines. This copying and sending takes up resources on the original machine, on the Internet's communications capacity, and on any new machines infected. For a major virus attack, the loss of resources can cost billions of dollars.

One variation on the more traditional application-borne computer virus is the e-mail virus. An e-mail virus attaches itself to a piece of e-mail instead of to a program. Another subspecies of computer virus is the "logic bomb." A logic bomb is a virus because it resides inside the operating system or an application; the variation is that a logic bomb executes its harmful side effect only when certain conditions are met, typically when the system clock reaches a particular date. At the appointed time, the virus can do something relatively harmless, like flashing a provocative text message on the screen; but it could also do something far more serious, such as erasing significant portions of the resident host's hard drive.

A virus requires a program or e-mail to hide in. But a computer worm works independently. A computer worm uses computer networks and security flaws to replicate itself on different networked computers. Each copy of the worm scans the network for an opening on another machine and tries to make a new copy on that machine. As this process is repeated over many generations, the computer worm spreads. As with viruses, both the propagation and any other side effects can be frivolous or draconian.

A Trojan horse is a complete computer program that masquerades as something different. For example, a web site might advertise a freeware computer game called Y. But when someone downloads and runs a copy of Y, Y erases the hard drive of the host machine. Unlike viruses, a Trojan horse does not include a self-replication mechanism inside its program.

Ethical Issues

Early in the history of computer development, some people thought of electronic infections as relatively harmless, high-tech pranks. But once these infections began to cost the public enormous amounts of time, energy, and money, they ceased to be laughing matters. The technical details that separate viruses, worms, and Trojan horses are useful distinctions when understanding the different techniques, but all infections share a common feature: They enter someone's computer without permission. Although different infections have different effects (and some claim to be benign), all of them take unauthorized control of another machine and/or memory.

In the early 1990s, there was actually some controversy about whether or not computer infections and other "hacking" activities were always unethical. In some instances benign infections simply used underutilized computer power in ways that did not compromise the owner's uses (Spafford 1992). But the reflective consensus in the early twenty-first century is that all infections and break-ins are wrong. Reasons for this consensus include the view that it causes real harms, it violates legitimate rights to non-intrusion, it steals resources that could be put to better use, and it encourages otherwise unnecessary spending on security that could be spent on better things (Johnson 2001).

Even when it is agreed that all computer infections are unethical, important questions remain. For example, most computer infections now known are aimed at Microsoft Corporation operating systems and applications. That may be a consequence of Microsoft's market share, of technical details about Microsoft's software, of hackers' attitudes toward Microsoft, or a combination of these. Each has ethical dimensions. When one condemns the creator of a harmful infection, should some of the blame for the damages not be shared by vendors who release software with security holes that are easily exploited? Are users who fail to install security updates or adopt easily broken passwords not partially responsible? Such questions are part of an ongoing discussion of responsibility that can be found in analyses of the degrees of victim contributions and extenuating circumstances with regard to a wide range or crimes, from fraud to theft and assault and battery.

Education

Consider also questions raised by teaching students about computer infections. Those offering such classes defend their actions as helping students learn how to defend against such infections; critics have argued that such classes may actually encourage students to write and propagate new infections.

Both the defenders and the critics of academic work on computer infections raise legitimate issues. Considering their positions consequentially, if such classes reduce the number and severity of infections, then they are morally justified; conversely, if they increase the number or severity of infections, then they are not justified. But it seems unlikely that enough information about consequences can be easily gathered to settle the question.

Another approach is to analyze classes that teach about computer infections in terms of course content. Surely it would be noncontroversial to teach historical facts about the occurance and severity of computer infections. Furthermore, discussing the ethics of computer infections and other attacks are also unlikely to raise objections. The content most likely to prove objectionable would be teaching the technical details of how to construct computer infections, with assignments that require students to design new infections.

Is it ethical to teach the technical details of computer infections? Consider an analogy: Is it ethical to teach accounting students the details of accounting fraud? Such classes exist and have not elicited the same kind of criticism that has been leveled against computer infection classes. It seems reasonable in both cases that professionals in the field should know how people have conducted "attacks" in order to detect and defend against them in the future.

Yet there are ethically significant differences between accounting and computing—the rules of proper accounting are more explicitly spelled out than the rules of "proper computing." Accountants are held to more formal, legal, and professional standards than computing professionals. Furthermore, it takes very little advanced skill to launch a computer attack, but it requires some sophistication (and often a high position in a company) to launch a major accounting fraud. Finally, although an accounting class might include the study of strategies to defraud a company, it seems unlikely that a student could actually implement a fraud during the class, whereas computer science students can indeed launch a computer virus (and some have).

The analogy suggests that the notion of teaching computer science students about computer infections seems reasonable, but that some cautions about what is taught and how it is taught may be necessary. There is no airtight case for or against classes that include details of computer infections, but there are two important perspectives to consider: consequentialist arguments and arguments from analogy. Other perspectives might include deontological obligations to share knowledge or to recognize traditions of forbidden knowledge, and the character or virtue implications for both teachers and students in such classes.

Preliminary explorations nevertheless suggest that the content of the courses and the context in which technical details are presented will determine whether or not such courses are ethical. One can envision a course in which a professor does not emphasize the responsibilities of a programmer and does not discuss the negative impact of computer infections; in such a class, the presentation of technical details of computer infections are likely inappropriate. One can also envision a course in which professional responsibilities and public safety are central themes; in such a course, details of computer infections might be entirely appropriate.

TABLE 1

Possible Sanctions Against Those Who Create and Launch Computer Infections

	Minor consequences to others	Major consequences to others
Unintended	Education	Education plus minor punishment
Intended	Education plus minor punishment	Education plus major punishment

Sanctions

If infecting systems that don't belong to you is wrong, it is necessary to consider appropriate sanctions against those who create and launch computer infections. In general, punishments for any unethical behavior should take into account both consequences of the act and intentions of the actor. Table 1 shows a broad view of how sanctions could be applied using considerations of intent and consequences.

Unintended minor consequences (as when a person experimenting designs a virus to see how it works and accidentally lets it get away, but it does very little damage) surely deserves little in the way of punishment, although some acknowledgement of the damage done seems appropriate. Unintended major consequences and intended minor consequences both deserve education plus some form of punishment, although probably not the same in each case. But intended major consequences could be assigned significant punishments, including jail and restrictions on future computer use.

The computer software community of hackers also has responsibilities to exercise social pressure and the punishment of ostracism on intentional offenders. Indeed, to some extent it seems to do this by reserving the pejorative term *crackers* for such persons. But professional organizations such as the Association for Computing Machinery might also instigate formal forms of ostracism. Codes of ethics for computing professionals such already include explicit prohibitions against computer attacks. For example, section 2.8 of the ACM Code of Ethics states: "Access computing and communication resources only when authorized to do so" (ACM Internet site). However, the ACM rarely disciplines members, and removal from the ACM is not seen as a significant threat to most hackers.

COMTE, AUGUSTE

One of the French founders of modern sociology, Isidore-Auguste-Marie-François-Xavier Comte, better known simply as Auguste Comte (1798–1857), was born in Montpellier on January 19 (30 *Nivose* Year VI in the revolutionary calendar) and tried to reconcile the ideals of the Revolution of 1789 with early nineteenth century society. Comte's higher education began at the École Polytechnique in Paris, although he was expelled after two years following a quarrel with one of his mathematics professor. He then briefly studied biology at the École de Médecine in Montpellier before returning to Paris. Among his early influences, the philosophy of the Marquis de Condorcet (1743–1794) had the greatest impact. In 1817, Comte began his close association with Claude-Henri de Saint-Simon (1760–1825), one of the founders of French socialist thought who envisaged the reorganization of society by an elite of philosophers, engineers, and scientists. After an angry break between the two in 1824, Comte spent the next twenty years delivering lectures on "social physics." He suffered periods of intense mental collapse and died isolated and bitter on September 5 in Paris.

Positive Philosophy

Building on Condorcet's theory of human progress, Comte constructed what he called a "positive philosophy." Central to his philosophy was the "law of the three stages" between theological (mythological or fictitious), metaphysical (abstract), and positive (empirical and descriptive) knowledge. Over the course of history and across a broad range of disciplines and dimensions of human culture, the myths of theology have been gradually replaced by the general principles of metaphysics that were, in Comte's own time, being superseded by positive or empirical scientific knowledge. The positive stage constitutes the highest stage of human history because it is only when science has become "positive" that human beings will truly understand the world. For Comte, astronomy was the first science to become positive, because its phenomena are universal and affect other sciences without itself being affected. Because it is so complex, the last science to become positive is "social physics" or sociology.

Comte divided social physics into statics and dynamics, order and progress. The idea of order appears in society when there is stability because all members hold the same beliefs, a stage that occurred with the triumph of medieval Christianity. The idea of progress appeared with the Protestant Reformation and the French Revolution. For Comte, the contemporary challenge was to reconcile or synthesize order and progress, because revolution had destroyed the medieval sense of order but not yet created a new one to take its place. According to Comte, this new order required not only science but religion, with a new clergy to preach the laws of society. Comte eventually proposed himself as the high priest of this new scientific religion, and from 1844 signed his works, "The Founder of Universal Religion, Great Priest of Humanity."

Comte's Influence

Comte has been severely criticized for proposing that a technocratic elite was needed to educate and discipline society (see, for instance, the remarks on Comte in his contemporary John Stuart Mill's book *On Liberty*, 1859). But Comte was also interested in the moral improvement of humanity as a whole, and a social order in which self-interest is restrained within the bounds of an appreciation of the good of others as well as oneself. Morality for him was constituted by devotion to the whole of society. Such an idea clearly represented a critique of the unqualified competitiveness characteristic of the Industrial Revolution. Indeed, the need for some authoritarian, technocratic guidance—perhaps imbued

Auguste Comte, 1798–1857. Comte developed a system of positive philosophy. He held that science and history culminate in a new science of humanity, to which he gave the name "sociology." *(The Library of Congress.)*

to some degree with a religious sensibility—to facilitate the creation of a legal framework that supports qualified capitalist competition is not easily dismissed.

The importance of Comte must be placed in the historical context of a century in which vast systems of ideas were being fashioned in response to the forces unleashed by the French and Industrial Revolutions. Although the law of the three stages sounds contrived, and his plans for a new positive religion utterly fantastic, Comte succeeded in introducing the scientific study of society into nineteenth century intellectual discourse. His vision of a science of society to complement the emerging science of nature remains of fundamental importance to the relationship between science, technology, and ethics.

CONFLICT OF INTEREST

A conflict of interest is a situation in which some person (whether an individual or corporate body) stands in a certain relation to one or more decisions. Often such persons are engineers, scientists, or organizations of engineers or scientists. On the standard view, *a person has a conflict of interest if, and only if, that person (a) is in a relationship with another requiring the exercise of judgment in the other's behalf and (b) has a (special) interest tending to interfere with the proper exercise of such judgment.*

Key Features of Conflict of Interest

The crucial terms here are *relationship, judgment, interest,* and *proper exercise.* Relationship is quite general, including any connection between persons or organizations justifying one's reliance on the other for a certain purpose. A relationship may be formal (as is that between the Academy of Science and the government it advises) or informal (as when an engineer responds to a neighbor's question about the best bicycle to buy). A relationship can last years (as the relationship between colleagues in a lab often does) or only a minute (as when one answers a stranger's question at a talk). The relationship required must, however, be fiduciary, that is, involve one person justifiably trusting (or, at least, being entitled to trust) another—to exercise judgment in the other's service.

Judgment refers to the ability to make certain kinds of decision correctly more often than would a simple clerk with a book of rules and all, and only, the same information. Insofar as decisions do not require judgment, they are *routine, ministerial, mechanical,* or *something a technician could do*; they have (something like) an algorithm. The decision maker contributes nothing special. Any difference between the decision maker's decision and that of someone equally well trained would mean that (at least) one of them erred (something easily shown by examining what they did). Ordinary math problems are routine in this way; so is the taking of readings from a gauge.

Where judgment is required, the decision is no longer routine. Judgment brings knowledge, skill, and insight to bear in unpredictable ways. Where judgment is necessary, different decision makers, however skilled, may disagree without either being obviously wrong. Over time, observers should be able to tell that some decision makers are better than others (indeed, that some are incompetent). But, except in extraordinary circumstances, an observer will not be able to do that *decision by decision;* nor will an observer be able to explain differences in outcomes in individual decisions merely by error—or even be able to establish decisively that one decision maker's judgment is better than another's in this or that case. Even if one decision maker is successful this time when another is not, the difference might as easily be the result of *dumb luck* as *insight*. Good judgment lasts. What makes a good scientist or a good engineer is good scientific or engineering judgment. Judgment is less general than *expertise*. Some of what is expected from experts is not judgment but merely special knowledge or routine application of a special skill.

Not every relationship, not even every relationship of trust or responsibility, requires judgment. A person may, for example, be asked to keep safe—but not look at—important lab notebooks until the owner returns. That person has been charged with a great trust as a fiduciary upon whom the owner may be relying to protect an important discovery. But the person need not exercise judgment to carry out the task. The task is entirely routine, however much the ability to behave as required is strained by a desire to peek. The notebooks need only be placed in a desk and left there until the owner returns and asks for them. The holder of the notebooks is a mere trustee, lacking the permissible options that make conflict of interest possible. Not all temptations to misbehave constitute conflict of interest in the strict sense.

Interest refers to any influence, loyalty, concern, emotion, or other feature of a situation tending to make a person's judgment (in that situation) less reliable than it would normally be, without rendering that person incompetent. Financial interests and family connections are the most common sources of conflict of interest, but love, prior statements, gratitude, and other subjective tugs on judgment can also be interests. For example, a biologist hired by a drug company to test some drug for efficacy has an interest (in the relevant sense) if the drug's inventor is a friend or enemy (just as if the biologist were paid with stock in the drug company).

What constitutes proper exercise of judgment is a *social fact,* that is, something decided by what people ordinarily expect, what the person exercising judgment or the group to which that person belongs invites others to expect, what that person has expressly contracted to do, and what various laws, professional codes, or other regulations require. Because what is proper exercise of judgment is so constituted, it changes over time and, at any time, may have a disputed boundary. For example, civil engineers in the United States today are expected to give substantial weight to considerations of environmental harm when deciding what to recommend, something (probably) not within the proper exercise of their judgment until the second half of the twentieth century.

The Problem with Conflict of Interest

What is wrong with conflict of interest? Having a conflict of interest is not wrong. However what one does about the conflict may be—for one of three reasons.

First, the person exercising judgment may be negligent in not responding to the conflict of interest. Society expects those who undertake to act in another's behalf to know the limits of their judgment when the limits are obvious. Conflict of interest *is* obvious. One cannot have an interest without knowing it—though one can easily fail to take notice of it or misjudge how much it might affect one's judgment. Insofar as the person exercising judgment is unaware of the conflict of interest, that person has failed to exercise reasonable care in acting in another's behalf. Failing to exercise reasonable care is negligent, and therefore the conduct is morally objectionable.

Second, if those justifiably relying on a person for a certain judgment do not know of the conflict of interest but the person knows (or should know) that they do not, then the person is allowing them to believe that the judgment in question is more reliable than it is—in effect, deceiving them. That deception is a betrayal of their (properly-placed) trust and therefore morally objectionable.

Third, even if the person exercising judgment informs those justifiably relying on that judgment that a conflict of interest exists, the judgment will still be less reliable than it ordinarily is. The person will still be less competent than usual—and perhaps appear less competent than members of the profession, occupation, or discipline in question should be. Conflict of interest can remain a technical problem, affecting reputation, even after it has ceased to be a moral problem.

How to Respond to Conflict of Interest

What can be done about conflict of interest? One common answer, one still enshrined in many codes, is: Avoid all conflicts of interest. That answer probably rests on at least one of two possible mistakes. One is assuming that all conflicts of interest can, as a practical matter, be avoided. Some certainly can be. For example, a journal editor can avoid most conflicts of interest by making sure all reviewing is *blind*. Reviewers would then (generally) not know what effect their official recommendations had on friends or enemies. An editor cannot, however, avoid all conflicts of interest in this way. Sometimes a reviewer will know enough to recognize that the author of a submission is an old friend (or enemy).

The other mistake is to assume that avoidance is the only proper response to conflict of interest. In fact, there are at least three others: escape, disclosure, and management.

Escape ends the conflict. So, for example, a reviewer who discovers that he or she is reviewing a friend's submission can stop reading, send the submission back to the editor with an explanation, and recommend a replacement.

Disclosure, even if sufficiently complete (and understood), merely gives those relying on a person's judgment the opportunity to give informed consent to the conflict of interest, to replace that person with another, or to adjust reliance in some less radical way (for example, by seeking a second opinion). Unlike escape, disclosure as such does not end the conflict of interest; it merely avoids the betrayal of trust.

Managing, though often the resolution reached after disclosure (as illustrated above), need not follow disclosure. Where disclosure is improper (because it would violate some rule of confidentiality) or impossible (because the person to whom disclosure should be made is absent, incompetent, or unable to respond in time), managing may still be a legitimate option.

Conclusion

Too frequently discussions of conflict of interest start with the biblical quotation, "Can a man have two masters?" This seems to be the wrong way to begin. The reason one cannot have two masters is that a master is someone to whom one owes complete loyalty, and complete loyalty to one excludes any loyalty to another. Having only one master *is* a strategy for avoiding conflict of interest, but a strategy making the concept uninteresting. Society must worry about conflict of interest only when avoiding all conflicts of interest is virtually impossible or so socially inefficient that there is general agreement that avoidance is often undesirable. Conflict of interest is an interesting concept only when loyalties are regularly and legitimately divided.

The term *conflict of interest* seems to have separated off from the related terms *conflicting interests* and *conflict of interests*," taking on the meaning given here, only in the middle of the twentieth century, a period in which two related trends seem to have accelerated. First, society has become more complex, making people increasingly dependent on experts. Second, society has become increasingly unsettled, making people increasingly reliant on strangers rather than on people they have known well for many years. People cannot manage the conflict of interest of those relied upon when they do not know enough about them. Society cannot tell experts to avoid all conflicts of interest because those experts could not then make a living. Society must therefore depend on such experts to disclose some conflicts (those that considerations of confidentiality allow them to disclose), to manage others, and to decline to exercise judgment where they can so decline without too much loss to those they serve. For that reason, the trend in codes of ethics in engineering and science has been away from flat prohibition of conflict of interest and toward more nuanced provisions. For example, the Code of Ethics of the Institute for Electrical and Electronic Engineers (1990) now urges members not only "to avoid real or perceived conflicts of interest whenever possible" but also "to disclose them to affected parties when they do exist."

CONFUCIAN PERSPECTIVES

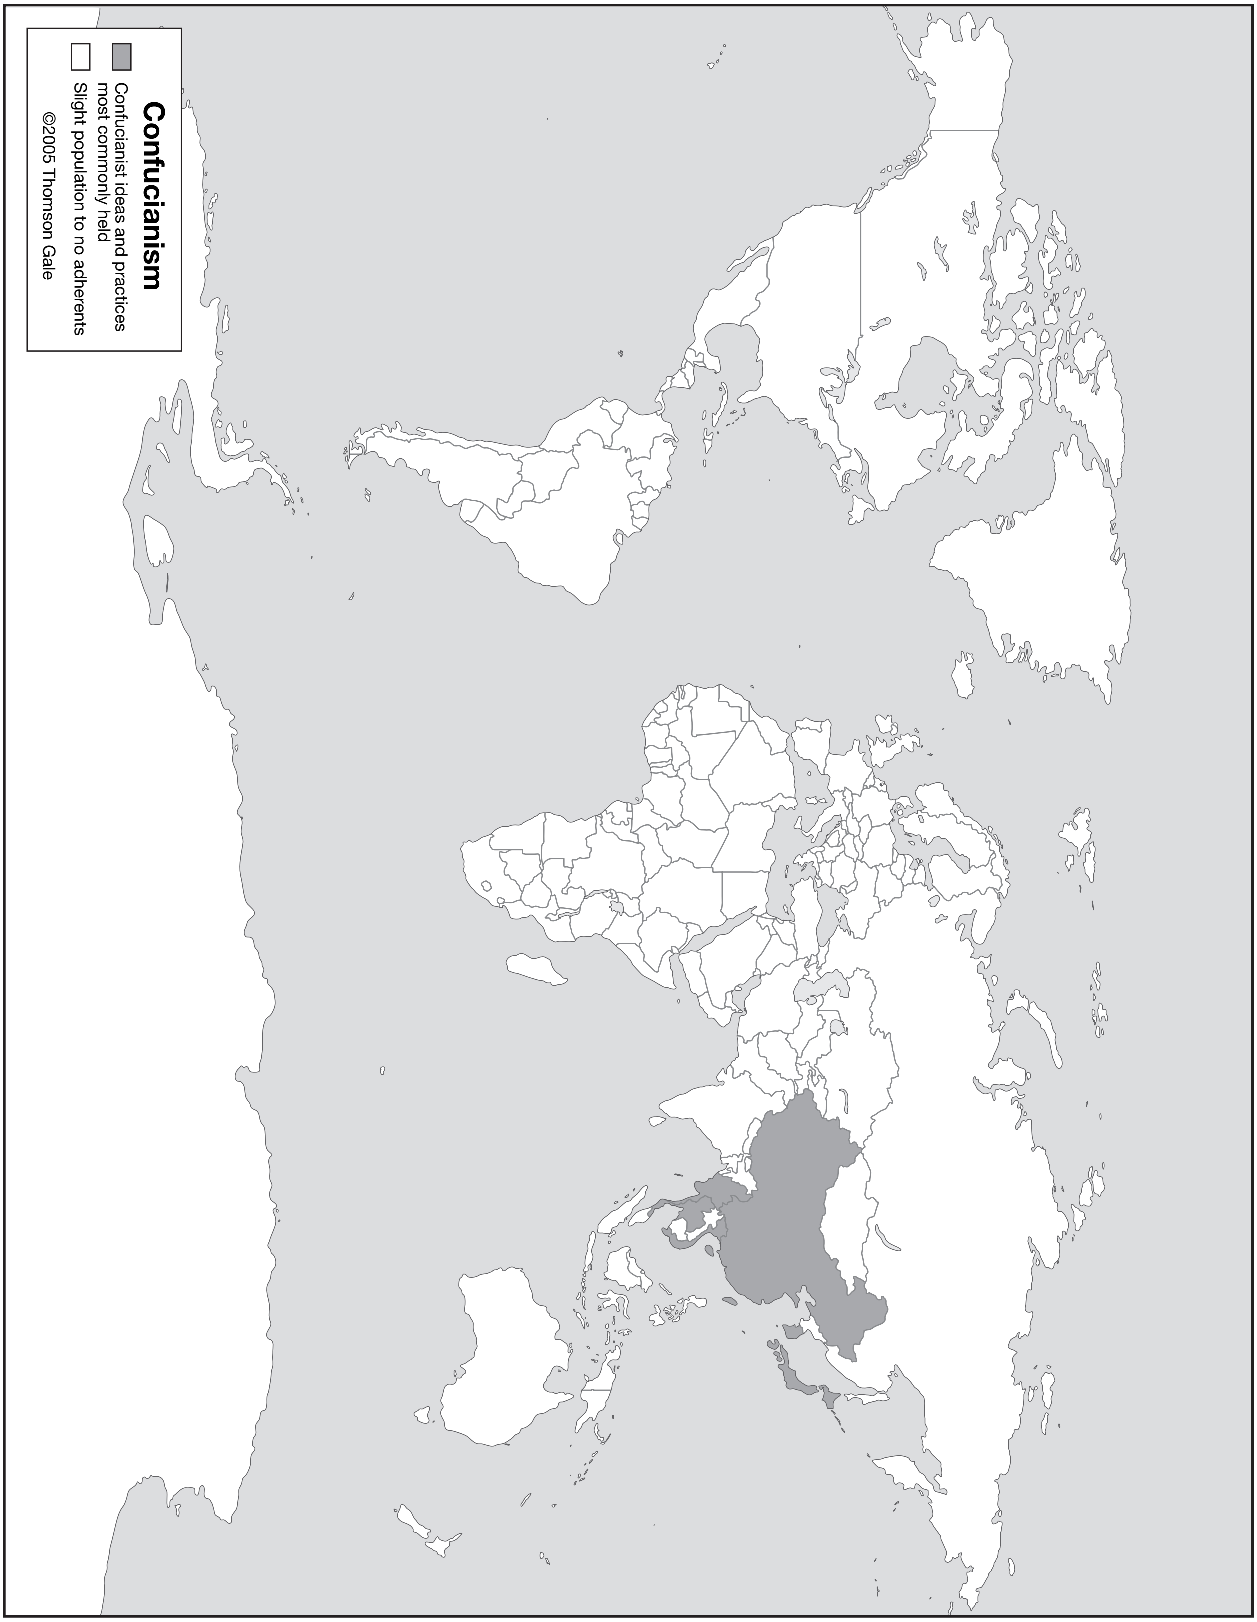
Confucianism originated more than 2,000 years ago in China in the thoughts of Confucius, or Kong Zi (Master Kong, 551–479 B.C.E.). Kong Zi lived during one of the formative periods of Chinese culture, when numerous philosophical schools, such as Daoism (Taoism) and Mohism, vied for social influence. Other major early thinkers in the Confucian tradition include Mencius, or Meng Zi (371–289 B.C.E.), and Xun Zi (298–238 B.C.E.). Confucianism was established as the state ideology during the Han dynasty (206 B.C.E.–220 C.E.). As an original thinker, a powerful persuader, and a successful educator, Kong Zi became the defining philosopher of Chinese culture and one of the most influential cultural philosophers in East Asia and beyond. In the early twenty-first century Confucianism stands for a distinctive voice in global dialogues on issues that range from human rights to gender equality. As a living tradition, Confucianism also provides a unique perspective on science, technology, and ethics.

Confucian Foundations

The primary text of Kong Zi's thought that is still in existence is the *Analects* (*Lun Yu*), a posthumous collection of his sayings and his disciples' reflective remarks on his teachings. Other major Confucian classics include *The Book of Meng Zi, The Book of Change, The Book of History, The Odes, The Book of Rites*, and *The Spring and Autumn*. Although the precise dates of these works cannot be ascertained, scholars generally believe they were compiled during the Spring–Autumn and Warring States period (770–221B.C.E.). The development of Confucianism usually is divided into three phases. Classical Confucianism was developed by Kong Zi and other early thinkers. Neo-Confucianism was developed during the Song (960–1276) and Ming (1368–1644) dynasties by thinkers such as Zhu Xi (1130–1200) and Wang Yangming (1472–1529). The third phase is contemporary New-Confucianism, represented by thinkers such as Xiong Shili (1885–1968) and Mou Zongsan (1909–1995).

Historically, however, Han-Confucianism as it developed during the Han dynasty is also an important episode not only because that was the period when the tradition first became dominant in China but also because Han-Confucians extensively incorporated the notions of *yin-yang* and the Five Phases (Water, Fire, Wood, Metal, and Earth) into Confucianism. Those notions later had a great influence on the relationship of Confucianism to science and technology.

Confucianism is primarily a moral philosophy with ethics as its core. Confucian ethics has been characterized as virtue ethics. It is concerned with developing a virtuous person rather than emphasizing the following of ethical principles. Confucians see human life as a journey toward the goal of forming a virtuous character in the context of the family and other interpersonal relationships.



Confucianism
Confucianist ideas and practices most commonly held
Slight population to no adherents
©2005 Thomson Gale

Confucianism is not a theism. Its moral philosophy does not rest on a god or a divine being. However, it holds that there is a cosmic moral order that serves as the foundation of the moral life. This order is not carved in stone and is not a static entity; it has to be sought through human endeavors and realized through human activities. In comparison with Daoism, Confucianism places more emphasis on a person's accomplishments in society and on the positive consequences of moral edification. Whereas Daoism leaves room for supernatural forces, Confucianism is focused firmly on the earthly world and its mundane affairs. Over a long period of history Confucianism and Daoism formed a unique complementary relationship in Chinese society.

Key Concepts

Key concepts of Confucian ethics include *dao, de, ren, li,* and *yi.* The first of these concepts, *dao,* or the Way, defines the cosmic moral order. Confucians understand the cosmos as a triadic unity of Heaven, Earth, and Humanity. The *dao* is found and realized in a harmonious interaction among these three components. When it is realized, the entire world goes smoothly and the myriad things in it thrive.

Human beings participate in the realization of the *dao* by developing their *de,* or virtues. Confucians have what may be called a "person-making" ethics: One makes one's own person through learning and by extending one's knowledge and social skills. Every person is born with the potential to become a sage. Whether a person realizes his or her moral potential depends on that person's own effort. A good person is one who realizes his or her moral potential and develops into a virtuous person, one with a good character.

Whereas *de* points to particular virtues in various aspects of human life, *ren,* or humanity, as the Confucian moral ideal, stands for holistic human excellence. A *ren* person is a fully developed and well-rounded individual. Kong Zi said that a *ren* person is one who can achieve five virtues: earnestness, consideration for others, trustworthiness, diligence, and generosity.

The meaning of *li* is complex. It has been translated into English as *rites, rituals, propriety,* and *rules of proper conduct.* In the Confucian moral life *li* is the social grammar, providing guidelines for socially appropriate behavior. Unlike *ren, li* is tangible in that it tells people what to do in specific circumstances. For example, it is *li* to yield a seat on the bus to an elderly person and not to speak loudly in the library. Learning *li* is a necessary step for a person to develop moral virtues and become *ren.* Observance of *li* is the natural path for a person of *ren.* A society without *li* is chaotic and uncivilized; an un-*li* person is socially retarded and barbarous. Confucians, however, do not take *li* to be absolute. Recognizing the complexity and the dynamic nature of social life, Confucians value the ability to determine a course of appropriate action in complex situations.

The concept of *yi* focuses principally on what is right and fitting in particular circumstances. It calls for sound judgment and reasonableness. At times *yi* may require people to forgo personal advantages in order to do what is right. A person of *yi* demonstrates moral maturity. Other important Confucian virtues include *xiao* (filial piety), *xue* (learning), and *zhi* (wisdom).

Applications to Science, Technology, and Ethics

As a complex philosophical tradition with a long history, Confucianism has a twofold relationship to science and technology. First, as a secular philosophy Confucianism has a natural affinity to science because it includes no superstitions and does not recognize supernatural forces. When asked, Kong Zi refused to speculate about gods, ghosts, and supernatural phenomena. His focus was entirely on this world and on things that can be known. In this respect Confucianism is not opposed to science and technology.

In ancient China technology had more to do with handicrafts than with science. The Confucian classic *Rites of the Zhou* (*Zhou Li*), which was compiled during the Warring States period, contains a chapter on various types of craftsmanship in society. It attributes to early sages the invention of various handicrafts, such as the making of knives and scissors, pottery, carriages, and boats, and explicitly recognizes the important role of handicrafts in society. The chapter maintains that excellence in craftsmanship requires an integration of four things:, good timing of the season, flourishing *qi* (cosmic energy) on earth, excellent material, and superior skills. From the Confucian perspective craftsmanship is not merely a matter of technique or skill but is understood holistically in the context of the Confucian cosmology. Whereas Daoism appeared to be antagonistic to handicraft, as indicated in the *Dao De Jing,* Confucianism was receptive to it because handicrafts can be instrumental to the prosperity of the family, which Confucianism values highly.

The affinity between Confucianism and science and technology has been evidenced by historical figures such as Shen Kuo (1031–1095), who was a prominent scientist in research, a successful technocrat in civic service, and a committed Confucian in his family life. His *Brush Talks from Dream Brook* is one of the most remarkable documents of early science and technology in China. Shen not only wrote commentaries on Confucian classics, a common practice among ancient Confucian scholars, but also in his theoretical discussions of scientific topics used philosophical concepts such as *yin-yang,* the Five Phases, and *qi*, which were shared by other Confucian scholars during his time. In Shen's eyes there is no contradiction between Confucianism and science and technology.

Traditional Chinese medicine has a close connection to Confucian cosmology. The *Yellow Emperor's Inner Chapters* (*Huang Di Nei Jing*), the primary ancient text of Chinese medical science and techniques, is consistent with Confucian cosmology. The fundamentals of the entire Chinese traditional medicine are rooted in the philosophical notions of *yin-yang,* the Five Phases, and *qi.* Although these notions also can be found in Daoism, Confucians embrace them profoundly, and they are the converging points of Confucianism and Daoism. Acupuncture, for example, is based on the belief that human health depends on the smooth flow of *qi* and a good balance of *yin-yang.* The philosophy of the Five Phases provides the foundation for Chinese herbal medicine in its belief that the myriad things in nature have various combinations of the Five Phases and that the balance of the Five Phases is instrumental to the balance of *yin-yang* and the nurturing of *qi.* For example, when someone's body has too much *yin* and is short of *yang,* a herb rich in Fire may boost that person's *yang* to restore the balance.

Confucius, 551 B.C.–479 A.D. Confucius founded his school of philosophy on the concepts of benevolence, ritual, and propriety. *(Source unknown.)*

Second, Confucianism is principally a moral philosophy and places the moral life above all other aspects of human activities. For Confucians the ultimate value of human activities depends solely on their contribution or lack of a contribution to the good moral life of humanity (*ren*). In other words, apart from its contribution to the good moral life, an activity does not possess any value.

This moral view has been subjected to narrow interpretations and at times has devalued science and technology. In particular, making too direct a connection between science and the moral life may not leave room for science to grow independently, which is often a necessary condition for the flourishing of science. Confucianism is not free from criticisms of this sort: At the beginning of the twentieth century one of the two main criticisms of Confucianism was its alleged impediment to science (the other was its alleged impediment to democracy). Some criticisms of Confucianism for its hostility to science might have been exaggerated, but they were not entirely groundless.

Kong Zi apparently was not interested in technical knowledge about the natural world. When a student asked him about agricultural knowledge and skills, his reaction was negative. Xun Zi was probably the only early Confucian who had a tendency to naturalize Confucianism, a viewpoint that could have assigned natural science a larger role in the Confucian value system if it had had a broader influence. Xun Zi believed that it is human nature to learn and to know and that what people learn and know is the nature of things. However, mainstream Confucian thought has always emphasized a moral worldview. That thought focuses on moral values as the core of the cosmos and centers human existence on moral existence. Kong Zi explicitly defined true knowledge as knowledge about human affairs rather than about the natural world. This attitude was reflected in the neo-Confucian Zhang Zai's (1020–1078) formulation of the contrast between "moral knowledge" and "knowledge of the senses" and his assertion that moral knowledge cannot grow out of knowledge of the senses. Placing these two kinds of knowledge in sharp contrast or even opposition further diminishes the importance of knowledge of the natural world in comparison to the importance of moral knowledge.

Zhu Xi was the second major figure after Xun Zi to offer a chance to elevate the status of knowledge about the natural world through his interpretation of *gewu zhizhi*, an ancient concept found in the *Daxue* chapter of the Confucian *Book of Rites*. He interpreted *gewu zhizhi* to mean the investigation of things and the expansion of knowledge. According to Zhu, things in the world have their reason or principle, which can be known through empirical observation. Zhu Xi evidently had a holistic view of the world and saw a direct connection between empirical knowledge of the natural world and moral knowledge. For him the purpose of *gewu zhizhi* is to improve people's moral knowledge. Because his notion of *gewu* includes the empirical study of the natural world, he opened a door to scientific knowledge. Presumably, the investigation of things could lead to scientific knowledge about the natural world.

Unfortunately, Zhu Xi's course was reversed by another major neo-Confucian thinker, Wang Yangming. Wang initially tried to act on Zhu's idea of *gewu zhizhi* by attempting to investigate the bamboo in his yard. However, he failed miserably because he could not get any meaningful knowledge through his diligent observation of the bamboo. Wang then changed course and claimed that all useful knowledge is to be found within the heart-mind (*xin*); there is no need to look outside the heart-mind. Wang's judgment inflated to an extreme the Confucian conviction that a person's primary mission in life is to develop his or her humanity and failed to assign adequate value to the pursuit of the knowledge of the natural world. This tendency lasted till the twentieth century.

Contemporary Discussions

As science started to gain ground in Chinese society in the early twentieth century, Confucian thinkers tried to preserve the territory of moral philosophy by separating science and philosophy into two distinct realms. They argued that whereas science deals with the physical world, (Confucian) philosophy deals with the metaphysical and moral realms; therefore, the two do not conflict. After the founding of the People's Republic of China in 1949, Confucianism was subjected to severe criticisms and at times brutal repression in mainland China, although it had a significant revival during the last two decades of the twentieth century.

However, Confucianism never stopped developing. Mou Zongsan, who lived his most productive years in fHong Kong during the second half of the twentieth century, articulated a new Confucian stance on science and greatly expanded the room within Confucianism for scientific knowledge. He maintained that traditional Confucian culture failed to give adequate recognition to the form of knowledge called *zhi xing* (formal, logical thinking) and argued that to embrace both science and democracy, the spirit of Chinese culture needed "to negate itself into" the mode of *zhi xing*. Mou's philosophy marked a turning point in the long debate among Confucian thinkers about the role science and technology play in the good life and was an important stage in the development of Confucianism. After Mou the importance of science and technology was no longer an issue for Confucians.

Some scholars have attempted to interpret the history of Confucianist interactions with science and technology in a different light, arguing that Confucianism has not been as unfriendly to science and technology as sometimes is alleged. They cite the fact that science and technology in early China under Confucianism flourished and that many ancient Confucian scholars were also great scientists and technological innovators. For example, it was during the Han dynasty, when Confucianism was made the state ideology, that the basic Chinese sciences were established. Those sciences included mathematics, mathematical harmonics, mathematical astronomy, and medicine. It is possible that the attitude of Confucianism toward science and technology varied at different times, affected by specific social circumstances and influenced by individual Confucian thinkers' personal beliefs. Confucianism might have been more congenial to science and technology at certain times. It is also true that within Confucianism there is a full range of opinions on issues related to science and technology, with some being more liberal and others more conservative.

Contemporary Confucians recognize the importance of science and technology in society and in moral philosophy. Because Confucianism advocates a virtue ethics and is concerned with the full development of the holistic person, it recognizes the indispensability of ethics in science and technology in achieving that goal. Furthermore, because the goal in Confucianism is to make the *ren* person, achieve a *ren* society, and generate a harmonious world, all human activities, including science, technology, and ethics, are to serve that purpose directly or indirectly. Kong Zi said that a good person should not be a mere tool. A committed Confucian does not engage in science for the sake of science or promote technology for the sake of technology. In addition to "Is it true?" or "Does it work?" a Confucian would ask questions such as "What purpose does it serve?" "How does it contribute to the good society?" and "Does it make the world a better place?"

A case can be made that Confucianism may be more receptive to contemporary medical research, such as embryonic stem cell research. Without a doctrine of the divinely created soul, Confucians believe that a person is not born with moral worth and has to earn it through moral cultivation. Therefore, strictly speaking, the human embryo or the fetus is merely a potential human person, not yet a moral entity. Drawing on this notion, Confucians may not see embryonic stem cell research, which requires the destruction of the embryo, as morally problematic. After all, cracking an acorn is not the same as destroying a giant oak tree even though an acorn could grow into a giant oak tree.

Although Confucianism is not opposed to the development of technology, with the rapid technological advancement in the early twenty-first century, Confucians are concerned with its negative impact on the environment, its harmful effects on a harmonious world where humans and nature are closely integrated. If one uses the word *ethics* broadly to encompass the Confucians' goals of the moral life, ethics remains the primary concern for Confucians; science and technology are important tools that serve these purposes.

CONSCIOUSNESS

Something is conscious if there is *something that it is like to be* that thing. This widely accepted definition, proposed by philosopher Thomas Nagel (1974, reprint 1997 p. 519), emphasizes the *subjective character* of conscious experience, which is the fundamental obstacle to its scientific investigation. Scientists have no objective access to conscious states (even their own) so consciousness can only be studied scientifically by indirect means, and some believe that a complete scientific description of the world can and should be made without reference to consciousness at all. However to exclude conscious decisions from the causal chain of events would undermine all ethical and legal systems based on personal responsibility for consciously willed actions.

In the 1980s, neurophysiologist Benjamin Libet showed that when subjects were asked to make a voluntary movement at a time of their own choosing, brain activity initiating the movement (the *readiness potential*) routinely preceded by about half a second the conscious decision to make the action. Many people interpreted this as scientific proof that conscious choice and freewill are illusory, which would fit with the view that the physical universe is causally closed and deterministic. Libet himself safeguards personal freedom of action by arguing that although the brain's non-conscious readiness potential initiates an action, there is still time for the conscious mind to monitor and abort the process before the action is carried through.

Libet's work was an early example of scientific research into consciousness that combines objective information about brain activity with subjective reports from experimental subjects concerning their conscious states. Earlier generations had been handicapped by the need to choose between subjective and objective methods. Typical of these were *introspectionism*, pioneered by German psychologist Wilhelm Wundt (1832–1920), which depended on individuals analyzing their subjective thoughts, feelings, and perceptions into thousands of basic mental sensations, and the *behaviorism* of John Watson (1878–1958) and his successor B. F. Skinner (1904–1990). Watson rejected introspection, maintaining that if psychologists wanted to be real scientists they must study objective, verifiable data, which meant observable behavior. Such was his influence that consciousness was effectively banned from psychology for half a century in the mid-1900s.

The scientific study of consciousness was rehabilitated in part by new technologies that allowed the working of the brain to be objectively studied while mental processes were being carried out. The *electroencephalogram* (EEG), recording electrical activity in the brain, was available from the 1930s and used by Libet among others. Brain scanning techniques such as *positron emission tomography* (PET) and *functional magnetic resonance imaging* (fMRI), developed in the 1980s and 1990s, enabled detailed observation of active areas of the brain at work and confirmed the hypothesis that mental states are closely related to the physical condition of nerve cells (neurons). Neuroscientists were now able to observe the areas of neural activity associated with particular conscious experiences reported by human subjects, or deduced from the behavior of animals such as monkeys. Various systems in the brain were investigated, from individual cells to large networks and pathways of interconnected neurons, in the quest to identify possible *neural correlates of consciousness* (NCCs).

The exact relationship between conscious experience and the physical brain, and how and why some brain processes are conscious at all, is the core dilemma. David Chalmers, Director of the Center for Consciousness Studies at the University of Arizona at Tucson, has dubbed it the *Hard Problem*. In the mid-twentieth century the influential Oxford philosopher Gilbert Ryle (1900–1976) dismissed Descartes's dualist concept of mind-body relation as the *ghost in the machine*, and opened the way for various materialist accounts of consciousness. By the turn of the millennium most consciousness researchers embraced some form of *non-reductive materialism*, which holds that mental states are wholly caused by the physical brain, but have some quality over and above the sum of their molecular components. Variations on this theme include *property dualism* (mental states exist as properties of underlying physical states), *dual aspect monism* (the mental and the physical are two ways of looking at a single underlying reality), *emergentism* (consciousness emerges at a certain level of complexity), and *panpsychism* (every material object has an actual or potential degree of consciousness).

Treating consciousness as a real aspect of the physical world brings it back into the realm of scientific inquiry and removes the suggestion that it is an *epiphenomenon*, lying outside the causal nexus of the universe. But it does not automatically refute the claim that free choice and moral responsibility are delusions. The physical world of which consciousness is a part still appears to be deterministic, at least according to classical physics. Researchers into artificial intelligence, for instance, have drawn parallels between neuronal activity in brains and the processing of information in computers The question of whether the conscious mind itself is computational, that is, completely describable mathematically and therefore in deterministic terms, is hotly disputed.

Deterministic views are challenged within science by evidence from quantum physics, although its relevance is disputed and some of the claims speculative. For example, Oxford mathematician Roger Penrose proposes that in certain special conditions, found in the microtubules within brain cells, quantum systems provide the physical mechanism that brings about noncomputational conscious events. From a different starting point, Berkeley physicist Henry Stapp argues that quantum theory can explain how consciousness plays a creative role in shaping events and creating the world as humans know it. These views are frequently criticized, but at the very least, quantum theory puts a large question mark over the old assumption that the universe is a collection of objective facts that are (in theory at least) completely knowable.

Consideration of the ethical questions posed by the investigation and manipulation of consciousness falls under the sub-discipline of neuroethics. But the challenge to produce an account of conscious experience that provides an adequate basis for morality at all, and is at the same time both philosophically and scientifically robust, lies at the heart of all consciousness studies.

CONSENSUS CONFERENCES

Consensus conferences are one of several practices (including citizen juries, scenario workshops, and deliberative polls, among others) intended to enhance deliberative public involvement in shaping social decision making about science and technology. Because public issues increasingly include complex scientific and technological components, and because the general public lacks the needed scientific knowledge, the management of those issues seems inevitably to slip out of the hands of ordinary citizens. Democratic governance, however, rests on the informed consent of ordinary people, and many observers worry that in numerous areas ordinary citizens are becoming less able to shape public policies.

Basic Issues

The basic concept behind consensus conferences is that public policies about science and technology will be improved significantly if policy makers can hear informed, deliberative public perceptions, concerns, and recommendations as they consider the choices they face. Informed and thoughtful public participation may also help to blunt two features of contemporary policy making about science and technology: intense and acrimonious partisan advocacy by both proponents and opponents of specific scientific and technological projects, and local Not-In-My-Backyard (NIMBY) campaigns based in communities likely to be directly affected by those projects. In the first case, proponents and opponents of specific science and technology projects make sensationalized and exaggerated claims about the wisdom and foresight of their perspective and the mean-spirited and hysterical positions of their antagonists. All too often, ordinary citizens (who must live with the consequences of the policy decision) are unable to sort through the conflicting claims and counterclaims. In NIMBY situations, local citizens—often frustrated by the blare and noise of partisan bickering, and distrustful of all sides in the controversy—organize to oppose, delay, and obstruct projects desired by others.

Both processes result in political and policy paralysis, the spread of cynicism and apathy, and delay in addressing pressing public needs. Consensus conferences seek to address both problems by providing a group of average, non-expert citizens with the opportunity and the resources to conduct an informed and deliberative investigation of specific technologies, to develop policy recommendations they can all endorse, and to deliver those recommendations to policy makers and the public. In this way, consensus conferences allow the deliberating citizens to confront partisan advocates with reliable information rather than sensationalism, and also help to dissipate cynicism about governmental decision making that contributes to NIMBYism.

Danish Model

The Danish Board of Technology (BOT), a research arm of the Danish Parliament, developed the basic model of a consensus conference. Several months before the parliament must address an issue with significant science and technology elements, members of the parliament may ask the BOT to conduct a consensus conference on the issue. The lead time helps assure that citizen evaluations and recommendations are available to legislators in time to help shape parliamentary debates.

The BOT takes several steps to implement a consensus conference:

- It assembles an Oversight Committee, made up of experts and stakeholders in the specific technology under inspection.
- It develops background information about the technology and its probable social, economic, political, and ethical implications.
- It recruits twelve to fifteen Danish citizens to serve as the citizen panel. The citizens are paid a stipend to cover the costs of participation.
- And, finally, it conducts the consensus conference and makes the results available to parliament, the press, and the public.

The Oversight Committee serves to guide development of the background materials that will be given to citizen panelists. Because the Oversight Committee is composed of individuals reflecting the full spectrum of opinions about the technology in question, the Committee helps to assure that background materials are fair, accurate, and accessible to ordinary people. The Oversight Committee also monitors recruitment and selection of the citizen-panelists. In a broad sense, the Oversight Committee serves to keep the entire process honest, to prevent intentional or unintentional partisan slanting of background materials or of makeup of the panel.

The actual work of the consensus conference typically takes place over three weekends, about one month apart. This marks the consensus conference as one of the most intense public participation techniques, because most other practices last only one or two days, or even two or three hours.

During the first weekend, the panelists get acquainted with each other, with the staff facilitating the sessions, and with the processes and goals of the conference. They read and discuss the background materials, and are encouraged to raise whatever issues or concerns are important to them. In this sense, the consensus conference differs from a traditional focus group in which the panelists are asked their reactions to issues raised by the focus group sponsors. In effect citizens are given control of the agenda in a consensus conference. During the second weekend, the citizen members continue to discuss the technology and the background materials, and to sharpen their issues and concerns. They also begin to develop a series of follow-on questions for content experts who will attend during the final sessions.

During the final weekend—the actual Consensus Conference—three things occur. On the first day, a series of content experts, who reflect the spectrum of opinions within the expert community, provide responses to the follow-on questions the panelists raised earlier. This is followed by an open-ended question-and-answer session, with all the experts and panelists present. The panelists can thus ask any remaining questions, probe earlier responses, and seek clarifications.

After this, panelists withdraw (along with a facilitator) to deliberate. Their goal is to arrive at a common set of policy recommendations that express their collective judgment about how best to manage the technology. This task often lasts into the early hours of the morning.

The panel's report is submitted to the content experts to catch any remaining technical errors, but the experts do not comment on the policy recommendations. The report is then delivered to parliament and the public at a press conference. The staff of the BOT point to the frequency with which contending policy constituencies refer to consensus conference reports during parliamentary debates as evidence that consensus conferences help to shape policy outcomes.

In Denmark consensus conferences have addressed an array of science and technology issues, such as genetically modified foods, infertility, the human genome project, teleworking, and transgenic animals. Consensus conferences have been organized in several other countries—including Argentina, Australia, Austria, Canada, France, Germany, Israel, Japan, the Netherlands, New Zealand, Norway, South Korea, Switzerland, and the United Kingdom—although no other country has adopted the practice as thoroughly as the Danes. Consensus conferences have been conducted about fifteen times in the United States as parts of public deliberation research.

Consensus conferences in the United States have been held at the University of Massachusetts ("Telecommunications and the Future of Democracy"), the University of New Hampshire ("Genetically-Engineered Foods"), and ten times at North Carolina State University (two conferences dealing with "Genetically Modified Foods," six Internet-based conferences dealing with "Global Warming," and two conferences dealing with "Nanotechnology"). The North Carolina State conferences were part of a National Science Foundation supported research project dealing with public deliberations about science and technology.

Further Developments

The literature about public deliberations points to a number of concerns or problems that arise when citizens deliberate together. Groups of average citizens, when deliberating, employ a variety of *decision heuristics* which, observers worry, may introduce distortions into their thinking. Ordinary citizens, for instance, seem to focus on the *risk of the month*, shifting concern from one kind of risk to another based on which risk is currently receiving the most public discussion or which has been in the news (the *availability heuristic*). Similarly they seem to draw conclusions about the dangers of specific products through *mental shortcuts*that can lead to factual errors about actual risks (*intuitive toxicology*). Risks or dangers that are exceptionally vivid also seem to gain greater public awareness, regardless of actual statistical probability (the *affect heuristic*). Critics also point to various *social cascades* in which unsubstantiated beliefs gain credibility simply because they are constantly repeated. Group polarization is another feature of some pubic deliberations. This involves the tendency for a group's final conclusions to support the group's original position, rather than a more centrist or moderate one.

The majority of studies pointing to such cognitive problems among ordinary citizens, however, focus on unfacilitated public deliberations. The current research suggests that many of these cognitive problems can be adequately addressed if professional and well-trained facilitators lead the public deliberations. Effective facilitation can, for instance, ameliorate the influence of strong-willed or domineering personalities, insure that citizen panelists are exposed to a wide argument pool, and detect and correct inappropriate decision heuristics. Consensus conferences, in particular, provide ample room for the beneficial effects of good facilitation, and provide sufficient time for the panelists to acquire substantial background information and to interact with a range of content experts. While these steps may not correct all cognitive and process issues in public deliberations, they can successfully address the most egregious problems.

Supporters of consensus conferences hope that the technique can be used wherever democratic governance of new technologies is pursued. While the outcomes of informed, deliberative citizen consideration of new technologies cannot substitute for the procedures of democratically elected government, consensus conferences may provide a mechanism for greater influence by ordinary citizens in the shaping of public policies concerning technologies that all must live with, and thereby create an enhanced level of democratic credibility for governmental decisions.

CONSEQUENCES

SEE *Unintended Consequences*.

CONSEQUENTIALISM

As a general category of ethical or moral theories, consequentialism refers to theories that evaluate rightness or wrongness based *exclusively* on the consequences or effects of an act or acts. Consequentialist theories may differ over what kinds of consequences matter, while agreeing that the rightness or wrongness of actions cannot be based on motives or intentions of those who act, nor on the conformity of the act to duty, virtue, piety, moral rules, or the law. Consequences are all that matter for ethics, on this view. According to consequentialists, some murders might turn out to be morally right, while some acts of sincere generosity might be wrong.

Consequentialism is the ethical theory most compatible with the empirical and quantitative focus of much of science and technology. When a consequentialist studies ethical issues in science and technology, an act is usually understood broadly to include national and local policies, programs, distributions of resources, implementations of new technologies, and the like. Consequentialism seems particularly well suited to evaluate these kinds of complex acts, because it shares with modern, positivistic science an emphasis on observation. Just as one might form and test a hypothesis about electromagnetic radiation, so too could one test an act or policy that one believes to be right. In both cases, one looks to results in the real world in order make an evaluation.

Also, consequentialist theories take into account short- and long-term effects, and hence can evaluate developments such as nuclear power, where the immediate good effects (electricity without air pollution) may be outweighed by later harmful effects (radioactive waste, illness). In focusing on observable effects over time, consequentialists seem to look in the obvious places for answers to ethical questions concerning emerging technologies. To evaluate such complicated developments as genetic engineering, nanotechnology, the Internet, or even automobile transportation, where else would one look but to the effects?

Despite the intuitive appeal of consequentialism for such ethical inquiries, the view has faced serious opposition, especially from philosophers, as its proponents try to specify which consequences are relevant to moral evaluation. The historical development of consequentialism shows a constant struggle to identify the morally relevant effects of acts and to measure them. Consequentialists have sought to elucidate a scientific ethical theory for difficult contemporary issues, but with mixed results.

The Classical View: Act Utilitarianism

The most influential version of consequentialism is known as *utilitarianism*. The basic idea behind this view is quite simple. One consequence that almost anyone would want from an act is an increase in happiness, because happiness is undeniably a good. This is the conception of the good from which utilitarianism begins, and further developments in utilitarian theory almost always get back, in some way, to the content and measure of happiness.

Utilitarians are not merely interested in their own happiness; they advocate the "greatest happiness of the greatest number." According to the founder of classical or *act utilitarianism*, Jeremy Bentham (1748–1832), an act is right if its overall tendency is to increase the proportion of happiness (or pleasure) to pain.

If one has a choice between several acts in some situation, one ought to choose the act with the best *net* effect on utility. In some cases this will be the act that increases everyone's utility. In other cases, the best act would do no more than decrease everyone's pain. For most complex acts and policies, though, the result is complicated; the same act may include both some utility and some disutility. Hence Bentham realized that he would need a quantitative method for calculating the best utilitarian act. He proposed a "felicific calculus" that attempted (unsuccessfully) to supply cardinal measurements for the utility of an act based on its intensity, duration, certainty, and similar factors. By summing measurements for every act over all those who would be affected, utilitarians could instruct society on how incrementally to increase the amount of utility its members enjoyed. Act utilitarianism, if carried out rigorously, promised a program of social reform. For individuals who used the theory to evaluate their acts, the calculus required them to count the happiness of others as though it were their own. In principle, it provided an argument for an impartial and equitable distribution of the fruits of the new industrial revolution.

Another significant aspect of Bentham's view is that his principle of utility seeks, in the long run, to maximize the utility of all sentient beings—every being that can feel pleasure or pain. In this way his theory grants moral status not just to humans, who alone can reason and talk, but also to *any* animal that can feel or suffer. Bentham argued that the pain of non-human animals must count in the felicific calculus; his view would inspire later animal rights advocates and contemporary utilitarians such as Peter Singer. Utilitarianism thus became the first modern moral theory to take seriously the harm done by humans to other animals.

Despite its progressive social and political tendencies, act utilitarianism faced major problems. Even if individuals could calculate a cardinal measurement of personal utility from a particular act, they could not be sure that this measurement was on the same scale as a measurement for another person. But the theory requires the summing of utilities over the class of those affected by the act. Utilitarianism requires cardinal *interpersonal* measurements of utility—numbers on the same scale, valid for everyone. Supposing that the theory could provide such a scale, it then seemed to *demand* constant calculation for every act, because what is required morally is to come up with the greatest sum of utility. Every option in acting would have to be considered, and such exhaustive calculations might lead to paralysis.

Finally, act utilitarianism seemed to embrace a brutish theory of the good; the pleasure of thousands of cows, chewing their cud, might outweigh the utility of a college education for one person. If there were tradeoffs to be made—and the emerging free markets of Bentham's time made those tradeoffs possible—one might end up with many satisfied cows instead of a few educated people. Worse still, act utilitarianism might ask a sacrifice of the rights of some for the utility of others. Because every good was to be reduced to utility, even future commitments of justice seemed to be beholden to the arithmetic of maximization.

Rule Utilitarianism

Bentham's protégé, John Stuart Mill (1806–1873), addressed some of the shortcomings of act utilitarianism by proposing three changes. First, he found Bentham's ethical calculations too cumbersome, and proposed instead that society adopt and enforce a set of rules which, when followed, were likely to produce the highest overall utility. The best way to be a utilitarian, on this view, would be to act according to a rule that, in conjunction with other rules, prescribed behavior that maximized total social utility. One rule could replace another in the set, provided that the change would contribute to greater overall utility. But absent now in Mill's *rule utilitarianism* was the requirement—or even the possibility—of a quantitative calculus for determining which acts to choose. Second, Mill introduced a qualitative distinction between higher and lower pleasures, thus undermining the notion of a common scale for ethical measurement, and implicitly relegating the happiness of non-human animals to insignificance. Finally, Mill argued that certain rules, what he called the rules of justice, were so important to the long-term security (and hence happiness) of society that they must be considered practically inviolable. The results of these changes made the application of rule utilitarianism less scientific but much more in line with common sense morality. Mill's theory still shared the goal of Bentham's original utilitarianism, but it allowed notions such as duties, rights, and virtues to be means to the end of increased social utility.

Market Consequentialism

By the early twentieth century, utilitarian moral philosophers and economists became interested in market activity as a replacement for the direct measurement of the consequences of an act. They saw preferences, revealed in market supply and demand, as an approximate (though indirect) indication of the utility that a single person gains by a market "act." They also were able to represent mathematically an individual's preferences over bundles of goods, and to prove some interesting theorems about these "utility functions" of individuals. By analyzing market preferences, economic consequentialists could provide quantifiable evidence of what made consumers happy. To be a consequentialist about market preferences meant to choose the act or policy that allowed all persons their highest-ordered preferences, given what an economy could supply.

The economic version of utilitarianism was made even more sophisticated by the addition of a formal theory of individual choice under uncertainty, introduced by John von Neumann and Oskar Morgenstern (1944). Their theory generated cardinal measurements of expected utilities for strategic individual choices, given plausible assumptions about an individual's utility function. Working from the results of von Neumann and Morgenstern, John Harsanyi (1955) would later provide a complementary justification of utilitarianism for social choice by employing the notion of a "social welfare function." By the end of the twentieth century, economists had transformed ethical questions over how to reach the best consequences into economic questions over how to increase market activity, trade, social welfare, and global production.

The economic consequentialists have influenced many other fields. In jurisprudence, a theory known as the economic analysis of law has advocated the interpretation of legal concepts so as to maximize wealth. In business and public policy, the cost-benefit analysis has been introduced as a decision procedure for large-scale projects. A question such as where to dump toxic waste, when addressed by the cost-benefit analysis, provides a utilitarian solution to disputes by reference to the hypothetical willingness to pay of the interested parties affected by the possible outcomes of the decision. It is not surprising then that hypothetical willingness to pay is affected by the actual ability to pay, and so the fact that dump sites end up in poor neighborhoods is explained by this "ethical" decision procedure. The Nobel laureate Amartya Sen (1970, 1985) has been the most important critic of utilitarian economics on these issues. His contributions to the debate have focused on poverty, development, and the measurement of "capability" (as opposed to raw utility) in accounting for the bases of social choice.

Pluralist Conseqentialism

Many contemporary philosophers worry that developments in utilitarian theory have undermined the spirit of consequentialism. They point out that the everyday conception of human flourishing is not as thin as wealth maximization. The British philosopher G.E. Moore even advocated an "ideal" utilitarianism that got rid of the notion of pleasure as the good, and replaced it with the good of aesthetic experience and friendship (1993). It now seems clear that, while utility may be a good, and wealth one approximation of it, there are many other goods that do not reduce to either utility or wealth. By adopting a pluralist conception of goods, critics of utilitarianism allow into the ethical decision process notions like interests, rights, human freedom, biodiversity, sustainability, and other non-economic values.

The pluralists continue to maintain that what is right to do is decided by reference exclusively to consequences—but now the list of goods in the accounting is much broader than utility. Here talk of maximization no longer makes sense; the goal is to optimize the plural goods that result from acts or policies. Stakeholder theory is one such form of consequentialism, because it tries to tailor corporate decisions to the interests of all those who have a stake in the workings of the company, and not merely to those who hold stock in it.

Special Challenges

How useful is consequentialism when one morally evaluates technologies? A particular area of ethical concern is the effect of current and near-term technologies on future generations. Nuclear power, genetic engineering, human cloning, genetic modification of food, and other momentous programs will all have effects far into the future. Some versions of consequentialism would require a counting of the effects on those who are not yet alive, even though their preferences cannot be known, and actions and choices have not yet had an impact on them. It may be assumed that, if they live, they will want clean air to breathe, clean water, safe food, and other such necessities. Harms to distant generations may be discounted by some factor, but should not be neglected entirely, for then all the consequences of acts and policies are not taken into account.

Beyond the uncertainty of how much to discount, there is a deep problem for consequentialism that has been called by Derek Parfit (1984) the "non-identity problem." One assumes that the broad technological choices that are made now could harm particular people in future generations. But a consequentialist in some future generation could not complain that current policies and choices made his or her life worse off, because the things done now will affect *who* is actually born. That person will not exist, unless people currently living do exactly the good or bad things that they end up doing. Changes in manufacturing, travel, city planning, leisure, and work will determine which future people will meet and partner, and at what point in time they will produce children. The same is true for changes in technology. Similarly, for actual persons alive in the early twenty-first century, it is extremely unlikely that *they* would have been conceived were it not for the transportation systems, migration patterns, world wars, and other life aspects of their parents.

Philosophical debate over consequentialism is likely to persist. Nonetheless, its focus on observable results and effects will keep it in the center of ethical inquiries where science and technology are concerned.

CONSERVATION AND PRESERVATION

Ideas of *conservation* and *preservation* play central roles in ethical discussions of science and technology, especially in relation to nature and the environment. The terms also figure prominently in museum and historical work, where programs of conservation (not losing) and preservation (protecting from deterioration) are associated with specialized sciences and technologies. With regard to environmental issues, the concepts appear more closely related, both implying respect for nature.

John Muir versus Gifford Pinchot

Since the early-twentieth-century break between Gifford Pinchot (1865–1946), first director of the U.S. Forest Service, and John Muir (1838–1914), founder of the Sierra Club, conservation and preservation have sometimes served as technical concepts with different connotations. In this context, conservation signals rational human use, preservation a protection from human use.

Although originally allies in creating Yellowstone, the first national park, in 1872, Pinchot and Muir took opposed positions in the debate, which lasted from 1909 to 1913, over building a dam in the Hetch Hetchy valley of Yosemite National Park in order to supply water to a growing San Francisco. Pinchot believed that "The first great fact about conservation is that it stands for development" (Pinchot 1910, p. 42); the only question was what kind of development, and whether for short-term single-focus exploitation or long-term multiple public use. For Muir, by contrast, national parks were to be preserved in their original form. "Dam Hetch Hetchy! As well dam for water-tanks the people's cathedrals and churches, for no holier temple has ever been consecrated by the heart of man" (Muir 1912, chap. 15).

Out of this debate, which Muir and the Sierra Club lost, began a tension in the environmental movement between those who seek to conserve and those who seek to preserve nature. Conservationists sometimes accuse preservationists of failing to appreciate human needs. Preservationists accuse conservationists of being too willing to compromise the intrinsic value of nature when faced with economic or political interests. The issue, in these terms, will only grow sharper as world population races toward doubling by 2050.

The Preservation-Conservation Spectrum

But the distinction between conservation and preservation is not always clear, and in fact environmental policies may often line up along a spectrum from protection of nature or ecosystems for their own sake to libertarian exploitation. The spectrum also to some degree parallels that between ecocentric (nature centered) and anthropocentric (human centered) environmental ethics. The extreme protectionist position, evident in wilderness preservation slogans and policies, and exemplified by *Earth First!* direct action, views natural systems as possessing intrinsic value independent of human use and as better off if protected from human interventions of any kind. Conservation would fall not necessarily on the other extreme, in which nature is presented as devoid of intrinsic value except insofar as it is available for obligatory human exploitation, but somewhere in the middle.

The spectrum is slightly complicated by self-defined conservationists such as those identifying with the *Wise Use* movement, which is especially hostile toward *radical environmentalists*. According to Wise Use advocates, the pastoral ideal was kidnapped by urban wilderness ideologues who lack the living relation to the land found among farmers and ranchers and thus fail to appreciate the value of the human transformation of the earth (Arnold 1996, 1998). But given its stress on the rights of property owners to develop land in virtually any way they see fit, Wise Use is perhaps more concerned with libertarian free enterprise than with the environment.

Nevertheless conservationists do tend to stress the importance of human interests, needs, and wants over any intrinsic values nature or the environment may be thought to possess. Yet this emphasis is easily combined with various gradations emphasizing high to moderate degrees of preservation of nature from human use and with a range of balances between natural and human needs in relation to natural exploitation.

Furthermore the spectrum need not be considered simply linear. Robert Paehlke (1989) argues that preservationist and conservationist views are distributed on a grid of two axes, with the left-right political spectrum crossed by a vertical axis running from environmentalism to anti-environmentalism. The point is that environmentalists and their opponents, on ethical as well as political grounds, use terms such as conservation and preservation—along with related terms such as sustainable development and restoration ecology—in myriad and often idiosyncratic ways. Careful analysis in conjunction with accurate observation of real-world practices is necessary to know what individual groups actually mean.

Practical Applications

The implications of these controversial word uses for science and technology may not always be obvious either. Certainly strong preservation environmentalists view major technological exploitations in nature (oil drilling and pipelines, for example) as wholly negative, whereas extreme opponents believe in a technological fix for any natural shortfall, even the extinction of species or ecosystems (through DNA rather than whole species preservation), while conservationists tend to be open to a modulated range of technological interventions, including the techniques of restoration ecology.

Radical preservationists sometimes oppose further scientific examination of nature, arguing instead for the sufficiency of existing research and for more aesthetic or experiential appreciation of nature. Their opponents, by contrast, often demand something close to scientific certitude concerning problems—as in the global climate change debate—to justify any change in exploitation patterns, and thus defend making more public funds available for environmental research. Such critics view radical preservationists as too willing to accept the flimsiest of scientific evidence.

In still one more somewhat ironic comparison, those who would protect the environment from human degradation often advocate advanced technologies that pollute less and promote high-tech gear to assist individuals in the noncontaminating exploration of wilderness. Such technologies may even include photographs and IMAX presentations designed to cultivate the aesthetic appreciation of nature as something good and beautiful in itself among those who may never have any direct wilderness experience. In opposition, those who would promote diversified human utilization sometimes find themselves apologizing for whatever technologies exist and denigrating innovations that could both improve exploitation and protect nature. One example might be defending personal automobile and snowmobile use in national parks when light rail or other innovations could enhance accessibility for all, including some such as the handicapped, who have previously been excluded. Diverse assessments of ecotourism have also been known to conflate expected conservation and preservation divides.

CONSERVATISM

An assessment of conservative ideas about the relationship between ethics, science, and technology must begin with a brief discussion of conservatism itself. Unlike liberalism, fascism, or communism, conservatism cannot be identified with a particular conception of the ideal society. In its broadest meaning, conservatism means simply "adherence to the old and tried, against the new and untried," as Abraham Lincoln put it in his Cooper Institute speech (Lincoln 1989, p. 122). If this definition is accepted, one can be "conservative" about almost anything that has lasted a long time.

In Europe and North America over the last few centuries, however, conservatism has been associated with a defense of classical liberalism in politics and economics against first the radicalism of the French Revolution and then against socialism, Communism, fascism, and Nazism. In making this defense, conservatism has also accepted and supported the achievements of science and technology so closely identified with liberalism and capitalism. European and North American conservatism since the French Revolution is thus an inherently paradoxical enterprise, because some of the key institutions it seeks to conserve, including science and technology, are themselves generators of change. Conservatives primarily interested in economics are more likely to welcome such change than religious and cultural conservatives. Conservatism nevertheless sharply differs from the philosophical liberalism of thinkers such as John Dewey or John Rawls in that all conservatives, whatever their primary interest, insist there are sources of moral authority beyond the liberal consensus. These include revealed religion, natural law, and the insights derived from humanistic study. Science, conservatives believe, cannot answer fundamental questions about the meaning of life, nor can technology resolve the most important ethical dilemmas.

Limited Criticism of Science and Technology

Because of its emphasis on the limits of knowledge that science can make available and the benefits technology may confer, conservatism is often mistakenly associated with the wholesale condemnation of technology associated with Romanticism and also promoted by radical theorists such as Herbert Marcuse who, in *One-Dimensional Man* (1964), views technology as a form of social control and domination. The Southern Agrarians, a group of poets and writers who defended the traditions of the U.S. South, including racial segregation, in *I'll Take My Stand* (1930), were writing as romantics rather than conservatives when they objected to technology itself, as when Andrew Lytle proclaimed "a war to the death between technology and the ordinary human functions of living" (p. 202) and argued that the South "should dread industrialism like a pizen snake" (p. 234). The most influential heir of the Agrarians, Richard Weaver (1910–1963), adopted a more representative conservative viewpoint when, in *Visions of Order* (1964), he criticized not science itself but "barbarism nourished by . . . scientistic fallacies" (p. 151) and "pseudoscientific images of man" (p. 153).

The Spanish philosopher José Ortega y Gasset (1883–1955) went further in defending science when he asserted in *The Revolt of the Masses* (1930) that "liberal democracy based on technical knowledge is the highest type of public life hitherto known" (p. 52). Yet mainstream twentieth century conservatives in England and the United States shared his belief that the key issue was to find a way to maintain the real achievements of liberal democracies in the face of totalitarianism, just as conservatives in the twenty-first century seek to guard those achievements against the threats posed by new political and religious fanaticisms. Ortega believed that totalitarian regimes were made possible by the rise of the "mass-man" who felt only "radical ingratitude" toward the developments in science and technology that "has made possible the ease of his existence" (p. 58).The masses do not grasp that the devices they take for granted are really "marvels of invention and construction which can only be maintained by great effort and foresight" (p. 60). Ortega believed scientists could scarcely avoid becoming mass-persons themselves, because the specialization required by modern science made it impossible for individual scientific workers to understand science as a whole and thus achieve comprehensive vision of the universe. At the same time Ortega warned that attempts to return to a pre-industrial way of life would be suicidal.

Limited Authority of Science and Technology

Western conservatism has accepted the authority of the physical and biological sciences within their own sphere, but has sharply questioned the application of the methods of the natural sciences to the study of human beings. Edmund Burke's description of the moving spirits of the French Revolution in his *Reflections* (1790) indicts not scientists but pseudo-scientists: "sophisters, oeconomists, and calculators" (p. 170). An American admirer of Burke, Irving Babbitt (1865–1933), based his New Humanism on the distinction between what Ralph Waldo Emerson called "law for man, and law for thing" in his "Ode, Inscribed to W. H. Channing." The neglect of that distinction, Babbitt argued in his first book *Literature and the American College* (1908), leads to an intellectual climate in which "Man himself and the products of his spirit, language, and literature, are treated not as having a law of their own, but as things; as entirely subject to the same methods that have won for science such triumphs over phenomenal nature" (p. 86). Babbitt summed up his views in a short 1930 essay, "What I Believe." Although he objects when "the pseudo-scientist claims for physical science a hegemony to which it is not entitled" (p. 11), he also disclaims the romantic condemnation of intellect itself. For Babbitt the exaltation of feeling unrestrained by thought and the exaltation of mechanical efficiency for its own sake are merely two sides of the same coin. He counters what he considers the dominant trend of the age with a call for a "positive and critical humanism" (p. 14) based on a reaffirmation of "the truths of the inner life" (p. 18).

Contradictions

George Santayana (1863–1952) argued in "The Genteel Tradition at Bay" (1931) that Babbitt's New Humanism was only the last gasp of a *genteel tradition* that neither expressed nor understood what was truly dynamic in American society. Santayana had described the United States in "The Genteel Tradition in American Philosophy" (1911) as a "country with two mentalities, one a survival of the beliefs and standards of the fathers, the other an expression of the instincts, practice, and discoveries of the younger generations" (p. 39). Scientific and especially technological developments were an expression of the younger generation, while religion, philosophy and the arts were under the control of the "hereditary spirit" (p. 39) of the genteel tradition. The contrast between the two mentalities could be symbolized by the difference between two characteristic products of American architecture: the "sky-scraper" (p. 40) and the "reproduction of the colonial mansion" (p. 40). A philosopher, Santayana intimated, should understand that the new society could not be judged according to the criteria of the genteel tradition but must be accepted on its merits and judged on its own terms.

In *Reason in Science* (1906) Santayana criticized the "school of political conservatives" (p. 307) who insist on retaining the language of "theology and metaphysics"(p. 307) rather than that of science because of the loss of social stability that might ensue. Such "sensitive conservatism" (p. 307) is "entangled in a pathetic delusion" (p. 307) ; it is "conservatism in a shipwreck" (p. 307). Santayana himself was more than ready to acknowledge the validity of science, which he considered "common knowledge extended and refined" (p. 393). He criticized the critique of science by idealist metaphysicians around the beginning of the twentieth century on grounds that seem applicable to the postmodernist critique of science at the beginning of the twenty-first. It is hardly convincing, observes Santayana, "when science is systematically disparaged in favour of a method that is merely disintegrating and incapable of establishing a single positive truth" (p. 312).

Russell Kirk (1918–1994) admired both Babbitt and Santayana and included both in his seminal *The Conservative Mind* (1953). In an essay on "Civilization Without Religion" (1996) Kirk goes further than Babbitt and disagrees with Santayana in arguing that the decline of European and North American civilization could be averted only by a "restoration of religious teachings as a credible body of doctrine" (p. 15). Even Kirk, however, is careful to criticize not science but rather a *scientistic* misunderstanding of the implications of science. According to Kirk, "the principal cause of the loss of the idea of the holy is the attitude called scientism" (p. 11). It is scientism, not science, that takes it as proved that "men and women are naked apes merely; that the ends of existence are production and consumption merely; that happiness is the gratification of sensual impulses; and that concepts of the resurrection of the flesh and the life everlasting are mere exploded superstitions" (p. 11). In an essay titled "Humane Learning in the Age of the Computer" (1996), Kirk argues that technology can never replace the flesh-and-blood teacher, but he does so in the name not only of the humanities but also of science, worrying that "if facility in operating computers tends to be emphasized at the expense of serious study of physics and mathematics, the springs of the scientific imagination may dry up" (p. 122).

Critique of Scientism

In "Science and the Studies of Man," a contribution to an anthology on *Scientism and Values* (1960), Eliseo Vivas makes a representative conservative argument when he criticizes the "so-called behavioral sciences" (p. 50) for attempting to adopt the methods and assume the prestige of chemistry and physics. Vivas does not deny and indeed insists on the validity of scientific method when applied in physics and biology, but he rejects the idea that "the only valid knowledge is scientific" (p. 50). Like most other conservatives, Vivas believes that "there is philosophical knowledge of a substantive nature and that there is moral and religious knowledge and, in a qualified sense, even aesthetic knowledge" (p. 50). Vivas argues that the attempt to study human beings and their institutions according to the methods of the natural sciences results not in science but in *scientism*.

The distinction between science and scientism was not, of course, noted only by conservatives. The prestige of science among radicals and militant reformers, however, made it difficult for them to draw a line with the clarity and firmness of conservatism, even when they wanted to do so. The appeal of Dewey's pragmatism, for example, was closely linked to his proposals to use scientific techniques to reform human society. Likewise two of the outstanding examples of scientism in the twentieth century, Marxism and Freudian psychoanalysis, appealed to those who wished to either radically change or destroy bourgeois society. Both used the vocabulary of science, and both attracted adherents by claiming the authority of science.

Though the influence of Marxism was vastly more destructive, both used their prestige to challenge and undermine the traditional moral principles at the heart of conservatism. By the twenty-first century the fraudulence of both has been revealed for all but the willfully blind to see. Other versions of scientism remain, however, including the attempt to use the prestige of the theory of biological evolution to shape a secularist philosophy of human nature and view of the universe.

The Conservative Middle Ground

In opposing repudiation of the concept of truth by postmodernist skepticism, conservatism in the twenty-first century has made common cause with the natural sciences in defending knowledge that is objective and universally true. Conservatives have opposed attempts to formulate a *feminist science* or any version of science based on ethnicity. Likewise conservatives have criticized the characterization of technology as in itself demonic as claimed by some environmental radicals.

In response to the development of biotechnology, however, conservatives such as Leon Kass have continued to be guided by traditional moral principles such as the sanctity of innocent human life and human dignity. Sometimes this has led them to oppose some new uses of medical technology, such as those involved in stem cell research. The same principle of the sanctity of life has also led conservatives to object to the withdrawal of technological support from patients without their consent, whether at the behest of the state or others. Conservatism in the twenty-first century, as earlier, continues to affirm the relevance and validity of traditional ethical principles in evaluating the moral implications of new developments in science and technology, whatever those might be.

In 1932 Winston Churchill observed that "while men are gathering knowledge and power with ever-increasing and measureless speed, their virtues and their wisdom have not shown any notable improvement" (p. 279). As a true conservative, however, Churchill believed that what was required was not "progress" in thought but rather he believed it "above all things important that the moral philosophy and spiritual conceptions of men and nations should hold their own amid these formidable scientific evolutions" (p. 279).

CONSTRUCTIVE TECHNOLOGY ASSESSMENT

The core idea of constructive technology assessment (CTA) is that the social problems surrounding technology can and must be addressed through the inclusion of a large diversity of actors in technological design and implementation processes, including especially social actors. Social actors are those who experience and/or articulate and define health, environmental, or other value-laden effects of evolving technologies but are not directly engaged in technological developments. They may be consumers, citizens, employees, corporations, social groups, and more. CTA activities thus depart from traditional technology assessment (TA), which limits itself to charting the effects of given technological options, and does not attempt directly to influence or broaden the design process.

Historical Background

During the last two decades of the twentieth century, TA was widely adopted in several countries in Europe and in the United States. At first mainly conducted by technical experts, it developed toward a more participatory mode, bringing public values and opinions into the assessment of new technologies (Grin and de Graaf 1996, Vig and Paschen 2000). Both conventional expert impact assessment and various forms of participatory TA focus on shaping public policies related to technical change. TA policies have often been institutionalized in separate organizations such as the U.S. Office of Technology Assessment and the Netherlands Organization for Technology Assessment (renamed in Rathenau Institute), which serve legislatures and try to inform the broader public.

The Rathenau Institute was also heavily involved in developing the theory and practice of CTA. Since its founding, CTA practices have been taken up by many organizations, including corporations, nongovernmental organizations (NGOs), and government agencies, although not necessarily in the same way and often not under this label. These actors face different opportunities and constraints depending on their position in the innovation process. They share, however, the insight that negotiation among all stakeholders is necessary in order to deal with social problems that come with technical change.

CTA activities can take the form of dialogue workshops, consensus conferences (public debates), scenario workshops, or citizen reports. These are methods that can be used to organize structured discussions between social actors and designers (or technological actors). They only become CTA practices, however, when they focus on influencing design and technical change (Schwarz and Thompson 1990, Misa et al. 2003, Schot and Rip 1998, Schot 2001, Sørensen and Williams 2002).

Because CTA addresses innovation, it becomes a form of technology policy, although regular technology policies are not aimed at the integration of societal aspects into technical change. Some organizations and authors have called for such integration. They have argued that technology policies should aim at promoting those technologies that promise positive societal effects or externalities, as economists would term them (Carnegie Commission on Science 1992, Freeman and Soete 1997).

CTA Perspective

From a broad historical perspective, CTA practices may be viewed as a new form of management, replacing a problematic modernist way of managing technology (Misa et al. 2003). The core of modernist management lies in the separation of technology and its social effects. The lack of what may be called negotiating space between the actors involved in the design process and spokespersons for actors who are directly affected by the technology is a feature of the modernization process as it has manifested itself until the beginning of the twenty-first century.

In the modern regime of technology management, two tracks are apparent: promotion and regulation. On the one hand, there have emerged separate sites—called laboratories—where designers are given plenty of room to tinker with new technologies without having to think about the effects, because creativity might suffer. After they have been tried and tested, the black boxes are sent off into the world to bring about welfare and progress. This model encourages just plugging the technology in; playing with the technology is even considered dangerous. On the other hand, there has emerged a regulatory arena to mitigate the appearance of negative effects. Regulation does not concern itself with steering the scientific and technical developments, but rather with setting limits to their application.

Beginning in the 1970s, more and more problems and limitations became associated with this dual-track approach. Problems cropped up and so-called negative side effects of existing technologies were not easily solved through ex post facto regulation. They only worsened. Environmental problems are good examples. Since the 1980s there has been an explosion of new governmental regulations including the use of economic instruments as well as great increases in knowledge of environmental problems and solutions. Environmental advisory agencies have flourished. Yet many environmental problems have not been solved. Chimney filters and catalytic converters appear unsatisfactory. It has become clear that environmental problems must be addressed through a drastic reduction of energy and resource use. Another form of production and consumption is required. This will not come about through government regulation only, also not if it would focus on creating new market mechanisms.

An alternative form of production and consumption implies not only making environmentally-friendly technologies, but also an alternative form of making technology. The character of the technology design and implementation process is in need of change. It must be broadened to include social aspects and actors. Ultimately such a broadening could lead to a change in the current pattern of technology management (the dual-track approach). New institutions should emerge that will become platforms for the constructive integration of technology and society. It is constructive not in the sense of conflict avoidance, but in the sense that all affected are in a position to take responsibility for the construction of technology and its effects.

Features of CTA

The view that design and implementation processes must be broadened is based on the presumption that social effects are present in the form of (sometimes implicit) assumptions about the world in which the product will function. Thus, when technologies are designed, assumptions are made about users, regulations, available infrastructures, and responsibilities between various actors.

In technology studies, the notion of *scripts* is used to refer to this set of assumptions (Akrich 1992). The effect of broadening (and thus of the application of CTA) is that the designers' scripts are articulated and laid out as early as possible to the users, governments, and other interested parties, all of whom have their own scripts, and who will feel the effects of the technology. From the point of view of CTA, it is important to make room for such an early and more regular confrontation and exchange of all the scripts. Thus CTA processes acquire their three normative beneficial features: (1) anticipation, (2) reflexivity, and (3) social learning.

ANTICIPATION. Whenever users, social groups, and citizens take part in the design processes, they are more likely to bring in social aspects at an early stage than are designers. Designers rarely anticipate social effect; they have a hard enough time anticipating market conditions in a timely fashion. They react to market signals and social effects only when they occur, which leads to ad hoc problem solving. In the field of management studies, this lack of sensitivity toward user needs has been identified as a barrier for successful innovation.

Despite the emphasis on anticipation, there is no presumption that all social effects can be predicted. On the contrary, it must be assumed that technological development is nonlinear and unpredictable. During development all kinds of unexpected side roads and branching emerge. The given unpredictability of technological development has two implications. First, anticipation must be organized into a regular activity, including during the phase of implementation. That is when unforeseen effects emerge by way of new interactions and applications. Owing to the importance of anticipating social effects as early as possible, corporations and other technology actors can be advised to organize a trajectory to develop scenarios for coping with social effects alongside product development trajectories. Second, the technology development process should be flexibly structured so that choices can be deferred or altered.

REFLEXIVITY. Broadening the design process results in being able to notice earlier and more clearly that social effects are coupled to specific technical options and that designers design not only technological but social effects. Scripts can no longer remain hidden. The effects that emerge are dependent not only on the designers' scripts but also often on the outcomes of complex interactions between designers, users, third parties, and the context in which these actors operate.

CTA activities aim to stimulate actors to take account of the presence of scripts and realize that technological developments and social effects are coproduced. Actors thereby become reflexive. They must integrate technology and its effects into their thoughts and actions. Consensus may be reached, but controversies could very well occur as CTA exposes hidden scripts and places them next to one another. This need not be such a great problem in societies where controversies are a routine and normal part of the process of technology development. Analyses of controversies have shown that attempts often are made to suppress reflexivity. Attempts are made to separate technical facts from assumptions about the social reality in which the technologies function. Controversies subsequently take the unproductive course of the dual-track regime, either emphasizing promotion or regulation of new technologies.

SOCIAL LEARNING PROCESSES. Learning may occur on two levels. First-order learning leads to developing a better ability to specify and define one's own design. Second-order learning means learning about one's own assumptions and scripts, learning that one is creating new couplings and demands. CTA relates to both forms of learning. It is important to embed technological development in social learning processes as early as possible so that users, designers, and third parties have the opportunity to scrutinize their own presumptions and come to new specifications. In practice, design processes then become more symmetrical from the beginning. As much attention is paid to technical as market and social issues. Design processes become open (so actors are ready to partake) and space is made for experimentation, for trying out various couplings and problem definitions.

Changing the Design Process

CTA activities are not directed in the first instance at such substantive goals as the reduction of environmental pollution, the defense of privacy, or other such social goals. Thus, for instance, the development of wind energy or a security system to guard against bank fraud cannot be automatically labeled CTA. The purpose of CTA is to shape technological development processes in such a way that social aspects are symmetrically considered.

When design processes assume the character of CTA, fewer undesired and more desired effects will result. Such a claim is based on two arguments: (1) By incorporating anticipation, reflexivity, and social learning, technology development becomes more transparent and more compliant to the wishes of various social actors. (2) In a society where CTA processes have become the norm, technology developers and those likely to be affected by the technology will be in the position to negotiate about the technology. An ability to formulate sociotechnical critique and contribute to design will become widespread. Resistance to specific social aspects will not be viewed as technophobia, but as an opportunity to optimize the design (or achieve a better fit in society).

The effect of CTA will not be to bring technology under control so that it plays a less dominant role in society. Rather, it aims to change the form of control and how technology development is played out. The goal is to anticipate earlier and more frequently, to set up design processes to stimulate reflexivity and learning, and thus to create greater space for experimentation. Possible technologies should be made more open and flexible so users easily can have control over them. Technological development will also become more complex. More coordination and new competencies will be required. In some cases the processes will slow. New institutions will emerge to encourage negotiation between developers, users, and third parties. Should design processes acquire the character of CTA, technologists will not suddenly see their work disappear or have it constantly evaluated by new bureaucracies. Almost all of the incremental design changes will not require negotiation. In the program of requirements, allowance routinely will have been made for social aspects (including flexibility). However, the variety of technological designs probably will increase, as more groups will be involved in their capacities as knowledge producers and technology developers.

The three quality criteria for CTA processes make apparent that broadening the design process is not an end in itself, and that "broader" does not necessarily mean "better." Broader is better only in those design processes where space has been created for anticipation, reflexivity, and learning. That provides some guarantee that processes should result in better technology, which is to say technology with more positive and fewer negative effects. These three criteria also allow existing CTA activities to be evaluated, and suggest directions for improvement.

CONSUMERISM

Consumerism is a way of life combining high levels of material affluence with an emphasis on symbolic and emotional meanings associated with shopping and possessions. The United States continues to lead the way, but the phenomenon increasingly is of global scope. Consumerism can be interpreted positively as a means of stimulating the economy while facilitating people's liberties to shape their identities and subcultures. In contrast, critics perceive consumerism as a manipulated and environmentally destructive habit leading to too many units of stuff being designed, produced, advertised, sold, and discarded (Rosenblatt 1999, World Watch Institute 2004). All may agree that "The one unambiguous result of modern capitalism, of the industrial revolution, and of marketing . . . is: In the way we live now, you are not what you make. You are what you consume" (Twitchell 2002, p. 1).

Infrastructure of Consumption

Consumerism involves not just the conventional *shopaholic,* but a complicated set of organizations, relationships, and ethically problematic practices involving science and technology. Product designers, manufacturing engineers, solid state physicists, and those trained in just about every other scientific and technical specialty have participated directly or indirectly in the development and spread of consumer society. Chemists created synthetic pesticides, PCBs, and PVC plastics, enabling businesses to produce and consumers to purchase products that inadvertently scattered billions of pounds of toxic compounds across the landscape. Civil engineers paved and built, making possible an automobile-centered way of life, that enhanced mobility while creating urban sprawl. Agricultural scientists helped construct the modern diet, combining unprecedented variety and nutrition with an obesity epidemic. Computer engineers' amazing achievements also were crucial in spreading pornography via the Internet, even though it was not the engineers themselves who produced or downloaded it.

Technologists are joined by government in fostering consumerism. The basic science integrated into leading-edge technologies such as carbon nanotubes derives partly from taxpayer-funded research and other government subsidies. Transport, electricity, communications, agriculture, and other infrastructure of consumer society all benefit from advantageous tax treatment or outright subsidy, a favorable legal environment, and government stimulation of the economy by means of monetary and fiscal policy. Military research and development (R&D) also has been indispensable; for example billions of aluminum beverage cans annually derive from aluminum smelting procedures developed for aircraft construction during the World War II.

Drawing in part on ideas developed via government-sponsored R&D, business executives search for market niches while hiring experts to deploy technological innovation as a competitive strategy. Franchises and fast food restaurants, *big box* stores and malls, cruise ships, theme parks, sports and musical performance arenas, resorts, and casinos all depend on technologically enabled data processing, communication, and transport of customers, merchandise, food, and drink from all over the globe. These and other forms of consumerism are reshaping everyday life worldwide by a process that some sociologists refer to as *McDonaldization.* The quest for efficiency, calculability, predictability, and "control through nonhuman technology" achieves amazing results, but cumulatively may constitute "the irrationality of rationality" (Ritzer 2004, p. 15–16).

Public Receptivity

As indispensable as technologists, business executives, and government officials have been in development of consumerism, they could not have done it without a receptive audience. If there is a dividing line between purchasing and consumerism, it perhaps occurs when purchasing becomes more about shopping and its psychosocial benefits than about actual use of the purchased items. Friends may prescribe a shopping trip for someone who is depressed; *bargains* and *sales* are avidly sought, even though the total expended is certain to be higher when one goes shopping than when one does not; and somewhere in many shoppers' minds is an expectation of approving looks or words that may be evoked by a new garment or tool. The symbolic, emotional, and interpersonal elements of consumerism are difficult to overstate.

That is not to deny that consumers exercise choice; of course they do, in part because the variety of possible purchases is so great that choice is inescapable. Nevertheless just as families come voluntarily to Disney World and then are channeled into preformed experiences, so more generally is consumer behavior in some respects channeled for the convenience and profitability of business. To attract customers, merchandisers play on consumers' envy, shame, and pride, expending 1 trillion dollars annually worldwide on advertising, attractive packaging, and other selling techniques. A small army of psychologists and statisticians conduct market research to learn how to stimulate sales, "constantly gaining more precision in pinpointing the demographic and lifestyle trends of consumer segments, employing new tools such as Internet *cookies* to monitor the *click-streams* of e-shoppers" (Cohen 2003, p. 402). The finance industry brilliantly stimulates the borrowing necessary to keep spending high.

Criticisms and Rejoinders

The disposable income required to purchase a growing array of goods and services is of course far more available to the affluent, who are located mainly in North America, Japan, and Europe. At the other end of the spectrum are approximately 1 billion persons who live in absolute poverty, about as many humans as the total number alive prior to the Industrial Revolution. To families without toilets or clean drinking water, television broadcasts the lifestyles of the rich and thereby stimulates consumer aspirations and helps spread consumer society across the globe. Within affluent cultures, intangible ethical consequences of consumerism appear to include deterioration of face-to-face community, increased rates of psychological depression without commensurate improvements in happiness (Lane 2000), and reduced interaction among family members as children turn increasingly to the televisions and computers in their bedrooms. Parents' long working hours sometimes come at the expense of sleep, leisure, family, and friends—a syndrome far more common in some countries (such as the United States) than in others (Schor 1998).

Consumerism is environmentally problematic in obvious ways, but also more subtly, as when distant consumers' appetites for shrimp, teak, and coffee disrupt fragile tropical ecosystems (Tucker 2002). Whether consumerism potentially can be made compatible with environmental sustainability is debatable. The formula for calculating ecological damage is roughly the total number of humans, multiplied by the amount consumed per person, multiplied by the resources utilized and toxicity released per unit of consumption. If the human population declines soon enough, and if technologists figure out how to dramatically reduce resource usage and pollution per unit produced and consumed, increasing material affluence per person might be compatible with greatly reduced environmental damage. Advocates of *natural capitalism* propose radically reconceptualized ways of providing housing, transport, and consumer products (Hawken et al. 1998, McDonough and Braungart 2002); and a few nanotechnologists believe that molecular manufacturing eventually may eliminate hazardous wastes and other side effects of production. As of the early twenty-first century, however, reductions in pollution per unit in most industries have been offset by population growth and by increased consumption per person.

Not everyone agrees with the above diagnosis. Among counterarguments, they point out that contemporary economies are organized to require an unpleasant choice: allow recession and unemployment, or stimulate the economy through ever-higher levels of consumer spending. In poorer nations, increased investment and purchasing theoretically might be devoted to basic needs including water supply systems, safe sanitation, housing, and nutrition. In the already affluent nations, however, economic growth tends to mean more elaborate barbeque grills, second homes, cosmetic surgery, and other luxuries. These are lesser evils, or not evils at all, to those who emphasize the benefits of full employment, interesting jobs, and liberty to purchase a lifestyle more of one's own choosing than previously possible for most of humanity, together with the value of technological innovation as a means of making life more diverse and more interesting (McCracken 1988).

The Challenge of Change

Few knowledgeable observers presently consider consumer trends compatible with environmental sustainability, but those concerned about unlimited consumerism face a difficult task in addressing the issue. It is easy to make products and production processes a bit greener by, for instance, creating biodegradable carpeting. But limiting the total volume of production and consumption is far more difficult, requiring people to forego some of what they have learned to want. Such a change in consumer mentality presumably would require slowing the drumbeat of messages encouraging consumption, and perhaps even a ban on advertising as well as tight restrictions on consumer credit. Such changes surely depend on ardent environmentalists and other slow-growth advocates winning more elections, which cannot happen without a different attitude among citizens. In other words, consumerism is constructed as a circle, a vicious circle in the eyes of critics.

Changed thinking among scientists, engineers, and other technically trained persons also might be necessary to intervene in the consumerist trajectory. In effect, technoscientists now gain governmental research funding by helping create weaponry, communications, transport, and other innovations helpful in military affairs and in economic activities valued by governing elites. A similar expectation leads industry to help fund scientific research, employ technoscientific consultants, and hire college graduates in chemistry, biotechnology, computer science, and other technical fields. All this makes good sense, in a way; but the partially unintended, collective consequences include the problematic aspects of consumerism.

Breaking out of the consumerist cycle would involve billions of persons over generations in evolving a commendable, interesting, high-technology, lower-consumption way of life. This, arguably, is the master challenge for human civilization—an activity so far-reaching and visionary that no one can fully imagine what would be involved. However a first step probably would require that more people begin to think of consumerism as an ethical, technological, economic, and political issue to be addressed.

CONTRACEPTION

SEE *Birth Control.*

CONTRACTS

Contracts are legally enforceable agreements between persons that specify transactions or define relations between them. Either informal or written, they may concern any lawful human transaction, from purchases and loans to hiring and marriage. In engineering and science, contracts play important roles because, in both domains, practitioners do a great deal of work under some form of contract. Defining what the parties are obligated or permitted to do, contracts establish an ethical framework for engineering and scientific work, and they present ethical problems. The ethical framework has at its core one or more promises. Because the promises are legally enforceable, they involve a third actor in addition to the promisor and the promisee, government.

Contracts in Engineering

For most engineers and many scientists, the employment contract frames their professional activities. American courts apply the common law doctrine of "employment at will" when interpreting employment contracts for engineers and scientists. Under this doctrine, the employer is free to hire and fire at will, and the employee is free to take up employment and resign at will. This means that an employer may dismiss an "at will" employee, in the words of the court in an often cited case, "for good cause, no cause, or even cause morally wrong, without thereby being guilty of moral wrong" (*Payne* v. *Western and Atlantic RR*, 81 Tenn. 507, 519–20 [1884]). As a consequence, for example, engineers have reason to fear that by asking challenging questions about the safety of a project, they risk being fired. The "employment at will" doctrine is subject to limitations expressly indicated in federal and state statutes (for example, civil rights laws), to public policy exceptions courts have worked out, and to express provisions in the employment contract, such as provision for a term of one year.

The contract includes the usual terms of employment: salary, compensation, health and pension benefits, etc., but in addition may include "employment agreements" concerning intellectual property, confidentiality, and restrictions on future employment. At the time of taking employment, engineers and scientists often enter these agreements with insufficient appreciation of the implications. Sometimes, in this way, engineers or scientists unwittingly enter agreements that are so restrictive they could not be enforced. An example is an agreement that excludes future employment with a competitor to the extent of putting the engineer's future livelihood at risk.

Engineers or scientists may be surprised to discover that they are legally and ethically obligated by the employment agreement to maintain the secrecy of certain information even after changing employers. At the next job, an engineer or scientist may have to decide whether particular indirect uses of information gained from a former employer are permissible. Engineers or scientists may also have to decide whether to maintain the confidentiality of information that they believe a client or customer needs to avoid certain harms.

Some have argued that the code of ethics does or should rank as an implied element of the engineer's or scientist's employment contract. Viewed this way, the code would provide a barrier protecting engineers or scientists from being required by their employers to engage in behavior that violates the code. One way to interpret this claim is by invoking the status of an engineer as a professional: An employee trained and hired as an engineer is bound by all the standards of engineering, including ethical standards. The employment contract cannot require engineers to violate their ethical standards. Courts, however, have not been receptive to this interpretation.

Contracts bear on engineers' and scientists' work in another important way—through the contractual agreements that their employers (or they themselves) make with other business organizations, non-profit organizations, interest groups, and government agencies at every level of government. Engineers' functions—design, testing, maintenance, and operations—and their project-related dealings with purchasing agents, marketing specialists, customers, vendors, and construction contractors, as well as with other engineers, are usually associated with such contracts. The same is true of scientists when they function similarly.

Some common ethical problems for engineers typically arise from contracts of this sort. An example is the "deadline problem" that occurs, for example, when engineers discover in the course of their work that they cannot meet both the specifications for the product and the delivery date to which they originally agreed. They may have to develop options, such as working overtime or negotiating a compromise.

Yet engineers contribute to devising these sorts of contracts as well as to implementing them. They participate in defining projects and determining specifications for products even when they do not directly take part in contract negotiations. Their judgments about the time and resources needed to complete projects (a new chemical plant, for example) often help to decide the terms of contracts by which they and other engineers are bound. Strategies of preventive ethics may help engineers avoid ethical problems associated with devising contracts.

So far, this entry has focused on ethical problems and strategies from the perspective of engineers and scientists as promisors. In most cases when engineers and scientists are promisors, the promissee is a large company or firm. The company's perspective brings to the fore other ethical problems and needs for preventive ethics. For example, employers cannot easily determine whether engineers are faithfully abiding by their promise to maintain the secrecy of information at a new place of employment. Companies cannot pursue former employees by legal means if they do not have tangible evidence of, for example, the transfer of confidential information to the new employer. From this perspective, strategies of preventive ethics, such as rewards for creativity to valuable employees, may be useful. Companies can also use contracts to provide incentives to valued employees to stay with the company and to departing employees to maintain desired confidentiality, in this way protecting engineers and scientists from temptations to which they are subject.

In consulting firms (for example, environmental consulting firms) that require or permit the firm's engineers and scientists to obtain and implement contracts on their own, other problems arise. Scientists or engineers may unwittingly enter contracts with clients whose interests collide with those of other clients of the firm. Problems about the treatment of their reports may arise for engineers and scientists in these firms, and also in other contexts. The firm may object to the engineer's client using a report in a press conference or require the engineer to suppress a report altogether. An academic engineer who does independent consulting under contract may have to decide how to handle a client's decision to bury a report revealing the client's responsibility for some harm.

Contracts in Science

In scientific research and in academic engineering, contracts are pervasive in defining conditions attaching to awards of funding necessary for conducting research. In universities, investigators, students, and postdoctoral scholars have a contractual duty to abide by the institution's rules. Informal agreements in research groups under these rules are similarly binding. Graduate students are often surprised to learn that they do not own data they themselves collect. They may perceive this rule or agreement in research groups as an unfair hindrance to advancing their careers. Nevertheless, they are ethically bound to abide by these agreements unless they can negotiate other terms with the principal investigator.

The power disparity among senior investigators, graduate students, postdoctoral scholars, and junior investigators complicates the ethical situation in research groups. Their leaders have the power to make the ground rules for conducting research in their groups. Those subject to this power and dependent on their leaders for research support and recommendations for future employment are not in a position to contest rules. Because of the power disparity, safeguards should be built into the ground rules to protect the vulnerable, less powerful members of groups. Senior investigators can begin by making informal understandings explicit and open to discussion and revision.

In conducting research for commercial sector firms, scientists and engineering researchers are required to sign contracts that allow firms proprietary control not only over copyrights and patents, but usually also over data, tools, resources, and techniques. As a consequence, "virtually any piece of information or equipment used in industry-sponsored research can become company property" (Resnick 1988, p. 31). By these agreements, even chemical formulas and DNA sequences can become company property.

These contracts also commonly require scientists and engineers in the commercial sector to submit their publications or public presentations for company review and to accept delays beyond the limit acceptable in academe. In some cases, companies suppress publication altogether, in this way requiring engineers or scientists to violate professional standards. In light of the central value of open publication in science, a value that serves science and the public welfare, these requirements present ethical conflicts for scientists.

As encompassing as these agreements are, courts have upheld them. In doing so, they represent the public's interest in ongoing scientific research and development. The underlying assumption is that such proprietary control is essential for companies to gain a return on the heavy investment required for scientific research and product development. Without the assurance of a return, they will not take the risk of investing. However, some companies may suppress results and refuse to share useful tools and resources beyond the need to realize the return on their investment. Consequently, scientists and the public may fail to receive the benefits of the propagation of new knowledge and inventions.

In the interests of the promisor, the promisee, and the public, companies should allow their scientists and engineers to publish results and share resources and tools in a timely fashion. Industry-sponsored research contracts should not require scientists or engineering researchers to violate professional standards. Rather, contracts between companies and researchers should be written to strike an appropriate balance between proprietary control over information and scientists' responsibilities to publish results and share resources to the benefit of science and the public.

This overview of ethical obligations, responsibilities, and ethical problems associated with contracts in science and engineering points to the need for practitioners in these domains to be taught to pay close attention to contracts. In many circumstances, engineers and scientists can influence the terms of contracts in such a way as to reduce the likelihood of their facing ethical problems later. Promisors and promisees can become oriented to devising and using strategies of preventive ethics to avoid violating professional ethical standards.

CORRUPTION

Corruption derives from the Latin verb *corrumpere*, which means to break into pieces, destroy, defraud, falsify, seduce, or bribe. But the meanings hardly end with those. They are merely one set of a procession of definitions and interpretations amassed over the centuries, all signifying some contagiously harmful, unjust, self-serving, often repulsive divergence from moral conduct.

Definitions

Corruption defies and defiles what is generally perceived as the common good. In its malevolent extreme—such as systematic and widespread murder, torture, rape, or pillage, undertaken to maximize power—corruption can attain the dimensions of evil. At the lesser extreme, acts such as bribery, embezzlement, plagiarism, or falsifying research data, when done on a small scale and episodically, can be seen as unethical, immoral, or deranged, though not necessarily corrupt. Scope can often define corruption.

Science has its own literal definitions of corruption. Data are sometimes called corrupted. In biology, corruption is the process of living matter's decomposition. Similarly, a spoiled laboratory sample can likewise be described as having been corrupted. Terms such as rot, putrescence, and decay all serve well as descriptives for the revulsion corruption can generate. Corruption covers a multitude of sins and therefore has an almost limitless repertoire of baleful synonyms and colorful case examples.

Scholarship on corruption in science is rare, in technology (e.g., patent piracy, computer hacking) increasingly frequent. But scholarly work on corruption in governments, wherever they may be, is abundant. The challenge in the science and technology sector is to connect the hidden motivations and behavior patterns of those in the technical world to that of the political and economic spheres so that technical professionals can play stronger roles in perceiving their own relevance in stemming corruption's incessant growth.

Organizational Approaches

A handful of organizations with ambitious programs to understand and prevent corruption have attempted to establish satisfactory definitions of corruption. The World Bank, which in 1999 launched a vigorous anti-corruption program, defines corruption as "the abuse of a public position for private gain." Transparency International, long the leading body in tracking and studying corruption, defines it as "behaviour on the part of officials in the public sector, whether politicians or civil servants, in which they improperly and unlawfully enrich themselves, or those close to them, by the misuse of the power entrusted to them." Because of the global trend toward the privatization of public functions, it extends that definition to abuses in the private sector.

A third body, the Organisation for Economic Co-operation and Development (OECD), shuns any attempt to define corruption but has undertaken considerable work in gathering statistics, convening conferences, and issuing reports on such subjects as bribery, export credits, corruption in individual countries, and corruption's impact on development.

Any generalized treatment of corruption that is less than criminal or evil can entail considerable subjective judgment, thus inviting both a self-critical eye and rhetorical reflection. Often the word is used loosely in tirades against political opponents, such as a "corrupt" policy by one political party or another involving the environment, the elderly, or illicit campaign tactics. Charges of corruption can be flung when scientists rally against the packing of technical panels by a government whose political party they oppose. In the brutal give and take of politics, judgments about corruption's severity and perhaps its very existence are best done with care, case by case, even item by item, with emotions held in tow.

The Situation within Science, Engineering, and Technology

Science, engineering, and technology—technology being the useful products of engineering—are themselves fertile soils for corruption. Under the thrust of technological change, they can serve as tools (genetic engineering, virology, the computer, and digital communications as examples) to expand the range of corruption's infectivity. Thus, right at the start, the technical world can be mired within conflicting goals when business, engineering, and science comingle. Not only that, but history displays the macabre paradox of science and engineering specifically employed for evil means such as the freezing of human beings by Nazi scientists to study the process of death and the feasibility of resuscitation, or the infamous Tuskegee Syphilis Study (1932–1972) on prison inmates in Tuskegee, Alabama, as well as the radiation experiments performed on unwitting human subjects by the Atomic Energy Commission from 1944 to 1974. Further, it could easily be argued that weak implementation of occupational safety and health laws leading to worker deaths is also a form of corruption of the public good.

The values of science, which derive from philosophical and moral thought, are their own protection against any infestation of corruption. The inner character of science contains the ethical outcome of improving the lot of humankind and adhering to a strict code that imposes integrity on its practitioners. For years, the scientific community has striven to reduce the incidence of data falsification, arguing that the act of falsification erodes the honesty and openness that feeds scientific progress. Thus, science contains within itself a moral value all scientists are trained to revere. But, like other human beings, scientists can cheat, lie, and steal. The question is whether one chooses to call such flaws corruption—whether to expand the definition of corruption to include the corruption of values. At this moment in the sociology and psychology of science, divergent behavior in the technical fields rests in the discipline of ethics, broad enough in itself.

Thus, the tracking and policing of unethical behavior among technical professionals has been left to science and engineering societies, journals devoted to science/society issues and to the field of misconduct and malpractice, inspectors general for the technical agencies of government, the agencies themselves (through, for example, the Office of Research Integrity at the National Institutes of Health), and science and engineering workplaces. Corruption involving science and technology, however, does come in for significant treatment in the corruption literature because the capital transferred for development projects that involve science and engineering is often skimmed for payoffs at either the contractor or government level. Thus it is clear that those within the science and engineering community whose work engages them in development projects have a stake in corruption at the level of the Third World. Whistleblowing is one major response by technical people to perceived violations of ethical practice among their higher-ups. Unfortunately, whistleblowers are too infrequently rewarded—and often punished—for acting on their sense of outrage.

How corruption can be differentiated from immorality is an open question. If a lie is immoral, then scientific fraud—whether by plagiarizing texts or falsifying data—is immoral as well. But whether it is corruption is more a question of philosophy than practicality. Oftentimes, examples of fudging laboratory work for neater results might well be seen as advancing the cause of a research project. If the loss of research support for a worthy program, for example, is threatened by a bit of discrepant data, then the researcher might consider "tidying up" the results for the sake of saving the grant.

Trends and Outlook

Where corruption in science and engineering perhaps bears most watching is in the relatively recent marriage between corporations and universities in conducting genetic engineering research. The field itself has long presented ethical and moral dilemmas, but the risk of corruption increases in the high intellectual property stakes involved in genetic discoveries. The fear is that academic and intellectual freedom has been "corrupted" when scientists working under the support of the corporation deliberately withhold data from colleagues at competing institutions. These practices have taken place to a disturbing extent with no final consensus in view.

Corruption will always be present within the human realm. The war on it in the developing world has become vigorous and is showing success. Evidence shows that as those countries democratize and generate more internal wealth, corruption will decrease. At the same time, however, the growth of new scientific and technological tools will render corruption increasingly creative and sophisticated. The incursion into personal privacy through sensor technology applied to "protect democracy" can be seen as chilling enough. The challenge, then, is to anticipate what new forms of infectious malfeasance loom as the science behind biotechnology and nanotechnology, and the digital instruments of technology generate new ways of doing harm.

COSMETICS

The term *cosmetics* comes from the Greek *kosmos* for order, referring in this case to the well-ordered face or appearance. Cosmetics are substances applied to the skin or hair to create a pleasing appearance. In the early-twenty-first century, they are alternately seen as the bane of modern women's existence (creating a time-consuming *third shift* [Wolf 1991] for women) and as a simple, popular tool for personal transformation. Some feminists deride the cosmetics industry as an ethically corrupt patriarchal institution that intentionally makes women feel that their natural faces are inadequate and exacerbates the identification of value with superficial appearance (Bordo 1995), whereas others cheer the liberating effects of bringing control over self-image and appearance within the grasp of every person. Ethical concerns raised in the history of the cosmetics industry remain and are exacerbated by technological innovations and the increasing consumer culture.

History of Cosmetics

The practice of painting and tattooing the body dates back to early-Neanderthal humans, when natural mud, ash, and natural dyes were used for not so much for enhancing beauty, but for camouflage, inspiring fear in others, and representation of animal gods in ritual ceremonies. In ancient Egypt, body painting focused on the eyes, with black antimony powder and green malachite lining used for protection from the sun as well as for decoration. Cosmetics and perfumes were used by both sexes in ancient Egypt and Rome. Later, in medieval Europe, strict religious norms identified cosmetics as the devil's work—a sign of vanity and deception. The Renaissance period brought cosmetics back in style, emphasizing the human ability to improve upon nature. In Elizabethan England, both sexes powdered their faces for a pale complexion, while women also used rouge and lip color, and covered the entire face with egg white for preservation. Men and women of the upper classes devoted significant amounts of money and time to maintaining an aristocratic appearance (Gunn 1973).

In *Hope in a Jar* (1998), social historian Kathy Peiss tells the story of the cosmetics industry in the United States. The American Revolution led to a rejection of the English tradition of wigs and facial powders as signs of aristocratic standing for men. Yet women's virtue continued to be linked with appearance. Women kept instructions for homemade cosmetics intermingled with potions for curing rashes and maintaining good health. Traditional family recipes (using household items such as oatmeal, lye, charcoal, and berries, among others) were commonly exchanged through social networks; for advice, one went to a friend or family member, not a pharmacist or physician. But more efficient and less risky substances were often available at the pharmacy, and soon women began buying special ingredients for their beauty concoctions. Pharmacists recognized an opportunity for packaging recipes of their own and selling them as finished products. Advertising created brand recognition and motivated women to seek the lifestyles they saw in print. Thus by the early 1930s, most women in the United States reported that *putting on a face* was a daily activity involving commercial beauty products (Peiss 1998).

Despite this increasing popularity for commercial cosmetics, early critics voiced concerns. Some questioned the monetary and time costs invested for such temporary results. Others expressed moral contempt for a practice that was viewed as an enemy of authenticity, a way to fake one's way into beauty. Early associations between cosmetics and women of low status (e.g., prostitutes and vaudeville showgirls) contributed to this distrust. Yet in a society that historically undervalued women's intellectual capacities and overemphasized their aesthetic value, the cosmetics industry flourished. Looking good was a ticket to increased social status. Even women who initially rejected cosmetics as an inappropriate solution to problems of inequality felt social pressure to use them. Similar pressures have more recently led to increased use of cosmetic surgery for women, the expansion of the cosmetics market to men's products, and biotech research into more effective and individualized cosmetics products.

As the cosmetics industry has become more dependent on science and technology, significant ethical issues have been highlighted, and termed *cosmethics*. The issues range from gender equity to safety concerns and animal testing. Codes of ethics have been formulated by the cosmetics industry to begin to address these issues as they arise in development, manufacturing, distribution, and advertising (ICMAD). In the United States, the Food and Drug Administration (FDA) does not require cosmetics safety testing prior to public sales because cosmetics are not considered drugs. However the FDA publishes guidelines for good manufacturing, and all cosmetics manufacturers must comply with the Food, Drug, and Cosmetic Act and the Fair Packaging and Labeling Act; products without substantiated safety must bear the warning, "The safety of this product has not been determined."

Equity Issues

The contemporary cosmetics industry was largely founded by women (e.g., Elizabeth Arden, Madam C. J. Walker), who recognized the opportunity to make use of recalcitrant appearance norms for their benefit (elevating women's status by turning men's weaknesses against them) and built on the tradition of women's home-beauty networks. Women who were overworked, underappreciated, lacked self-esteem, or simply desired attention for themselves were offered a medium through which to connect with other women, pamper each other, and share concerns. Furthermore women could experiment with new identities for themselves through the use of cosmetics. Such benefits continue to be heralded in the early-twenty-first century. Of course, for convenience, most women settle on a standard routine that best fits their sense of themselves. Thus, in order to maintain a *normal* appearance, they come to rely on regular purchases of the associated products. Consumer purchases are required simply to be oneself. How ironic that the product heralded as an opportunity for self-creation, self-care, and shared intimacy among women turns into a requirement of time, energy, and financial investment. In a society highly attuned to appearance, serious consequences ride on conforming to the norm: preservation of jobs, relationships, and self-esteem. Indeed the pernicious dynamic of commercialization and biased norms of appearance has resulted in studies showing that many contemporary women spend significant time each day applying cosmetics, find them essential to wear in a wide variety of circumstances, and believe that their attractiveness depends on cosmetics (Cash and Wunderlee 1987, Kelson et al. 1990).

Various cosmetics. Use of cosmetics for the purpose of enhancing beauty dates back to ancient Egypt. *(AP/Wide World Photos.)*

This situation is problematic for several reasons. First, although emphasis on men's grooming is increasing (Bordo 2000), the value placed on appearance is still decidedly greater for women than men. For women, the use of cosmetics is tied to social status and credibility in the workplace (Dellinger and Williams 1997). Second the image of beauty proclaimed by the industry is decidedly narrow, favoring a white, Western ideal, even when models are from different racial or ethnic groups (Perlmutter 2000, Bordo 1995). This imposition of one version of beauty on all reinforces the historically unjust social status of many women of color. The Western beauty bias can also be seen in scholarship on racialized uses of cosmetic surgery (Kaw 1993).

Safety and Animal Testing

To ensure that cosmetics are safe for human use, animal testing has been employed to determine toxicity and likely reactions to chemicals in the products. The LD-50 test (lethal toxicity for 50% of the animals tested) started in 1927 (Singer 1999) and was developed to determine the strength of various drugs for medical purposes. The testing quickly spread to other applications, including ingestion of lipstick and other cosmetics. It was an industry standard until the early 1980s, when animals rights groups pressured the industries to rethink both the efficacy and ethics of the test. Given species differences and drastic disparities in the amount and time frame for ingestion, the applicability of the test for human usage was unclear at best, and half the experimental animal populations had to die to complete the test. As one activist wrote, "The test defies common sense. Does one really need to know how many bars of pure Ivory soap kill a dog?" (Singer 1999, p. 10). Following public pressure, in 1985 the cosmetics industry moved to a limited test that feeds a smaller amount of the product to a smaller group of animals, and discontinues the study if no harmful effects are found. Similarly, since the 1940s, the Draize eye test has used conscious but immobilized rabbits to ascertain effects such as redness, blistering, and blindness that might result from direct contact of a cosmetic product with the eye. Rabbits' eyes are dabbed with the product, and observed over time to record eye damage and discomfort. Pressure from animal rights activists for alternative models to ensure safety convinced the industry to contribute its own funds to research aimed at refinement, reduction, and replacement of animal use. *Animal-free testing* now has marketing appeal as well as ethical grounding. In 2002 the European Parliament banned the sales of animal-tested cosmetics produced throughout the European Union, a ban that will, in the future, apply to animal-tested cosmetics produced in other areas of the world.

Although contemporary cosmetics has advanced significantly from the heyday of animal testing and the previous dangers of unregulated and untested products (e.g., in the Elizabethan period the use of ceruse, or white lead, for complexion whitening led to toxic reactions, sometimes with deadly consequences), the risks of cosmetic use have not been eradicated. Advances in science and technology have brought the advent of *cosmeceuticals* or beauty products designed to make use of medical and pharmaceutical advances for nonmedical purposes. These include Retin A-enriched facial cream to diminish wrinkles, baldness treatments, and other cosmetic products with biologically active agents. In the United States, this rapidly growing industry (Lamas 2003) is not subject to regulation and testing by the FDA because cosmeceuticals are not considered drugs (which affect the body's structure and function). Yet this claim is difficult to confirm without the very testing that has been waived due to the categorization scheme. Cosmeceuticals are often sold in the offices of dermatologists and other physicians, and may be easily mistaken for tested medical treatments by patient-consumers. Even overlooking the likely ethical conflict of interests, one wonders whether such new and improved cosmetic treatments really advance human options or instead quietly increase burdens, as people try to keep up appearances.

COSMOLOGY

The night sky is a primal wonder whose infinite nature spurs a longing to understand human existence. The realization that they are beneath a vastness and majesty beyond their personal experience impels people to attempt to know themselves and their place in all that there is. This is a religious impulse and is also the impulse behind cosmology.

From Astronomy to Cosmology

Cosmology is, however, a uniquely modern science of the history, structure, and dynamics of the universe. Although *astronomy* is a transliteration from the Greek, the word *cosmology* is a seventeenth-century coinage from an imaginary Greek term. It thus denotes a new, uniquely scientific way to deal with primal wonder about the night sky that was designed to replace the myths that represented primordial efforts to respond to that wonder.

The myths on which traditional societies were built were inspired by and speak to the origins of humankind and its place in the universe. Because the nature of the firmament is unknowable by the direct senses, until recently those myths were untestable and therefore perennial. The birth of technology changed that situation. Tools that take advantage of natural laws and allow humankind to manipulate those laws changed what was knowable. Systematic observations of the motion of the planets that were motivated by Tycho Brahe's (1546–1601) desire to find God's perfection in the sky led Johannes Kepler (1571–1630) to devise a model of the solar system with the sun at its center. Timepieces and levers set the stage for Isaac Newton's (1643–1727) grasp of gravity and its implications for the cosmos. Newton's calculus, a kind of conceptual technology, captured physical law with a generality and precision of unprecedented scope.

Today fossil light from the beginning of time is collected by immense machines both on the earth and in space and analyzed electronically to reveal the most intimate details of the universe and its beginnings. Modern cosmology weaves a creation story that passes the tests of science. The same methodology that has laid out physical truth and made possible the ability to control nature has allowed humankind to know the extent and origin of all that there is. In the process the inevitable imperial nature of science has taken over, displacing the old myths with cold certainty and weakening the ground beneath religions, belief systems, and structures of morality. As science replaces older foundational beliefs, it becomes complicit in the moral confusion of the modern age.

Can heaven survive the heat death of the universe? Will the cherished views of earlier cultures on the origin and meaning of human existence be another casualty of modern science? As astronomers divine the mysteries of the origin and evolution of the universe, are they culpable for the elimination of worldviews that may have had legitimate purposes but did not stand up to the scrutiny of scientific methodology?

The Emergence of the Big Bang Theory

In 1929 the astronomer Edwin Hubble (1889–1953) announced that the recessional velocities of galaxies are proportional to how far away they are. The farthest galaxies were said to be receding the fastest, as measured by the Doppler shifts of their emitted light. The Doppler shift is the stretching of light waves from objects that are receding from the earth at high velocity. Hence, distant galaxies appear redder. The constant of proportionality (between distance and recession velocity) became known as the Hubble constant. The implications of this relationship are profound. The simplest explanation of it is that at some time in the very distant past all the galaxies were packed together. The reciprocal of the Hubble constant is approximately the age of the universe: about 14 billion years.

How far back in time is it possible to see? What immense, sophisticated, and expensive instruments are required to see something as esoteric as the first light of the universe? In fact, one can see the radiation from the explosion of the Big Bang in almost every living room in the United States and almost any household in the world. All that it is necessary to do is to unplug the cable from a television set and set it to a channel where there is no broadcast. Part of that chaotic, somewhat disturbing pattern known as snow is the microwave echo of the Big Bang, which was released when the universe became transparent 200,000 years after it was born.

In 1965 Arnio Penzias (b. 1933) and Robert Wilson (b. 1936) of Bell Laboratories were working on a state-of-the-art antenna for the emerging technology of satellite telecommunications. Wherever they pointed their antenna in the sky, they heard a constant hum. In one of the most serendipitous discoveries in the history science, the cosmic microwave background (CMB) radiation had been found, and at a frequency exactly in agreement with the theory of the Big Bang (Sciama 1973). (Penzias and Wilson won the 1978 Nobel Prize for their discovery.) Since the Big Bang space has been cooling as it expands. If one runs the movie of the evolution of the universe backward to the point where all the galaxies coalesce, one finds that the "primeval egg" began expanding at nearly the speed of light 14 billion years ago. From the inferno of creation to the present the science of thermodynamics predicts that space should have cooled to 2.7 degrees Celsius above absolute zero. The frequencies Penzias and Wilson heard in the CMB correspond exactly to that temperature.

Cosmology and nuclear physics began to merge when scientists started to consider the first three minutes of the universe, a point made clear in Steven Weinberg's *The First Three Minutes: A Modern View of the Origin of the Universe* (Weinberg 1977). During that time all the fundamental particles—the neutrons, protons, and electrons that make up atoms and the rest of the fundamental particle zoo—were formed. As the universe expanded and cooled, mostly hydrogen nuclei were formed, but a fraction of them teamed with neutrons to make helium, deuterium, and lithium. According to nuclear physics, the relative amounts of each of these elements are quite sensitive to the conditions of the early universe. From that period of nucleosynthesis right after the Big Bang nuclear physics predicted that the universe should have been formed with about 76 percent hydrogen, 24 percent helium, and less than 1 percent heavier elements. In an affirmation of the Big Bang theory spectroscopists have shown that wherever one looks in the universe those ratios prevail.

With the evidence provided by Hubble's observation that the universe is expanding, the measurement of the CMB, and the correct prediction of nucleosynthesis during the first three minutes of the universe the Big Bang has been accepted as the real story of the universe. However, adjustments have been made to it.

The Structure of the Universe

A map of the universe as it is currently understood is shown in Figure 1. The bottom of the chart shows the center of the earth, and the top represents the farthest that can be seen: the CMB. The scale is logarithmic so that any quarter inch on the chart represents ten times the distance of the quarter inch below it. Two populations of artificial satellites populate space immediately above the earth: low orbit satellites at about 200 miles and geostationary satellites at 23,000 miles. The planets, asteroid belt, and Kuiper belt can be seen in the bottom half of the chart. The Kuiper belt is a vast ring of large comets that orbit the sun outside Pluto. Midway on the chart is the Oort cloud, a much larger spherical shell of comets that are bound loosely to the sun. Nearby stars, galactic stars, and the center and edge of the galaxy follow as one moves outward. The Milky Way is part of the local group, a loose collection of about two dozen galaxies that are gravitationally bound. Beyond that is the large-scale structure of the universe. Galaxies fill the heavens in these vast reaches, but they are not randomly placed. Not only do they form clusters, there are coherent structures that are significant fractions of the size of the universe. The Great Wall is one such structure: a long filament of galaxies that is 300 million light-years from the earth.

In fact, the large-scale structure of the universe is foamy and filamentary, as shown in Figure 2 (Gott et al. 2004). In this figure each point represents a galaxy: The foamy nature of the universe can be seen out to 2.7 billion light-years in this diagram. The foam seems to become less dense farther from the earth or, equivalently, farther back in time. In fact, it extends as far back as can be seen. The blank wedge-shaped regions are places in the sky where it is impossible to see out of this galaxy. This is the plane of the Milky Way.

The foamy structure of the universe must be indicative of the small, quantum asymmetries that were imparted during the Big Bang. One can imagine that a perfectly spherical explosion would result in a smooth, uniform universe with no structure. However, somehow

FIGURE 1

A Map of the Universe

A map of the Universe (Gott et al., 2004). The vertical axis is distance on a logarithmic scale. At the bottom is th center of the Earth, and at the top is the most distant feature of the Universe, the Cosmic Microwave Background.

small asymmetries must have been present and were amplified by the force of gravity as the universe evolved and expanded. The structure that is seen is not consistent with the amount of matter and energy observed in the universe. There does not appear to be enough gravity to hold it all together, and this is where dark matter comes in.

Dark Matter

The direct evidence for dark matter is simple. Galaxies usually exist in gravitationally bound clusters of a few to several dozen. The motion of the galaxies around their common center, a matter of Newtonian physics, is completely inconsistent with the amount of matter that is seen. The motion of individual galaxies within a cluster can be explained only by the existence of an additional strong gravitational field. In fact, every galaxy or cluster must have a spherical halo of matter around it that is undetectable with electromagnetic radiation but is five times more abundant than the matter in the galaxies themselves. Little else is known about this mysterious cold dark matter, but its existence is generally accepted and there is an ongoing effort to detect it directly.

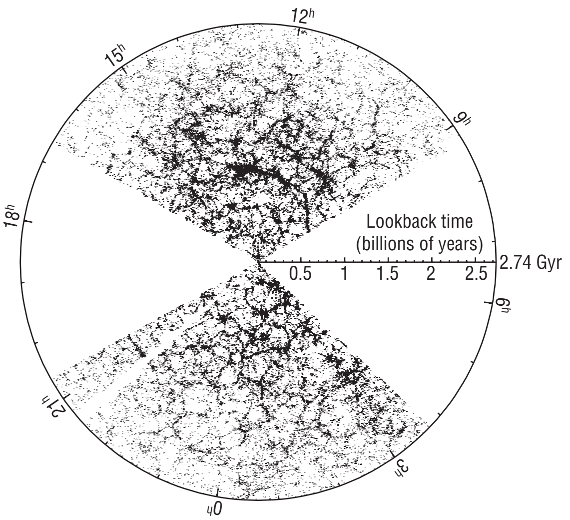
The Cosmic Microwave Background and Dark Energy

The microwave background also has structure. If the universe began as a microscopic primeval egg, it must have undergone vigorous quantum fluctuations in energy, shape, and even dimensionality. The imprint of those quantum fluctuations is seen in the spatial structure of the microwave background. To an incredible degree, however (about one part in a million), the microwave background is uniform. This implies that at one time the universe was small enough that it could come to thermal equilibrium but then grew rapidly, freezing in both the large-scale isotropy and the quantum fluctuations. This freezing in would have happened during an inflationary period when the universe accelerated outward at an exponential rate.

This is a decidedly nonintuitive move for a universe to make. What caused the universe to accelerate in the first place? In the old standard model of the Big Bang, without inflation, a prime mover is required, but only at the instant of creation. The explosion casts matter and

FIGURE 2

A Map of the Universe out to 2.74 Billion Light Years from the Earth



SOURCE: Gott, J. Richard and Mario Juric et al. for the SDSS Collaboration.

A map of the Universe out to 2.74 billion light years from the Earth (Gott et al., 2004). The scale is linear. Galaxies are represented by dots; the large scale, foamy, bubbly, filamentary structure of the Universe is visible. The blank wedges on the left and right are due to our lack of ability to see outside our own galaxy in these regions. They are in the plane of the Milky Way.

energy outward, expanding under this initial, unimaginable force but eventually slowing down as gravity pulls everything back to the center. The central question in cosmology at the start of the twenty-first century has been, What is the density of the universe? If the density is too low, gravity will never win and the universe will expand forever. If the density is high, beyond a critical point, the universe eventually will slow to a stop and begin to fall in on itself. The end is the Big Crunch, perhaps followed by reincarnation as the cycle begins all over again.

Neither of these scenarios appears to be the likely fate of the universe, however, based on the smooth nature of the microwave background radiation. Instead, the universe appears to exist in a state in between these scenarios, like a penny that has landed on its edge. It seems that the universe is flat, a spacetime geometry that means that the universe will continue to expand forever, although more and more slowly, approaching a stop at *t* equals infinity. The problem is that when one adds up all the mass and energy and dark matter, the universe is shy of the total amount required for a flat geometry by a factor of two.

This is where two problems are solved at once by the inflationary theory. There are quantum mechanical reasons to suspect that the vacuum itself has energy. That is, there is some underlying fabric that wildly undulates, popping fundamental particles into existence from nothing and swiftly returning them to the weave. Those particles have been observed, although the nature of the fabric and the energy it imparts to the vacuum remain mysterious. At one time the physicist Albert Einstein (1879–1955) postulated that energy, which he inserted into his equations as a cosmological constant. His goal was to produce a model of a steady-state universe, infinite and isotropic in time and space, largely because he felt that that was more aesthetically reasonable than a universe that began with a Big Bang. Although Alexander Friedman (1888–1925) showed that the Big Bang was a valid solution to Einstein's equations, Einstein abhorred that theory. However, he abhorred the ad hoc adjustment to his equations even more, and when the empirical evidence for a Big Bang could not be ignored, he declared the cosmological constant his biggest mistake. On new empirical grounds it must be included again, although a fundamental theory of its origins probably will require the achievement of a grand unified theory, a theory of everything, that string theory seems to promise for the future (Greene 2003).

This quantum vacuum energy is called the dark energy, and there is twice as much of it as there is of everything else that can be seen and measured. The dark energy has been implicated in the inflationary era of the universe and may have been the driving force for it. Still, aside from problems with identifying the quantum vacuum energy with the missing energy of the universe, the invention of the dark energy seems contrived.

There has, however, been an important recent discovery whose status has increased steadily. By very carefully measuring the red shifts, and hence the recessional velocities of galaxies deep into the universe, cosmologists have been able to map the evolution of the expansion rate of the universe. They have found that although the universe slowed down steadily after inflation, as a result of gravity, about 5 billion years ago it began to speed up again (Greene 2003). Today not only is the universe expanding, its expansion rate is increasing. The universe is accelerating, and something must be causing that. The culprit is the dark energy that permeates the vacuum.

The Story of The Creation

The newest creation story is surely not the final answer. A final theory will emerge only when there is a full understanding of how gravity is related to the other three forces and when the theories of gravitation and quantum mechanics are united. Enormous conceptual progress has been made with the development of string theory and its big brother, M (membrane) theory. String theory envisions particles as one-dimensional strings that vibrate not only in the known universe but also within six other hidden dimensions that are curled too small to be seen but that exist at every point in space (Greene 2003). A majority of cosmologists and theoretical physicists consider string theory the most promising and testable avenue for developing a true "theory of everything."

In the beginning there was an incredibly hot multidimensional nugget that was about one Planck scale (10^{-33} centimeters) in length. According to string theory, this Planckian egg is the smallest that anything can be. Squeezing it tighter makes it bigger and cooler. String theory avoids the singularity of the conventional Big Bang theory by considering the behavior of matter and energy at the very finest scales. It cannot say, however, what may have existed before this state, although this is an area of ongoing research.

The nugget had the entire mass of the universe in it, and it underwent transitions in its topography rapidly and randomly. Between 10^{-36} and 10^{-34} seconds after the start of time three dimensions suddenly broke free of their confining strings and inflated ferociously in a violent, exponential expansion. Alan Guth (b. 1947) of the Massachusetts Institute of Technology first showed that inflationary expansion of the universe represents a particular solution to Einstein's equations and can explain a deeply perplexing aspect of the CMB: its overall isotropy. The remaining dimensions stayed curled together, fundamentally influencing the nature of the particles and forces that became manifest in the three macroscopic dimensions. At one-hundred-thousandth of a second quarks began to clump into protons and neutrons.

Meanwhile, as the universe cooled, something strange was happening to the force within it. It was born with only one force, but as it cooled, it underwent phase transitions by which new forces were cleaved from the original one. Ultimately, for reasons that are not understood, the universe ended up with four forces: gravitation, electromagnetism, and the weak and strong nuclear forces. From a hundredth of a second to three minutes after the Big Bang the elements were formed. At 200,000 years the universe had cooled enough for stable atoms to form. In other words, the universe cooled from a plasma to a gas and became transparent. The photons streaming outward at that time are the blips seen on television sets.

Perhaps a billion years after the Big Bang galaxies began to form. The universe continued to expand at close to the speed of light, but the relentless action of gravity caused its expansion to slow. However, 9 billion years after the origin of the universe its expansion began to accelerate, most likely as a result of the repulsive force of the quantum vacuum energy. If this trend continues, the acceleration of the universe will cause galaxies to fly ever more rapidly away from one another. Some day even the closest galaxy will be too far away to see; the galaxies will be beyond the light horizon. Some day all the fuel for the stars will be used up, first hydrogen and then helium, carbon, and oxygen, until the last sun flickers and the universe is plunged into eternal darkness.

The Ethical and Political Dimensions of Cosmology

For many scientific disciplines the cause-and-effect relationship between scientific outcomes and the well-being of people is of great importance: Scientific results and their technological progeny are the dominant forces shaping the future of the world. The role science will play in determining the quality of life for every human being on the planet is of course determined by the elite that funds science. In this way all scientific enterprise is embedded in the greater moral problem of how individuals and groups should conduct themselves. Is it better for the powerful to channel their efforts solely for competitive self-benefit or to distribute knowledge and technology among all people? What are the consequences of pushing technologies on societies that may not want them? In some fields these issues spring directly from contemplation of the promise and implications of their projects. If it is possible to choose the human qualities of a person through genetic engineering, who will decide what those qualities will be, and to whose progeny will they go? Other subjects may be further afield, but the conceptual shift forced on science by the quantum nature of the infinitesimal in the 1920s has led to the most transforming technology in history: electronics.

Cosmology evokes a sense of the most benign and pure of sciences. The fascination of contemplating what is out there, combined with the fact that humankind cannot do anything to it, lends the study of space its alluring innocence. That of course is the old view. Cosmology is coming dangerously close to asking God rather direct questions.

To some degree scientific disciplines can be categorized by how influential ethics is thought to be in a particular field. Indeed, the ethical weight of astronomy, compared with that of genetics, lends it a kind of lightness and purity that is perceived by the people who fund it. Virtually everyone on the planet has gazed up and rested briefly in that human space where one wonders what it all is and what it all means. The pursuit of these wonders feels ennobling, partly because of the human space it comes from and partly because it is difficult to imagine how contemplation of the stars could alter the fate of humankind.

The modern science of cosmology is perhaps as far removed from the day-to-day concerns of humanity as any human endeavor can be. Futurists may conjure colorful uses for the discoveries of scientific research on the nature and origin of the universe, but this is not a matter of dealing with transistors or life-extending drugs. No one argues that cosmology is studied because of its economic impact. However, this does not mean that the study of the universe lacks an economic impact. The latest discoveries in astronomy have always depended on progress in computer, space, and detector technology (Tegmark 2002). Synergism between the astronomical sciences and industrial and military concerns is strong and growing, and both enterprises benefit.

Philosophical Issues

As self-aware beings people share a special, emergent property of the universe: consciousness. Is the quality of this aspect of nature in some way different from, say, the way space is curved as a result of the distribution of mass in the universe? What is special about the way living, replicating systems employ available resources to thrive, evolve, and produce beings that are capable of studying the deepest questions about their existence? Is mind a statistically unlikely property to have emerged from a universe with 1,000,000,000,000,000,000,000 solar systems? Or is the quality of mind ubiquitous and unifying like gravitation or other universal physical laws? Science is engaged in exploring the origin and nature of the universe as it never has before, along with the role of life and consciousness within it.

Every culture has a cosmology. Science has become the sine qua non of truth, and its revelations are taken as gospel. The insights of science into the nature of the universe therefore are assumed to or allowed to subsume all prior knowledge. It is incumbent on all scientists to ask whether their work leads to living together in harmony or interferes with that harmony. Where is the role of heart or spirit in the exploration of the cosmos or, for that matter, in any scientific endeavor? The scientific study of the origin and structure of the universe is a journey that has begun to yield answers to questions that once were the purview of religion and myth. What is done with this knowledge and what its ultimate meaning may be should be an essential component of the science of cosmology.

CRIME

Crimes are commissions of acts that are publicly proscribed or the omissions of duties that thereby make offenders liable to legal punishment. More colloquially, a crime is any grave offense, particularly against morality, and thus something reprehensible, foolish, or disgraceful. Criminal behavior is in most cases unethical; it has also been subjected to scientific study in criminology. Technological change has in turn given rise to new forms of crime.

Legal Traditions

In some legal traditions, there is a distinction between *crimes* and *torts*. The former are offenses against the state or society that are enforced by agents of the state. The latter are offenses against specific citizens, which the machinery of the state will enforce only if victims pursue their grievances in the form of a civil suit. The boundary between these categories is fluid, as discussed below with respect to homicide's historical transition from tort to crime. In keeping with ordinary parlance, both sorts of offenses are considered here.

What qualifies as crime in both its technical and informal meanings is cross-culturally variable, because laws and norms are cross-culturally variable. Premarital sex, profanity, abortion, political dissent, alcohol use, homosexuality, littering, and remaining standing in the presence of the king are all crimes in some societies but not in others. Theories of crime are thus concerned not only with the causes of criminal behavior, but with social norms and the labeling of acts. However, the fact that what is considered crime varies between times and places does not imply that it is arbitrarily constituted. There is substantial overlap in the content of criminal codes, both written and traditional, from around the world. The acts that are most consistently criminalized are concentrated in a few principal domains: certain acts of violence, certain sexual acts, certain acts of expropriation, and certain betrayals of the collectivity to rival collectivities. In general, crime entails self-interested action that violates the interests of others.

Most crimes have identifiable victims, and for criminal sanctions to be widely accepted as legitimate and just, it is important both that the victimization was undeserved and that the offender behaved with inadequate consideration of the victim's interests. Law sometimes excludes consideration of whether a victimization was deserved when deciding an offender's guilt, but this is by no means generally true—consider the breadth of cases in which "provocation" can mitigate criminal responsibility—and even where it is true, the prevalent defense practice of "putting the victim on trial" suggests that desert is a more influential consideration than a literal reading of criminal codes might suggest. As for the offender, it is not enough in Anglo-American law that a wrongful act (an *actus reus*) was committed; there must also have been a wrongful intent (*mens rea*).

The essence of the *mens rea* criterion is that the wrong-doer was overvaluing his own interests and undervaluing those of others. The two principal justifications for criminal sanctions both demand such a criterion. If criminal sanctions constitute just moral retribution, then assigning culpability without reference to intent is wrong. Alternatively, if criminal sanctions are justified by their social utility, then punishing outcomes without regard to intentions is unlikely to deter antisocial behavior. However, the concept of *mens rea* is necessarily broader than just a specifically *malevolent* intent, because it encompasses reckless disregard for the well-being of others, thereby permitting the criminalization of acts such as drunk driving in which the perpetrator may have intended no harm to anyone but was still excessively overvaluing his own desires relative to the interests of others.

In modern nation-states, criminal offenses are considered offenses against the state and it is the state that prosecutes them. This practice has evolved historically from the "self-help" justice characteristic of traditional societies lacking professional police or judiciary, where victims or their relatives might demand material compensation or undertake retaliatory action in response to offenses against persons or property. Blood revenge in retaliation for homicide and persistent blood feuds between lineages are cross-culturally widespread manifestations of such self-help justice. The first step toward a criminal justice system occurs when a socially recognized power, such as a king or a council of elders, rules on the validity of grievances and hence the legitimacy of retaliation. Note, however, that punitive response remains in the hands of victims, with the consequence, for example, that killing someone who lacked family and friends would not be penalized.

It is only relatively recently that nation-states have assumed the responsibility (at least in principle) of punishing violations against all citizens. In Britain, for example, crimes became crimes against the state only after the Norman conquest of 1066, and even then, a murder victim's lord or kinsman might still negotiate monetary compensation from the killer or his/her kin. However, because such agreements did not affect prosecution by the crown and resultant fines, confiscation of the offender's belongings, and corporal or capital punishment, and because William the Conqueror also treated private retaliation as a crime, there was little incentive for a killer or his kinsmen to reach an accord with the victims. These practices gradually faded away, as did any central role for victims of crime other than as witnesses.

From the king's or state's perspective, blood revenge and feuds between powerful families were disruptive of social order, jeopardized the tax base, and weakened societal defensive capabilities against external threat. Why the citizenry succumbed to the rise of state authority also seems clear. An ideal of impersonal state-administered justice has been associated historically, and presumably causally, with a decline in the solidarity of kin groups and a rise in contractual relationships and individual responsibility. Impersonal justice is widely considered essential for keeping the citizenry safe from predatory victimization, and it certainly does extend the umbrella of protection to the relatively powerless. Moreover, even those with retaliatory and deterrent capability may welcome it. In the case of homicides, for example, the powerful as well as the weak may be relieved to relinquish the duty of vengeance, but only if they can trust the machinery of state to punish their enemies on their behalf.

Criminology

Although crimes always entail conflicts of interest, not all conflictual action is criminal. It follows that a general theory of crime requires both a theory of the nature of human interests and a theory of what legitimizes some, but not other, ways of pursuing self-interest at others' expense. The academic discipline of criminology arose primarily within sociology, and most theories of crime rely primarily on sociological concepts such as inequity, power, norms, legitimacy, and social control. Underlying psychological theories, in the form of assumptions about human desires, developmental susceptibilities, and social inferences, are typically more implicit than explicit, and at an even more basic level, criminological theories almost never explicitly address the origins and elements of a human being's interests, which must be identified before one can recognize violations thereof. Arguably, this question is within the domain of evolutionary biology, which provides the only relevant scientific theory, namely that the apprehension of where one's interests reside has evolved to promote Darwinian fitness within the circumstances prevailing in ancestral environments. This level of analysis is uniquely able to shed light on such questions as why rape is considered a particularly horrific violation regardless of attendant physical trauma, why men are more likely than women to respond violently to social disadvantage, why maternally perpetrated infanticide is widely considered a less heinous offense than other homicides if indeed it is an offense at all, and why adultery is a sexually asymmetrical offense defined as sexual contact between a married woman and a man other than her husband in all premodern legal codes.

Psychological science is primarily concerned with elucidating the mental and behavioral processes characteristic of a prototypical human being: how memories are laid down and retrieved, how people make probabilistic inferences, what emotions people all share, and so forth. A secondary focus of psychological science is the elucidation of how individuals differ. Both lines of inquiry are relevant to understanding crime.

At the panhuman level of analysis, psychologists investigate basic mental processes, and attempt to explain historical, cultural, and ecological variability in behavior as contingent products of a universal psychology's responses to variable circumstances and experiences. Anger, for example, is a motivational/emotional state that can be elicited in any normal person, with characteristic effects on physiology and information processing; it plays a role both in mobilizing physiological resources for violent action and in advertising one's likelihood of engaging in such action. Note that these claims entail hypotheses about the functions of being angry. A psychologist who assumes, for example, that the principal function of the psychophysiology of anger is to mobilize the organism for effective physical assaults will look for a somewhat different set of manifestations and social controls than another who instead assumes that anger functions primarily to threaten and deter so as to limit the costs of violent confrontations. Within this universalist research tradition, the reasons why people vary in their frequency and intensity of anger are to be sought in the social and material forces impinging upon them.

Notwithstanding advances in the understanding of how this universal human response operates, both centrally and peripherally, it is also evident that individuals differ in their responses to identical circumstances and stimuli. Whether these differences can be attributed to the cumulative effects of prior experiences acting on a universal human nature, or instead require a different sort of theory of individual differences, is not always apparent. Psychiatrists have identified a personality type that is disproportionately responsible for crime, especially violent crime: the "antisocial personality." Risk factors associated with the development and maintenance of antisocial personality include poverty, maleness, early maturity, poor school performance, parental criminal history, and psychopathology, implying that antisocial personality is in large part a facultative developmental response to experiential indicators of the lesser utility of developing a more "prosocial" personality. However, there is also evidence from twin and adoption studies that antisocial personality is substantially heritable, implying that individual differences in behavior are attributable to genetic differences.

Despite a large body of research on the genetics of crime, there has been relatively little consideration of this puzzle: why does genetic variability affecting phenomena such as criminal behavior exist? The reason for asking is because natural selection generally tends to eliminate genotypes with suboptimal phenotypic consequences, and one might expect that selection would have favored a panhuman phenotypic "design" with violence and other conflict behavior under appropriate contingent control. One possible answer to the puzzle is that heritable variation in antisocial behavior is a modern phenomenon and there has been insufficient time and/or fitness cost to eliminate the variability from human populations. A more interesting possibility is that antisocial personality types have social and material advantages in populations where they are rare and can exploit the trust and friendliness of the prosocial types.

Discussions of crime are often couched in the language of pathology. This is appropriate insofar as criminal acts reflect psychoses, delusions, and brain damage, but the language of pathology can mislead. Pathologies are failures of anatomical, physiological, and psychological adaptations, as a result of mishap, senescent decline, or subversion by biotic agents, such that the adaptations are no longer achieving the functions for which they evolved. The prototype of a pathology is a fracture: A broken bone can no longer perform its function. But crimes against people and property are not clearly pathological, and the term is certainly not applicable to violence in general. Violence is often well-regulated, self-interested behavior, and there are parts of the normally-functioning human brain that are dedicated to the production of controlled violence. The misconception that human violence is pathological has perhaps been reinforced by studies linking it to disadvantaged backgrounds and environments, but these associations are by no means universal. In nonstate societies, violence has been a prominent attribute of high-status men and a contributor to their social success. In modern state societies, the welfare of most people no longer depends on their own or their allies' violent capabilities, so violence is relatively rare and relatively likely to reflect psychological pathology. Nevertheless, disproportionate numbers of violent offenders are drawn from groups who lack access to the opportunities and protective state services available to more fortunate citizens, and who therefore find themselves in "self-help" circumstances much like those experienced by most people's ancestors.

Most crime is committed by men, and more specifically by young men. Criminologists and other social scientists have offered various hypotheses to explain these facts, but most of these hypotheses invoke local aspects of particular societies and thus provide no candidate explanation for the cross-cultural generality. Such consistently gendered behavior is better understood in terms of the different selection pressures confronting humanity's male versus female ancestors. There is morphological, physiological, developmental, and psychological evidence that humans evolved under chronic circumstances in which the variance in fitness was greater among males than among females: men had both a higher ceiling on their potential progeny and a higher chance of dying childless. In human beings, as in other animals, a higher variance in reproductive success has selected for a psyche that is more inclined to see life as a competitive contest with same-sex rivals, and is more willing to accept risks in the pursuit of material and social resources, including a willingness to embrace dangerous confrontations.

Criminal offenders have been characterized as lacking self-control and the capacity to delay gratification. In effect, criminal offenders tend to value the near future more highly, relative to more distant futures, than do law-abiding citizens. Discussion of these phenomena often presupposes that steep discounting of the future is dysfunctional, but an alternative view is that the human psyche has been designed by selection to adjust the discount rate ("patience") in relation to age, sex, and social and material circumstances. In this view, a short time horizon may be a rational response to information that indicates an uncertain or low probability of surviving to reap delayed benefits, and the sort of reckless, risk-accepting mindset that facilitates criminal acts may be aroused when the expected material or social profits from safer courses of action are negligible.

Variations in rates of crime are social phenomena, affected by sociological and demographic variables such as local cultural practices and the population's age structure. Elucidating exactly how and why these variables affect criminal acts by some and not other citizens is a project requiring interdisciplinary synthesis involving all social and biological sciences.

CRITICAL SOCIAL THEORY

Critical social theory constitutes an effort to rethink and reform Marxist social criticism; it characteristically rejects mainstream political and intellectual views, criticizes capitalism, promotes human liberation, and consequently attempts to expose domination and oppression in their many forms. The extent to which science and technology may be associated with domination and oppression has been a major theme of critical theory.

Background and Method

Critical theory is not so much a particular theory as a tradition of thought historically associated with the Institute for Social Research, founded at the University of Frankfurt, Germany, in 1923. It is thus also commonly known as the Frankfurt School. The rise of Nazism forced Institute members into exile in 1933; the Institute then became affiliated with the Studies in Philosophy and Social Science program at Columbia University in New York City in 1935. The original school was reestablished in Frankfurt in 1953.

The Frankfurt School was a multidisciplinary group that included philosophers, sociologists, economists, political scientists, legal theorists, psychoanalysts, and others. Key members of the first generation were Max Horkheimer (1895–1973), Theodor Adorno (1903–1969), Erich Fromm (1900–1980), Herbert Marcuse (1898–1979), Leo Lowenthal (1900–1993), and Franz Neumann (1900–1954), with Walter Benjamin (1892–1940) as a close associate. Important members of second and third generations include Jürgen Habermas (a student of Adorno), Axel Honneth, Andrew Feenberg (a student of Habermas), Douglas Kellner, Steven Best (a student of Kellner), Albrecht Wellmer, Claus Offe, Nancy Fraser, and Martin Beck Matustik. Distributed now among institutions in the United States (Kellner is at the University of California in Los Angeles, Best at the University of Texas in El Paso, Fraser at the New School in New York) and Canada (Feenberg is at Simon Fraser University in Vancouver, British Columbia) as well as Germany, critical theorists have continued to include as part of their engagements with contemporary issues a critical dialogue with the works of Immanuel Kant (1724–1804), Georg Wilhelm Friedrich Hegel (1770–1831), Karl Marx (1818–1883), Søren Kierkegaard (1813–1855), Max Weber (1864–1920), Gyorgy Lukács (1885–1971), and Sigmund Freud (1856–1939).

The key method of critical theory is *immanent critique*, which focuses on the internal tensions of the theory or social form under analysis. Using immanent critique, critical theorists identify the internal contradictions in society and in thought, with the aim of analyzing and identifying (a) prospects for progressive social change and (b) those structures of society and consciousness that contribute to human domination. Critical theorists aim to aid the process of progressive social change by identifying not only what is, but also identifying the existing (explicit and implicit) ideals of any given situation, and analyzing the gap between what is and what might and ought to be. When applying immanent critique to science and technology, critical theorists identify both oppressive and the liberatory potentials.

Regarding science and technology, all critical theorists hold that science and technology are intertwined into a single complex or realm of human activity that in the early twenty-first century is commonly called *technoscience*. Further, they believe that technoscience is not neutral with respect to human values, but rather creates and bears value. They argue that the tools people use shape ways of life in societies where technoscience has become pervasive. Hence, how individuals do things determines who and what they are, and technological development transforms what it is to be human. But while critical theorists agree that the apparently neutral formulations of science and technology often hide oppressive or repressive interests, they differ in their ideas about whether technoscience is of necessity a force for dehumanization, and if not, why and how it might serve as a force for greater freedom.

From Hope to Dystopia: Horkheimer and Adorno

One strand of the critical theory tradition contains an initially hopeful view that technoscientific progress might inevitably drive forward human progress and contribute to the realization of greater freedom. This later gives way to a dystopian view, in which technoscience is equated with domination. In the 1920 and 1930s, many members of the Institute adopted a rather orthodox version of Marxism, arguing that the socialist revolution is a natural and inevitable outcome of the internal contradictions of capitalism. In line with this idea, Horkheimer, the second director of the Institute and the person who first named the members' work "critical theory," argues that progress in the forces of production has created objective possibilities for human liberation. These possibilities have not yet been realized because capitalism limits the progress of science and technology and thus restricts human progress. For Horkheimer, only a social and political revolution can unleash greater progress in the technosciences and harness technoscience to the cause of human liberation (Horkheimer 1972).

INSTRUMENTAL DOMINATION. While in exile in the United States during the late 1930s and 1940s, Horkheimer and Adorno reconceptualized their views on science and technology. They came to believe that the project of the European Enlightenment has turned into a mythology, and that modern reason and modern autonomy are rooted in the domination of non-human nature, other humans, and people's inner lives (Adorno and Horkheimer, 2002). They claim that the ideal of the Enlightenment is an ever-larger rational conversation about goals, values, and desires that expands the realm of human knowledge and action. Thus, they believe, the Enlightenment is an effort to increase human freedom and self-determination. But the course of reason since the Enlightenment has been increasingly to refuse to think about real alternatives. Rationality becomes, they argue, reduced to instrumental thinking: that is, to reasoning about efficient means to already given ends. This mode of thinking—instrumental reasoning—has become, they argue, the mode of thought characteristic of western culture in general, and of the technosciences in particular.

As they investigate the increasing integration of economics and politics, they find that society is ever more structured around the capitalist value of profit making and the technoscientific value of efficiency. Technological advances, including the increasing fragmentation and mechanization of work tasks, transform the work process. Work becomes more repetitive and mind numbing; workers are ever more isolated from one another, and have ever less time to critically reflect on their work or lives.

Thus, for Adorno and Horkheimer, technoscientific development brings with it increasing dehumanization. Modern institutions and ideas, including transnational organizations and democracy, are shaped and guided by instrumental rationality, and exist primarily to preserve themselves. It is no longer possible to ask about, or critically evaluate, ends; these are taken for granted. Because only questions about means can be considered by instrumental rationality, questions about ends are now considered irrational. So the progress of Enlightenment reason, restricted to instrumental rationality, contradicts the very goal sought by the Enlightenment—the increasing liberation of human beings. And modern technoscience, which should contribute to greater human freedom, increasingly becomes a cage of our own making.

CULTURE INDUSTRY. According to Adorno and Horkheimer, technology now carries the values of capitalism and of a consumer society. They coin the term "culture industry" to signify the process of the industrialization of mass-produced culture and the commercial imperatives that drive the system. The culture industry creates distractions, and the semblance of freedom (such as through the choice of which TV show to watch, or which breakfast cereal to purchase). But it offers no real alternative and only serves to distract people from careful reflection on the conditions of their lives. Adorno and Horkheimer attempt to demonstrate that the products of the culture industry commodify and mechanize everyday life, and that consumers of popular culture accept the pre-given ends of their culture and worry about how to organize their lives to acquire as many of these goods as possible. Thus the values of efficiency and instrumentality that characterize the technosciences and industrial production slowly shape the whole of society.

They further claim that in contemporary culture there is little critical awareness of technology because what is thinkable is constrained to those options considered rational under a narrow instrumental definition of rationality. Thus it is difficult for people to think of technology as a bearer of values. The technosciences appear to be value neutral, and the values of efficiency and instrumentality seem to be the only values it is rational to adopt. Hence, the dominant conception of technoscience is as something good if in the right hands. Adorno and Horkheimer argue that so long as instrumental reasoning is the dominant mode of thinking in Western culture, then human liberation will be blocked. Further, because instrumental rationality characterizes the Enlightenment and subsequent cultures at their very core, and is at the essence of technoscience, then technoscience necessarily leads to domination and dehumanization.

This increasingly dystopian view of technoscience is reinforced by the exposure of the great depths of evil that technoscience produced in the service of fascism, and in the Soviet system. By focusing only on means, many engineers, scientists, and technicians made death camps more efficient and produced propaganda and weapons for the oppression and control of people. As Horkheimer and Adorno understand things, all of this was made possible by instrumental reason that comes to see everything, even human beings, as objects of study and manipulation. They see liberal capitalism as also a system of domination because the growth of the culture industry, and the spread of technocratic thinking, only spreads domination over inner and outer nature. This process is all the more insidious because it does not appear as domination, but rather as entertainment, or simply as reality.

AESTHETIC LIBERATION. There is, however, one sphere of culture, they argue, that resists instrumentalization, and this is the fine arts. The great artists have, in their works, preserved and exemplified autonomy, thereby resisting merely instrumental concerns. In his last great work Adorno develops a complex theory of aesthetic resistance as maintaining a critical function, and as preserving the last vestige of humanness in an increasingly technological and inhumane world (Adorno 1998).

There are many questions and responses to this version of critical theory and its dystopian view of technoscience. American pragmatists, especially John Dewey and Larry Hickman, develop a version of instrumentalism that, rather than rejecting critical reflection on the ends of activity, requires it. Pragmatists have further criticized Adorno and Horkheimer for their increasing disengagement from any projects of real social change. Another criticism is that the work of Adorno and Horkheimer is elitist and escapist, especially in recommending the highly formal and abstract work of artists such as Arnold Schönberg (1874–1951). Such a detached view fails to live up to the goal of decreasing oppression. From within critical theory, Benjamin, Marcuse, Habermas, and Feenberg all break with dire pessimism and offer theories of technoscience as potentially aiding human liberation.

Liberatory Possibilities

There is another strand of thinking about technoscience within critical theory, composed of those who reject the pessimism of Horkheimer and Adorno and who maintain that technoscience can be useful in fighting domination. As with critical theory as a whole, this tradition contains multiple particular positions, some of which are at odds with each other. All maintain, however, the method of immanent critique, and the commitment to a critical analysis of culture with the aim of aiding human liberation. The four strands of critical theory that identify liberatory possibilities in technoscience are:

(1) the idea that technological change will sweep away old and oppressive cultural forms (Benjamin);

(2) that technoscience is oppressive under capitalism, but might be otherwise under a different social order, and hence might embody different values (Marcuse);

(3) that technoscience has an internal logic appropriate to its own realm, but that it must be restrained or all of life will fall under its sway (Habermas);

(4) that technoscience always contains internal contradictions, and thus always contains potentials both for oppression and liberation (Feenberg, Kellner, and Best).

WALTER BENJAMIN. The idea that technological change might sweep away oppressive aspects of culture is most clearly stated by Benjamin. For him, there are progressive possibilities in new technologies of cultural production, especially film, radio, and photography. Traditional forms of art maintain their cultural power through the aura of the authentic original. This gives the great works of art a mythic status that has served to present, maintain, and further the power of some, such as the church, the wealthy, and the state, over others.

Benjamin argues that the technologies of mechanical reproduction break down the aura and shatter the myth of authenticity. For example, not only is it difficult to determine which, if any, photographic print is the original, but also mechanical reproduction allows people to replicate the great works from history. Thus high culture loses its mystifying power. Further, media culture could cultivate individuals better able to judge and analyze their culture. By processing the flow of images in film, people develop the ability to better parry and comprehend the erratic and powerful flow of experiences in industrialized, urbanized societies. For Benjamin, the buildings, pictures, and stories of avant-garde artists, work that was often highly dependent on technology, was a form in which humanity was preparing itself to survive even the darkest night of fascism.

HERBERT MARCUSE. The position that technoscience is oppressive under capitalism, but might be otherwise, is clearly articulated in the work of Marcuse. Unlike Adorno and Horkheimer, who see technoscience as having a necessarily oppressive essence, Marcuse believes it is possible to identify and understand the specific historical and social forces that lead to oppressive technoscience.

Under capitalism, Marcuse argues, technology produces a mass culture that habituates individuals to conform to the dominant patterns of thought and behavior, and thus provides powerful instruments of social control and domination. This is so, he claims, because under capitalism, technology reflects particular class interests in what he calls a "one-dimensional society" (Marcuse 1964). Consumer culture, which is made possible by the rapid advances of the technosciences, is seductive, and sexually charged, while work is ever longer and more soul-killing. Rather than the sublimation of desire discussed by Freud, which leads to the great and meaningful products of human culture, Marcuse identifies a process of repressive desublimation in which everything becomes sexualized, but meaning and satisfaction are ever more elusive.

However, for Marcuse, technology could, through its advance and transformation, mechanize most socially necessary work, and thus free human beings for greater creative self-expression and social experimentation. Technology would cease to be autonomous, as it is in the one-dimensional society, and would become subordinate to a substantive notion of the good life, one that is fundamentally aesthetic in nature. Marcuse has an aesthetic model of human beings as free, self-creative beings. He believes that only spontaneous creative activity could break out of the one-dimensionality of life under capitalism. Hence, a new form of technoscience, one that embodies not mere instrumentality, but also allows for spontaneity and creativity, might further human liberation. Because of the centrality of one-dimensional intrumental rationality in modern society, Marcuse hypothesized that the likely sources of the ideas and energies for radical social change, including new forms of science and technology, would come not from the working class as traditionally conceived, but would be found in those most marginalized in society—people of color, women, and the disenchanted young. Among others, Angela Davis was both inspired by, and inspiration for Marcuse's work.

Critics rightly note that this alternative is highly speculative and underdeveloped. In his development of still another strand of critical theory that sees technoscience in a potentially positive light, Habermas criticizes Marcuse's position as hopeless romanticism, and one that dangerously will restrict the careful use of instrumental reasoning in the areas where it is appropriate to use it.

JÜRGEN HABERMAS. The third version of critical theory that views technoscience as having some liberatory potential is exemplified in the work of Habermas. He argues that technoscience brings great benefits to humans in modern cultures, and that insofar as it is concerned with technoscientific questions it should remain true to its own internal values. A problem arises when individuals allow technoscience and technoscientific values to take over other realms of human life that should not be organized around values of productivity and efficiency. Habermas criticizes the tendency of modern societies to subject all areas of human life to instrumental reasoning. For example, the sorts of thinking best suited to determining how to build a bridge are not the same as those best suited to nurturing friendship, neither are the skills and modes of thinking that characterize consumption those best suited to responsible citizenship. Habermas claims that it is dangerous to allow the values of either realm to seep into the other. On the one hand, the result is dehumanization of human relationships, and many of the destructive possibilities identified by other critical theorists. On the other, the consequence is bad science, and the pursuit of technical knowledge will be subordinated to ideology. Thus, technoscience, properly constrained, is necessary to human liberation, and to decreasing suffering and oppression.

Some critics argue that his position offers no concrete criteria for changing technology. Others claim that his position is hopelessly naïve, and that the technosciences cannot be constrained in the manner he suggests, so that Habermas's theory is actually a justification of the status quo.

ANDREW FEENBERG. The most recent work in critical theory of technology adopts a fourth position and argues that technoscience always contains contradictory possibilities. This is so because there are many dimensions to technoscience, many of which traditional accounts fail to identify. For this reason Feenberg argues that technology should be reconceived of through instrumentalization theory. This theory distinguishes between the understanding of technology by technical experts and philosophers of technology, and the understanding of technology within a specific social context by those who use it and are affected by it. Users of technology often deploy it in unintended and often unanticipated but imaginative ways. These uses often challenge existing technological systems and social orders. By better understanding and developing these contradictory potentials, he argues, the critical theorist can further the goal of assisting the cause of human liberation. Feenberg continues the Frankfurt school interest in popular culture, but is more sensitive to the political complexity of contemporary culture, and thus to the ambipotent nature of technological change. His work engages not only theorists such as Habermas and Heidegger, but included empirically rich case studies of French communications technologies, Japanese conceptions of technology, science fiction, and film. Feenberg returns the tradition of critical social theory to its multi-disciplinary roots, and is active in empirical research on the development and uses of technology, especially educational technologies.

DOUGLAS KELLNER AND STEVEN BEST. Kellner and Best bring critical theory into dialogue with postmodern and poststructuralist thinkers such as Jean Baudrillard, Michel Foucault, and Arthur Croker. Along with Feenberg, they also bring critical theory into dialogue with the pragmatist tradition. Kellner and Best also continue and revitalize the tradition of culture industry critique. However, unlike Adorno, they work to identify the contradictory potentials present in popular culture. Kellner has long explored the oppositional possibilities within technology, especially in alternative media and education. Best is also expanding critical theory into environmental philosophy.

Assessment

Contemporary critical theorists agree that there are liberatory possibilities in technoscience, but only the careful use of human will and consciousness can bring these to fruition. The future of critical theory promises an ever-greater dialogue with other applied traditions in philosophy, especially with pragmatism. Although some, such as Larry Hickman, have argued that critical theory is still too tied to an anti-technology paradigm that limits its practical usefulness, critical theorists are becoming more involved in concrete issues, from the alternative media work of Kellner to the work on computer-based learning of Feenberg, and this trend too promises to make critical theory more empirically rich, and thus better able to work toward the goal of increasing the realm of human freedom.

CULTURAL LAG

The U.S. sociologist William F. Ogburn (1886–1959) developed the concept of cultural lag, which occurs when unequal rates or degrees of change between interdependent parts of culture leads to "maladjustment" (1922). According to Ogburn, as new inventions are introduced into society, a maladjustment occurs and a period of adjustment is required. Most often these inventions are technological in nature, and are part of what he termed "material culture." However, Ogburn noted that "non-material culture" can also drive change. For example, he cites India in the early years of Buddhism as a case where religion was driving change in other areas of culture (1964).

Ogburn's classic description of technologically-driven cultural lag was the period required for society to adapt to the speed of the automobile (1964). It took some time for the social institutions and customs of road building to adapt to the ability of new cars to travel much faster than horses and older car models. A more pressing example is provided by the advent of nuclear

FIGURE 1

Relationship Between New Technology and Culture

weapons, which represent an enormous leap in scientific knowledge without a complimentary advance in political institutions capable of regulating and using that knowledge wisely. Another example is provided by the rapid advances in biomedical technologies and the ability of institutionalized ethics committees, such as Institutional Review Boards (IRBs) and Institutional Biosafety Committees (IBCs), to adapt to those changes and make wise decisions. The depletion of natural resources, especially oil, represents a broader interpretation of cultural lag, where changes in the material environment may outpace the cultural response to those changes.

Numerous other cases exist where science and technology have advanced more rapidly than the spiritual, social, or political aspects of culture. Indeed, the anthropological studies collected by Edward H. Spicer (1952) and H. Russell Bernard and Pertti J. Pelto (1987) document examples of a relationship that Bernard and Pelto simplify as shown in Figure 1. Such maladjustment can prove socially harmful.

However, the concept of cultural lag must be interpreted and applied carefully in order to avoid dubious assumptions about progress. First, it must be recognized that culture can also lead rather than follow. Many historical analyses of how modern science and technology arose in Europe after the 1500s, such as those by Max Weber (1904), Lynn White, Jr. (1978), and others, have argued that cultural change preceded technological change. Second, it need not follow that "lagging" aspects of culture must simply be altered in order to "catch up" with more rapidly changing elements. If applied interculturally, the concept can also promote Eurocentric assumptions about "underdeveloped" parts of the world, and lead to irresponsible transfer and application of technologies.

Several evaluations of cultural lag exist in terms of its ability to describe and predict cultural change (Brinkman and Brinkman 1997). More important, however, is the need to deconstruct any bias toward an inadequate notion of *progress* within the metaphor of cultural lag. It is intuitive that various parts of culture change at different rates and thus no longer fit together smoothly. Yet this does not necessarily mean that one part now "lags behind" another. The metaphor of *cultural lag* easily connotes the "failure" of different cultures or parts of culture to adjust to change, as if there were no agency or choice outside of simply running along the treadmill of material change.

In other words, as Alvin Toffler argues, cultural lag needs a balancing term of "future shock," which describes "the shattering stress and disorientation that we induce in individuals by subjecting them to too much change in too short a time" (1970, p. 4). Building directly off of Ogburn's concept, Toffler explains, "The concept of future shock ... suggests that there must be balance, not merely between rates of change in different sectors [of society], but between the pace of environmental change and the limited pace of human response. For future shock grows out of the increasing lag between the two" (p. 5).

He makes the argument that rapid change is neither indisputably good nor out of one's control to shape and sometimes slow down. The future can arrive too soon for society's own good. This highlights the central idea within cultural lag of proportionality, equilibrium, and harmony (the right adjustment) among the parts of culture. As Toffler argues, "The only way to maintain any semblance of equilibrium ... will be to meet invention with invention—to design new personal and social change-regulators. Thus we need neither blind acceptance nor blind resistance, but an array of creative strategies for shaping, deflecting, accelerating, or decelerating change selectively" (p. 331). Achieving this selective change is not a simple, technical matter of "catching up," but rather a series of decisions about the meaning of the good life and the ideal society.

CYBERCULTURE

In a restricted but popular sense, cyberculture denotes the hacker subculture along with various social and artistic manifestations; as such it references feedback loops, computer slang, video games, the Internet, hypertext, virtual communities, and more. In a wider and more argumentative sense, cyberculture refers to contemporary culture in its totality, insofar as it has been influenced by cybernetic technology and its creative ideas. In both senses cyberculture has become a new scientific and technological context that stimulates ethical reflection.

Historical Development

The term *cyberculture* appeared in the 1980s but is ultimately dependent on Norbert Wiener's creation of the science of "cybernetics" (1948). An initial cyberculture emerged before the term itself when the scholarly community attempted to apply cybernetics to the interpretation of phenomena in psychology, economics, politics, anthropology, and education. The work of Gregory Bateson (1972) and Heinz von Foerster (1984) in the development of "second-order cybernetics" was central to this development, as was the promotion of information and systems theory. In the Soviet Union cybernetics, after initially being rejected under late Stalinism as another form of bourgeois ideology, also exercised a special attraction as a possible means to reconcile central planning with the increasing complexities of large-scale systems that were straining under top-down management inefficiencies (Gerovitch 2002). Cyberculture in these senses was never so named, and was never more than an issue among specialist intellectuals.

A second-stage cyberculture emerged in science fiction from the mid-1980s. Bruce Bethke (in his 1983 short story "Cyberpunk"), William Gibson (in 1984's *Neuromancer*), and others developed a new form of science fiction; in opposition to classical science fiction, which had become somewhat domesticated, such authors introduced raw (punklike) elements and expressed a negative vision of the short-term future. Bruce Sterling (1986) provides a general introduction to this form of cyberculture. Promoted in part simply by the linguistic accident that *cyber* could be easily prefixed to anything from space to sex, cyberculture experienced a rapid inflationary moment in *cyburbia* and *cyberia, cyberphilia* and *cyberphobia*.

Science-fiction writer Neal Stephenson justified this inflation by declaring: "Our concept of cyberspace, cyberculture, and cyber-everything is . . . a European idea, rooted in Deuteronomy, Socrates, Galileo, Jefferson, Edison, Jobs, Wozniak, glasnost, perestroika, and the United Federation of Planets" (1994, p. 100). In this sense, cyberculture includes everything from science and technology to politics and literature as it has been altered by the mediation of computers, digital interactivity, and "hacktivism" (Himanen 2001). From such an amplified perspective, cyberculture is simply that culture which emerges through symbiosis with cybernetic or information technology, itself understood as the fulfillment of technoscience, after the manner of Martin Heidegger's identification of cybernetics as the ultimate stage of metaphysics (Heidegger 1972). Indeed, the methods of experimentation and logical analysis that are central to science have now been supplemented with simulation modeling that introduces something such as cyber-experimentation into science.

Using a distinction between culture (of and related to nature or the body) and civilization (of or related to politics and rationality), cyberculture may also be thought of as constituted primarily by those human interactions with the material world of advanced technological artifice that are replacing nature as the basic context for human experience. Cybertechnology in some form has come to exist in the background of all new political orders and rational discourse, and even encourages human beings to consider the ways in which they are becoming cyborgs (Haraway 1991) or posthumans (Hayles 1999).

The general examination of cyberculture in these disparate senses is found in cyberculture studies, which includes the more focused field of cyborg studies. According to David Silver, director of the Resource Center for Cyberculture Studies, this kind of activity has passed from popular promotion based on the image of a "cybernetic frontier" through an initial scholarly concern for sociological (virtual communities) and psychological (online identity transformation) implications, to what he terms "critical cyberculture studies." In critical cyberculture studies the ethical issues implicit in such works as Howard Rheingold's *The Virtual Community: Homesteading on the Electronic Frontier* (1993) and Sherry Turkle's *Life on the Screen: Identity in the Age of the Internet* (1995) become explicit themes.

Ethical Issues

The shift from description to critical assessment has taken place around four overlapping themes. First, questions are raised about the personal and environmental safety of cybernetic hardware. The silicon chip and carbon-zinc battery industries are not as obviously polluting as steel mills and chemical plants; they nonetheless present major challenges to worker safety and environmental contamination in both the production and disposal cycles. Safety and ergonomic issues are further associated with the use of screens (eyestrain) and hands (keyboard and mouse strain).

Second, critical issues are further associated with economic and political discussions of dot-com cyber-industries. Concerns for the economic and political impacts of automation extend into discussions about cybernation, cybercrime, accounting fraud, marketing hype, treatment of labor, and concentrations of wealth and power in the networked society. Debates about a possible digital divide also fit in this category. At the same time, Pekka Himanen (2001) has argued that a distinctive cyber-economics is growing out of the "hacker ethic" applied to business affairs using open-source software. Finally, questions of cyberpower have been posed in relation to adaptions of the Internet to enhance democracy, to plot or practice criminal and terrorist communications (including venial hacking or "cracking" and the launching of viruses), and to police those same communications.

Third, detailed historical, sociological, and psychological studies have attempted to contextualize the practices characteristic of cyberculture. Empirical case studies qualify both promotional hype and jeremiad alarms. Cybersex is not unexpectedly one of the most written about topics (see, for example, Ben-Ze'ev 2004). But cyberculture is revealed as not so much cut loose from culture as culture in a new form, full of subtle negotiations taking place between online and off-line worlds, yet still with persistent dangers. The standards of acceptable behavior in cyberspace—for online communications, for instance—are constructed in ways that mirror what happens in playgrounds or offices.

Fourth, the narratives of cyberculture call for aesthetic and literary criticism. What are the distinctive structures of motion pictures of the cyberfuture such as *Blade Runner* (1982), *The Terminator* (1984), and *The Matrix* (1999)? Is cyberart a distinctive form that enhances—or does it only exploit and entertain? Can computers write poetry? In what ways do such stories and productions inform or obscure the phenomena they both use and challenge? What distinctive roles do violence, glamour, sex, and speed play in cyberspace? The mass production of virtual pornography, including bestiality and pederasty, poses special questions for cultural criticism.

These four themes, along with issues of ethical responsibilities among cyberprofessionals and questions about the ontological status of cyberrealities, are included in an increasing number of books focused on cyberethics. (The Association for Information Systems nevertheless restricts "cyberethics" to information system ethics.) Although all these themes appear in other encyclopedia articles, their relations deserve to be highlighted here to emphasize synergies and interactions among the various dimensions of coming to ethical terms with the new life human beings are creating for themselves through cyberculture, whether narrowly or broadly defined.

CYBERNETICS

Cybernetics is defined classically as the study of "control and communication in the animal and the machine" (Wiener 1948). After the decline of classical cybernetics, the field underwent a rebirth as "second-order cybernetics" in the early 1970s. Second-order cybernetics is more closely and more obviously involved with ethics than classical cybernetics (and certainly promotes a radically different worldview), but both have important contributions to make to reflections on science, technology, and ethics. Cyberculture, an increasingly important phenomenon that includes elements as diverse as email and chat rooms, electronic commerce and gaming, virtual reality and digital politics, has its origins not just in computers but also in the lesser known field of cybernetics (from which it takes its name).

Cybernetics

Cybernetics was originally promoted by the mathematician Norbert Wiener (1894–1964) in his 1948 book of that name (although W. Ross Ashby's 1956 book, *An Introduction to Cybernetics*, is considered the classic introductory text). The terms of cybernetics (including *goals* and *purposiveness*, *feedback*, and *mechanism as metaphor*) had been previously used, as was the concept of control as attaining and maintaining desired states, rather than restricting the actions of others—but not as concepts forged into a coherent field. In the development of cybernetics, two groups were particularly important: the informal association of Wiener, Arturo Rosenblueth (1900–1970), and Julian Bigelow (1913–2003) at the Massachusetts Institute of Technology (MIT); and the Josiah Macy Jr. Foundation meetings on "Circular, Causal, and Feedback Mechanisms" (which assumed the supertitle "Cybernetics" after the publication of Wiener's book), which included Warren McCulloch (1898–1969), Walter Pitts (1923–1969), Margaret Mead (1901–1978), Gregory Bateson (1904–1980), Heinz von Foerster (1911–2002), and Wiener and Rosenblueth.

The term *cybernetics* was derived from the Greek *kybernetes*, meaning "helmsman," and the field initially examined the behavior of (often complex) systems to develop models for improving system performance. The models were based on a notion of universally applicable mechanism: No essential differentiation was made between animate and inanimate systems. Examination of behaviors meant that systems which seemed impossibly complex or obscure no longer needed to remain so. If cyberneticians could not see what constituted a system, they could treat the system as a black box, which, through careful study of the inputs and consequent outputs, could be notionally "whitened" to the point that a viable mechanism relating input and output could be imagined, even if the actual mechanism remained unknown.

The intention was that systems would become controllable or better able to achieve the aims for which they were intended. The systems that cyberneticians studied were assumed to have observer-defined goals. Potential for error was understood to be omnipresent. To correct an aberration in the behavior of a system, differences between the (hypothesized) goal and behavior were examined, and the system adjusted to compensate for any difference (error). The process of error determination and correction continued until the system began to attain (and continue to attain) its goal.

Although the physical systems initially considered by cyberneticians were military and mechanical (starting with antiaircraft guns and developed through W. Grey Walter's electronic "tortoise" and Ashby's "homeostat," as much as through the computer and the robot), the animate quickly grew to be of equal significance. Application to social, anthropological, and psychological issues was pursued by Mead and Bateson (Bateson 1972a), especially in regard to mental health issues—a concern that Bateson shared with Ashby, also a psychologist. Management cybernetics was born of Stafford Beer (1926–2002) in the 1960s, and Gordon Pask (1928–1996) began cybernetic studies of teaching and learning in the 1950s.

There are many similarities between classical cybernetics and the slightly later mathematical theory of communication, or information theory, of Claude Shannon and Warren Weaver (1949); and general systems theory and its siblings, such as systems science, as developed by Ludwig von Bertalanffy (1950), making differentiation between these approaches difficult. Which term is used is frequently no more than a personal preference or historical accident. All of these approaches made notable contributions to such scientific and technological understandings and developments as the relationship between wholes and parts, automated control systems, approaches to complexity, developments in computing and communications hardware and software, and homeostasis in biological systems—to list but a few.

Early on, Wiener recognized ethical dangers in the cybernetic approach. The conjunction of animal and machine, even used metaphorically, has ethical implications—especially when the metaphor is predominantly of the animal as machine rather than the machine as animal. Another typical (and well-known) danger is that associated with the power of the machine, as exemplified, for example, in Isaac Asimov's "Three Laws of Robotics," from his science-fiction writings, which read:

First Law: A robot may not injure a human being, or, through inaction, allow a human being to come to harm.

Second Law: A robot must obey orders given it by human beings, except where such orders would conflict with the First Law.

Third Law: A robot must protect its own existence as long as such protection does not conflict with the First or Second Law. (Asimov 1942)

Wiener's *Human Use of Human Beings* (1950) is his attempt to come to terms with the most important of these dangers. He was not alone in this awareness. These ethical considerations, however, are not peculiar to cybernetics.

Second-Order Cybernetics

The initial promise of cybernetics was more than could be delivered, and the subject fell out of favor. By 1970 its funding base had eroded (with assistance from the Mansfield Agreement, a U.S. law introduced to prevent the military from funding any speculative research, or research that might not lead to an immediate military outcome). For some cyberneticians this indicated retrenchment, for others reconsideration leading to a new beginning: second-order cybernetics. The critical insight differentiating second-order cybernetics from classical (first-order) cybernetics is that second-order cybernetics takes cybernetic circularity more seriously.

Classical cybernetics exists within a worldview in which energy considerations reign paramount. The feedback loop is understood as requiring insignificant amounts of energy, thus creating a hierarchy. The controller, using relatively (and ignorably) little energy, controls the controlled, which is the big energy using part of the system. In second-order cybernetics, form and information are considered in preference to energy. In a second-order cybernetic control loop, the information passed between controller and controlled is understood to be of equal status. First-order hierarchy disappears. Each component in the loop contributes to the control of the whole. In effect, each component controls the other and the controller/controlled distinction is seen as a matter of role. The circular form of the cybernetic system is no longer disguised.

The difference was not initially presented this way. The originator of second-order cybernetics, von Foerster, made the following distinction on the frontispiece of his compilation "The Cybernetics of Cybernetics" (1975):

> First order cybernetics—the cybernetics of observed systems / Second order cybernetics—the cybernetics of observing systems.

These two characterizations, however, appear similar if one treats *observe* and *control* as interchangeable verbs, and remembers that the observing/controlling system is observing/controlling the observed/controlled system in order to develop understanding, which requires feedback. Furthermore, these concerns are similar to those expressed in the involved observer of Ernst von Glasersfeld's *Radical Constructivism* (1987).

The circular systems of Second Order Cybernetics are essentially autonomous. Their stability derives from their (internal) maintenance of their circular processes. To an external observer they may appear to veer wildly. An example is the Autopoietic system of Humberto Maturana, Francisco Varela and Ricardo Uribe. This system constructs and then maintains itself, providing a model of "life"—or, rather, "living." Such systems are said to be *organisationally closed* but *informationally open*: the form of the system maintains (distinguishes) itself, is in this manner autonomous (Maturana and Varela 1992). Information enters, passes through (is processed by) and exits it. The system distinguishes itself as itself. Because these systems are autonomous, any meaning the information passing through them may have is unique, private to each system. Communication between these systems cannot be by transmission of meaning because each system builds its own meaning: Meanings are not communicated. Uncoded communication may, however, occur through conversation. Pask's conversation theory (a formalized version of everyday conversation developed, initially, to support communication in learning environments) provides a structure to sustain communication that is formally equivalent to the other circular systems of second-order cybernetics (Glanville 1996).

Admitting autonomy and conversation requires a system that accepts that, individually, one sees differently and understand uniquely, while acting as though one believes the objects one observes are the same. Otherwise, one's relativism would lead to isolation because one has nothing communicable and there is no one to communicate with. Ranulph Glanville's theory of "Objects" (1975) provides the framework that allows individuals to believe they each make different observations of the world, yet can act as if observing the same "Object"—the essential conceptual basis making second-order cybernetics and its ethical implications viable.

Second-order cybernetics has made notable contributions in such areas of human understanding as learning, conversational communication, and the emergence of the unanticipated (often through conversational processes). In particular, through the concepts and mechanisms of autopoiesis, it has aided in the understanding of how social systems acquire stability. Nevertheless, second-order cybernetics is probably better thought of more as a way of understanding than as a technology.

Ethics

There are those who would argue that, perhaps more than any other scientific or technological field, second-order cybernetics constitutes an effort to develop a scientific basis for ethics. As such it constitutes an important contribution to any discussion concerned with science, technology, and ethics. This section sketches the basis of this contribution.

Second-order cybernetics' circular systems are autonomous—the starting point for the ethical implications of second-order cybernetics. Von Foerster was among the first to register the ethical dimension in his essay, originally published in 1973, titled "On Constructing a Reality" (von Foerster 2003a); even more relevant was his 1992 essay, "Ethics and Second-Order Cybernetics." (Von Foerster's 1993 German book *KybernEthik* originated the term *CybernEthics*.)

Von Foerster proposed two imperatives:

> Ethical imperative:/Act always so as to increase the number of choices. / Aesthetical imperative: / If you desire to see, learn how to act.

The ethical imperative insists that cybernetics has a dimension in ethics. Cybernetics implies generosity, increasing options. Von Foerster contrasted the essential meanness of morality (restrictions applied to others) to the generosity of ethics (which comes from within.)

The origin of this ethical concern can be seen to lie in the age-old question of what reality, if any, we can know independent of our knowing (i.e., is there a mind-independent reality [MIR]?). Although making a strong assumption of MIR is now commonplace, the question is in principle undecidable. Von Foerster remarked, "only we can decide the undecidable," leaving responsibility for answering this question (and, hence, for determining how we act) with each individual: one pursues whichever option one chooses. One's approach to one's world starts from this choice, which can be made once, or remade at will.

In second-order cybernetics, one's understanding of the world may be said to derive from a position of essential ignorance. The black box provides a mechanism for this. The understanding an observer builds through interacting with experience is (in the black box model) tentative: A reliable description of behavior emanating from the box may suggest it has been whitened, but nothing about the black box and our relationship to it has changed. It remains unopened (and unopenable)—provisional, as black as ever. Knowledge gained from using this model is based in profound ignorance. One cannot, therefore, insist on rightness and should tread warily, respecting the different views of others. The ethical implication of ignorance is respect for the views of others since one can never be certain, oneself. The views of others are considered as equal in stature to one's own—which does not mean theirs—or one's own—are either correct or viable.

Furthermore, the relationship between the behaviors (or signals), that is, the input and the output that black boxes are taken to act on—causing input to become output—results from interaction between observers and their own black boxes. Causality and its legal counterpart, blame, are seen to arise not from mechanism but from patterns observed by observers. The value of this understanding in how one acts cannot be overemphasized, and is confirmed in many psychotherapies that depend for their effectiveness on persuading people that the blaming causality they see is their construction and responsibility. It is not what happens to one that matters, but how one responds to it.

The black box model requires that one distinguishes: If there is no distinction between behaviors there is nothing to experience. In essence, why distinguish myself if I am alone? Distinguishing myself, I distinguish myself also from another. This act of distinguishing brings into being and implies mutualism:

whatever qualities may be attributed to one side of the distinction may (but need not) be attributed to the other. What I take for myself I may give you—this is von Foerster's ethical imperative again.

Distinctions, made in observing, can be considered a basis upon which observers construct experience, including experience of themselves. In order to assume experience is not solipsistic we assume that the other constructs (its experience of) itself (and us) in a reciprocal manner—another form of mutuality. Self-construction and maintenance indicate organizational closure: There is a boundary (it distinguishes its self) and the system is autonomous. An autonomous system is responsible. It has built itself, maintains itself (is organizationally closed), while it remains informationally open (communicates with its environment, thus substantiating the claim that, in distinguishing, one both distinguishes and distinguishes from). Bateson brings these ideas together when he uses the notion of difference (distinction) to define information: the difference that makes a difference (Bateson 1972b). The acceptance of responsibility grows out of autonomy (von Foerster 2003b): Autonomous systems are responsible for their actions. Here is the source of the aesthetical imperative.

There remains communication—that is, conversation. When communication is understood as individual construction of—and responsibility for—meaning and understanding by each participant (rather than the transmission of meanings and understandings), one can see that to understand the other one trusts the other's goodwill, acting with generosity, trust, honesty, and openness to build the understandings one will map onto each other's. This is an interaction. Teaching and learning (and much else beside) are interactive—the reason Pask developed conversation theory.

In turn, this understanding reveals that all one knows requires an observer's (knower's) presence, an understanding crucial in how one treats learning. Maturana said, "Everything said is said by an observer." Von Foerster retorted, "Everything said is said to an observer" (Von Foerster in Krippendorf 1979, p. 5). Respecting the observer is an ethical behavior.

Conclusion

Second-order cybernetics implies individuals are willing to treat each other, and (other, second-order) cybernetic systems, with a goodwill and generosity that can and should be understood as ethical implications. These go against some of the meaner understandings people currently and fashionably hold about their position in the world. Second-order cybernetics provides, in the ethical arena, hope and delight: those behaviors that are often considered higher, more civilized, and better are assumed and sustained in this way of understanding—a better-than-good reason for taking its lessons seriously.

CYBERSPACE

Cyberspace is a term used to describe a new kind of "space" that has been made possible by the Internet. The word has a short but complex history with obscure and shifting meanings and constitutes a context for ethical issues related to science and technology.

In everyday life the notion of space is self-evident and denotes that, along with time, "in which" people live. In mathematics it refers to a collection of elements, such as points, that satisfy certain mathematical postulates. In both cases space is more given than created. In the first case, space is given, while in the second case it is a created, abstract space that people can understand conceptually but cannot directly experience.

The term *cyberspace* gained notice after William Gibson's use of it in his science fiction novel *Neuromancer* (1984). Through one of the novel's characters Gibson speaks of cyberspace as "consensual hallucination experienced daily by billions" of people, thus referring to a "non-real" space that is common to all. More specifically, he speaks about a "graphical representation of data" that emerges by abstraction from "every computer." One comes to be in cyberspace by turning a switch "on" and thus producing an instantaneous transition to it. Once there, people can enjoy the "bodiless exultation of cyberspace." Although they are somewhat confusing, these are powerful characterizations.

Background

The prefix *cyber* derives from *cybernetics*, a term coined by the mathematician Norbert Wiener (1894–1964) in 1948 to denote the study of control processes in machines and animals. That term was derived from the Greek *kubernetes*, meaning "governor" or "pilot." Cyberspace, then, is a kind of "controlled," humanly produced space.

Different Senses

In one of its senses cyberspace refers to the "spaces" associated with virtual reality, an advanced computer-based technology in which people wear headsets with stereoscopic displays, carry trackers that sense their motion, and use special input devices. With the help of those devices people navigate in "simulated" spaces, typically graphical representations of three-dimensional mathematical spaces. The integrated use of these devices creates an experience of immersion in a "virtual" reality, thus realizing an important aspect of Gibson's vision: that it is possible to enter into cyberspace, leaving the body behind.

In another sense, which became predominant in the mid-1990s, cyberspace refers to the integrated "space" made possible by the Internet, which is populated by large numbers of entities of various kinds and in which people perform multiple activities. Although this space does not support immersion, it brings to life another important ingredient of Gibson's cyberspace: the fact that it is common to all.

In *City of Bits*, William Mitchell approaches the Internet from the perspective of space and place and suggests that "the worldwide computer network—the electronic agora—subverts, displaces, and radically redefines our notions of gathering place, community, and urban life" (1995, p. 8). Mitchell proposes that the Internet is *antispatial* in the sense that it is "nowhere in particular but everywhere at once" and that it is *noncorporeal* because people's identity in it is "electronic" and disembodied. In addition, because of this disembodiment, the constructions others make of people in an effort to give those people an identity are *fragmented*. Also, the Internet favors *asynchronic* communication.

Increasingly, the word *Internet* is being invested with a broad meaning to encompass the notion of cyberspace in the second sense discussed above. For this reason ethical issues arising in cyberspace are covered under the entry "Internet." Other ethical issues are discussed in the entries "Cyberculture" and "Computer Ethics."

Perceptive analysis of several dimensions of the Internet and cyberspace, made partly from the point of view of architecture, with its emphasis on space and place, and partly from the author's early experience with the Internet.

CYBORGS

A cyborg is a crossbreed of a human and a machine. The cyborg metaphor was coined by the astronautics researcher Manfred Clynes and the psychiatrist Nathan Kline (Clynes and Kline 1960, pp. 26–27), who argued that space travel required the development of "self-regulating human-machine systems." Such systems were termed cyborgs, from *cyb*ernetic technology and *org*anism. However, the term is not restricted to astronautics. Robotic beings that blur the distinction between humans and machines inhabit myriad science fiction novels and films, such as *Star Trek* (1979), *Robocop* (1987), *Blade Runner* (1982), and *Terminator* (1984). Above all, *cyborg* derives its intellectual influence from Donna Haraway's "Cyborg Manifesto (1985).

This manifesto rang in Haraway's presence as a leading theorist in the field broadly defined as science and technology studies. Haraway was educated as a primatologist, philosopher and historian of science and technology. In the early twenty-first century she teaches as a professor of the history of consciousness at the university at Santa Cruz, United States. In addition to a long list of essays, Haraway is the author of *Crystals, Fabrics and Fields* (1976), *Primate Visions* (1989) and most recently, the *Companion Species Manifesto* (2003), in which she revises her view of cyborgs by arguing that dogs are more important.

The Cyborg Manifesto is a complex, ironic, cacophonous text. Although it initially was addressed to feminist thinkers, it has had a considerable impact in the broader field of science and technology studies. It moves from reflection on the human condition in technological culture to a critique of politics and power relations. Haraway's critique includes current feminist strategies, which she describes as an extension of "identity politics" that defends fixed identities by victimizing the excluded. The manifesto argues for the pleasure of confusing identities. It invites feminists to play with ideas as hybridization and crossing boundaries.

People ceaselessly strive for an ordered world. Science and technology are considered as means to improve that ordering. But at the same time, they unwillingly destroy the ordering principles. As a result of findings in science, technology, and medicine, traditional binary oppositions between human and animal, organism and machine, nature and culture, man and woman, fact and fiction, body and mind, and subject and object increasingly have been blurred. Humans and animals more and more resemble cyborgs, with their bodies being equipped with pacemakers, dental prostheses, implants, and xenotransplants or modified by genetic engineering or cloning. Outside the body the dependency between living beings and machines has increased too.

The cyborg is not only a descriptive category. According to Haraway, the blurring of borders should be actively pursued. "By the late twentieth century, our time, a mythic time, we are all chimeras, theorized and fabricated hybrids of machine and organism; in short we are cyborgs. The cyborg is our ontology; it gives us our politics" (Haraway 1994, p. 150).

Cyborgs not only disrupt orderly power structures and fixed interests but also signify a challenge to settled politics, which assumes that binary oppositions or identities are natural distinctions. Actually those oppositions are cultural constructions. Haraway underlines the critical function of the cyborg concept, especially for feminist politics. The current dualistic thinking involves a "logic of dominance" because the parts of the dualisms are not equivalent. Thus, the logic produces hierarchies that legitimize men dominating women, whites dominating blacks, and humans dominating animals.

Instead, Haraway suggests that people should undermine these hierarchies by actively exploring and mobilizing the blurring of borders. "Perhaps, ironically, we can learn from our fusions with animals and machines how not to be man, the embodiment of western logos"(Haraway 1991b, p. 173).

This might suggest that Haraway simply reinforces what science and technology already do: blurring boundaries. But Haraway wants to make explicit the assumed identities and boundaries, whereas science and technology blur them in an implicit and unintended way in their strive for control of nature and order. This unintended blurring has also been articulated by the French philosopher Bruno Latour in "we have never been modern" (Latour 1993). Latour speaks about *hybrids*, which are mixtures of humans and nonhumans, like cyborgs. According to Latour, modern science and technology have caused a "proliferation of hybrids." Cyborg politics tries to escape the logic of dominance and its inherent essentialism: "Queering what counts as nature is my categorical imperative. Queering specific normalized categories is not for the easy frisson of transgression, but for the hope of lovable worlds" (Haraway 1994, p. 60).

The virtue of cyborg politics is that as soon as individuals acknowledge their identities and boundaries to be culturally constructed, they can reconstruct them in a more thoughtful way. And as soon as people acknowledge that their identity and that of others is necessarily fragmented, they can no longer dominate others, neither be dominated, Haraway asserts. Thus, the ironical play with boundaries is not without obligations. Players should take responsibility in reconstructing them (Haraway 1991a). The model of dominance should be replaced for a model of responsibility for other people as well as for machines. Like people, machines have no singular identity: "the machine is us, our processes, an aspect of our embodiment. We can be responsible for machines, *they* do not dominate or threaten us. We are responsible for boundaries, we are they" (Haraway 1991b, p. 180). However, how this responsibility towards machines and boundaries should be shaped in practice, remains unsettled in Haraway's work.

The philosophical importance of cyborg politics is not situated entirely in its anti-essentialism, for this is a common philosophical theme (Munnik 2001). Its importance is in the focus on the political potencies and challenges of technology crossing fundamental boundaries. Cyborg politics distinguishes itself from most critical approaches by not one-sidedly stressing the fearful risks of new technologies. By emphasizing peoples' responsibility of reconstructing identities, cyborg theory offers a radical and original approach toward the philosophy of technology.

D

DAMS

Dams, barriers to alter flowing bodies of water, are among the most ancient and powerful examples of the proclivity of humans to alter nature for their own benefit. (Dams are also a type of construction shared with other animals, that is, beavers.) Before the advent of written history, dams were already being built to provide water storage and irrigation. An earthen dam in the Orontes Valley in Syria was ancient when visited by the Greek geographer Strabo around the beginning of the Common Era. The oldest large dam of which traces survive today is at Sadd-el-Kafara, near Cairo. Ninety-eight meters long, there are indications that it was intended to stand 125 meters high. It is estimated that this structure was built around 2500 B.C.E.

Dam Engineering

Despite their ubiquity and importance, dams are a stepchild of traditional engineering. Premodern treatises on construction such as Vitruvius's *De architectura* (first century B.C.E.) do not mention dams, although Roman dam achievements were not to be matched for 1,500 years. The scientific engineering of dams begins in the 1800s and was one of the early achievements of civil engineering as it replaced trial-and-error intuition with empirical rules of thumb for dam design.

In terms of function, dams primarily supply water for irrigation or urban use, or serve as sources of power. In conjunction with closely related structures called dikes, dams may also protect from flooding and/or facilitate transportation by creating navigable bodies of water such as canals.

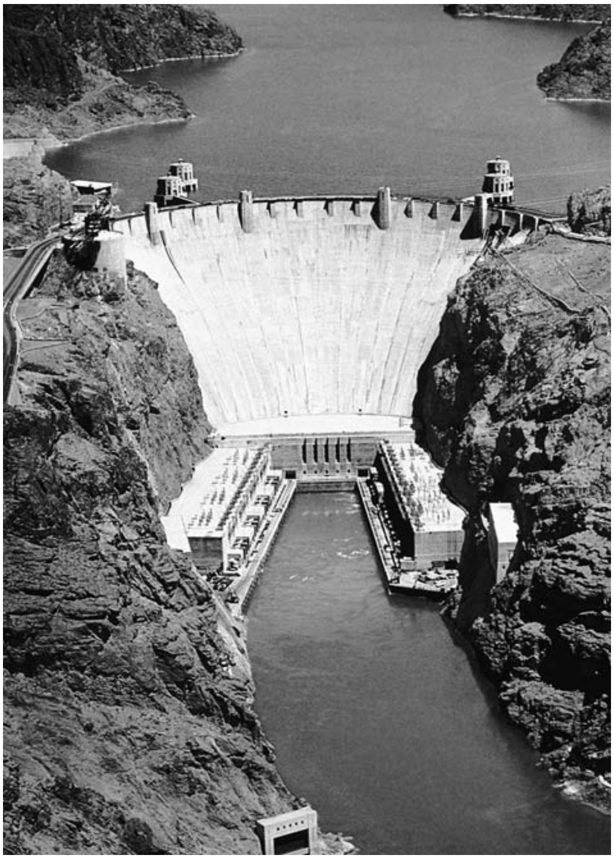
In terms of design, dams are of two basic types: earth- or rock-filled gravity embankment dams and masonry or concrete dams. The former take the general shape of a large-based equilateral triangle with sloping embankments facing both upstream and downstream; the latter have more the shape of a right-angle triangle with a perpendicular upstream face and a sloping downstream face.

It was not until the mid-1800s that French engineers designed the first dams using scientific procedures to determine such issues as the slope of repose for embankments. At the same time engineers began to consider the geological structures on which various types of dams might rest and to analyze the internal stresses of masonry and concrete dams. Such analyses promoted the design of arch dams, in which a vertical upstream face is given a convex horizontal curve to help transfer forces from the impounded water into the walls of a canyon. The engineering of auxiliary structures such as spillways, locks, and power conversion systems also became part of dam design.

Progressive demands for water and power together with advances in dam engineering led in the first half of the twentieth century to what may be called the golden age of dam construction. But the second half of the twentieth century witnessed a technical reassessment of dam engineering in terms of safety and ecology, social and natural.

Dam Debates

For most of human history, dams were conceived and built with an eye only to the task to be accomplished, such as water storage, irrigation, or more recently,



Hoover Dam. Constructed in 1935, the dam holds back twelve trillion gallons of water and generates enough hydroelectric power to serve 1.3 million people. (*© Corbis.*)

promotion of tourism, and without much concern for other implications, such as the impact on local populations or the environment. Of all major rivers in the United States, only the Salmon and Yellowstone are without dams. Half of the American wetlands that existed in 1790 have been flooded and destroyed by dam projects—up to 80 percent in river states such as Missouri, where one-third of all the water in the Missouri River is stored behind dams.

At the same time some experts argue that dams are often inefficient mechanisms for water storage, spreading water out over large areas in hot, dry desert climates where it evaporates. As much as 8 percent of Colorado River water may be lost to evaporation behind the Glen Canyon Dam in northern Arizona. Dams, by promoting water use, also contribute to the eventual depletion of aquifers.

In the modern world dams nevertheless continue to be seen as important symbols of human domination of the environment, sometimes outweighing all other issues. China's Three Gorges Dam, which will flood thousands of acres of agricultural land and displace more than one million people, is nevertheless viewed by the Chinese government as a powerful symbol of mastery and progress.

DAM SAFETY AND FAILURES. Like other huge, complex human technology projects, dams can fail if ill-designed or negligently maintained. The most famous failure in the United States was that of the South Fork Dam in Johnstown, Pennsylvania, in May 1889. Over the years, successive owners of the dam made dangerous modifications, eliminating outlet pipes, reducing its height, and narrowing the spillway. During an unprecedented rainfall, the water rose 3 meters (10 feet) above the usual lake level, breaking the dam and inundating Johnstown, with the loss of almost 3,000 lives.

RELOCATING PEOPLE. Dam projects have often involved the removal of the populations least able to defend themselves politically. Most often the groups forced to relocate are poor members of minority groups, subsisting on small-scale agriculture.

In June 1957 Congress voted the creation of Kinzua Dam in western New York, flooding half of a Seneca Indian reservation. More than 500 Seneca were forcibly moved in the dead of winter to trailer camps. Without access to hunting grounds, and denied compensation for their homes, these already poor individuals were, according to the sociologist Joy A. Bilharz (1998), driven into greater poverty, which lasted for decades.

Organized political opposition to large dam projects was pioneered in India, where in the late 1940s important projects backed by the prime minister, Jawaharlal Nehru, made little provision for the relocation of affected villages. Large demonstrations and other opposition increased the costs unacceptably, causing the government to back away from some of these projects.

ENVIRONMENTAL CONCERNS. During the twentieth century, the environmental movement advanced the argument that natural beauty was a factor to be taken into account in dam construction. John Muir led an early campaign against the O'Shaughnessy Dam in Yosemite National Park's Hetch Hetchy Valley on the grounds that it would destroy a unique environment. Later came the related idea that wild species themselves had interests worthy of protection, interests that might be harmed by dam construction. Environmentalists went to court to end construction of the Tellico Dam on the Little Tennessee River, on the grounds that it would destroy the remaining population of snail darters, an endangered fish. In response, federal courts halted construction of a dam already 80 percent completed. In

1978 the U.S. Supreme Court affirmed the court order halting construction, stating that the Endangered Species Act unambiguously bars projects that threaten the continued existence of a listed species. Congress, however, later passed legislation exempting Tellico from the Endangered Species Act, and the dam was completed.

Egypt's Aswan High Dam has been argued to have caused an environmental disaster, starving the Mediterranean of nutrients, making croplands excessively salty, and creating a reservoir in one of the highest evaporation zones on Earth.

DAM REMOVALS. Because of changing views of the utility of dams and the relative importance of environmental considerations, more than 500 dam removal projects were undertaken in the United States during the last decades of the twentieth century. The first dam removed for purely environmental reasons was the Quaker Neck Dam on the Neuse River in North Carolina. Built in 1952 to provide cooling water for a steam-driven electrical generating plant owned by Carolina Power & Light Company, the dam prevented shad from migrating upstream. The shad catch, 318,000 kilograms (700,000 pounds) in 1951, was only 11,400 kilograms (25,000 pounds) by 1996.

Carolina Power & Light was glad to get rid of Quaker Neck. The dam was expensive to maintain and also created litter and liability problems. Instead of the dam, a canal between two channels of the river now provides cooling water. More than 1,600 kilometers (1,000 miles) of local rivers have since been reopened to fish.

As the political and psychological importance of dams has faded and other considerations have come to the fore, Americans have stopped building dams. Since the mid-1970s, there has not been a single major dam construction project commenced in the United States.

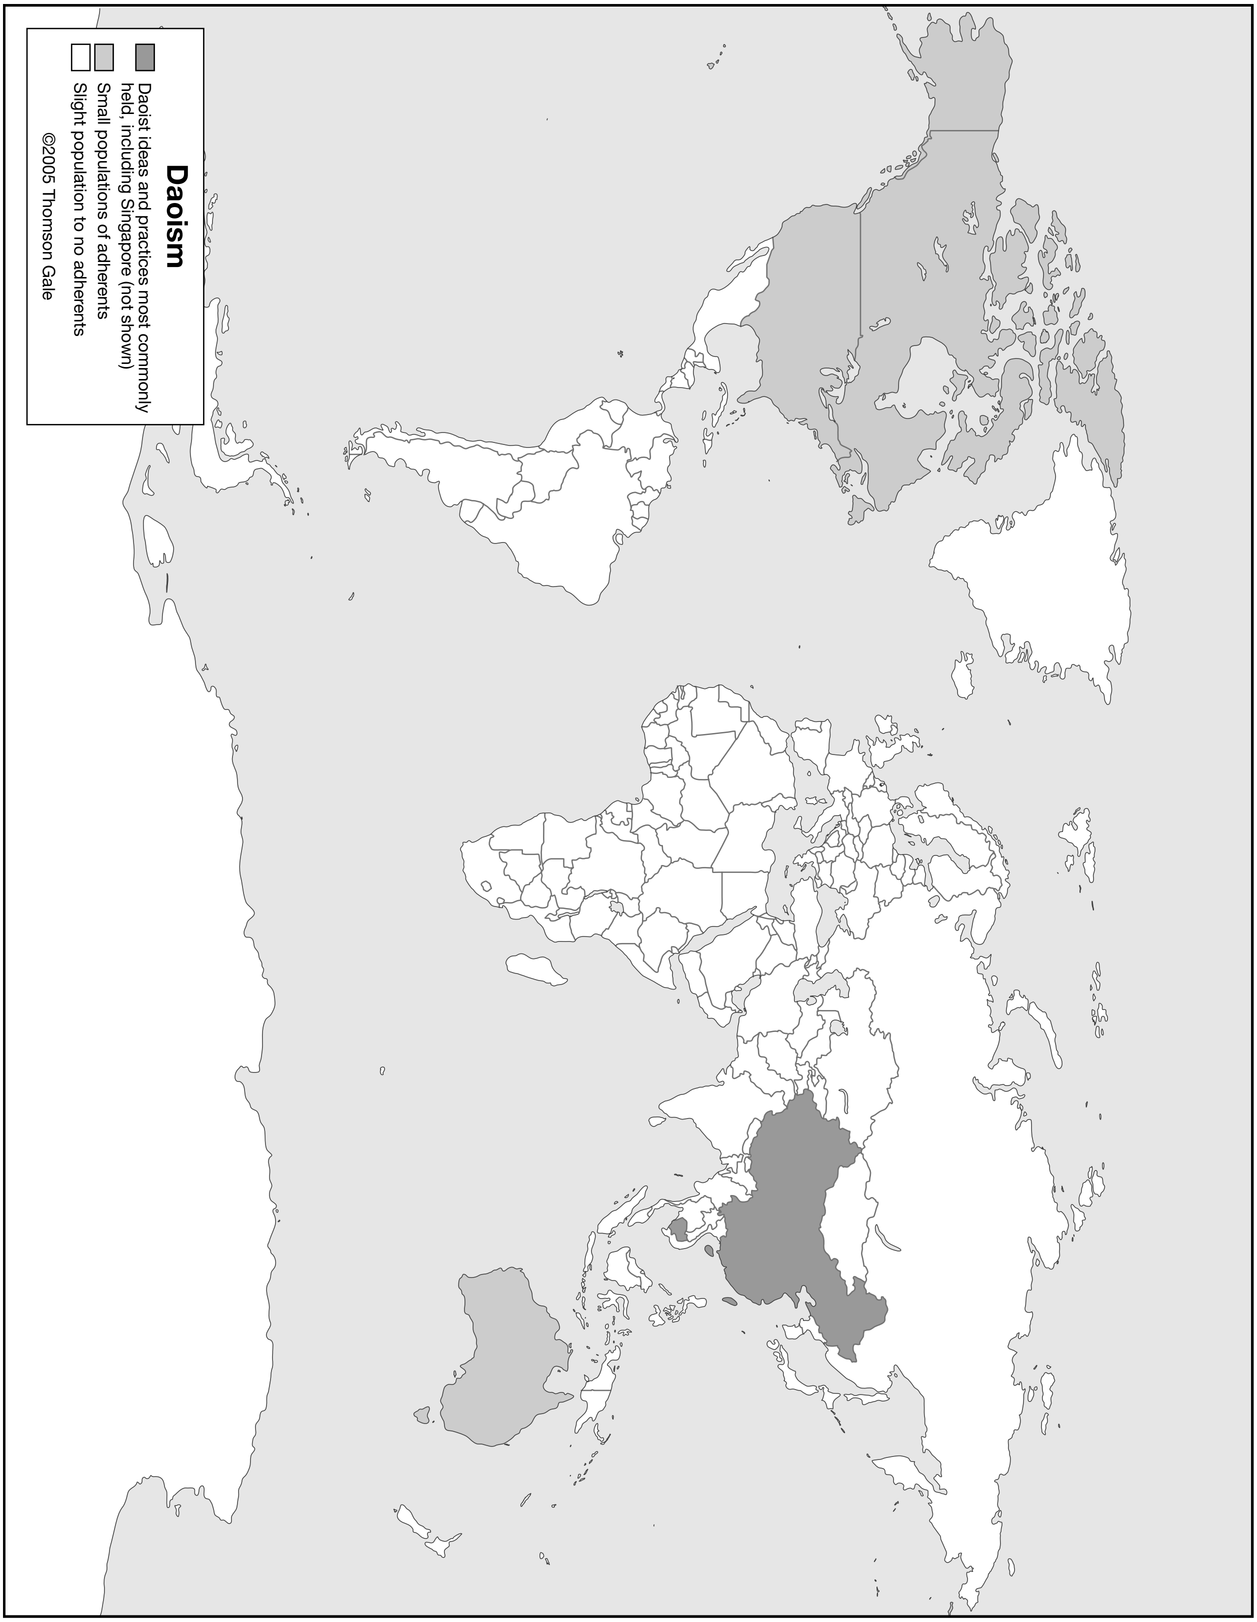
DAOIST PERSPECTIVES

The word *Daoism* (or *Taoism*) was coined in the early nineteenth century from the Chinese expression "*dao jiao* teachings" (*tao*), which encompasses both the intellectual activities and historical religious movements that shaped the various and changing meanings of the term *Dao* (or *Tao*), meaning, literally, "the Way." Modern scholars have claimed that the term specifically refers to Daoist schools or Daoist sects, though some European Daoism scholars contend that this distinction is unnecessary or even misleading. In contemporary academic circles the words *religion* and *philosophy* are inevitably applied to Chinese traditions; one must remember, however, that in the Chinese context these two words



Daoism

diverge from their Western usages. Nevertheless, Daoism has suggestive importance as a perspective on science, technology, and ethics.

Daoist philosophy is attributed to Laozi, who, according to the ancient and authoritative *Records of History,* is believed to have been an elder contemporary of Confucius (551–479 B.C.E.) and the author of the *Laozi* (*Daode jing,* or *Tao-te-ching*), a work roughly 5,000 characters long. This traditional account has been challenged by skeptics, yet the three Guodian bamboo versions of the *Laozi* unearthed in 1997 prove that the text was extant and prevailing in the fourth century B.C.E. and may have been composed still earlier. Another founding thinker of Daoism was Zhuangzi. He and his followers created the *Zhuangzi,* a much longer work that is full of thought-provoking fables, stories, anecdotes, and inspiring ideas and arguments.

The religious worship of Laozi, together with the Buddha, is recounted in the official dynastic history in the first century C.E. Daoist religious movements, inspired by and combined with immortality beliefs, traditional medicine, yin–yang theories, *Yijing* (Classic of change) theories, and prognostication and apocrypha, developed in the following centuries. Regional Daoist religious activities, however, were not recognized by an independent royal court until the fifth century C.E. Because of its origination, Daoist religion had strong associations with folk and royal religious practices and beliefs, such as polytheistic worship, the pursuit of longevity, and the belief in immortality, physical or spiritual. Daoist priests and scholars may simultaneously be believers in Buddhism and practitioners of Confucianism.

A Philosophical Paradox

Daoism is commonly tagged as a sort of irrational mysticism. Actually, Daoist attitudes toward science and technology are mixed and varied. There are statements in the *Laozi* that seem directed against knowledge and artistry: "Eliminate knowledge, get rid of differentiation, and the people will benefit one hundredfold. Eliminate craftiness, get rid of profit, and there will be no robbers and thieves" (chap. 19, bamboo version). "The more cunning and skill a person possesses, the more vicious things will occur" (chap. 57).

In the *Zhuangzi,* one can find stories such as this one: Confucius's disciple Zigong while traveling saw an old man working in a garden. Having dug his channels, he made many trips to a well, returning with water in a large jar. This caused him a great expenditure of energy for very small returns. Zigong said to him, "There is a contrivance by means of which a hundred plots of ground may be irrigated in one day. Little effort will thus accomplish much. Would you, Sir, not like to try it?" After hearing Zigong's description of the contrivance based on the lever principle, the farmer's face suddenly changed and he laughed, "I have heard from my master," he said, "that those who have cunning devices use cunning in their affairs, and that those who use cunning in their affairs have cunning hearts. . . . I already knew all about it, but I would be ashamed to use it" (chap. 19). The farmer presents a typical Daoist criticism of technology and scientific invention. This is nevertheless a moral observation on the side effects of technological inventions, not an overall theory about technology and science.

Actually, the *Zhuangzi* contains many intriguing fables praising craftsmen who demonstrate fascinating artistry, such as boatmen, a butcher, sword makers, carvers of bell stands, arrow makers, and wheelwrights. A wheelwright once gave a lesson to the Duke Huan about the limitations of communication through the example of his artistry. He said:

> If my stroke is too slow, then the tool bites deep but is not steady; if my stroke is too fast, then it is steady but does not go deep. The right pace, neither too slow nor too fast, is the hand responding to the heart. But I cannot tell the skill by words to my son and he cannot learn it from me. Thus, it is that though in my seventieth year, I am still making wheels. The ancient author of the classic you are reading are dead and gone—so then what you are reading, is but the sages' dregs and refuse! (chap. 13)

This fable is not only a paean to the artisan and his artistry but also an ancient version of modern or postmodern theories of hermeneutics and linguistics.

In one chapter, the *Zhuangzi* raises questions about the natural world and its movements:

> How ceaselessly heaven revolves! How constantly earth abides at rest! Do the sun and the moon contend about their respective places? Is there someone presiding over and directing these things? Who binds and connects them together? Who causes and maintains them, without trouble or exertion? . . . Then how does a cloud become rain, and the rain again form clouds?" (chap. 14)

These questions come from and in turn stimulate curiosity about the natural world, which inspires investigation into scientific and technological mysteries. Daoism considers human beings to be equally part of the natural world and has a strong interest in the ultimate origins of, reasons behind, mechanisms of, and mysteries of the universe, including human lives—especially in comparison with Confucianism and Buddhism.

One distinctively Daoist concept is *wuwei* (nonaction), which is often misunderstood as inactivity or literally doing nothing. But the *Huainanzi* (142 B.C.E.), a Daoist work of the early Han period, argues that this term does not mean inactivity. *Wuwei* actually suggests that no personal prejudice interferes with the universal Way and that no desires or obsessions lead the true courses of Daoist techniques astray. To undertake an enterprise one must follow reason, and to realize an achievement one must take account of surrounding conditions to be consistent with the principle of naturalness. For example, if one used fire to dry up a well or led the waters of the Huai River uphill to irrigate a mountain, these would be contrary to the principle of naturalness and be called taking action (*youwei*, the opposite of *wuwei*). Nevertheless, such activities as using boats on water or sledges on sand, making fields on high ground, and reserving low ground for a pond constitute Daoist *wuwei* or nonaction. This interpretation of *wuwei*, deriving from the *Laozi*'s idea of "assisting the naturalness of the ten thousand things without daring to act," promotes a rational and observant attitude in everyday life, which favors the scientific spirit.

Religious Pursuits

While Daoist thinkers presented reflective and inspiring ideas, religious scholars and priests, in their informal roles as inventors, practitioners, compilers, or distributors, made great practical and academic contributions to the development of science and technology in China. According to the first official 5,305-volume *Daoist Canon* (completed in 1445), Daoist scholarship and practice pursued knowledge and technology in various fields, such as chemistry, mineralogy, biology, botany, pharmacy, medicine, anatomy, sexology, physics, mathematics, astronomy, and cosmology. Ancient Daoists were not professional scientists or technicians, and their essential concern was attaining longevity and material immortality, rather than science and technology for their own sake. This pursuit makes Daoism distinct among religions and led Daoists to seriously observe and explore the natural world, including the human body and life, from generation to generation. Thus, religious enterprise provided fertile ground for the development of science and technology.

A good example of this confluence is the discovery of gunpowder. Joseph Needham (1981) contends that saltpeter (potassium nitrate) was recognized and isolated at least by the fifth century in China. This first compounding of an explosive mixture arose in the course of exploring the chemical and pharmaceutical properties of a great variety of inorganic and organic substances. It was the hope of realizing longevity and physical immortality that led to this discovery, one of the greatest technical achievements of the medieval Chinese world. One finds the first reference to it in the ninth century, toward the end of the Tang dynasty, in a description of the mixing of charcoal, saltpeter, and sulfur. This mention occurs in a Daoist book that strongly recommends not mixing these substances, especially with arsenic, because some alchemists who had done so had the mixture deflagrate, singe their beards, and even burn down the house in which they were working.

The fields of medicine and pharmacology were also directly shaped by the Daoist pursuit of longevity and immortality. Daoist scholars and priests advanced Chinese medical theory and compiled important herbal medicine classics. Tao Hongjing (451–536), a direct descendant of the founder of the Supreme Purity Sect, is the most prominent of these scholars. His eighty works involve astronomy, calendrics, geography, literature, arts, and the arts of war, in addition to medicine and pharmacology. He argued that humans control human destiny, not Heaven. The reason people die early is not because of fate, but because their way of living harms their spirits or bodies. A piece of semifinished pottery is made of earth, yet is different from earth. Still it will dissolve in water before it is fired, even though it has already dried. If it is not fired properly, it will not hold up. If it is fired well and becomes thoroughly strong, it will survive over vast stretches of time. Similarly, people who pursue immortality take drugs and elixirs to make the body strong, breathe in fresh air, and participate in gymnastic exercise.

All these practices complement each other without conflict. If the spirit and the body are refined together, as in a senior immortal, one can ride clouds and drive a dragon; if the spirit and the body become separated, as in a junior immortal, one can leave one's old body and take on a new one. To preserve spirit and body, Daoists emphasized the significance of moderation in desires and emotion. It is impossible for the average person to have no desires or do nothing, but they can keep their minds in a state of harmony and minimize concerns. The "seven kinds of emotion" (anger, anxiety, worry, sorrow, fear, aversion, and astonishment) and the "six desires" (for life and death, and of the eyes, ears, mouth, and nose) are all harmful to the spirit and should be controlled.

Tao Hongjing also argued that the harm caused by bad eating habits is more serious than that of lust, because people eat daily, and he urged restraint in taking food. To be healthy, he claimed, less food is better than being overly full; walking after meals is more helpful than lying down; and physical labor is preferable to an easy life. Most of this early Daoist's advice accords with suggestions from modern doctors and professional medical workers.

Furthermore, Tao Hongjing compiled the *Collected Commentaries on Medicinal Herbs*, without which the contents of the earliest Chinese medicine classics would have been lost forever. He was the person who created a typology of Chinese medicinal herbs and inorganic substances in the treatment of various diseases and symptoms; this became and remains the foundation of Chinese medical theory.

According to Daoist tradition, the technology of sexual life is related to prolonging youth and vigor, though it was rejected by some later Daoists. Ge Hong (283–364?) once argued that sexual intercourse was necessary to achieve longevity and immortality. Even if one were to take all the famous medicines, Ge claimed, without knowledge of how to store up the essence of life through sexual activity, attaining health, let alone longevity, would be impossible. While people should not give up sex entirely, lest they contract melancholia through inactivity and die prematurely from the many illnesses resulting from depression and celibacy, overindulgence can diminish one's life, and it is only by harmonizing the two extremes that damage can be avoided.

It was further held that foreplay and slow and complete arousal are important for healthy intercourse. Men should pay attention to women's reflexes step by step and delay climax to adjust for the differential in arousal time to ensure the woman's full satisfaction. Some of these theories seem to have been confirmed and adopted by modern sexologists. Kristofer Schipper (1993), a Dutch Daoist scholar, claims that Chinese sex manuals reflect an impressive knowledge of female anatomy and reflexes; they are the only ancient books on this subject that do not present sexuality solely from the male point of view. Indeed, compared to other traditions, Daoism includes much less discrimination against women, perhaps because of Daoists' strong belief in the harmony of yin and yang, which work in all things and processes in the universe.

Modern Resonance

Although Daoism is an indigenous Chinese cultural tradition of some antiquity, modern scientists have found that it resonates with certain aspects of the spirit of modern science and responds to modern social and environmental issues. Raymond J. Barnett (1986) found a surprising degree of similarity between Daoism and biological science in their views on death, reversion (cyclicity of phenomena), the place of humans in the universe, and the complementary interactions of dichotomous systems. The use of the terms yin and yang is similar to the way scientists describe the behavior of subatomic particles: One can say some things about these particles, but only if one realizes that what is said is a statement of statistical probability and that a certain modicum of uncertainty is unavoidable. And in the autonomic nervous system both the sympathetic and parasympathetic subsystems, like the yin and yang, affect most organs. The state of an organ is not a function of one system being totally "off" and the other totally "on." Rather, the health of an organ depends on the balance between the activities of both systems, with each able to change its input and alter the balance.

Similar parallels between Daoist ideas and science are too numerous to be discussed at length, but a few deserve brief mentions. James W. Stines (1985) demonstrated that the philosophy of science of British chemist Michael Polanyi (1891–1976), especially his theory of tacit knowledge, correlated with Daoist intuition. Hideki Yukawa (1907–1981), who in 1949 became the first Japanese physicist to receive a Noble Prize, claimed that his creativeness was greatly inspired by Laozi's and Zhuangzi's philosophical insights. The famous American humanistic psychologist Abraham H. Maslow (1993) found the advantage and complementary role of Daoist objectivity in scientific investigation. Fritjof Capra, in his best-seller *The Dao of Physics* (2000), revealed the parallel between Daoism (along with other Eastern traditions) and the notion of a basic "quantum interconnectedness" emphasized by the Danish physicist Niels Bohr (1885–1962) and the German physicist Werner Heisenberg (1901–1976). Norman J. Girardot and colleagues (2001) discuss broadly and significantly the relationship of Daoism and modern ecological issues. Finally, one should certainly not forget the pioneer researcher Needham, who contended that Daoist thought is basic to Chinese science and technology.

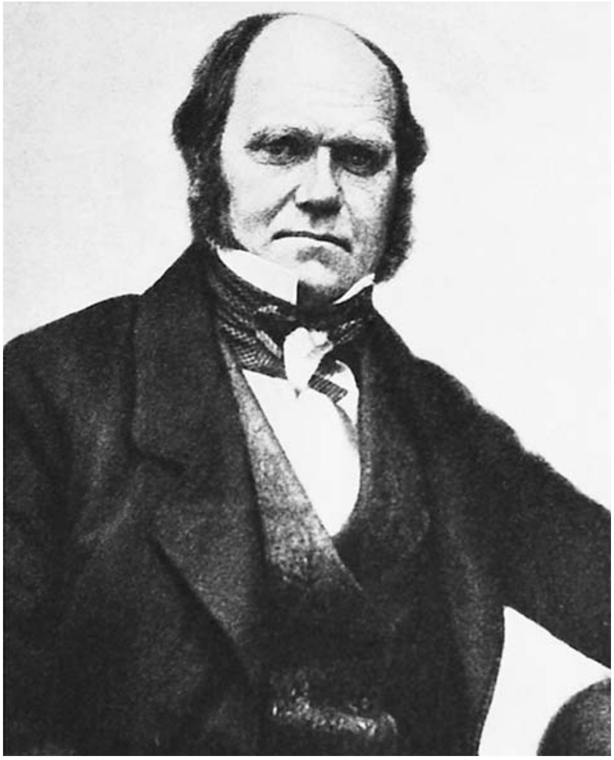
DARWIN, CHARLES

Naturalist Charles Darwin originated the theory of evolution by means of natural selection. Darwin (1809–1882), who was born in Shrewsbury, England, on February 12, established the modern scientific understanding of humanity's place in nature. After his undergraduate education at Cambridge, Darwin served for nearly five years as a naturalist aboard a surveying ship, HMS *Beagle,* which traveled up and down the coasts of South America and then circled the globe. Darwin spent several years after his voyage publishing the results of his researches into fossils, botany, zoology, and geology. On the basis of this work, he formulated his initial ideas on evolution in the late 1830s and then spent two decades developing the theory of natural selection before publishing his chief work, *On the Origin of Species by Means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life* (1859). In *The Descent of Man, and Selection in Relation to Sex* (1871), Darwin explicitly included human beings within the theory of evolution and analyzed the biological basis of human social and moral behavior. Darwin died on April 19 in England and is buried at Westminster Abbey.

In his autobiography, Darwin says that the one book he most admired as an undergraduate was William Paley's *Natural Theology: or, Evidences of the Existence and Attributes of the Deity, Collected from the Appearances of Nature* (1802). Paley (1743–1805) was the best-known proponent of natural theology, a school of thought that combined providential theology with inquiry into adaptive structures in animals. From the perspective of natural theology, adaptive structure or *design* is evidence for the beneficent governance of the world by its creator. Darwin's theory of natural selection provided an alternative scientific explanation for adaptive structure. Within Darwin's theory, adaptive structure is the result of *natural selection.* Innate variations in physiology or anatomy regularly occur. Many such variations are neutral or harmful to an organism, but some variations offer advantages that enable an organism to survive or reproduce more effectively than its competitors. These favorable variations are inherited and transmitted, and over many generations inherited variations produce new species.

Darwin's theory of natural selection is not grounded in theology or ethics, but it has implications for metaphysical and ethical beliefs. In his later years, Darwin became a professed agnostic, but at the time of writing *On the Origin of Species*, he was still vaguely theistic and



Charles Darwin, 1809–1882. Darwin discovered that natural selection was the agent for the transmutation of organisms during evolution, a theory he presented in *Origin of Species*. (© *Bettmann/Corbis*.)

regarded the development of life on earth as the result of a divine creation. The evolutionary process that he explains nonetheless exhibits qualities of ruthlessness and cruelty. In order to describe this process, Darwin frequently uses metaphors such as the "Struggle for Life," the "battle of life," or the "war of nature." In all species, many more individuals are born than can ever survive or reproduce. This disproportion between birth rates and the rates of survival and reproduction provides the competitive situation within which natural selection operates. Individuals within and among species compete for food and other resources; individuals of one species prey on individuals of other species; and most species eventually become extinct and leave no successor species. In a letter of 1856 to his botanist friend Joseph Hooker (1817–1911), Darwin exclaims almost in despair over "the clumsy, wasteful, blundering, low, and horribly cruel works of nature!" In the last paragraph of the *Origin,* he declares that there is "grandeur in this view of life," but it is a grandeur that emerges out of "famine and death."

Both before and after Darwin, it has been common practice to invest the larger natural order with some moral quality, either of beneficence or of ruthlessness, and to use that quality as a model or norm for human ethical behavior. The injunction to *follow nature* has been interpreted to mean either that one should imitate the supposedly benign character of the providential order or that one should ignore all conventional social constraints and seek only to satisfy one's own desire and ambition. Since the middle of the nineteenth century, many thinkers have rejected this approach and have argued that human morality is something separate from the natural order. In their view, humans should not follow nature but should instead cultivate their own specifically human moral sentiments independently of nature. Among Darwin's contemporaries, John Stuart Mill and Thomas Henry Huxley (1825–1895) advocated this moral philosophy, and in the later twentieth century it was advocated by prominent Darwinian thinkers such as George C. Williams (b. 1926), Richard Alexander (b. 1929), Richard Dawkins (b. 1941), and Donald Symons (b. 1942).

Darwin's own theory of human morality breaks away from the idea that one should take the larger order of nature as the model for human moral behavior, but Darwin does not argue that human morality is simply separate from the order of nature. He argues instead that human moral sentiments derive from the evolved and adapted structure of human psychology. The human capacity for moral behavior results from two aspects of our evolved psychology: our character as social animals, and our uniquely human ability to think abstractly. Our social nature enables us to feel sympathy for other humans, to feel pain at their suffering and pleasure at their happiness. Our ability to think abstractly makes it possible for us to rise above the present moment, to link the present with the past and future, and thus to take account of the long-term consequences of our behavior.

In typical Victorian fashion, Darwin hoped that humanity would progress steadily toward a higher state of moral consciousness, and he envisioned human moral progress as circles of sympathy expanding out from kin and tribe, to nations and cultures, to all human beings, and eventually to all life on earth. At the highest level of human development, Darwin hoped that humans would become ecological curators for the earth.

In *Descent of Man,* Darwin considered the issue of eugenics. He acknowledged that care of the weak has dysgenic effects, but he nonetheless rejected *social Darwinism* or ruthless social competition because, he felt, that sort of behavior would damage the more "noble" qualities of social sympathy on which all human moral behavior depends.

From the second through the sixth decade of the twentieth century, the adaptationist psychology that Darwin inaugurated in *Descent of Man* went into eclipse, supplanted by the belief that culture and society control behavior and are not themselves prompted and constrained by biology. The advent of human sociobiology in the 1970s brought Darwinian thinking back into psychology, anthropology, and the other human sciences. In sociobiology and related schools such as *human ethology*, *evolutionary psychology*, and *behavioral ecology*, the adaptationist view of human nature has had a deep and far-reaching influence on twenty-first century ethical thinking. For contemporary Darwinian theorists of human ethical behavior, the most significant issue under debate is a question about the level at which natural selection operates. Proponents of *selfish gene* theory argue that natural selection operates exclusively at the level of genes, and they extrapolate the idea of "selfishness" from the level of genes to the level of individual human motives. Proponents of *group selection*, in contrast, affirm the reality of altruistic or "unselfish" motives. Many theorists argue that selection operates at multiple levels and that these levels are interactive and interdependent. The idea of a genetically encoded "altruism" that ultimately subverts inclusive fitness would contradict the logic of natural selection, but a co-operative and interdependent structure is a fact of evolutionary history and manifests itself at the level of cells, organs, social groups, and ecosystems.

DC-10 CASE

• • •

The troubled history of the DC-10 aircraft, especially in relation to questions raised as a result of its involvement in three major accidents between 1974 and 1989, provides a multidimensional case study in the ethics of engineering design and the uses of technology.

The DC-10 is a wide-bodied aircraft with two wing engines and a third engine distinctively placed in the tail fin. It was introduced into commercial service in 1972, during a time of unusually intense competition in the U.S. aviation industry. The market would support only two viable manufacturers, and because the Boeing 747 was well established, either Lockheed Corporation or McDonnell Douglas Corporation would have to withdraw and suffer a substantial financial loss. McDonnell Douglas won the competition, but evidence of its haste to beat Lockheed is reflected in these case studies.

Design Vulnerability

Because airliners fly at high altitudes, the passenger cabin must be pressurized, up to 38 pounds per square inch. Because a heavy floor able to withstand this force would not be economical, the cargo hold is also pressurized. Thus the floor has to be strong enough to support only the weight of passengers, crew, seats, and so on. If, however, either part of the aircraft experiences a sudden decompression, the loss of equalizing pressure would cause the floor to buckle or collapse, resulting in damage to the control system, which is located in the interior spaces of the floor beams.

The 1972 Windsor Incident

Less than a year after the DC-10 was in service, a rear cargo door was improperly closed on a flight from Detroit, Michigan, and it blew open over Windsor, Ontario, causing the floor above it to collapse downward. Only the skill of the American Airlines pilot and a very lightly loaded airplane enabled the plane to land safely.

Ordinarily a problem of this magnitude would result in the Federal Aviation Administration (FAA) issuing an Airworthiness Directive (AD), a public document that has the force of law, requiring owners of a particular aircraft to modify their airplanes within a certain time. But the FAA charter contains a dual mandate: The FAA must not only ensure aviation safety but also promote the aviation industry. An AD at this time would have given Lockheed a competitive advantage by drawing attention to the DC-10 problem. Instead, John Sheaffer, the head of the FAA, finessed these conflicting objectives by making a "gentleman's agreement" with McDonnell Douglas to develop a fix for the cargo door and implement it through service bulletins sent only to owners of DC-10s, thus avoiding harmful publicity.

Two weeks after Windsor, Dan Applegate, head of project engineering at Convair, a subcontractor for the DC-10 cargo doors, expressed grave doubts about the "Band-Aid" fixes being proposed for the cargo door lock and latch system. He took his concerns to higher management in an effort to have Convair contact McDonnell Douglas and develop a more secure fix. Although he wrote a strong memo, management felt its hands were tied by a "reliance clause" in the contract, which stated that if Convair disagreed with the design philosophy it must make its concerns known in the design stage or pay for any later required changes. Because DC-10s were already rolling off the production line, Convair was faced with the prospect of paying for expensive retrofits to the DC-10 if it raised questions now. No approach to McDonnell Douglas was made.

The 1974 Paris Crash

When the service bulletins were sent out, many DC-10s were sitting on the McDonnell Douglas lot awaiting delivery. Ship 29, later sold to Turkish Airlines, was recorded as having all service bulletins for the cargo door performed, but in fact a critical item was omitted. Critics believe that an AD would have been taken more seriously.

On a fully loaded flight from Paris to London, on March 3, 1974, Ship 29 lost its rear cargo door shortly after takeoff, and the floor collapsed. Deprived of its control system, the plane crashed: Six passengers from the rear of the aircraft were found, still strapped in their seats, nine miles away; the cargo door that failed was nearby. French investigators collected more than 20,000 human fragments of the 346 passengers and crew. At the time, it was the worst aircraft accident in history.

The 1979 Chicago Crash

On May 25, 1979, American Airlines DC-10 crashed shortly after takeoff from Chicago when a wing engine broke loose and damaged the leading edge of the wing. Loss of the engine and damage to the wing resulted in decreased lift: One wing was pushing up harder than the other. A photo shows the plane, wings vertical, plunging to the ground.

Had the pilots known that the wing was damaged, they would have been able to take corrective measures to control the plane. But they could not see the wing from the cockpit and had to rely on instruments. Ironically, the needed warning devices were powered by the engine that broke off, and there was no provision for a backup power supply. The crash killed all 271 persons onboard the DC-10 and two persons on the ground.

The separation of the engine was caused by a maintenance procedure designed to save more than 200 person-hours of work. The engine is held in place by a large pylon attached to the wing, and the McDonnell Douglas removal procedure required that the engine (weighing 5,000 kilograms) be removed first, followed by the pylon (900 kilograms). The new procedure used a forklift to bear the weight of the engine, allowing engine and pylon to be removed as a unit. The pylon is not designed for the stresses this procedure can introduce and developed cracks, which eventually led to it and the engine breaking away from the wing.

It is normal for airlines to develop innovative maintenance procedures without FAA approval. McDonnell Douglas knew that Continental Airlines and American were using the forklift procedure and that it required extreme precision in positioning. It also knew that Continental had reported two cases of cracks to the pylons that required repair. Neither the FAA nor American learned of these potential dangers because FAA regulations do not require such reporting. But an engineer's first professional obligation is to protect the public from harm, and engineers at McDonnell Douglas and Continental had clear evidence of the danger of this procedure and should have investigated further and warned others. For a professional, following the regulations is not good enough when there is clear evidence of danger.

The 1989 Sioux City, Iowa, Crash

On July 19, 1989, a United Airlines DC-10 tail engine disintegrated in flight, resulting in the loss of fluid in all three hydraulic systems. The 170-kilogram front fan disk, rotating at high speed, broke apart, and the fragments took out everything in their path. Without hydraulics, none of the control surfaces on the wings and tail could be operated. The plane could only be crudely maneuvered by varying the speed of the two wing

A McDonnell-Douglas DC-10. A string of highly publicized crashes doomed the aircraft to a short lifespan. (© *George Hall/Corbis*.)

engines. Remarkably, the pilots managed to crash-land at the Sioux City, Iowa, airport, with only 111 deaths among the 296 passengers.

The other wide-body jet with a large tail engine, the Lockheed L-1011, has four independent hydraulic systems, one of which has a shutoff valve forward of the engine. If there is a leak, the valve closes the line, preventing further fluid loss. After the accident, the FAA issued an airworthiness directive requiring a shutoff valve for the DC-10.

Assessment

All three DC-10 crashes were caused by failures that need not have resulted in the loss of the aircraft. The inadequately protected control system of the DC-10 allowed these otherwise predictable problems to cause the crashes that took 728 lives. It would be satisfying to find engineers and managers who clearly disregarded the safety of air travelers, but the reality is a complex and ambiguous interplay of engineering, design, financial, legal, historical, and organizational factors that allowed an underprotected aircraft to enter the stream of commerce. Without the intense economic competition with Lockheed, there might have been more attention to the cargo door design, redundancy added to warning systems, and a shutoff valve placed in the hydraulic lines. Add to this Douglas Aircraft Company's complete dominance of the aviation industry from the 1930s to the 1950s, which may have fostered a climate of complacency about the problems with the DC-10. (McDonnell Douglas had been formed in 1967 from the merger of Douglas Aircraft and McDonnell Aircraft Corporation.) The regulatory safety net, as always, was catching up to the problems posed by the new generation of wide-body jets.

After each of these crashes the FAA required changes in design, procedures, or training. Critics call this "tombstone technology," meaning that safety changes are made only if there are enough deaths to prove the changes are needed. But safety is defined as "of acceptable risk," which changes over time, and often it takes a severe accident to determine what level of risk is socially acceptable. Safety entails higher costs, and regulators must try to balance the safety and cost factors in evaluating complex, sophisticated technology that has a substantial interface with large numbers of people. Inevitably, mistakes will sometimes be made and innocent people will die before adequate regulations are in place.

DDT

DDT ranks among the most infamous acronyms in history. During the mid-twentieth century, its effectiveness at killing insects made it one of the miracle products of wartime investments in science and technology. Yet within thirty years, many industrialized countries banned the synthetic insecticide due to fears of its long-term effects on humans and wildlife. At the turn of the twenty-first century, the devastating resurgence of malaria across the developing world reignited debates over the ethics of using DDT.

The chemical compound that is DDT, dichlorodiphenyl-trichloroethane, was first synthesized in 1873, but not until 1939 did Swiss chemist Paul Müller discover its insecticidal properties. The U.S. military used DDT during World War II to protect soldiers and civilians from the destructive insect-borne diseases typhus and malaria. DDT's persistence and its broad spectrum of action made it extremely successful at killing insects over a long period, in small doses, and at low cost. In response to civilian demand, the U.S. government made the celebrated chemical available to the public in 1945, despite private concerns among federal scientists of potential long-term hazards. The agricultural and public health promise of DDT led to mass aerial spraying programs, and Müller won the 1948 Nobel Prize in physiology or medicine. Production by U.S. companies increased from 10 million pounds in 1944 to more than 100 million pounds in 1951.

Rachel Carson burst the bubble of confidence concerning the safety of DDT in 1962 with her best-selling exposé of the overuse of synthetic chemical pesticides, *Silent Spring*. The book publicized scientific evidence of the toxic effects of DDT on humans and animals, including nervous system dysfunction, reproductive abnormalities, and cancer. It explained how DDT's insolubility in water and fat-solubility enable it to persist in the soil and water, enter the food chain, and accumulate in the fatty tissues of non-target organisms such as the bald eagle, whose plummeting numbers were linked to DDT-induced eggshell thinning. *Silent Spring* also showed how mosquitoes and other target insect populations develop genetic resistance to DDT, thereby undermining its efficacy.

Carson criticized the arrogance of entomologists who presumed they could control pests by waging chemical warfare. She made a strong ethical argument for the need to respect the other creatures with which humans share the earth. Although some critics accused her of privileging wildlife over people, she testified to Congress on behalf of "the right of the citizen to be secure in his own home against the intrusion of poisons applied by other persons" (Lear 1997, p. 454). Spurred by increasing evidence of DDT's carcinogenicity, Congress banned the sale of DDT in the United States in 1972. Within three decades DDT was banned in thirty-four countries, and severely restricted in thirty-four others. It continued to be used in several developing nations, primarily in the *malaria belt*.

Since the 1970s, malaria has become one of the deadliest infectious diseases in the world, killing at least 1.1 million people each year. Children under age five comprise more than half the victims. Many environmentalists and health experts blame malaria's huge resurgence on the overuse of both chemical insecticides and anti-malarial drugs, which led their respective targets—anopheles mosquitoes and plasmodium parasites—to develop genetic resistance. Anti-DDT groups advocate preventive methods, including the use of mosquito nets dipped in the nontoxic insecticide permethrin and the cultivation of fish that consume mosquito larvae, as part of a systematic approach to the disease. In their opinion, DDT should be used only as a last resort due to its well-documented negative effects.

In contrast a strong opposition movement argues that DDT is still the cheapest, most effective anti-malarial measure, and that its declining use is responsible for the recent resurgence of malaria. Pro-DDT groups condemn environmentalists for scaring developing countries from using the chemical, and for caring more about bald eagles than suffering children. They point to scientific studies that fail to confirm evidence of long-term risks of exposure to DDT, and contend that it serves as a crucial insect repellent even in places

Two women are sprayed with DDT. Although widely used in pesticides in the 1940s and 50s, the compound has been banned in North America and most of Europe since the 1970s due to fears of detrimental long-term effects. *(The Library of Congress.)*

where mosquitoes have become resistant. From their perspective, it is unethical not to utilize DDT as a first resort against malaria, because its life-saving capacity for millions of people outweighs any potential negative environmental or human health effects.

Despite such conflicting outlooks, a compromise was struck in 2001, when delegates from 127 nations signed an international treaty to phase out twelve toxic, persistent, fat-soluble chemicals, including DDT. After intense debate, developing nations received exemptions permitting them to continue using DDT against the mosquito vectors of malaria until safer, affordable substitutes become available. The Stockholm Convention on Persistent Organic Pollutants entered into force on May 17, 2004.

DEATH AND DYING

Death is defined as the irreversible loss of biological life functions, and occurs in all organisms. It is the inevitable conclusion of a finite existence, and is often applied by analogy even to geological features that contain life (the death of a river), social orders (death of a city), or machines (one's car or computer died). Science can study the phenomenon of death, technology may delay its approach, but medicine cannot cure humans of their mortality.

Dying, by contrast, is the process that leads to death, and is a distinctly human event, embedded in numerous moral traditions and well-circumscribed by prescriptions for appropriate conduct in its presence. No other animal attends as carefully to the dying process or accords it such significance. Modern medical technologies, including drugs and therapies, aim to delay the onset of this process (life-saving technologies), extend it (life-sustaining or life-support technologies), take control of it (technologies of euthanasia), or provide comfort (palliative technologies) as the time of death nears. Whereas premodern thought commonly interpreted dying in religious terms, viewing it as a process of transformation from one state to another and calling forth techniques of ritual engagement with larger orders of reality, contemporary technical achievements are the result of aspirations for control over the process that pose challenges in a moral framework.

Historical and Cultural Background

As described by the cultural historian Philippe Ariès (1991), the European experience of death has itself undergone significant transformations. Dying is not simply a basic feature of the human condition and the termination of an individual history; it has its own history. From the Graeco-Roman world up through the first millennium of the Christian era, death was so ever-present as to have been accepted as a normal aspect of human affairs. Theologically death was also often interpreted as a result of living in a fallen world marked by sin. When someone died, people paid their respects but did not dwell on the issue because of the greater importance of the community as a whole.

During the eleventh century in Europe, the rise of individualism brought with it a new perspective on death as a threat not to the community but to the self, which in turn gave rise to the development of *Ars moriendi* or treatises on the art of dying well. In the sixteenth century the emphasis shifted toward concern for the death of loved ones in a family. The romantic pathos at the death bed of family and friends ironically contributed to the transfer of the event of dying from home to hospital, where it acquired a higher public profile.

How is it, asks Ariès, that "the community feels less and less involved in the death of one of its members"? One answer is that the community "no longer thinks it necessary to defend itself against a nature which has been domesticated once and for all by the advance of technology" (Ariès 1991, p. 612). Another is that individualism has fractured the sense of solidarity. As death ceases to be a public threat it is progressively transformed into an emotional issue and relegated to the realm of privacy. Medical science and technology are brought in to study the process and reduce the pain, but behind this rational management "the death of the patient in the hospital, covered with tubes, [becomes] a popular image, more terrifying than the … skeleton of macabre rhetoric" (Ariès 1991, p. 614).

There are, however, other perspectives on death and dying that have likewise been impacted by scientific and technological change. Outside European traditions, for instance, the Hindu view embraces death as part of a great spiritual journey. The soul is in a state of continuous evolution and awareness from the limited to the limitless. Death separates the indestructible soul-body from the weakened physical-body. The soul-body reincarnates a physical-body, which matures and develops the soul-body in a life and death cycle. The act of reincarnation enables the soul to renew its work of resolving karma or moral effects arising from failures to conduct oneself in harmony with the dharma or moral order of the cosmos. The fulfillment of this process leads to liberation from the cycle of rebirth in a state called *moksha* and is characterized by *sat chit ananda* or limitless being, awareness, and bliss.

One influential Buddhist tradition *The Tibetan Book of the Dead* (from the fourteenth or fifteenth centuries), a guidebook for the deceased that echoes similar Egyptian, Daoist, and even Kabbalist literature, teaches how death is a process of moving toward pure truth. Once liberated from the confines of a mortal body, awareness enters a series of intermediate states called *bardos* in which it experiences various, sometimes frightening visions. To work through these *bardos* calls for assistance in order to attain either reincarnation or nirvana, a state in which confusion and suffering cease.

Across these various cultural perspectives one common theme is a distinction between natural and unnatural death and dying (Young). Natural deaths are associated with old age and disease, unnatural with accident and murder. In Hinduism, Jainism, Buddhism, Confucianism, and Daoism natural death has a normative value, thus implying criticism of the technological or artificial manipulations of the dying process, especially in the form of active euthanasia. Insofar as the natural is also seen as a manifestation of the spiritual, such a view reaffirms death as a gateway between the natural and the supernatural.

It is in reaction against such metaphysical perspectives—perspectives that have much in common with the premodern Christian views—that the Enlightenment gave birth to the typically modern, empirical explanation of death and efforts to take instrumental control of dying. From the invention of the microscope and the discovery of a small pox vaccination emerged the germ theory of disease. According to germ theory, microbes enter a body and attack its metabolic functioning. Public health initiatives are thus required to develop external means of protection against such attacks. With the discovery of antibiotics physicians were able to go inside the body and kill germs there as well. Death is no longer considered a consequence of sin, but is simply the result of disease and old age.

The Psychology of Dying and Death Redefined

Further developments in scientific and technological medicine have made it possible not only to protect from and respond to disease, but to aggressively manage the dying process with lifesaving or life-support technologies and to provide high-tech palliative care—and even take control of it with techniques for euthanasia. Psychological models of the dying process (which faintly echo the traditional guidebooks for the dying) and efforts to redefine death itself highlight alternative responses to the challenges thus raised.

The most popular psychological analysis of the dying process is *On Death and Dying* (1969) by Elizabeth Kübler-Ross. In her thanatology, she distinguishes five stages of dying through which people progress when informed that they have a terminal illness: denial, anger, bargaining, depression, and acceptance. This analysis has become so influential that some advocate its application in other situations in which people suffer loss or experience traumatic change. Indeed in the face of issues arising from revolutionary new technologies such as human cloning, there is room to argue that a culture passes through stages in which there is public denial of the possibility, anger at its scientific creation, bargaining for how it is to be used, depression that it seems inevitable, and finally acceptance as just another aspect of the advanced technological condition. Others, however, advocate modification and revision of Kübler-Ross's model, although no one has rejected the general idea that in the course of dying people typically go through different stages. To what extent this description is a normative as well as a descriptive paradigm remains unclear.

Kübler-Ross and others (see Moody 2001) also claim that empirical studies of the dying process and especially near-death experiences confirm the existence of an afterlife. This is a highly contentious position that nevertheless to some extent makes common cause with traditional guidebooks for the art of dying. More widely accepted are manuals that provide psychological guidance that extend Kübler-Ross's original approach (see Byock 1998).

In contrast to psychological studies of the dying experience, which was simply an open research question inviting scientific scrutiny, the need to redefine death was made acute by techno-medical advances. Death was traditionally defined in metabolic terms and indicated by cardiac or pulmonary arrest. But with the invention of artifacts that are able to substitute for the functions of heart and lungs, the human metabolism can often be indefinitely sustained. The Karen Ann Quinlan case of 1975, in which parents were initially denied the right to remove their comatose daughter from life support, was only one of a series of related cases that brought this issue to public attention, and served as a powerful stimulus to the creation of the field of bioethics. In response the 1978 Presidential Commission on the Study of Ethical Problems in Medicine and Biomedical and Behavioral Research, in conjunction with the American Bar Association (ABA), the American Medical Association (AMA), and the National Conference of Commissioners of Uniform State Laws, proposed a Uniform Determination of Death Act (UDDA). According to this draft act, "An individual who has sustained either (1) irreversible cessation of circulatory and respiratory function, or (2) irreversible cessation of the entire brain, including the brain stem, is dead." The draft UDDA has in various forms been enacted in most of the United States and has become the most widely adopted standard.

Tensions in Autonomy

As dying and death are reconceptualized under the influence of ever-advancing science and technology, a host of related decisions become progressively problematic—especially with regard to autonomy, one of the fundamental principles of contemporary Western ethics. The individual right to choose or self-determine whether or not to be placed on life-sustaining treatment is typical. Traditionally people did not have the *right to choose* their deaths. Age, accidents, sicknesses, and disease determined it for them. Individuals were ultimately passive as death approached. The goal of the patient-physician relationship was no more than the easing of symptoms related to life-limiting illnesses or the aging process.

All this changed as personal autonomy became a moral ideal and medical procedures and therapies altered what constituted unpreventable death and sustainable life. For example, during the late-nineteenth and early-twentieth centuries many patients with life-threatening conditions such as polio were sent home to die. By the late 1920s, lifesaving treatments such as the iron lung enabled them to live for years in machines that breathed for them. Under such conditions, even mere acceptance of whatever contemporary medical procedure has the most professional momentum behind it constitutes a choice, and the traditional attitude of passive acceptance in the face of extreme illness increasingly means an acceptance not of nature but of science and technology.

The dying and those who care for them are thus faced with progressively difficult decisions regarding nutrition, hydration, antibiotics, ventilation, and a host of more aggressive medical technologies. Dilemmas become especially apparent when advanced techniques of life-support enable sustaining basic metabolic functions with little hope for full recovery. Attempts to reflect on the dimensions of autonomous decision making under such conditions involve at least four overlapping tensions: (a) informed consent and ignorance; (b) private decisions and public demands; (c) curative care and futile care; and (d) benefits of treatment and the burden of care.

The tension between informed consent and ignorance is particularly difficult to negotiate when considering high-tech medical treatments under the stress of illness and pain that may well be terminal. Although there is a widely shared consensus that patients must be informed about and freely consent to treatments, how much should patients be expected to understand? What are the communication responsibilities of medical professionals? Even when patients claim to understand, can they always be trusted? What if they want to avoid becoming knowledgeable about their condition or desire to abdicate decision making to others, whether family members or medical professionals?

When confronting tensions between private decisions and public demands in a pluralistic society, it is commonly argued that private decisions take precedence. Presumably personal values inform private decisions while public attitudes differ and reflect fragmented cultural, religious, and emotional biases. For example, although most Americans express public opposition to euthanasia or physician-assisted suicide, they are personally more accepting when faced with extended, terminal suffering and pain. Thus there is a tendency to promote individual choice. Certainly most states and many countries give people the opportunity to make their wishes known with respect to possible life-limiting illnesses in the form of physician directives, medical powers-of-attorney, and do-not-resuscitate (DNR) orders.

A third tension arises between curative care and futile care. The desire to extend life is pervasive in Western cultures, but life support treatments sometimes prolong death more than they extend life. Curative care employs life-supporting technologies with the goal of recovery, but the consequences of living on continuous life-support, without hope of recovery, must be considered as well. The alternative of palliation or comfort care that allows the process of dying to take its course is another option. There are even instances when an otherwise curative procedure such as chemotherapy may be used as a palliative treatment.

Closely related to the curative versus futility tension is one between quality of life and quality of function. Quality of life issues generally revolve around physical or mental disabilities, which may impede but not destroy a person's ability to interact with and engage the environment. For example, persons with head injuries confined to hospital beds may be aware of the environment and engage the world around them. Although their quality of life is altered, such circumstance does not justify withholding or withdrawing life-sustaining treatment. Quality of function issues, however, may justify withdrawal of life-sustaining treatments when the ability to function is seriously impaired due to some significant pathology. Persons with head injuries who are in a persistent vegetative state and unaware of or unable to engage their environment have a low quality of functioning.

Finally tensions exists between the benefits of treatment and the burden of care. Life-support treatment always comes with both physical and financial costs. Therapies such as ventilation carry risks of infection, aspiration, and skin breakdown. When outcomes are successful, benefits are usually taken to outweigh burdens, although burn victim Dax Cowart has argued that this is not always so (Kliever 1989). Moreover while it is generally agreed that financial costs should not be the determinative factor when considering life-support, they must be considered. As the private burdens and public costs for funding life-support technologies rise, some argue that there are instances in which individuals may have a duty to die.

Burdens of care also often raise questions of equity and social justice. In principle all persons should have equal access to life-saving and life-sustaining technologies. In reality the poor, uneducated, and uninsured are far less likely to be treated or have the opportunity to make decisions about such treatment. At the same time, although it is commonly argued that death and dying decisions must relate to personal needs, some forms of this position have been challenged as excessively individualistic.

The Question of Modernity

Once viewed as spiritual experiences, in the early-twenty-first century death and dying are often considered no more than the cessation of metabolic or brain functioning. However, related issues continue to provoke strong responses because views on death and dying emerge in a variety of cultural contexts. It often appears that as technology and medicines advance, the fear of death increases, encouraging greater efforts to prolong life. Daniel Callahan (1973, 2000) argues that a fundamental rejection and fear of death is at the foundation of modern science and technology.

Certainly in Western scientific and technological culture, death has a negative connotation. Attempts to deny death are manifest both in the scientific efforts to map its physiological details and genetic basis as well as in technological efforts to hold it at bay as long as possible. Denial is further reinforced through the sequestering of the aged, ill, and dying, especially in the United States. Such individuals are institutionalized in hospitals, long-term nursing facilities, and retirement villages. Euphemisms such as *slumber*, *expired*, and *passed away* further reinforce the denial of death. Even contemporary religious customs enforce denial by limiting grieving time and trying to help families cope with personal losses.

Yet in an insightful reflection on death and dying in relation to the ideal of autonomy and technological mastery—what is termed the *instrumental activism* of the West—Talcott Parsons and Victor Lidz suggest an alternative interpretation. They identify a range of efforts to control and manage death and dying through "scientific medicine and public health services designed to protect life; insurance, retirement, and estate planning to manage the practical consequences of deaths; and mourning customs that emphasize recovery of survivors' abilities to perform ordinary social roles soon after the death of family members, friends, and associates" (Parsons and Lidz 2004a, p. 597). From such perspective, what others described as attempts to hide or ignore death are seen as techniques for its management under conditions in which there is no strong cultural consensus about the meaning of either life or death, short of what can be concluded from the empirical evidence (that it is bound to occur) and postulated on the basis of scientific theory (its evolutionary benefits to both organisms and society).

To what extent might these same techniques be integrated into a different cultural context in which death and dying continue to be experienced as a spiritual transition between worlds? The question is not easy to answer, and may not be answerable at all apart from historical efforts at adaptation. But whether the standard bioethical efforts to promote patient autonomy, equity of access, and a quality hospital experience can transcend the contemporary cultural framework remains unclear.

DEATH PENALTY

There is an ongoing crucial debate within the criminal justice system as to the moral status of the death penalty. Retentionists hold that the death penalty is morally justified; abolitionists argue that it is not. Proponents of the death penalty justify it from either a retributive or a utilitarian framework, sometimes using both theories for a combined justification. Abolitionists reject these contentions arguing that the principle of the sanctity of human life gives each person an inalienable right to life and thus prohibits imposition of the death penalty. Scientific research and technological developments provide modest contributions to both arguments.

Retributive Arguments

The retributivist argues (1) that all the guilty deserve to be punished; (2) that only the guilty deserve to be punished; and (3) that the guilty deserve a punishment proportional to their crime. It follows that death is a suitable punishment for anyone who commits a capital offense (that is, those offenses such as murder and treason that are especially morally heinous). The concept is suggested in the Bible: "Thou shalt give life for life, an eye for an eye, a tooth for a tooth, a hand for a hand, burning for burning, wound for wound, stripe for stripe" (*Exod*. 21: 23–25).

A classic expression of the retributivist position on the death penalty is Immanuel Kant's statement that if an offender "has committed murder, he must *die*. In this case, no possible substitute can satisfy justice. For there is no *parallel* between death and even the most miserable life, so that there is no equality of crime and retribution unless the perpetrator is judicially put to death (at all events without any maltreatment which might make humanity an object of horror in the person of the sufferer)" (Kant 1887, p. 155).

For Kant, the death penalty was a conclusion of the argument for justice: just recompense to the victim and just punishment to the offender. As a person of dignity, the victim deserves (as a kind of compensatory justice) to have the offender harmed in proportion to the gravity of the crime, and as a person of high worth and responsibility, the offender is deserving of the death penalty. Accordingly the torturer should be tortured exactly to the severity that he tortured the victim, the rapist should be raped, and the cheater should be harmed to a degree equal to that suffered by the one cheated. Criminals deserve such punishment in accordance with the principle of proportionality.

The abolitionist disagrees. Putting the criminal to death only compounds evil. If killing is an evil, then the evil is doubled when the state executes the murderer, violating the latter's right to life. The state commits *legalized murder*. To quote the famous eighteenth-century abolitionist Cesare di Beccaria, "The death penalty cannot be useful because of the example of barbarity it gives to men … it seems to me absurd that the laws … which punish homicide should themselves commit it" (*On Crimes and Punishment*, 1764).

The retentionist responds that the abolitionist is mistaken. The state does not violate the criminal's right to life, for the right to life (more precisely, the right not to be killed) is not an absolute right that can never be overridden (or forfeited). If the right to life were absolute, one could not kill an aggressor even when such action is necessary to defend one's own life or the lives of loved ones. It is a *prima facie* or conditional right that can be superseded in light of a superior moral reason. The individual right to life, liberty, and property is connected to the societal duty to respect the rights of others to life, liberty, and property. A person can forfeit the right to liberty by violating the liberty rights of others. A person can forfeit property rights by violating the property rights of others. Similarly the right to life can be forfeited when a person violates the right to life of another. An individual's *prima facie* right to life no longer exists if that person has committed murder.

Utilitarian Arguments

The utilitarian argument for capital punishment is that it deters would-be offenders from committing first degree murder (that is, types of murder that seem especially vicious, brutal, or deleterious, such as assassination). However some studies that compared states that allow capital punishment to those that do not permit it concluded that imprisonment works as well as the death penalty in deterring homicide. Other studies purport to show that when complex sociological data (race, heredity, regional lines, standards of housing, education, and opportunities, among others) are taken into account, the death penalty does deter. Anecdotal evidence exists to support this. Abolitionists argue that isolated cases are poor indicia of the reality regarding deterrence.

Abolitionists point out that the United States is the only Western democracy to retain the death penalty. The retentionist responds that this is not an argument, but an appeal to popularity. Furthermore, in many Western countries that prohibit the death penalty (such as England, Italy, and France), there is evidence that the majority of citizens favor it.

Scientific and Technological Contributions

Science and technological issues are relevant to the debate in so far as some argue that neuroscience and psychology show that criminals, including murderers, commit crimes due to neurological dysfunction and are not responsible for what they do. However the same arguments could be used to deny human responsibility altogether.

An application of technology to the death penalty is illustrated by attempts to find more benign forms of execution, for example, replacing the electric chair (which some consider cruel and unusual punishment) with lethal injection. Such changes have caused debate about whether the condemned deserves humane treatment or should be subjected to some pain and anxiety as part of the punishment.

Other abolitionists argue, on the basis of social scientific studies, that the U.S. penal system is inherently unfair, is biased against the poor and minorities, and favors the rich who can afford to hire better legal counsel. Furthermore they contend that there is always the possibility that an innocent person will be executed. The retentionist, recognizing these dangers, responds, Amend it, don't end it.

DECISION SUPPORT SYSTEMS

Decision support systems (DSS) are tools meant to assist in human decision-making (Turban and Aronson 2001). In an increasingly complex and rapidly changing world where information from human, software, and sensor sources can be overwhelming, DSS tools can serve as a bridge between the social and technical spheres. DSS tools offer support based on formal, technical approaches, but do so within a context that is often largely socially mediated.

Most DSS tools are assembled out of hardware devices and software constructs. The hardware devices, in the early twenty-first century, are dominated by digital computers and peripherals such as sensors, network infrastructure, and display and alerting devices meant to interact with these. Historically, many DSS were hardwired to solve a specific task; control systems in nuclear power plants are an example. DSS hardware is increasingly dominated by physically distributed systems that make use of wired and wireless networks to gather and share information from and with remote sources (Shim et al. 2002). The convergence of remote sensing, sensor-networks, and distributed computational grids using the Internet as a foundation in the late 1990s–early 2000's reflects this trend.

The software, or algorithmic, component of DSS derives from historical research in statistics, operations research, cybernetics, artificial intelligence, knowledge management, and cognitive science. In early monitoring decision support systems the algorithms were typically hard-wired into the system, and these systems tended to be unchanging once built. Software-based decision support allows for multiple approaches to be applied in parallel, and for systems to evolve either through new software development or via software that "learns" through artificial intelligence techniques such as rule induction (Turban and Aronson 2001).

When used appropriately, DSS tools are not meant to replace human decision-making—they are meant to make it more effective (Sprague and Watson 1996). DSS tools do this by presenting justified answers with explanations, displaying key data relevant to the current problem, performing calculations in support of user decision tasks, showing related cases to suggest alternatives, and alerting the user to current states and patterns. In order to be a support rather than a hindrance, these tools must be constructed with careful attention to human cognitive constraints. As a result, DSS design is a prime area of human-computer interaction and usability research. In many cases, DSS tools make use of adaptive software interfaces; depending on the situation, different contents will be displayed on the interface, so as not to overwhelm the user with secondary or irrelevant information.

Decision Support Tools

Decision support tools fall into two broad classes: those that operate at the pace of the user (for example, to support planning decisions) and those that operate at or near the pace of real-time world events (such as air traffic control systems). The decision-making domain can be further divided into situations in which the system can be completely and accurately defined (in other words, closed and formal systems) and those where this is not feasible, desirable, or possible. The former is not normally considered a prime situation for decision *support* because a formal situation can be addressed without human intervention, while the latter requires the hybrid human-machine pairing found in DSS. In the case of open systems, heuristic approximations (rules of thumb) are needed in lieu of formal models; these may also be needed in cases in which a formal model exists but cannot be computed in a reasonable amount of time.

Systems that operate at the pace of the user provide support for such tasks as planning and allocation, medical and technical diagnosis, and design. Typical examples include systems used in urban planning to support the complex process of utility construction, zoning, tax valuation, and environmental monitoring, and those used in business to determine when new facilities are needed for manufacturing. Such tools include significant historical case-knowledge and can be transitional with training systems that support and educate the user. Formal knowledge, often stored as rules in a modifiable knowledge base, represent both the state of the world that the system operates on and the processes by which decisions transform that world. In the cases where formal knowledge of state and process are not available, heuristic rules in a DSS expert system or associations in a neural network model might provide an approximate model. DSS tools typically provide both a ranked list of possible courses of action and a measure of certainty for each, in some cases coupled with the details of the resolution process (Giarratano and Riley 2005).

Systems that operate at or near real time provide support for monitoring natural or human systems. Nuclear power plant, air traffic control, and flood monitoring systems are typical examples, and recent disasters with each of these illustrate that these systems are fallible and have dire consequences when they fail. These systems typically provide support in a very short time frame and must not distract the user from the proper performance of critical tasks. By integrating data from physical devices (such as radar, water level monitors, and traffic density sensors) over a network with local heuristics, a real-time DSS can activate alarms, control safety equipment semi-automatically or automatically, allow operators to interact with a large system efficiently, provide rapid feedback, and show alternative cause and effect cases. A central issue in the design of such systems is that they should degrade gracefully; a flood monitoring system that fails utterly if one cable is shorted-out, for example, is of little use in a real emergency.

History of Decision Support Research and Tools

As indicated above, DSS evolved out of a wide range of disciplines in response to the need for planning-support and monitoring-support tools. Management and executive information systems, where model and data-based systems dominated, reflect the planning need; control and alerting systems, where sensor and model-based alerting systems were central, reflect the monitoring need. The original research on the fusion of the source disciplines, and in particular the blending of cognitive with artificial intelligence approaches, took place at Carnegie-Mellon University in the 1950s (Simon 1960). This research both defined the start of DSS and also was seminal in the history of artificial intelligence; these fields have to a large degree co-evolved ever since. By the 1970's research groups in DSS were widespread in business schools and electrical engineering departments at universities, in government research labs, and in private companies. Interestingly, ubiquitous computer peripherals such as the mouse originated as part of decision support research efforts.

By the 1980s the research scope for DSS had expanded dramatically, to include research on group-based decision making, on the management of knowledge and documents, to include highly specialized tools such as expert-system shells (tools for building new expert systems by adding only knowledge-based rules), to incorporate hypertext documentation, and towards the construction of distributed multi-user environments for decision making. In the mid-1980s the journal *Decision Support Systems* began publishing, and was soon followed by other academic journals. The appearance of the World Wide Web in the early 1990's sparked a renewed interest in distributed DSS and in document- and case-libraries that continues in the early twenty-first century.

Outstanding Technical Issues with Decision Support Tools

DSS tools, as described above, integrate data with formal or heuristic models to generate information in support of human decision making. A significant issue facing the builders of these tools is exactly how to define formal models or heuristics; experts make extensive use of tacit knowledge and are notoriously unreliable at reporting how they actually do make decisions (Stefik 1995). If the rules provided by domain experts do not reflect how they actually address decisions, there is little hope that the resulting automated system will perform well in practice.

A second, related, issue is that some systems are by their very nature difficult to assess. Chaotic systems, such as weather patterns, show such extreme sensitivity to initial (or sensed) conditions that long-term prediction and hence decision support is difficult at best. Even worse, many systems cannot be considered in isolation from the decision support tool itself; DSS tools for stock market trading, for example, have fundamentally changed the nature of markets.

Finally, both the DSS tools and the infrastructure on which they operate (typically, computer hardware and software) require periodic maintenance and are subject to failure from outside causes. Over the life of a DSS tool intended to, for example, monitor the electrical power distribution grid, changes to both the tools themselves (the hardware, the operating system, and the code of the tool) and to their greater environment (for example, the dramatic increase in computer viruses in recent history) mean that maintaining a reliable and effective DSS can be a challenge. It cannot be certain that a DSS that performs well now will do so even in the immediate future.

Ethical Issues

Decision support rules and cases by their very nature include values about what is important in a decision-making task. As a result, there are significant ethical issues around their construction and use (see, for example, Meredith and Arnott 2003 for a review of medical ethics issues). By deciding what constitutes efficient use in a planning support system for business, or what constitutes the warning signs of cardiac arrest in an intensive care monitoring system, these tools reflect the values and beliefs of the experts whose knowledge was used to construct the system. Additionally, the social obligation of those who build DSS tools is an issue. On the one hand, these are tools for specific purposes; on the other hand, many social and natural systems are so interrelated that, in choosing to build an isolated and affordable system, many issues will be left unresolved.

The ruling assumption of efforts to build DSS tools is that decision-making is primarily a technical process rather than a political and dialogical one. The bias here is not so much intellectual as informational: It may overestimate the usefulness of information in the decision-making process. Rather than more information, or ever more elaborate displays, people might need more time to reflect upon a problem. Coming to understand another perspective on an issue is a matter of sympathy and open-mindedness, not necessarily information delivery. Delivering detailed information, cases, and suggested courses of action to a single user is opposed to the idea of community-base processes. While placing these issues outside of the scope of a system design might be a useful design decision from a technical position, it is a value-laden judgment.

In fairness, the decision support literature does occasionally recognize that the public needs a better understanding not only of technology but also of science. There is often little appreciation, however, that decision support is an ethical and political process as much as a technical one—or that the flow of information needs to involve the scientist, the engineer, and the public. Exactly how the political process can be engaged for systems that must by their very nature operate in real time is an open question. Certainly the process of knowledge and value capture for such systems could be much more open than is currently the norm.

A second pressing issue regarding DSS tools is the degree to which the data, knowledge, sensors, and results of their integration represent a limitation on individual freedoms and/or an invasion of privacy. DSS tools based on expert-systems approaches actively monitor every credit card transaction made. Semi-automatic face recognition systems are widespread. Radio-frequency identification tags built into price tags on consumer goods allow consumer behavior to be monitored in real-time. Cell-phone records provide not only who a person was speaking to, but where they were at the time. Decision support tools for national security, market research, and strategic planning integrate information, apply rules, and inform decisions that affect human freedom and privacy every day.

Conclusions

DSS tools will only become more common in the future. The widespread reach of Internet connections and the dramatic decrease in the cost of sensors is driving the creation of decision support tools within governments and industries worldwide. It remains to be seen how these systems may impact on human lifestyles, freedoms, and privacy, and whether these tools can continue to evolve to handle the difficult questions facing decision makers in a complex and changing world.

DECISION THEORY

Decision theory is the science of rational choice in situations in which there is uncertainty about the outcome. Rational choice theory asserts that individuals whose behavior satisfies a few plausible conditions (such as transitivity, which means that if A is preferred to B and B is preferred to C, then A is preferred to C) will behave as though they are maximizing a preference function defined over the choice outcomes. For instance, consider an agent with the preference function $u(a, n)$ defined over two goods, Apples and Nuts, and with an amount of money M to spend. Thus, u(2, 5) is the "utility" the agent derives from consuming two apples and five nuts (for this reason, economists call a preference function a *utility function*). If the prices of Apples and Nuts are p_a and p_n, the individual will choose the amount of Apples a and the amount of Nuts n that will maximize $u(a, n)$, subject to the constraint that the total cost is not greater than M (i.e., $p_a a + p_n n \leq M$). Decision theory deals with such choices when there is uncertainty regarding the amount of Apples and Nuts that will be delivered.

Decision theory relies on probability theory, the development of which began in the seventeenth and eighteenth centuries, associated with scholars such as Blaise Pascal (1623–1662), Daniel Bernoulli (1700–1782), and Thomas Bayes (1702–1761). The analysis here will be confined to the case where there is only a finite set of outcomes A, written as $A = \{a_1, \ldots, a_n\}$. A *probability distribution* over A is called a *lottery* and consists of n numbers $p_1, \ldots, p_n$ such that each $p_i \geq 0$ and $p_1 + \cdots + p_n = 1$. In this case p_i is interpreted as the probability that outcome a_i occurs.

The Expected Value and Expected Utility of a Lottery

One of the first problems addressed by probability theorists was the determination of the *certainty equivalent* of a lottery: If someone offers to sell a person a lottery with monetary prizes for a certain amount of money, what is the maximum the buyer should be willing to pay? Early probability theorists suggested that that person should be willing to pay the "average" payoff of the lottery. However, it soon was shown that the average payoff of lottery x is equal to its expected value, which is defined as $\mathbf{E}x = p_1a_1 + \cdots + p_na_n$. For instance, the expected value of a lottery that pays $1,000,000 with a probability of 1/1,000,000 has an expected value of $1.

Daniel Bernoulli, however, developed a simple example, known as the *St. Petersburg Paradox*, that clearly showed that the idea that people will pay the expected value must be incorrect. Suppose a person is offered either a sum of money M or the following lottery: A coin is tossed a number of times until it turns up heads, after which the game is over. If the first toss is heads, the person is paid $1. If the first toss is tails and the second is heads, that person is paid $2, and so on, with each additional round paying twice as much ($4, $8, ...). Most people, if offered M = $20, will take this rather than play the coin-tossing game, yet the expected value of the game is infinite:

$$\mathbf{E} = \tfrac{1}{2}\times 1 + \tfrac{1}{4}\times 2 + \tfrac{1}{8}\times 4 + \ldots = \tfrac{1}{2} + \tfrac{1}{2} + \tfrac{1}{2} + \ldots = \infty.$$

Bernoulli suggested that the problem here is that the "utility" of each additional unit of money *decreases* as the amount increases, just as the additional utility of each additional scoop of ice cream decreases for a consumer. He suggested that the utility of money may be logarithmic and that people maximize the expected utility of a lottery, not the expected value. If the utility of an amount of money M is log(M), the expected utility of the St. Petersburg lottery is

$$\begin{aligned}\mathbf{E} &= \tfrac{1}{2}\log(1) + \tfrac{1}{4}\log(2) + \tfrac{1}{8}\log(4) + \tfrac{1}{16}\log(8) + \ldots\\ &= 0 + 0.17 + 0.17 + 0.13 + 0.09 + \ldots\\ &\approx 1.66\end{aligned}$$

The von Neumann–Morganstern Axioms

A general model of expected utility was not developed until centuries later. John von Neumann (1903–1957) and Oskar Morgenstern (1902–1976) developed decision theory as a model of rational choice in regard to lotteries. They supplied three conditions from which the expected utility principle could be derived. The first was, as in standard rational choice theory, that the agent has a weak preference relation $\succeq$ that is complete and transitive over the set of lotteries. By *complete* it is meant that for any two lotteries x and y, one is weakly preferred to the other (i.e., either $x \succeq y$ or $y \succeq x$). This is called a weak preference because any lottery x is weakly preferred to itself (i.e., for any lottery x, there is $x \succeq x$). Strong preference can be defined $\succ$ as $x \succ y$ means that "it is false that $y \succ x$." By *transitive* it is meant that if x is weakly preferred to y and y is weakly preferred to z, then x is weakly preferred to z ($x \succeq y$ and $y \succeq z$ implies $x \succeq z$).

Suppose x and y are lotteries and suppose p is a probability (i.e., a number between zero and one). One writes $px + (1 - p)y$ for the lottery that gives lottery x with probability p and lottery y with probability $1 - p$. For instance, suppose x is the lottery that pays off $20 with probability 0.25 and $10 with probability 0.75 and suppose y is the lottery that pays off $5 with probability 0.90 and $100 with probability 0.10. Then $0.33x + 0.67y$ is the lottery that pays off x with probability 0.33 and y with probability 0.67. This so-called compound lottery thus has payoffs $0.33x + 0.67y = 0.33[0.25(\$20) + 0.75(\$10)] + 0.67[0.90(\$5) + 0.10(\$100)]$, and so this is a lottery that pays $20 with probability (0.33)(0.25) = 0.0825, pays $10 with probability (0.33)(0.75) = 0.2475, pays $5 with probability (0.67)(0.90) = 0.6030, and pays $100 with probability (0.67)(0.10) = 0.067. Note that these probabilities add up to one, as they should. As an exercise, one may check to see that if $\mathbf{E}x$ and $\mathbf{E}y$ are the expected values of lotteries x and y, then $a\mathbf{E}x + (1 - a)\mathbf{E}y$ is the expected value of the lottery $ax + (1 - a)y$.

The second von Neumann–Morgenstern condition is that if $x \succ y$ and z is any lottery and $p < 1$ is a probability, then $px + (1 - p)z \succ py + (1 - p)z$. This is called the *independence* condition. It says that the value of a prize depends only on the prize and the probability of winning it, not on other payoffs or probabilities.

The third condition is that if x, y, z are lotteries and $x \succ y \succ z$, there are numbers p and q such that $px + (1 - p)z \succ y \succ qx + (1 - q)z$. This says that there is no lottery that is infinitely valuable or infinitely distasteful. This is called the *Archimedean condition*.

With these three conditions von Neumann and Morgenstern showed that the agent has a utility function $u(a)$ defined over the outcomes $a_1, \cdots, a_n$ such that for any two lotteries $x = p_1a_1 + \cdots + p_na_n$ and $y = q_1a_1 + \cdots + q_na_n$, $x \succ y$ if and only if

$$p_1u(a_1) + p_2u(a_2) + \cdots + p_n\mathrm{u}(a_n) > q_1u(a_1) + q_2u(a_2) + \cdots + q_n\mathrm{u}(a_n).$$

Note that the first sum is the expected value of the lottery x in which the payoffs are replaced by the *utility* of the payoffs, and this also applies to the second sum. This motivates the definition of the expected utility of a lottery x as

$$\mathbf{E}_pu = p_1u(a_1) + p_2u(a_2) + \cdots + p_n\mathrm{u}(a_n).$$

The *expected utility theorem* thus states that an individual whose behavior satisfies the conditions listed above (complete transitive preferences that satisfy the independence and Archimedean conditions) chooses among lotteries to maximize expected utility.

Subjective Probability Theory

The purpose of decision theory is to explain and predict behavior, and an agent's behavior depends on that agent's *subjective assessments* of the likelihood of different outcomes. Modern *subjective probability theory* was developed in the twentieth century by Frank Ramsey (1903–1930) and Bruno de Finetti (1906–1985) and was applied to decision theory by Leonard Savage (1917–1971).

Savage begins with a set of all possible mutually exclusive "states of the world" that are relevant for an agent's decision. For instance, to decide whether to buy a new car, a couple may consider (a) possible changes in their employment and health status over the next few years, (b) whether they may increase their family's size, (c) whether next year's models will be better or more affordable than this year's, and (d) whether they can find a lower price elsewhere.

Savage then defines an action f such that $f(s)$ is an outcome or payoff for each state of the world $s \in S$. For instance, for the couple, $f(s)$ = "buy car" for some states of the world and $f(s)$ = "don't buy car" for the other states. Savage shows that if the decision maker has preferences for actions that satisfy certain plausible conditions, it is possible to infer a probability distribution p over states of the world S and a utility function u over outcomes such that the decision maker maximizes expected utility $\mathbf{E}_pu(s) = \sum_{s\in S} p(s)u(s)$ (Kreps 1988).

Violations of Expected Utility Theory

The expected utility approach to decision theory is used widely in behavioral modeling, virtually to the exclusion of other approaches. However, laboratory studies of actual behavior have revealed consistent deviations from the application of the theory. For one thing, there are indications that the independence axiom may be violated, implying that the probability weights in the expression for $\mathbf{E}_pu(s)$ may be *nonlinear*. This fact was first discovered by Maurice Allais (b. 1911, winner of a Nobel Prize in economics in 1988), using the following schema.

Consider a choice between lotteries x_1, which offers \$1,000,000 with probability one, and x_2, which offers a 10 percent chance for \$5,000,000, an 89 percent chance for \$1,000,000, and a 1 percent chance for \$0. Consider a second choice between lotteries y_1, which offers a 10 percent chance for \$5,000,000 and a 90 percent chance for \$0, and y_2, which offers an 11 percent chance at \$1,000,000 and an 89 percent chance for \$0. An individual who prefers x_1 to x_2 prefers an 11 percent chance of \$1,000,000 to a 10 percent chance of \$5,000,000 plus a 1 percent chance of \$0. If an 89 percent chance of \$0 is added to both of these possibilities, this individual, if maximizing expected utility, must prefer an 11 percent chance of \$1,000,000 to a 10 percent chance of \$5,000,000 and therefore must prefer y_2 to y_1. However, in fact, most people prefer x_1 and y_2. An analysis of this and other violations of the independence axiom is provided in the work of Mark Machina (1989).

A second violation of the expected utility model is *loss aversion*, which first was proposed by Daniel Kahneman (b. 1934, winner of a Nobel Prize in economics in 2003) and Amos Tversky (1937–1996) in a 1991 paper. For example, if faced with the choice between a lottery that pays \$5 with probability one and a lottery that pays \$10 with probability ½ and \$0 with probability ½, most people will choose the former (they are said to be *risk-averse* because they prefer the expected value of a risky lottery to the risky lottery). For instance, a risk-averse person will prefer a certain \$5 to a risky lottery with expected value \$5, such as either winning \$10 or winning \$0, each with probability ½. However, if they are given \$10 (say, for showing up for an experimental session) and are faced with the choice between a lottery that loses \$5 with probability one and another that loses \$10 with probability ½ and loses \$0 with probability ½, most people will choose the latter. In this case the subjects are *risk-loving*. Note that the subjects go home with the same amount of money in either lottery. This is certainly a violation of the expected utility theorem. Loss aversion explains many phenomena that defy explanation in traditional decision theory, including the so-called *endowment effect* (Kahneman, Knetch, and Thaler 1990) and the *status quo bias* (Samuelson and Zeckhauser 1988).

Assessment

The rational choice model and its subsidiary, rational decision theory, offer the most powerful analytic tools for modeling human behavior and the behavior of living organisms in general. The laboratory experiments of Allais, Kahneman and Tversky and others (for a summary, see Kahneman and Tversky, 2000) show that in some circumstances expressions more complex than expected utility are needed and that there are important parameters in an individual's preference function, such as the current time and the agent's possessions at the time when decisions are made. Decision theory has been criticized, but its critics have offered nothing that could replace it, and the criticisms generally have been mutually contradictory and often misinformed.

The most famous sustained critique was offered by Herbert Simon (1916–2001, winner of a Nobel Prize in economics in 1978), who suggested that agents do not maximize but instead satisfy "bounded rationality." Simon's observations are correct but are not incompatible with rational decision theory as long as one adds a cost of decision making and interprets probabilities as subjective, not objective. Several disciplines in the social sciences, including sociology, anthropology, and social psychology, implicitly critique the theory by ignoring it in formulating their underlying core theories. This may account for their relative lack of coherence compared with disciplines that embrace rational choice theory (Gintis 2004).

Perhaps the major implication of decision theory is that human beings have a declining marginal utility of money. This is evidenced by the ubiquity of risk aversion and the willingness of individuals to insure against loss. This has an important ethical implication: A dollar transferred from a rich person to a poor person will increase the well-being of the poor person much more than it will reduce the well-being of the rich person.

Some philosophers and philosophically minded economists have played word games in attempting to refute this obvious implication of declining marginal utility (e.g., by suggesting that welfare is not comparable across individuals, an implausible assertion), but its force remains. It implies that with everything else being equal, a more equal distribution of wealth would improve the general welfare. Of course, there are often considerations that act against this principle, such as the maintenance of effective economic incentives and the just treatment of and respect for the rights of the wealthy.

DEFORESTATION AND DESERTIFICATION

A common claim of defenders of tropical rain forests is that because of the shallowness of rain forest soils cutting down those forests for crops or cattle grazing will lead to massive soil erosion and eventually create deserts in areas where lush forests once grew and provided a high percentage of the earth's biodiversity (Sponsel, Headland, and Bailey 1996; Burch 1994; *The Burning Season* 1994).

Complexity of Causes

However, the causes of desertification are much more complex than this scenario would suggest. It is true, for instance, that in the Mediterranean Basin deforestation over centuries has been a significant factor in desertification from Spain and the western part of North Africa in the west to Lebanon and Palestine in the east. Nevertheless, cutting down forests was only one among several human factors that advanced desertification in that region, along with climatic factors:

> First and most fundamental are climate factors. Here is one summary: Conditions [for desertification] are common in the Northern and Southern hemispheres between 20° and 30° latitude.... The most common factor in determining climate is the intense equatorial solar radiation, which heats the air and generates high levels of humidity. Warm tropical air rises; as it does it cools, and the atmospheric moisture condenses. That results in high rainfall patterns in the equatorial region. The rotating earth causes these air masses to move away from the equator toward both poles, and the air begins to descend on either side of the Tropic of Capricorn and the Tropic of Cancer around the 30° latitudinal band. As the air descends it warms and relative humidity declines, resulting in a warm belt of aridity around the globe (Mares 1999, p. 169).

This is the explanation for the existence of deserts worldwide, but for many people concerned with science, technology, and ethics the term *desertification* has a different meaning:

> Desertification is the degradation of productive drylands, including the Savannas of Africa, the Great Plains and the Pampas of the Americas, the Steppes of Asia, the "outback" of Australia and the margins of the Mediterranean. Desertification is occurring to such a degree that some lands can no longer sustain life (Middleton and Thomas 1997, p. iv).

It is controversial whether humans can do anything about climate change, and so the basic formation of the world's deserts is of less interest here—specifically as an ethical or social problem to the mitigation of which science and technology might contribute—than is desertification in the latter sense. However, even with respect to desertification related to humans and their lifestyles over the millennia, the issue is enormously complex.

Attempts at Remediation

One area of increasing desertification is the Mediterranean Basin of southern and southeastern Europe, along with limited areas of western and eastern North Africa. The *World Atlas of Desertification* (Middleton and Thomas 1997) is a product of the United Nations Environment Program (UNEP) and is related to the United Nations Convention to Combat Desertification (CCD). The atlas contains a chapter, "Desertification and Land Use in Mediterranean Europe," that helps illustrate the complexities of the issue. For example, the atlas states: "The region has suffered from land degradation at least since the Bronze Age" (p. 129). There has been damaging "terrace construction over many centuries . . . [and] in recent years major changes in the population distribution have occurred with . . . the movement of people to the major cities and coastal areas [for tourism] and the development of irrigated agriculture and industry . . . [with attendant] flooding and erosion, groundwater depletion, salinization and loss of ecosystem integrity" (p. 129). One of the hardest-hit areas is southeastern Spain, in a country that has seen all these impacts for centuries, including massive deforestation and extensive irrigated farming in the Valencia region.

One of the goals of the UNEP/CCD program is to utilize the latest science and technology, including remote sensing techniques to map desertification advances, and the Mediterranean Desertification and Land Use (MEDALUS) project includes the Guadalentin Target Area in southeastern Spain: "The most degraded and eroding areas are . . . former common grazing lands that were taken into cultivation due to an expansion of mechanized agriculture in the 1960s and . . . were abandoned, as systems failed" (p. 131).

All these factors have been at work to varying degrees throughout the Mediterranean Basin, where there is ongoing desertification. MEDALUS scientific studies and rehabilitative efforts are ongoing throughout the region, from Portugal, to Italy, to Greece and Asia Minor.

Desertification is increasing rapidly in the world's best-known desert, the Sahara, and particularly along its southern border, the Sahel region. Two major causes are overgrazing, especially after prolonged drought beginning in the 1960s, and the use of brushwood as fuel in homes (Middleton and Thomas 1997, pp. 46–48 and 68–69, 168ff).

The *World Atlas* includes reports on the Middle East, southern Asia, Australia, China, and Mexico. A United Nations CCD conference report, *Sustainable Land Use in Deserts* (Breckle, Veste, and Wucherer 2001) covers the Aral Sea reclamation effort, changing patterns of overgrazing in South Africa, the monitoring of desertification in Uzbekistan and Kazakhstan, and reclamation efforts in Israel, among many other topics.

Ethical Issues

The ethics of desertification reflects extremely diluted responsibilities. Since the Bronze Age in the Mediterranean Basin, for example, up to the present (such as in Spain), farmers have tried in numerous ways to eke out a hard living in arid lands. Some people would lay blame primarily on government planning agencies for overirrigation and groundwater depletion, salinization, and other impacts of population density and tourism in arid regions. However, in any particular case it is difficult to lay too much blame on individual agents, although some environmental ethicists would blame a culture that is and has been for centuries heedless of impacts on arid lands.

In regard to science, technology, and rehabilitation/restoration projects such as those of UNEP/CCD, it may be too early to tell whether they will be effective in the long run against what is widely perceived to be rapidly advancing desertification.

DEHUMANIZATION

SEE *Humanization and Dehumanization*.

DEMATERIALIZATION AND IMMATERIALIZATION

Dematerialization refers to technological production using less energy and fewer or lighter-weight materials. *Immaterialization* is a similar approach, militating against the consumption of material goods.

Dematerialization

The concept of dematerialization is strongly associated with the work of economist and planner Paul Hawken, who proposed that industry should recalibrate inputs and outputs to adapt to environmental constraints. "To accomplish this, industrial design would employ 'dematerialization,' using less material per unit of output; improving industrial processes and materials employed to minimize inputs; and a large scale shift away from carbon-based fuels to hydrogen fuel, an evolution already under way that is referred to as 'decarbonization'" (Hawken 1993, p. 63). Indeed, Hawken sees dematerialization as a long-term trend, because much contemporary technology—refrigerators, televisions, cars, even houses—already weigh less and use less material than they did in the 1970s. According to Hawken's calculations, during the ten year period from 1972 to 1982, the redesign of automobiles in the United States reduced annual resource use by 250 million tons of steel, rubber, plastic, aluminum, iron, zinc, copper, and glass. Hawken's approach thus implies a rejection of heavy industry as the foundation of a technological economy, and is allied with notions of industrial ecology, green design, and natural capitalism.

Hawken, however, credits Buckminster Fuller (1895–1983) with originating the concept of dematerialization, which Fuller called "ephemeralization." Fuller's own invention of the geodesic dome was an example of ephemeralization, because it weighed only three percent of what a traditional structure of equivalent size would weigh, while being even more earthquake- and fire-resistant. According to Fuller, ephemeralization had already triumphed in his day. "[B]etween 1900 and today," he said in 1968, "we have gone from less than one percent to more than forty percent of humanity living at a high standard [with] the amount of resources [consumed per person] continually decreasing . . ." This "came only as fall-out of the doing-more-with-less design philosophy" (Fuller 1970, p. 68).

Fuller also described a design curve under which technologies increase in size soon after their invention until they "reach a giant peak, after which miniaturization sets in" (p. 73). Subsequent developments in personal computer, cell-phone, and portable music technologies such as CD, MP3, and iPod players bear out Fuller's theory. The prospects of nanotechnology provided further confirmation. He concluded, playfully, that "Ephemeralization trends towards an ultimate doing of everything with nothing at all—which is a trend of the omniweighable physical to be mastered by the omniweightless metaphysics of human intellect" (p. 73).

Dematerialization is also operative in science. The replacement of field work and laboratory experimentation by computer modeling and simulation may be described as another type of dematerialization.

Immaterialization

The immaterialization of consumption, as a companion process to dematerialization in production, has weak and strong forms. (It should not be confused with immaterialism in metaphysics, regarding the reality of immaterial phenomena such as the mind or soul.)

In its weak form, immaterialization is simply the consumption of dematerialized consumer goods—the same ones purchased in the past, such as refrigerators or automobiles, but now manufactured using less energy and materials. These goods are designed to consume less energy when used, and to be more easily recyclable, so that there is reduced waste.

In its strong form, immaterialization of consumption refers to the replacement of material goods with immaterial ones such as services, information, and social relationships. The use of an electronic telephone directory is an immaterial alternative to the use of a large paperback telephone directory. The Finnish cell phone manufacturer Nokia, whose motto is "Connecting People," sees both dematerialization and immaterialization as ways to promote a sustainable consumer economy. Immaterialization thus reflects another aspect of the service economy and the information, or knowledge, society.

Immaterialization in the strong sense also points toward possible cultural transformations, including shifts in ideas about the good life. Material consumption is not a good in itself, but a means to the end of human well-being. When analyzed in terms of well-being rather than material goods, productivity may actually be decreasing; human beings may be consuming more, but enjoying it less. Certainly the marginal utility of another unit of material consumption has declined, suggesting cultural or spiritual goods such as music and meditation as more inherently fulfilling than the purchase of another television set, however dematerialized. Yet just as the paperless office has remained full of paper, so immaterialized goods seem always to be complemented with material, such as music posters, coffee table art books, designer wardrobes, and specialized furniture for those who practice meditation.

DEMOCRACY

Democracy poses problems for science and technology because it leads to potential conflicts between two strong sets of ethical values. Democracy prizes the ethics of inclusiveness and political equality. Within a democratic system all citizens have an equal say in collective decisions. The fields of science and technology embrace the ethics of autonomy and respect for scientifically established findings, regardless of how other citizens receive or are affected by those findings. Scholars and practitioners have proposed a variety of processes and institutions in an attempt to resolve these conflicts.

Historical Development

Over the centuries philosophers have developed various conceptions about the nature of democracy. These different versions of democracy pose distinct conflicts among ethical values linked to science and technology, as well as suggest different solutions to those problems.

The classic form of democracy or rule by the people is generally taken from Athens in the fifth century B.C.E., where a form of direct or participatory government was practiced by the free males of the city-state. In Rome from the fifth to the first centuries B.C.E. there developed a classic form of republican or representative democracy, in which individuals are elected by the people to handle governmental decision making. During the Middle Ages democratic forms of government were relegated to the margins of public life where they continued to play important roles in religious institutions such as monasteries; they reemerged into public affairs during the rise of modern nation–states. Indeed modern political philosophy is characterized by diverse and continuing arguments for the primacy and legitimacy of democratic institutions, and struggles with efforts to create appropriate functioning democratic organizations under historically unique conditions.

One common observation is that the development of modern forms of science, technology, and democracy have in fact gone hand in hand. Modern science itself asserted a radical democracy, although only among a scientifically educated elite. The industrial revolution was certainly associated with the extension of political rights—from white property owners to all men to women. Expansions of citizenship have in turn been associated with the expansion of consumer economies, which thereby influenced technological change. And in many instances expansions in democracy have been proposed as solutions to the problems caused by scientific or technological change. Reflecting such associations, many commentators on science-technology-democracy relations have tended to emphasize synergies rather than oppositions. Certainly this was true of Alex de Tocqueville's *Democracy in America* (1835 and 1840), a perspective repeated even more forcefully in Daniel Boorstin's *The Republic of Technology* (1978).

Especially since the early mid-twentieth century, however, questions and problems have become increasingly prominent. Taking the two basic forms of democracy in reverse order to their historical origins, one may describe these as related to representation and direct democracy.

REPRESENTATION. After World War II scientists gained a great deal of attention and prestige from the government. Due to the scientists' great success in developing technologies for the war, from radar to nuclear weapons, government officials hired them into agencies and national laboratories and put them on important advisory committees. These developments raised the issue of how best to bring scientists and engineers, and their expertise, into the decision-making processes of representative democracy. This political involvement of scientists threatened two important ethical values. First, how could scientists avoid compromising their scientific autonomy and integrity as they became more involved in politics? Would they be able to speak freely, unencumbered by motivations of the government officials for whom they worked? When they advised government about research budgets, which affected them directly, would they succumb to the conflicts of interest that such roles entailed?

Second, how would this new scientific elite affect democracy? Would scientific pronouncements simply trump other forms of advice and political input? If the subject at hand was purely technical, deference to technical advice might be appropriate. However most important scientific and technological policy issues are a complex mixture of technical and political or social considerations, and scholars have shown that, in practice, it is difficult to separate these two features, even if it is desirable in principle. This concern over scientists gaining excessive power was most famously stated in President Dwight D. Eisenhower's famous warnings about a military-industrial complex in his farewell address in 1961.

DIRECT DEMOCRACY. Most theories of democracy state that citizens need to do more than simply vote for officials every few years. A robust democracy requires that citizens be able to participate directly, either as groups or individuals, in political decision making. If the issue at hand involves extensive scientific or technological knowledge, how can nonscientific citizens participate in deciding such an issue, an important democratic value, while still respecting the technical competence of experts, an important scientific value?

Responding to Problems

Late-twentieth-century developments in democratic theory have included a broad spectrum of responses to perceived problems in the science-technology-democracy relationship. These responses have included analyses and criticisms of a number of phenomena related especially to representation and direct democracy centered around such issues as peer review, lobbying, advisory bodies, and deliberation.

REPRESENTATION. A number of government agencies, in contrast to the direct mission driven distribution of funds by a program director on the basis of personal assessment have adopted peer review as a means to distribute funds. After World War II the federal government dramatically increased its funding of scientific and technological research. Following the model that it had developed during the war, much of that research was performed outside of the government itself. Instead of becoming the dominant employer of scientists, the government decided to fund scientists who were employed by universities or businesses.

In peer-reviewed funding, scientists submit proposals to the government requesting funding for particular research projects. Peer review is a method for evaluating and ranking those proposals and deciding which ones to fund. The funding agency, such as the National Science Foundation (NSF) or the National Institutes of Health (NIH), identifies scientists outside of government who are experts in the field relevant to the proposed research, who are the peers of the scientist submitting the proposal. Those scientists then review and evaluate the proposal, providing an expert opinion of its technical merits. The government keeps the names of the reviewers confidential so that they feel free to be objective in evaluating the proposal without having to worry about reprisals from the people they are reviewing. These reviews powerfully influence who the government funds.

Peer review is not perfect and has engendered numerous controversies and studies. Scientists also try to influence the total size of the government research budget, often through individual or group lobbying of Congress or the executive branch. In addition, many scientists may adapt their research agendas to be responsive to growing parts of the budget, which means that they are not as autonomous as peer review may make them appear. However it is still a reasonable attempt to balance scientific and democratic values. Scientists independent of the government provide evaluations of the merit of the proposed scientific research, emphasizing the ethics of scientific independence and autonomy. However, in many cases government officials make the final decisions on funding and in all cases governmental institutions determine the total amount of money that the government gives out for research, which lets representative institutions influence the research as well, emphasizing the value of democratic accountability.

Second, the federal government has created a host of science and technology advisory bodies. These groups attempt to bring technical expertise into making and executing government policy in a manner that respects both scientific integrity and democratic accountability. Some of these bodies are part of the government itself, and its scientists are government employees, as in the congressional Office of Technology Assessment (OTA) (disbanded by Congress in 1995) or the Office of Science and Technology Policy, an advisory group to the president. In addition, the government employs numerous technical specialists in various agencies and national laboratories.

In addition, the federal government utilizes many advisory committees made up of scientists and engineers from outside the government. Numerous agencies have such advisory committees and the White House has the President's Committee of Advisors on Science and Technology (PCAST). The National Academy of Sciences (NAS) also has an elaborate system for providing technical advice to the government. NAS, a private, though congressionally chartered, organization, possesses a research arm, the National Research Council (NRC). NRC assembles experts in particular fields to prepare reports that summarize the state of the science related to some particular topic. These groups have no formal authority, but they give the agencies access to expertise that is outside of government agencies and so hopefully is independent of such agencies' agendas. Of course the effectiveness of these advisory groups depends on the quality of the people appointed to them. In addition, these advisory groups lack any democratic accountability.

SOLVING PROBLEMS OF DIRECT PARTICIPATION. Citizens participate in policy making in two ways, either as groups or as individuals. The process of participating in groups is often called interest group liberalism, or pluralism. The justification for pluralism assumes that citizens recognize their interests and how government policy affects those interests. To further their interests they organize themselves into private groups and those groups pool their resources so that they may influence government policy. Different groups have different resources, from large numbers of voters to large sums of money to social status to charismatic leaders.

Such groups often center around scientific and technological issues and are a major part of the policy process. They include environmental groups, organizations representing different scientific disciplines, groups that lobby for research on certain diseases, industry groups that seek support for particular technologies, and so on. Many scholars have written about such groups and the ways they try to influence policy. In terms of ethical values, interest group involvement in scientific issues reflects the values that underlie pluralist democracy more generally. Pluralism requires only that all groups have equal opportunities to participate in politics. Groups are only supposed to represent their interests, as they perceive them. While outright lying about relevant science violates a general ethic of honesty, this form of democracy has no process to resolve more subtle scientific and technological disagreements. In most public disputes over scientific and technological issues, experts will disagree about some of the scientific questions. Within interest group pluralism, the groups have no obligation to find ways to resolve those disagreements; the theory assumes that honest competition among the groups will lead to satisfactory resolution of the issues, scientific and otherwise.

Citizens may also participate in scientific and technological policy issues as individuals. Scholars have concluded that this sort of participation works best when it involves extensive deliberation. In other words, citizens do not simply give their off-the-cuff opinion on some issue, either through voting or responding to an opinion poll. Instead they become involved in a process that requires them to learn about the issue and discuss it with others.

Theories of deliberative democracy have stated that such a process not only informs citizens about the substance of an issue, but also gives them a broader outlook, making them think about the public interest as well as their narrow private interests. It is the process of learning about and debating an issue, in an environment that is conducive to friendly give-and-take, which not only lets citizens state their interests but also makes them better citizens in how they think about their interests. This development satisfies a democratic ethic important to this theory of democracy, that citizens learn to deliberate over the public interest instead of merely advocating private interests.

The Cambridge Experimental Review Board is a classic example of such deliberation. In 1976 two universities in Cambridge, Massachusetts wanted to build biotechnology laboratories in the city. People in and out of the biology discipline worried that genetically modified organisms might escape from the labs and harm people. Cambridge is a very densely populated city and the building of these labs, and the risks that might accompany them, became a highly charged political issue. The mayor decided to appoint a special review board, consisting of ordinary citizens, to decide whether and under what circumstances the universities should be allowed to build the labs. The board heard testimony from all concerned parties, including university scientists who wanted to build the labs and people who opposed them. In the end the board decided to let the labs be built, with certain safety procedures for their operation. Those procedures were very similar to the ones later adopted by NIH, the principal federal funding agency for such research. NIH could impose regulatory conditions on the universities that it funded. Almost all sides to the controversy praised the work that the board had done.

This process encountered all the ethical issues related to science and democracy. Citizens had to learn about the technical issues. They did not have to become scientists, but had to understand the issues well enough to make sensible policy decisions about them. In educating citizens, the process demonstrated respect for scientific integrity. The process also satisfied the norms of deliberative democracy, in that it involved citizens deeply in an issue that potentially affected their lives, gave them the means to learn about it, and gave them the power to actually decide about it. The downside to this process, and all deliberative processes, is that it involved directly only a few citizens out of the many that lived in the city and required that they spend a great deal of time on the issue. Deliberative processes always involve this tradeoff: In exchange for deep participation, one sacrifices broad participation.

Since the 1970s organizations have sponsored a host of experiments using different forms of deliberative participation. For example, deliberative polling combines traditional opinion polling with a deliberative process. The process begins with a representative sample of citizens taking an opinion poll on the issue at hand. After the poll, the same group then assembles for a weekend of deliberation on the issue, guided by facilitators and with experts available to answer questions. At the end of the deliberations they are polled again. In most cases, their opinions change, often significantly, as a result of the deliberation.

A deliberative form of participation closer to the Cambridge example is the consensus conference. Initially developed in Denmark, this process brings together a small number of citizens to deliberate and see if they can reach a consensus on some issue, usually related to science and technology. The group then reports their results. In Denmark consensus conferences provide important input to parliament. In the United States they have not yet attained any official status. The not-for-profit organization The Loka Institute and a few academic groups have sponsored consensus conferences.

Contemporary Issues

Previous discussion of the practical issues of representation and participation are complemented by general theoretical discussions of technology and democracy. Among these discussions, one of the more salient arguments has been that of Langdon Winner and Richard Sclove that technological design itself constitutes a kind of political constitution writing that can be more or less democratic. These scholars point out that particular configurations of technological systems can favor some groups and discourage others, politically and socially, as well as economically. These social effects may be designed into technologies or may be unintended consequences, but either way, the "artifacts have politics," as Langdon Winner put it. This scholarly work means that those who are concerned with the science-technology-democracy relationship have to focus on the actual designs of the technologies themselves, as well as the institutions that govern them.

In the early twenty-first century forms of direct participation like consensus conferences are limited in the United States and do not enjoy the formal authority that they do in places like Denmark. However they are growing in number and their advocates hope they will have effects on policy making by local or state governments by force of moral suasion if not by law. All forms of participation, via groups or individuals, are growing in the United States and elsewhere. Legislation mandates some form of participation in many policy areas and some private firms are taking public participation seriously. So large is this activity that the government and business officials who run such programs have started their own professional association, the International Association for Public Participation, an organization that now has more than 1,000 members from twenty-two countries. Many of the issues in which such participation occurs involves science and technology.

One of the most difficult issues to deal with at the intersection of democracy and science and technology is the problem of boundaries between science and politics. As indicated above, one important aspect of democratizing science and technology is respecting the scientific value of the autonomy and integrity of science. But what parts of issues belong to the realm of science and what parts to the realm of politics? At first glance, this seems like an obvious question. The scientific parts of an issue are technical details about the issue, things that one would clearly ask of a technical expert, such as the existing reserves of oil, the toxicity of some pollutant, or the risks to patients of some new medical treatment. The political parts of an issue would seem to be questions like how much should oil be taxed and under what circumstances, or at what level is injury from pollution is politically acceptable. However these questions are not so neatly technical or political. Existing reserves of oil are uncertain, so for policy purposes should there be a high, low, or intermediate estimate? The toxicity of a pollutant may depend on whether the people exposed are healthy or more susceptible to it, as someone with asthma may be to air pollutants. Are we talking about toxicity for the average population or the most vulnerable members of the population? Answering these questions requires a complex mixture of technical and political decisions, which means that the boundaries between the technical and political parts of the issue are negotiated and often changing, not fixed and prompted by nature. An important part of participation is enabling participants to recognize and debate these boundaries. Only then can such participation satisfy both the scientific and democratic values involved in the process.

DEONTOLOGY

Deontology refers to a general category of ethical or moral theories that define right action in terms of duties and moral rules. Deontologists focus on the rightness of an act and not on what results from the act. Right action may end up being pleasant or unpleasant for the agent, may meet with approval or condemnation from others, and may produce pleasure, riches, pain, or even go unnoticed. What is crucial on this view is that right action is *obligatory*, and that the goal of moral behavior is simply that it be performed. The slogan of much of deontology is that the right is independent of the good. Deontology is opposed, therefore, to consequentialist or teleological theories in which the goal of moral behavior is the achievement of some good or beneficial state of affairs for oneself or others. For deontologists, the end of moral action is the very performance of it. For consequentialists, moral action is a means to some further end.

There are three interrelated questions that any deontological theory must answer. First, what is the content of duty? Which rules direct human beings to morally right action? Second, what is the logic of these duties or rules? Can their claims be delayed or defeated? Can they make conflicting claims? Third, why must human beings follow exactly those duties and rules, and not others? That is, what grounds or validates them as moral requirements?

The relevance of deontological ethics to issues in science and technology is not immediately obvious. Typical duties or rules in these theories are often quite abstract and sometimes address personal morality; hence they seem ill suited to broad and complicated questions in technical fields. As a matter of personal morality, deontologists might require one never to lie or steal, to give to charity, and to avoid unnecessary harm to people and animals. These rules are often internalized and are supported by religious, social, and civil institutions, and in some cases by enlightened self-interest. But is there a duty to support open source software, or to reject nanotechnology, or to avoid animal experimentation for human products? What list of rules is relevant to moral quandaries over cloning or information privacy?

Though the specific connection between ethical duties and scientific and technological practices may not be immediately obvious, it is clear that deontology can and should play an important role in evaluating these practices. Deontological theories give one a way to evaluate types of acts, so that one can judge a token of an act as obligatory, permissible, or forbidden even before the act is committed. Consequentialist evaluations, on the other hand, must await an accounting of the consequences of scientific and technological acts. Waiting on the consequentialist analysis may be perilous, because the long-term results of large-scale enterprises are often impossible to anticipate and very difficult to repair. As Edward Tenner (1997) has pointed out, modern technology often exacts a kind of revenge in the scope and severity of unintended consequences. Especially in fields such as bioethics, practitioners have often wanted bright lines between right and wrong acts in their ethical guidelines. That is, they want to have ethical rules or principals that are not wholly contingent on consequences. A form of deontological view in bioethics known as principalism focuses on the need for clear guidelines for action in order to avoid problems with unintended and far-reaching consequences of treatments and clinical practices. Even the basic and broadly applicable principle "Do no harm!" is deontological; it does not allow a tradeoff of benefit for some at the cost of harm to others.

Two deontological theories, from the works of Immanuel Kant (1724–1804) and W. D. Ross (1877–1971), serve as the foundations for much work in deontological ethics. Because they differ significantly in the content, logic, and ground of duties, it will be useful to examine them in modest detail before returning to questions of science and technology.

The Categorical Imperative

Kant developed the most important deontological ethical theory in Western philosophy. Scholars have come to agree that Kant provided not so much a list of duties as a procedure for determining duties. The procedure that specifies duty is the categorical imperative or *unconditional command* of morality. Kant articulated the categorical imperative in several distinct formulations. Even though these formulations provide different ways of generating duties, Kant maintained that his systematic ethic of duties was *rigorous*—in the technical sense that a "conflict of duties is inconceivable" (Kant 1997, p. 224). Indeed, a main feature of Kant's ethics is its reliance on consistency or harmony in action. This feature can be seen in the first formulation of Kant's categorical imperative, which goes as follows: "*Act only on that maxim through which you can at the same time will that it become a universal law*" (Kant 1997, p. 421).

Because a maxim in Kant's theory is a plan of action, the categorical imperative above provides an ethical test for intended actions, presumably to be used before one commits them. The point of the test is that one ought to be able to endorse the *universal* acceptability of the plans or intentions behind actions. People should not be partial to plans simply because they conceived such plans; the plans must be acceptable from any point of view. Maxims that cannot be universalized will produce logical contradiction or *disharmony* when they are run through the test of the categorical imperative. The grounding or validation of this principle lies in the universality of practical reason. For Kant, ethical duties arise from what is common to humans as rational beings. Humans have a kind of freedom that is gained in *creating* universal moral laws through intentional behavior. This moral and rational activity is, for Kant, what produces *self-legislation* or autonomy, and autonomy allows humans to transcend their animal nature.

The ability of humans to act from freely chosen moral rules explains the special moral status they enjoy; humans are, according to Kant, *ends-in-themselves*. Consequently this conception of a special status gives rise to another formulation of the categorical imperative: "*Act in such a way that you always treat humanity [yours or another person's] never merely as a means but always at the same time as an end-in-itself*" (Kant 1995a, p. 429).

This special moral status or intrinsic value implies that humans ought never to be valued as less significant than things that have merely instrumental value. Things of instrumental value are mere tools, and though they can be traded off with one another, they can never be more important than intrinsically valuable things. All technology is in some sense a mere tool; no matter how many resources society pours into technologies, the moral status of humans is supposed to trump the value of mere tools. Kantian duties are designed to protect that status.

The application of Kant's theory to issues in the ethics of technology produces intriguing questions. Do some technologies help persons treat others as mere means? The moral inquiry would have to consider aspects of the technologies and see whether technologies have "maxims" themselves—what Günther Anders called a "mode of treatment incarnated in those instruments" (Anders 1961, p. 134). These aspects might include the anonymity of online communities, the distributed effects of computer viruses, the externalizing of costs by polluting corporations, or the inherent destructiveness of a nuclear weapon. Further, one might ask whether some technologies *themselves* treat persons as mere means? Such a worry is related to Martin Heidegger's view that, under modern technology, humanity becomes a *standing reserve* to be exploited, and to Herbert Marcuse's claim that such a technological society debases humans by providing a *smooth comfortable unfreedom*. While these critics of technology do not always identify themselves as Kantians, the influence of Kant's humanistic account of duties has been so deep and broad that it is almost inescapable. Still there are deontologists who have parted ways with the Kantian tradition.

Prima Facie Duties

According to the British philosopher W. D. (Sir David) Ross, moral duties are not universal and unconditional constraints of universal practical reason. Rather they are conditional or prima facie obligations to act that arise out of the various relations in which humans stand to one another: neighbor, friend, parent, debtor, fellow citizen, and the like. This view gives content to duties based on a kind of role morality. It is through moral reflection that one apprehends these duties as being grounded in the nature of situated relations. Duty is something that, for Ross, arises between people, and not merely within the rational being as such. What exactly these prima facie duties are is not infallibly known until the problematic situations present themselves.

Nonetheless, Ross thinks, situated moral agents can grasp some obvious basic forms of duties. Fidelity, reparation, gratitude, justice, beneficence, self-improvement, and non-maleficence are what he identifies as nonreducible categories of duty—he admits that there may be others. Ultimately these duties are known by moral intuition and are objectively part of the world of moral relations and circumstances that humans inhabit. Much as one knows, in the right moment, what word *fits* in a poem, so too can one know what to do when duty makes demands. Sometimes an agent will intuit that more than a single duty applies, and in these cases must judge which duty carries more weight in order to resolve the conflict.

Ross's view is therefore both flexible and pluralistic, and is grounded in the actual roles of human lives. In these respects, it provides a foundation for a variety of professional codes of ethics, many of which are found in the scientific and technological community.

Hans Jonas and the Imperative of Responsibility

While Kant and Ross argued specifically against consequentialist theories in explaining their respective deontological views, other theorists are motivated by concerns over consequences in ways that influence the content of duties. Such is the case with the *imperative of responsibility* put forward by Hans Jonas (1984). Jonas calls for a new formula of duty because he thinks that traditional ethical theories are not up to the task of protecting the human species in light of the power of modern technology. His worry relates directly to the irreversible damage that modern technology could do to the biosphere, and hence to the human species. Because humans have acquired the ability to radically change nature through technology, they must adjust their ethics to constrain that power.

In language intentionally reminiscent of Kant's categorical imperative, Jonas gives his formula of duty as follows: "Act so that the effects of your action are compatible with the permanence of genuine human life" or so that they are "not destructive of the future possibility of such life" (Jonas 1984, p. 11). Referring to Kant's first version of the categorical imperative, Jonas criticizes its reliance on the test of logical consistency to establish duties. There is no *logical* contradiction, he notes, in preferring the future to the present, or in allowing the extinction of the human species by despoiling the biosphere. The imperative of responsibility, as a deontological obligation, differs from the ethics of Kant and Ross because it claims that humans owe something to others who are not now alive. For Jonas, neither the rational nature nor the particular, situated relations of human beings exhaustively define their duties. Indeed one will never be in situated relationships with people in far-off generations, but remoteness in time does not absolve the living of responsibilities to them.

Are All Duties Deontological?

Most professional codes of ethics in science and engineering consist of duties and rules. Does it follow that their authors tacitly accept the deontological orientation in ethics? It does not, and there is an important lesson here about the choice between deontology and other ethical orientations. The primary difference between professional codes and deontological ethical theories is that, in the former, the duties or rules are put forth as instrumental for competent or even excellent conduct within the particular profession. Some duties are directed toward the interests of clients or firms, but ultimately the performance of these duties supports the particular profession. The grounding of duties in professional codes resembles the function of rules under rule utilitarianism.

These rules would not be morally required for the general public, as would the rules of a deontological ethics. Professional codes are tools to improve the profession; the end of right action, in this case, is dependent upon the good of the profession, and the content of duties will depend on the particular views of the authors concerning that good.

Further Applications and Challenges

Duty ethics have been applied with some success in technological fields where consequentialist or utilitarian reasoning seems inappropriate. In biomedical ethics there is general acceptance of the view that do-not-resuscitate orders and living wills are to be respected, even when doing so means death for the patient and possibly great unhappiness for loved ones. In computer ethics, the argument for privacy of personal data does not generally depend on the use to which *stolen* data would be put. It is the principle, and not the damage, that is at the heart of the issue. There also seem to be lines of a deontological sort that *cannot be crossed* when it comes to some forms of experimentation on animals and treatment of human research subjects. For some emerging technologies, there are well-grounded deontological reasons for opposing research and development, even though the technologies eventually could yield great benefits. No one denies the good of the end, but they do deny that the end justifies any and all means. Where the claims of duties are not well grounded, a deontological approach to ethics runs the risk of sounding reactionary and moralistic.

DESCARTES, RENÉ

René Descartes (1596–1650) was born in La Haye (now Descartes), France, on March 31, and he died in Stockholm, Sweden, on February 11. Although of Roman Catholic heritage, he lived in a region controlled by Protestant Huguenots at a time when Protestants and Catholics were frequently at war. His inherited wealth

René Descartes, 1596–1650. Descartes ranks as one of the most important and influential thinkers in modern western history. His views on science and technology are similar to those of Francis Bacon. *(The Library of Congress.)*

allowed him freedom to study and travel around Europe. He made important contributions to metaphysics, mathematics, and physiology. In mathematics, he invented coordinate geometry, which combines algebra and geometry into a powerful tool for the mathematical study of the physical world. Although he offered proofs for the existence of God and the immortality of the soul, he was suspected of being an atheistic materialist, and lived in fear of persecution. When Galileo Galilei (1564–1642) was condemned in 1633 as a heretic for teaching that the earth revolved around the sun, Descartes suppressed any publication of his agreement with Galileo. After Descartes's death, his books were put on the Catholic Church's Index of Prohibited Books.

Because he broke away from scholastic Aristotelianism and thought through the philosophic implications of a new science of nature, Descartes is often called the founder of modern philosophy. Using six ideas—doubt, method, morality, certainty, mechanism, and mastery—he set the stage for modern science in a way that has had lasting impact while being subject to continuous debate.

Doubt and Method

Descartes's most famous book is the *Discourse on Method* (1637), which is divided into six parts, each developing one of the key ideas that run throughout his writing. In Part One, he presents the idea of doubt. He rejects all traditional thinking because it does not produce proven conclusions that can guide life. The traditional liberal arts education promotes philosophical disputes that are never resolved. Similarly, the moral customs of people around the world are contradictory, and there is no reliable way to resolve this confusion. So Descartes decides to turn inward, to seek within himself some source of conclusive knowledge.

Although modern science often seems to require doubting all traditional beliefs and customs, historians of science have noticed that modern science depends on intellectual traditions. Scientists tend to work within what Thomas S. Kuhn (1922–1996) called "paradigms," broad intellectual frameworks that organize research. To doubt everything received from one's society would deprive one of any starting point for inquiry. And insofar as science is a collective enterprise, it requires that scientists share social norms of thought and conduct. When scientists challenge a traditional belief, it is because they have found resources within their inherited traditions for doing so. Even Galileo's challenge to the traditional idea that the earth was the center of the universe arose from his appeal to an alternative, heliocentric theory that was thousands of years old.

In Part Two, Descartes presents the idea of method. He summarizes his method for scientific inquiry in four rules:

(1) accept only those ideas that are so clearly and distinctly present to the mind as to be self-evident,

(2) divide difficult problems into simple parts that are manageable,

(3) solve problems by moving in small steps from simple to complex,

(4) survey every part of the reasoning so that nothing is overlooked.

Descartes has formulated these rules of scientific method by generalizing from the procedures in geometrical demonstrations, in which one moves from self-evident principles (definitions and axioms) to solve complex problems by moving step by step from simple ideas to more complex propositions.

Many philosophers of science question the adequacy of the Cartesian method for explaining modern science. Michael Polanyi (1891–1976), for example, argued that there is always a personal judgment in scientific discovery that cannot be reduced to the formalized procedures demanded by such a method. The insight for grasping fruitful ideas in scientific research does not arise from an impersonal method. Jacques Hadamard (1865–1963) surveyed the lives of some famous mathematicians to show that even mathematical reasoning depends on personal, intuitive judgments that go beyond formal logic.

Morality and Certainty

In Part Three, Descartes presents the idea of morality. He admits that his scientific method could not give him moral knowledge to guide his conduct. So he had to adopt a "provisional morality" by which he could live while working to complete his intellectual project. His provisional moral code consists of four rules:

(1) accept whatever customs, laws, and religious beliefs prevail in one's country;

(2) act decisively according to the most probable opinions as if they were absolutely certain;

(3) change desires rather than the world;

(4) realize that the pursuit of truth is the best life for an intellectual person such as himself.

If Cartesian scientists cannot derive morality from their science, then they have to accept whatever moral and religious customs happen to be traditional in their society. This suggests a fundamental problem with modern science—that progress in scientific knowledge does not bring progress in moral knowledge. Cartesian scientists cannot even provide a scientific argument for the moral worth of a life devoted to science. The life of Cartesian science is incoherent. On the one hand, Cartesian scientists doubt everything and refuse to accept anything that is not proven true. On the other, they must accept the moral and religious prejudices of their society because their science cannot produce moral and religious knowledge. Ultimately, this could lead to moral nihilism with the thought that moral value is beyond scientific knowledge and must be left to unexamined prejudice. One must wonder, therefore, whether a scientifically grounded morality is possible.

In Part Four, Descartes presents the idea of certainty. "I think, therefore I am." This most famous claim of Descartes captures his thought that while doubting everything, he cannot doubt his existence, because this is confirmed by his very act of doubting. To doubt is to think, and to think presupposes his existence as a thinker. Beyond this, another idea comes to him—the idea of a perfect being—and this leads him to infer that God's existence is a self-evident certainty. From having the idea of God as a perfect being, Descartes concludes that God must exist, because if he did not exist, he would not be perfect. Descartes derives this ontological argument for God's existence from Anselm of Canterbury (1033 or 1034–1109).

Few people have found the ontological argument a persuasive proof for God's existence, and Descartes's restatement of the argument is weak. This has led some readers to suspect that he is not serious about the argument, and that it is part of his provisional morality to profess belief in the religion of his country to protect himself from persecution. Some readers see this as an indication that modern science as Descartes conceives of it is inherently atheistic.

"I think, therefore I am." Is this an immediately self-certifying truth? Or does it rather, as Friedrich Nietzsche (1844–1900) argued in *Beyond Good and Evil* (1886), illustrate "the prejudices of philosophers"? How does Descartes know that if there is thinking, there must be an "I" to do the thinking? How does he even know what thinking is? Has he perhaps confused thinking with feeling or willing? One could easily continue asking such questions to point out the numerous assumptions buried in Descartes's seemingly simple intuition, assumptions that are not self-evident, assumptions in need of proof if the Cartesian method is to be upheld. One might conclude that even the most rigorous science cannot attain complete certainty, because every proof depends ultimately on some fundamental assumptions that cannot themselves be proven.

Mechanism and Mastery

In Part Five, Descartes presents the idea of mechanism. He expresses reluctance to fully state his mechanistic view of the world, because it would be unpopular. He sketches his physics, explaining how the universe could have emerged through purely mechanical laws. He explains how all life, including the human body, can be explained as governed by mechanical causes. He declares, however, that the "rational soul" of a human being cannot be derived from the mechanical laws of nature, and therefore it must have been specially created by God.

Historians of science have identified Cartesian mechanism as fundamental for modern science. Prior to the seventeenth century, people generally understood nature through the metaphor of the world as a living organism. The Earth was a nurturing Mother. But modern Cartesian science understood nature through the metaphor of the world as a dead machine. The earth was matter in motion.

This mechanical view of the world was criticized as atheistic materialism, because it seemed to deny the immaterial and immortal reality of God and the soul. Descartes defended himself against such criticisms by affirming his belief in God and the soul. He insisted that material body and immaterial soul were two utterly different substances. In his *Treatise of Man* (1664), Descartes explained the physiology of the human body and brain as matter in motion determined by mechanical forces. This was not published until after his death, because he feared it would be too unpopular. Later, Julien Offray de La Mettrie (1709–1751) argued in his book *Man a Machine* (1748) that Descartes had shown that all living beings—including human beings—were merely machines. La Mettrie suggested that Descartes's dualistic separation between body and soul was only a trick to protect himself against persecution from the theological authorities.

The view of the human mind as a computational mechanism has been a powerful influence in the modern science of the brain. This has led some computer scientists to the thought that sufficiently complex computers will eventually replicate or surpass human intelligence. In some stories by Isaac Asimov (1920–1992), robots become Cartesian thinkers, declaring "I think, therefore I am!" But some prominent scientists such as John C. Eccles (1903–1997) argue that human self-conscious thought manifests the uniquely human power of an immaterial soul. So the debate continues over whether science can fully explain the human soul as a material mechanism.

In Part Six, Descartes presents the idea of mastery. The general aim of scientific research should be conquering nature for human benefit. The specific aim should be making such advances in medical science that human health would be improved dramatically, perhaps even to the point of prolonging life and thus conquering death. In this way, human beings would become "the masters and possessors of nature."

Descartes thus joins the project of Francis Bacon (1561–1626) for directing modern science and technology to the mastery of nature for relieving human suffering and enhancing human life. In support of this project, Descartes offers a distinctly modern vision of human beings scientifically constructing and technologically manipulating nature so that they can become like God.

DES (DIETHYLSTILBESTROL) CHILDREN

The scientific world was shocked by the 1971 discovery of the devastating effects in young women of a drug, diethylstilbestrol (DES), taken by their mothers twenty years earlier. The story of DES, from its discovery and widespread marketing without adequate testing or proof of efficacy, to the banning of its use by pregnant women, provides a good example of the serious harm that can result from inadequately protective regulation of new drugs and technologies.

Historical Development

In 1938, Sir E. Charles Dodd formulated DES, the first orally active, synthetic estrogen. This (nonsteroidal) estrogen, estimated to be five times as potent as estradiol, was very inexpensive and simple to synthesize. Because it was not patented, the developing pharmaceutical industry quickly began worldwide production; it was ultimately marketed under more than two hundred brand names for a wide range of indications. DES underwent very limited toxicological testing, a fate common to pharmaceutical products at that time.

Experiments with high doses of DES in women threatening to abort were conducted a few years later. The use of DES for prevention of miscarriage was promoted by the work of Drs. Olive and George Smith, who conducted multiple (uncontrolled) trials of DES for use in pregnancy throughout the 1940s. Despite limited evidence of safety or efficacy, the drug was deemed effective for this purpose and safe for mother and fetus. In 1947, DES obtained market approval in the United States for use in pregnancy in cases of threatened abortion and hormonal inadequacy.

Following the first poorly supported claims of the effectiveness of DES for the prevention of miscarriage, several studies were carried out to assess its efficacy, with mixed results. As these studies became more rigorous, support for the use of DES declined. In 1953, W.J. Dieckmann and colleagues demonstrated the lack of efficacy when DES was compared to a placebo in a randomized trial of pregnant women. Although the authors concluded that DES was ineffective, the drug continued to be prescribed even to women without previous pregnancy problems or evidence of threatened pregnancy. A reanalysis of Dieckmann's data in 1978, which showed that DES actually increased the risk of miscarriage, noted that had the data been properly analyzed in 1953, nearly twenty years of unnecessary exposure to DES could have been avoided.

The dangers of DES were not discovered, however, until 1971. Dr. A.L. Herbst and colleagues identified seven cases of a rare vaginal cancer (vaginal clear cell adenocarcinoma) in a single hospital. Using a case-control study they linked this rare cancer to the young women's prenatal exposure to DES. The results were so overwhelming that the Food and Drug Administration (FDA), in its November 1971 bulletin, declared that DES was contraindicated for use in pregnancy. Subsequent data demonstrated DES to be teratogenic as well as carcinogenic, and showed extensive damage to the reproductive systems of both men and women who had been exposed prenatally.

Elsewhere in the world, DES continued to be sold to pregnant women, in some countries into the 1980s. The fact that DES was prescribed for so long after its lack of efficacy had been demonstrated and dangers recognized illustrates a massive drug system failure.

In fact, it was not the lack of efficacy that triggered the end of marketing of DES for use in pregnancy, but a fortuitous accident. The cancer that DES caused in young women is extremely rare. It is estimated to have occurred in less than one in a thousand exposed daughters. If the cancer cases originally detected by Herbst and his colleagues had been diagnosed in several different medical centers, rather than at a single hospital (Massachusetts General Hospital, where DES use had been high as the site of the Smiths early experiments, the dangers of DES might well have gone unrecognized. Thus, this cancer, its link to DES, and other consequences of DES exposure might well have gone undetected.

DES Case Lessons

The DES story demonstrates that long-term and hidden effects of hormonal exposure may result from prenatal exposure, and that such consequences may be devastating. Could the mishap have been prevented? Where did science, society, and technology fail?

First, no long-term toxicity tests were ever carried out. Ironically, Dodds, the discoverer of DES, wrote in 1965, "I suppose we have to be very thankful that [DES] did prove to be such a non-toxic substance," referring to the minimal testing it underwent before marketing. Six years later the dangers of DES were identified.

Second, DES was put on the market without adequate proof of efficacy. Adequate pre-market testing would have shown that DES was never effective for the prevention of miscarriage. Therefore, a properly conducted and analyzed clinical trial might have avoided the entire episode. This accident is less likely in the early twenty-first century for pharmaceuticals, where thorough toxicity testing and evidence of efficacy are required prior to marketing.

Third, the widespread use of DES was furthered by the faith, prevalent at the time, in the advances of science and human abilities to control nature. DES was believed to be safe and effective, and both "modern and scientific." Its use became fashionable and there was pressure on physicians from peers and patients to prescribe DES. In the Netherlands, for example, the use of DES was aided by endorsement of the Queen's gynecologist.

Pharmaceutical retailers and advertising promoted the effectiveness and safety of DES to doctors and consumers. In fact, some manufacturers promoted it as a panacea for use in all pregnancies. The eagerness of the pharmaceutical companies to sell this profitable, unpatented product was compounded by the failure of medical and regulatory agencies to react rapidly to the emerging evidence.

Even prior to marketing for use in pregnancy, DES was a known animal carcinogen, a suspect human carcinogen, and a drug that had been shown to produce observable changes in the offspring of women exposed in pregnancy. Moreover, after DES was proven to be ineffective for use in pregnancy in 1953, a review of its risks and benefits should have resulted in immediate contraindication of this use. Had DES been withdrawn for use in pregnancy at that time, the unnecessary and tragic exposure of millions of mothers, sons, and daughters could have been avoided.

Regulatory authorities are also more alert in the early 2000s to reporting of adverse drug reactions and more inclined to take action than they were in the 1960s and 1970s. However, it should be remembered that regulation of non-pharmaceuticals is far from rigorous, and prenatal exposure to non-pharmaceuticals may also convey serious risk. The DES lesson can serve to raise consciousness about the dangers of inadequately identifying those risks.

DESIGN ETHICS

Design ethics concerns moral behavior and responsible choices in the practice of design. It guides how designers work with clients, colleagues, and the end users of products, how they conduct the design process, how they determine the features of products, and how they assess the ethical significance or moral worth of the products that result from the activity of designing. Ethical considerations have always played a role in design thinking, but the development of scientific knowledge and technology has deepened awareness of the ethical dimensions of design. As designers incorporate new knowledge of physical and human nature as well as new forms of technology into their products, people are increasingly aware of the consequences of design for individuals, societies, cultures, and the natural environment.

The design arts are important because they are the means by which scientific knowledge and technological possibilities are converted into concrete, practical form in products that serve the needs and desires of individuals and communities. Design is difficult to define because of its breadth of application. One can discuss the design of scientific experiments, of theories of nature and society, of political systems and individual actions, of works of fine art, and of the everyday products created by engineering and the other useful or practical arts. In all of these examples, design may be described generally as the art of forethought by which society seeks to anticipate and integrate all of the factors that bear on the final result of creative human effort.

Descriptive definitions have a useful place in explaining the nature of design for a general audience—for example, "design is the art of forethought," "design is planning for action," "design is making things right." However a formal definition has the advantage of bringing together all of the causes or elements of design in a single idea so that their functional relationships are clear, and provides a framework for distinguishing and exploring the ethical dimensions of design. The following formal definition serves present purposes: *Design is the human power of conceiving, planning, and bringing to reality all of the products that serve human beings in the accomplishment of their individual and collective purposes*. There are four ethical dimensions represented in this definition, each identifying an area of ethical issues and potential moral conflict that often complicates the activity of designing but also enhances the value of the designer's work. These dimensions represent the web of means and ends that are the central concern of ethics and moral conduct in design.

Character and Personal Values

The first ethical dimension of design arises from the human power or ability to design. One may reasonably argue that design itself is morally neutral because the art is only an instrument of human action. However designers are not morally neutral. They possess values and preferences, beliefs about what is good and bad for human beings, and an array of intellectual and moral virtues or vices that constitute personal character. The power or ability to design is embedded in a human being, within the character of the designer. Personal accounts, written statements, manifestos, and biographies are the beginnings of the study of ethics in design. They provide direct and indirect evidence of individual character and personal values, and often include accounts of the moral dilemmas and decisions that individuals have made in the course of their careers. Thus the first ethical dimension of design is the character and personal morality of the designer.

Integrity of Performance

A second ethical dimension arises from the activity of conceiving, planning, and bringing products to reality. These activities are the immediate goal or purpose of design. The standard of performance demonstrates fidelity to the art of design itself and is a matter of personal and professional integrity. In the film *The Bridge on the River Kwai* (1957), a British colonel and his fellow prisoners of war are instructed by their Japanese captors to build a railway bridge for the transportation of troops and munitions. For the colonel, constructing the best bridge—*a proper bridge*— is a matter of personal and professional integrity, and he pushes his men harder than their captors to complete the work on schedule. The tragedy of his narrow commitment emerges at the end of the film when the colonel realizes that his obsession with achieving the immediate goal of professional performance in the prison camp conflicts profoundly with the ultimate goal of his service in the British army. Ultimate goals are another ethical dimension of design to be considered later, but this film, while a work of fiction, effectively illustrates the second ethical dimension of design.

Performing well raises other closely related ethical issues. Designers are responsible for relationships with others involved in performance of the art. In some cases the designer works alone and is responsible directly to a client. Ethical standards of fairness, honesty, and loyalty serve to guide the client relationship, as in any personal or business dealing. In most cases, however, the designer works with other individuals and has shared responsibility for maintaining those relationships according to ethical standards. For example because of the increasing complexity of products, technology, and other factors, designers work in teams with fellow designers or with technical specialists from a variety of disciplines and professions. There are also new practices of participatory design in which clients and even representatives of the end users of products participate directly in the design process. Finally there is an increasing emphasis in some forms of design on user research, requiring the ethical treatment of human subjects.

Guidance in these matters comes partly from personal morality, but also from professional codes of ethics formulated and established by professional societies. Because many of the branches of design are young—some were established as professions only in the early and middle decades of the twentieth century—designers turned to already established professional associations, such as those for medicine, law, business, engineering, and architecture, for guidance on many ethical issues, including how to formulate their codes. At the beginning of the twenty-first century, designers continue to look to those professions for sophisticated practical discussions of emerging ethical issues. The codes of ethics of national organizations such as the American Institute of Architects (AIA), the Industrial Designers Society of America (IDSA), and the American Institute of Graphic Arts (AIGA) and their international counterparts have evolved gradually. They began with issues of competence, integrity, and professionalism, emphasizing ethical standards in technical practice and education, in business matters, and in compliance with laws and regulatory codes associated with safety. They expanded to include intellectual property rights and the general area of service in the public interest, such as preservation of the cultural trust and sustainability of the human community. The evolution corresponds to the successive ethical dimensions of design.

Product Integrity

A third ethical dimension, product integrity, arises from the nature of the products created through the art of design. Product integrity should be distinguished from the end purpose or worth of products. It is the synthesis of form and materials by which one judges a product to be well or poorly designed. There are specific ethical issues of product integrity for each kind of design (engineering, communication, industrial, and architectural design), but in general the issues concern safety and reliability, compliance with laws and regulatory codes, sustainability in its various aspects, and service to the public good. Products are created to serve human beings in their various activities and pursuits. Anything that directly or indirectly harms a human being or harms someone or something for which a human being is responsible presents a serious problem of product integrity requiring both technical and ethical consideration.

Because of the complex nature of human-made products, it is important to distinguish three elements of form that identify design issues as well as their associated ethical considerations. These elements concern what is *useful*, *usable*, and *desirable* in all products. Their successful integration is one of the fundamental challenges of design thinking.

1. Structural Integrity of Form. This element involves technological reasoning that ensures the proper performance of a product so that it is useful in supporting an activity. In some products technological reasoning means employing mechanical and electrical principles in an efficient and safe relationship. In computer software the reasoning follows logical principles and best practices of program layout in order to create efficient and reliable computation and, increasingly, security of information. In graphic or communication design, the reasoning of form and content follows more general principles for the presentation of information and arguments about the subject that the designer seeks to communicate. Honesty and truth become serious ethical issues when communication design is employed in marketing, packaging, and instructional materials. Structural integrity of the physical form and of information is the frontline of safety and reliability.

2. Usability of Form. This element requires product features such as operating controls, control surfaces, information displays, seats, doors, and panels that allow human beings to access and operate a product—or deliberately prevent dangerous access or operation of a product—and maintain it in a safe and reliable condition. In design these are sometimes called *affordances*, because they afford a human being with access to the form in the way that doors provide access to a building. By analogy one can easily see the extension of the usability features of mechanical products into software and even products of visual and verbal communication. Software is accessed by means of a user interface, meaning all of the features presented on a computer screen that allow a human being to operate and control the software. In graphics and communication design, the size of fonts, the layout of information, and similar matters allow a person to understand what is being communicated. It is more than a technical matter when, for example, bus signs and timetables are printed in font sizes that are too small for elders to read. Unfortunately usability is often seen only in terms of the immediate use or functioning of a product. In reality usability issues affect the entire lifecycle of products. Can the product be produced efficiently and safely, can it be operated effectively, can it be maintained, and can it be disassembled and disposed of or recycled safely? These are technical issues with significant ethical implications for design thinking.

3. Aesthetics of Form. This element is sometimes a puzzling subject for scientists and engineers, but for the designer it is the final element in the creation of a complete product. The aesthetic element of form makes a product desirable to possess and use. Many products that are otherwise useful and even usable are incomplete and fail to be integrated into the everyday lives of human beings because the form is not aesthetically pleasing. This is a source of confusion and consternation to inventors and developers and sometimes to policy makers who seek to influence individual and social behavior through the adoption of certain products—for example, seat belts in automobiles or products that support recycling or sustainability.

Part of the misunderstanding of aesthetics rests with the term itself. In its original and broadest meaning, aesthetics refers to the pleasurable or painful sensations that human beings feel through their senses. In this meaning all products have an aesthetic element, by accident or by design. The sound of a door closing, the texture of a control surface, the visual appearance of information in a software interface, the smell of plastics and metals, the taste of medicine: All are examples of the aesthetic element of form. Over time aesthetics has taken on a second, more restricted meaning as the study and theory of beauty. The psychological, social, cultural, and philosophical significance of aesthetics is a complex and profound subject. One way to understand the place of aesthetics in design is how it leads a human being to identify with a product. Identification with a product—to imagine a product as a desirable part of one's lifestyle and a valuable extension of the user into the world—shows how important the aesthetic element of form may be in design thinking.

The complexity of aesthetics points toward several areas of ethical issues that the designer must consider. Aesthetics plays a subtle and important role in supporting the usability of products and, hence contributes to safety and accessibility. Aesthetics also concerns the social, cultural, and even political value placed on sensations of pleasure and pain. Economic necessity plays an important role in the degree of luxury that products provide, but local community values also influence what is acceptable in making products pleasurable. Adapting products to local values is an ethical consideration for the designer and the designer's client. It is closely related to the issue of *appropriate technology*, which concerns selecting the kind of technology for a product that is suited to the economic, environmental, and social or cultural conditions of people.

There are further ethical issues surrounding beauty: what it is, its value, its use as a political instrument to affect the development of society and culture, helping to achieve the goals of one or another cultural agenda. For some there is aesthetic delight in the intelligent working of a product such as a mechanical or electronic device. The beauty of an idea realized in concrete form may itself be captivating. However this and other forms of beauty often flow from individual delight into social and political movements, taking on further ethical and moral significance. For example the so-called *modernists* of twentieth-century design believed that creating a certain kind of formal beauty in their products would have a direct effect in improving the values and behavior of people. The *good design* movement of the 1950s is a specific example. In contrast the so-called *post-modernists* of the 1980s and early 1990s used other concepts of beauty and even anti-beauty to express cultural diversity and encourage alternative aesthetic values. In both cases the aesthetics of design was associated with moral values.

In addition to ethics of product form, there are ethical issues involved in the materials employed in bringing a form to reality. Traditional and new materials present hazards that the designer has a responsibility to understand and respect. The selection of proper materials literally supports structural integrity in engineering, industrial design, and architecture. There are also ethical implications when designers make excessive use of materials or of particularly precious materials, because this may be regarded as a waste of natural resources. Similarly there are ethical issues surrounding the long-term impact of materials on human beings and on the natural environment. Developments in science and technology are a source of the problem of sustainability, and play a role in society's efforts to create sustainable communities. Many people believe that the designer and the designer's client have a newly recognized responsibility for creating products that support the goal of sustainability.

The development of science and technology has had profound impact on products and product forms, an influence that will only grow through the development of designer materials by means of biotechnology, nanotechnology, and other methods. Perhaps most importantly it has broadened the understanding of what a product of design is. At the beginning of the twentieth century, a product was regarded simply as a tangible, physical artifact, whether a consumer good or industrial machinery or medical and scientific instruments or a building. At the beginning of the twenty-first century, these product categories remain but have been the object of much elaboration. The categories of the physical have also increased to include chemical and biological products as physical artifacts that result from design thinking. Furthermore people recognize that information products, visual communications, services and processes, and even organizations are products of design thinking, subject to forethought and requiring careful, responsible decision making in their creation.

The broadening of the general understanding of what a product is comes from several factors associated with the development of science and technology. One is the concept of a system, which depends on a rational ordering or relationship of parts to achieve some goal. Rationalization and standardization now play a fundamental role in design and product development, supporting mass production and mass communication. Another factor is the development of new materials and the machines to process and shape them. Closely related to both of these factors is the development of digital technology, with scientific and industrial applications as well as applications suited to the daily lives of human beings through personal devices as well as access to information and communication through the internet. Among the many factors that have changed the understanding of what a product is, perhaps the most important, from an ethical perspective, is assessment of the consequences of the product's creation on the lives of individuals, society, and the natural world. This has come through the application of the physical and biological sciences, tracing the impact of products far beyond the marketplace (Winner 1986). It has also come through the development and application of the psychological and social sciences. Base-line efforts in these sciences during the twentieth century have resulted in the gathering of information that allows informed discussion of social policy and the philosophical implications of science, technology, and design.

Ethical Standards and the Ultimate Purpose of Design

A fourth ethical dimension of design arises from the service nature of the design arts, and presents some of the most difficult ethical issues designers face. The design arts are fundamentally a practical service to human beings in the accomplishment of individual and collective purposes. That is, the end purpose of design is to help other people accomplish their own purposes. This is where the personal character and morality of the individual designer, as well as the other ethical dimensions of design, are inevitably placed in a larger social, political, religious, and philosophical context. What is the moral significance of the particular purposes that designers are asked to serve? What is the moral worth of particular products that seek to achieve these purposes? What consequences will products have for individuals, society, and the natural environment in the short and long terms? What ethical standards can designers employ in making decisions about the proper use of design?

Ethical guidance in these matters comes from several sources including personal morality, professional organizations, the institutions of government, religious teachings, and philosophy. The potential for moral conflicts and dilemmas is so great that in this fourth ethical dimension the ethical problems of design are essentially the same as the ethical problems of citizenship and practical living in general. It is difficult to distinguish design from politics, political science, and political philosophy. This reaffirms Aristotle's treatment of ethics and politics: They do not address different subject matters but the same subject matter from different perspectives.

Nonetheless there are grounds for continuing to treat design ethics as a distinct problem with a distinct perspective on individual and social life. For example the natural and social sciences study what already exists in the world, but design seeks to create what is possible and does not yet exist—design is concerned with invention and innovation and, generally, with matters that may be other than they are through human action. This is the basis for Herbert A. Simon's treatment of design as *the sciences of the artificial*. Whether one refers to design as an art or a science, most designers would agree with Simon that design is a systematic discipline involving choices that are "aimed at changing existing situations into preferred ones" (Simon 1981, p. 129). One implication has special significance for ethics. Following other philosophers, Caroline Whitbeck has observed that the traditional discourse of ethics tends to emphasize making moral judgments—the critique or evaluation of actions already taken. In contrast she argues that ethics may be considered from the perspective of the moral agent seeking to devise ethical courses of action (Whitbeck 1998). This argument—that ethics itself is a form of designing—is directed primarily toward the ethics of professional conduct, how designers relate to supervisors and clients, and how designers or any one else may respond creatively and responsibly to ethical and moral problems in their work.

The argument may be expanded in a direction that many designers would acknowledge: Not only is ethics a form of designing, but designing is a form of ethics. One aspect of the designer's creativity and responsibility is to devise ethical courses of action that navigate the moral dilemmas of practical life. This happens in the normal course of the design process when, for example, the designer studies the client's brief or charge and finds it inadequate or inappropriate for solving the problem that may be the real concern of the client. This leads to a rethinking and recasting of the initial purpose set by the client, often reached through negotiation over the nature of the product to be created.

In a broader sense, moral issues are addressed when the designer employs clear and well-articulated ethical standards in making decisions about the proper use of design in any particular situation. There is no single set of ethical standards in the field of design; the pluralism of the human community in general is mirrored in the design community in particular. However there are distinct ethical positions in the discussions of designers, and they bear a recognizable relationship to positions in the tradition of formal ethical theory. Two of these positions point toward a natural foundation of design ethics, and two others point toward conventional and arbitrary foundations established by human beings.

Designers whose ethical position is grounded on a natural foundation typically argue that the products of design should be *good*, in the sense that they affirm the proper place of human beings in the spiritual and natural order of the world. This position finds its strongest premises in spiritual teachings and some forms of philosophy (Nelson 1957). Alternatively they argue that products should be *appropriate and just*, in the sense that they are appropriate for human nature and the physical and cultural environment within which people live, and that they support fair and equitable relationships among all human beings. This position finds its strongest premises in human dignity and the development of human rights, encompassing civil and political rights, economic rights, and cultural rights (Buchanan 2001).

Designers whose ethical position is grounded on conventional and arbitrary foundations typically argue that products should satisfy the *needs and desires of human beings* within acceptable constraints. The constraints at issue are the simply conventional expectations of a community and what is considered normal in the physical, psychological, and social condition of human beings in a particular time and place. The strongest premises are drawn from the study of manners, taste, and prevailing laws, and by scientific study of what is normal and abnormal in the body and mind. Alternatively various designers argue that products are merely *instrumental*, in the sense that they are useful in enabling human beings to achieve any of their wants and desires, limited only by the power of individuals and the state to curb willfully destructive actions and turn creativity in acceptable directions. This position draws its strongest premises from the concept of the *social contract*, upon which it is argued that any state is created.

As observed earlier, the development of scientific knowledge and technology has had a profound effect on human understanding of the nature and consequences of the products created by the design arts, deepening consciousness of the ethical dimensions of design. Additionally the development of design thinking has made important contributions to discussions of science, technology, and ethics. Nowhere is this more evident than in the central concern of design to humanize technology and place the advancement of scientific knowledge in the context of practical impact on human life. The contributions are typically made through the concrete expression of design thinking in real products that influence daily life rather than through writing about design. As designers have ventured out from traditional products and product forms, their explorations and experiments in creating new products have provided the concrete cases that focus discussion of ethical issues and the limits of science and technology. In many instances, the design arts have been deliberately employed to provoke critical debate in the general public about the place of science and technology in community life.

Toward an Ethical History of Design

An ethical history of design would present the origins and development of design from the perspective of designers as moral agents, tracing the successive issues and ethical dimensions of design as they have arisen through individual and collective action. Such a history has not yet been written or even attempted because the formal study of ethics has received little attention among designers and scholars of design studies. Indeed there are grounds for arguing that the formal study of ethics in the philosophy of design began no earlier than the mid-1990s, with the publication of articles by authors such as Alain Findelli and Carl Mitcham. Mitcham's "Ethics into Design" draws from philosophical discussions of ethics, the philosophy of technology, and the development of ethics in engineering. He argues that the two traditions of design in the twentieth century—design as art and aesthetic sensitivity and design as science and logical process—"must be complemented by the introduction of ethics into design, in order to contribute to the development of a genuinely comprehensive philosophy of design" (Mitcham 1995, p. 174). Mitcham's essay is important because it gives disciplined philosophical focus to the many discussions of ethics, politics, and morality that have shaped design since the beginning of the twentieth century.

Several such discussions have made important contributions in opening up new lines of thinking. In the late-nineteenth century, the political writings of William Morris (1834–1896) introduced ideas about socialism that helped to shape the arts and crafts movement and questioned the value of industrialization. The documents of the Bauhaus in Germany—for example, the essays included in *Scope of Total Architecture* (1962) by Walter Gropius (1883–1969)—helped to set the moral agenda of modernism. Artist Laszlo Moholy-Nagy's (1895–1946) *Vision in Motion* (1947) developed these ideas further and contributed to a form of humanism in design. Work at the Ulm school of design, particularly under the influence of the *Frankfurt School* of social theory, showed a struggle between sociopolitical questioning and the introduction of scientific methods into the design process. The writings of George Nelson (1908–1986) elevated discussions of *good design* to a higher moral concern for the responsibilities of the designer and true good in products. Kenji Ekuan's *Aesthetics of the Japanese Lunchbox* (1998) offered a Buddhist perspective on issues of ethics and morality in product design. Victor Papanek's *Design for the Real World: Human Ecology and Social Change* (1984) and *The Green Imperative* (1995) introduced the ideas of appropriate technology and sustainability to design thinking. In *Cradle to Cradle* (2002), William McDonough and Michael Braungart extend the theory of sustainability in a controversial discussion of industrial design and architecture. Beginning in 1982, the journal *Design Issues: History, Criticism, Theory* provided a venue for some of the most important discussions of design ethics. Authors such as Alain Findelli, Richard Buchanan, Ezio Manzini, Tony Fry, and Victor Margolin addressed practical as well as philosophical issues surrounding design ethics, and their work poses a challenge for a new generation of students of design. The continuing pace of scientific and technological development and the growing sophistication of reflections on design, supported by new doctoral programs and research in many universities, suggest that design ethics will become a progressively more important subject.

DESSAUER, FRIEDRICH

Friedrich Dessauer (1881–1963) was born in Aschaffenburg, Germany, on July 19, and died in Frankfurt am Main on February 16. He led an active life as an inventor, entrepreneur, politician, theologian, and philosopher who put forth a strong ethical justification of technology as being even more significant than science. On the basis of his experience with technological creativity Dessauer argued that the act of invention goes beyond appearance to provide contact with Kantian things-in-themselves and, in theological terminology, realizes the *imago dei* in which human beings have been created.

Early in his life Dessauer became fascinated with Wilhelm Röntgen's (1845–1923) discovery of X-rays (1895), which promised a penetration of appearances, and his design of high-energy X-ray power supplies earned him a doctorate in 1917. As an inventor and entrepreneur he developed techniques for deep-penetration X-ray therapy in which weak rays are aimed from different angles to intersect at a point inside the body where their combined energy can be lethal to a tumor while having less of an effect on the surrounding tissues. While continuing his work in biophysics, after 1924 Dessauer was a Christian Democratic member of the Reichstag until he was forced to leave Germany in 1933 because of his anti-Nazi stance. After World War II Dessauer returned to lead the Max Planck Institute for Biophysics until he died from cancer brought on by X-ray burns incurred during his experimental work.

Beginning in the 1920s, Dessauer also pursued a wide-ranging intellectual dialogue about the meaning of modern technology. Especially in *Philosophie der Technik* (1927) and *Streit um die Technik* (1956), Dessuaer defended a Kantian and Platonic theory of technology. In the *Critique of Pure Reason* Immanuel Kant (1724–1804) had argued that scientific knowledge is limited to appearances (the phenomenal world) and unable to grasp "things-in-themselves" (noumena). Subsequent critiques of moral reasoning and aesthetic judgment required the positing of a "transcendent" reality but precluded direct contact with it. In his "fourth critique" of technological making Dessauer argued for existential engineering contact with noumena:

> The Platonic idea descends into the imagination, recasting it. The airplane as thing-in-itself lies fixed in the absolute idea and comes into the empirical world as a new, autonomous essence when the inventor's subjective idea has sufficiently approached the being-such of the thing. . . .[And] it is possible to verify . . . [that] the thing-in-itself . . . has been captured [when] the thing works. (Dessauer 1927, p. 70)

Invention creates "real being from ideas," that is, engenders "existence out of essence" (Dessauer 1956, p. 234).

In conjunction with this metaphysics Dessuaer further articulated a moral assessment of technology that went beyond a simple consideration of practical benefits or risks. The autonomous, world-transforming consequences of modern technology bear witness to its transcendent moral value. Human beings create technologies, but the results, resembling those of "a mountain range, a river, an ice age, or a planet," extend creation.

> It is a colossal fate, to be actively participating in creation in such fashion that something made by us remains in the visible world, continuing to operate with inconceivable autonomous power. It is *the greatest earthly experience of mortals* (Dessauer 1927, p. 66).

For Dessauer invention is a mystical experience.

Although seldom stated as forthrightly as Dessauer put it, this view of technological activity as a supreme participation in the dynamics of reality arguably has influenced the ethos of cutting-edge engineering practice, as is discussed in David Noble's *The Religion of Technology* (1997). It is a view that merits more conscious examination in terms of both its strengths and its weaknesses than it has received.

DETERMINISM

Philosophical questions about determinism involve the nature of the causal structure of the world. Given the occurrence of some factor or factors C that cause an effect E, could E have turned out otherwise than it did? Determinists answer *no*: In a strictly deterministic world all things happen by necessity, as a direct function of their causal antecedents. Indeterminists hold that E might not have occurred, even with exactly the same initial conditions, because of the possibility of true randomness or free will.

General Forms of Determinism

Early religious versions of determinism were based on the belief that people's lives are supernaturally ordained. As exemplified in the tale of Oedipus, even actions taken to try to avoid what the gods have in store turn out to be the means of sealing that destiny. Predestinarianism, a view held by some Christian sects, states that God controls and foreordains the events of human lives so that it is determined in advance whether one will go to heaven or hell. A related view holds that determinism follows from God's omniscience; if the future is undetermined, God cannot be said to be all-knowing. Modern forms of determinism dispense with supernatural beings and hold that invariable laws of nature fix events.

Determinism sometimes is defined in terms of predictability. The philosopher Karl Popper (1902–1994) called this "scientific" determinism. In a commonly performed thought experiment one imagines a Cartesian demon who knows all the laws of nature and the complete, precise state of the world at some time T; if the world is strictly determined, the demon can use that information to predict any future or past event with any degree of accuracy. Real scientists lack perfect theories and perfect data, and so imperfect prediction in practice does not by itself speak against predictability in principle. (Prediction is still possible in an indeterministic world, but only probabilistically.) Classical Newtonian physics typically is thought to describe a deterministic world—though John Earman (b. 1942) identifies a possible exception) as does relativistic Einsteinian physics.

How is determinism relevant to ethics? Some philosophers argue that if universal determinism is the case, morality is impossible because personal ethical responsibility requires the possibility of free action: One cannot be blamed or praised for doing something if one could not have done otherwise. Such incompatibilists hold that morality requires undetermined free will. Compatibilists argue that morality is possible even in a deterministic world. Some go further and hold that the kind of free will that is essential to morality actually requires determinism. If the world is indeterministic and people's actions result from mere chance, people are no more moral than a flipped coin.

Specific Forms of Determinism

Even if one sets aside such global issues, questions about determinism remain ethically significant at other levels of explanation. Various specific forms of determinism posit one or another causal factor as the driving force of change in human life and can be considered separately.

Is biology destiny? Explaining the social roles and behavior of men and women by reference to their sex, for example, is a common form of biological determinism. To specify further that genes are the ultimate biological determinant is genetic determinism. Are all human behaviors, thoughts, and feelings determined by basic characteristics of human nature and individual past experiences? Psychological determinism was a basic assumption of the psychologist Sigmund Freud's (1856–1939) psychoanalytic theory, which held that nothing that human beings do is ever accidental but instead is the result of the forces of the unconscious. The nature versus nurture debate (e.g., regarding the cause of sexual orientation) often is couched in terms of a choice between biological determinism and social determinism.

Other forms of social determinism include economic determinism: the view that economic forces are the fundamental determinants of social and political change. This thesis commonly is attributed to the political philosophers Karl Marx (1818–1883) and Friedrich Engels (1820–1895), though their thesis was more focused, stating that the mode of production determines social consciousness. They argued that because the material forces of production are given at a certain stage in history and people have no choice about whether to enter into such relations of production, the broad structure of people's social, political, and intellectual life is set by forces beyond their control.

Technological determinism tries to explain human history in terms of tools and machines. In a classic example a simple advance in cavalry technology—the stirrup—changed military and political history. However, many people consider this to be too narrow a conception, arguing that technology properly includes the entirety of material culture or even nonmaterial technologies such as knowledge and processes. In reaction against this view advocates of cultural determinism or the related view of social constructivism emphasize that technology itself is human-made and carries the imprint of the social and historical circumstances that formed it.

One could extend this list of midlevel determinist theses, with each thesis being distinguished by a claim that some causal factor determines some general, social effect. All such determinist theses come in stronger or weaker versions, depending on the claimed autonomy of the cause. A hard technological determinist, for example, would argue that technology develops by its own internal laws with a one-way effect on social structures, whereas a soft technological determinist would allow that the development and influence of technology could be mediated by other factors.

This issue sometimes is conflated with questions about reduction. Strictly speaking, reduction is the explanation of one thing in terms of another (typically though not necessarily its components) with no implication of exclusivity. However, one sometimes speaks derogatorily of an explanation as being "reductionistic" when a factor is claimed to determine something without acknowledging other causes.

Qualifications

With the accumulation of scientific evidence and the advance of technology it is possible to modify assessments of particular determinist theses. For instance, it is not a foregone conclusion that the world is fully deterministic. Indeed, evidence from quantum mechanics indicates that chance processes are a part of the causal structure of the world. Some ethicists, such as Robert Kane (b. 1938), have argued that quantum indeterminacy is what allows the possibility of human free will. By contrast, evidence from biology, psychology, and cognitive science that reveals causes of behavior, thoughts, and feelings may be taken to weaken the plausibility of free will. Even these very general issues can play a role in discussions of practical ethical matters, such as penal policy.

Midlevel determinist theses may have other ethical implications. For instance, as science identifies some causal factor as a determinant of social change or another ethically salient effect, people acquire (or lose) moral responsibility for such effects to the degree that they can control (or not control) the cause. Thus, to the degree that in (re)making technology people (re)make the world, people bear a responsibility to make ethical choices about what forms of technology to pursue or reject. The philosopher Herbert Marcuse (1898–1979), for instance, argued that technology dominates all other forms of control and that although people designed machines to free themselves, those machines often determine people's lives for the worse. If this is the case, their value should be reexamined. Similarly, people may have a responsibility to pursue technologies that would improve their lives. The debate over genetic engineering and other biotechnologies involves all these issues. If it is possible to reengineer human nature, should that be done?

The global questions about the relationship between universal determinism, indeterminism, free will, and morality remain paradoxical. However, advances in science and philosophy can help resolve questions about midlevel determinist hypotheses. For instance, one can sort out many issues by moving from a simple two-place parsing of the causal relation C causes E to a four-place analysis: C causes E in situation S, relative to some alternative *a* (CaSE). This analysis recognizes that there are always multiple causal factors that produce a given effect and places that people choose not to focus on for a particular question—a pragmatic matter—in "situation S." (The specified alternative does not contribute to the effect but provides a baseline against which to measure whether C's effect is positive or negative and to what degree.)

This model makes it clear that no single factor determines an effect by itself and that an effect can have multiple explanations, all equally legitimate and objective, depending on the (pragmatically delimited) situation. For instance, it is reasonable to say that a trait is determined by a gene only if specific environmental factors are taken as given. Thus, the thesis of genetic determinism is seen to be incorrect if it is taken in an exclusive reductionistic sense, though it can be correct in particular cases (that is, if scientific evidence shows that a particular gene causes effect E in a given environmental situation) in the same way that the environment can be said to determine the effect (if science shows that it is an explanatory causal factor of E, given a set genetic situation). This more fine-grained causal analysis allows a more precise assessment of determinist theses and thus a better moral evaluation.

DEVELOPMENT

SEE *Change and Development.*

DEVELOPMENT ETHICS

Since the mid-twentieth century development has been promoted as the process of overcoming the condition of deprivation that prevails in many regions of the world. Underdevelopment is, correspondingly, a situation from which people and governments want to remove themselves, using science and technology to increase efficiency and generate innovations in the production of goods and services. Social science plays a crucial role in explaining the causes of and finding solutions to underdevelopment.

Development discourse often acts like an ideology, either as an uncritical recipe for all kinds of social ills or as a way of justifying policies that benefit the powerful while speciously purporting to aid the poor. In their 1992 work *The Development Dictionary: A Guide to Knowledge as Power* Wolfgang Sachs, Ivan Illich, Vandana Shiva, Arturo Esteva, and others recommend dropping development discourse altogether as being part of a project based on the quantitative and global instead of the qualitative and local. They also consider development to be an imposition from outside and above. As an example, they explain that the countries dominated by the United States after World War II only became *underdeveloped* when Harry S. Truman in his 1949 inaugural speech announced a program aimed at improving what he called underdeveloped areas. Before that the label did not exist.

But the distinction between the two kinds of countries was already in place. Some were rich, powerful, and dominant; others were—and continue to be—poor, weak, and dependent. By using the categories of imperialism and neocolonialism instead of development and underdevelopment, Marxists point to the historical roots of the difference, although political strategies to fight neocolonial relations are obviously not the same as development plans, and success in the first aspect does not guarantee success in the second.

There is no controversy as to the description of underdevelopment in terms of lack of food, shelter, education, health care, job opportunities, rule of law, good governance, and political power. Developing nations—formerly known as the Third World and sometimes as the South—share similar problems although to different degrees. The countries consistently listed at the bottom of the United Nations Development Programme (UNDP) annual report suffer acutely from an overall condition of deprivation, often aggravated by civil strife and corruption. It is not coincidence that many of the countries at the top of the list were colonial powers and that *all* the nations at the bottom were colonies of those at the top until the late-twentieth century.

Defining Development

It is more difficult to define a developed country for at least three reasons. First there are several models of development. The United States and Canada, for instance, are both developed countries in the usual definition of the term. But they are not developed in exactly the same way. Their social security and health care systems operate differently and do not cover similar percentages of the population.

Second it is not contradictory to state that there are varying degrees of underdevelopment but no real development so far in the world. There is room for improvement even in countries such as Norway and Sweden with a human development index close to 1 according to the 2001 UNDP report.

Third development create new problems. Homelessness is more of a problem in countries at advanced stages of change than in societies devoted to subsistence agriculture where family ties are stronger. The connection between mass consumption and clinical depression has been documented by Yale psychologist Robert E. Lane.

Moreover the very idea of development has experienced an evolution as a consequence of both a deeper theoretical understanding of what *developed* means and because of the practical problems encountered by governments and international agencies. An asymmetry can thus be found between development and underdevelopment. Whereas underdevelopment has referred to similar facts and conditions since the term began to be used, development has taken on different meanings, so that the notion itself shows a history of development. From development as economic growth, the notion became more complex to include world peace (Pope Paul VI; growth with equity [Amin 1977]); satisfaction of basic needs (Streeten 1981); sustainable development (Brundtland Report of the World Commission on Environment and Development 1987); and development as freedom (Sen 1999), and human security measured in the index used by the Global Environmental Change and Human Security (GECHS) Project, based at the University of Victoria in Canada.

Ethics of Development

Among the most important tasks of the ethics of development is to work out an evolved notion of development and to propose alternative models to governments, international agencies, non-governmental organizations (NGOs), and communities. Louis Joseph Lebret (1959) and Denis Goulet (1965, 1971) are considered pioneers in this endeavor, and as a critical examination of the values underlying plans for social change, development ethics reached maturity when the International Development Ethics Association (IDEA) was founded in Costa Rica in 1987. IDEA has been active in this work since its inception through conferences held in the Americas, Europe, India, and Africa. Another important task is to assess technological innovation from an ethical perspective. New technologies and their implications for the well-being of humans and nature pose urgent ethical questions. Experience demonstrates that technology is a necessary condition for the improvement of human well-being, but that it can also do harm.

Harmful technologies are scientifically unsound, wasteful, unsustainable, or inappropriate for their declared purposes. Trofim Denisovitch Lysenko's agricultural methods imposed by Stalin in the Soviet Union had no scientific basis and led to widespread famine. Those opposed to Lysenko's ideas and methods were persecuted and many died in prison. China's backyard iron furnaces during the period known as the Great Leap Forward (1958–1963) were a great failure, a cause of starvation for many millions, and led to the destruction of the precious few forests remaining in China at the time. Bad technologies in principle can be corrected or abandoned as soon as their inadequacies are clearly known, but some political regimes seem reluctant to do that.

Evil technologies are designed to enslave or eliminate individuals and groups. They respond to irrational hate, lust for power, or blind ideological commitments.

Adolph Hitler's use of technology in the so-called Final Solution is an example. Torture instruments are widely used by repressive regimes, and terrorists employ different destructive technologies to wreak havoc among civilians.

Given the fact that technology can be used to do harm, it is important to discuss how to ethically assess it. According to some, technology is ethically neutral, and ethics becomes relevant only when dealing with applications of objects and processes. Responsibility would thus lie only with the users of technologies, not with the engineers who designed them. But because the possible uses and abuses of technology are already present at the design stage, questions of aims and purposes, of good and evil, arise even before artifacts come into being. This is especially true of highly specific technologies. Although a hammer can be used to drive a nail or to commit murder, electric chairs have very few possible uses. It seems contradictory to justify building a torture chamber on the grounds that some other possible benign uses may be found for it.

How technology modifies the environment is another question that can and should be answered at the design stage. Any answer implies values held either by individuals, corporations, governments, or societies. Who makes the decisions, and on what grounds, are likewise ethical issues of great importance. The ethical principles of inclusion and participation are relevant here: As a general rule, the opinions of those affected by decisions should be taken into consideration.

Underdevelopment and Asymmetrical Relations between Countries

A particular problem is posed by the asymmetry in power between developed and developing nations. Two examples of asymmetrical relations are often mentioned in this connection: the patent system and subsidies. First the patent system internationally enforced in the early-twenty-first century and as interpreted by many in developing nations and by the UNDP's *Human Development Report 2001* is so rigid that it stifles possibilities of implementing changes necessary for the improvement of conditions in developing nations. One of the consequences of the strict imposition of the patent system is to give legal status and political power to huge monopolies that render it difficult for weak countries to develop their own technologies and protect their citizens from disease and death. In this connection, the Human Development Report 2001 mentions an emerging consensus on the unfair redistribution of knowledge as a consequence of intellectual property rights. It points out that since the late twentieth century the scope of patent claims has broadened considerably at the same time that the use of patents by corporations has become far more aggressive. Among those who may be interested in claiming patents, corporations are in the best position to do so because their focus on small improvements is geared to meet the required criteria for patenting. They also have the advantage of easy access to expensive legal advice in order to defend their patents under civil law. With such legal protection internationally enforced, companies use patent claims as a business asset to stake out their slice of the market. Although the report advocates fairness in international mechanisms for the protection of intellectual property, it also expresses concern because of the signals that the cards are stacked against latecomers. Another source of concern is the unequal relation between powerful corporations and the weak governments of developing countries. As pointed out by the UNDP report, advanced nations routinely issue compulsory licenses for pharmaceuticals and other products during national emergencies, and impose public, noncommercial use and antitrust measures. However by 2001 not a single compulsory license had been issued by a developing nation due to fear of the loss of foreign investments and the cost of possible litigation. Even the production of generic drugs is usually contested by advanced nations in trade negotiations with developing countries. Early-twenty-first century developed nations have profited enormously from the flow of information, discoveries, and inventions of previous eras and often have resorted to reverse engineering (procedures that are no longer available to developing nations because of the strict imposition of the patent system) to catch up with inventions. Yet they routinely oppose any such moves by developing nations.

Second the asymmetry among nations is also obvious in subsidies: In trade negotiations developed countries require developing nations to eliminate subsidies in the production of goods and services for export but refuse to abide by the same strictures. Marxists, dependency-theory scientists, and dependency-ethics theoreticians all denounce these unequal relations as an obstacle to the development of poor nations.

Ethics and Development Plans

Like technologies, development plans are designed for specific purposes and according to certain values, though implicit. Also as is the case in technologies, the selection of problems to be solved and the methods of solving them illustrate the values of decision makers. Those who formulate development plans often do so without consulting the people who may suffer the consequences of implementation of those plans.

Development ethics may follow two approaches. According to the first, which dates back to Plato and Aristotle and can also be found in the work of Hegel, justice is the main purpose of ethics and the state is the proper instrument by which to achieve a just society. Beyond commutative justice, in which personal differences are not taken into consideration in transactions between individuals, distributive justice aims at equality among people in unequal conditions. There must be an entity, which is greater than the individual, that is concerned with the interests of the many as opposed to the profits of the few; that entity is the state. Development ethics, in this perspective, is traditional ethics dressed in new clothes.

Some feel that a different approach is needed because there is little relation between public policies and distributive justice in modern states. They point out that politics is most often conceived of as the art of acquiring and keeping power. Rulers often stay in power by resorting to violence because they want to enrich themselves and their cronies or impose a particular ideology. Justice is the least of their concerns, and propaganda deflects the attention of the people from this fact. Consequently most people do not relate justice to the actions of the ruling classes and have many reasons to believe that governments are best described as instruments of injustice.

This view explains why ethics is often invoked against the rule of power and employed to overturn unjust laws. Because development plans in the hands of governments determined to impose a particular ideology or follow purely technocratic criteria often lead to suffering for the masses, development ethics, under this approach, is not simply traditional ethics in disguise. Rather development ethics is a critique of the unexamined ends and means that can form the basis of a new way of governing, a voice for the victims of development projects, and a call for accountability of those who consider themselves to be experts. Because development ethics risks placing too much importance on *development* and too little on *ethics*, it must have a strong theoretical foundation.

In light of the above discussion, an analysis of the connection between development and technology is useful. Development, in its social and economic sense and in the most general terms, is often conceived of as an increase in income or consumption per capita, plus social change. The first aspect is referred to as economic growth, which is easy to measure but can be used for purposes other than the improvement of conditions of the population, for instance, when a country fosters economic growth as a means to achieve military power. Social change is more difficult to define or measure, and has been described as the idea of development evolved.

The important role of technology in both aspects of development is obvious. W. W. Rostow (1987) argues that post-Newtonian science and technology are conditions for economic take-off, a means to break through the limits of per person output traditionally imposed on nontechnologically advanced societies. Technology applied to agriculture makes labor more productive, thereby preparing traditional societies for the transition to high consumption, and freeing large numbers of people for work in industry. Technology also makes possible large-scale industrial production. As an impetus for social change, advances in technology create new techniques, careers, jobs, opportunities, businesses, procedures, legislation, and even lifestyles. According to sociologist David Freeman in *Technology and Society* (1974), the social impact of technology follows four successive phases. First new technological products simplify daily tasks and chores. A pocket calculator is easier to handle than a slide rule; a word processor more versatile than a typewriter. Second job qualifications change. In the early-twenty-first century, secretaries are expected to use computers, instead of just type and file. Third allocation of authority and prestige also changes. Those who have expertise in cutting-edge technologies are in high demand and therefore make more money and enjoy greater social status than people working in older technologies. Finally values held in great esteem by society change. The values of traditional as opposed to industrial societies differ.

Thus changes in how human beings make things lead to cultural change. Even the valuation of change is subject to modification. As pointed out by Rostow, the value system of traditional societies ruled out major changes whereas modern societies incorporate the assumption that transformation and growth will occur. Commercial propaganda in high-consumption societies emphasize change as valuable in itself.

Because technology influences morality by changes in valuation, it is possible to perform an ethical analysis of social change brought about by technology. For example, a society that uses advanced technology to build weapons of mass destruction, and in which the military enjoys great prestige, is not morally the same as one that uses advanced technology to improve conditions for the poor. The fact that a technology is new, and even that it allows for greater productivity, does not mean that it is better. It may increase the gap between the rich and poor, or damage the environment. Increased productivity in agriculture due to new methods is usually associated with monoculture, whereas traditional agricultural practices, with their typical combination of different species, were safer both for human beings and for the environment.

One argument for preserving older technologies is that there is no way to tell when and how they may be needed as practical solutions in the future. In the event that certain technologies can no longer be used, knowing the old way of doing things may represent the difference between life and death. Each particular technology requires certain conditions for its functioning and more advanced technologies usually require more specific inputs. If such inputs (electricity, for instance) are not available, the ability to use alternative technologies is crucial. Because of the increasing dependency of technology on science, science is central to development. Government agencies dedicated to the promotion of scientific and technological research have existed in Latin America and other developing areas since the 1970s. The success of such agencies is not uniform, but the Latin American countries included in the 2001 UNDP report as countries with high human development (Argentina, Uruguay, Costa Rica, and Chile) also enjoy a long tradition of public support for science and technology.

Mastery of mathematics, physics, chemistry, and biology is the foundation of technological advancement. The social sciences also play an important role in developing nations. Because underdevelopment is a social condition, a scientific explanation could be found in social sciences. Development plans nevertheless tend to marginalize the importance of input from those disciplines.

Ethics of Science and Technology in Development

Before development economics existed, Francis Bacon (1561–1626) sought knowledge that could alleviate human misery. Gottfried Wilhelm Leibniz (1646–1716) struggled to develop a logical method to solve all kinds of theoretical and practical problems, which he employed in an attempt to alleviate the social ills he saw in Europe. David Hume (1711–1776) and Adam Smith (1723–1790) discussed the difference between rich and poor countries and whether it was morally desirable to bridge the gap. Their answer was affirmative.

After the Industrial Revolution in Great Britain in the late-eighteenth and early-nineteenth centuries, other countries experienced similar profound economic and social changes. In the nineteenth century, aspiration to better social conditions was summarized in the idea of *progress*. In the twentieth century, countries with different political regimes formulated and implemented far–reaching economic plans such as the Four-Year Plans in Germany and the Five-Year Plans in the Soviet Union in the 1930s, as well as Franklin D. Roosevelt's famous 100 Days, which included a number of measures designed to reverse the effects of the Great Depression. In the 1950s a clear distinction between the two kinds of countries entered the political arena, and plans were explicitly created to make change.

It became clear that development plans were not useful to large numbers of people forced to change their lives as part of the implementation of those plans. Several critics have examined the ends and means of development, the values implicit in plans, and the real beneficiaries of change. Denis Goulet (1965) devised a method to examine the choice of problems and solutions in light of values implicit and explicit. Because development ethics as conceived by authors such as Goulet and David A. Crocker aims at proposing alternative models to development, the question arises as to the feasibility of those models. Respect for cultural values is essential for these alternatives to succeed. Proponents hope that the social change brought about through such models will have a solid foundation and be, consequently, more sustainable for succeeding generations. The next generation should have at least the same natural, human-made and human capital than the previous one. If it has less than the previous generation, then development is not sustainable.

The connection of science and technology with development focuses on two questions: What, if any, is the relation between science and technology? and How do either or both relate to socioeconomic development? From the perspective of ethics, however, the basic question is not whether science and technology are subject to ethical analysis, but how science and technology can be used ethically for development.

A Development Ethics

At first glance, the answer to this question is simple. Development is morally justified when human beings are not mere *objects* in plans and projects but *subjects*, in the sense of being free agents who want to improve their condition. This position assumes that development plans are valid instruments by which to insure the universal right to an adequate standard of living, as expressed in Article of the Universal Declaration of Human Rights, and that each person is entitled to economic, social, and cultural entitlements as a member of society. Human development must be realized through national effort, but government plans and policies often ignore those who should benefit from them. Thus it is necessary to ground the legitimacy of plans and projects in the active role of development subjects. Without adequate living standards, human life cannot flourish, but an arbitrary imposition of change denies human beings the condition of being free agents.

Science and technology, whatever their relation to development, should be included in the process of making human beings actors instead of passive recipients. In addition to taking into consideration local knowledge, scientific theories must be relevant in the solution of the problems of the dispossessed. An economic approach that fails to appreciate the importance of unemployment and asymmetrical relations in trade is morally defective. An economics of development able to explain the difference between developed and developing regions of the world is needed. But, in addition, an economics *for* development must be created. The same is true for other social sciences, especially psychology and anthropology. Also, obviously, the resources of natural science should be harnessed in the effort to increase productivity and reduce poverty.

A second stage in the move from passive recipient to actor concerns the formulation of development plans and projects. Local knowledge, techniques, and technologies are usually more efficient and appropriate than imported ones, a point often made in Latin American fiction, for example in Jorge Amado's novel *Gabriela, Clove and Cinnamon* (1974). Local values embedded in cultural practices must respectfully be taken into account; mere lip service to those values, which is typical of political and social manipulation, should be condemned. When respect for a culture and its values is genuine, development plans are not arbitrary but are the outcome of consideration of the aspirations and desires of those who will be affected. Values that are deeply ingrained in cultures may be inimical to development and thus pose a challenge to development ethics. An ethics that includes not only values but also duties and obligations may counter antidevelopment sentiment.

However it is not enough for people to realize themselves as actors in development. Even when a project is rooted in local values and is the result of negotiation among individuals and groups, it may be morally indefensible or technically defective. Democracy guarantees public participation, but this in turn does not insure a morally correct result. Hence the interplay between insiders and outsiders in development is important, a point often made by Crocker.

Insiders are in a good position to incorporate local values into the process, whereas outsiders are not influenced by such values when assessing the rights and wrongs of plans and projects. Local experiences may be relevant but limited; outside expertise may be less relevant but wider in scope. For a fruitful collaboration to occur, insiders and outsiders must share some basic values and be committed to similar goals in connection with the improvement of human conditions. Thus development ethics can be conceived as a dialogue among cultures aimed at sharing valuable experiences in the struggle to overcome obstacles in the path of free social agents.

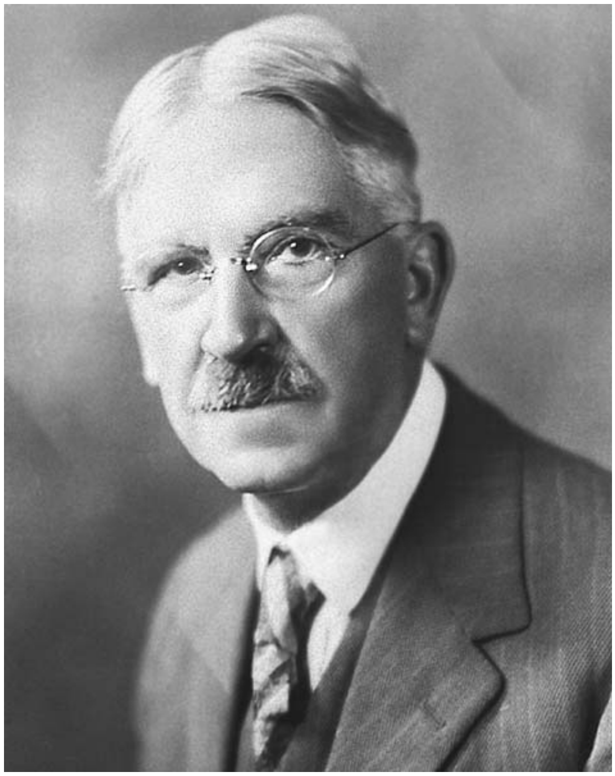
DEWEY, JOHN

Born in Burlington, Vermont, on October 20, John Dewey (1859–1952) lived a long and productive life as a psychologist, social activist, public intellectual, educator, and philosopher. Educated at the University of Vermont and Johns Hopkins, Dewey taught philosophy at the universities of Michigan, Minnesota, and Chicago, and Columbia University. He initiated the progressive



John Dewey, 1859–1952. During the first half of the 20th century, Dewey was America's most famous exponent of a pragmatic philosophy that celebrated the traditional values of democracy and the efficacy of reason and universal education. *(The Library of Congress.)*

laboratory school at the University of Chicago, where his reforms in methods of education could be put into practice. He was instrumental in founding the American Association of University Professors (AAUP), helped found the National Association for the Advancement of Colored People (NAACP), and was active in the American Civil Liberties Union (ACLU). Dewey remained active until shortly before his death in New York City on June 1.

Dewey's philosophical pragmatism, which he called "instrumentalism," is both an extended argument for and an application of intelligence-in-action. Intelligence-in-action, human reasoning understood as fallible and revisable, aims to ameliorate existing problems (ethical, scientific, technical, social, aesthetic, and so on). It is rooted in the insights and methodologies of modern science and technology.

Intellectual Influences

At Vermont, Dewey studied the work of Charles Darwin (1809–1882) and evolutionary theory, from which he learned the inadequacy of static models of nature, and the importance of focusing on the interaction between an organism and its environment. For Darwin, living organisms are products of a natural, temporal process in which lineages of organisms adapt to their environments. These environments are significantly determined by the organisms that occupy them. At Johns Hopkins, Dewey studied the organic model of nature in German idealism, the power of scientific methodology, and, with Charles Sanders Peirce (1839–1914), the notion that the methods and values of the natural sciences and technology (technosciences) should serve as a model for all human inquiry. Strongly influenced also by William James (1842–1910), Dewey became a proponent of philosophical naturalism. For Dewey, knowledge and inquiry develop as adaptive human responses to environing conditions which aim at reshaping those conditions.

Inquiry as Scientific and Technological

Along with Peirce and James, Dewey took the open, experimental, and practical nature of technoscientific inquiry to be the paradigmatic example of all inquiry. For Dewey, all inquiry is similar in form to technoscientific inquiry in that it is fallibilistic, resolves in practice some initial question through an experimental method, but provides no final absolute answer. In *Studies in Logical Theory* (1903), Dewey identifies four phases in the process of inquiry. It begins with the *problematic situation,* a situation in which one's instinctive or habitual responses to the environment are inadequate to fulfill needs and desires. Dewey stresses throughout his work that the uncertainty of the problematic situation is not inherently cognitive, but also practical and existential. The second phase of the process requires the *formulation of a question* that captures the problem and thus defines the boundaries within which the resolution of the initial problematic situation must be addressed. In the third, *reflective phase* of the process, the cognitive elements of inquiry, such as ideas and theories, are evaluated as possible solutions. Fourth, these solutions are *tested in action.* If the new resulting situation resolves the initial problem in a manner conducive to productive activity, then the solution will become part of the habits of living and thus a part of the existential circumstances of human life.

This method of inquiry works because, as Dewey points out in *Experience and Nature* (1925), human experience of the world includes both the stable, patterned regularity that allows for prediction and intervention and the transitory and contingent aspects of things. Hence, although for Dewey people know the world in terms of causal laws and mathematical relationships, such instrumental value of understanding and controlling their situations should not blind them to the sensuous characteristics of everyday life. Thus, not surprisingly, the value of technoscientific understanding and practice is most significantly realized when humans have sufficient and consistent control over their circumstances that they can live well.

Science, Technology, and the Good Life

Dewey rejects the distinction between moral and nonmoral knowledge because all knowledge has possibilities for transforming life, and arises through inquiry into a problematic situation. Thus, all knowledge has moral dimensions. Throughout his more explicitly aesthetic, ethical, and social writings, Dewey stresses the need for open-ended, flexible, and experimental approaches to problems, approaches that strive to identify means for pursuing identifiable human goods ("ends-in-view") and that include a critical examination of the consequences of these means.

For Dewey, people live well when they cultivate the habits of thinking and living most conducive to a full flourishing life. In *Ethics* (1932) he describes the flourishing life as one in which individuals cultivate interests in goods that recommend themselves in the light of calm reflection. In works such as *Human Nature and Conduct* (1922) and *Art as Experience* (1934), he argues that a good life is one characterized by (a) the resolution of conflicts of habit and interest within the individual and within society; (b) the release from rote activity in favor of enjoying variety and creative action; and (c) the enriched appreciation of human culture and the world at large. Pursuing these ends constitutes the central issue of individual ethical concern. The paramount goal of public policy is nurturing the collective means for their realization. Achieving these goals requires intelligence in action, best cultivated through democratic habits in everyday life, and education and practice in technoscientific modes of inquiry.

In the late twentieth and early twenty-first centuries, Dewey's ideas have had increasing influence in areas of applied philosophy such as philosophy of technology, bioethics, and environmental ethics. Nonetheless, Dewey has often been criticized as a mere apologist for the status quo and for a narrow straight-line instrumentalism that leaves no room for reflection on, or critical evaluation of, ends. Others criticize his work by noting that technoscience has unleashed great horrors on the world (such as nuclear weapons and environmental degradation), and increased the possibilities of social control and manipulation (Taylorism, mass media, surveillance, and so on). Dewey does not deny that technoscience has sometimes failed, but this has not been due to something intrinsic to science and technology. Failures in the use of science and technology are rather failures to consistently employ intelligence-in-action; failures of inquiry, failures to be sufficiently experimental, reflective, and open.

Among the influential interpreters of Dewey's work, especially as it applies to science, technology, and ethics, are Paul Durbin (b. 1933) and Larry A. Hickman. For some years Durbin has argued what has come to be known as the "social worker thesis," that philosophers dealing with science, engineering, and medicine have obligations similar to social workers not simply to analyze problems but to become socially and politically engaged in their solution. Hickman, director of the Center for Dewey Studies (Southern Illinois University at Carbondale), argues that Dewey's pragmatism offers the best account of how to develop moral intelligence and then bring it to bear in the context of an advancing technoscientific culture.

DIAGNOSTIC AND STATISTICAL MANUAL OF MENTAL DISORDERS

• • •

The Diagnostic and Statistical Manual of Mental Disorders (DSM) represents the most influential effort in the field of mental health to identify psychological and psychiatric abnormalities for the purposes of treatment. The extent to which this effort has been pursued in a rigorously scientific manner, and the ethical issues surrounding the distinction between normal and abnormal mental functioning, are important questions for clarification and debate.

The DSM, which has been compiled and published by the American Psychiatric Association (APA) since its first publication in 1952, is intended to serve as a standard tool for mental health professionals in the diagnosis of mental illness. In addition to providing the field with a definition of the term *mental disorder,* the fourth edition of the manual (DSM-IV-TR; APA 2000) contains a catalog of the clinical symptoms of 365 different mental disorders (for example, obsessive–compulsive disorder, borderline personality disorder), which are organized into sixteen major diagnostic classes (such as anxiety disorders, personality disorders, and so on).

With each subsequent edition, the classifications provided by the DSM have become more widely referenced in the field of psychopathology. In addition, the DSM system of diagnosis has become increasingly central to the communication between mental health professionals and those outside the field, such as lawyers, insurance companies, and the media. Nevertheless, the system remains highly controversial, even among those who have contributed to its development. Some of this controversy surrounds the general issue of whether or not the diagnosis of mental illness is a scientific endeavor at all. More specific criticism has also been leveled, however, at the specific approaches the DSM has taken over its history to describe or explain mental disorders. In both cases, the debate over the DSM has often raised fundamental questions about the nature and diagnosis of mental illness.

The Origins and History of the DSM

As Gerald N. Grob (1991) has detailed, psychiatrists of the early 1900s were largely uncomfortable with the idea that the symptoms of mental illness could be broken down into any meaningful classification scheme. The professionals of this period tended to view the individual case as highly unique and subject to a wide variety of interrelated personal and environmental variables. Various classification schemes were proposed between 1900 and 1920, including a collaborative effort of the U.S. Bureau of the Census and the existing version of the American Psychiatric Association that produced a taxonomy of twenty-two categories of mental disorder, most of which were predicated on a particular form of biological abnormality. Such systems, however, were largely irrelevant in clinical practice or research. Instead, they served primarily to provide gross survey categories for hospitals and local governments to use in the compilation of statistics on rates of mental illness among different demographic and ethnic groups and on standards of care across different communities.

During World War II, however, mental health professionals began caring for large numbers of patients (i.e., soldiers) who did not require long-term confinement in a hospital. These patients showed psychophysical, personality, and acute stress disorders that were not well documented and that added significant variety to the existing classifications of mental illness. Inspired by these circumstances, the APA formed a committee of experts to establish a diagnostic system that expanded upon systems developed for the U.S. armed forces and adapted the international statistical classification of diseases, injuries, and causes of death, developed by the World Health Organization, for use in the United States. This process involved a significant expansion and reorganization of the existing systems and culminated in the publication of the first DSM (DSM-I) in 1952. The DSM-I (and the subsequent DSM-II, published in 1968) represented a major turning point in the nature and purpose of a taxonomy of mental disorders. For one thing, it was the first attempt to standardize psychiatric diagnoses according to a particular theory of mental illness (that is, psychoanalytic theory). Moreover, the DSM was proposed to advance the science, and not just the administration, of mental health services. By providing mental health professionals with a common diagnostic language and by grounding the descriptions of the disorders in the prevailing psychoanalytic theory, the DSM was intended to further stimulate and synthesize research into the nature of mental illness.

These first two editions of the DSM, however, were not received with unequivocal support. The two primary complaints mental health professionals voiced against the DSM concerned the lack of evidence for the distinctions it made among various disorders and the small number of experts involved in determining the classification scheme. The reliance on psychoanalytic concepts was also increasingly questioned given the rise of more empirical and behavioral approaches in clinical settings. In response the APA took a distinctively different approach to developing the third (DSM-III, 1980) and fourth (DSM-IV, 1994) editions. For each of these editions, expert researchers and clinicians were organized into work groups for each category of disorders (e.g., anxiety disorders, substance-abuse disorders). These groups conducted reviews of the available literature to determine whether or not the criteria for each disorder and the distinctions among disorders were supported by empirical evidence. Although the findings from the work groups continued to be compiled and reviewed by committee, the emphasis on research increased both the objectivity of the decision-making process and the number of professionals who could influence the final product. The manual also became accessible to a wider range of professionals by abandoning a central theoretical perspective and adopting a focus on clinically observable symptoms such as thoughts of suicide or repetitive behaviors.

Current Issues in the Development and Application of the DSM

The primary purpose for the development of the DSM has always been its use as a clinical tool for guiding the assessment and treatment of mental disorders. Perhaps the greatest strength of the DSM is its usefulness in differential diagnosis. For example, a patient's complaint of feeling down or depressed can be evaluated in light of other clinical symptoms that are present and compared with the criteria for disorders such as Major Depressive Episode and Adjustment Disorder with Depressed Mood. Although disorders such as these share some common features, distinctions among them with regard to etiology (cause) and prognosis may provide important guidance for treatment planning. In fact, some clinicians argue that the future of mental health as a science depends heavily on the ability of professionals to distinguish among treatments that are or are not effective for specific diagnoses. Such an approach ultimately leads to the matching of treatment with diagnosis based on support from available research.

An important problem with such an approach, however, is that patients with distinctly different symptoms and clinical presentations can receive the same diagnosis. In the DSM-IV, for example, each disorder is characterized by a set of equally weighted criteria. Patients need not meet all criteria for a given disorder in order to fit the diagnosis. This flexibility allows for more reliable diagnosis across clinicians, but it can also lead to minimal overlap in symptoms between any two patients with the same diagnosis. Often, symptoms that these patients do not share play a major role in treatment planning and clinical management.

A similar problem concerns the frequency with which patients meet criteria for more than one disorder at a given time (known as comorbidity). As Lee Anna Clark, David Watson, and Sarah Reynolds (1995) have noted, more than half of all individuals with a DSM diagnosis also meet criteria for another disorder. In many cases, the presence of a second disorder is a significant issue that has a dramatic effect on a patient's response to a given treatment.

A third problem with the use of the DSM in treatment planning is the lack of a coherent theoretical framework for understanding the causes and progressions of the various disorders. This limitation is ironic, given that a descriptive, symptom-focused approach was deliberately adopted in the DSM-III and DSM-IV to make the manual accessible to a range of professionals with different theoretical orientations. Clinicians inevitably rely on a particular theoretical framework in assessment and treatment planning, however, and so a purely descriptive manual cannot help but appear removed from reality in clinical settings.

Beyond its clinical utility, the DSM has also been developed to facilitate research and communication among professionals regarding the nature of mental illness. Prior to the development of the DSM, clinicians developed colloquial classification schemes that did not generalize far beyond their immediate setting. Although many professionals of the time considered such an approach to be unavoidable, they also recognized the difficulties this posed for efforts to increase or disseminate their base of knowledge. The DSM has certainly increased systematic research into mental illness and placed that research in a framework that is accessible to a broader scientific community. A prominent example is the dramatic increase of research in personality disorders that has occurred because these disorders were given special emphasis in the DSM-III (Widiger and Shea 1991).

The question remains, however, whether this proliferation in research has resulted in any real increases in scientific knowledge concerning mental illness. For instance, critics have noted that as the DSM classifications have become more widely adopted, they have begun to take on the nature of assumptions rather than scientific problems to be investigated. Thus, researchers may rely on DSM criteria instead of independent, theoretically driven criteria in selecting research participants. In this way, the DSM has become a somewhat self-perpetuating framework.

In addition, it is important to keep in mind that the ultimate decisions about making changes to the manual are not purely empirical exercises. Such decisions must appeal to fundamental assumptions about principles concerning the nature of mental illness and the goals of the system itself. Along these lines, Arthur C. Houts (2002) has argued that it is unlikely that the continual expansion of the DSM from 106 disorders in 1952 to 365 disorders in 1994 represents real scientific advance in the ability to detect and diagnose mental illness. In particular, this expansion of labels has not occurred alongside the necessary solidification of a limited number of "covering" or "synthesizing" laws that would explain how all these new disorders relate to one another. A more specific and highly publicized example of this problem concerns the removal of homosexuality as a mental disorder in the third edition of the DSM. Regardless of whether or not homosexuality should be included in the DSM as a mental disorder, even the leadership of the revision process has admitted that the decision was ultimately based more on social pressures than on the weight of scientific evidence (Spitzer, Williams, and Skodol 1980).

A third central purpose for the development of the DSM concerns the justification of professional services and judgments. Particularly in the arenas of insurance reimbursement and legal proceedings, mental health professionals are expected to demonstrate that their evaluations and treatment plans meet some standard of common practice in the profession. With respect to insurance, however, it continues to be difficult to justify treatment decisions based on a particular diagnostic picture. Because of the heterogeneity of patients who can share a given diagnosis and because the DSM continues to explicitly require clinical judgment in assigning a diagnosis and planning treatment, the assignment of a particular diagnosis to a patient can have very little impact on the clinical services provided to that patient. Furthermore, clinicians often use DSM diagnoses for purely instrumental reasons (e.g., to promote or protect the relationship with the patient, to obtain services from a resistant insurance provider). In a common example, clinicians, in order to avoid stigmatizing or scandalizing a patient, will often diagnose the person with adjustment disorder (which connotes a more transient and normative reaction to stress) instead of a more serious disorder even though the patient meets the criteria for the latter. With regard to the courts, mental health professionals cannot assume that a particular DSM diagnosis of mental illness bears any correspondence to the legal definition of "mental disease" or "mental defect." Thus, questions of diagnosis are often abandoned altogether in the courtroom in favor of more straightforward comparisons of symptoms and states of mind with legal definitions of sanity.

Future Directions for the DSM

Shortly after publication of the DSM-IV, clinicians began expressing hopes that future editions would address several fundamental flaws in the current classification scheme, in addition to those mentioned above. Perhaps the most common desire is to move away from categorical (i.e., yes or no) diagnosis of mental disorders and toward a system of rating patients on a small number of basic, personological dimensions (e.g., personality traits). Proponents argue that such a system would have greater value in guiding differential diagnosis, would help consolidate the growing number of disorders, and would more validly reflect the dynamic nature of the individual. A less radical revision that, presumably, would also reduce the degree of disparate diagnoses is John F. Kihlstrom's (2002) proposal that the current phenomenological groupings of symptoms be replaced with diagnoses based on laboratory findings such as characteristic cognitive or affective deficits. Finally, Thomas A. Widiger and Lee Anna Clark (2000) recommend that greater attention be paid to the most basic element of the diagnostic system: the establishment of meaningful boundaries between normal and abnormal psychological functioning. Common to all these proposals is a need for the DSM to develop a more unified and coherent framework of mental illness that is more validly rooted in the fundamental nature of the human person.

Central to the ongoing debates surrounding the DSM, then, is the role of values and metaphysical assumptions in defining psychological normality and, thus, providing a foundation for the identification and treatment of abnormality. Whereas empirical science may be invaluable in describing the mental, emotional and physical processes underlying psychological disorders, interpretation of these descriptions inevitably proceeds from a framework containing statements about the nature of human abilities, the kind of life worth living, and the ideal form of relationships among persons or between persons and their environment. As Daniel Robinson (1997) has argued, any theory of psychological disorder and therapy that is divorced from these questions fails to answer the question, "therapy for what?" because it will fail to account for the kind of healing or remediation that is necessary. These kinds of metaphysical issues, which are also assuming an increasingly central role in the ethics of the biological and genetic sciences, bring into clearer relief the nature and limits of a scientific attempt to identify problems or deficiencies in the psychological life of persons.

This most recent revision updates the text of the DSM-IV to include the results of research conducted after 1992. The revision is intended to maintain the usefulness of the DSM as an educational resource between major editions.

Clark, Lee Anna, David Watson, and Sarah Reynolds. (1995). "Diagnosis and Classification of Psychopathology: Challenges to the Current System and Future Directions." *Annual Review of Psychology* 46: 121–153. The authors review the purposes of a diagnostic taxonomy and consider alternatives to the current, descriptive approach. Research failing to support categorical diagnosis of psychopathology is highlighted.

Grob, Gerald N. (1991). "Origins of DSM-I: A Study in Appearance and Reality." *American Journal of Psychiatry* 148(4): 421–431. Examines the social and political context in which the DSM-I was developed.

Houts, Arthur C. (2002). "Discovery, Invention, and the Expansion of the Modern Diagnostic and Statistical Manuals of Mental Disorders." In *Rethinking the DSM: A Psychological Perspective,* ed. Larry E. Beutler and Mary L. Malik. Washington, DC: American Psychological Association. Analyzes the assumption that the proliferation of DSM diagnostic labels across editions represents actual scientific progress in the assessment and differentiation of psychological disorders.

Kihlstrom, John F. (2002). "To Honor Kraepelin . . . : From Symptoms to Pathology in the Diagnosis of Mental Illness." In *Rethinking the DSM: A Psychological Perspective,* ed. Larry E. Beutler and Mary L. Malik. Washington, DC: American Psychological Association. Argues that a taxonomy based on laboratory observations would advance the science of psychopathology and return the practice of psychological diagnosis to its historical roots.

Robinson, Daniel N. (1997). "Therapy as Theory and as Civics." *Theory and Psychology* 7(5): 675–681. The author suggests that fitness for the moral and civic aspects of human life provides the grounding for any theories of mental disorder and any attempts at psychotherapy.

Spitzer, Robert L., Janet B. W. Williams, and Andrew E. Skodol. (1980). "DSM-III: The Major Achievements and an Overview." *American Journal of Psychiatry* 137(2): 151–164. Leaders from the task force on DSM-III describe the origins of its development and the reasons for the major transition toward an atheoretical approach to defining and classifying mental disorders.

Widiger, Thomas A., and Lee Anna Clark. (2000). "Toward DSM-V and the Classification of Psychopathology." *Psychological Bulletin* 126(6): 946–963. Discusses the more significant issues of disagreement and debate surrounding the DSM-IV and recommends continued exploration of alternatives to the current perspective.

Widiger, Thomas A., and Tracie Shea. (1991). "Differentiation off Axis I and Axis II Disorders. *Journal of Abnormal Psychology* 100(3): 399–406. Suggests that the distinction between personality and symptomatic disorders first introduced in DSM-III ignores important relationships between them and instances of significant overlap in symptomatology.

DIGITAL DIVIDE

The *digital divide* refers to the gap between those who can effectively benefit from information and computing technologies (ICTs) and those who cannot. The term is a social construction that emerged in the latter half of the 1990s, after the Internet came into the public domain and the World Wide Web (Web) exploded into the largest repository of human knowledge that has ever existed. For those who can both contribute and retrieve information from the Web, ICTs hold the promise of broad collaborations in science and technology, transparency in government, rationality of markets, and shared understandings between peoples. Sadly this utopian promise applies only to an elite few. As of 2003, less than ten percent of the world's 6.4 billion people have had access to the Web (NielsenNetRatings, February 2003). While information poverty is rarely blamed as a direct cause of human suffering, the digital divide raises ethical questions of universal access. Like access to food or clean water, access to essential information has moral and ethical implications that merit consideration in the formation of public policy.

Differing Divides

The digital divide is a problem of multiple dimensions. In 1999 Rob Kling summarized the problem from (a) a technical aspect referring to availability of the infrastructure, the hardware, and the software of ICTs, and (b) a social aspect referring to the skills required to manipulate technical resources. Pippa Norris (2001) described (a) a global divide revealing different capabilities between the industrialized and developing nations; (b) a social divide referring to inequalities within a given population; and (c) a democratic divide allowing for different levels of civic participation by means of ITCs. And Kenneth Keniston (2004) distinguished four social divisions:

1. those who are rich and powerful and those who are not;
2. those who speak English and those who do not;
3. those who live in technically well-established regions and those who do not;
4. those who are technically savvy and those who are not.

From a global perspective, a high concentration of access to ICTs is observed in North America, Europe and the Northern Asia Pacific while access is noticeably sparse in the southern regions of the globe, particularly in Africa, rural India, and the southern regions of Asia. The poorer nations, plagued by multiple burdens of debt, disease, and ignorance are those least likely to benefit from Internet access.

The entry costs to secure equipment and to set up services are far beyond the means of most poor communities. Startup costs and expenses of technical maintenance compete with resources needed for essential human survival. Policy makers are challenged to find justification for investment in ICTs when local and national resources are limited and where the urgent needs of people for basic nutrition, health care, and education remain unsatisfied. If ICT development is justified in these countries, it is on the belief that ICTs are instruments to be wielded in order to meet essential human needs.

Overcoming Divides

One formidable obstacle to ICT diffusion is language. There is a self-perpetuating cultural hegemony associated with ICTs (Keniston 2004). By the year 2000, only 20 percent of all Web sites in the world were in languages other than English, and most of these were in Japanese, German, French, Spanish, Portuguese, and Chinese. But in the larger regions of Africa, India, and south Asia, less than 10 percent of people are English-literate while the rest, more than 2 billion, speak languages that are sparsely represented on the Web. Because of the language barrier the majority of people in these regions have little use for computers. Those who do not use computers have little means to drive market demands for computer applications in their language. Left simply to the market, this Anglo-Saxon hegemonic cycle will continue unhindered.

If the digital divide is viewed purely as a technical problem, the solution is within reach. European and North American capitalism has the means to intervene where market forces lack the power to bridge the divide. It is not an unrealistic task to tie every nation, every tribe, and every community, no matter how isolated, into a common interconnected information infrastructure. It is within technical means to manufacture low-cost, durable computers for wide distribution. It is within fiscal means to distribute these devices to places where computers are most lacking. Gifted programmers and translators can be recruited to convert existing online resources into many different languages.

Beyond Technical Issues

While such technical solutions can be conceived, the problem of the digital divide is not primarily a technical problem. Expenditure of monies for ICTs comes with no guarantee that problems that plague the poor of the world will be addressed. Policy makers cannot simply thrust technology into people's hands with any expectation that it will be used. Experimentation has shown that new initiatives tend to fail unless they are built from existing social and economic structures (Warshauer 2003). ICT projects must be conceived from an assessment of actual needs defined locally by target populations. Planners must pay attention to existing human networks and social systems, taking into account local language and cultural factors, literacy and educational levels of users, and institutional and social structures of the community.

M. S. Swaminathan, one of India's best-known scientists, suggests that if technological and information empowerment is to reach the unreached, then policy makers must focus their "attention to the poorest person" (Swaminathan 2001, p. 1). This concept, coined by Gandhi as *antyodaya*, provides a model for technical development using a bottom-up approach. Digital initiatives of the Swaminathan Research Foundation have demonstrated how ICTs can change the lives of the poor in remote villages by strategies that enlist local involvement from their inception. Projects begin from assessments of specific local needs and by instituting practices that rely entirely on local villagers rather than distant agencies and technical experts. Including the excluded in the empowerment brought by knowledge and skills is the most effective approach to harnessing technologies in the interests of the poor. The divide may never be fully closed, but where a bridge is to be spanned, it will be constructed by active participants from both sides.

Keniston, Kenneth (2004). "Introduction: The Four Digital Divides." In *IT Experience in India: Bridging the Digital Divide*, ed. Kenneth Keniston and Deepak Kumar. Delhi: SagePublishers, pp. 11–36. This book examines the history of the "digital divide" as seen from observers on both sides of the abyss. A collection of essays from social scientists, policy analysts, and technologists, the book lends special focus to the social and technical problems that emerge with introduction of new technologies in remote and impoverished regions. It reviews the fundamental issues facing policy makers whose decisions impact the balance between expert direction and local control, between modern goals and traditional values, and between future hopes and immediate needs.

Kling, Rob. (1999). "Can the 'Next Generation Internet' Effectively Support 'Ordinary Citizens'?" *The Information Society* 15: 57–63. Rob Kling (1944–2003) was professor of information systems at the School of Library and Information Science at Indiana University. This article was originally delivered as a white paper in 1988 to the Clinton Presidential Advisory Committee on High Performance Computing and Communications, Information Technology, and the Next Generation Internet (NGI). Kling advocated a focus on social value in planning and resource allocation for the NGI. Policies should privilege methods of Internet access for ordinary people over exotic media advances that benefit only technological elites. NGI initiatives should seek to reduce cost and improve value for ordinary citizens and strengthen IT infrastructures for the public commons.

Norris, Pippa. (2001). *Digital Divide: Civic Engagement, Information Poverty, and the Internet Worldwide*. New York: Cambridge University Press. Pippa Norris is Associate Director of Research at the Shorenstein Center on the Press, Politics and Public Policy at Harvard University. This book examines the digital divide from case studies involving Internet access of users from 179 countries. Norris describes the ways in which people in different cultures make use of the Internet for information and civic engagement and she attempts to provide a descriptive model to explain patterns of participation on the Internet. Norris reviews the manner that institutional entities have created or enabled opportunities for public engagement and she analyzes how the various publics have responded to these opportunities.

Warschauer, Mark. (2003). "Demystifying The Digital Divide." *Scientific American* 289(2): 42–48. Mark Warschauer teaches Informatics in the Department of Education at the University of California at Irvine. He has

conducted qualitative research on technology adoption in Egypt, China, India, Brazil, Singapore. In a three-year longitudinal case study in Egypt, Warschauer examined the steps that governmental agencies took to introduce ICTs in the schools and he observed the various impacts that were manifested from those initiatives. From his observations, Warschauer concluded that policies which promote the mere presence of new technologies in schools without a corresponding emphasis on social mobilization and transformation can squander limited resources while leaving problems of sociotechnical inequities in tact.

INTERNET RESOURCES

NielsenNetRatings. (2003). "Global Internet Population Grows an Average of Four Percent Year-Over-Year"" Available from http://www.nielsen-netratings.com/pr/pr_030220.pdf. Nielsen NetRatings provide ongoing measurement of Internet usage. Detailed information collected by Nielsen is intended primarily for commercial use, however summaries are published monthly and may be accessed at http://www.nielsen-netratings.com/news.jsp?section=dat_gi.

Swaminathan, Monkombu Sambasivan. (2001). "Antyodaya Pathway of Bridging the Digital Divide." Available from http://www.worldbank.org/wbi/B-SPAN/docs/antyoday.pdf. (Lecture delivered before the Tilak Smarak Trust, Pune, India, August 1, 2001.) Through his involvement in hybrid grain research in the 1960s, geneticist Monkombu Sambasivan Swaminathan played a principle role in the introduction of high-yielding wheat varieties that significantly contributed to India's "Green Revolution" (1967–1978). In 1987 the celebrated scientist created the Swaminathan Foundation, with the aim of supporting fledgling technological development projects that directly address hunger, poverty and environmental concerns. The foundation is known for its emphasis on bottom-up participatory approaches to economic development where local control is the key element to the introduction of new technologies.

DIGITAL LIBRARIES

Digital libraries are organized collections of information resources and associated tools for creating, archiving, sharing, searching, and using information that can be accessed electronically. Digital libraries differ from traditional libraries in that they exist in the "cyber world" of computers and the Internet rather than in the "brick and mortar world" of physical buildings. Digital libraries can store any type of information resource (often referred to as documents or objects) as long as the resource can be represented electronically. Examples include hypertexts, archival images, computer simulations, digital video, and, most uniquely, real-time scientific data such as temperature readings from remote meteorological instruments connected to the Internet.

The digitization of resources enables easy and rapid access to, as well as manipulation of, digital library content. The content of a digital library object (such as a hypertext of George Orwell's novel, *1984*) includes both the data inherent in the nature of the object (for example, the text of *1984*) and metadata that describe various aspects of the data (such as creator, owner, reproduction rights, and version). Both data and metadata may also include links or relationships to other data or metadata that may be internal or external to any specific digital library (for instance, the text of *1984* might include links to comments by readers derived from a literary listserv or study notes provided by teachers using the novel in their classes).

The concepts of organization and selection separate digital libraries from the Internet as a whole. Whereas information on the Internet is chaotic and expanding faster than either humans or existing technologies can trace accurately, the information in a digital library has been organized in some manner to provide the resource collection, cataloging, and service functions of a traditional library. In addition, the resources in digital libraries have gone through some sort of formal selection process based on clear criteria, such as including only resources that come from original materials or authoritative sources. Digital libraries are thus an effort to address the problem of information overload often associated with the Internet.

Origins

Although the concept of digital libraries has been traced back to nineteenth-century scientific fiction writers such as H. G. Wells, most library historians credit Vannevar Bush's description of the memex in the July 1945 edition of *Atlantic Monthly* as the original source. Despite being limited to analog technologies such as microfilm that seem crude in the early twenty-first century, Bush anticipated several key features of digital libraries, including rapid and accurate access to scientific and cultural information.

Contemporary conceptions of digital libraries developed in tandem with the rapid growth of the Internet and especially the widespread, flexible access to digital information afforded by the development of World Wide Web browsers in the early 1990s. For example, in the United States, Phase One of the Digital Libraries Initiative was launched in 1993 when the National Science Foundation (NSF), the Defense Advanced Research Projects Agency (DARPA), and the National Aeronautics and Space Administration (NASA) provided six universities with nearly $25 million to develop digital library test-beds. Another pioneer digital library effort was the U.S. Library of Congress's American Memory project. This groundbreaking digital collection of historical artifacts was first made available on interactive videodiscs, later on CD-ROMs, and most recently via the Internet. Related digital library projects have been underway in Europe, Canada, and elsewhere since the mid-1990s.

In 1998 Phase Two of the Digital Libraries Initiative (DLI2) was launched with funding from NSF, DARPA, NASA, the Library of Congress, the National Library of Medicine, the National Endowment for the Humanities (NEH), and the Federal Bureau of Investigation (FBI). The seemingly strange bedfellows supporting DLI2 suggests some of the ethical issues surrounding digital libraries. These include privacy (who can find out about the resources someone has accessed via digital libraries?), security (who decides what information should or should not be freely accessible?), intellectual property (who owns what information?), hegemony (who controls the access to information?), and globalization (who assures that cultural identity is not weakened or even destroyed by digital libraries?).

Challenges: Technical and Ethical

The technical challenges confronting librarians, computer scientists, cognitive psychologists, and others working on the frontiers of digital libraries are formidable. These include interoperability (what protocols and standards are needed to ensure that distributed digital libraries will provide widespread interconnected access?), access (what types of user interfaces are most effective in providing easy access to diverse communities of users seeking information for different reasons?), preservation (what technologies are needed to assure the long-term survival of digital information resources?), and sustainability (what financial resources are needed to support the maintenance of digital libraries, and how can they be procured?).

In a manner similar to the science of genetics and the Human Genome Project, ethical debates about the ultimate status and value of information science and digital libraries may be even more complex than the technological challenges. It is inevitable that much information will be primarily available through digital technologies in the foreseeable future, a result that leads to complex social and ethical questions that must be addressed. How can traditional library values such as providing all people with free access to high-quality information be upheld when large corporations increasingly seek to profit by selling the information they control? Will the "digital divide" (that is, the unequal access to information technologies currently inherent in the growth of the Internet, which is largely controlled by Western powers such as the United States and the European Union) be decreased or increased by the development of digital libraries? How can the validity of information resources be established when increasingly sophisticated technologies threaten fundamental concepts such as authorship and copyright? How can digital libraries be designed to improve education at all levels?

In his 2000 book *Digital Libraries*, William Y. Arms concludes that "a dream of future libraries combines everything that we most prize about traditional methods with the best that online information can offer. In some nightmares, the worst aspects of each are combined" (p. 272). Although the future of digital libraries is unclear, digital libraries will nevertheless influence the future.

DIGNITY

Dignity in modern Europe and North America is that quality of an individual human person that warrants treating him or her as an end, never merely as a means to some further end. Many things have a price; they are exchangeable for something of equal or greater value.

A human person has no price and is not exchangeable; nothing has more value. Philosopher Immanuel Kant (1724–1804) gave voice to the Enlightenment view by saying that dignity is "an intrinsic, unconditioned, incomparable worth or worthiness" (Kant, p. 36). In a context of expanding technological ability to treat many topics, including persons, as means, the concept of dignity has been associated with the setting of boundaries on such treatments.

In common parlance society distinguishes between expressing dignity and having dignity. To *express dignity* is to behave in a dignified manner, to retain composure and a sense of self-worth in a difficult situation. To *have dignity* is a status independent of any behavior. It is to be treated by others as a person of worth or with respect. It is the second of these, having dignity, that carries moral weight. Every person has dignity regardless of his or her wealth, class, education, age, gender, or demonstrated abilities. Dignity is said to be inherent, inborn.

What is the warrant for the assumption that each person has dignity? The capacity to reason or to make moral judgments are Enlightenment criteria by which human beings are distinguished from other sentient creatures. The theological tradition shared by Jews and Christians locates the ground of dignity in the *imago dei*, the image of God within the human race; and Christians add the incarnation, according to which God enters into the humiliation of becoming human in order to exalt the human race. These provide justification for belief in dignity plus modern commitments to human rights and social equality.

Metaphysically dignity is innate or inborn—that is, dignity applies universally to all human beings regardless of distinctive personal characteristics. Phenomenologically, however, dignity is relational—that is, dignity is first conferred and then claimed. When a family treats infants and young children as persons of worth, these children grow up to see themselves as worthy, as valuable in themselves. Then they are able to express dignity by claiming their rights in society. One way to view the ethical task of persons in free societies is to affirm our responsibility to confer dignity upon persons who are marginalized politically or economically or socially, so that they will be able to rise up and claim equal rights. To be treated by others as having dignity enables one to rise up and express that dignity.

Societal Threats to Dignity

Human dignity today faces four threats. First, quite obviously, totalitarian governments and repressive religious regimes deny a sense of final value to their citizens. Problems of how to deal with such governments or religious traditions, especially in a world increasingly linked by technological means of communication and scientific research, remains a serious political issue.

Second, animal rights groups accuse European and North American society of *speciesism* and seek to confer dignity on nonhuman creatures and, in some cases, on the environment. The extent to which dignity applies to animals, plants, or even certain artifacts such as works of art, remains a debated issue.

Third, modern industrial economics appears to treat individuals impersonally, as part of a mass. Karl Marx (1818–1883) reflected this threat when describing factory workers as flesh and blood appendages to machines of steel. Science and technology also are frequently seen as the instruments whereby bureaucratized industry is given the power to destroy traditional family values and undermine the personal relationships necessary for dignity to enjoy a conferring context.

In recent years the Roman Catholic Church has become one of the world's champions of human dignity against this third threat. Social forces enhanced by biomedical technologies appear to compromise social commitments to protect human life at all costs. Abortion—both therapeutic and elective—seems to threaten life at the beginning; and certain forms of euthanasia seem to threaten life at the end. Ethical debates over pregnancy termination and end-of-life medical practices appear to Vatican eyes as a hardening of hearts against those who cannot protect themselves from the economics of an increasingly technology-dependent civilization. Pope John Paul II referred to this as the *culture of death*. The Pope believes that at conception God places a newly created immortal soul in the conceptus; and the presence of this soul establishes morally protectable dignity. This translates into an ethics that will not allow society to put to death a person with a soul, whether prior to birth or when suffering from a terminal illness. In our culture of death "the criterion of personal dignity—which demands respect, generosity and service—is replaced by the criterion of efficiency, functionality and usefulness: others are considered not for what they are, but for what they have, do and produce. This is the supremacy of the strong over the weak" (Pope John Paul II, p. 42).

The fourth threat, at least in the eyes of the public, comes from genetic research and biotechnology. This is because DNA has become associated with the essence of a human person. DNA is said to be the so-called *blueprint*. Manipulation of one's genes, then, appears to subordinate one's essence to some further end. Proposals for *designer children* or *perfect children* through genetic selection and genetic engineering appear to subordinate the welfare of the children to the images and ends of the parents. Proposals for human reproductive cloning, resulting in two persons with identical genomes, appear to violate the individuality of both for purposes exacted by those making the cloning decision. Such proposals elicit public anxiety over the possible loss of dignity.

This fourth threat to human dignity is more apparent than real. It is a mistake to identify DNA with human essence. No matter how significant one's genome may be, genes alone do not constitute a person. Even identical twins, who share the same genome, develop their own private self-awareness and express their own individual claims to worth. Dignity is not lodged in DNA. Any person coming into the world having been influenced by genetic technologies will enter into the same sets of relationships that confer or deny dignity. Metaphysically no amount of genetic manipulation will reduce a person's dignity

As a belief held by a culture, dignity is a conviction that must be rearticulated in the face of threats. Even though built into this conviction is the idea that human worth is innate or inborn, social ethics requires that it be conferred, cultivated, enhanced, and fought for. The doctrine that each person already has dignity is actually a hope that some day all people will realize—and express—dignity.

DIRECT DEMOCRACY

The modern, mainstream democratic ideal has been republican or representative democracy, but the original Greek ideal was direct democratic participation in all major decisions by all citizens. To some extent even administrative actions were directly democratic, insofar as various executive and judicial functions were determined by lot. Along with direct democracy, two general terms around which efforts to theoretically and practically promote such broad contemporary involvement of citizens in their own governance are those of participatory and anticipatory democracy. In as much as both are argued to be especially facilitated by advanced telecommunications technologies such as television and the Internet, terms of choice range from digital and e-democracy to teledemocracy.

Background

The modern roots of contemporary direct democracy ideals are nineteenth-century anarchist experiments in Europe and populous and progressive movements in the United States. Populism, which reflected agrarian interests, and progressivism, more urban based, sought to institutionalize the citizen legislative initiative, the referendum, and the recall. The participatory democracy movement itself has been closely associated with theories of strong, radical, grass roots, deliberative, and consensus democracy. Anticipatory democracy gives direct democracy a futurist spin. Bioregional democracy is a related notion stressing environmental or ecological issues. Cyberdemocracy stresses virtual reality both as means and as end.

The unifying thread in such diverse direct democracy movements is that all citizens, not just their periodically elected representatives, have rights and responsibilities to contribute to collective decision making. Independent of arguments for such rights and responsibilities, and analyses of the strengths and weaknesses of participatory democracy, one of the most well-developed efforts to promote citizen participation through advanced telecommunications is the Direct Democracy Campaign (DDC) in Great Britain. Using the motto *Let the people decide*, the DDC has advanced a number of specific proposals. The popular initiative would require the government to hold a binding referendum on an issue if 2 percent of the electorate submitted a petition to this effect. The popular veto would allow 1 percent of the electorate to challenge any existing legislation and call for a binding referendum. Moreover according to the DDC web site, "the era of pencil crosses on paper must give way to an age of secure electronic communication."

In the United States, although the theory of participatory democracy emerged in left-wing political circles during the 1960s, proposals for the utilization of advanced telecommunications technologies were promoted more in right-wing political circles during the 1970s. Post 1960s left-wing work moved in the direction of trying to get citizens directly involved in processes of scientific and engineering design decision making, using such means as consensus conferences and by often questioning the adequacy of electronic or virtual participation (Sclove 1995).

Liberal theorists have on occasion utilized measurement theory, especially as applied in psychology by S. S. Stevens (1946), to make some critical assessment of representative democracy and propose reforms that might serve to attract more citizen involvement or enhance the justice of decision making. Among various mathematical or scientific models for enhancing the influence of minority viewpoints or interests are, for example, possibilities for proportional representation, which again might be facilitated by technological means.

Right-wing work, by contrast, has been more populist and positive about electronic democracy. Indeed conservative futurist Alvin Toffler has argued that technological change at once demands intensified, anticipatory democracy as a "continuing plebiscite on the future" (Toffler 1970, p. 422) and provides the "imaginative new technologies" (Toffler 1970, p. 424) to make this possible. Clem Bezold (1978) further advanced the idea of anticipatory democracy. Brian Martin (demarchy) and Robin Hanson (futarchy) have proposed other related ideas appealing to or utilizing market theory.

Outside Great Britain and the United States, efforts to promote and practice participatory democracy utilizing advanced telecommunications technologies exist in, among other countries, Switzerland, Canada, Australia, and New Zealand. Often these efforts exist most vigorously at the local or regional levels. As expected, they have also sponsored numerous web sites.

Questions

Historically there have been three main objections to direct democracy. One is that it provides for no check on emotional responses to complex situations. Another is that most people do not have time or interest enough to become sufficiently educated in the issues to participate intelligently. A third is that there is simply no technical means by which it could work in a modern, large-scale nation-state.

According to Toffler (1980) all three objections can be met. There could be structural or constitutional requirements for a cooling-off period or a second vote on certain issues. Increased affluence and leisure give people more time for politics, and in fact when offered the chance many citizens take advantage of opportunities to become informed about an issue. Social learning generally takes place through trial and error. Finally contemporary communications technologies, especially the Internet, make direct electronic democracy realistically feasible.

More specific questions about the utilization of advanced technological means of communication have also been raised. Has C-SPAN improved democratic intelligence? To what extent can the Internet promote critical reflection and engagement with the nonvirtual world in which political action ultimately takes place?

DISABILITY

Science and technology are pursued for human benefit. But the particular benefits of scientific research and technological development are the result of human activities embodying various cultural, economic, and ethical frameworks as well as the perspectives, purposes, and prejudices of any given society and of powerful groups within it. One group that should benefit includes disabled people. But such benefit will in large measure depend on the governance of science and technology, the involvement of disabled people themselves in their governance, and on the very concept of disability, an issue that is more contentious than commonly recognized. With regard to science, technology, and disability, there are at least two ethical issues that deserve more consideration than they are usually given: What perception of disabled people guides scientific research and technological development? What role do disabled people play in this process?

Solutions Follow Perceptions

Science and technology for disabled people depend on how so-called *disabilities* and disabled people are perceived. Definitions of disability range from the biomedical and economic to the liberal, social-political, minority rights, and universalist models (Penney 2002). These may nevertheless be reduced to three main perspectives:

The *medical individualistic perspective* (MP) sees disabled people as patients in need of being treated so that their level of functioning and appearance approaches that of the so-called non-disabled people (the norm). It assumes that disabled people perceive themselves as patients, and their own biological reality as defective or subnormal. It promotes the use of science and technology for the development of normative therapies for disabled people.

The *transhumanist perspective* (TP) is similar to the medical perspective with the modification that it sees both disabled and non-disabled people as patients. The human body in general is judged to be defective and in need of indefinite enhancement. Even normally existing abilities are subject to being raised above the norm or complemented with new abilities. The transhumanist (or *posthumanist*) perspective does not accept a given norm, and thus does not accept the subnormal/normal distinction between the disabled and non-disabled. The human body in general is seen as subnormal and in need of scientific-technological enforcement. It is no accident that Ray Kurzweil, inventor of the computer voice synthesizer the Kurzweil Reader for the blind, is also a strong proponent of transhumanist technological transformations for everyone.

The *social justice perspective* (SP) does not see disabled people as patients in need of treatment or enhancement so much as society in need of transformation. It assumes that most problems faced by disabled people are not generated by their non-normative bodies or capabilities but by the inability of society to fully integrate, support, and accept individuals with different biological realities and abilities. The social justice perspective encourages the use of science and technology to alter the physical environment so that disabled people may more easily interact with non-disabled people. The focus is on social, not medical, cures.

The social perspective also allows *able-ism* to be seen as analogous to racism or sexism, with able-ism constituting a network of beliefs and practices that yield a particular kind of self and body (the corporeal standard) that is then projected as the perfect, species-typical, and therefore essential and fully human. From the viewpoint of able-ism, disability becomes a diminished state of being human.

The social perspective on disability does not deny that disabled people possess certain biological realities (such as having no legs), which make them different in their abilities and cause them to deviate from a norm. However, it views the "need to fit a norm" as the main problem, and questions whether all deviations from the norm require a medical solution (adherence to the norm). Maybe in some cases a social solution (change or elimination of norm) would be just as appropriate. Neither does the social perspective deny the existence of symptomatic acute medical problems that should be treated. It simply questions the increasing medicalization of non-normative characteristics and sees many so-called diseases, defects and impairments not as acute medical problems but as societal constructions (Wolbring 2003b). It questions whether medical solutions are always the best response.

Scientific research and technological development may emphasize fixing the disabled (on an MP basis); science and technology may also seek to enhance the disabled (on a TP basis). Or technology especially can be used to reconstruct the world in ways that allow the disabled to interact freely with others without altering their biological identity/reality (on an SP basis). "Barrier-free access" is, for example, an SP program.

Society has a long history of adopting the MP approach to seeing disabilities. Many legal instruments describe a disabled person as someone with subnormal or diminished functioning in need of *special* care. They do not see disabled people as having a biological reality leading to *different* sets of abilities, *different* ways of functioning and *different* needs. The medical understanding of disabilities is essential for the acceptance and marketability of many scientific and technological applications such as genetic and non-genetic prebirth testing and genetic and non-genetic therapies and enhancements.

However, this traditional focus is being replaced by a transhumanist focus on science and technology as a means to not just meet norms but to enhance existing abilities and add new ones. It is becoming increasingly difficult to draw a line between therapy and enhancement. If one believes someone is defective without legs, and finds it acceptable to develop artificial legs that function like normal biological legs restoring the normative characteristics of walking (medical cure), one has a hard time justifying the denial of artificial that improve on the natural capabilities of biological legs (running faster, jumping higher) and that might add capabilities beyond the scope of normal biological legs such as climbing walls (transhumanist enhancements).

Scientific and technological research with an SP justification to develop software and hardware that allows the usage by clients with the widest range of abilities is rare. This reflects the fact that most product development is geared toward the largest common denominator in the market so as to ensure the highest profit. Products are seldom developed for disabled people because their numbers are not big enough to make a profit. Without a change in social policies and dynamics, this will not change significantly. In the United States, the Americans with Disabilities Act (ADA), which resulted from the lobbying of the disabled as a public interest group, created a new market for barrier free access and other technological developments.

Roles For Disabled People

Can disabled people influence the indicated dynamics? Do they have to accept the medical or transhumanist perspectives on disabilities? Is it possible for them to promote the social justice perspective?

The disabilities rights movement and emergence of disability activism in the early 1980s provides one kind of answer to such questions (see Shapiro 1994). Disabled persons, no matter how they are defined, worked together in ways that led, in the United States for instance, to passage of the Americans with Disabilities Act (ADA) of 1990, the focus of which was on changing the environmental parameters of the lives of disabled people. However the ADA has been siege ever since its passing, and although it was somewhat successful with access issues, the ADA does not sufficiently cover emerging technologies; nor has it decreased the development of technologies that focus on the medical perception of disability. An increase of the presence of disabled persons among the ranks of scientists, engineers, and ethicists would be another means of more specifically influencing scientific and technology policy.

Certainly some negative consequences of science and technology can be avoided by integrating ethics into the governance of science and technology. But what kind of ethics? Ethical guidelines are not always free from biases that reflect the perspectives, purposes, and prejudices of the most powerful social groups. Much debate about science policy and the legal regulation of technology appears to accept the medical perspective of disability, with some qualified influence of the transhumanist perspective, but little appreciation of the social justice perspective (see, e.g., Harris 2000; Singer 2001; UNESCO 2003; and Wolbring 2003a and 2003c). One of the most effective ways for disabled persons who might object to this situation to counter it is to themselves become involved in policy national and international formation.

At the same time, disabled persons need not shy from inviting non-disabled people of power to ask themselves the following questions:

- Does scientific and technological decision making lead to further marginalization of disabled people?
- Does scientific and technological practice allow disabled people to freely choose their self-identity?
- Do science and technology by themselves have similar impacts on disabled and non-disabled people?
- Does the transhumanist perspective force non-disabled people to enhance their abilities and does it encourage society to make these new abilities eventually the new norm ("normative creep") that makes society less accepting of differences?
- What policy guidelines are needed to promote science and technology for the common good in an inclusive society?
- How the governance of science and technology be made more inclusive and diverse?

It advances the notion that preimplantation genetic diagnostic and germ-line interventions are ethically permissible if done for medical reasons. It denounces sex selection on the grounds that intervention is done for social reasons.

DISCOURSE ETHICS

Discourse ethics (DE) has two aims: to specify the ideal conditions for discourse, and to ground ethics in the agreements reached through the exercise of such discourse. DE thus instantiates the intuition that if people discuss issues in fair and open ways, the resulting conclusions will be morally binding for those appropriately involved in the conversation. Such a view of ethics has special relevance in a scientific and technological world characterized by expanding means of communication. DE may also arguably provide the best framework for understanding the ethics of scientists and engineers operating within their professional communities.

Theoretical Framework

Discourse ethics is primarily associated with the work of Karl-Otto Apel (1980) and Jürgen Habermas, who conjoins his own theory of communicative rationality and action (1981) with Apel's insights (Habermas 1983, 1989). Apel and Habermas root DE in Immanuel Kant's emphasis on the primacy of moral autonomy for both the individual and the moral community (Apel 2001) and in Aristotle's understanding of the importance of human community praxis as the crucible in which all theory must be tested. More broadly DE includes the work of John Rawls (1971), Stephen Toulmin (Jonsen and Toulmin 1990), and Richard Rorty (1989). As Robert Cavalier notes, each of these thinkers argues for "widening reflective equilibrium by embedding empathy and detailed reciprocity into moral reflection and by placing the deliberative process within the intelligent conduct of communal inquiry" (Cavalier Internet site). DE has deeply influenced not only philosophy and sociology—but also, in keeping with its praxis orientation, such applied fields as business ethics (Blickle et al. 1997) and nursing (Marck 2000).

Apel-Habermasian DE seeks to circumscribe—and justify—the *ideal speech situation* in which members of a *democratic* community, free of domination (*herrschafts-freie*), engage in a rational dialogue or debate in order to achieve consensus about the fundamental rules of the community. Drawing on the Kantian understanding that rules are morally legitimate only as free human beings consent to follow them, Habermas argues that such community rules may emerge from discourse that meets certain necessary (but not sufficient) conditions—the first of which is freedom and equality for participants. In his essay "Justice and Solidarity" (1989), Habermas summarizes the basic intuition of discourse ethics with the statement that "under the moral point of view, one must be able to test whether a norm or a mode of action could be generally accepted by those affected by it, such that their acceptance would be rationally motivated and hence uncoerced" (Habermas 1989, p. 6).

In "*Diskursethik: Notizen zu einem Begründungsprogram*" [Discourse Ethics: Notes on Philosophical Justification] (1983), Habermas further emphasizes the importance of *perspective-taking* on the part of all discourse participants: Possible norms for a community can be legitimate only if they emerge from a discourse setting that "constrains all affected to adopt the perspectives of all others in the balancing of interests" (Habermas 1990, p. 65). These conditions of free but rational debate, shaped by such perspective-taking, issue in legitimate *universal norms*—meaning that (a) all who are affected by a proposed norm are willing to accept the consequences and side effects likely to follow from observing that norm, and (b) these consequences are preferred over those of other possible norms under consideration.

Seyla Benhabib notes that such norms are better characterized as *quasi*-universal. They are morally legitimate for the specific discourse community whose debate and dialogue generates them. But diverse communities, shaped by different histories, traditions, and contexts, may come to agree upon a range of possible norms rather than a single monolithic set (Benhabib 1986). In this way, consistent with its Aristotelian and Kantian roots, DE establishes an *ethical pluralism*—in contrast with both monolithic ethical *dogmatism* (asserting that only a single set of norms can be right) and *relativism* (asserting that any set of values and norms is as acceptable as any other).

To circumscribe such discourse more carefully, Habermas refines a set of rules first proposed by Robert Alexy (1978). According to Habermas (1990, p. 86), these are:

1. Every subject with the competence to speak and act is allowed to take part in a discourse.

2a. Everyone is allowed to question any assertion whatever.

2b. Everyone is allowed to introduce any assertion whatever into the discourse.

2c. Everyone is allowed to express his (or her) attitudes, desires, and needs.

3. No speaker may be prevented, by internal or external coercion, from exercising his (or her) rights as laid down in (1) and (2).

Finally, partly in response to feminist and postmodernist critiques that his discourse ethics exhibits a masculine form of rationalism, especially because of the exclusion of emotion, Habermas argues that a sense of *solidarity* is also required between participants.

In short the conditions for the practical discourse out of which (quasi-) universally valid norms may emerge include the free participation and acceptance of all who are affected by such norms, as such norms meet their interests—where such participation is shaped by rational debate, perspective-taking, and solidarity.

Discourse Ethics in Technology and Science

Discourse ethics thus intends to define the conditions of a free and democratic discourse concerning important norms that affect all members of a community. It aims to do so in ways that are directly *practical* for the real and pressing problems facing both local and more comprehensive communities. In this light, DE would seem well-suited for circumscribing discourse concerning pressing issues provoked by science and technology.

Indeed DE can be seen to be implicitly at work in a first instance in the Technology Assessment (TA) movement. Beginning in the 1970s in the United States, and then developing further in Europe, TA seeks to develop ways for programmatically assessing the risks and benefits of proposed or emerging technologies, in order to determine whether the technology *ought* to be developed and deployed in light of central social values, such as protecting both human life and the larger environment. Rather than having decisions regarding new technologies made solely by a relatively narrow circle of scientists and market-dependent corporations, one version of TA has sought to *democratize* technology development by enlarging the circle of decision-makers to include non-technical citizens' representatives. One dramatic instantiation of such democratic technology assessment emerged in the consensus conferences developed by the National Institutes of Health (NIH) in the United States in the 1970s (Jacoby 1985) and then expanded upon, initially in Denmark in 1985 (Klüver 1995). Such consensus conferences were occasioned by the issues raised by the Human Genome Project and genetically modified (GMO) foods, and were composed of carefully structured dialogues involving scientific and technological experts, policy experts, political representatives, and lay or non-technical citizens. Subsequently held throughout Scandinavia and Europe, they have also been applied to issues raised by emerging information technologies (for example, see Anderson and Jæger 1997).

Although not explicitly developed as such, consensus conferences are clearly consistent with the goals and sensibilities of DE, beginning with the intuition that democratic control of science and technology depends on citizens' discourse intended to generate consensus on those values and norms affecting the members of a community—in this case, with regard to the possible development and implementation of technologies with both obvious and not-so-obvious benefits and risks for human beings and their environment. Indeed Barbara Skorupinski and Konrad Ott (2002) have argued that the European consensus conferences, as efforts to develop what they call *participatory Technology Assessment* (pTA), are rooted not only in basic notions of democratic governance, but also precisely in the work of Habermas. They review six examples of such consensus conferences from the 1990s—including a Danish conference on GMO food, as well as Swiss and German conferences on genetic technology—to argue that these represent a sometimes imperfect implementation of DE. Similarly Richard Brown (1998) has argued that the environmental justice movement, including the specific history of Love Canal, can be evaluated in DE terms. To make his case, however, Brown develops a notion of science as narration in order to fit science more directly into the rhetorical and communicative DE frameworks.

Along with its ability to provide a framework for promoting the external democratic discussion of technology, DE may in a second instance also illuminate the internal structure of the scientific and technical communities—especially in terms of professional ethics. Robert Merton, the mid-twentieth-century founder of the sociology of science, analyzed the ethos of the scientific community as producing knowledge that is universal, commonly owned, not tied to special interests, and fallible (Merton 1942). Since Merton there has been considerable debate about the status of these norms, especially insofar as detailed case studies in the history and sociology of science have revealed the often parochial, egotistic, self-interested, and dogmatic behavior of scientists. Using DE, however, it might be possible to reconstruct the norms of professional science as precisely those principles that promote technical communication, and thus properly articulated and taught by means of professional ethics codes.

Pragmatic Discourse Ethics

Although discourse ethics has not been applied explicitly to analyzing or interpreting professional ethics in science or engineering, the explicit work in relation to TA has been carried forward in special areas. For example, Matthias Kettner (1999) has elaborated additional conditions for moral discourse, such as *bracketing of power differentials* and *nonstrategic transparency* (that is, avoiding lies of omission), especially as applied to issues in bioethics. Similarly Jozef Keulartz and his colleagues, in *Pragmatist Ethics for a Technological Culture* (2002), sought to bridge Habermasian DE and pragmatism to deal with issues in agricultural ethics. In particular Paul Thompson (2002) draws on the American pragmatist tradition to avoid what he argues is a crucial failure of DE in Habermas—namely, that the emphasis on ideal speech situations tends to focus on debate *about* ethics (meta-ethics), rather than, as needed, move forward consensus-building about pressing issues.

DE has further played both a theoretical and practical role in connection with the Internet and the World Wide Web. For example, DE has been used to structure online dialogues regarding important but highly controversial social issues such as abortion. These dialogues in fact realize the potential of DE to achieve consensus on important community norms, insofar as they bring to the foreground important normative agreements on the part of those holding otherwise opposed positions, agreements that made a *pluralistic* resolution of the abortion debate possible (Ess and Cavalier 1997). In 2002 DE served as the framework for the ethics working committee of the Association of Internet Researchers (AoIR), as they sought to develop the first set of ethical guidelines designed specifically for online research—and with a view toward recognizing and sustaining the genuinely *global* ethical and cultural diversity entailed in such research. The guidelines stand as an example of important consensus on ethical norms achieved by participants from throughout the world.

The Future of Discourse Ethics?

Despite its promotion of a pluralistic universalism—namely, one that recognizes a wide range of possible discourse resolutions as shaped, for example, by diverse cultural traditions—discourse ethics is more prominent on both theoretical and practical levels in the Germanic cultures of Northern Europe than elsewhere. This regionalized predominance reflects a still larger cultural divide between the United States and Europe in terms of how to take up important ethical issues in science and technology. Thus Jeffrey Burkhardt, Paul Thompson, and Tarla Peterson (2000) note that European analysis and discussion of agricultural and food ethics is marked by a strong preference for *deontological* approaches to ethics, in contrast with the U.S. preference for *utilitarian* approaches. This same contrast can be seen in European approaches to data privacy protection and research ethics (as more deontological) versus American approaches (as more utilitarian).

That is, deontological approaches are associated with Kant and his emphasis on duties to individuals, which is required by their status as rational, autonomous beings. Kantian deontology is a central influence in DE. By contrast, utilitarian approaches—long associated with the Anglo-American philosophical tradition shaped by Jeremy Bentham and John Stuart Mill—seek instead to determine *the greatest good for the greatest number* through a kind of moral calculus that prefers those acts which maximize benefits and minimize costs. Markets, in particular, are justified on utilitarian grounds: While individuals and groups will inevitably lose out in market competition, such competition is justified as leading to greater economic efficiency and thus greater good for at least the greater number. Deontologists are wary of such strictly utilitarian approaches, precisely because they can result in the rights and interests of a minority being sacrificed for the ostensible benefit of the majority.

The Germanic reliance on DE in consensus conferences is thus consistent with the larger preference for deontological approaches. Indeed the European Commission continues to fund important initiatives concerning the ethical dimensions of emerging technologies such as GMO foods, human cloning, stem cell research, and therapeutic cloning research. By contrast the United States abolished the Office for Technology Assessment in 1995. Paul Riedenberg's observation about data privacy protection appears more generally true: The United States pursues a market-oriented (and thus more utilitarian) approach, in contrast with the European reliance on "socially-protective, rights-based governance"—an emphasis on the role of government to protect deontological rights and values (Reidenberg 2000, p. 1315).

In particular the success of consensus conferences in Europe—especially Scandinavia—appears tied to a well-defined set of conditions, beginning with the commonly held value that "democracy is only possible in a society where all citizens are enlightened enough to make an informed and conscious choice" in electing their representatives and voting—where such enlightenment further requires high levels of general education (Anderson and Jæger 1997, p. 150). Moreover the frameworks for Danish consensus conferences explicitly note that "market forces should not be the only forces involved" in deciding the design and deployment of information technology, which should further serve such fundamental deontological values as "free access to information and exchange of information" and "democracy and individual access to influence" (Anderson and Jæger 1997, p. 151). Consensus conferences thus exemplify what Reidenberg describes as the European emphasis on socially-protective, rights-based governance, in contrast with the U.S. utilitarian preference for market-oriented approaches.

Insofar as consensus conferences approximate DE ideals, societies must be committed to citizen enlightenment, as fostered by a strong educational system, and to citizen involvement in democratic processes, including those such as consensus conferences, as fostered by free access to information. In the twenty-first century, however, budgets for education systems continue to shrink and countries around the world are increasingly influenced by the U.S. emphasis on market forces alone to resolve important social issues. This is clearly a move away from socially-protective, rights-based governance in general, and from a belief that government should foster citizen assessment and possible regulation of technological development and deployment in particular. Spending taxpayers' funds on consensus conferences for the assessment of emerging technologies is explicitly criticized. Such circumstances are hardly promising for the application of DE to pressing issues in science and technology.

Nevertheless more promising conditions for DE as applied to democratic procedures for assessing science and technology may emerge in the future. Indeed such conditions are necessary for the sake of democratic procedures in TA. In addition the human, social, ethical, and financial resources required for DE and consensus conferences are the resources needed to realize and further more broadly the Enlightenment project of liberation and democracy.

DISTANCE

One of the well-recognized benefits of science and technology is that they reduce distance across both space and time. Science looks back in time toward the origins of the cosmos and provides information about microscopic phenomena and distant planets. Technologies of transportation and communication reduce the significance of distance limitations on human travel and personal interaction, making globalization a commonplace experience. But while celebrating the ways in which science and technology bring the far near, some thought must also be given to the ways science and technology can make the near far.

The social critic Ivan Illich (1973) was among the first to note some cultural and political implications of distance reversal. The automobile, for instance, brings the suburbs within a daily commuting distance of the central city, while simultaneously placing a living interaction with the city itself outside the bounds of a simple stroll. Illich argued that automobiles "can shape a city into its image," practically ruling out other forms of locomotion. He coined the term *radical monopoly* to designate this type of exclusivity in rendering a service. Something analogous occurs when the telephone, the Internet, and cell phone enhance interactions with distant relatives and friends, while tending to situate immediate neighbors in other worlds. Such technologies invite people to virtually traverse distances at the same time that they might be contributing decisively to the impoverishment of local collectives, communities, and urban spaces. The advent of online education likewise tends to obscure the importance of nearness in knowledge acquisition (Huyke 2001).

As science attaches to the knowledge of distant places and times a kind of exotic glamour, one has to work hard to pay attention to what is immediately at hand. As people get used to online education, for instance, the illustrations brought forth by distant experts may outshine local experience and events. With the advent of biotechnology, high-yielding herbicide-resistant plants of major commodity crops become available throughout the world, shackling farmers to the patented plants and herbicides of a few multinational conglomerates, while also diverting them from local forms of agriculture and a more diverse produce.

Other commentators highlight the positive potential of such transformations in the character of distance. From the perspective of critical social theory, Andrew Feenberg (2002) calls for the democratic design and control of systems that facilitate self-organizing, nonterritorial communities throughout the globe. He likewise defends online education (which used to be called "distance education"), as long as it is "shaped by educational dialogue rather than the production-oriented logic of automation" (p. 130). The phenomenologist Don Ihde (1990) acknowledges an inevitable overwhelming of near "monocultural lifeworlds"—that is, ingrown German or Italian cultures, and especially indigenous cultures—but argues that independent of political efforts to limit the damage, such lifeworlds will become "pluricultural" through selective adoptions and incorporations. With the use of image-technologies, future traditions will inevitably be characterized by multiplicity and abundance, or what Ihde calls plurality. The local adaptation of global trends, a bringing of the far near sometimes known as "glocalization," can free individuals from the limitations of too specifically conceived traditions.

A third response seeks to identify those conditions that allow for personal, political, and cultural flourishing in the context of sciences and technologies that will continue to bring the far close and make the near distant. One insightful representative of this approach is the philosopher Albert Borgmann. In his 1984 book, *Technology and the Character of Contemporary Life,* Borgmann argued that the key to the good life is engagement with what he calls "focal things and practices" that order and intensify human experience, such as playing music or cross-country running. Contemporary technology, however, exhibits a guiding pattern, which he terms the "device paradigm," that is at odds with such experiences. Rather than needing to be played, music is able to be consumed by CDs and other devices, and running easily becomes an activity that takes place on a running machine rather than in nature.

The abstract problem of distance reversal is made concrete in the technological device itself, which increasingly hides its own near inner workings in favor of unhindered delivery of some commodity. The traditional hearth called forth ordered engagement in cutting wood and tending fire, and how it produced heat was transparent for all to see. The central heating system reduces engagement to a maintenance contract and is more or less mysterious to the consumer. Other examples permeate contemporary life: Few people know how digital clocks work, but such devices unambiguously state the time. Without the burdens of cooking, processed food is everywhere and available at any time. Humans progressively construct a world monopolized by the prominent availability of goods and a parallel disappearance of things and practices that might engage and challenge. Genuine nearness that could lead to "the unity of achievement and enjoyment, of competence and consummation" is replaced by the easy consumption of commodities that in the past would have required the expenditure of time or the traversing of space (Borgmann 1984, pp. 202–203). In the case of virtual reality, the line between the real and the virtual gets blurred in the context of "a deceptive sense of ease and expertise" that comes with digitalized cultural information about things (Borgmann 1999, p. 176).

Borgmann argues for a distinctive reform of technology. He has repeatedly called for the design of technologies that engage people bodily, socially, and politically. In opposition to Illich before him, Borgmann believes that more appropriate or enabling technologies will not constitute the deciding difference for a reformed future, because technological devices exhibit their own perfections and attractiveness. Instead he calls for a two-sector economy that would limit production with devices and of devices, leaving room for and encouragement of focal things and practices. To what extent such a project is politically feasible remains at issue. How it might help meet the challenges of time and space displacements found in scientific knowledge and technological tendencies is yet to be explored.

DOMINANCE

For students of animal behavior, *dominance* refers to the phenomenon by which individuals of a social species organize themselves with regard to access to resources. Although some social species appear to be egalitarian in many respects, close observations reveal differential access among individuals in nearly all cases, especially when resources are in short supply. These resources may include food, nest sites, mates, or any other considerations that have consequences for evolutionary success, or fitness; a dominance hierarchy is one of the most common patterns whereby access to these resources is established.

Dominance Hierarchies and Relationships

Although dominance relationships have in the past been seen as a species characteristic in themselves, they most importantly reflect differences in size, aggressiveness, and/or motivation among individuals, with these differences generating, in turn, a hierarchy of access to fitness-enhancing opportunities. It also appears to be beneficial to individuals to recognize their competitive relationship with respect to others, because without such recognition considerable time and energy might be wasted re-establishing priority, not to mention risking injury if a confrontation results in actual fighting. A signal characteristic of dominance hierarchies is that despite their aggressive underpinnings, animal societies characterized by rigid dominance relationships tend to experience relatively little actual fighting.

Most specialists maintain that—as with other biological phenomenon—there are no ethical implications of animal dominance relationships per se. While human observers may be inclined to deplore the *unfairness* whereby some individuals achieve disproportionate access to resources while others are comparatively excluded, dominance relationships, by definition, are not egalitarian. Indeed, during the late-nineteenth and early-twentieth centuries, when social Darwinism was especially influential, dominance relationships among human beings were considered admirable, as a working out of natural law. In the early twenty-first century, biologists acknowledge that dominance relationships among animals do indeed reflect the working out of natural tendencies and inclinations, as do predator-prey relationships, or the patterns of energy flow among different levels of natural communities. Just as neither eagles nor decomposing bacteria are good or bad, the same is true of dominance hierarchies. They are part of natural life, and as such, ethically neutral.

From an evolutionary perspective, dominance relationships among individuals develop because individuals are selected to maximize their fitness, their success in projecting copies of their genes into the future. Natural selection rewards those who succeed in doing so, and, in certain cases, this success is achieved by establishing one's self in a clearly defined situation of social superiority over others.

This is not to say that dominance relationships develop by some sort of intentional decision process on the part of the animals themselves, in which the latter get together and agree to establish a hierarchy. Rather, individuals who are somewhat larger, more aggressive, smarter, or who may have enjoyed such advantages in the past, simply assert themselves and, by virtue of that circumstance, succeed in gaining priority. Natural selection, in turn, supports those who achieve this success insofar as priority to food, mates, and nesting sites, among other things, correlates positively with ultimate reproductive success. Gene combinations that lead to success in such competition are favored in succeeding generations.

In some cases—barnyard chickens are the classic example—individuals end up establishing a *pecking order* whereby individual 1 dominates individual 2 and all those below, individual 2 dominates individual 3 and all those below, with that pattern continuing. However, dominance relationships are not always linear, nor are they always transitive: In many territorial species, for example, individual 1 may dominate individual 2, and individual 2 dominates individual 3, but individual 3 may dominate individual 1! In others—harem-keeping or polygynous species, such as elk, for example—there may be a single dominant individual (the dominant bull), who is clearly *number one*, with a less clear hierarchy among the remaining subordinate males.

Dominance relationships among animals depend upon an often tacit acknowledgment of the existing situation, on the part of dominants and subordinates alike. Thus once a dominance relationship is established, it is typically unnecessary for the various participants to fight—or even, in most cases, to engage in elaborate threat and subordination behavior—in order to maintain the pattern. When a dominance pattern is well established, individuals promptly respond to their mutual relationships by recognizing each other as individuals. (Indeed, this rapid, tacit response can be taken as powerful evidence of the participants' capacity to recognize individuals in the first place.)

Traditionally, dominance hierarchies have been seen as relatively immutable. More recent studies, however, have shown that they are not. Even though hierarchical relationships among animals tend to be resistant to change, they are subject to modification, as when a dominant male harem-keeper among langur monkeys is overthrown by one of the previously subordinate bachelors. Similarly, dominance hierarchies among female animals commonly vary as a function of hormonal and reproductive state: Breeding females and those in estrous often experience a temporary increase in their dominance status.

Correlation to Human Dominance Patterns

There is considerable variation in the nature of dominance relationships among different animal species, even some that are closely related. Chimpanzee social behavior, for instance, is generally oriented along lines of male dominance whereas the dominance system of bonobos (formerly known as pygmy chimpanzees) is primarily structured by the interactions of females. This, in turn, leads to question as to which animal system—if any—is most appropriate for understanding social dominance among human beings. Nonetheless biologists as well as increasing numbers of social scientists believe that in some complex way the biological nature of human beings underlies the nature of human politics just as that of other species underlies their pattern of social interactions.

Status signaling has also received considerable research attention. Although it seems legitimate to distinguish between physical characteristics (such as elaborate crests, ruffles, and antlers) used to achieve success in sexual selection by generating greater attractiveness to members of the opposite sex, such traits often also contribute to success in same-sex competition, and thus, with regard to dominance relationships. Would-be competitors are themselves more fit if they respond appropriately to indicators of probable physical or even mental superiority rather then subject themselves to possible injury or time wastage finding out *who is successful relative to whom*. Additionally it is probably adaptive for potential mates to employ the same traits that are used to establish and maintain same-sex dominance relationships as signals that generate success in between-sex courtship. This is because such traits—if genuinely connected to health and vitality—would lead to more successful offspring and hence be appropriate signals for an individual of one sex to employ in choosing a potential mate, and also because any offspring of such a union, insofar as they possessed these characteristics, would likely to be attractive to the next generation of *choosers*.

Among human beings dominance is a function of many things, including physical characteristics, intellectual qualities, and the control of material resources. Social dominance typically goes beyond the merely physical ability to intimidate a would-be rival, and carries with it signifiers of social rank such as clothing, make of automobile, speech patterns, and self-confidence. As in the case of animals, it is difficult —and perhaps impossible—to separate intrasexual from intersexual aspects of dominance. There is evidence that mastery of technology contributes to social dominance, and moreover, that the pursuit of technological and scientific success is generated, albeit unconsciously, by an underlying pursuit of social dominance (which itself is pursued because of its ultimate connection with reproductive success). The fact that such connections and motivations—if they exist—are not consciously pursued, does not make them any less genuine. At the same time, even as biologists are agreed that dominance and the pursuit of dominance is *natural,* there is no evidence that it is either ethically privileged or, by contrast, to be disparaged.

DOUBLE EFFECT AND DUAL USE

In moral philosophy the principle of double effect traditionally refers to conflict situations in which an action or series of actions will result in multiple effects, some good and some bad. It parallels the contemporary policy concept of dual use: the idea that scientific knowledge or technological artifacts can serve multiple purposes, depending on the context. Dual use targeting and dual use research are areas that sometimes raise ethical dilemmas about the production and use of scientific knowledge and technologies but on other occasions provide multiple justifications for a single policy. Double effect seldom is referred to explicitly in those situations, but its general conditions may provide conceptual clarity with regard to moral permissibility. However, at the level of practical political decision making activities such as risk assessment, technology assessment, and scenario building provide better guidance for handling the ethical problems posed by dual use situations than does double effect reasoning.

Double Effect

Still widely discussed in the bioethics literature, the principle of double effect originated in Catholic scholastic moral philosophy, specifically in the discussion by the theologian Thomas Aquinas (1224–1274) of killing in self-defense:

> A single act may have two effects, of which only one is intended, while the other is incidental to that intention. But the way in which a moral act is to be classified depends on what is intended, not what goes beyond such an intention. Therefore, from the act of a person defending himself a twofold effect can follow: one, the saving of one's own life; the other the killing of the aggressor. (*Summa theologiae,* IIaIIae, q.64, a.7)

This raises the central distinction in double effect reasoning between intention and foresight (Aulisio 1995). In a morally acceptable case of killing in self-defense, the death of the aggressor is a foreseeable effect but the intention is to preserve one's own life. If, however, the killing was intended and not merely foreseen, it is considered homicide.

Originally formulated in slightly more complex terms, the principle of double effect commonly is stated as follows: An action with multiple effects, good and bad, is permissible if and only if (1) one is not committed to intending the bad effects either as the means or the end and (2) there is a proportionate reason for bringing about the bad effects (Bole 1991). The proportionality clause arises from Thomas's insistence that one should not use more violence than necessary in defending oneself: "An act that is properly motivated may, nevertheless, become vitiated, if it is not proportionate to the end intended" (*Summa theologiae,* IIaIIae, q. 64, a. 7). Subsequent interpreters saw this condition as referring more broadly to the overall balance of good and bad effects.

Paradigm applications of double effect in Catholic bioethics pertain to cases of maternal-fetal conflict and distinctions between palliative care and euthanasia. Double effect also has been used in debates about the use of embryos in medical research. Many theorists question the relevance of double effect reasoning outside the Catholic moral framework (Boyle 1991). Some have argued that although the distinction between intention and foresight is difficult to apply practically, double effect nonetheless applies in any of the multiple moral frameworks that incorporate deontological constraints (in the form of intention) on consequentialist considerations (Kagan 1989). (Deontology asserts that certain acts are intrinsically right or wrong, whereas consequentalism asserts that the rightness or wrongness of an act depends on its consequences.) Traces of double effect reasoning can be seen even in Anglo-American law, for example, in the distinction between first-degree murder and manslaughter.

Double Effect and Dual Use

The concept of dual use is not well formulated for general use but can be understood in light of the principle of double effect as referring to any activity, artifact, or body of knowledge that is intended to bring about good effects but also has foreseeable negative consequences. This definition, however, excludes one of its most common applications: cost-sharing research programs involving industry and the military. For example, the U.S. Department of Defense operates a Dual Use Science and Technology Program to fund jointly with industry partners technologies that can be of use both on the battlefield and in the market. Defined in this sense, dual use is somewhat difficult to consider under the principle of double effect because there is no admitted or foreseen bad result, only multiple good ones. It merely refers to basic research with the potential for positive benefits in more than one sector of the economy and thus offers multiple justifications for governmental support. It is often the case that if political support for a research program cannot be marshaled with one argument (knowledge production alone), scientists have few qualms about appealing to others, such as military or health benefits and economic competitiveness. However, in this case ethical questions arise about whether both uses are equally sound or valid and whether rhetorical appeals to one may contaminate the other.

Insofar as dual use implies both good and bad outcomes, the concept presents even more fundamental challenges for social policies in regard to public support of science and technology. Stanley Rosen introduces the problem by noting that "all fundamental aspects of the natural sciences . . . may lead to the destruction of the human race. . . . Whereas no one would argue the wisdom of attempting to prevent a nuclear holocaust or the biochemical pollution of the environment, not many are prepared to admit that the only secure way in which to protect ourselves against science is to abolish it entirely" (Rosen 1989, p. 8). Security requires not only the abolition of science but also the destruction of all children because it is impossible to be certain who eventually may produce knowledge that threatens human existence. Rosen calls this the "ultimate absurdity of the attack against the enlightenment" (Rosen 1989, p. 9).

This absurdity follows from the notion of dual use because nearly all knowledge and artifacts, despite good intentions, could produce foreseeable bad effects. Examples can be as exotic as the "grey goo" (uncontrolled replication of nanotechnology) envisioned by Bill Joy (2000), as mundane as using a pen as a stabbing instrument, or as horrifying as the deadly use of commercial airplanes by terrorists on September 11, 2001. Rosen's point is that the only way to guarantee safety is to ban science and its technological products entirely.

Of course, society does not follow this absurd logic because most people feel that the benefits provided by science and technology (the intended good effects) make it worthwhile to risk some of the foreseeable bad effects. People seek a judicious regulation of scientific inquiry and technological progress, and it is in this middle ground that the major ethical questions are raised by dual use phenomena: Do the foreseeable bad effects outweigh the intended positive ones? Are there ways to minimize the negative effects without compromising the positive ones? Are there some foreseeable consequences that are so appalling that people should ban the production or dissemination of knowledge in a certain area altogether?

These questions show the importance of the proportionality condition of the principle of double effect. In fact, proportionality is disclosed through activities such as risk assessment, technology assessment, and scenario building. Those activities involve processes of weighing the good and bad effects of research and technology in light of uncertainty about their relative probabilities. The distinction between intention and foresight is less difficult to apply, at least in theory, because if someone is attempting intentionally to bring about bad effects, say, by engineering a supervirulent pathogen, it seems obvious that there should be intervention to end that work. Indeed, in the realm of biotechnology dual use situations are difficult to deal with precisely because bad effects are not intended (cures, vaccines, and other good effects are intended) but nonetheless are foreseeable. Dual use situations present practical challenges to regulate research and ensure the proper use of technology in cases in which double effect analysis provides some insight and conceptual clarity. Dual use can be conceived of more broadly than can the conditions of double effect, however, because some bad effects of science and technology may be unforeseeable, let alone unintended.

Conduct of War and Biological Research

Precision-guided munitions and satellite-aided navigation have enhanced the accuracy of aerial bombardment. Although this has improved the ability of military planners to minimize collateral damage, it has raised an ethical dilemma: Military leaders are faced with questions of the legitimacy of dual use targeting, or the destruction of targets that affect both military operations and civilian lives. An example of such dual use targeting was the destruction of Iraqi electrical power facilities by the U.S. military in Operation Desert Storm in 1991.

Under the principle of double effect such activity would be deemed morally acceptable if the intention was not to harm or kill civilians (a bad effect that is foreseen but unintended) and the good effects outweighed the bad. This application of the principle of double effect relates to the idea of the just war that can be traced back to the theologian Augustine 354–430). Thomas expanded Augustine's idea that one cannot be held accountable for unintended effects caused by chance by applying that principle to include even foreseeable unintended effects that are not due entirely to chance. Like all versions of morality in terms of principles or formulas, however, the principle of double effect only establishes basic guidelines, and the majority of the work lies in deciding how and by whom such judgments about good and bad effects should be made.

Nuclear science provides the paradigmatic case of dual use summarized in the tension between physicists' initial hopes of "atoms for peace" and the grim reality of international proliferation of nuclear weapons. The dual nature of civilian and military use of nuclear science and technology poses grave problems in international relations, as witnessed by suspicions that Iran and other nations were developing nuclear weapons while claiming that such research was intended for civilian use only. The added possibility that terrorists could acquire weapons-grade nuclear material raises the stakes even higher.

The same concerns have surfaced around nanotechnology but have taken on a more mature form in regard to biological research. In 2004 the U.S. National Research Council (NRC) issued a report titled *Biotechnology Research in an Age of Terrorism*. Presenting recommendations to minimize the misuse of biotechnology, the authors warned: "In the life sciences . . . the same techniques used to gain insight and understanding regarding the fundamental life processes for the benefit of human health and welfare may also be used to create a new generation of [biological warfare] agents by hostile governments and individuals" (U.S. National Research Council 2004, p. 19). Attention was paid to the risk that dangerous research agents could be stolen or diverted for malevolent purposes and the risk that research may result in knowledge or techniques that could facilitate the creation of novel pathogens. The report characterizes the central tension as one of reducing the risks of the foreseeable unintended bad effects while allowing for the continuation of the good effects yielded by biomedical research. One major dilemma is the trade-off between national security and scientific freedom of inquiry.

The distinction between intention and foresight and the proportionality condition are reasonable concepts for understanding the nature of this dual use situation. Clearly, mechanisms must be in place to ensure that researchers are not working intentionally toward bad effects either directly in the laboratory or covertly by sharing information with terrorists or other enemies. The more difficult questions, however, are left even when the assumption is made that no malevolent intentions exist.

The U.S. government established the National Science Advisory Board for Biosecurity (NSABB) to provide advice to federal departments and agencies on ways to improve biosecurity, which refers to practices and procedures designed to minimize the bad effects of biological research while maximizing the good effects. The U.S. Patriot Act of 2001 and the Bioterrorism Preparedness and Response Act of 2002 established the statutory and regulatory basis for protecting biological materials from misuse. The NSABB develops criteria for identifying dual use research and formulates guidelines for its oversight and the public presentation, communication, and publication of potentially sensitive research. It works with scientists to develop a code of conduct and training programs in biosecurity issues. NSABB rules apply only to federally funded research. A possible avenue for the oversight of dual use research is Institutional Biosafety Committees (IBCs) for case-by-case review and approval.

The mechanisms fashioned by the NSABB for the regulation of dual use research are a good example of how the general spirit of double effect analysis is manifested in specific actions, raising political issues such as the proper balance of self-regulation by the scientific community and outside intervention. Members of IBCs and those involved in implementing other NSABB rules face the challenge of interpreting and applying the general guidelines provided by the principle of double effect in the sense that they must wrestle with difficult ethical dilemmas posed by good intentions and their foreseeable bad effects.

DRUGS

Drugs are notoriously difficult to define and yet present some of the most difficult ethical issues for the science and technology on which they are based. At the simplest level, drugs are molecules whose biochemical effects have been classified as socially desirable or undesirable in different times and places. *Dorland's Medical Dictionary* defines a drug as a "chemical compound that may be used on or administered to humans or animals as an aid in the diagnosis, treatment, or prevention of disease or other abnormal condition, for relief of pain or suffering, or to control or improve any physiologic or pathologic condition" (p. 510). But this ignores so-called *recreational drugs*, which may be described as substances used mainly for their psychoactive properties and pleasurable effects.

Historically drugs have been derived from plants and other natural materials and thus their production relied on indigeneous forms of knowledge and premodern techniques, often appropriated for modern applications. Over half of drugs in clinical use today continue to be derived from natural sources—including the excretions of insects, animal organisms, or microbes—from which they are extracted through direct or indirect processes (Aldridge 1998). The other half is synthesized through chemical processes that are now industrialized.

International Regulation

Ethical issues relating to human exploitation of indigenous knowledge and resources—sometimes called *bio- prospecting*—became central with the rise of a multinational pharmaceutical industry in the mid- to late-twentieth century. International treaties now provide safeguards that guarantee countries sovereign right over their genetic resources and a share of pharmaceutical profits derived from them. Yet such treaties also make national drug policy inflexible, inhibit innovation, and do not necessarily guarantee that indigenous groups that provide genetic materials are fairly compensated.

Given the high profit margins and relatively recession-proof nature of the pharmaceutical industry, drug production, marketing, distribution, and consumption are tightly regulated through a complex series of legal protocols and social controls that start from a set of international treaties that are coordinated through the United Nations Single Convention (1961), still the foundational document of international drug control (McAllister 2000). Prior to 1961 nine separate international treaties governed illicit or addictive drugs, primarily narcotics (opium and its derivatives), coca and its derivatives, and marijuana/hashish. The Single Convention defined the boundary between licit and illicit drugs, as well as legitimate medical and illegitimate, nonmedical, or recreational use, granting expert committees of the World Health Organization (WHO) authority for adding or altering *drug schedules*, which define how strictly drugs are regulated according to the level of their abuse liability. The Single Convention also mandated that national governments create and maintain drug-control agencies, and otherwise required signers to conform their domestic drug policies to its international mandate.

Regulation in the United States

Regulatory regimes are divided in the United States between illicit drugs, regulated by the Federal Bureau of Narcotics (FBN), the Treasury Department unit responsible for enforcing the Volstead Act (alcohol prohibition) and the Harrison Act, which transmuted into the Drug Enforcement Administration (DEA) in 1973; and licit drugs, regulated by the Food and Drug Administration (FDA) following the Food, Drug, and Cosmetic Act (1938). The 1938 Act granted the FDA authority to designate which drugs would be available only with a physician's prescription (Swann 1988). The liberalization of prescription laws in the 1960s and 1970s culminated in direct-to-consumer (DTC) advertising briefly becoming legal in the United States in the early 1980s prior to an FDA-imposed moratorium finally lifted in 1997. Supranational organizations such as the European Union have limited the spread of direct-to-consumer advertising (DTC) of prescription drugs. New Zealand is currently the only other country besides the United States that allows DTC, although it is under consideration elsewhere.

Well into the twentieth century, *proprietary medicines* were unregulated in terms of production, advertising, marketing, or distribution. Heavy advertising of commercial compounds emerged in the mid-nineteenth century United States, as patent medicine manufacturers were among the first to market their products nationally. Total advertising expenditures for proprietary medicines soon exceeded those of all other products combined; it was not unusual for nineteenth-century advertising budgets to exceed $100,000 per year, and some reached the million-dollar mark.

Narcotic drugs were restricted to prescription by the Harrison Act (1914), an outcome of growing international concern about widespread use and abuse of opiates, which were one of the few effective drugs then considered part of the medical armamentarium. An ongoing search for a non-addicting analgesic mounted by the National Research Committee propelled early-twentieth century innovation in the U.S. pharmaceutical industry in the context of concerns about addiction liability (Acker 2002). Addiction remains a classically public problem to which a coordinated federal response is understood as necessary, despite disagreement over the form that it should take. The United States remains the largest consumer of illicit drugs and has continued to struggle against what has proven a largely intractable problem. Basic research efforts into the neurobiochemistry of addiction led to the visualization of multiple opiate receptors, long hypothesized to exist, in the early 1970s. Federally funded studies of drug addiction have shifted away from the social and health consequences of abuse, and toward the use of molecular and animal models in establishing the basic neurobiological and now biogenetic mechanisms of drug action.

Drug Evaluation

Classified according to what is known about their mechanism of action, as well as their predominant effects on human and animal populations, both prescription and over-the-counter drugs must now be evaluated for safety, efficacy, abuse liability, and therapeutic effects. First their metabolic effects must be determined in animal models. Clinical trials in healthy human volunteers take place after pharmacokinetic studies in animals. Trials are divided into four phases, three of which take place before licensing and one of which occurs once patients are prescribed the drug by participating physicians. The large-scale clinical trials system in place in the United States since the 1960s is complex, lengthy, and expensive. Both the FDA and the National Institutes of Health (NIH) reluctantly became involved in regulating and coordinating the testing and licensure system for new drugs (Hertzman and Feltner 1997). Ethical concerns relevant to clinical trials include determinations of the capacity for informed consent of experimental human subjects; balancing rights to privacy and confidentiality with public access to information; the design and execution of double-blind, placebo-controlled studies; and how to go about occasionally halting a trial as adverse effects become clear.

Ethical questions are raised both in terms of the type of drug development, production, marketing, and distribution being promoted; and the conditions of use. Drugs play a different role depending upon whether they are administered within allopathic or homeopathic therapeutic regimes. Homeopathy involves the administration of minute dosages of drugs designed to produce symptoms in healthy persons that mimic the symptoms of the disease for which the person is being treated. Developed by Samuel Hahnemann (1755–1843), homeopathy has been the target of many conflicting claims concerning its safety and efficacy in the face of the dominant practice in western medicine, allopathic treatment, which seeks to produce conditions that are incompatible or antagonistic to the disease. Many aspects of complementary and alternative medicine (CAM) are now being explored through large-scale clinical trials, since tremendously high percentages of U.S. patients now seek alternative practitioners in conjunction with allopathic practitioners, leading to a vast and less regulated market for so-called nutraceuticals, off-label use of pharmaceutical drugs, and herbal remedies untested by scientific regimes.

One of the major events in twentieth century history of drugs was the coincidence between the trend toward deinstitutionalization of mental hospitals that began in the 1940s with the psychopharmacological revolution that occurred upon introduction of a major tranquilizer, chlorpromazine (CPZ, marketed as Thorazine in the United States and Largactil in Europe), in the 1950s. This was followed by the first popular use of pep pills (amphetamines) and the mass marketing of minor tranquilizers such as Miltown in the late 1950s, which brought advances in psychopharmacology to popular attention (Smith 1991). Since that time periodic concerns have surfaced as to the social value of drugs used for performance enhancement or marketed widely as lifestyle drugs in ways that have changed the meaning of *medical use*. Pfizer Pharmaceutical's introduction of Viagra, a drug used to temporarily correct erectile dysfunction and targeted toward relatively affluent male consumers, brought to light disparities in insurance coverage of lifestyle drugs such as the lack of insurance coverage for female contraceptives, whose coverage has been restricted due to the abortion controversy. This *Viagra gap* illustrates one of the persistently troubling ethical issues in the domain of drugs, namely that of research and development targeted toward developing or widening markets among the affluent through lifestyle or look-alike drugs that are simply a means for drug companies to gain market share, compared to the relative lack of attention to drugs for treating orphan diseases that seriously affect small numbers of individuals, or those diseases—such as malaria or schistosomiasis—that mainly affect individuals in the developing world.

While the FDA is often regarded as an agency that largely serves the needs of the pharmaceutical industry, three major reproductive health controversies of the 1960s and 1970s propelled the FDA into taking a somewhat proactive regulatory role. These were the development of hormonal methods of contraception; widespread prescription of Thalidomide to pregnant women in Europe, while the drug was still experimental in the United States when it was demonstrated to cause severe birth defects; and prescription of diethylstilbestrol (DES), which caused *in utero* defects and increased rates of cancer in the children of women who took it. These controversies arose simultaneously with interrelated social movements that targeted health and physician-patient relationships, including the patients' rights movement, the consumer rights movement, the women's health movement, and, later, the HIV/AIDS movement. These social movements sought to limit the use of certain classes of therapies such as electroshock (ECT) and drugs such as the major tranquilizers or benzodiazepines (Valium) among certain populations. They also agitated for increased inclusion in clinical trials, earlier and more democratic access to experimental drugs, and expanded patients' rights including privacy, confidentiality, and informed consent.

Pharmacogenomics

Pharmacogenomics is the attempt to identify individual, genetic variation in drug response—metabolism, transport, and receptors—and to extend those findings to population genetics through a variety of information and visualization technologies. Pharmacogenomics promises individually tailored medications that would likely decrease adverse drug reactions, currently the fourth leading cause of death in the United States.

Projects in this research arena raise novel ethical and legal issues related to the creation of sample repositories or banks of genetic materials that would enable hypothesis-driven research on statistically significant differences in the phenotypes of human subjects. Such research could help establish the safety, efficacy, and compatibility of certain classes of drugs for particular individuals or populations; and could be used to create a complex set of biomarkers that describe the particular complement of different neuroreceptors that an individual has that may make him or her more or less responsive to a range of addictive substances (tobacco, opiates, and others) or prescribed medications. Pharmacogenetic databanking is potentially useful for avoiding adverse consequences but could also create a rationale for genetic and health-related discrimination. As with previous advances in the field of pharmacology, pharmacogenetics presents a double-edged sword, and its meaning and ethical value will be determined by the social contexts in which it is deployed.

René Dubos, 1901–1982. Dubos pioneered in the development of antibiotics and was an important writer on humanitarian and ecological subjects. *(© Bettmann/Corbis.)*

DUBOS, RENÉ

René Jules Dubos (1901–1982), the French-American microbiologist and Pulitzer Prize-winning author, was born in Saint-Brice-sous-Forêt, France, on February 20. At the age of twenty-three, after completing his undergraduate training in agronomy, he used the money he made from translating scientific writings to travel to the United States. There he spent the rest of his prolific career, making groundbreaking contributions to antibiotic development, tuberculosis research, and environmental philosophy. René Dubos died in New York City on his eighty-first birthday.

Dubos's early work as a translator exposed him to the research of the Russian microbiologist Sergei Winogradsky, who stressed the importance of studying soil microbes in their natural setting, not just the sterile conditions of the laboratory. As Dubos reminisced late in life, "I have been restating that idea in all forms ever since. The main intellectual attitude that has governed all aspects of my professional life has been to study things, from microbes to man, not per se but in their complex relationships" (quoted in Kostelanetz 1980, p. 195). He earned his doctorate in agricultural microbiology from Rutgers University in 1927, and soon after won a fellowship from the Rockefeller Institute for Medical Research to find a way to disarm the microbe that causes pneumonia by destroying its protective polysaccharide coating. His unconventional approach entailed collecting dozens of soil samples in search of a bacterium that could decompose the material in question. Dubos's success led to his 1939 discovery of gramicidin, the first commercially produced antibiotic, which in turn stimulated efforts by other researchers to develop the antibacterial drugs that revolutionized medicine during the mid-twentieth century.

Dubos's ecological approach enabled him to predict the development of bacterial resistance to antibiotic drugs in the early 1940s, decades before antibiotic drug failure became a global health crisis. His subsequent research on the bacterium that causes tuberculosis, which killed his first wife, sharpened his appreciation of the social determinants of the disease, and his growing conviction that controlling microbial diseases required much more than eradicating the responsible microbes. In *The Mirage of Health* (1959) and *Man Adapting* (1965), Dubos challenged the dominant paradigm of scientific medicine by emphasizing the environmental determinants of disease, and the impossibility of vanquishing infectious diseases due to the constant flux of environmental conditions. A colleague at the Rockefeller University, Walsh McDermott, later hailed Dubos as "the conscience of modern medicine."

During the late 1960s and 1970s, Dubos's long career studying the links between environment, health, and disease facilitated his transformation into "the philosopher of the earth," as the *New York Times* called him near the end of his life. Dubos won the Pulitzer Prize for his book *So Human an Animal* (1968), in which he presents a holistic critique of modern civilization:

> Most of man's problems in the modern world arise from the constant and unavoidable exposure to the stimuli of urban and industrial civilization, the varied aspects of environmental pollution, the physiological disturbances associated with sudden changes in ways of life, the estrangement from the conditions and natural cycles under which human evolution took place, the emotional trauma and the paradoxical solitude in congested cities, the monotony, boredom and compulsory leisure—in brief, all the environmental conditions that undisciplined technology creates. (Dubos 1968, p. 216–217)

In later publications, Dubos elaborated his philosophy that humans can overcome such problems by creating what he called humanized environments that meet modern physiological, emotional, and esthetic human needs. His argument that humans can improve on nature by applying ecological insights to the built environment set him apart from the prominent pessimists of the burgeoning environmental movement, attracting widespread attention. The United Nations commissioned Dubos to chair a group of experts for the landmark 1972 United Nations Conference on the Human Environment, and to coauthor its influential background report, *Only One Earth* (1972).

Dubos's experience with the environmental megaconferences of the 1970s convinced him that solving global environmental problems requires dealing with them at the regional level, with respect to their unique physical, technological, economic, and cultural contexts. His practical approach spawned the famous phrase *Think globally, act locally,* which continues to inspire environmental activists around the world. He linked the maxim with his ecological insights and ethical concerns in *The Wooing of Earth* (1980): "Global thinking and local action both require understanding of ecological systems, but ecological management can be effective only if it takes into consideration the visceral and spiritual values that link us to the earth." Therefore "ecological thinking must be supplemented by humanistic value judgments concerning the effect of our choices and actions on the quality of the relationship between humankind and earth, in the future as well as in the present" (Dubos 1980, p. 157).

To promote such ideas in the policymaking arena, in 1975 he cofounded what later became the internationally recognized René Dubos Center for Human Environments. For reasons that include his prescient warnings against the overuse of antibiotics to his humanistic perception of environmental problems, Dubos deserves a central place among the foremost twentieth-century scholars of science, technology, and ethics.

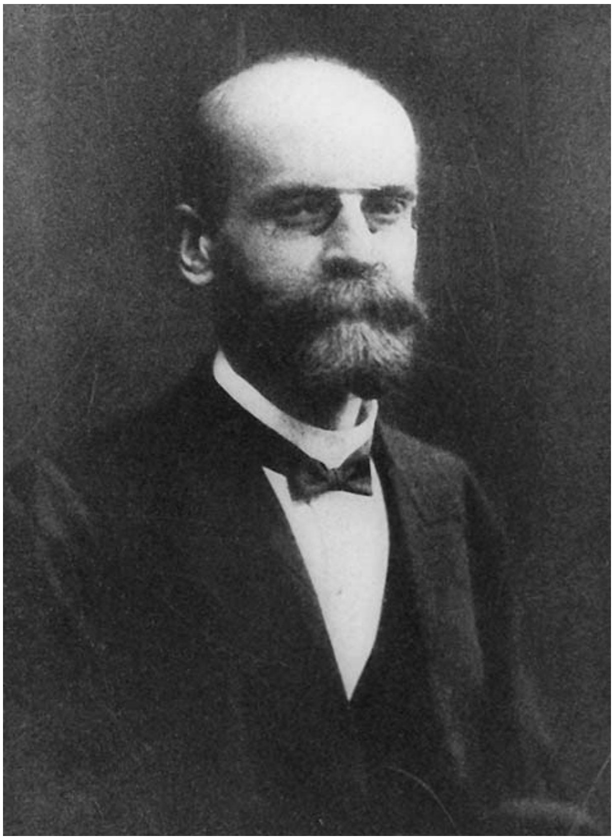
DURKHEIM, ÉMILE

Émile Durkheim (1858–1917), the son and grandson of rabbis, was born in the Alsatian town of Épinal, Vosges, France, on April 15. In 1887 he married Louise Julie Dreyfus, and the death of their son in World War I hastened Durkheim's own premature end in Paris on November 15.



Émile Durkheim, 1858–1917. Durkheim was one of the founders of 20th-century sociology. *(The Library of Congress.)*

In 1870, when Durkheim was twelve, German troops occupied his home during the Franco-Prussian War, forcing him to confront a normless, anomic (unstable) social environment and loss of collective well-being that was later to figure as a theme in his sociological research. He attended the École Normale Superieure (1879–1882), France's best teachers' college, and formed an early friendship with Jean Jaurès (1859–1914), later a leading socialist, which broadened Durkheim's academic and political interests to include philosophy and political action. In 1887 he was named professor at the University of Bordeaux, where he became the first person to teach social sciences in France, and from which he moved to the University of Paris in 1902. As a youth he had been schooled in the traditional education of male Jews, but when still young found himself attracted to Catholic mysticism, eventually dispensing with formal religion altogether. Nevertheless, a deeply religious and ethically alert sensibility shaped virtually all his mature scholarship, though skillfully recast in secular, scientific terms.

Durkheim's central sociological argument, which extends from his earliest to his final works, holds that a scientifically crafted theory of societal morality could prevent the sort of "anomie" that he thought afflicted citizens within France's Third Republic (1870–1940), and that extended as well to all rapidly industrializing nations. He treated this topic in his dissertation, *The Division of Labor in Society* (1893), a book with now almost biblical significance in sociology. Durkheim posed this question: How might morally binding norms be promulgated within a secularized and diversified society? His answer was that such norms would have to be shaped through professional groups, each of which would be responsible for guiding and monitoring the behavior of its members.

Other important works include *Suicide* (1897), which demonstrates that killing oneself is as much a sociological as a psychological event, and *The Rules of Sociological Method* (1895), which points to the "social fact" as the foundation of social research, thus separating sociology from the work of the other social sciences. The book he regarded his masterpiece, *The Elementary Forms of the Religious Life* (1912), is an exhaustive study of aboriginal religious practices compared with their modern progenies. With his nephew Marcel Mauss (1872–1950), Durkheim also cowrote *Primitive Classification* (1903), an innovative study in what came to be called "the sociology of knowledge." Highlighting as examples Australian aboriginals, the Zuni, Sioux, and Chinese, the two authors showed that the contrasting ways different societies arrange knowledge is a direct reflection of their particular forms of social organization; that is, they concluded, mental categories repeat social configurations. This was a direct attack on conventional epistemology, which held that all humans comprehend and analyze their environment in roughly the same way.

What gives Durkheim a unique status in the living tradition of classical social theory is his ability to blend science with ethics, as part of his lifelong effort to create what he called a "science of morality." To twenty-first-century ears this seems a quixotic venture, because science and ethical maxims have been severed one from the other (at least since Max Weber wrote "Science as a Vocation" in 1917, if not before), particularly among researchers whose principal allegiance is to scientific procedure. Yet even in his *Rules of Sociological Method* (still a key text for apprentice sociologists), he showed that identifying "social facts" is never an end in itself, but rather a realist propaedeutic (preparatory study) to understanding how norms operate in various societies, and how deviant behavior is curtailed or controlled.

In a famous essay, "The Dualism of Human Nature and Its Social Conditions," Durkheim invoked "the old formula *homo duplex*," explaining that "Far from being simple, our inner life has something that is like a double center of gravity. On the one hand is our individuality—and more particularly, our body in which it is based; on the other is everything that is in us that expresses *something other than ourselves*" (1973 [1914], p. 152; emphases added). Durkheim's deeply ambivalent relation to "pure" science originates in his divided loyalties as expressed in this essay: On one side stands the scientist looking for "laws" of social life; on the other is the ethicist and philosopher of culture, whose main goal is to identify, albeit via strictly scientific methods, the "something other" that encourages people to lay aside their natural egocentricity and embrace values that often conflict with their own best, individualized interests.

From his earliest work in *Division of Labor* and *Suicide* up through his masterly *Elementary Forms*, Durkheim always sang the praises of modern science and insisted that sociology be imbued with rigorous positivism. Yet never far away from his gaze were the "larger questions" that had troubled ethicists since Plato and Confucius, culminating in Leo Tolstoy's famous question: "What constitutes a life worth living?" To this pressing query, science has no answer, as Durkheim well knew.

In addition to his virtuosic sociological research, Durkheim also established the first scholarly journal of sociology in France, trained an entire generation of anthropologists and sociologists (many of them, along with his son, slaughtered in World War I), and wrote a posthumously published history of education in France that remains a standard work. Given all these scholarly achievements, many argue that Durkheim is indeed the father of modern sociology and the first to lay out in exact terms how the sociological viewpoint differs from that of its allied disciplines.

DUTCH PERSPECTIVES

In the Netherlands, various styles of applied ethical research can be distinguished. They have resulted in "best practices" that formerly regarded each other as competitive, but tend to see themselves as complementary in the early twenty-first century.

Two Preliminary Observations

A first general observation is historical. Twenty centuries ago, the border of the Roman Empire followed the Rhine, thus dissecting the area that later was to become the Netherlands into a southern part (inside the empire) and a northern and western part (outside the empire). This division has written itself into the Dutch cultural landscape in an astonishingly obstinate manner. It is still noticeable today, in terms of dialect, culture, manners, ethics, and religion. Whereas before the onset of secularization the south was predominantly Catholic (that is, oriented toward "Rome"), the north and west were predominantly Protestant.

This difference in cultural geography continues to be visible in the domain of ethics. In the south, ethical research tends to be oriented toward and influenced by

Continental (notably German and French) intellectual developments and trends. Thus, ethicists from this area are influenced mainly by hermeneutical or phenomenological approaches. Ethicists from the northern and western part, however, are more likely to be influenced by analytical approaches and debates. They often subscribe to theories and views that dominate the Anglo-American spheres of influence. Although the difference has become less obvious than it was in the 1980s, the two ethical profiles remain distinguishable.

A second observation has to do with the international status of Dutch ethics. It has been said that Dutch philosophy is the philosophy of the country that possesses the largest harbor in the world, namely Rotterdam (Nauta 1990). And because ethics is a special discipline within the broader field of philosophy, this goes for ethics as well. What does it mean? One might say that Dutch ethicists are better at importing and exporting than at producing philosophy. In terms of style, the Dutch are neither as "profound" as the Germans nor as sensitive to new trends as the French. They do have a special talent, however, for intellectual transfer. Their mastery of international scholarly languages such as English, German, and French also plays a role here. Dutch philosophers often serve as intellectual intermediaries. This is, of course, a generalization, but a systematic review of academic performance will show that as a rule the Dutch tend to focus on assessing, processing and connecting ideas rather than on originating them.

Three Styles of Ethical Research

Three styles of ethical research exist in the Netherlands. They start from different understandings of what ethics is.

(1) ethics = analyzing and solving moral problems

(2) ethics = intellectual reflection

(3) ethics = moral conflict management

According to the first option, which is based on a more or less Anglo-American approach, an ethicist is someone who analyzes moral problems and formulates possible solutions, usually by applying a set of moral principles (ethical input) to problem cases (solutions as output).

The second option reflects a more hermeneutical or Continental way of thinking. An ethicist is seen as someone who tries to interpret certain forms of moral discourse by situating them in a broader cultural and historical perspective. The focus is on understanding, rather than on solving, problems. The philosophical ethicist works toward a "diagnosis" rather than a "solution."

The third option entails a more pragmatic approach. The ethicist identifies stakeholders and value perspectives, and works toward consensus formation, based on stakeholder participation, by means of interviews, workshops, and similar techniques.

These three ways of doing ethical research entail different views on the relationship between expert knowledge and public knowledge. According to the first option, ethicists are experts, perhaps even "ethical engineers" (Van Willigenburg 1991). They have learned to analyze moral problems in a professional manner. Consistency is important, even if this means that ethicists distance themselves from common intuitions and conventional morality.

According to the second option, however, the ethicist's expert knowledge is knowledge of moral traditions, of types of discourse, or of fundamental cultural attitudes that are noticeable in the ways in which moral debates evolve and problem cases are being framed and presented (Van Tongeren 1994). The ethicist relies on erudition rather than analytical tools. The attention is directed toward fundamental issues rather than concrete problems. In other words, the problem cases at hand are regarded as exemplifications of broader, cultural issues.

According to the third option, it is not the ethicist's job to add new insights, but rather to build on the knowledge, values, and intuitions of the stakeholders involved. Rather than performing desk research, the ethicist enters into dialogue with others, inviting them to articulate and clarify their (tacit) views. The ethicist's expertise is of a pragmatic and intermediary nature (Keulartz et al. 2002). Ethicists have at their disposal a toolbox for moral deliberation and moral conflict management. Their input in the decision-making process does not come from ethics as such, but from the views and experiences of stakeholders themselves.

Through the late 1990s, the first style of doing ethical research dominated (the public image of) institutionalized ethics in the Netherlands, whereas the second style was more prevalent in academic circles. Since the early 2000s, the pragmatist approach is gaining ground. In fact, Dutch ethicists tend to be flexible when it comes to method in the early twenty-first century. To some extent, they are willing and able to use all three models, depending on context. Congenial with the pragmatist turn, but not exactly identical with it, is the *empirical turn* in ethics. More and more often, research in applied ethics involves the collection of empirical data and the use of tools borrowed from the social sciences such as interviews, questionnaires, and participant observation.

Ethics of Science and Technology: Examples

In the Netherlands, as elsewhere, moral disputes tend to arise in response to technological changes. Initially, the growing interest in ethical research was associated with medical or clinical ethics. An interesting case is the famous Dutch euthanasia debate that started around 1970 in response to the dramatic increase of medical technology and therefore of treatment options with which many lives, that previously would have had no chance of survival, could now be saved, or at least prolonged. The debate was triggered by Jan Hendrik van den Berg (1978), a physician who was also trained as a phenomenologist, and therefore a representative of Continental philosophy. Moral problems involved in end-of-life decision were interpreted as indications that something was fundamentally wrong with current views and attitudes toward life and death *as such*. Soon, however, the debate was taken over by applied ethicists who subscribed to an analytical approach. On the basis of the principle of autonomy, they argued in favor of the patients' right to refuse treatment or even to request that physicians end their lives. Eventually, the ethical debate over euthanasia shifted toward a more pragmatic and empirical approach: How are end-of-life decisions actually taken, and by whom, how often, and on what grounds? Last but not least, what kind of technical contrivances co-influence decisions of this type?

During the 1990s, the attention of professional ethicists in the Netherlands drifted away from euthanasia. Reproductive technologies, biotechnology, genetic modification of organisms, and animal research became important items of concern. Even more so than in the case of medical ethics, moral disputes arose in response to technological change. These debates thus exemplified the ways in which technological developments influence ethical controversies. After the introduction of recombinant DNA techniques in the 1970s and 1980s, the genetically modified research animal became an important object of research, and knockout experiments (deleting genes) became an important research tool.

This new technology had a major impact on ethical debates concerning laboratory animals. It caused the focus of the debate to shift away from traditional concerns (animal suffering and animal welfare) to issues involved in the recently acquired power of biologists to modify—to *change*—their laboratory animals, and to adapt them to research requirements. Concepts such as integrity and intrinsic value, borrowed from medical and environmental ethics, respectively, were used to articulate new moral concerns over genetic engineering.

Furthermore, the three styles of ethical research distinguished above are recognizable here as well, although demarcations are somewhat less rigid than before. The majority of contributions to animal ethics and biotechnology ethics since 2000 adhere to a more or less analytical approach. Their usual aim is to enrich a traditional, consequentionalist view (focusing on animal welfare and animal suffering) with deontological elements, using concepts such as integrity and intrinsic value (Heeger and Brom 2001). A more Continental and phenomenological approach, however, is represented here as well. Its aim is to elucidate the different ways in which animals are perceived. Thus, the scientific understanding of animalhood is confronted with life-world perspectives and artistic perspectives. In other words, this line of research studies the various conditions under which relationships with animals (notably in the context of research practices) evolve (Zwart 2000). Finally, promising examples of empirical and pragmatic approaches have begun to enter the animal ethics scene as well.

Early Twenty-First-Century Developments

Genomics, the most recent chapter in the history of the life sciences and their technological applications, is what occupies the majority of ethicists in the Netherlands in the early twenty-first century. The basic trend is toward establishing large, multidisciplinary programs in the domain of ethical, legal, and social issues (ELSI) research. In the context of such programs, ethicists (of various styles and backgrounds) collaborate, not only together, but also with experts coming from various other disciplines, such as the social sciences, psychology, cultural studies, communications, economics, and law. This trend is sometimes referred to as the "elsification" of science and technology.

During the 1990s, the focus of applied ethicists tended to be on the individual or institutional level (the micro- and meso-level) rather than on the societal (or macro-) level. The empirical turn in ethics likewise tended to restrict itself to research on a relatively small scale. But in the early 2000s it became clear that the most challenging issues involved in so-called "enabling technologies," such as genomics, will present themselves on a much broader, cultural, and societal scale. Rather that providing information on discrete monogenetic defects (relevant for specific target groups), for example, genomics is expected to inundate the public realm with genetic information on multifactorial health risks that will be relevant for virtually everybody.

Although the ethics of science and technology in the Netherlands tends to focus on the life sciences and biotechnology, and on genomics in particular, this is but one example of "enabling technologies" that are emerging in research laboratories in the early twenty-first century. Other technologies, notably Information and Communication Technologies (ICT) and nanotechnology, are items of concern as well (Van den Hoven 1999; De Mul 1999). They are regarded as enabling technologies in the sense that they will give birth to a wide variety of applications. As ethical debates tend to reflect technological developments, the agenda of ethics will no doubt continue to orient itself toward these three major scientific and technological breakthroughs of the past and coming decades.

Genomics, ICT and nanotechnologies will give birth to a wide variety of new and yet unanswered questions. How will new technologies in these fields change existing roles and responsibilities of professionals and citizens? How can the knowledge and information that is generated in these fields be evaluated and used; how can abuse be prevented? In answering these questions, ethicists will find themselves no longer alone, but in the company of (in particular) scholars from Science and Technology Studies (STS) and from the Philosophy of Technology (who often are members of the STS community in a broader sense).

STS scholars study the ways in which science and technology are intertwined (in terms of content and organization, but also socially) with the development of modern societies and cultures. Science and technology are regarded not as the producers or influencers of society and culture, but both science and technology on the one hand and society and culture on the other are seen as interacting with one another and as *co-producing* one another. While STS formerly focused on the deconstruction of epistemological claims, thereby underpinning the idea that there are different ways to perceive nature or reality, the field in the early 2000s tends to move towards a more normative and hence ethically oriented approach. Constructive Technology Assessment (CTA) for example, geared towards the "management of technology in society," aims at early feedback and learning cycles in the development of new technologies, particularly with respect to the societal use and entrenchment of new technologies (Rip et al. 1995, Schot et al. 1997).

The ambition of STS scholars to put on the agenda the political question "how to help shape the technological culture we live in" has influenced the landscape of STS into a more normative direction (Bijker 1995 among others). Large technological "projects," and the transformations they are expected to induce, such as nanotechnology, genomics, and ICT, thus have increased the interest for ethical and normative questions from different fields and disciplines. Ethical questions have become the domain of an interdisciplinary research field. Put differently, "elsification" (entrenchment of ethical, legal and social projects in large technological programs) has enhanced new forms of ethical research, characterized by interdisciplinary collaboration, proximity to scientific consortia, and sensitivity to social change. The development of new interdisciplinary modes of doing ethical research also gives rise to new networks and institutions. Interesting examples are Nanonet and the establishment of the Centre for Society and Genomics (CSG) at the University of Nijmegen.

Institutionalization

It is to be expected that in the near future collaboration between philosophers and ethicists on the one hand and social science researchers on the other will continue to increase. At the moment, they still can be seen as separate domains. Research in the Netherlands is organized on the basis of research schools that assemble experts from various universities into common programs. With regard to research into the societal aspects of science and technology, two research schools are particularly relevant: the Onderzoekschool Ethiek (the Netherlands School for Research in Practical Philosophy) and the Onderzoeksschool Wetenschap, Technologie en Moderne Cultuur (the Netherlands Graduate Research School Science, Technology, and Modern Culture, WTMC). Both research schools were established in 1994. In the Netherlands School for Research in Practical Philosophy the analytical style is dominant, but pragmatic and Continental approaches are represented as well. Methodology and epistemology of ethics have been important issues from the very outset, and the "empirical turn in ethics" is a major item of concern. The Netherlands Graduate Research School Science, Technology, and Modern Culture brings together researchers from the interdisciplinary field of science and technology studies (STS). In the Netherlands, STS emerged in the late 1960s as a result of new interactions between history, philosophy and sociology of science. The focus of WTMC is on the interrelatedness and interpenetration of science, technology, and society. The membership list of WTMC indicates that the school recruits scholars from the sociology of science, history of technology, philosophy of technology, philosophy of science, arts and culture, psychology, political sciences, science dynamics and policy and innovation studies.

Although demarcations in terms of style have become less obvious than in the past, the Netherlands School for Research in Practical Philosophy is dominated by ethicists who come from an analytical background, although Continental and phenomenological approaches to technology are present as well. The Netherlands Graduate Research School Science, Technology, and Modern Culture is oriented more toward pragmatism and constructionism. Yet, as was already noticed, within the Dutch STS community, interest in normative (ethical) issues has increased in the past five years. See for example Verbeek (2003), who analyzes the ways in which artifacts influence human experience, while new technologies are interpreted as material answers to ethical questions.

The Future

Until recently, bioethics and the philosophy of technology were seen as separate fields. As has been indicated, this will no longer hold in the near future. Bioethics increasingly will have to regard itself as an ethics of science and technology. A broader understanding of the coevolution of science and technology thus will have to become an integral part of bioethics. The emphasis (within applied ethics and bioethics) on the micro-level will shift towards the development of science and technology *at large* and towards ethical and philosophical questions concerning the role of science and technology in modern societies. The focus on (and the interest for) the moral aspects of (for example) the interaction between physicians and patients, or between laboratory researchers and laboratory animals, will be increasingly overshadowed by the need to address the social dynamics of technological change. These broader issue will dominate the future agenda of bioethics, applied ethics and—as it often does already—the philosophy of technology.

Ethics can be expected to broaden its perspective and become an increasingly interdisciplinary endeavor. And while ethicists will "discover" the importance of the broader social and cultural impact of technological innovations, social scientists already working on these questions will increasingly acknowledge the importance of the normative issues they tended to avoid in the past.

EARTH

In science and philosophy earth (German *Erde,* Greek *ge*) can refer to one in a set of primordial material elements (earth, air, fire, and water, for the Greeks; wood, fire, earth, metal, water, for the Chinese) and to the physical body on which humankind lives. As physical home, the Earth serves as the reflective horizon or framework for human self-awareness and as a contingent unity among the array of individual entities they encounter. The Earth, defined by an elemental earthiness of rock and soil, is that which grounds the identity of humans in both physical and psychological senses, independent of wherever they may venture in information networks or outer space, while serving as a fund of resources available for exploitation. The tensions between these various approaches are imaged in the diagrammatic icon of the atom and the photo of the blue planet taken from space: matter that is mostly space and a life-giving sphere that appears more water than rock and calls perhaps for technological management.

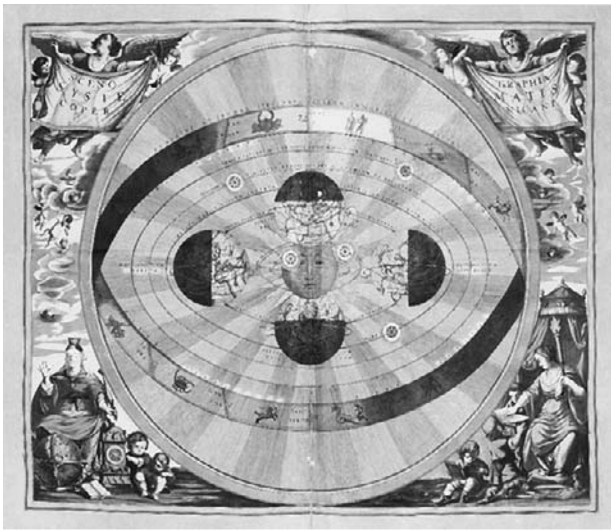
Earth Science and Engineering

As soil and matter, earth has become a distinctive object for science and technology. The material out of which all things are made has itself become subject to chemical processing, synthesis, and nuclear engineering. The scientific study of matter existing independent of humans has expanded to examining those new forms of matter intentionally and unintentionally designed by humans and the interactions between the two, especially insofar as they may impact on humans themselves. As a planet the Earth is a body in space with a stable orbit at a distance from the sun suitable for the origin and evolution of life. During its 4.56 billion years the Earth has given rise to an abundance of organisms, first in the sea, and then diversifying and evolving to occupy land and air. As recipient of heat energy from both the sun and its own core, the Earth is a site of dynamic terrestrial behavior. The seven major tectonic plates comprising its rocky outer crust diverge and then compensate through convergence; its land masses, ocean basins, islands, and other prominent features such as volcanoes, mountains, plains, and valleys have gone through continual development—producing new materials essential of life and humans. Hominids appeared on the Earth 7 million years ago and Homo sapiens about 200,000 years ago. Humans began to till the Earth about 10,000 years ago.

This early-twenty-first-century perspective on earth and the Earth sees them as dynamic complexities inviting examination and provoking manipulation. Especially with regard to the Earth, it is now perceived as a nexus of interactions between the solar system and its own atomic and subatomic foundations, as well as of exchanges between its own landmasses, oceans, atmosphere, and living organisms. Through earth system science these have in turn become, because of human technological powers and their commercial development, also subject to speculative engineering management. Earth system science is complemented by the possibilities of earth systems engineering and thus challenged to reflect ethically on both ends and means.

Philosophies of the Earth

The Earth has throughout human history been a focus of philosophizing, central to ethics, and a framework for self-understanding. For the Greeks, the Earth was implicated



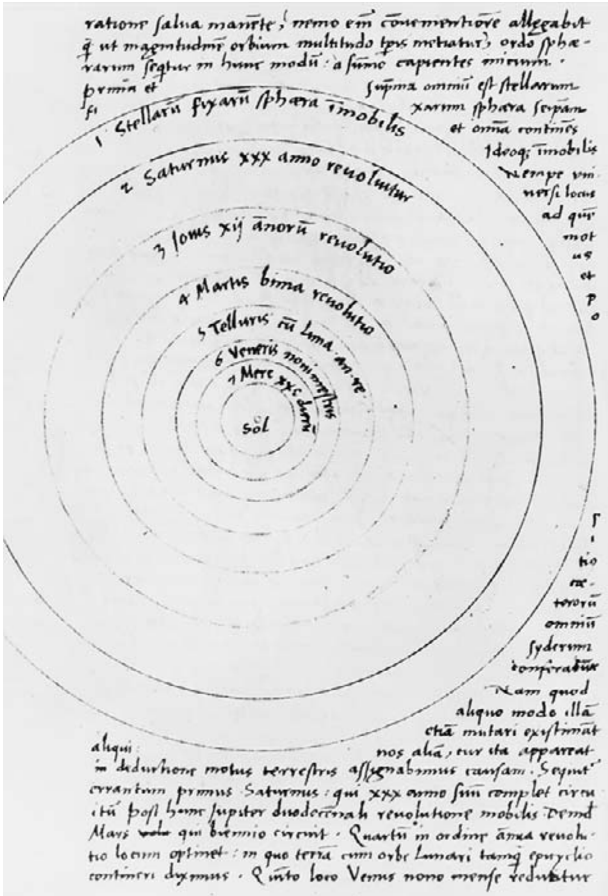
A print by Andea Cellario entitled "Harmonia Macrocosmica," showing the Ptolemaic system. Proposed by Claudius Ptolemy in the 2nd century A.D., the system postulated that the earth was at the center of the universe, and was accepted for more than 1000 years. *(© Enzo & Paolo Ragazzini/Corbis.)*

in their cosmology not only as planet and home of humanity, as focus of the gods who lived above its plane, and in relation to the heavens; its core constituent, earth, was also one of the four elements, earth, water, air, and fire. The Earth itself was a compound of the four elements. For the Chinese, the earth and heaven are the two forces responsible for engineering and completing nature and all its aspects. Earth and heaven also work together to create the five Chinese elements: wood, fire, earth, metal, and water. As an element, the Earth is located at the center and is the cauldron, with the other four elements located in the four outer directions, east, west, north and south. Earth is also the element of the "naked" animal, the human, of the actions is representative of "thought." The element earth is also associated with the sense of touch, the sound of singing, the organ of the spleen, and the virtue of good faith. There have been two related controversies about the place of the Earth within cosmological, metaphysical, and ethical visions: whether the Earth is the center of a given scheme of existence or is only an element in a vaster cosmos, and whether the earth is a site of corruption at a distance from a purer realm or is a unique locus of corporeal and spiritual development.

Plato approaches both issues in his atypical dialogue, the *Timaeus*. He describes an original Demiurge who takes the elements of earth, fire, air, and water and "out of such elements which are four in number, the body of the world was created, and it was harmonized by proportion, and therefore has the spirit of friendship; and having been reconciled to itself, it was indissoluble by the hand of any other than the framer" (33, c). This picture of the Earth as a model of balance, harmony, and fairness is complemented by a *world soul* infusing the world with a vitality and rationality of fair proportion: "The world became a living creature truly endowed with soul and intelligence by the providence of god" (30, c). The Earth as an entity in the cosmos is described as located at the center and surrounded by the moon, the sun, and five planets in circular orbits. This picture from the *Timaeus* is opposed by another from the *Phaedo*. There Plato writes of the "earth and the stones and all the places [as] corrupted and corroded, as things in the sea are by brine so that nothing worth mention grows in the sea, and there is nothing perfect there, one might say, but caves and sand and infinite mud and slime wherever there is any earth, things worth nothing" (110, b). He condemns the passions and senses for "nailing" people to the Earth that, by its attractive power, can "drunkenly" estrange human souls from their true home in the aether beyond (83, d). His emphasis on the immaterial nature of the soul and its kinship with the intelligible structure underlying reality leads to a condemnation of the earthly as tempting snare.

Aristotle, by contrast, observes the Earth and catalogues its differences in beings—animate and inanimate—embracing "the delight we take in our senses," especially the sense of sight as indicating that "this, most of all the senses, makes us know and brings to light many differences between things" (980, a). His vision of the Earth as a nexus of beings defined by their *for sake of which*—their purpose as fully actualized—working in concert with other beings' drive to actualization, renders a grandeur to the dynamism and wholeness of the Earth and the totality of its excellences fully realized. His cosmological vision in *On the Heavens* further emphasizes this foundation status because "the earth does not move and does not lie elsewhere than at the center." Aristotle's placing of the Earth at the center of the cosmos around which the sphere of the fixed stars daily rotates, carrying with it the spheres of the sun, moon, and planets, is the authority cited by Ptolemy (85–165 C.E.) in working out his plan of the Earth in relation to the heavens.

The shift in perspective known as the Copernican Revolution began when the Polish astronomer Nicolaus Copernicus (1473–1543) wrote his *Little Commentary* (1514). He argued that there was no one center to the universe, the Earth's center is not the center of the universe, the rotation of the Earth accounts for the apparent daily rotation of the stars, and the Earth revolves in a vast space. These ideas helped inaugurate the thinking that Galileo Galilei (1564–1642) would confirm a



Page from Copernicus's *De Revolutionbus Orbium Coelestium*, showing a sun-centered solar system. This conception of the universe represented a historical shift in thinking from an earlier view in which the Earth was seen as the center of the cosmos. *(© Hulton/Archive. Reproduced by permission.)*

century later. This philosophy not only displaced the Earth from its central position in religious cosmologies, but made the planet itself into a composite of more basic materials to be analyzed and manipulated.

The Cartesian method of analysis led several European scientists in the 1860s to articulate how the basic constituents of all chemical compounds could be broken down into their simplest components. These elements, as measured and compared by their atomic weight, were arrayed in a chart, the periodic table, that both presented them sequentially (giving them an atomic number based on their atomic mass) and grouped them according to their electron configuration, which gives them similar chemical behavior such as the group of inert gases or that of alkali metals, for example. The table as presented in 1869 by the Russian chemist Dmitrii I. Mendeleev is still used with little revision other than filling in spaces left blank for predicted new elements.

Earths and Ethics

The approach to earth as a composite or collection of discrete units has informed one dominant modern philosophical perspective. Seen in terms of external relations among material constituents, this perspective tends toward a utilitarian approach to ethical problems. If the greatest number of people benefit from some alteration or use of an environment, or if some part of the environment which occurs naturally can be functionally replaced through technological advance, then utilitarianism allows for these alterations of the earth, even if they might involve a diminution in its diversity or degradations in its ecological viability. This approach has nevertheless promoted the rights of excluded social groups in arguments for environmental justice, as well as suggested that animals have rights as part of the earth (Singer 1990).

A contrasting philosophical perspective contends that the Earth has a distinct holistic identity, perhaps inseparably intertwined with the collective identity of humanity. Explorations of this option often rely on James Lovelock's *Gaia: A New Look at Life on Earth* (1979), in which he posited the Earth is an evolving, self-regulating organism. In this view, the planet through its temperature, gaseous constituents, minerals, acidity, and many other factors maintains a homeostasis by active feedback processes operating in the biota. Other philosophical views, while not seeing the planet itself as a living being, do envision human identity as internally related to aspects of the earth in such a way that these relationships themselves constitute the identity of both, such as in the work of Arne Ness, Dave Abram, Glen Mazis, or Freya Matthews. From such a perspective a utilitarian ethics fails to adequately safeguard either the Earth or humanity and all those parts of the biosphere due respect for their intrinsic work.

Returning to the question of the Earth as the horizon for humanity's sense of meaning and purpose, one path in philosophy is that first proposed by Friedrich Nietzsche in *Thus Spoke Zarathustra* (1883) and its claim that the nihilism of modern culture can only be undercut by a reevaluation of values and a reidentification of humanity as no disembodied spirit but as an animal of passion, body, sensuality, *and* reason—whose greatest challenge is to create value and meaning while obeying the injunction to "remain faithful to the earth." Edmund Husserl called the Earth the *foundation* [*Boden*] of the sense of being human and likened the planet to an ark that would always be with humanity as its abiding sense of identity no matter where humanity ventured.

For Martin Heidegger, humans open up a horizon for meaning and purpose through the way that art and other institutions open "the strife between earth and world," as he articulated in "the Origin of the Work of Art." The artist, like other creators, must initiate a dynamic struggle between the context of meaning and value, which makes up the "world" of various epochs and cultures with the opacity and resistance of the sheer materiality of the earth. The earth both anchors and occludes this birth of meaning, so it is literally "grounded" and yet never fully fathomable, but suggestive. In his analysis of the elements fire, water, air, and earth, Gaston Bachelard saw the Earth as the dimension which gives humanity a *rootedness,* and a sense of infinite depth, as well as a resistance against which meaning is forged in action. The resistance of the earth is the "partner of the will." Humans are motivated to create and shape in response to the earth. Differing visions and temperaments respond to the continuum of earth in its span from hardness to softness. Humanity is motivated to forge the earth into creations as well as struggle against earth's gravity towards flight.

Increasingly, too, there is a growing interchange of Western philosophy with global philosophical perspectives that suggests the inseparability of humanity and earth. These ideas include the Buddhist emphasis on the ontological interdependence of all living and nonliving beings expressed through the concept of "emptiness," which might be better evoked as the relativity among all beings, as well as the depiction of the Buddha's original inspiration to seek enlightenment after shedding tears at seeing the worms and insects cut up by the plows making furrows in the fields with the same grief he would have had for the death of his family. There is the Daoist sense of *nonacting* [Wu wei] in which the beings of the Earth act through humans or as the Way [Dao] itself is the dynamic interplay of the entities of the Earth—"the ten thousand things"—as well as the Earth itself as a larger field of energy. Within North America, there is the Native American sense that all beings are part of Mother Earth or the Great Spirit, living on *turtle island,* the community of two-legged, four-legged, and all other beings of the four directions.

A challenge ahead is whether these philosophical perspectives can integrated with earth system science and engineering at the micro and macro scales in which they are now being practiced in order to give some basis for ethical decision making and a coherent perspective.

EARTHQUAKE ENGINEERING

Earthquake engineering is the collective effort of earth scientists, geotechnical engineers, structural engineers, and public policymakers to provide a built environment that is safe in the event of an earthquake. A significant part of this effort and the focus here is related to structural engineering, which involves the design and construction of structures and the anchorage of nonstructural building contents. Additionally structural evaluations and targeted retrofit of existing structures can be utilized to mitigate the risk of human and economic loss from an expected maximum probabilistic earthquake at a given site due to building collapse, loss of building contents, or economic downtime. Earthquake engineering thus constitutes a case study in specific relations between science, technology, and ethics.

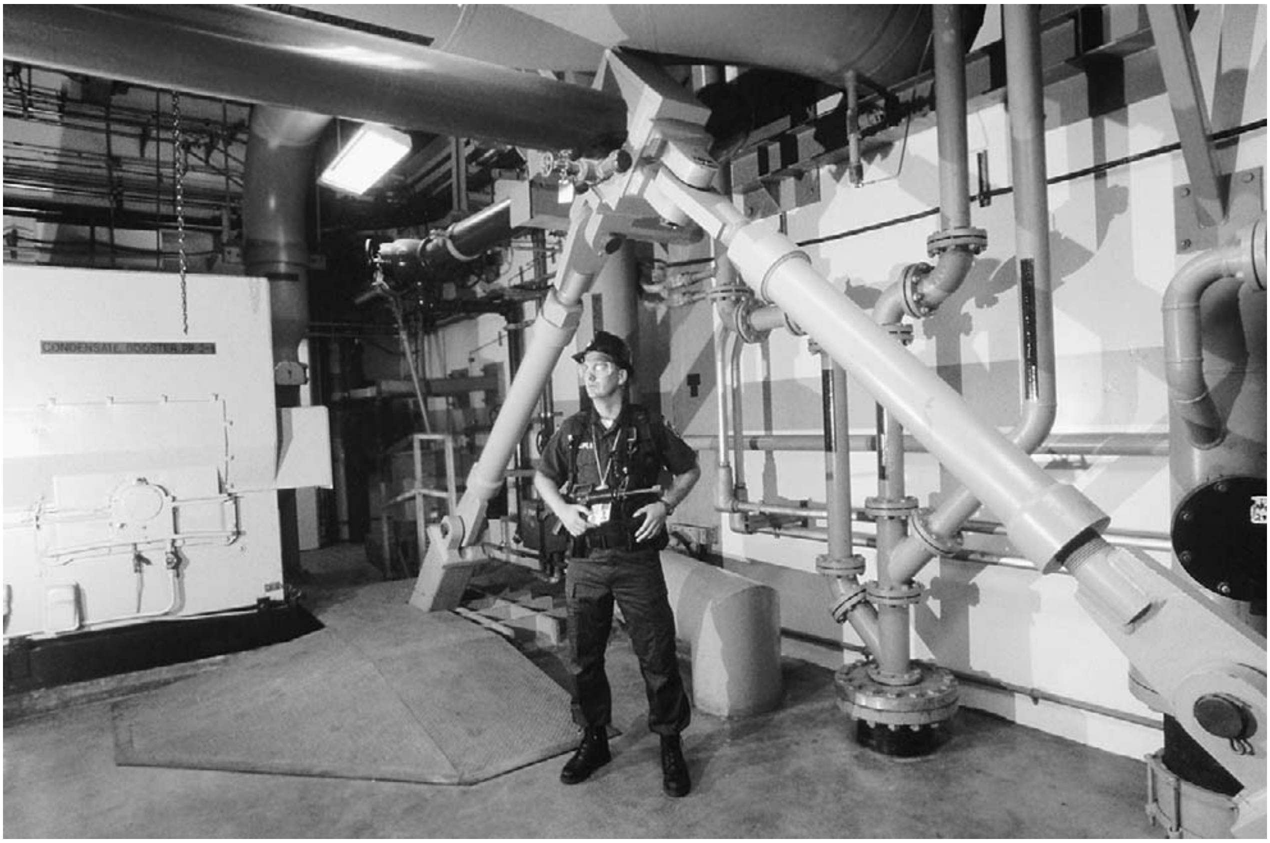
Historical and Technical Background

Interest in constructing buildings to provide greater resistance to earthquakes arose in association with the scientific and professional development of engineering, especially from the late 1800s and early 1900s, in response to large earthquake damages that occurred in Japan, Italy, and California. For instance, the earthquake near San Francisco, in April 1906 (magnitude M = 7.8 on the Richter scale, 3,000 fatalities) destroyed structures in an area 350 miles long by 70 miles wide, and was the most expensive natural disaster in U.S. history until hurricane Andrew in 1992, with $500 million in damages (equivalent to $10 billion in 2004 dollars).

In order to defend investments and continue growth, initial press reports from San Francisco minimized the quake itself and focused instead on the fires started by downed electrical wires, cracked gas lines, and broken stoves (Geschwind 2001). Yet shaken by this and related events, California has become one of the most progressive states in the public reduction of earthquake risk through engineering design. More recent major losses in August 1999 in Izmit, Turkey (M = 7.6, 17,000 fatalities); January 2001 in Gujarat, India (M = 7.7, 20,000 fatalities); and December 2003 in Bam, Iran (M = 6.6, 43,000 fatalities) have promoted recognition of the need to deal systematically with earthquakes in the regions affected.

Despite the length of time since public attention was first drawn to earthquake risks, earthquake engineering remains a young science because of the relative infrequency of large quakes and the tremendous number of variables involved. Since the 1960s, earthquake-engineering development has made important progress by moving to incorporate knowledge from the pure geosciences with structural engineering, moving even toward multidisciplinary efforts to include sociology, economics, lifeline systems, and public policy (Bozorgnia et al. 2004). The scientific study of earthquakes or *seismology* is also relevant (see Bolt 1993).

Complete or partial structural collapse is the major cause of fatalities from earthquakes worldwide; earthquakes themselves seldom kill people, collapsing buildings do. Earthquake energy causes structures not sufficiently designed to resist earthquakes to move laterally. At this point, a building may lose its load carrying capacity and collapse under its own weight. Portions of buildings (such as roof parapet walls) or the interior nonstructural contents (refrigerators, bookshelves, and so on) can topple onto inhabitants inside or outside the building. Directly adjacent buildings can pound into each other, serving sometimes to stabilize each other when neighboring structures are on both sides (termed bookends) or to cause additional damage if a neighboring structure is on one side only or the floors do not align. Buildings on corners of city blocks are known to perform poorly, being pushed into the street due to one-sided pounding. Tsunamis, or tidal waves triggered by seafloor seismic movements, are another source of damage. Fires can be initiated from broken gas or electrical lines. Water saturated soil can lose its strength during dynamic shaking, and landslides or soil liquefaction may cause buildings to slide, be buried, or sink as if into quicksand.



A security officer stands next to a seismic brace inside the Diablo Canyon Nuclear Power Plant. Braces like these are representative of the technological advances in earthquake engineering. *(© Roger Ressmeyer/Corbis.)*

To affect a structure, earthquake energy must first transmit through the bedrock from the *epicenter*, or the fault rupture location, through the soil above the bedrock (if any), through the foundation system, and then up through the building itself. All of these elements between the epicenter and building structure affect the level of lateral force (termed *base shear*) used for structural design. Frequency of ground motion can vary with distance from the epicenter, directivity, type of fault rupture, and magnitude. In the United States, the U.S. Geological Survey (USGS) maintains probabilistic earthquake demand topography maps based on statistical analyses of seismicity, referenced by building codes and design standards and used by structural engineers for design.

Engineering judgment, based on experience and observation of damage during past earthquakes, is relied on heavily in approximating earthquake demand, structural analysis, and overall structural design. Geotechnical engineers determine site soil conditions and site-specific seismic hazard. Structural engineers model the structural mass and stiffness, or how much a building moves when pushed laterally, based on the earthquake-resisting structural system used in design. Dynamic force and displacement limits are assumed based on structural detailing of connections and experimental testing results. Though material standards are used to set minimum criteria for material properties, there still exists some variability in material strength and ductility, requiring designing for a range of properties. Due to these many variables, two identical structures at different locations may require quite different earthquake-resisting systems.

After an earthquake, it is often difficult to know immediately if a building is severely damaged. The structure is typically covered by finishes, suspended ceilings, and fireproofing that need to be removed for visual investigation of connections, cracking, and other damage. In the United States, structural engineers may travel thousands of miles to aid in the initial building tagging and reconnaissance efforts, to quickly assign a red (no entry, evacuate), yellow (limited entry), or green (functional) placard at the entrance points. Developments in instrumentation have allowed for real-time building motions to be streamed over the Internet, which facilitates accuracy in initial tagging, but visual observation remains the primary basis for evaluation. In the case of a large office building, red tagging means the loss of weeks or months of revenue. In the case of hospitals and emergency response centers, a decision to evacuate means disruption of critical care during an emergency situation, increasing the death rate. For such reasons, engineers have an ethical responsibility to be extremely careful about a recommendation to evacuate a damaged building.

As architecture, construction materials, technology, and economics of construction evolve, seismic engineering evolves as well. Assumptions made during design are put to the test in future earthquakes, both validating previous thinking and exposing flaws. After the January 1994 earthquake in Northridge, California (M = 6.7, 60 fatalities, $40 billion in damage), it was found that many steel beam-to-column connections in relatively new structures had fractured at yield stress in buildings across the city, much different than the ductile behavior assumed in design. The structural engineering community initiated a six-year research project funded primarily by the U.S. Federal Emergency Management Agency (FEMA) to determine the cause of the poor performance, devise repair schemes, determine new design procedures that would produce desired ductile behavior, and modify building codes to avoid similar failures in future earthquakes (SAC 2000).

Building Codes, Economics of Construction, and Seismic Loss

In general the purpose of building codes is to protect public safety. But building codes and design standards, like the structures and societies in which they exist, are not permanent static entities, but dynamic and evolving to meet the demands and knowledge of changing times.

To minimize construction costs, building codes function as minimum requirements to permit damage from an earthquake but prevent collapse of the main structure, structural attachments, or contents. New buildings are expected to be repairable after a major earthquake, but some may be too costly to repair. Engineers have a responsibility to inform clients that building codes are not intended to preserve a structure, but do provide opportunities to increase the structural capacity or add special elements such as supplemental energy dissipation devices (viscous dampers and friction dampers, among others) or base isolation to reduce damage permissible by design codes.

Building owners are thus able to increase a building's earthquake *performance level* if they are willing to pay the additional construction and design costs. Generally, however, it is difficult to sell higher performance engineering and construction costs to owners in the United States. In Japan and New Zealand, by contrast, higher performance structural elements are more frequently used. Building codes increase earthquake demand for critical structures, such as hospitals, schools, and communications hubs, with the intent that less damage occur during a major earthquake allowing the structure to remain operational afterward. In capitalist societies, history has shown that either economic incentives (tax breaks) or the threat of a facility being closed are often required to make building owners decide to retrofit. Both tactics are used in California (Geschwind 2001).

It is cheaper by far to allow for seismic forces during initial design than to incur damage or to retrofit later. Considering seismic forces initially may increase construction costs by 2 to 5 percent. Retrofit costs are typically on the order of 20 to 50 percent of original construction costs, excluding design fees and business interruption costs (Conrad 2004). Though seemingly inexpensive in comparison with the potential loss of the entire structure, there is major resistance to a 5 percent increase in construction cost from building owners, developers, and engineers not familiar with seismic design, especially in areas where the earthquake return period is longer than 100 years, when building codes (as in the United States) assume the typical building life to be fifty years. The area along the Mississippi River between St. Louis, Missouri, and Memphis, Tennessee, experienced three magnitude 7.8 to 8.1 earthquakes in 1811 and 1812, which reportedly moved furniture in James Madison's white house and rang church bells in Boston, yet many in the local communities maintain that designing for earthquakes is too costly. Money not spent on seismic retrofit for public facilities could theoretically be spent on the salaries of police and teachers, better hospital care, highway upgrades, and social programs. However probabilistic risk analysis demonstrates that ignoring earthquakes in design is often much more costly in the long run than short-term benefits of construction savings or budget reallocations.

In addition to loss of life, earthquake damages can significantly affect the local and world economies. The January 1995 earthquake in Kobe, Japan (M = 6.9, 5,502 fatalities) caused more than $120 billion in economic loss. It is estimated that a similar earthquake in a major metropolitan area in the United States could result in a comparable loss (House Committee on Science, Subcommittee on Research, 2003). In the United States, earthquakes pose significant risk to 75 million Americans in 39 states. Averaging single event losses over the time between events, total annualized damages in the United States have been estimated at approximately $4.4 billion (House Committee on Science, Subcommittee on Research, 2003). When industrial transportation and utility losses are considered,

TABLE 1

Magnitude and Intensity of Significant Earthquakes

Date	Time (GMT)	Place	Latitude	Longitude	Fatalities	Intensity	Magnitude
January 23, 1556		Shensi, China	34.5	109.7	830,000	–	~8
November 1, 1755	10:16	Lisbon, Portugal	36.0	−11.0	70,000	–	~8.7
December 16, 1811	08:00	New Madrid, MO, USA	36.6	−89.6		–	~8.1
January 23, 1812	15:00	New Madrid, MO, USA	36.6	−89.6		12	~7.8
February 7, 1812	09:45	New Madrid, MO, USA	36.6	−89.6		12	~8
August 31, 1886	02:51	Charleston, SC, USA	32.9	−80.0	60	–	~7.3
June 15, 1896	19:32	Sanriku, Japan	39.5	144.0		–	~8.5
June 12, 1897	11:06	Assam, India	26.0	91.0	1,500	–	~8.3
April 18, 1906	13:12	San Francisco, CA, USA (San Andreas fault from Cape Mendocino to San Juan Bautista)			3,000	11	7.8
August 17, 1906	00:40	Valparaiso, Chile	−33.0	−72.0	20,000	11	8.2

SOURCE: U.S. Geological Survey, Earthquakes Hazards Program. Available from http://earthquake.usgs.gov; National Geophysical Data Center. Available from http://www.ngdc.noaa.gov/seg/.

Earthquake Intensity is a measure of earthquake size based on observed damage of buildings and other structures on the earth's surface. Intensity is measured on a scale of 1 to 10+, with 10+ representing the most damage. Intensity is a different measurement than earthquake Magnitude, a measure of the strain energy released over the area of fault rupture. Magnitude is not a linear scale; each 1.0 increase in magnitude number represents greater than a factor of 30 times total energy released. Values of Intensity and Magnitude do not numerically correlate between different earthquake events due to local geology, depth of fault rupture, existing construction, and many other factors.

the estimated annual damage approaches $10 billion (Bonneville 2004). The September 11, 2001, terrorist attacks in the United States caused approximately 3,000 deaths and $100 billion in losses, roughly the same proportions as a major earthquake. Just as insurance, travel, and security measures have been increased throughout the world in response to the attacks of September 11, 2001, preparing for the next major earthquake would lessen the worldwide economic effects of future events.

Seismic Risk Analysis and Societal Response

Since 1990 financial risk management analysis has been increasingly utilized by various levels of government, large corporations, and universities to understand and work toward reducing the financial impacts of major earthquakes. For example, a small one-story structure storing landscaping equipment may not be as important to a client as a one-story structure that houses emergency generators and an essential communications antenna. If the one-story structure is a collapse hazard, the owner may decide to strengthen the structure or move essential components to reduce risk.

Risk analyses use various loss estimating measures. The most common is the probable maximum loss (PML) due to a major earthquake, presented as a percentage of the building value. A 50-percent PML anticipates that half of the building will be damaged beyond repair in a major earthquake. Risk assessments need to be periodically updated to show progress and to reevaluate a client's portfolio with the ever-improving tools available to structural engineers produced through new research, analysis software, code developments, and observed damage. Values of PML studies need to be defined and investigated carefully as each methodology or computer program assumes slightly different parameters (Dong 2000).

Three requirements must be satisfied for a successful earthquake resistant design protocol. First, there must be practical structural design standards that reflect current observations and research, standards that are used by engineers and legally enforced as minimum requirements. Second, there must be thorough structural engineering performed by qualified and licensed engineers that leads to clear and explicit construction drawings. Third, construction must be monitored by qualified inspectors or by the designing engineers to ensure that the intended materials are used and construction proceeds as shown in the drawings and specifications. In case of unforeseen construction difficulties, the structural engineer must be involved in a solution that meets the intent of the design without compromising the structure, but also is as economic as possible.

If one or two of these three requirements are satisfied, the protocol is not successful. For example, after the 1999 earthquake in Izmit, Turkey, reports focused on shoddy construction and unenforceable building codes. Building codes are quite good in Turkey, closely following the standards published in the United States. However, for cultural reasons the building codes are frequently not enforced when a design is reviewed, and the contractor is held neither to building to the design standard nor to having an engineered design (EERI 1999).

Due to the Izmit earthquake, efforts to mitigate current and future earthquake risk in Europe are underway in Turkey, as well as Greece, Portugal, Italy, and the rest of the European Union (Spence 2003). All countries with moderate or high earthquake risk have their own cultural, financial, and political barriers toward earthquake risk mitigation. However, as has been demonstrated in the United States, Japan, and elsewhere when the three requirements of practical codes, sound structural design, and construction monitoring work together, earthquake risk is decreased as new buildings replace older ones.

It is extremely difficult for developing countries to mitigate seismic risk. Priorities are on more immediate needs such as food, clean water, and disease prevention and on the effects of poverty and war. Construction uses available materials and follows traditional methods without structural calculations. While economic losses in developing countries may not be as high as in the United States, loss of life is much more severe, potentially approaching the proportions of the July 1976 earthquake in Tangshan, China ($M = 7.5$), where between 250,000 and 655,000 people were killed and more injured when nearly the entire city was razed.

Population expansion, and hence the rate of construction using traditional (seismically unsafe) methods, is at a much higher rate in countries such as India or Nepal than in the United States, exponentially increasing the earthquake risk in these countries. It is estimated that the risk of fatalities in developing countries compared to industrialized countries is 10 to 100 times greater—and increasing. This trend is the largest ethical and functional difficulty worldwide with regard to earthquake risk. In addition to moral obligations to reduce earthquake risk in developing countries, there are financial reasons as well. Due to economic globalization, a major disaster in a developing country has direct immediate and long-term financial impact on the world economy.

EARTH SYSTEMS ENGINEERING AND MANAGEMENT

The biosphere, at levels from the landscape to the genome, is increasingly a product of human activity. At a landscape level, islands and mainland regions are affected by agriculture, resource extraction, human settlement, pollution, and invasive species transported by humans. Few biological communities can be found that do not reflect human predation, management, or consumption. At the organism level, species are being genetically engineered by humans to increase agricultural yields; reduce pesticide consumption; reduce demand for land for agriculture; enable plant growth under saline conditions and thereby conserve fresh water resources; produce new drugs; reduce disease; and support a healthier human diet. At the genomic level, the human genome has been mapped, as has that of selected bacteria, yeast, plants, and other mammals.

Moreover too little of the discussion about the potential effects of advancements in cutting-edge fields, such as nanotechnology, biotechnology, and information and communication technology (ICT), is focused on their global impacts on integrated human-natural systems. Major human systems, from urban to economic to philosophic systems, increasingly are reflected in the physical behavior and structure of natural systems, yet there is little study and understanding of these subtle but powerful interactions.

A planet thus dominated by the activities, intentional and unintentional, of one species is a new historical phenomenon. This species is affecting a complex, dynamic system of which it is a part. Changes in such systems cannot be predicted by linear causal models; witness the continuous debate over the extent global warming is occurring, and its likely consequences. Probabilistic models and continuous data collection can help human beings enter into a dialogue with these coupled human-technological-environmental systems.

Appropriate data-gathering, modeling and dialogue is impeded by the absence of an intellectual framework within which such broad technological trends, and their cumulative impact on global human-natural systems, can be conceptualized. The current base of scientific and technical knowledge, governance institutions, and ethical approaches are inadequate to this challenge (Allenby 2001). Managing these highly complex systems requires an integration of the physical and social sciences that is difficult for both cultural and disciplinary reasons, and the institutional structures that would foster this understanding, and enable its implementation, do not yet exist.

Emergence of Earth Systems Engineering and Management

The challenge of the anthropogenic Earth drove Brad Allenby to propose Earth Systems Engineering and Management (ESEM), an interdisciplinary framework for perceiving, understanding, and managing complex, coupled human-natural-technological systems. It reflects not just the need to respond to, and manage, systems at scales of complexity and interconnection that current practices cannot cope with, but also to minimize the risk and scale of unplanned or undesirable perturbations in coupled human or natural systems. It does not replace traditional scientific, engineering, and social science disciplines or study; rather it draws on and integrates them to enable responsible, rational, and ethical response to the relatively new phenomenon of the anthropogenic Earth. Therefore, ESEM draws heavily on related work in multiple fields (Clark 1989, Turner et al. 1990).

ESEM is a response to a broad set of multidisciplinary questions that are relatively intractable to twenty-first-century disciplinary and policy approaches: How, for example, will people cope with the potential ramifications for environmental systems of nanotechnology, biotechnology, and ICT? How can they begin to redesign human relationships with complex ecosystems such as the Everglades; engineer and manage urban centers to be more sustainable; or design Internet products and services to reduce environmental impact while increasing quality of life?

The Ethics of ESEM

Dealing responsibly with the complex web of interconnections between human and natural systems will thus require experts skilled in new approaches and frameworks, capable of creating policy and design options that protect environmental and social values while providing the desired human functionality. Such an ESEM approach requires both a rigorous understanding of the human, natural, and technological dimensions of complex systems, and an ability to design inclusive strategies to address them, all the while recognizing that no single approach or framework is likely to be able to capture the true complexity of such systems.

Even at this nascent stage, it is possible to begin to establish a set of principles applicable to ESEM (Allenby 2002):

(a) Try to articulate the current state of a system and desired future states, consulting with multiple stakeholders. Establish a process for continuous sharing of knowledge and revision of system goals, based on continuous monitoring of multiple system variables and their interactions. Anticipate potential problematic system responses to the extent possible, and identify markers or metrics by which shifts in probability of their occurrence may be tracked.

(b) The complex, information dense and unpredictable systems that are the subject of ESEM cannot be centrally or explicitly controlled. ESEM practitioners will have to be reflective, seeing themselves as an integral component of the system, closely coupled with its evolution and subject to many of its dynamics.

(c) Whenever possible, engineered changes should be incremental and reversible. In all cases, scale-up should allow for the fact that, especially in complex systems, discontinuities and emergent characteristics are the rule, not the exception, as scales change. Lock-in of inappropriate or untested design choices, as systems evolve over time, should be avoided.

(d) ESEM projects should support the evolution of system resiliency, not just redundancy. In a tightly coupled complex system, a failure of one component can be fatal, and it is virtually impossible to build in sufficient redundancy for every component (Perrow 1984). The space shuttle is an example. Resilient systems are loosely coupled; the system as a whole can adapt to failures in one component. The Internet is an example, as are many natural systems. However, even in resilient systems, there are tipping points where the amount of disruption exceeds the ability of the system to adapt, and a major transformation occurs. Therefore, even resilient systems require monitoring and management.

To succeed, ESEM depends on the development of an Earth Systems Engineer (ESE) who would have a core area of expertise, perhaps environmental science or systems engineering or social psychology, and be able to take a global systems view of environmental problems. The ESE would have to be what Collins and Evans call an interactional expert, capable of facilitating deep, thoughtful conversations across disciplinary boundaries (Collins and Evans 2002) that enable productive trading zones (Galison 1997) for managing complex environmental systems (Gorman and Mehalik 2002). The ESE would also be involved in the creation of new data monitoring and modeling tools that would add rigor to ESEM. To assess its value, the ESEM approach needs to be piloted on several complex systems, and the results described in detailed case-studies from which others can learn. The ESEM framework has the potential to facilitate intelligent management of trading zones centered on converging technologies: nanotechnology, biotechnology, information technology and cognition (Gorman 2003).

ECOLOGICAL ECONOMICS

Economics is frequently defined as the science of the allocation of scarce resources among alternative desirable ends. The first question this implies—What are the desired ends?—is ultimately a question of values and ethics. Most economists would agree that while the ultimate desired end is too difficult to define, increasing social welfare serves as a reasonable placeholder. Seeking to establish itself as an objective, value-free science, mainstream (neoclassical) economics strives to maximize welfare as measured by the dollar value of market goods plus the imputed dollar value of nonmarket goods and services produced. Therefore neoclassical economists, including natural resource and environmental economists, devote most of their attention to markets, which under certain strict conditions efficiently allocate resources toward uses that maximize dollar values. Taking an explicitly ethical position, ecological economics asserts that ecological sustainability and just distribution take priority over efficient allocation as prerequisites to increasing social welfare. Markets cannot be relied upon unless these first two priorities have been met.

Once the desired ends have been determined, ecological economists rely on insights from physics and ecology to assess the nature of the scarce resources. Only then do they seek appropriate allocative mechanisms, drawing from mainstream economics as well as other social sciences. Ecological economics embraces the full complexity of the economic question, and the full range of inquiry necessary to answer it. It lays no claim to being a value-free science, but rather works to be a transdisciplinary field, integrating knowledge and skills from both the humanities and sciences. (Costanza, Daly, and Bartholomew 1991; Norgaard 1989).

As an emerging transdiscipline, ecological economics has an exceptionally broad scope of inquiry, and has not yet achieved the level of consensus that characterizes an established science. This overview leaves out much brilliant work, and not all ecological economists will agree with all it says.

The Resources of Nature and the Nature of Resources

An understanding of scarce resources begins with hard science and the laws of thermodynamics. The first law states that the quantity of matter-energy cannot be created or destroyed and remains constant in a closed system. Everything produced by humans (human-made capital) must come from raw materials supplied by nature (natural capital). Any waste produced by the economy must return to the ecosystem. In contrast, most standard microeconomics textbooks argue that through specialization and trade, society can "increase production with no change in resources" (Parkin 2003, p. 42).

The second law of thermodynamics states that entropy never decreases in an isolated system. From the perspective of economics, entropy can be thought of as a measure of used-up-ness, or the extent to which the capacity of matter-energy to perform work or be useful has been exhausted. When oil is burned to run an engine or heat a house, the energy it contains is not destroyed in performing this work, but it cannot be used again for the same purpose. When the steel in cars rusts and flakes off, it does not disappear but is scattered about the ecosystem so randomly one cannot gather it back up. The quantity of matter-energy is constant in a system, but the quality is constantly deteriorating. These laws suggest that human-made capital will inevitably be used up or worn out and return to the ecosystem as high entropy waste. A constant flow of low entropy natural capital is required simply to maintain the economy.

Fortunately the Earth is not an isolated system, because the sun provides a daily source of low entropy energy. But it is this solar inflow that limits the physical size of the economy in the long run, not the nonrenewable stock of fossil fuels. While fossil fuels can be used up as quickly as one chooses, solar energy comes at a fixed rate. People can therefore use fossil fuels to achieve rapid physical growth of the economic system, but not to create a sustainable system (Georgescu-Roegen 1971).

Humans depend not only on raw materials provided by nature, but like all other species on the planet, are sustained by the solar-powered life support functions of healthy ecosystems. All of human technology simply cannot provide the climate stability, waste absorption capacity, water regulation, and other essentials that more than 6 billion people require to survive. In other words, natural capital has two components. Ecosystem goods are the raw materials provided by nature, as well as the structural components of the ecosystem. Ecosystem services are the valuable functions that emerge when those structural components interact in a complex ecosystem to create a whole greater than the sum of the parts. When humans remove low entropy raw materials from nature to build the economy and return high entropy waste, they must pay an opportunity cost measured in both ecosystem goods and services lost.

These laws of thermodynamics are responsible for the core vision of ecological economists: The human system is sustained and contained by the global ecosystem. When the physical size of the economic system increases, it does not expand into a void, but must instead consume and displace the natural capital on which humans depend for survival (Daly and Farley 2003).

Scale, Distribution, and Allocation

As a consequence of the ecological economists' core vision, their primary concern is with *scale*—the physical size of the human economy relative to the ecosystem that contains and sustains it. The scale of the economy cannot exceed the capacity of the ecosystem to sustain it. This priority emerges from an understanding of the laws of physics combined with an ethical responsibility to future generations.

Sustainable scale is necessary, but inadequate. Virtually all economists accept the law of diminishing marginal utility—the more one has of something, the less an additional unit is worth. As human-made capital increases, its marginal utility diminishes. A corollary is the law of increasing opportunity costs—as natural capital dwindles, the opportunity costs of continued losses increase. Increasing opportunity costs must eventually surpass diminishing marginal utility. At this point, an economic system has reached its optimal scale, and the physical growth of the economy should stop—though economic development, as measured by improvements in social welfare, can still continue.

Two hundred years ago when market economies were emerging, human-made capital was relatively scarce and natural capital abundant. Economists logically focused on allocating the former. In the early twenty-first century, however, it is natural capital that constrains economic development. If people need more fish or timber, the problem is depleted fish stocks and forests, not a shortage of boats or chainsaws. It is likely that humans have exhausted nearly half the planet's supply of conventional petroleum in less than 150 years (Campbell and Laherrère 1998), threatening to destabilize the global climate in the process. Yet natural capital does not increase in fecundity or quantity in response to an increase in price—the driving force behind markets.

However while natural capital does not respond to price signals, technology does: As a resource becomes scarce, its price goes up, and people can either use it more efficiently or create a substitute, leading many conventional economists to conclude that resource scarcity imposes no limits on economic growth. At one extreme, economists such as Julian Simon deny that natural resources are finite and argue that a growing human population brings more brainpower to solve society's problems (Simon 1996). Similar claims from statistician Bjørn Lomborg (2001), supposedly based on evaluation of empirical data, have received considerable publicity, but the quality of his scholarship raises serious concerns (Rennie 2002). For example, he accepts without question a doubling and even tripling of estimated oil reserves in several member states of the Organization of the Oil Exporting Countries (OPEC) that took place shortly before their quota negotiations in 1988, while rejecting as implausible four out of five scenarios for climate change from an intensively peer-reviewed report by leading scientists working with the International Protocol on Climate Change (Schneider 2002). Nonetheless more credible technological optimists such as Amory Lovins are actively creating pollution reducing, resource and energy efficient technologies such as the hydrogen powered *hyper-car*.

While not denying its importance, ecological economists are leery of undue faith in technological advance for both practical and ethical reasons. In practical terms few ecosystem services even have a price to signal market scarcity and thus induce technological innovation, and even imputed prices cannot capture the fact that most ecosystem services do not have clear substitutes (Gowdy 1997). While there is a greater capacity to develop substitutes for ecosystem goods than for services, efficiency improvements have physical limits, and continued economic growth must eventually lead to more resource use, more waste output, and diminishing marginal utility—a growing fleet of hyper-cars will still require more roads and parking lots and induce more traffic jams. The fact is that efficiency in resource use rarely stimulates frugality, but frugality quite often stimulates efficiency (Daly and Farley 2003). From the viewpoint of ethics, no one can say for certain what technologies will emerge and when, and the gamble is whether or not future technologies will create substitutes for critical resources before they are exhausted. Ecological economists weigh the gains from winning against the costs of losing. If the technological optimists are wrong, continued increases in the rate of resource use could lead to the irreversible loss of vital ecosystem life support functions. If the optimists are right, then limiting resource extraction and waste emissions will impose only short term costs to standards of living while technological innovation develops substitutes.

Thus ecological economists operate on the assumption that natural capital has become the scarcest resource required to achieve the desired ends, and recognize that markets fail to respond to this scarcity and cannot be relied on as a mechanism for determining desirable scale. Environmental economists in contrast believe markets can determine desirable scale if they calculate the dollar value of ecosystem services then feed this information back into the market system. However all economic production degrades ecosystem services through resource extraction and again through waste emissions. Two prices must be calculated for every price the market detects. This defeats the whole purpose of a market whose virtue is its reliance on decentralized information. Ecological economists believe scale should be determined by a participatory democratic process informed by appropriate experts and the ethical values of citizens. Stakes are high, decisions are urgent, and facts are uncertain. Society must act quickly, but should err on the side of caution and leave room to adapt as it learns more (Funtowicz and Ravetz 1992; Prugh, Costanza, and Daly 2000). The Endangered Species, Clean Air, and Clean Water acts in the United States and the Montreal Protocol on ozone depleting substances are only a few examples of this approach. In sum, while environmental economists in contrast strive to calculate prices first, and then allow scale to adjust, ecological economists strive to determine the desirable scale first, and then allow prices to adjust.

The second priority for ecological economists is just distribution, which emerges in part from their concern with scale. What ethical system would allow a concern for the welfare of people not yet born, and ignore the welfare of those alive and suffering today? If a finite planet imposes finite limits on the size of the economy, then society cannot grow its way out of poverty, and alleviating poverty requires redistribution. On practical grounds, no one living in poverty can really afford to think about the future—hungry people around the world will sacrifice essential natural capital for immediate needs. Unjust distribution is therefore incompatible with ecological sustainability.

How markets allocate resources depends on the initial distribution. For example, a society with highly unequal distribution will allocate resources toward both slums and yachts, while one with more equal distribution will allocate resources toward neither. A given market allocation is therefore no more desirable than the initial distribution that produced it. Nonetheless the tradition in neoclassical economics is to leave the distribution question to other disciplines or policymakers, while ecological economists consider just distribution a prerequisite to desirable allocation.

Distribution should also be decided by a participatory democratic process. Three principles can guide the decision. Wealth created by nature and society as a whole should be equally distributed. Those who degrade that wealth, through pollution or resource depletion, for example, should compensate society for its loss. Those who benefit from society should provide compensation in proportion to their gains.

The third priority for ecological economists is efficiency. Once society has ensured the preservation of enough natural capital to sustain the system, and that remaining resources are justly distributed, those resources should be allocated toward uses that generate as much welfare as possible. Markets can be an efficient allocative mechanism when resources are privately owned, use by one person precludes used by another, and production and consumption have minimal impacts on others. When these conditions do not hold, markets alone will fail to generate efficient outcomes, and society must again rely on participatory democratic decision making to allocate resources, complemented when appropriate by market mechanisms.

ECOLOGICAL FOOTPRINT

In the early 1990s, Dr. William Rees and a graduate student, Mathis Wackernagel, developed and quantified the first "ecological footprint" for the city of Vancouver, Canada. Fundamental to this research was answering the question, "how large an area of productive land is needed to sustain a defined population indefinitely, wherever on earth that land is located?" Ecological footprints build on earlier studies, all designed to quantify the natural resources used by humans and compare that to those that are available. However, footprints are distinguished, according to leading practitioners, by the many categories of human activity included in the ana-

Ecological footprint and biocapacity figures for representative countries around the world. Ecological deficit refers to the extent that a country's footprint exceeds its biocapacity.

lysis, and by the measure's ability to compare current demand with current ecological limits (biocapacity).

The ecological footprint is an environmental accounting tool that measures human impact on nature, based on the ability of nature to renewably produce the resources that humans use and absorb the ensuing waste. Footprinting provides a way to aggregate into a single composite measure many of the ecological impacts associated with built-up land (i.e., roads and buildings), food, energy, solid waste, and other forms of waste or consumption. The result represents the impact or footprint. Using an area-based measure, such as hectares or acres, the size of a footprint can be compared to the renewable services the Earth's biocapacity can produce in a given year. The footprint methodology can be used to evaluate a population's progress toward ecological sustainability.

The footprint has been criticized on a variety of fronts, primarily related to the complex methodology that underlies the measure, as well as the applications for which it is appropriate. Along with other aggregate indicators, the footprint has been criticized for obscuring the components and assumptions that comprise the measure. While the methodology behind the measure is readily available, it is complicated and therefore not approachable without some technical background. Other critics argue that the premise of living within resource limitations can be overcome with technological innovation. It is true that in many ways the footprint is a worst-case scenario because it describes the situation if there are no technological improvements; but the converse, counting on improvements, could be risky in the long run as well.

When a country or community uses more renewable resources than are available, it has exceeded ecological limits. It will not be sustainable over an indefinite period of time. Such a situation can occur over a relatively short time-span because natural capital can be depleted to fill the renewable resource gap. Imports can also meet society's needs, but may simply shift depletion of natural capital around the globe. Over time, global stocks may be depleted to the point where they cannot regenerate or require significant human intervention to do so.

The *Living Planet Report 2002* contains footprints of countries with populations greater than one million. Estimates for the year 1999 show that the average American required approximately 9.6 hectares (24 acres) of ecologically productive land to sustain his or her lifestyle. In comparison, the average Canadian lived on a footprint that was nearly one-third smaller (6.9 global hectares or 17 acres), while the average Italian lived on an ecological footprint that was less than half the size (3.8 global hectares or 9 acres) of the American's. Each of these footprints can be compared to the amount of ecologically productive land area available locally or to the amount available globally on per person basis (1.9 hectares or 4.7 acres). See Table 1.

Footprint Methodology

The basic procedure for the footprint methodology is to determine annual global productivity and assimilation capacity (biocapacity) of major land areas. Then, this biocapacity is compared to the demands placed on it by human consumption and waste production. Productive lands are aggregated as cropland, pasture, forest, fisheries, and built-up land. Built-up land is generally assumed to occupy former cropland, as this is the predominant settlement pattern in human history. The present footprint methodology holds that less than one quarter of the Earth's surface provides sufficiently concentrated biomass to be considered biologically productive—leaving out deep ocean areas, deserts, frozen tundra, and other less productive parts of nature. Biocapacity can change: both negatively, due to land alterations such as desertification; and positively, due to improvements in technology that result in higher yields.

Ecological footprints can be calculated using two basic approaches: component and compound. Component footprinting is a bottom-up approach consisting of calculating the ecological footprints of individual parts of a system and then adding them up. Compound footprinting, on the other hand, is a top-down approach using aggregate figures such as production, imports, and exports of agriculture, energy, and other commodities, usually for nations.

Using either methodology, human consumption and waste components of a footprint are attributed to the final point of utilization (where a product is used up and enters the waste stream), regardless of where the output is actually assimilated. For example, some waste products, such as carbon dioxide, may be assimilated well outside the boundaries of the place where they are actually emitted, either because the wastes are carried away from the point of use or because the wastes are generated at a remote production site.

The final footprint results from the comparison of global biocapacity to consumption and waste. High available biocapacity allows for more or larger footprints, and higher levels of consumption require more biologically productive land. Consumption beyond renewable levels of biocapacity requires the depletion of natural capital and is considered unsustainable if it draws resources down to the point at which they cannot regenerate.

Measuring the ecological footprint of energy is a particularly significant and complex challenge that can be addressed in a variety of ways. A primary question that arises concerns the type of energy that is being used. Highly renewable forms of energy production, such as wind and solar power, typically have footprints equivalent to the land area they occupy plus the materials embodied in the collection mechanism. At the other extreme, nuclear energy is inherently unsustainable both because the resources it utilizes are non-renewable and extremely toxic, and because the potential destruction from nuclear accidents produces a dramatic increase in footprint area. The current approach is to convert nuclear energy to the equivalent fossil fuel impact. The footprint of fossil fuels can be calculated as either the amount of land area that would be required to grow and harvest an equivalent amount of fuelwood, or as the amount of land area required to assimilate associated carbon dioxide emissions. The latter approach is the most typically used in footprint accounts.

Footprint calculations through the beginning of the twenty-first century have assumed optimistic yield factors for foods and forests (making them conservative) and have left unmeasured many of the impacts associated with pollution, water use, and habitat and species decline. Though improvements are being made in the methodology, the ecological footprint cannot be considered a definitive measurement of humanity's ecological impact without significant additions.

Applications

Footprinting provides a methodology to evaluate potential tradeoffs among alternative actions, designs, energy sources, policies and products. It can be used as a yardstick for measuring humanity's impact on the earth in terms of ecological sustainability. Research in the field has provided the stimulus and foundation for academics at universities throughout the world. The ecological footprint has informed discussions and debates from the global to local level in national governments, meetings of the United Nations, research institutes, and municipal sustainability initiatives.

Footprints change over time, as populations change, consumption patterns shift, and biocapacity increases or decreases. The changes allow humanity to see its progress toward sustainability, at a global, national, state, and local level.

ECOLOGICAL INTEGRITY

Ecological or biological integrity originated as an ethical concept in the wake of Aldo Leopold (1949) and has been present in the law, both domestic and international, and part of public policy since its appearance in the 1972 U.S. Clean Water Act (CWA). Ecological integrity has also filtered into the language of a great number of mission and vision statements internationally, as well as being clearly present in the Great Lakes Water Quality Agreement between the United States and Canada, which was ratified in 1988.

The generic concept of integrity connotes a valuable whole, the state of being whole or undiminished, unimpaired, or in perfect condition. Integrity in common usage is thus an umbrella concept that encompasses a variety of other notions. Although integrity may be developed in other contexts, wild nature provides paradigmatic examples for applied reflection and research.

Because of the extent of human exploitation of the planet, examples are most often found in those places that, until recently, have been least hospitable to dense human occupancy and industrial development, such as deserts, the high Arctic, high-altitude mountain ranges, the ocean depths, and the less accessible reaches of forests. Wild nature is also found in locations such as national parks that have been deemed worthy of official protection.

Among the most important aspects of integrity are the autopoietic (self-creative) capacities of life to organize, regenerate, reproduce, sustain, adapt, develop, and evolve over time at a specific location. Thus integrity defines the *evolutionary and biogeographical processes* of a system as well as its parts or elements at a specific location (Angermeier and Karr 1994). Another aspect, discussed by James Karr in relation to water and Reed Noss (1992) regarding terrestrial systems, is the question of what spatial requirements are needed to maintain native ecosystems. Climatic conditions and other biophysical phenomena constitute further systems of interacting and interdependent components that can be analyzed as an open hierarchy of systems. Every organism comprises a system of organic subsystems and interacts with other organisms and abiotic elements to constitute larger ecological systems of progressively wider scope up to the biosphere.

Ecological Integrity and Science

Finally ecological integrity is both "valued and valuable as it bridges the concerns of science and public policy" (Westra et al. 2000, pp. 20–22). For example, in response to the deteriorating condition of our freshwaters, the CWA has its objective: "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters" (sec. 101[a]). Against this backdrop, Karr developed the multimetric Index of Biological Integrity (IBI) to give empirical meaning to the goal of the CWA (Karr and Chu 1999). Karr defines ecological integrity as "the sum of physical, chemical, and biological integrity." Biological integrity, in turn, is "the capacity to support and maintain a balanced, integrated, adaptive biological system having full range of elements (genes, species, and assemblages) and processes (mutation, demography, biotic interactions, nutrient and energy dynamics, and metapopulation processes) expected in the natural habitat of a region" (Karr and Chu 1999, pp. 40–41). Scientists can measure the extent to which a biota deviates from integrity by employing an IBI that is calibrated from a baseline condition found "at site with a biota that is the product of evolutionary and biogeographic processes in the relative absence of the effects of modern human activity" (Karr 1996, p. 97)—in other words, wild nature. Degradation or loss of integrity is thus any human-induced positive or negative divergence from this baseline for a variety of biological attributes (Westra et al. 2000). Noss's Wildlands Project, which aims to reconnect the wild in North America, from Mexico to Alaska (Noss 1992, Noss and Cooperrider 1994) utilizes the ecosystem approach to argue the importance of conserving areas of integrity.

But the most salient aspect of ecosystem processes (including all their components) is their life-sustaining function, not only within wild nature or the *corridor surrounding wild areas* although these are the main concerns of conservation biologists. The significance of life-sustaining functions is that ultimately they support life everywhere. Gretchen Daily (1997), for instance, specifies in some detail the functions provided by *nature's services*, and her work is crucial in the effort to connect respect for natural systems integrity and human rights.

Arguments against the value of ecological integrity for public policy have identified the concept as *stipulative* rather than fully scientific (Shrader-Frechette 1995). In a similar vein even the concept of ecology as such has been criticized as *not robust* enough to guide public policy (Shrader-Frechette and McCoy 1993). But ecological integrity is already a part of public policy, thus requiring consideration of its meaning and the role its inclusion should play in policy, rather than arguing for its rejection. Further to maintain that "we need a middle path—dictated in part by human not merely biocentric theory" (Shrader-Frechette 1995, p. 141) ignores how humans do not exist apart from other organisms: Biocentrism is life-oriented, and this principle is increasingly accepted not only by science, but in the law.

The routine use of Karr's IBI to reach general conclusions illustrates the ethical effectiveness of the scientific concept of ecological integrity in public policy. The law analyzes a crime or victim under a particular set of circumstances. But public policy must abstract from specifics. Disintegrity (or lack of integrity) and *environmental crime* (Birnie and Boyle 2002) are global in scope and need international fora and broad concepts to ensure that they will be proscribed and possibly eliminated.

In addition, there is mounting evidence to connect disintegrity or *biotic impoverishment* (Karr 1993) in all its forms, from pollutions, climate change, toxic wastes, and encroachment into the wild (Westra 2000) to human morbidity, mortality, and abnormal functioning. International law has enacted a number of instruments to protect human rights (Fidler 2001) and the World Health Organization (WHO) invited the Global Ecological Integrity Project (1992–1999) to consult with it. This collaboration eventually produced a document titled "Ecological Integrity and Sustainable Development: Cornerstones of Public Health" (1999) (Soskolne and Bertollini).

The Ethics of Integrity

Because of this global connection between health and integrity, and the right to life and to *living* (Cançado Trindade 1992), a true understanding of ecological integrity reconnects human life with the wild, and the rights of the latter with those of the former. The ethics of integrity primarily involves respect for *ecological rights* (Taylor 1998) without limiting these to the human rights that are the primary focus of the law. The main point of an ethic of integrity is that it is a *new* ethic (Karr 1993), one founded on recent science demonstrating the interdependence between humankind and its habitats. Environmental ethicists may prefer to focus on one or the other aspect of this interconnected *whole*—biocentrism or anthropocentrism. While biocentrists accept the presence of humankind as such within the rest of nature, anthropocentrists attempt to separate the two, in direct conflict with ecological science.

If, as argued, human health and function are both directly and indirectly affected by disintegrity (Soskolne and Bertollini Internet article), then no theory can properly separate one from the other. The strength of the proverbial canary-in-the-mine example is based on the fact that the demise of the canary anticipates that of the miner. Hence it is necessary to accept a general imperative of respect for ecological integrity. Onora O'Neill makes this point well:

> The injustice of destroying natural and man-made environments can also be thought of in two ways. In the first place, their destruction is unjust because it is a further way by which others can be injured: systematic or gratuitous destruction of the means of life creates vulnerabilities, which facilitate direct injuries to individuals. . . . Secondly, the principle of destroying natural and man-made environments, in the sense of destroying their reproductive and regenerative powers, is not universalizable. (O'Neill 1996, p. 176)

In addition, the *vulnerability* that follows the destruction of integrity links this concept to environmental justice. The *principle of integrity* together with appropriate second order principles would ensure (a) the defense of the *basic rights* of humankind (Shue 1996) as well as (b) the support of environmental justice globally, because it would ensure the presence of the *preconditions* of agency and thus the ability of all humans to exercise their rights as agents (Gewirth 1982, Beyerveld and Brownsword 2001).

Ecological integrity is thus not an empty metaphor or a grand theory of little utility. It is a concept robust enough to support a solid ethical stance, one that reinstates humans in nature while respecting the latter, thus permitting clear answers in cases of conflicts between (present) economic human interests and (long-term) ecological concerns.

Ecological Integrity and the Law

It is reasonable to conceive of humanity as being morally responsible to protect the integrity of the whole ecosystem, and for that responsibility to be translated into such mechanisms as standard setting in a manner that is cognizant of ecological thresholds (Taylor 1998). Insofar as such responsibility is justified as a protection of human life and health, breaches of environmental regulations deserve not just economic penalties but criminal ones. Nevertheless there is a growing parallel movement to recognize the intrinsic value of both the components and the processes of natural systems, not only in philosophy (Westra 1998, Callicott 1987, Stone 1974, Leopold 1949), but also in the law (Brooks et al. 2002).

A number of international legal instruments also reflect the emerging global ecological concerns, and thus include language about respect for the intrinsic value of both natural entities and processes. This point is illustrated by a project involving the justices of the world's highest courts, which is funded by the United Nations Environment Programme (UNEP). The project's biocentric goal, as outlined by Judge Arthur Chaksalson of South Africa, is one of the most important results of the Johannesburg meeting (also known as "Rio+10"). The 2000 Draft International Covenant on Environment and Development incorporates the mandates of the Earth Charter, which was adopted by a United Nations Economic, Scientific, and Cultural Organization (UNESCO) resolution on October 16, 2003, in its language, and includes articles on ecological integrity and the intrinsic value of nature.

Although the positions advanced in these international initiatives are present in law, economic interests often obscure the opposition between the basic rights of persons and peoples and the property rights of legal entities and institutions. In the process courts tend to weigh these incommensurable values as though they were equal. But the right to life and the survival of peoples is not comparable to economic benefits or even the survival of corporate and industrial enterprises.

An additional connection arises from a consideration of *ecological integrity* a complex concept that, after several years of funded work, the Global Ecological Integrity Project eventually defined in 2000 (Westra et al. 2000). The protection of basic human rights through recognition of the need for ecological integrity, as Holmes Rolston (1993) acknowledges, is a step in the emerging awareness of humanity as an integral part of the biosphere (Westra 1998, Taylor 1998).

On the basis of the biocentric foundation for ecological integrity, it is necessary to move toward the twin goals of deterrence and restraint, as is done in the case of assaults, rapes, and other violent crimes. Laws that restrain unbridled property rights represent a first target; but efforts should not be limited to action within the realm of tort law. The reason is obvious: Economic harms are transferable, thus acceptable to the perpetrators of such harms, although the real harms produced are often incompensable. As Brooks and his colleagues indicate in reference to U.S. law, science is now available to support appeals to interdependence. "Not only has conservation biology as a discipline and biodiversity as a concept become an important part of national forest and endangered species management, but major court cases reviewing biodiversity determinations have been decided" (Brooks et al. 2002, p. 373). In addition, Earth System Science increasingly provides "multidisciplinary and interdisciplinary science framework for understanding global scale problems," including the relations and the functioning of "global systems that include the land, oceans and the atmosphere" (Brooks et al. 2002, p. 345). In essence, the ecosystem approach and systematic science of ecological integrity have contributed support to what Antonio A. Cançado Trindade terms "the globalization of human rights protection and of environmental protection" (Cançado Trindade 1992, p. 247).

As noted these ideals are contained in the language and the principles of the Earth Charter. The global reach of these ethics and charters, to be effective, must be supported by a supranational juridical entity such as the European Court of Human Rights. As the case for environmental or, better yet, ecological rights, becomes stronger and more accepted in the international law, the best solution as suggested by Patricia Birnie and Adam Boyle could be to empower the United Nations (UN). It might be desirable "to invest the UN Security Council, or some other UN organ with the power to act in the interests of 'ecological security,' taking universally binding decisions in the interests of all mankind and the environment (Birnie and Boyle 2002, p. 754). Empowering the United Nations in this way would foster support for programs based on the abundant evidence linking ecology and human rights and could become the basis for a new global environmental/human order (Westra 2004).

ECOLOGICAL RESTORATION

Ecological restoration (hereafter restoration) is "the process of assisting the recovery of an ecosystem that has been damaged, degraded or destroyed" (Society for Ecological Restoration Science & Policy Working Group). *Restoration ecology* and ecological restoration are terms often interchanged: The former is the scientific practice that is contained within the broader embrace of the latter, which incorporates both science *and* many varieties of technological and political practice.

Restoration refers to an array of salutary human interventions in ecological processes, including the elimination of weedy species that choke out diverse native assemblies, prevention of harmful activities (such as excess nutrient loads), rejuvenation of soil conditions that foster vigorous plant communities, reestablishment of extirpated species, and rebuilt webs of social participation that foster ecologically rich and productive ecosystems. The metaphor of healing is often used to describe what restorationists do.

However not everyone regards restoration as a fully positive practice. Some view it as a technological response to ecological damage, while others worry that restoration deflects attention from avoiding harm in the first place. There is also concern that restored ecosystems may be simply pale imitations of nature, and that ecosystems are always more complicated than those seeking to restore them can truly understand. Restoration practice is driven by the tension between a technological approach to restoration—technological restoration—and a participatory, humble, culturally aware approach, or what this author terms "focal restoration." The furious debates among practicing restorationists regarding these issues and others provide particular perspectives on relations between science, technology, and ethics. Moreover, conceptual clarity offers practitioners a guide to pitfalls and opportunities for good restoration.

Concept and Origins

Restoration is practiced in all regions of the world, although what counts as restoration varies according to cultural perspective and socioeconomic condition. This has complicated the creation of a precise definition of this relatively new field, especially because international conversation and cooperative projects have become more common in the early-twenty-first century. In North America, the aim is typically to restore an ecosystem to its predisturbance condition under the presumption that reversion to a pristine, original state is the ideal end point. In Europe and other regions, long and continuous human occupation has resulted in landscapes that present a distinctively cultural benchmark. In many regions of the southern hemisphere, and especially in areas where poverty and civil disruption prevail, the focus is on restoration of productive landscapes that support both ecological and cultural ideals.

No comprehensive history of restoration is available, especially one that treats diverse international perspectives. North Americans often claim to be the founders of restoration, in part because of a tradition in the twentieth century of supporting scientific and practical restoration capacity including the formation of the premier organization devoted to restoration, the Society for Ecological Restoration International (founded 1987). Prairie restoration projects at the University of Wisconsin Arboretum under the direction of Aldo Leopold, Theodore Sperry, and Henry Greene in the 1930s are often cited as inaugural moments in modern restoration. Important as these efforts are, there were prior influential developments in applied ecology, rehabilitation (the recovery of a landscape to productive capability), revegetation, and naturalistic gardening that made the Wisconsin projects possible (Perrow and Davy 2002; Mills 1995; Jordan, Gilpin, and Aber 1987). Restoration was being practiced under different guises in North America, Europe, and other regions of the world prior to the twentieth century, and, as historical accounts of these efforts are written, a tangled and interconnected lineage will undoubtedly be revealed.

Points at Issue

A spate of articles written since the 1980s has positioned restoration as one of the most hotly contested issues in environmental philosophy. Why is this? Philosophers, many environmentalists, and some restorationists are uneasy about claims that ecosystems can in fact be restored. Much turns on the standards set for restoration, most prominently the demands for historical accuracy. If the aim is to reset ecosystems to some prior time or sequence, then restoration is by definition an austere and limited practice, depending on a limited ranges of options and choices.

If the demands for historical fidelity are relaxed, the practice opens up, although enlargement of scope creates other problems. What are appropriate boundaries on restoration? How much history is necessary? How precise ought be the demands for ecological integrity? (Ecological integrity is an umbrella term that describes the capacity of an ecosystem to adjust to change—resiliency, elasticity, stress response, and so on [Kay 1991]). How much should human agency matter? How much should human participation in ecological processes matter? Without much digging, restoration turns into a conceptual quagmire, which is occasionally vexing for practitioners and always intriguing for philosophers (Throop 2002).

Arguably what has proved most contentious is the instrumental character of restoration. At worst, some would argue, restoration is a mere technological fix, that is a forgery of nature, and deflects attention from pressing and underlying environmental problems (Eliot 1997). While few hold such a dim view and most acknowledge that restoration creates value, there is a fundamental concern that restoration is a practice that grew up and thrives in a technological culture. Indeed restoration is always a series of deliberate interventions in ecological processes. As restorative capacity rises, so does the risk that such capacity will be used as a justification for destruction or careless modification of ecosystems. The challenge is to keep restoration from becoming an apologia for environmental destruction while manifesting a powerful will to repair the damage that continues to be done. Hence most restorationists operate under the belief that their actions benefit nonhuman species and enrich the social engagement between people and ecosystems. Limiting human will and ensuring that restoration does not become an end in itself is a central challenge.

The Future of Restoration

The tendency to think of restoration in technological terms is abetted by increasingly large projects—restoration megaprojects such as Florida's Everglades restoration—that are driven by typically top-down imperatives and serve primarily as emblems of environmental responsibility. The dominant tradition in restoration encompasses relatively small-scale projects that depend on bottom-up participation; these projects are deeply embedded in locality and enliven human communities. While the appearance to some observers that restoration is a set of prescriptions imposed on nature, in fact most restoration projects to date are modest in intention, self-reflexive, and tentative; exactly the opposite of what one might think of as large-scale technologically constituted practices.

Restoration practitioners are approaching a crossroads at which they will have to choose between *technological* and *focal* restoration, which focuses on community and participation (Higgs 2003). Focal restoration is one term for describing the alternative or antidote to technological restoration, and derives from Borgmann's (1984) formulation of "focal practice," in which the relations between "things" and practices are brought to the center and given priority. When focusing on something that truly matters to a community—an ecosystem to be restored for instance—the values of that community and the integrity of the thing are given heightened respect. Other terms such as "ecocultural" restoration are found in the restoration literature with roughly the same intention, but this author prefers the identification of focal restoration with its robust commentary about, and philosophy of, technology. The choice between technological and focal restoration may not be exclusive or stark, but reflective practitioners must decide which vision of restoration is appropriate. Scholarly and popular criticism has raised awareness of the risks that restoration will become thoroughly enmeshed in technological culture. The challenge is to steer along the road of participation, with respect for ecological process, modesty, and humility.

Ecological restoration has stirred profound debates about the constitution of nature in a technological society and human relations with ecosystems. Perhaps as much as any other practice, restoration has brought a conceptual spotlight to issues that arise in environmental management, conservation biology and other related endeavors. In particular, restoration demands attention to the social, economic and political relationships people have with places, which inspires a broader perspective on the scientific and technical dimensions. It is, therefore, insufficient to discuss "restoration ecology" without "ecological restoration; both matter to achieving the socially constituted goal of good restoration. The dynamic character of ecosystems also poses some fascinating challenges to other uses of the term restoration, such as those found in art, architecture, and literature.

ECOLOGY

The word *ecology* is derived from the Greek *oikos*, "household," and *logos*, "reason," thus indicating the logic of living creatures in their homes. Although *oikos* originally indicated only human households, as a term coined in 1866 by Ernst Haeckel, ecology names a biological science such as molecular biology or evolutionary biology, though often thought to be less mature, that studies organism–environment relations. Closely related to ecology in this sense are conservation biology and environmental science. Ecology, the science, studies ecosystems at multiple levels and scales in space and time. Ecosystems have proved to be often quite complicated and resist analysis. Experiments in the field are difficult, and the systems may be partly chaotic.

In part because of such complications ecology has become the focus of a particular set of discussions related to science, technology, and ethics. The term *ecological ethics* may, for instance, call for doing ethics in the light of what ecologists have found in their studies of the world. Perhaps it is appropriate, at times, for humans to imitate the way ecologies themselves function, or look toward ecosystems as fundamental goods to be appreciated and preserved. Given these associations, ecology can also feed into a worldview or philosophy.

What has been called the environmental or ecological crisis seems to rest on assumptions about or commitment to the goodness of ecosystems in the face of threats to their continuing vitality from pollution or other phenomena. Ecology thus becomes mixed with ethics in urging that humans ought to find a lifestyle more respectful or harmonious with nature. As the founder of wildlife management, Aldo Leopold, argued: "A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise" (Leopold 1968 [1949], pp. 224–225). More recently, since the United Nations Conference on Environment and Development (1992), the focus has been a sustainable economy based on a sustainable biosphere.

Leading Concepts

Leading concepts in ecology involve ecosystems (a term coined by Arthur G. Tansley in 1935), a succession of communities rejuvenated by disturbances, energy flow, niches and habitats, food chains and webs, carrying capacity, populations and survival rates, diversity, and stability. A main claim is that every organism is what it is where it is, its place essential to its being, the "skin-out" environment as vital as "skin-in" metabolisms. Early ecologists described organism–environment relations in terms of homeostasis, equilibrium, and balance. Contemporary ecologists give a greater role to contingency, flux, dynamic change, or even chaos. Others emphasize self-organizing systems (autopoiesis).

As subsequent studies have shown, any ecological stability is not simply homeostatic but quite dynamic, and may differ with local systems, the level of analysis, and over time. There are perennial processes—wind, rain, soil, photosynthesis, competition, predation, symbiosis, trophic pyramids, and networks. Ecosystems may wander or be stable within bounds. When unusual disturbances come, ecosystems can be displaced beyond recovery of their former patterns. Then they settle into new equilibria. Ecosystems are always on a historical trajectory, a dynamism of chaos and order entwined.

Ecology, Technology, Management

How far can human environmental policy be drawn from ecology? The question raises classical is/ought concerns about moving from facts to values, and worries about the naturalistic fallacy. Perhaps ecology, a "piecemeal" science, can offer no more than generalizations of regional or local scope, and supply various concepts (such as eutrophication of lakes, keystone species, nutrient recycling, niches, and succession) for analyzing particular circumstances. Humans could then step in with their management objectives and reshape ecosystems consonant with cultural goals.

Certainly humans have always had to rest their cultures upon a natural life-support system. The human technosphere is constructed inside the biosphere. In the future this could change; the technosphere could supersede the biosphere. The natural sciences would be increasingly replaced by the sciences of the artificial, as in computer science, or materials science (as with Teflon), or engineered biotas. Edward Yoxen (1983) has celebrated the prospect: "The living world can now be viewed as a vast organic Lego kit inviting combination, hybridisation, and continual rebuilding. . . . Thus our image of nature is coming more and more to emphasise human intervention through a process of design" (pp. 2, 15).

Ecosystem management (if not more global, planetary management) appeals alike to scientists, who see the need for understanding ecosystems objectively and for applied technologies, as well as to landscape architects and environmental engineers, who see nature as redesigned home, and finally to humanists, who desire benefits for people. A good thing in nature may not be a good in culture, and vice versa. Viruses kill people; people's cities kill wild animals. The combined ecosystem/management policy promises to operate at systemwide levels, presumably to manage for indefinite sustainability, alike of ecosystems and their outputs. Such management sees nature as "natural resources" at the same time that it has a "respect nature" dimension. Christian ethicists note that the secular word *manager* is a stand-in for the earlier theological word *steward*, and also that the biblical "dominion" involves more cultivating a garden Earth than conquering and controlling it.

At the same time, ecosystem management has been criticized as an umbrella idea under which different managers can include almost anything they wish, because what one is to manage ecosystems for is left unspecified. They might be managed for maximum sustainable yield, for equal opportunity in the next generation, for maximum biodiversity, or for quick profit. Nevertheless there usually is the idea of fitting human uses into ongoing ecosystem health or integrity. There is less overconfidence than with those who view nature as a vast Lego kit and seek to redesign the planet. This is often a matter of managing human uses of their ecosystems with as much care as one is managing, or revising, wild nature.

Editing a 1989 *Scientific American* issue on "Managing Planet Earth," William C. Clark identified two central questions: "What kind of planet do we want? What kind of planet can we get?" (Clark 1989, p. 47). Over great stretches of Earth, evolutionary and ecosystemic nature has been diminished in favor of engineered design. Nature is at an end. The principal novelty of the millenium is that Earth will be a managed planet. Humans will make it a better home for themselves.

Ecological Limits?

Such claims raise concerns about how far nature can and ought to be transformed into humanized nature. Ecologists are likely to fear the arrogance rather than to celebrate the expertise of such planetary engineers. Much transformation is the positive result of human managerial successes: widespread irrigation, agricultural production, electric power. But just as often there are unintended, undesired results: The seeds of exotic weeds are carried afar on ships and trains; the landscape is increasingly weedy. Toxic, nondegradable agricultural chemicals seep into the nooks and crannies of all nature. Industrial production and mass consumption produces global climate change. The "dominion" mentality is what led to the ecological crisis; more clever dominion, the ultimate technological fix, is a dangerous myth. Rather people should think of humans as fitting themselves into a sustainable biosphere, as members of a larger community of life on Earth, as a better logic of our being at home on Earth.

But, critics rejoin, the community of life on Earth is already human-centered; this is the fact of the matter. The end of nature may be, in its own way, a sad thing; but it is inevitable, and the culture that replaces nature has many compensating values. Humans too belong on the planet. With the arrival of humans, and their technologies, pristine nature vanishes. Nature does not vanish equally and everywhere, but there has been loosed on the planet such a power that wild nature will never again be the dominant determinant of what takes place on the inhabited landscapes.

Should this rebuilding of humanity's Earth home be thought of as a sort of dialectic: nature the thesis, culture the antithesis, and the synthesis a humanized nature? Possibly, but there is a still better ecological model: that of an ellipse with two foci. Some events are generated under the control of a culture focus: society, its economics, its politics, its technologies. Under the other focus, nature, some events take place in the absence of humans—wild, spontaneous, ecological, evolutionary nature (in parks, reserves, and wilderness areas).

From a larger ecological perspective, a domain of hybrid or synthetic events is generated under the simultaneous control of both foci, the result of integrated influences from nature and culture. Human labor and craft put natural properties to use in culture, mixing the two to good effect in agricultural, industrial, scientific, medical, and technological applications. *Symbiosis* is a parallel biological word.

Lest technologists become too arrogant, there is a sense in which nature has not ended and never will. Humans stave off natural forces, but the natural forces can and will return, if one takes away the humans. Nature is forever lingering around. Nature bats last. In, with, and under even the most technologically sophisticated culture, there is always this once and future nature.

Ecological Is and Ought

Scientists and ethicists alike have traditionally divided their disciplines into realms of the is and the ought, facts and values. No study of nature, it has been argued, will tell humans how they ought to behave. But this neat division is challenged by ecologists and their philosophical and ethical interpreters. There may be goods (values) in nature that humans ought to consider and care for. Animals, plants, and species, integrated into ecosystems, may embody values that, though nonmoral, count morally when moral agents encounter them. Ecology invites human beings to open their eyes and to appreciate realities that are valuable in ways humans ought to respect.

Ecological or environmental science may thus inform environmental technology and environmental ethics in subtle ways. Scientists describe the order, dynamic stability, and diversity in biotic communities. They analyze interdependence, or speak of health or integrity, perhaps of resilience or efficiency. Scientists describe the adapted fit that organisms have in their niches. They analyze an ecosystem as flourishing, as self-organizing. Strictly interpreted, these are only descriptions; and yet they embody already quasi-evaluative terms, perhaps not always but often enough that by the time the descriptions of ecosystems are in, some values are already there, putting constraints on what we think might be appropriate human technological development of such areas.

Ethicists can with considerable plausibility also claim that neither conservation, nor a sustainable biosphere, nor sustainable development, nor a well-managed planet, nor any other harmony between humans and nature can be gained until persons learn to use Earth both justly and charitably. These twin concepts are found neither in wild nature nor in any science that studies nature, nor in any technology as such. One needs human ecology, humane ecology, and this requires insight more into human nature than into wild nature. True, humans cannot know the right way to act if they are ignorant of the causal outcomes in the ecosystems they modify. And they cannot act successfully without technology. But there must be more, and here ethics is required to keep science, technology, and life human and humane on this, humanity's home planet.

ECONOMICS AND ETHICS

Economics often is regarded as the most successful of the social sciences in developing a scientific theory of social behavior. Therefore, economics is a science with manifest ethical implications.

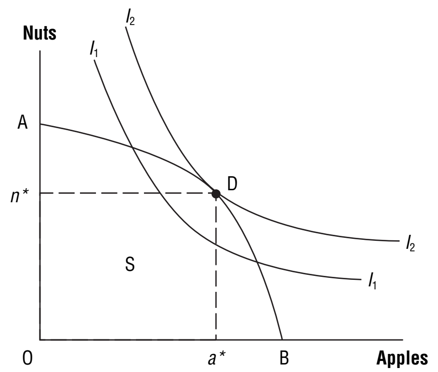
General Equilibrium Theory

Contemporary economic theory is based on the *general equilibrium model* first outlined by the nineteenth-century Swiss economist Léon Walras (1834–1910) and perfected in the post–World War II era by Kenneth Arrow (b. 1921; winner of a Nobel Prize in economics in 1972) and others. The Walrasian general equilibrium model includes firms, which transform production inputs (land, labor, natural resources, capital goods such as buildings and machines, and intermediate goods produced by other firms) into outputs (including consumer goods and services) by using a technologically determined production function that summarizes the most technically efficient way to transform a specific array of inputs into a particular output or array of outputs. The only other actors in the general equilibrium model are individuals and government. Individuals supply labor to firms and own the land, natural resources, and capital, which they supply to firms, and also are consumers who use the income they derive from supplying inputs to production to purchase goods and services that they then consume. The government enforces property rights and contracts and intervenes to alter economic outcomes that are considered inefficient or inequitable.

The general equilibrium model assumes that there are many firms competing to supply each good desired

FIGURE 1

Individual Welfare Maximization



SOURCE: Courtesy of Herbert Gintis.

by consumers. Equilibrium takes the form of a set of prices for the production inputs and outputs so that supply equals demand for each good as well as for labor, land, capital, and natural resource inputs. General equilibrium theory shows that once the equilibrium prices are known, if individuals and firms are allowed to trade in competitive markets, the equilibrium allocation of production inputs and outputs will emerge. This process often is called *market clearing*.

General equilibrium theory assumes that each individual has a *preference function* that reflects that individual's labor supply and consumption rankings, as described by *rational choice theory* and *decision theory*. The central property of preferences in the theory is that they are self-regarding; this means that individuals care only about their personal labor supply and commodity consumption. It also means that individuals are completely indifferent to the welfare of others and never willingly sacrifice on behalf of other market participants. To make this assumption more palatable, the individuals in general equilibrium theory often are described as families, thus allowing for nonmarket altruistic interactions among nuclear family members.

Consumer Sovereignty

The most important ethical judgment in general equilibrium theory is that involving *consumer sovereignty*: A state of affairs A is normatively better than a state of affairs B for individuals if, with everything else being equal, these individuals prefer the labor and consumption bundles they have in state A over those they have in state B. For a graphic illustration, assume that there are only two goods, Apples (*a*) and Nuts (*n*). Suppose the consumer is restricted to choosing from the Apples-Nuts bundles depicted by region *S* in Figure 1, bounded by OADB.

In this figure I_1I_1 *and* I_2I_2 *represent indifference curves*, which are sets of points along which the consumer is equally well off. These curves exhibit *diminishing marginal rates of substitution*; this means that the greater the ratio of nuts to apples is, the more the individual values apples over nuts, and vice versa. Note that the indifference curve I_1 intersects the interior of region S, and so an agent may increase his or her consumption of both Apples and Nuts. Thus, that individual can shift out his or her indifference curve, and hence increase his or her utility, as long as that indifference curve continues to intersect region S. The consumer is thus best off with indifference curve I_2, which intersects S at the single point D, at which point the indifference curve is tangent to the constraint set S. Consumer sovereignty judges consumption point D, at which the individual consumes a^* units of Apples and n^* units of Nuts, to be a welfare optimum for the individual.

Consumer sovereignty is a problematic ethical judgment in at least three ways. First, it ignores the distribution of economic benefits across individuals. If individual I_1 is very rich and all the other individuals in the economy are very poor, it can be said that society as a whole is normatively better if I_1 is made even richer as long as this is not done at the expense of the other individuals. Assuming that individuals are self-regarding, this is a plausible ethical statement, but if the poor care about equity and are hurt when their relative deprivation is exacerbated, the consumer sovereignty judgment will be flawed. In fact, it appears that individuals do care not only about their own consumption but about how it compares with that of others as well, and so improving the consumption opportunities of one group can hurt another group (Lane 1993).

A second problem with the consumer sovereignty principle lies in its failure to recognize that individuals may prefer things that are not in their own interest. For instance, it is in the nature of the addiction that a cigarette smoker prefers smoking to abstaining, but even smokers recognize that they would be better off if they abstained. Consumer sovereignty at one time was an inviolable article of faith for economists, who considered evaluating people's preferences an insulting and socially undesirable form of paternalism. Widespread phenomena such as obesity, recreational drug use, and substance addiction have convinced many economists that there is a role for government intervention to curb consumer sovereignty in such spheres. However, these sentiments are restricted to a few well-defined areas.

The values promoted by economic theory are generally hostile to the notion that scientists and the educated elite (e.g., teachers, preachers, and social workers) know best what is good for everyone else.

The third problem is that consumer sovereignty implies that individuals care only about their own well-being, whereas people often care about each other. In fact, people often positively value contributing to the welfare of the less well off and to the punishment of social transgressors.

Pareto Efficiency

Consumer sovereignty leads to a very simple but powerful means of comparing the normative worth of two economic situations. One says that state A is *Pareto superior* to state B if at least one person is better off in state A than in state B and no one is worse off in state A than in state B, where *better off* and *worse off* are synonyms for *higher up* and *lower down* on one's preference ordering according to consumer sovereignty. It then can be said that state A is *Pareto efficient* if there is no other state that is Pareto superior to it. These conditions are named after the nineteenth-century Italian engineer and sociologist Vilfredo Pareto (1848–1923).

The important point here is that the Pareto efficiency condition expresses the very weak ethical judgment that society is better off when one member is better off and none worse off, and an individual is better off when he or she has more of what he or she prefers. Any maximally ethically desirable state of the economy will be Pareto efficient because otherwise, by definition, there would be a normatively superior state. Thus, one can separate the normative question "Who deserves to get what?" completely from the positive, nonethical question "What are the conditions for Pareto efficiency?"

The relationship between Pareto efficiency and the normative question of the distribution of welfare among individuals was diagramed by the English economist Francis Ysidro Edgeworth (1845–1926) in what has come to be known as the Edgeworth Box diagram (see Figure 2). One can consider a simple economy with two individuals (I_1 and I_2), two goods (Apples and Nuts), no labor, and no firms—the two individuals simply trade with each other. The width of the rectangle represents the total amount of Apples, and the height represents the amount of Nuts.

Suppose point C represents the initial wealth of the two individuals so that I_1 has FG Apples and 1E Nuts and I_2 has G2 Apples and EF Nuts. The curve

$$I_1^c$$

represents an indifference curve for I_1, a locus of points (combinations of Apples and Nuts) among which I_1 is indifferent, preferring all the points to the northeast to points on the curve and preferring all points on the curve to points to the southwest of the curve. Similarly,

$$I_2^c$$

is an indifference curve for I_2. Note that point D lies on both curves, and it is easy to see that D is Pareto efficient because any move away from it will make either I_1 or I_2 worse off. Clearly, the initial point C makes both agents worse off than they are at D, and so it would benefit them to trade, with I_1 increasing the amount of Apples in his bundle by getting them from I_2 and I_2 increasing the amount of Nuts in her bundle by getting them from I_1.

The locus of points 1ADB2 is called the *contract curve* and is the set of Pareto efficient points for this economy. Note that at point 1 individual 2 gets everything, whereas at point 2 individual 1 gets everything. The points between represent different distributions of the benefits of the total supply of Apples and Nuts in the economy. Of course, I_1 prefers C to most of the points on the contract curve below C and I_2 prefers C to most of the points on the contract curve above C. To find out exactly which point or points each individual prefers, one can draw the indifference curves for the two agents that go through C and see where they hit the contract curve. Suppose they hit at C_1 and C_2 (not shown in the figure). Then the two agents will be willing to trade at any point on the contract curve between C_1 and C_2.

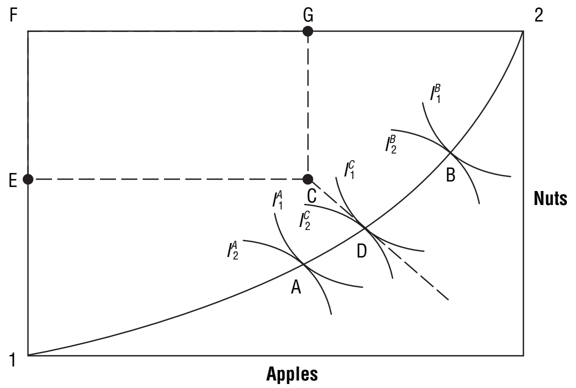
Implications for Ethics

The general equilibrium model has several important implications for ethical theory. The First Fundamental Theorem of Welfare Economics states that any equilibrium of the market economy is Pareto efficient. Note that this conclusion depends on the assumption of self-regarding preferences. If, for instance, above a certain income level people care only about their relative position in the distribution of material benefits, a market-interfering law that prohibited people from working more than a certain number of hours per week could increase the welfare of all people.

Suppose that the various production sectors have production functions that do not depend on one another and that efficient firm size is sufficiently small that there

FIGURE 2

The Edgeworth Box



SOURCE: Courtesy of Herbert Gintis.

can be many firms producing each good in equilibrium. Then a Second Fundamental Theorem of Welfare Economics holds. This theorem states that if the economy satisfies the conditions stated above and a few technical conditions, any Pareto efficient allocation can be supported by a suitable initial distribution of ownership rights in land, natural resources, capital goods, and labor. This theorem successfully separates the positive (technical, scientific) issues of Pareto efficiency from the normative issue of who deserves to get what.

Perhaps the most distinctive normative characteristic of the Walrasian general equilibrium model is its strong commitment to separating considerations of technical efficiency from considerations of normative distribution. This separation is completely justified only if there is a mechanism to distribute initial ownership rights in a way that achieves an ethically desired distribution of welfare. The separation nevertheless often is defended by saying that if the economy attends to the efficiency side of the dichotomy rather than sacrificing efficiency in the name of equity, in the long run most individuals will be better off. This is doubtless a defensible position, although there are often government interventions that promote efficiency and satisfy egalitarian goals as well (Bowles and Gintis 1996).

Several aspects of the general equilibrium model render it an imperfect basis for making judgments about social policy and ethics. First, people are not entirely self-regarding. Rather, they are what may be called strong reciprocators who prefer to reward those who help them and contribute to social goals and to punish those who hurt them or act in an antisocial manner (Gintis, Bowles, Boyd, and Fehr 2003). Strong reciprocators prefer to redistribute resources to the needy if the recipients are considered worthy but not otherwise. This leads to social policies that would not be envisioned under the assumption of the general equilibrium model that people are self-regarding (Fong, Bowles, and Gintis 2004).

In addition, the idea of achieving social equity by means of an initial distribution of wealth among individuals in society followed by market exchange ignores the problem that with incomplete knowledge of the future the process of egalitarian redistribution away from the wealthy and toward the needy will have to be repeated time and time again as the economy moves away from a condition of basic equality to one of severe inequality. That type of redistribution may be infeasible because of the ensuing individual disincentives to accumulate wealth and income-earning capacity.

To see this one must remember that the general equilibrium model assumes that all goods and services are marketable and can be the subject of contracts that are enforced costlessly by a third party such as the judicial system. For instance, several behaviors that are critical to high levels of productivity—hard work, maintenance of productive equipment, entrepreneurial risk taking, and the like—are difficult to monitor and thus cannot be specified fully in any contract that is enforceable at a low cost. As a result key economic actors, namely, employees and managers, must be motivated by incomplete contracts in which monetary rewards are contingent on their performance. However, when incentive rewards are necessary to motivate behavior, egalitarian redistribution works against those who supply a high level of effort, leading to a dampening of the incentive system. Hence, it may be impossible in practice to separate efficiency from equity issues.

Another problem with periodic egalitarian redistribution is that it may violate the principles of justice that many people hold. According to the English philosopher John Locke,

> every man has a property in his own person. . . . The labour of his body, and the work of his hands, we may say, are properly his. Whatsoever then he removes out of the state that nature hath provided, and left it in, he hath mixed his labour with, and joined to it something that is his own, and thereby makes it his property (*Second Treatise on Government* (*Of Property* Chapter 5, Section 27).).

Such values would preclude the involuntary redistribution of wealth even if it furthered widely approved egalitarian ends.

In short, technical efficiency and normative issues concerning justice and equality cannot be separated in the manner intended in the Walrasian general equilibrium model. Moreover, because individuals are not completely self-regarding, social policies based on this model will fail to tap the genuine egalitarian motives of voters and citizens. This said, it would be folly to use these shortcomings to override completely the assumption in the Walrasian model that in the long run economic efficiency and efficiency-oriented technical change are more likely to help the less well off. Insofar as this is the case, issues of egalitarian reform should be biased as much as possible toward efficiency-enhancing redistributions such as education, training, and the financing of small business and small-scale farming.

Contracts

Another important set of issues arises when it is recognized that the neoclassical assumption that contracts can be written and enforced costlessly generally does not hold for either labor or capital. In the case of labor an employer can offer workers a legally binding wage, but a worker cannot offer the employer a legally binding amount of effort and care. This is the case because effort and care are not sufficiently measurable that a violation would hold up in a court of law. Therefore, employers generally enter into long-term agreements with their employees, using the threat of termination and the promise of promotion to elicit a high level of performance. However, this practice will motivate employees only if dismissal is costly to an employee, and this will be the case generally only if it is difficult to obtain comparable employment with another firm. That will be the case only if there is *equilibrium unemployment* in the economy. It can be shown that if employers follow this strategy of worker motivation, there indeed will be unemployment in equilibrium (Gintis 1976, Shapiro and Stiglitz 1984, Bowles 1985, Gintis and Ishikawa 1987, Bowles and Gintis 2000).

This situation accounts for the fact that employers generally have power over their employees in the sense that employers can use the threat of dismissal to induce employees to bend to their will, whereas the converse is not true. Although this power may be used benignly, it also may be used in an unethical manner, as occurs when employers force employees to accept unhealthy working conditions or subject them to sexual harassment and other forms of personal humiliation and discrimination.

In the case of capital the difficulty in contract enforcement arises because the borrower cannot make an easily enforced promise to repay a loan. Of course, a wealthy borrower can offer collateral in the form of valuable assets that the lender has the right to seize if the borrower defaults. Nonwealthy borrowers who lack collateral thus are frozen out of many capital markets. Special credit institutions have arisen to give nonwealthy individuals access to credit for home and automobile ownership as well as credit cards for consumer purchases. In the case of home and automobile purchases the asset itself provide collateral, and requiring the buyer to provide a sizable down payment assures the lender against sustaining a loss. In the case of credit cards the threat of a loss of one's credit rating and hence future access to consumer credit serves to protect lenders against loss (Bowles and Gintis 2000).

The absence of costlessly enforced contracts in capital markets has several important social implications. First, demand generally exceeds supply, leading to credit rationing (Stiglitz and Weiss 1981) in which wealthy agents have access to loans whereas nonwealthy agents do not. Second, banks and other lending agencies have the same sort of power over borrowers that employers have over employees by virtue of their superior "short-side" market position. This power is subject to abuse by lenders, although large borrowers have a counterbalancing power to injure lenders so that in effect it is only the small borrower who must be protected against the arbitrary actions of lenders (Bowles and Gintis 2000).

ECONOMICS: OVERVIEW

In economics, issues of science, technology, and ethics are more diverse than in any other scientific or technological discipline. In the first instance, like all the sciences, economics is both dependent on and independent of ethics. Its methods involve internal commitments of an ethical character (e.g., truth telling) but are subject to external ethical oversight (e.g., with regard to the proper treatment of human participants in empirical research). At the same time, as the entry on "Economics and Ethics" points out, the content of the science may have ethical implications in ways that physics, for instance, does not.

In the second instance, insofar as economics constitutes a technique or technology, it may provide guidance for how to achieve externally determined ends. As such it exhibits multiple interactions with various ethical, legal, and policy perspectives. Such interactions are referenced in entries such as those on "Capitalism," "Market Theory," "Political Economy," and "Science Policy."

Modern Economics

Economics in the modern sense (also called "neoclassical economics") is the science of the allocation and utilization of resources under conditions of scarcity, that is, when there are not enough resources or goods to satisfy all human needs or wants. In a widely adopted definition, for example, the British economist Lionel Robbins (1932) describes economics as "the science which studies human behavior as a relationship between ends and scarce means which have alternatives uses" (p. 16). Insofar as economics assumes that most goods and services are scarce or insufficient to satisfy human wants, and that by and large all human wants are legitimate, economics places the free satisfaction of individual human desires at the top of its own internal moral hierarchy. This may be described as the ethics of economics, one that further provides a basic justification for modern technology as a means to increase efficiency in exploitation, production, and distribution, and has been subject to extended historicophilosophical assessment and some criticism (see, e.g., Polanyi 1944, Dumont 1977, Rhoads 1985, Achterhuis 1988, Nelson 2001).

The science of economics is divided into two main overlapping branches dealing with smaller scale and larger scale economic phenomena. The economic analysis of scarcity and the pursuit of productive efficiency in the sense of maximizing satisfaction (or utilities) among individuals at the level of consumers, firms, and markets is called microeconomics. The economic analysis of scarcity at the national level, usually in terms of policies that promote or hinder gross economic productivity, employment, investment, or inflation, is called macroeconomics. There is a greater consensus about the principles operative in and recommendations for behaviors in microeconomics than in macroeconomics.

A strong consensus at the level of microeconomics is exhibited around what are known as the first and second theorems of welfare economics. It is universally agreed that both theorems follow logically from the general equilibrium model—even while there are disagreements about the plausibility of the assumptions necessary for the theory to hold that make problematic any policy recommendations based on it. Again, see "Economics and Ethics."

The first theorem states that the general equilibrium in a competitive economy is Pareto efficient. A special kind of efficiency, Pareto efficiency (as formulated by the Italian engineer economist Vilfredo Pareto) is that situation in which it is not possible to make anyone better off without making someone else worse off. A competitive general equilibrium refers to the outcome in an ideal setting in which consumers are able, in a free and well-informed manner, to exchange goods and services in an open market with multiple independent producers. Of course, this ideal is not always the reality.

The second theorem states that any feasible allocation of welfare to economic actors can be achieved by the appropriate assignment of property rights to agents, followed by competitive production and exchange. What this means is that any desired Pareto-efficient outcome can be achieved simply by an appropriate initial distribution of property rights followed by free-market activity.

It is important to note that because of debates about the assumptions behind the model on which these theorems rely, they do not in themselves fully justify the market economy. The market economy based on private property upheld by the state simply seems to work better in achieving popularly approved welfare goals than alternative systems.

Insofar as economics involves both scientific theory about decision-making and techniques (or technologies) for decision-making, it has further implications for ethics. Indeed, those special economic analyses found in "Game Theory" and its generalization known as "Rational Choice Theory" have on occasion been presented as scientific assessments of some aspects of human behavior that also have normative force.

The less than strong consensus at the level of macroeconomics is reflected in extended debates about how science and technology contribute to national economic productivity, employment, investment, or inflation. These debates are reviewed in the entries on "Innovation," "Invention," "Political Economy," and "Science Policy." They are also related to a host of studies in the history and sociology of science, technology, and economic change that are relevant but not considered at length (see, e.g., Rosenberg 1976, 1982, 1994; Mokyr 1990, 2002; Rosenberg, Landau, and Mowery 1992; Mirowski and Sent 2002).

Still a third main branch of economic analysis concerns development. This field of economics and its special relations to science, technology, and ethics is considered in the entry on "Development Ethics."

Postmodern Economic Issues

Along with these three main branches of economics, there are a number of closely related specialized forms that qualify or extend the modern economic framework. Two of these have been given special entries: "Ecological Economics" and "Environmental Economics."

Environmental economics, which began to be recognized as a special field in the 1970s, seeks to adapt the principles of micro- or welfare economics to satisfying individual environmental desires for clean water and clean air by seeking to identify the best market mechanisms to promote pollution or emission reductions and waste management. To some extent it is often argued that this requires the social scientific management of markets.

Ecological economics, which emerged in the 1980s, especially contends that market mechanisms are insufficient to evaluate ecological phenomena. As a result, it seeks new ways to conceptualize, for instance, the carrying capacity of the environment and the economic value of natural goods and services.

Both environmental and ecological economics, because they require experts to adjust or correct markets to make them reflect social values, must deal with the problem formulated by social choice theory. Social choice theory concerns the question of whether societies—rather than individuals—can be said to have preferences, and if so, how these preferences relate to the preferences of the individual members of a society. The core result of social choice theory is an impossibility theorem, formulated by the economist Kenneth J. Arrow (1970), that challenges the notion that a society can rank its options in a coherent way. Arrow's theorem states that if everyone in a society has individual preferences that satisfy some basic principles of consistency, and applies these preferences to rank-order a set of options, unless everyone has the same preferences (or agrees to appoint a dictator) there will be no way to add up the individual preferences to achieve a social preference ranking that retains the consistency observed in individual preferences.

EDISON, THOMAS ALVA

Inventor and entrepreneur Thomas A. Edison (1847–1931) was born in Milan, Ohio, on February 11, and became the most prolific inventor in U.S. history, with a record 1,093 patents. Through his technological innovations and companies, "The Wizard of Menlo Park" (in New Jersey, where his laboratory was located) helped found the electric light and power, sound recording, and motion picture industries, and contributed substantially to the telecommunications, battery, and cement industries. He was also close friends with Henry Ford, the pioneer of mass production. Edison established the first industrial laboratories devoted to inventing new technologies and recast invention as part of a larger process of innovation that encompassed manufacturing and marketing. The philosopher Alfred North Whitehead famously credited him with the invention of a method of invention. Edison died in West Orange, New Jersey, on October 18.

Thomas Alva Edison, 1847-1931. The American inventor held hundreds of patents, most for electrical devices and electric light and power. Although the phonograph and incandescent lamp are best known, perhaps his greatest invention was organized research. *(© UPI/Corbis-Bettmann.)*

The Invention Process and Intellectual Property

After working as a telegraph operator in the mid-1860s, Edison began his inventive career by becoming a contract inventor in the telegraph industry. At a time when general incorporation laws were just beginning to reshape American business, these companies were learning how to deal with technological innovation. Concerns over conflict of interest were also just beginning to emerge, and Edison saw no conflict in working for companies in direct competition with each other.

Perhaps the best-known conflict of interest in Edison's early career arose over his most important telegraph invention—the quadruplex telegraph, which enabled four messages to be sent simultaneously over one wire. Edison worked on this invention under an informal arrangement with Western Union Telegraph. At the same time he was working under more formal contracts with officials of the Automatic Telegraph Company to develop a competing system that used machinery rather than human operators to send messages at high speeds. After successfully demonstrating his quadruplex in the fall of 1874 on Western Union lines, Edison sought payment from the company, but

Western Union did not act promptly on what he believed were relatively modest demands for payment. Facing the loss of his house and shop in Newark due to the general economic depression caused by the Panic of 1873, Edison felt free to sell his rights in the invention to railroad financier Jay Gould, who was in the process of creating a competing telegraph network by combining several small competing firms including Automatic Telegraph. Although Western Union had to sue to assert its rights to the invention, the company nonetheless agreed to retain Edison's services to continue work on multiple telegraph systems, but this time under a formal contract. Later Edison signed another agreement with Western Union that secured all his work related to landline telegraphy, including the new telephone technology.

Edison entered into this latter contract in early 1877 in an effort to secure support for his new Menlo park laboratory, the first devoted to the creation and commercialization of new technologies. Edison's *invention factory* played a key role in the creation not just of specific devices but of methodological research and development leading to market innovation. Indeed, in order to make the incandescent light bulb commercially viable, Edison created a system for the distribution of electricity and designed the manufacturing technology for producing lamps.

As the laboratory and its workforce grew, Edison depended more and more on the assistance of a large staff of experimenters and machinists who made important contributions to his inventive efforts. As a consequence, he was faced with finding ways to give appropriate credit and financial awards for their work. At the time employees entered the laboratory they were made to understand that they were working on Edison's ideas, and that their work on his inventions would be credited to him.

Nonetheless the issue of credit remained a tricky one. While Edison and his assistants perceived their role as working on his ideas, he gave general directions and relied on their abilities to work out important details. Edison thus generally made it a policy to take out the key patents, while permitting assistants to take out ancillary patents he considered to be primarily their contribution. At the time, U.S. patent law gave priority to an employer in disputes with employees and discouraged joint inventions unless a true partnership in the invention could be demonstrated. In lieu of joint patents or other credit for their inventive assistance, Edison gave his chief experimenters an interest in royalties and other profits. He also placed many of them in management positions in his companies, and some became partners. Edison continued these policies at the larger laboratory he opened in West Orange, New Jersey, in 1887.

The issue of credit was also a significant one for Edison's competitors, particularly because of the popular image of him as the primary inventor of several new technologies. Edison's reputation was partially a consequence of the fact that he had a much more sophisticated understanding of invention than his contemporaries. Edison saw invention as just the first stage of a larger process of innovation. Thus he took a leading role in marketing the inventions he developed through companies he established and that bore the Edison name. Because his name was associated with the technology he continued to make improvements to insure its reputation as well as his own. This kept him in the public eye as reporters wrote stories about his latest improvements.

Edison's public image was also a result of his skill at public relations. He had developed an understanding of the newspaper business while working as a press-wire telegraph operator and, after becoming famous for inventing the phonograph, he had established close relationships with several reporters in New York City who found Edison a ready source of news, opinion, and human interest. Thus even when other inventors made important technical contributions, the public credited Edison first.

While Edison's willingness to make announcements through the press aided his marketing efforts, it created problems for his scientific reputation. When Edison claimed that he had observed a new natural phenomenon and termed it *etheric force* in 1875, he made his first announcements through the newspapers and continued to press his claims through press interviews rather than through the scientific journals as did his opponents. Similarly after British inventor David Hughes's claim to the invention of the microphone appeared in the scientific journal *Nature,* Edison launched a public attack through the New York City newspapers rather than responding in the scientific press. In both cases, Edison's claims in the scientific community were weakened by his failure to adhere to the norms of scientific publication and debate.

While Edison saw himself as a member of the larger scientific community and presented papers before the American Association for the Advancement of Science (AAAS) and the National Academy of Sciences (NAS) in the 1870s and 1880s, he was foremost an inventor and more interested in attracting public interest in his work than advancing scientific knowledge. Nonetheless when his inventive work produced devices that were primarily useful for scientific research he was willing to forego royalties in their manufacture and make them available to the scientific community. This occurred with a heat measurer he called the tasimeter in 1878, when he gave some early light bulbs to scientific researchers in 1880, and with his work on X-ray technology in 1886.

Public Policy Issues

Because the public saw Edison as a leading figure of science and technology, his comments on important public issues could carry significant weight. In two instances his reputation proved crucial to the enactment of public policy.

In the first and more controversial instance, Edison was asked in 1888 for his expert opinion on the establishment of electrocution as a more humane form of execution than hanging. Although opposed to the death penalty, Edison agreed to support this position and also allowed Harold P. Brown, a self-taught electrician, to conduct experiments on animal electrocutions at his laboratory. These experiments in support of electrocution were undertaken in part due to Edison's firm belief in the dangers of high-voltage electricity, and thus his ethical opposition to its public use.

But it also stemmed from the increasing competition his low-voltage direct-current (DC) electrical system was receiving from the high-voltage alternating current (AC) system being marketed by George Westinghouse. The debate on electrocution thus became wrapped up in this commercial struggle. Edison's strong opposition to high-voltage and the demonstrations at his laboratory that showed high-voltage AC to be more dangerous than high-voltage DC led him to champion the electric chair and testify on behalf of the state in the appeals of the first death penalty case involving electrocution. Edison would later regret his role in the development of the electric chair but never gave up his opposition to high-voltage electricity.

Edison's other significant involvement in public policy came as the result of a 1915 *New York Times* interview in which he urged greater military preparedness and the need for a national research laboratory to develop new military technologies for defense. This led Secretary of the Navy Josephus Daniels to ask Edison to establish and head a new Naval Consulting Board. The Board was made up of leading inventors, engineers, and industrial research scientists. Edison would eventually lose the larger debate within the Board over the nature of the research laboratory. Based on the newer style of industrial research laboratories, the new Naval Laboratory, which was not established until after World War I and was headed by naval officers rather than civilians, focused on science-based research leading to the development of small-scale prototypes. It was not a works laboratory like Edison's, equipped with extensive machine shop facilities for turning prototypes into commercial technology.

The differences over the Naval Laboratory were also reflected in Edison's own contribution to research during World War I. Although Edison developed forty-two inventions that he believed could contribute to the war effort, the Navy adopted none. Instead the Navy officers responsible for introducing new technology turned to the efforts of those researchers whose approach included the mathematical rigor and theoretical basis that their university educations had taught them were the foundations of modern research.

The growing differences between Edison and more youthful researchers marked a shift in the nature of scientific and technical training. This shift became more evident by the end of Edison's life, when news accounts treated him as the last of the lone cut-and-try inventors rather than the creator of the first industrial research laboratory. A closer study of his life, however, reveals that in the course of reshaping the ways in which invention took place, including at his laboratories, Edison was faced with many of the same ethical issues encountered by twenty-first-century inventors and industrial researchers.

EDUCATION

Any regular practice, for example, agriculture, craft production, navigation, or scholarship, requires learning opportunities for novice practitioners, which have often been provided in workplaces, or through informal instruction and self-directed study. This survey, however, will be limited to *formal* education, that is, to teaching and learning in institutions such as colleges and universities established exclusively for these purposes.

A broad historical account (to be elaborated below) of scientific and technical education in relation to ethics runs as follows.

Science and ethics initially were intimately related in ancient education, while technology was explicitly excluded. Medieval Christians were ambivalent about ancient pagan science, because they held an opposing notion of moral perfection. Greek science nonetheless retained a minor place in medieval education, though its intimate association with ethics was weakened insofar as morality was religiously based. When classical learning was recovered in Western Europe by the mid-thirteenth century, and the scholastics sought to render it consistent with church teachings, natural philosophy (science) and moral philosophy were added to the curriculum as standard, but distinct, university subjects.

Renaissance scholarship facilitated the scientific revolution of the sixteenth and seventeenth centuries. By the start of the eighteenth century, however, modern science had become divorced from teaching in the English universities, and had forged new institutional links with technology and commerce. Ethics, however, was revitalized as a university subject by the contributions of Renaissance humanists. Natural science was reestablished as a teaching field in the early-nineteenth century. Technology remained excluded from North American colleges, and moral philosophers attempted to harmonize the new science with the prevailing Protestant worldview and morality. New German universities, however, rejected all association with religious creeds and devoted themselves to the free study and teaching of science.

Engineering, agriculture, and other technical and professional fields became university degree subjects late in the nineteenth century in both England and the United States. Politics, economics, and sociology became separated from moral philosophy as positive sciences, and ethics attained autonomy from moral theology, becoming merely one academic discipline among others in the secular multiversity. The resulting civilization of science, technology, business enterprise, and the nation-state gained unprecedented control of nature and social life in the twentieth century.

The technoscientific civilization has nevertheless experienced a profound ethical crisis as a result of the atomic bomb, environmental pollution, resource depletion, nuclear accidents, and other *techno-shocks*. Many scholars and social leaders came to fear that technoscience had outstripped social capacities for its ethical control, and that it even threatened human survival. Some science, technology, and ethics professors, therefore, collaborated in forging closer relationships between their fields, in an attempt to bring ethical judgment to bear on further developments in science and technology.

From Greek *Paedeia* to Medieval Scholasticism

Systems of education in science and technology that have taken on worldwide influence have their root influences in classical school experiences. It is thus appropriate that the present survey should highlight this historical background.

SCIENCE AND ETHICS CONJOINED. Formal elementary education was established for free males in several Greek city-states by the fifth century B.C.E., taking place in the *didaskaleion*, the area set aside for teaching. After learning to read and write, older children learned classic literature and music. Youths attended public gymnasiums for physical and character training and military preparation. Beyond this level, education in the fifth century was not standardized. The gymnasiums, however, became sites for discussion groups and lectures given by sophists.

Science and ethics were esoteric subjects taught informally by masters to a few chosen disciples.

Science and ethics, however, were not distinct subjects. Pythagoras of Samos (ca. 580–500 B.C.E.), and Democritus of Abdera (460–370 B.C.E.), are important examples. Pythagoras of Samos studied arithmetic, astronomy, geometry and music at Miletus, and possibly also at Babylon and Egypt. Pythagorean ethics held that virtue was a harmony of the soul that mirrored the harmony of the spheres, and that mathematics is the pathway to moral perfection. In contrast Democritus conceived the natural world, including the soul, as a machine behaving in accordance with laws of matter, so that freedom of action is an illusion to be overcome by reflection on the determinism in nature. A state of tranquil acceptance of mechanistic reality is thus the ethical good.

By the fourth century B.C.E., more formal philosophical schools evolved from the informal learning at the gymnasiums, and Athens became the recognized center of learning. The school of Isocrates, based on the rhetorical teachings of the sophists, opened in 390 B.C.E.. In 387 B.C.E., Plato (428–347 B.C.E.) established a school with a program of study similar to that of Pythagoras. It came to be called the Academy because of its location near the Groves of Academus. Aristotle (384–322 B.C.E.) gave lectures after 335 B.C.E. at the gymnasium dedicated to Apollo Lyceios; his school became known as the Lyceum. Aristotle distinguished between theoretical and practical studies; science and ethics were taught as distinct subjects. Aristotle nonetheless agreed with Pythagoras and Plato that the highest good is contemplative knowledge, and thus he taught that the highest ethical life is not practical action in the polis, but theoretical contemplation.

Both Plato and Aristotle distinguished technical arts from those suitable for liberal education. In the Philebus (55e–56a) Plato argued that when the mathematics was abstracted from technical arts such as navigation and architecture, what remained was intellectually trivial. The educational program Plato laid out for the Guardians in Book 7 of the *Republic* (380 B.C.E.) was based on the four Pythagorean mathematical arts: arithmetic, geometry, astronomy, and harmonics. All of these he conceived entirely in abstract terms, with sensory observations and utilitarian applications removed. (*Real* astronomy, for example, had no concern for the sun, moon, or stars, but only with solids in revolution.) Aristotle considered technical arts degrading and slavish. (*Politics* Bk 3, 1277a5-a12, 1277b34-1278a14). As handcrafts workers engage in repetitive acts, they "are like certain lifeless things that act . . . without knowing what they do, as fire burns"(*Metaphysics* Bk 1, 981a13–b9).

The Athenian schools continued under new leaders (or *scholarchs*) after the death of the masters. While Aristotle's school devoted itself almost exclusively to natural science, the other schools continued to offer a program in which science and ethics were intertwined, but ethics soon became predominant. In 306 Epicurus (341–270 B.C.E.) established a school that followed the teachings of Democritus. Zeno of Citium in Cyprus (c. 335–263 B.C.E.), teaching at the painted column or stoa, taught a *stoic* ethic of rational preferences ordered according to nature, mastery of passions, and indifference to fate.

The theory of the liberal arts attained a definite form by the first century B.C.E. By that time the circle of learning, the *enkyklos paedeia,* had come to include logic, rhetoric, grammar (literature), and the four Pythagorean mathematical sciences. In the Roman Latin schools, however, the literary arts dominated. Mathematical subjects were recognized, but taught cursorily, if at all.

ROMAN AND MEDIEVAL SCHOOLING. The educated classes during both the Roman and medieval periods admired but exhibited a certain ambivalence regarding classical learning. Neoplatonic philosophers of the Roman period, for instance, preserved the Pythagorean and Platonic program—mathematical study for ethical perfection—but were more oriented toward education that would serve overt political ends, as with oratory. More than their pagan peers, perhaps, early Roman Christians admired Neoplatonism because of its unworldly and ascetic emphases. It made a deep impression on Augustine of Hippo (354–430 C.E.), and inspired the grand educational project of Boethius (480–525 C.E.).

Boethius, noting that prevailing Latin textbooks in grammar and rhetoric were adequate, sought to revitalize the *enkyklopaideia* by preparing Latin handbooks on logic and the four mathematical disciplines, for which he invented the name *the quadrivium*. Following the Neoplatonists, Boethius conceived these studies as pathways from the sensible world to supersensible reality as a means of ethical perfection. Boethius's manuals (on arithmetic, logic, and music) became standard school and university textbooks for almost 1,000 years.

The death of Boethius in 525 C.E. and the closing of the Platonic Academy of Athens, by the Eastern Emperor Justinian in 529 C.E., mark the end of Greek learning in the West. Barbarians gradually also destroyed the Latin schools, and eventually even Latin classics were unavailable in Western Europe. Greek classics were preserved at Byzantium and then entered the stream of Islamic learning. Latin classics were preserved in Ireland.

LATIN SCHOOLS REVIVED AND UNIVERSITIES BORN. Charlemagne, crowned Holy Roman Emperor in 800, sought to revive learning in order to provide educated clergy and administrators for his realm, and ordered his cathedrals to establish schools. An organized program of teaching, however, requires textbooks, and in logic and the sciences only those of Boethius, preserved in Ireland, were available. The Church retained a deep ambivalence about pagan learning, which contained a view of moral perfection at odds with its own as best expressed in Tertullian's famous question, "What has Athens to do with Jerusalem?"

Nonetheless the cathedral schools were, in theory, organized along classical lines: a grammar school for logic, rhetoric and grammar (for the first time called the *trivium*), followed by a higher school for the *quadrivium*. In practice, while the *trivium* provided useful training for clergy and administrators, the *quadrivium* was often neglected. Most schools could manage only practical arithmetic for calculation, geometry for architecture and surveying, and astronomy to calculate Easter. Science education improved in some cathedral schools in the eleventh century. At Reims Gerbert of Auillac (955–1003), acquainted with Arabic scholarship in Spain, refreshed the *quadrivium* by using Arabic numerals, the abacus for calculation, and the astrolobe for astronomical observation.

In 1079 Pope Gregory VII issued a papal decree ordering all cathedrals and monasteries to open schools for the training of clergy. As schooling expanded it became necessary to regulate teacher preparation and licensure. The church claimed a monopoly over teaching licenses (*licencia docendi*). Municipal chancellors offered these licenses only to those intending to teach in their districts.

Some municipalities, however, attracted students from many regions, and gained recognition as *studia generale*, whose degrees (licenses) were recognized throughout Europe. These *universities* were divided into lower schools for the seven liberal arts plus schools for law, theology, and medicine. Two models for the university emerged: one at Paris, Oxford, and Cambridge, where the arts course predominated; the other at Bologna and Salerno, where, contrary to the dictates of Plato and Aristotle, the arts course became merely a minor preliminary to technical education in the professions.

Science education in the arts course remained grossly inadequate. By papal decree, lectures on the *quadrivium* could be offered only on public holidays. By the last third of the twelfth century, however, the importation of classical texts from Muslim Spain reached its peak. Adelade of Bath had translated Euclid's *Elements*, and the Aristotelian corpus was made available in Latin translation.

SCHOLASTICISM: SCIENCE, ETHICS, AND RELIGION. In the thirteenth century the challenging task of assimilating the classical inheritance began. In geometry, for example, the study of Euclid prompted new discoveries in optics by Robert Grosseteste (c. 1170–1253) and his student Roger Bacon (c. 1220–1292). Grosseteste, chancellor of Oxford (1215–1221), made optical studies, wrote a commentary on Aristotle's *Posterior Analytics*, and championed empirical inquiry. Bacon, who said he had learned more from simple craftsmen than from famous professors, carried on Grosseteste's empirical studies of lenses as aides to natural vision.

Assimilation of Aristotle's writings in natural and moral philosophy was among the greatest challenges faced by the thirteenth century universities. Pope Innocent III banned the study of Aristotelian natural philosophy in 1210. A committee was formed in 1231 to expunge all heretical ideas from his texts so they might be suitable for teaching, and by 1255, Aristotle's works returned to the syllabus. Scholasticism, the project of rendering the classical inheritance compatible with church teachings, came to dominate university studies. Thomas Aquinas (1224–1274), the greatest of the scholastics, saw that with the recovery of ancient learning, the seven liberal arts had become inadequate as a pattern of study, and the arts course was expanded to include the *three philosophies*: metaphysics, natural philosophy (empirical science), and moral philosophy.

The scholastic method of education stressed formal definition and logical argument. The scarcity of books dictated its primary tools: lectures (where books were publicly read and interpreted), recitations (where students demonstrated their familiarity with the books), and public disputations (where students presented public arguments in syllogistic form). Scholastic natural philosophy thus remained confined to theory, logical argument, and thought experiment. Controlled observations and technical applications were rare. The old textbooks dominated the syllabus for centuries. Scholasticism, while useful as a method of organizing official knowledge and conveying it in a standard form as preparation for professional studies, failed to encourage systematic and creative scientific studies, and eventually became bogged down in fruitless verbal controversies.

Early Modernity: Science, Technology, Humanism, and the Reformation

By the fifteenth century medieval institutions no longer provided Europe with either social order or a rational world picture. Renaissance humanists, working outside the universities and in opposition to scholasticism, sought inspiration in the pagan classics for reshaping learning and civic life. They praised Aristotle's ethics, and placed moral philosophy at the center of their curriculum. Claiming that moral virtue grew from emulation of classical authors and orators, they tied ethics closely with rhetoric, history, literature, and classical languages in a complex that became the humanities.

The humanists, however, rejected Aristotelian logic as artificially formal. They promoted a practical, natural logic based on study of the arguments of the great orators, thereby incorporating logic within rhetoric. They also rejected Aristotle's qualitative natural philosophy in favor of Plato's quantitative approach, thus easing the path for Nicolaus Copernicus, Johannes Kepler, and Galileo Galilei. The latter's aphorism that *the book of nature is written in mathematical characters* might have been taken directly from Plato. Humanists made few direct contributions to scientific scholarship, as the recovery of pagan scientific classics had been completed, but their intellectual independence and daring established a new spirit of learning congenial to later modern scientific inquiry.

Martin Luther and John Calvin, the leaders of the Protestant Reformation, were themselves humanist scholars. Their encouragement of the close reading of scriptural texts stimulated close reading of the book of nature. Protestantism directly undermined scholasticism, as it eliminated the need to square classical authorities, including Aristotle, with Catholic Church teachings. The new Protestant universities of Northern Europe could start afresh, and thereby became leaders in incorporating modern science into their curricula.

THE SCIENTIFIC REVOLUTION AND ITS SOCIAL INSTITUTIONS. The fifteenth and sixteenth centuries were periods of rapid developments in commerce, navigation and ship construction, instrument making, mining, and mechanics. These new conditions, when conjoined with the mathematical knowledge brought to the Christian West from Byzantium and Muslim Spain, illuminated new pathways for the growth of scientific knowledge.

Until the seventeenth century Europe possessed no scientific societies or journals to stimulate or publish reports of new investigations. To develop an infrastructure for science required a vision, a site for meetings of scientists and technical experts, a critical mass of expert scientific workers, and an organization to stimulate and assess significant scientific achievements and make them widely known through its publications. The coordination of these factors in England led to the establishment of the Royal Society in 1660.

Francis Bacon (1561–1626) framed the vision. He maintained, against both classical authorities and the scholastics, that the only useful knowledge was based on empirical study of nature, and that a clear method for scientific work would provide human mastery over the natural world. Under such conditions, *knowledge is power*. His inductive method, though a technical failure, shaped an agenda for practically useful science that included close study of mechanical crafts.

Thomas Gresham (1519–1579), a wealthy London merchant, provided the site, by endowing a college for merchants and craftsmen that opened in 1598. Gresham College offered no degrees, but provided free public lecture courses in rhetoric, astronomy, geometry, music, divinity, medicine (physic), and law. The Gresham professors were selected from among the most eminent scholars of their time. The first Gresham Professor of Geometry, Henry Briggs, developed logarithmic tables and popularized their use. The college's central location in London provided the ideal meeting place for scientists and technicians. Briggs also made it the central clearing house for scientific and technical information.

Oxford provided the critical mass of scientific experts. When Briggs was appointed the first Savilian Professor of Geometry at Oxford in 1619, he strengthened ties between Gresham College and the university. In the 1640s a group of distinguished natural philosophers including John Wilkins (of Wadham College), Seth Ward (later the Savilian Professor of Astronomy), Robert Boyle, William Petty (later professor of anatomy), and Jonathan Goddard (of Merton College) frequently attended Christopher Wren's lectures at Gresham College and then met with coworkers, including navigators and instrument makers. Boyle called this group the *invisible college*.

In 1651 the Oxford Philosophical Society was formed and began publishing transactions. A similar organization failed at Cambridge because no scholars were willing to perform experiments. In 1660 members of the invisible college formed a national society, which was incorporated by royal charter as the Royal Society in 1662. It soon established its offices and meetings at Gresham College, and published its own transactions. Other nations established parallel societies. In France, Jean-Baptiste Colbert founded the Academie des Sciences in 1666, which was reorganized with royal approval in 1699. In Germany Frederick the Great founded the Academie der Wissenschafften in 1700, with Gottfried Wilhelm Leibniz as the first president. By the beginning of the eighteenth century the infrastructure for European science was in place.

SCIENCE EDUCATION. While English university scholars were central in the scientific revolution, science teaching retained its medieval character. The colleges at Oxford and Cambridge were at first mere residence halls, whose tutors were simply older men taking responsibility for the conduct and finances of younger students. By tradition recent graduates (regents masters) of the colleges were required to lecture. By the sixteenth century, however, the regents lecture system had broken down, and the universities recognized the need for a new organization of teaching, including appointment of permanent lecturers.

Lady Margaret, mother of Henry VII, endowed professorships of theology at both Oxford and Cambridge (1497–1502). Sir Robert Rede provided in his will for lectureships at Cambridge in philosophy, logic, and rhetoric. Henry VIII added royal patronage to this trend after conducting visits to the universities in 1535, following his break from the Roman church. Henry's reforms, reflecting the humanist spirit of the sixteenth century; replaced scholastic textbooks with humanist commentaries on Aristotle's natural and moral philosophy. Henry also endowed Regius professorships in classical Greek and Hebrew, as well as divinity, medicine, and civil law. A series of similar endowments and appointments include, for example, the Henry Lucas Professorship of Mathematics at Cambridge, which Isaac Newton held from 1669 to 1701.

These distinguished professorships had almost no impact on teaching, however, because the colleges, which were wealthier and more powerful than the universities, completely dominated teaching. Students were required to live in colleges, where tutors were assigned to lecture and conduct recitations on authorized texts. The tutors were generalists offering instruction on the *ordinary* subjects required for disputations and exams. Professors lectured only on *extraordinary* subjects outside the mandated curriculum. Since colleges prevented universities from examining students on extraordinary subjects for several centuries, few students attended the professorial lectures, and eventually few professors even bothered to deliver them. Not one of the three Regius professors of physic (medicine) at Cambridge from 1700 to 1817 gave a single lecture.

The situation was different in Germany. The first modern university opened at Halle in 1694. Gottingen rivaled Halle as a center of learning after its opening in 1736. The University of Berlin was established in 1800, under the direction of William von Humboldt. Berlin adopted the Platonic ideal, training leaders as philosophers. Professors combined original research with teaching, and students worked closely with professors on research projects. Students thus acquired the cultural and scientific heritage in the very process of working alongside those who knew it best. Berlin rejected attachments to religious creeds and schools of thought, accepting subservience only to science and learning. It thus added to the arts and professional universities of the middle ages a third model, the research university, which soon dominated Protestant Europe.

Science and Ethics in Eighteenth-and Nineteenth-Century American Colleges

The first colleges in the New World, Harvard (1636) and William and Mary (1693) based their statutes on those of the colleges of Cambridge and Oxford. As in England, while mathematics and science were given lip service, the seventeenth-century teachers lacked knowledge of current developments. In 1700 in North America the modern scientific subjects were still associated with navigation and mechanical arts, not with college education. The lack of constraint by an entrenched teaching elite, however, eased the way for their introduction into colleges.

ACADEMIC SCIENCE AND ETHICS IN THE EIGHTEENTH CENTURY. In the mid-eighteenth century Yale acquired some scientific apparatus, and introduced Newton's fluxions to the math curriculum. John Winthrop, the Hollis Professor of Mathematics and Natural Philosophy at Harvard (1738–1779), removed the last traces of Aristotle from the course in natural philosophy and introduced the new science of Galileo and Newton. When the American Philosophical Society for Promotion of Useful Knowledge was established in Philadelphia in 1769, with Benjamin Franklin serving as president, however, the founding members were amateur investigators rather than teachers. The society had

650 members by 1800, but only fifteen of 124 noted college teachers of the period ever became members.

Moral philosophy underwent a more profound revolution. John Locke's "Essay Concerning Human Understanding" (1690), with its consideration of the foundations of moral knowledge, was in the curriculum by 1720. By mid-century moral philosophy was central to both the college curriculum and public discourse, attracting the attention of such Enlightenment leaders as Franklin, Thomas Jefferson, and Benjamin Rush. The American Revolution further invigorated the Enlightenment spirit. William Paley's widely adopted textbook *Moral and Political Philosophy* (1785) presented Christian utilitarianism as a natural science based on empirical observations and first principles, which included the natural rights of man as expressed by Locke. Paley, in his *Natural Theology* (1802), based the existence of God, as the divine intelligence governing the universe, on the argument from design. A course on natural theology was added to the curriculum.

ACADEMIC SCIENCE AND ETHICS IN THE FIRST HALF OF THE NINETEENTH CENTURY. By 1820, as rapid advances took place in U.S. commerce and industry, leaders demanded that mathematics and science in the colleges be improved and made more practical. Mark Hopkins of Amherst called Francis Bacon's notion of knowledge as power the single most influential idea in the popular mind in the early-nineteenth-century. Science teaching, as a result, got a large boost between 1820 and 1850, though reformers had to contend with inadequate textbooks, untrained teachers, and lack of apparatus.

By 1836 adequate textbooks were available in algebra, geometry, trigonometry, analytical geometry, and calculus, and by 1840 calculus was a standard part of the liberal arts course. By 1850 natural philosophy had been reorganized as physics, chemistry, and natural history (biology and geology, formally subjects for amateur naturalists). Physics had been further divided into mechanics, hydrostatics, electricity and magnetism, and chromatics, and textbooks treating these topics in sufficient mathematical detail were widely available. By 1860 five clearly defined courses in natural science—astronomy, physics, chemistry, biology, and geology (including mineralogy)—were part of the liberal arts curriculum.

Prospective teachers began to study in the Protestant universities of Northern Europe. In 1802 President Timothy Dwight of Yale urged Benjamin Silliman (1779–1864), a distinguished graduate, to prepare himself for a professorship in chemistry by studying at the University of Edinburgh. He emerged in 1805 with current knowledge in theoretical and experimental chemistry, as well as practical knowledge of geology, mineralogy, and zoology. George Tinknor (1791–1871) was among the first Americans to prepare for a professorship at a German university; on his return from the University of Gottingen in 1817, he became a professor at Harvard and introduced German methods of study and research. Foreign preparation of college teachers remained the norm until U.S. research universities were established late in the nineteenth century.

The value of laboratory apparatus expanded twenty fold between 1820 and 1850. The introduction of the blackboard transformed mathematics teaching; professors were for the first time able to exhibit spontaneous thoughts and invite groups of students to the board, where the former could watch assigned problems worked out and probe methods of reasoning. Laboratories introduced similar changes in science teaching.

By 1850 the revolution in the liberal arts college was complete. The question of technology—mechanical, agricultural, and mercantile arts—now had to be faced due to popular demand for practical training. In 1828 a famous *Yale Report* maintained that mathematics and science belonged in the college, but not technology. Amherst issued an almost identical report. Despite public pressures, these sentiments prevailed among college leaders until the Civil War, although their marketing efforts emphasized the practical value of college education as early as 1850.

The college curriculum, however, had by then become seriously overcrowded due to the expansion of science and mathematics. Indeed demands for new scientific courses continued to proliferate. National surveys and requirements of the mineral industries created demands for separate mineralogy courses; developments in medical education led to demands for courses in organic chemistry and physiology. The colleges attempted to resolve these conflicts by introducing practical *partial* scientific courses outside the required curriculum, and diploma programs in *parallel* scientific schools such as the Lawrence School of Science at Harvard (1847) and the Sheffield School at Yale (1854). These efforts, though marketed as practical alternatives to the college course, failed because the programs lacked the prestige of a college education and provided no specific qualification for any position in the U.S. economy of that era.

Moral philosophers writing under the influence of New School Calvinism, a doctrine emphasizing that theology was completely compatible with human standards of reason and morality, did not resist the expansion of science. Instead they discarded the enlightenment empiricism of Locke and Paley, which they saw as undermining religion by making human reason self-sufficient. In its place they adopted the Scottish common sense philosophy of Thomas Reid and Dugald Stewart, which held that sense experience must always be actively assimilated by active powers instilled by God in the human mind, and that moral duties were presented immediately as intuitions.

The typical class in moral philosophy was taught as a capstone course by the college president, who deployed common sense principles as bases for conclusions on the ethical issues of the day. The *Elements of Moral Science* (1835) by Francis Wayland, president of Brown, was based on common sense realism, and became the most widely adopted textbook of its era. While the presidents did not even wish to dictate the results of science, they could strive to contain them within the consensus Protestant worldview and framework for moral action. This period in moral philosophy has thus been perceptively labeled as the era of *Protestant scholasticism*.

The Birth of the Multiversity

In the 1860s U.S. colleges faced three main criticisms: The curriculum was overcrowded with science and mathematics, which most students found daunting and unrelated to career plans, and threatened to marginalize the traditional humanities; the college was seen as elitist in neglecting technical and professional subjects; and due to the absence of research, colleges were failing to advance knowledge in the sciences and useful arts. The Massachusetts Institute of Technology's (MIT) founder and first president, William Barton Rogers, was among those who argued that practical studies and research would require a new kind of institution beyond the traditional network of liberal arts colleges.

Union College introduced a bachelor of science degree, parallel to its bachelor of arts degree, by 1828. Wayland, at Brown, proposed an elective system to alleviate the crowding of the prescribed curriculum as early as 1850. Charles Elliot made free election of courses central to his reform of Harvard after assuming the presidency in 1869, and other colleges soon followed Harvard's lead.

Technical and professional studies gained a foothold when Rensselaer Polytechnic Institute (RPI) opened in 1824 to provide engineering education. RPI was reorganized in 1849 and established the template for the engineering curriculum: humanities, physical science, mathematics, and hands-on shop training. The Morrill Land Grant Act of 1861 provided federal funding for colleges in the agricultural and mechanical arts. MIT, founded in 1861, was reorganized in 1865 under the provisions of the act, while Cornell, chartered in 1862, used funds from both the act and private sources for programs primarily in the agricultural and mechanical arts. Cornell soon became a model institution for maintaining harmony among its humanities, sciences, and technical-professional curricula.

The reorganization of industry into a national mass-production system created a vast demand for engineers, and universities reorganized engineering education to meet the need. In the early 1870s Victor Della Vos of the Moscow Imperial Technical School developed a new approach to practical training based on a careful sequencing of skills in shop-like classrooms. His method became widely adopted for practical elements of engineering education after John Runkle of MIT saw it exhibited at the Philadelphia Centennial Exposition in 1876. Engineering science, however, became increasingly dominant in the engineering curriculum. Universities soon added similar science-based degree programs in architecture, forestry, and veterinary medicine.

Because of the lack of opportunities for research training in the United States, many scholars before the 1870s traveled to Scotland or Germany for advanced degrees. Yale awarded the first Ph.D. in the United States in 1861, but graduate education was only institutionalized with the establishment of new research universities: Johns Hopkins (1876), Clark (1889), Stanford (1891), and the University of Chicago (1892).

At Oxford and Cambridge, from 1820 to 1850, the colleges felt the same pressures as their U.S. counterparts, and made modest accommodations. At Cambridge earning *distinction* in *both* classics and mathematics was dropped as a requirement for an honors degree in 1850. The moral science tripos and natural science tripos were introduced in 1851, providing students with two distinct areas of concentration. In the 1850s, and again in the 1880s, however, royal commissions were appointed to suggest education reforms to parliament. By 1890 the established colleges had lost their control over teaching. Instead the colleges provided lecturers for courses open to all university students, and cooperated in funding university-wide professorships. Early in the twentieth century the teaching staffs were reorganized, on an all-university basis, into branches corresponding to the main divisions of study. Civic university colleges opening in Leeds Manchester and Liverpool in the 1880s, like their Morrill Land

Grant Act counterparts, introduced technical and professional studies.

ETHICS IN THE LATE-NINETEENTH-CENTURY COLLEGE. Prior to the 1850s zoology, botany, and geology were offered primarily as bases for natural theology, by providing evidence of intelligent design in the universe. Charles Darwin (1809–1882) found natural theology, based on Paley's intricate demonstrations of the perfect adjustment of organisms and their environments, the most valuable course he attended at Cambridge. But like many others, he found it implausible that predesigned organisms would be dropped, ready-made, into preexisting niches. His theory of natural selection, as a mechanical explanation of organism-environment compatibility, helped to undermine the harmony between biological science and belief in divine intelligence.

Moral philosophy, or *moral science* as it was frequently called, was by 1900 becoming subdivided, as natural philosophy had been a half century earlier, into its component sciences: ethics, politics, sociology, and economics. Some college presidents continued to teach ethics as a senior course, though theological foundations were now downplayed in favor of exhortations to moral leadership in society. Gradually, however, ethics became merely one of the many specialist subjects students could elect to study.

By the turn of the twentieth century scientific rationality was the one core value of higher education. The Protestant worldview, with its religious constitution for moral action, had lost its intellectual and social authority. Free from all authoritative constraints, university-trained professionals began the march of progress through an allegedly 'value-free' technoscience that by the end of the century had transformed the way humans lived.

TECHNOSCIENTIFIC CIVILIZATION IN CRISIS As early as 1923, however, Henry Churchill King of Oberlin, one of the few clergyman-presidents still teaching moral philosophy, noted a "strange contradiction" between the arrogance of the new scientists with their acclaimed alliance with the forces of nature, and the pervasive sense that modern civilization is unleashing forces that are irresistible and inevitable. By the mid-twentieth century this contradiction was sharpened, as seductive new technologies pushed many areas of human activity beyond effective control. Medical technology gave us wonder drugs that cured age-old diseases, but drug resistant strains appeared and some diseases returned. Nuclear scientists created power plants that used *atoms for peace*, but nuclear power programs contributed to the proliferation of nuclear weapons. Humans conquered space, but created a race for space-based weapons. Computers dramatically increased human productivity, and also led to increased surveillance of all human activities.

Dramatic events—the atom bomb, DDT and asbestos, thalidomide babies, environmental pollution, napalm in Vietnam, the 1970s oil shocks, urban smog, electricity blackouts, Bhopal, the *Challenger* disaster, Three Mile Island and Chernobyl, Exxon-Valdez, global warming, the ozone hole, cloning, job outsourcing through network technologies, and child addictions to violent computer games—keep forcing this contradiction upon public consciousness. Science and technology can contribute to human life, but also create problems that challenge ethical guidelines and problem-solving capabilities.

The idea of continuous progress through science and technology is no more plausible in the early-twenty-first century than the idea of a fixed universe designed by divine intelligence was after Darwin. Scholars and public leaders are thus called upon to shape a new postmodern ethical vision for technological civilization.

Since the 1970s some science, technology, and ethics scholars have initiated collaborative efforts to forge a closer relationship among their fields. Applied ethical studies of agriculture, engineering, biomedical science, and computer technology have provided a knowledge base for mandated courses in professional ethics. Science and technology courses explicitly tied to social issues have been introduced in general education at universities and secondary schools to enable graduates to participate as democratic citizens in the ethical modulation of science and technology.

A significant problem is that contemporary moral philosophers, unlike those of Catholic or Protestant scholasticism, have neither a specific moral authority of their own, nor the backing of institutions with broad-based social authority. Their authority rests upon their positions in the multiversity, whose core value of unconstrained technoscientific rationality is precisely what is now in question.

At the start of the twenty-first century, therefore, significant questions remain about both the capacity of the human community to constrain scientific and technological developments within ethical bounds, and the role of institutions of formal education in fostering and maintaining that capacity.

EFFICIENCY

In the fields of technological innovation, economic development, business management, and public policy planning, as well as in everyday life, efficiency is a pivotal criterion that guides the behavior of both individuals and institutions. The widespread utilization of this criterion, however, raises serious epistemological, methodological, and practical questions, along with ethical challenges. Although efficiency may seem to be a clear, morally neutral concept, difficulties arise in conjunction with its extremely abstract character, the vast array of interpretations involved in concrete applications, and the fact that its pursuit may crowd out or obscure other important values.

Origins and Abstractions

The term *efficiency* is derived from the Latin *efficere* ("to produce, effect, or make"). In his *Physics,* Aristotle sees *causa efficiens* as one of the four factors (along with formal, material, and final causation) that explain change. Traditionally, efficiency has been understood as the agency or power of something or someone to bring about results, to produce a desired effect. In this sense there was no clear distinction between *efficiency, effectiveness,* and *efficacy* until the second half of the nineteenth century, when the term was given a technical meaning in the field of engineering.

The contemporary technical concept of efficiency arose from analyses of engine performance, or what is known as thermodynamic efficiency. The performance of an engine was defined as a ratio of the useful work obtained to the energy (heat) used. At best, the maximal amount of energy obtained would be the same as the energy consumed in the process. The concept then was used in economic theory, disseminated through the work of an engineer turned social scientist, Vilfredo Pareto (1848–1923), and other influential economists and engineers (Mitcham 1994). Economists saw themselves as engineers who were managing the scarce resources devoted to promoting social welfare, just as engineers attempted to find economic solutions to technological problems. The concept of efficiency moved into the political and public domains during the twentieth century, becoming a universally applied value. In the twenty-first century it is widely accepted that to be effective—that is, to obtain the intended goals—is not enough. It is also necessary to be efficient, that is, to obtain the intended results without wasting resources.

There are several definitions of the concept in its widest scope. The most common usages define efficiency as a ratio of results to resources or, alternatively, of ends to means or outputs to inputs. An activity, process, design, or system is said to reach maximum efficiency if (1) a desired result (output) is obtained through the use of the minimal possible amount of resources (input), (2) the maximal amount of results from a given resource is obtained, or in general (3) a combination of results and resources is obtained in such a way that it is not possible to increase any of the results or reduce any of the resources without reducing some other result (or amount of a result) or increasing some other resource (or amount of a resource).

Multiple Meanings

In its various usages the concept of efficiency gives rise to multiple meanings when this abstract idea is given specific applications: technical efficiency, energy efficiency, economic efficiency, resource efficiency, productive efficiency, market efficiency, and ecological efficiency, among others. Imprecise use, lack of agreement among experts, different backgrounds of expertise and technical traditions, hidden assumptions, the mathematical and practical complexities involved in making measurements, and other factors often make it extremely difficult to know the extent to which these terms should be taken as mere delimitations of a more general concept or, rather, suggest different but related concepts. The situation becomes more complicated when one considers the wide array of uses of the concept in heterogeneous fields such as energy technology, agriculture, health care, business management, public administration, and academic or personal performance. As a consequence, there is a huge technical literature dealing with these problems. Philosophical analyses that do not take the definition of efficiency for granted are uncommon, although there are exceptions, such as the work of Mario Bunge (1989), Stanley Carpenter (1983), Miguel Angel Quintanilla (1989), and Henryk Skolimowski (1966).

Initially it seems easy to distinguish between purely technological or engineering and economic conceptualizations. The engineering solution to a problem is efficient when it uses the smallest amount of technological means independently of economic constraints. In real-life situations, however, technological means often must be measured in economic terms. For instance, although it is technically feasible to obtain gold from other elements, the cost of the procedure is so high compared with the value of the results that any attempt would be inefficient because of the excessive resources that must be used to achieve the objective.

Even in economics assessments generally are not equivalent. Narrowly productive points of view and the quest for personal profit repeatedly conflict with efficiency requirements in terms of social welfare. To harmonize legitimate aspirations with both personal gain and social benefit, economists, acting in effect as political assessors, resort to cost-benefit analyses that are supposed to identify a so-called Pareto optimum, which is defined as that situation in which it is not possible through any reallocation of resources to make any person better off without making someone else worse off without compensation.

Critics such as Amartya Sen (2002) have exposed the weaknesses in this conception and attempted to find more rigorous and fair alternatives. Because it does not take into account the problems associated with the fair distribution of public spending, the application of the Pareto optimum maintains unjust situations. Suppose there is a fixed public spending budget of $100 to be distributed between education and airport infrastructure. If the education budget is increased by $10 to make it easier for the poorest members of society to attend university on scholarship, that amount must be subtracted from the budget to improve airport infrastructure. Therefore, some benefit at the expense of others. The Pareto optimum no longer is reached because it would advise against any change in the assigned budgets. However, it would be difficult to defend denying scholarships to qualified students so that people who can afford a good education can reach their favorite vacation spots more easily.

Because efficiency is essentially context-dependent, many of the problems that arise in discussing it are caused by attempts to decide what counts as a resource or result and what is considered valuable, desirable, feasible, or even possible (Carpenter 1983, de Cózar 2000). Efficiency is not determined by preexisting conditions but is constructed by deciding which factors to consider in defining the problem and frequently by actively modifying the physical, economic, and legal environment in which an intervention is made to change the state of things. Geographical limits, the temporal vector, side effects, and other elements further frame the context of an intervention.

Aware of the practical problems raised by seeking the most efficient solution, or optimization, Herbert Simon (1982) proposed the concept of *satisficing:* the attempt to achieve a good, if not perfect, solution. A large telecommunications company may decide not to develop a radically new system of communication even though it is faster, more powerful, and easier to use if it has no clear estimation of the cost of gathering the information required to predict the success of the new technology in the market. This cost, together with the cost of research and development, can surpass the profits the innovation is projected to generate for the company. In other words, the company would be content with satisficing its behavior by making less ambitious improvements. Alternatively, a company might gamble on this major innovation if it were confident in its ability to influence, among other aspects of its social environment, public regulations and the perceived needs of the consumers.

Obscuring Other Values

Contextuality is a key issue in understanding the conflict between the modern technological project and the criticisms leveled at it by many philosophers of technology. The technological impulse is tied intimately to the design of increasingly more efficient machines, devices, tools, systems, and processes. In the course of this activity, which has contributed much to humanity in terms of safety, health, and welfare, the technological mind typically delimits problems in the narrowest possible way and then searches for basically quantitative solutions. Its success depends on this strategy, and much of the attraction of efficiency for experts and nonexperts alike lies in the perception that it always provides (as it really does in some cases) a mathematical, *automatic* comparison between alternatives that can be used to determine the best path to follow.

In this manner a descriptive concept becomes a prescriptive one. Arguments for efficiency appear to derive prescriptions from a dispassionate description of objects and situations, thus hiding the often conflicting values that lie behind decision making in real-world situations. For instance, Amory Lovins (1977) has argued in effect that proposals to build more efficient power plants ignore the possible desirability of reducing energy consumption by increasing the insulation of buildings.

It is important to remember that despite its familiarity, the concern for efficiency is relatively recent. The novelty of the current situation is that efficiency is being converted into an absolute criterion for decisions in many facets of life. As Jacques Ellul (1954) observed, if modern technological activity becomes indistinguishable from the pursuit of absolute efficiency, an ethics of nonpower is also conceivable. Such an ethics can, and indeed must, pose a limit to the *cult of efficiency* and its abuses. As Carl Mitcham suggests, there is a parallel between the well-known *naturalistic fallacy* and an *efficiency fallacy*. The philosopher David Hume (1711–1776) argued that *ought-statements* cannot be inferred from *is-statements*, and G. E. Moore (1873–1958) warned against equating goodness with some natural property. In regard to something that is said to be natural, with the implication that it is good, one may still reasonably ask, But is it good? Similarly, after one says that something is efficient, it makes sense to ask, But is it good? Twentieth-century history exhibits a long list of cases in which unethical goals were pursued with bloodcurdling efficiency. Therefore, one should define the goals one judges as good and only then, if appropriate, look for the means to achieve them efficiently.

Bunge, Mario. (1989). *Treatise on Basic Philosophy*. Vol. 8. Dordrecht, Netherlands: Reidel. Bunge's extensive work contains one of the first attempts at dealing with efficiency as a key concept to consider in philosophy of technology but his approach remains too close to the neopositivistic paradigm.

Carpenter, Stanley R. (1983). "Alternative Technology and the Norm of Efficiency." *Research in Philosophy and Technology* 6: 65–76. A pioneer paper that contributes to the clarity and precision of discussions on technological practice that invoke efficiency, while at the same time adopting a critical stance on the abuse of this criterion.

De Cózar-Escalante, José Manuel. (2000). "Toward a Philosophical Analysis of Efficiency." *Research in Philosophy and Technology* 19: 87–100. This essay identifies two problems of the concept of efficiency (unicity and applicability) and argues for a critical reconsideration of efficiency in social life.

Ellul, Jacques. (1954). *La Technique, ou l'enjea du siècle*. Paris: A. Colin. Trans. by John Wilkinson as *The Technological Society* (1964). New York: Knopf. In this book Ellul defines technique as the totality of methods rationally arrived at and having absolute efficiency (for a given stage of development) in every field of human activity. One of the main aims of Ellul's work is to denounce the fixed end of technological design and activity, by which the multiplicity of means and ends are reduced to only one: the most efficient.

Mitcham, Carl. (1994). *Thinking through Technology: The Path between Engineering and Philosophy*. Chicago: University of Chicago Press. In his comprehensive revision of the most important analyses of the technological phenomenon, Mitcham includes useful information as well as insightful remarks about the meaning of efficiency in technological design and everyday life.

Quintanilla, Miguel Angel. (1989). *Tecnología: Un enfoque filosófico* [Technology: A philosophical approach]. Madrid: Fundesco. In a brief section of this book the author works out a formal definition of efficiency as a basis upon which to further distinguish other technological criteria.

Sen, Amartya. (2002). *Rationality and Freedom*. Cambridge, MA: Belknap Press. The reputed economist Amartya Sen is known, among other contributions to economic, social and ethical theory, for his sharp criticism of standard models of rational behaviour. Being reductionist and ill-conceived, those models tend to obscure crucial aspects of an individual's choice in real life situations.

Simon, Herbert A. (1982). *Models of Bounded Rationality*. Cambridge, MA: MIT Press. During his long career, Simon did impressive work to establish the strength and limits of rational design and management. One of his more interesting findings was the concept of bounded rationality: even if often is not realistic to search for the most efficient solution in absolute terms, a solution that is good enough can be achieved within the bounds set by the specific context in which the problem is stated.

Skolimowski, Henryk. (1966). "The Structure of Thinking in Technology." *Technology and Culture* 7(3): 371–383. Reprinted in *Philosophy and Technology: Readings in the Philosophical Problems of Technology* (1972), ed. Carl Mitcham and Robert Mackey. New York: Free Press. An early attempt at philosophically clarifying the concept of efficiency and its role as an ideal in engineering. However, Skolimowski's analysis has some weaknesses, especially because it does not clearly distinguish efficiency from effectiveness.

EINSTEIN, ALBERT

Albert Einstein (1879–1955) was born in Ulm, Germany, on March 14 into a middle-class assimilated German-Jewish family; by the time of his death on April 18 in Princeton, New Jersey, he was recognized as being equal in accomplishment to Isaac Newton, but one significantly more publicly involved in human affairs.

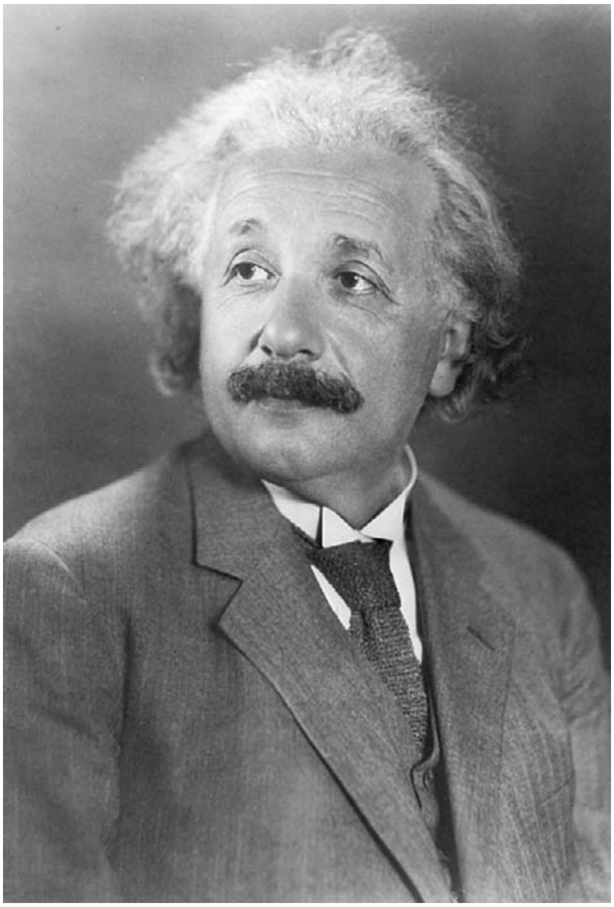
Life

Einstein showed precociousness in science and mathematics, with mixed accomplishment in other areas. He spent his early professional years in Switzerland working in the patent office. At age twenty-six—in the *miracle year* of 1905—he published several papers on special relativity, on the particle (photon) nature of light, resulting in the *complementary* idea that light was both a wave and a particle, and seminal papers in statistical physics. His general theory of relativity, first conceived in about 1907, achieved its final form in 1915. This theory was dramatically confirmed by its successful explanation of the hitherto mysterious precession of the perihelion of the planet Mercury, and with the observation during a solar eclipse of predicted bending of starlight by the Sun's gravitational field in 1919. It was especially this latter event that led to world fame.

Einstein's private life was not very dramatic; he was married twice and had two children. He emigrated to the United States at the time of Adolf Hitler's ascent in 1932, settling at the Institute for Advanced Studies at Princeton. He remained there for the rest of his life, continuing his physics research unabated, particularly his search for a *unified field theory*.

Achievements in Science

Einstein is best known for his theories of special and general relativity, although he also made enormous contributions to quantum mechanics, statistical mechanics, condensed matter physics, and cosmology. Through his contributions to the understanding of the nature of light and atomic structure, his revolutionary concepts of space and time, and his famous equation of $E = Mc^2$ (Energy equals mass times the speed of light squared) that shows the equivalence of mass and energy and led the way to the creation of controlled nuclear reactors and nuclear weapons, his impact on contemporary society and culture touches everyone.



Albert Einstein, 1879–1955. The German-born American physicist revolutionized the science of physics. He is best known for his theory of relativity. *(The Library of Congress.)*

Other less commonly appreciated impacts derive from early work on radiation theory, which led to the concept of stimulated light emission, the basis for the laser. In the 1990s his prediction, inspired by an earlier paper of Satyendra Nath Bose, of what is now known as Bose-Einstein Condensation, led to an entirely new field of physics that studies the macroscopic effects of quantum mechanics on extremely cold gaseous systems. The theory had been used earlier to help explain superconductivity and superfluidity.

Even this list of achievements does not adequately describe Einstein's involvement with the world of physics. Throughout his life he was in continual touch with numerous colleagues; he read voraciously and was fully involved with the developing conceptual framework of the new views of nature required by quantum physics and relativity. He was generous with his contemporaries, freely offering and taking suggestions from correspondents throughout the world, while eagerly conducting ongoing dialogues with the other great physicists then active, including Niels Bohr, Max Planck, Werner Heisenberg, Wolfgang Pauli, and Erwin Schrödinger. Although he was one of the original formulators of quantum mechanics he was never satisfied that it represented a complete theory, because it assumed the statistical nature of microscopic events, while he firmly believed in the Newtonian idea of causality in nature. Accordingly he always felt that quantum mechanics was incomplete, awaiting a deeper explanation for the statistical nature of the wave function in terms of a more causal theory. Einstein's often quoted statement, "God does not play dice," reflects this view. His *minority opinion* has resulted in an enormous literature on the interpretation of quantum theory, continuing with non-diminishing intensity into the twenty-first century.

Einstein's vision of a unified field theory that would unite all the known forces of nature into a single theoretical structure drove his research efforts during the last thirty years of his life. Although this incomparable challenge led to only limited success in his own hands, this holy grail of modern physics continues to inspire future generations of theoretical physicists.

Politics and Ethics

Einstein's overarching goal in physics was to formulate unifying principles for all phenomena in nature. This philosophy extended itself to other aspects of his life, including personal habits, and his deep involvement with issues such as world peace, human rights, and social justice. He was an implacable foe of militarism, even during his residence in Germany in World War I. He became the victim of intense anti-Semitism in Germany during the inter-war period, when his physics, especially relativity, was attacked as being *Jewish physics*. Although he espoused many liberal causes, he was never attracted to Communism and opposed Stalinist Soviet Russia as strongly as Nazi Germany. He was an unswerving advocate of international government and international control of armaments, including nuclear weapons. His advocacy of such positions often resulted in conflicts with authority, including the U.S. government. The Federal Bureau of Investigation (FBI) dossier on him consists of 1,427 pages. Although a non-practicing Jew, he was a strong supporter of the state of Israel, and was even proposed, at the time of Chaim Weizmann's death in 1952, to be its next President (although he swiftly turned down the invitation).

Additionally Einstein's name is indelibly connected with the atomic bomb, not only because of his famous formula for energy-mass equivalence but also because of the letter he signed in 1939, written by his friend Leo Szillard, alerting President Franklin Delano Roosevelt to the possibility that Germany might be working on the development of such a weapon. In his later years he regretted this action. Indeed, after Hiroshima and Nagasaki he argued that "everything has changed, save our modes of thinking" and that "the bomb [presents] a problem not to physics but of ethics." In 1955, in response to development of the hydrogen bomb, he co-signed with Bertrand Russell a public manifesto calling on all scientists to become involved in helping to reverse the nuclear arms race.

It is important to remember, however, that Einstein's concern for the social implications of science and technology always remained central to his core of beliefs. In 1931, for instance, in a talk at the California Institute of Technology, he told students that "concern for man himself and his fate must always form the field interest of all technical endeavors."

The literature on Einstein—his life, science, and beliefs—is overwhelming. There are more than 4 million Internet sites containing his name. As one noteworthy example, see the American Institute of Physics History site. At the end of the twentieth century *Time* magazine called him the *person of the century*. He remains the personification of the scientist. Einstein's combination of pure brilliance, high ideals, personal integrity, as well as human weaknesses yield the picture of a human being at the highest level of achievement.

ELLUL, JACQUES

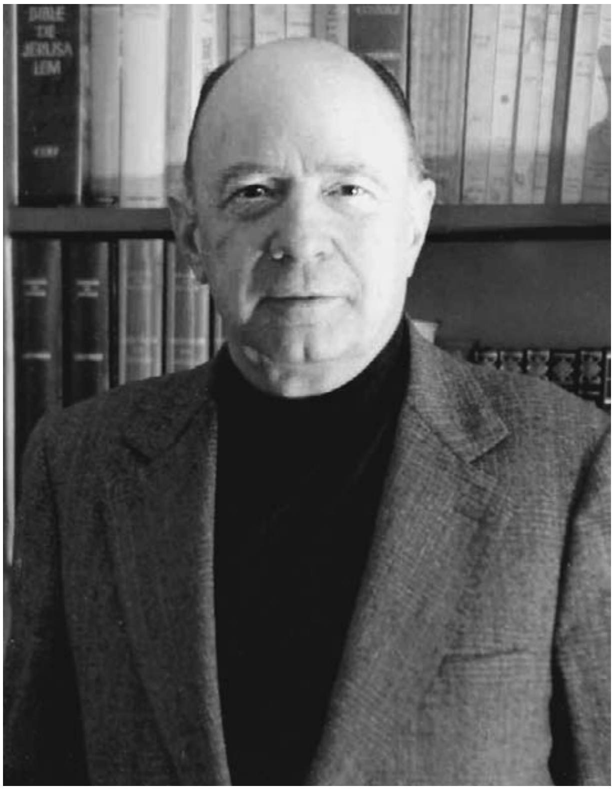
Jacques Ellul (1912–1994) was born in Bordeaux on January 6 and spent his academic career as Professor of the History and Sociology of Institutions at the University of Bordeaux Law Faculty and Professor in its Institute of Political Studies. His more than fifty books and hundreds of articles range across Christian theology, ethics, and biblical studies as well as sociological analysis and critique of mass media and communication, bureaucracy, and modern law and politics. He died in Bordeaux on May 19.

Technique: Ellul's Central Thesis

At the heart of his sociological works is his study of technology or, the term he preferred, Technique (*la technique*). Indeed Ellul initially became widely known in the English-speaking world for *The Technological Society* (1964). Its intellectual significance and originality derives in part from its argument being conceived twenty years before the original French edition (*La Technique* [1954]) when, after reading Karl Marx's *Capital,* Ellul (a law student in his early twenties) concluded that Technique, not capital, was central to modern civilization. This seminal idea was subsequently developed with Bernard Charbonneau in the French personalist movement of the 1930s.

Ellul was adamant that *la technique* "does not mean machines, technology, or this or that procedure for attaining an end" (Ellul 1964, p. xxv). He defined it as "the totality of methods rationally arrived at and having absolute efficiency (for a given stage of development) in every field of human activity" (Ellul 1964, p. xxv). Technique is, in other words, a universal category (Ellul compares it to *dog* rather than *spaniel*) embracing all the various self-consciously developed means found in art, politics, law, economics, and other spheres of human life. Central to these means is a quest for efficiency that is the defining characteristic of Ellul's account of Technique.

Two theses drive Ellul's analysis. First that "no social, human or spiritual fact is so important as the fact of technique in the modern world" (Ellul 1964, p. 3). Second that the contemporary "technical phenomenon . . . has almost nothing in common with the technical phenomenon of the past" (Ellul 1964, p. 78). Whereas previously Technique was limited and diverse, social changes in the eighteenth and nineteenth centuries led to its dominance and totally changed the relationship between Technique and society.



Jacques Ellul, 1912-1994. Ellul was a French thinker, sociologist, theologian, and Christian anarchist. He wrote several books against the "technological society," and some about Christianity and politics. *(© Patrick Chastenet.)*

In addition to its *rationality* and *artificiality*, Ellul proposes five more controversial characteristics of modern Technique. First there is *automatism* of technical choice because inefficient methods are eliminated and *the one best way* predominates. Second *self-augmentation* exists as technical developments automatically engender further innovations. Third Technique is characterized by *monism* as different techniques form an interconnected whole. This means that individual technologies must not be isolated and analyzed apart from an understanding of the wider technical phenomenon. Fourth there is a technical *universalism* that is both geographic (here Ellul offers an analysis that anticipates globalization) and qualitative (as every area of life is subordinated to technical efficiency). Fifth, and decisive for the novelty and hegemony of Technique, is its *autonomy*. This means Technique is no longer controlled by economics, politics, religion, or ethics; the common belief in Technique as a neutral means is false.

These five features are returned to in *The Technological System* (1980) where Ellul argues they characterize an elaborate technical system within society. The characteristic of *uncertainty*—seen in such factors as the ambivalence of technical progress and the unpredictability of its development—is then added in his *The Technological Bluff* (1990) that critiques contemporary discourse about Technique.

Technique in Society and Criticisms of the Analysis

Ellul's analysis leads him to conclude that whereas previous societies developed through the dialectical play of different social forces, it is now dominated by Technique. Most of *The Technological Society* is an account of the society that Technique is creating in relation to economics, politics, law, the state, and human affairs such as education, entertainment, sports, and more. Both there and in such works as *Propaganda* (1965) and *The Political Illusion* (1967) the prescience and power of Ellul's analysis remain striking at the beginning of the twenty-first century and explain why some describe him as a prophet. Having initially claimed Technique no longer belongs within human civilization but has established a technical civilization, Ellul later extended this, arguing that the social environment that had earlier replaced humanity's natural environment has in turn now been replaced by a technical *milieu:* Technique provides humans with what they need to live, is that which now threatens and endangers them, and is most immediate to them.

Most seriously, Ellul believed that Technique was incompatible with a truly human civilization. Technique focuses on quantitative improvements and facts rather than qualitative change based on values. It is a means of power—a central Ellul theme—and not subject to human values. Although it originally enhanced human freedom, building civilization by enabling people to overcome natural and social constraints and necessities, Technique has become human fate and a form of necessity. What used to be a means to freedom for humans has become a condition of slavery. In the terms of Ellul's theological writings, Technique is a contemporary idol that attracts human faith, hope, love, and devotion; a locus of the sacred in a supposedly secular society (Ellul 1975).

The criticism constantly made against Ellul is that he is a technophobe and a fatalist. Although the all-embracing nature of Technique in his work and his often caustic style of writing creates problems, Ellul's desire was "to arouse the reader to an awareness of technological necessity and what it means" and present "a call to the sleeper to awake" in order to challenge the destruction of human civilization. In later writings, Ellul sketched a new ethics of response to the dominance of Technique. This comprises the need for proper recognition of the other person (reflecting Ellul's personalism) and of nature (Ellul was an early environmentalist) and an ethics of voluntary limitation, rejecting the technical mindset that whatever can be done therefore should be done. The practice of such an *ethics of non-power* is very difficult in a world dominated by technological power and is a central part of Ellul's ethic for Christians that he suggests.

From the early 1930s, Ellul's aim was to help people understand and preserve a sense of criticism vis-à-vis technical civilization. More than half a century after it was written, his *Technological Society* remains an insightful, even if at times infuriating, analysis of modern Technique and its effects on contemporary society.

EMBRYONIC STEM CELLS

In 1998 a team of researchers reported that they had isolated and removed stem cells from the inner cell mass of human embryos that had been donated by couples undergoing fertility treatment (Thomson et al. 1998). The embryos had divided for several days to reach the blastocyst stage of approximately 100 cells. At this stage embryos have a hollow sphere in the middle, an outer layer of cells committed to forming the placenta and other cell lines, and a mass of undifferentiated cells pushed to one side (inner cell mass). The cells in the inner mass have, for a short time, the capacity to develop into all cells in the human body, and are known as embryonic stem (ES) cells. The researchers' announcement that they had isolated ES cells in human embryos generated considerable interest because it suggested that the cells could be removed, cultured, and coaxed to differentiate for use in medical therapy. Among other things, it was thought that large supplies of specialized cells could be widely available and used to replace cells destroyed by Parkinson's disease, Alzheimer's disease, neural cord injuries, and other diseases and conditions. The announcement also generated controversy because the act of removing ES cells destroys the embryo. In the years since, research has been limited to pre-clinical studies. Numerous safety issues must be addressed before clinical trials ethically can be conducted.

Ethical Issues

Of the many ethical issue raised by ES cell research, four are described here. First what is the moral status of human embryos? Some individuals argue that embryos have the same moral status as persons, which means it would be purposefully unethical to destroy embryos for any reason. Others argue that embryos are potential human beings that do not share the same rights as children and adults. For them, the destruction of embryos may be warranted under certain circumstances.

Second, independent of the particular moral status of human embryos, will ES cell research contribute to a mindset that treats embryos as commodities? Some express concern that using embryos for medical purposes will turn embryos into merchandise and diminish the dignity of humans in the process. Others counter that strict rules overseeing ES cell research protect human dignity while respecting the interests of patients who need therapies

Third, are ES cells necessary for medical therapies? Proponents of ES cell research claim that ES cells are versatile and easy to work with, and that they raise significant hope for effective medical therapies. Opponents claim that adult stem cells, found in human tissues and not requiring the destruction of human embryos, also hold the potential for medical therapies and provide a viable alternative form of research.

Fourth, what impact does the source of the embryos have on the ethics of ES cell research? The embryos used by James Thomson and his colleagues were donated for research by couples who were patients at in vitro fertilization (IVF) programs and who no longer needed stored embryos for their conception efforts. Arguably these embryos were created for an ethical purpose (reproduction) but were not needed; therefore it would be appropriate to secure some good from them before their inevitable destruction. It has also been advocated that embryos may need to be created solely for ES cell removal in order to secure a sufficient number of healthy and genetically diverse embryos to meet research and therapeutic needs. Critics, however, contend that this would be less ethical than using donated embryos, because the embryos would be created with the intention of destroying them. Still another possible source of ES cells is from the creation of embryos through a cloning technique (somatic cell nuclear transfer), in which the intended patient's nucleus would be used to create an embryo for deriving genetically compatible ES cells. Creating cells specifically for a patient would presumably eliminate the need for anti-rejection drugs. Critics, however, argue that therapeutic cloning would tempt individuals to use the embryos for reproduction rather than therapy.

Policy issues

Policy issues for human ES cell research have revolved around whether governments should fund studies involving ES cells. The issue became volatile immediately after the announced isolation of human ES cells in 1998. In the United States, the U.S. Congress held hearings on the question, numerous interest groups lobbied both for and against funding, and policy advisory bodies convened to make recommendations (Bonnicksen 2002). For example, the National Bioethics Advisory Commission concluded it would be ethical to fund the removal and use of ES cells from donated embryos (National Bioethics Advisory Commission 1999). A working group convened by the National Institutes of Health (NIH), however, concluded it was appropriate to fund only the use of ES cells (National Institutes of Health 1999). The removal of cells (and hence destruction of the embryo) would have to be funded privately. Both groups agreed the government should not fund research creating embryos solely for ES cell removal.

Following intense lobbying by, among others, right-to-life groups opposed to federal funding and scientific associations and patient advocacy groups supporting funding, President George W. Bush announced a limited compromise position on August 9, 2001 (Vogel 2001). Under the new policy, the federal government would consider funding a narrow range of proposals in which (a) ES cells had been removed with private funds prior to the date and time of Bush's speech, and (b) the embryos were donated with informed consent by couples in IVF programs. At the time it was thought approximately sixty ES cell lines worldwide met these conditions. Within a couple of years, however, it became clear that fewer than fifteen cell lines were available for research.

Opponents argue that the government should not fund research that many people regard as immoral. Advocates argue that governmental funding is necessary for the potential of this research to succeed and for new therapies to become available to help persons with presently untreatable illnesses. Funding also has the benefit of opening the door to federal oversight of the research. Assuming ES cell research lives up to its potential, more studies will be conducted in the future and new cell lines will be needed to meet the standards required for clinical tests of medical therapies. If funding remains strictly limited, research will be conducted with private sector funding outside the public eye. Inasmuch as ES cell issues generate intense discourse, it is ironic that ES cell research will proceed without the public scrutiny that comes with significant federal funding.

Debates over the ethics of cell research are ongoing in nations worldwide. For example, in Europe differences among nations have precluded funding for ES cell research by the European Union (Vogel 2003). Research is proceeding in individual nations with accommodating governmental policy, such as the United Kingdom where, among other things, a UK stem cell bank has been set up with government backing (nibsc.ac.uk/divisions/dbi/stemcell.html).

EMERGENT INFECTIOUS DISEASES

Emergent infectious diseases (EIDs) are conditions caused by pathogenic microorganisms or parasites that have recently appeared or reappeared in human or animal populations. Typically, EID agents have begun to change the range of their infection, spread through new vectors or the movement of preexisting vectors, rely on shifts in patterns of host susceptibility, or have only recently been identified as the causes of existing diseases. This includes reemerging disease agents once thought to have been eradicated, but that have returned in resistant strains, or as a result of disintegrating public health infrastructure. Emergent diseases have tremendous impact on human health, and the health of pets and livestock. Furthermore, they pose a threat to biodiversity because many wild animal species are also at risk.

Science and Origins

An emerging infection can be caused by such viral agents as Ebola virus, HIV, or the SARS-associated corona-virus (SARS-CoV) identified as the cause of severe acute respiratory syndrome (SARS); bacteria such as methicillin-resistant *Staphylococcus aureus* (MRSA); or prions responsible for bovine spongiform encephalopathy (BSE, or "mad cow disease"), scrapie in sheep, chronic wasting disease in wild and domesticated deer and elk, and variant Creutzfeldt-Jakob disease (vCJD) in humans.

Emergence of an infectious agent is a two-step procedure: introduction into a new host species, followed by dissemination into a population. Varied origins include the evolution of a new virus or variant, bacteria, or prion; the introduction from another species (zoonoses); or dissemination from a smaller into a larger population. The latter two are usually the result of some environmental, social, or political disturbance bringing the naive host population into contact with the infectious agent.

Emergence can be illustrated through the case of Ebola virus, a virus of zoonotic origin. In 1995, a Swiss scientist died from Ebola while studying a chimpanzee population in the Côte d'Ivoire. In January of 1996, twenty-nine of thirty-seven confirmed cases of Ebola in a Gabon village were traced to contact with a dead chimpanzee.

Viruses and bacteria often mutate and adapt through the exchange of genetic material that can select for traits such as virulence, adaptability to different host organisms, and resistance to antiviral drugs or antibiotics. Viruses are ephemeral entities that undergo antigenic mutation, and adapt to new ranges of host, or vector.

A viral example that captures many of the characteristics of an EID is influenza caused by the influenza virus. Many influenza epidemics threatened public health throughout the twentieth century. A mutated influenza virus that originated in swine or avian hosts caused the 1918 Spanish flu pandemic, which killed more than twenty million people worldwide. It is thought that mixed variants of human and avian strains of influenza virus caused the 1957 Asian flu and the 1968 Hong Kong flu pandemics. In these cases, a preexisting swine or avian influenza virus either infected human beings directly and became adapted to the new hosts, or else previously-existing human variants of the influenza virus obtained genetic information from animal viruses. In some of these cases, the virulence of the newly adapted influenza virus was great enough to explode in the newly-acquired human host population, expanding throughout the global population.

Between 1998 and 1999, the previously unknown Nipah virus claimed 105 lives and resulted in the slaughter of 1.1 million hogs in Malaysia. Nipah virus exemplifies many of the characteristics of a newly emergent virus. It is carried by flying foxes (*Pteropus vampyrus*). The emergence of Nipah virus from the flying fox reservoir resulted from environmental changes in the infected hosts' environment. A drought allowed fires, set to clear land, to run out of control, destroying the flying foxes' habitat and food source. Many flying foxes set up new residence in orchards, often run in conjunction with swine husbandry operations. It has been

A crowd of people in Zaire watch health workers who have come to deal with an epidemic of the Ebola virus. Since its discovery in 1976, different strands of Ebola have caused epidemics with 50 to 90 percent mortality in several countries in Africa. *(© Patrick Robert/Corbis.)*

suggested the bats contaminated fruit that was then fed to the pigs, who then infected their caretakers. Changing environmental conditions and agricultural practices create conditions where the hosts of infectious diseases come into contact with new, potential hosts, with sometimes tragic consequences.

Of particular concern to public health is the emergence of infections by bacteria that have developed resistance traits to a variety of antibiotics. Antimicrobials are perceived as essential for combating both human and animal bacterial infections. In 1945, penicillin discoverer Alexander Fleming (1881–1955) warned of the danger of antibiotic resistance when bacteria in his lab developed resistance traits to penicillin through mutations and a process of natural selection. Resistance also develops through the transference of genes from resistant to non-resistant bacteria. An early case of the danger recumbent in the transference of genes for resistance is ampicillin-resistant *Haemophilus influenzae* and *Neisseria gonorrhoeae,* which appeared in the early to mid 1970s. Both diseases shared genetic material thought to have been transferred from one species of bacteria to another (Levy 2002).

It is now considered an item of scientific faith that the use of antimicrobials will favor the selection of resistant strains for most bacterial species. Some authors stipulate increasing resistance is the inevitable outcome of antimicrobial use in both human health and agricultural contexts (Levy 2002). Stuart Levy has coined the expression "the antibiotic paradox" to characterize the intertwined promises and threats of antimicrobial use.

Impacts

Antimicrobial resistant bacteria are increasingly ubiquitous, and their costs are immense and growing. One overview of the human health literature on resistance notes MRSA has been reported in community-based infections at rates from twenty to sixty-two percent of cases in the 1990s. This study reports widespread rising resistance to second and third generation cephalosporins in *Enterobacter* species, suggesting antimicrobial resistance has "become a fact of hospital life and is so common that it often goes unnoted until it is either extreme or epidemic" (Weinstein 1998, p. 215).

A 2001 Center for Disease Control and Prevention (CDC) publication notes "as we enter the 21st century, many important drug options for the treatment of common infections are becoming increasingly limited, expensive, and in some cases, nonexistent."

In a 1969 speech, the U.S. Surgeon General proclaimed that the frontiers of infectious diseases had been reached, remaining problems in the United States were marginal, and that it was the responsibility of the medical establishment to focus on chronic illness. Antibiotics were proclaimed miracle drugs (Levy 2002). They were understood to be an increasingly effective weapon in the armamentarium against bacterial infections and, with the promise of many new viral vaccines, it was believed the technology existed to eradicate disease worldwide.

With a growing awareness of the vastness of epizootic reservoirs of infectious agents, endemic changes in environment and agriculture, increasingly rapid global movement of animal and human populations, and growing problems with antibiotic resistance, this era of optimism is at an end.

Ethics and Policy Issues

One consequence of the emergent character of these diseases is the burden of uncertainty under which policy makers must function—far greater than the uncertainties faced by policy makers dealing with well understood risks such as cigarette smoking or automobile driving. The next EID may be innocuous, or it may be a deadly pandemic. This uncertainty makes it difficult to compare the risks of EIDs to other, more certain public health hazards. Indeed, one reason the media often covers EIDs more closely is because of this uncertainty.

Contemporary efforts to defend against EIDs follow the stages of prevention, detection, and response. Optimal allocation of resources among these stages is a question that has generated much controversy.

Conventional approaches to public health are incapable of preventing many of the factors that are presently increasing the rate of disease emergence. Public health institutions rarely have the resources or the mandates to put a halt to rapid environmental change or to changing patterns of agriculture, let alone to control the increased global movement of human and animal populations.

In the case of resistant bacteria, restrictions and judicious use guidelines on antibiotic use in human and animal health have been suggested as well as a curtailment of their use as growth promotants in the animal industries (Rollin 2001). Rising levels of resistance have fueled a debate over responsibility between representatives of the human and animal medical fields. For example, in 2004 the U.S. Food and Drug Administration was revising its drug approval and labeling procedure for antimicrobials to be used in animal agriculture, and a number of European countries have banned their use as growth promotants under the precautionary principle. The CDC and a variety of private initiatives are instituting educational programs encouraging patients and medical professionals to curtail their use of antibiotics. In the United States as of 2004, there was no legislation to further restrict doctors' prescriptions of antibiotics.

In the United States, responsibility for managing emerging infectious diseases is distributed widely. The CDC often takes the lead, but in instances of food-borne disease, the Food and Drug Administration (FDA) and the Department of Agriculture (USDA) are also involved. In the case of antimicrobial resistance, a U.S. federal government interagency task force initiated in 1999 involved more than eleven agencies and departments.

The implementation of vaccines as a means of prevention is hindered by the contemporary market in pharmaceuticals. Pharmaceutical companies tend to focus research and development monies on profitable repeatable treatments for chronic ailments. Vaccines and antibiotics—which will only be used once or a few times per individual over their lifetime—do not provide the same return on investment. Incentives, regulatory assistance, or an alternative drug research and development system is needed to address these gaps in the preventive armamentarium.

Around the turn of the twenty-first century, greater emphasis has been placed on understanding the role of industrial agri-food practices in the spread of infectious diseases. In the United States, rapid progress in the development of new techniques for managing industrial animal agriculture for food safety concerns have been hindered by the sometimes conflicting mandates of the principal governmental agencies involved in dealing with emerging diseases among food animals, including the CDC, the FDA, and the USDA.

Some policy suggestions have focused on early detection of aberrant syndromes through disease surveillance, on the anticipation of new host and virus interactions brought about by changing ecological and agricultural conditions, and on the control of new diseases through planned response. Similar surveillance tactics have been suggested to deal with antimicrobial-resistant bacteria.

There is limited but growing international coordination of emerging infectious disease surveillance and response. Most surveillance and response systems are national in scope. This includes the CDC, particularly

A health officer checks the temperature of an arriving passenger at Kuala Lumpur International Airport as part of a screening for Severe Acute Respiratory Syndrome (SARS). After the first outbreak occurred in China, the disease spread rapidly, reaching other countries via international travellers. *(© Reuters/Corbis.)*

the National Center for Infectious Diseases, which often responds to emerging disease emergencies outside the United States. Another CDC program, jointly run with the USDA, is the National Antimicrobial Resistance Monitoring System (NARMS).

At the international level, there are two institutions of note. The United Nations World Health Organization (UN-WHO) Communicable Disease Surveillance and Response is the principal international organization that identifies, verifies, and responds internationally to epidemics of infectious disease. This organization is overworked and underfunded. Animal diseases are monitored and managed by the Office Internationale des Epizooties (OIE), organized under the World Trade Organization (WTO) to maintain animal health and welfare worldwide. The OIE publishes trade standards on the presence of epizootic diseases, animal health, and food safety that govern the importation of animals and animal products between WTO member countries.

Responses to EIDs are administered by the above agencies and organizations and relevant agencies within a particular nationality's borders. Responses range from quarantine of humans and animals to radical eradication programs such as the slaughter of infected animals, vaccination programs, and mass-treatment with a variety of antiviral and antibiotic drugs.

The development of new antiviral and antibiotic medication suffers from the same market-induced problems as the development of new vaccines. Incentives or the creation of new, perhaps not-for-profit, institutions of drug research and development could alleviate the current dearth in treatment options. The National Institute of Health (NIH) supports research in drug development, but the costs of bringing these new drugs to market are still deemed prohibitive by many pharmaceutical companies.

Quarantines and mass animal slaughter wreak emotional, moral, social, and economic havoc. The

2003 SARS epidemic shut down international trade and travel and damaged the economic lives of cities as far apart as Toronto and Hong Kong. Foot and mouth disease and bovine spongiform encephalopathy (BSE) eradication programs in the United Kingdom resulted in massive animal slaughter, and in movement bans that eventually necessitated the welfare slaughter of even more animals as feed stocks were depleted. This devastated the British rural economy, and seriously affected British agricultural trade with Europe. Quarantines, animal slaughter, and animal movement bans are currently the most effective means of coping with an epidemic, but there is much research that needs to be done on how to lessen the impact of these techniques on the affected populations of humans and animals.

EMOTION

The role of emotions in moral behavior has been debated by ethicists since ancient Greece. The scientific study of emotions is much more recent, yet the advances in twenty-first century understanding of the neural mechanisms that subserve emotions take on added meaning in the context of these ancient debates. New developments in *emotional technologies* add further nuances to these old questions. This entry provides a brief account of what emotions are, outlines the way emotions have been viewed in some major philosophical traditions, and discusses the ethical questions raised by some forms of technology.

What Are Emotions?

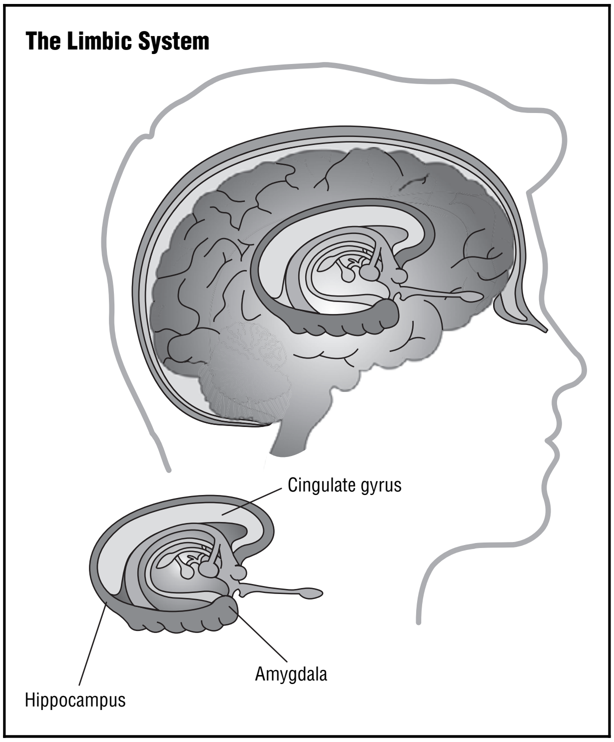
Emotions may be defined in a number of ways (Evans 2001). From a neurobiological perspective, emotions are defined in terms of the neural mechanisms that implement emotional processes in the brains of humans and other animals. In all mammals most emotional processes are mediated by a set of neural structures known collectively as the *limbic system*. The limbic system is an ill-defined term, but usually refers to a variety of subcortical structures, including the hippocampus, the cingulate gyrus, the anterior thalamus, and the amygdala (see Figure 1).

Neurobiological definitions of emotion can be regarded as parochial, because they exclude organisms that lack brains like those of humans from having emotions. A less chauvinistic alternative would be to define emotions in functional terms—that is, as dispositions to behave in certain ways. Fear, for example, disposes the organism to mobilize defensive and flight behaviors, and to focus attention on possible threats.

Functional definitions of emotion have been criticized on the grounds that they leave out feelings. Feelings—the conscious awareness of emotional states—have often been regarded as the central component of emotions, but some neuroscientists such as Antonio Damasio prefer to distinguish between emotions, which they regard as objectively measurable processes, and subjective feelings.

Emotions may be distinguished from other affective phenomena such as moods and personality traits by temporal duration. Many psychologists regard emotions as relatively rapid and brief processes, lasting no more than a minute or two, and class longer-lasting affective states

FIGURE 1



The human brain, with some of the limbic structures highlighted.

as moods, although this distinction is not universally accepted.

Emotions in Philosophy and Ethics

At the risk of over-simplification, it is useful to distinguish three main traditions in Western thought regarding the role of emotions in moral behavior. First many thinkers, such as Plato (c. 428–348 B.C.E. and Immanuel Kant (1724–1804), have regarded emotions principally as obstacles to good conduct. Plato compared the rational mind to a charioteer whose task was to keep his horses (his emotions) under a tight rein. Kant argued that good actions were only truly moral when performed purely out of concern for the moral law, and not motivated by any emotion.

A second tradition, exemplified by thinkers such as Aristotle (384–322) B.C.E. and economist Adam Smith (1723–1790), has regarded emotions as vital ingredients in generating moral behavior. Aristotelian ethics is based on the idea of virtue, which is a *golden mean* halfway between opposing vices. Because many vices are defined as deficits or excesses of particular emotions, Aristotelian virtues may be regarded as optimal midpoints between emotional extremes. This ancient approach to ethics finds many echoes in the modern concept of *emotional intelligence*, which also stresses the need for cultivating emotional self-regulation. Smith argued that certain social emotions such as sympathy, which he called *moral sentiments*, lay at the heart of all ethical conduct.

Finally, a third tradition takes issue with both of the preceding positions, arguing that all moral judgments are merely an expression of the speaker's emotions. According to this view, championed by philosopher David Hume (1711–1776), when someone says that a certain action is right or wrong, what is meant is that the speaker has a feeling of approval or disapproval toward the action. This is sometimes referred to as the *emotive theory of ethics*.

More recently the philosophy of emotions has begun to address other questions besides the role of emotions in moral behavior. Contemporary philosophers such as Paul Griffiths, for example, have argued that emotions are such a heterogenous bunch of phenomena that they cannot constitute a single natural kind. Others have attempted to clarify the complex relationship between emotions and rationality (de Sousa 1991).

Emotions and Technology

Since its very beginning, much human technology has been driven by the desire to exert greater control over the emotional states. Many human inventions, from cooking to music, may be viewed as *technologies of mood*, in the sense that they are designed primarily to induce certain emotions in the user. Modern developments such as psychotherapy and antidepressants, therefore, may increase the effectiveness of the ability to manipulate emotions by artificial means, but the ethical questions they raise are not new. The objections raised by critics such as Francis Fukuyama (2002) to the possibility of *cosmetic psychopharmacology*, in which people manipulate their emotional states at will by means of sophisticated new drugs, have many echoes in ongoing debates about authenticity. Such objections seem to some to smack of *psychopharmacological Calvinism*, the niggardly belief that happiness must be earned the hard way—that is, without the help of drugs (Kramer 1994). The inflammatory rhetoric that has so far characterized such debates needs to be eliminated if people are to have a mature and reasoned discussion about the benefits and dangers of developing more powerful technologies for influencing moods and emotions.

Other modern technologies raise ethical questions that had not previously been considered. The advent of neuroimaging techniques and other means of monitoring emotional processes that were previously thought to be irreducibly private and subjective raises new issues of neural privacy. How much of one's emotional life should others be able to assess by means of these technologies, and how reliable are they? These questions will become more urgent as new technologies such as *sensitive clothing* (garments with embedded sensors that monitor physiological changes) and brain-machine interfaces permit further intrusion into the emotional lives of others.

Another technology that raises new ethical questions concerning emotions is affective computing, a branch of artificial intelligence that attempts to build emotional machines (Picard 1997). One line of thinking in robotics argues that robots will need emotions if they are to be truly autonomous, and some commercially available entertainment robots already come programmed with a repertoire of basic emotions. It is arguable, of course, whether such mechanisms constitute genuine emotions or merely simulated emotions, but this distinction may be irrelevant because people tend to react to such robots as if they possessed genuine emotions. The ethical problems raised by such developments have been explored in great detail in science fiction, from Isaac Asimov's (1920–1992) short story "The Bicentennial Man" (1976) to Arthur C. Clarke's famous novel *2001: A Space Odyssey* (1968). While such fictional scenarios often postulate devices that are far in advance of available technology, the questions they raise are deep and sometimes disturbing. In Asimov's short story, for example, a robot redesigns his own circuitry so that he may experience the whole range of human emotions. Because some rights are often held to be contingent on having certain emotional capacities, a robot with human-like feelings might have to be accorded a moral status equivalent to that of a human. There are parallels here with the animal rights movement, which has placed great emphasis on the capacity of certain animals for pain and suffering in its attempts to provide them with greater legal protection.

More sinister scenarios envision emotional machines turning against their human creators, raising the question of whether efforts in affective computing should be curtailed. In Clarke's novel, for example, an onboard computer called HAL turns against the crew of the spaceship Discovery I, killing all but one of the astronauts. Asimov has suggested that such dangers might be avoided by programming machines to obey certain principles such as his *three laws of robotics*, stated in several of his stories and novels from 1950 onwards (including "The Bicentennial Man"), of which the first is that "a robot may not injure a human being or, through inaction, allow a human being to come to harm." Yet it is hard to see how such principles could be implemented in a computer program.

This list of issues raised by technologies of emotion is not exhaustive, but illustrates how a greater understanding of emotions impacts ethics. Science and technology have powerful emotional dimensions that are often ignored by those involved in developing them. Yet it is vital to think about these dimensions, because adverse emotional reactions to new technologies among the general public can have serious consequences. From the Luddites, eighteenth-century English artisans who destroyed machinery during the industrial revolution, to twenty-first century environmentalists who oppose the planting of genetically engineered crops, new technologies have often inspired deep feelings of mistrust. Those developing future technologies risk provoking similar reactions unless they engage the public at large in open and informed debate in which emotional dimensions are addressed as well as the scientific facts.

EMOTIONAL INTELLIGENCE

Emotional Intelligence (EI) or Emotional Quotient (EQ) is a concept that challenges the assumption that the Intelligence Quotient (IQ) is the best predictor of professional success. Unlike IQ, which proposes to be a measurement of innate potential that is relatively stable, the proponents of EI maintain that it is a continuously developing ability, competency, or skill in which "the sky is the limit" (Segal 1997, p. 19). The same proponents claim that developing one's EQ is the key to succeeding in activities from academics, sales, customer service, and management to improving marriages, mental and physical health, lowering crime, and even an individual's spiritual relationship with God. Research on EI and attempts to apply it constitute extensions of science and technology into the ethical realm. In contrast the critics of EI argue that the concept is too all-encompassing, with EI measurements contributing little beyond existent constructs and its predictive claims largely unverified (Matthews et al. 2003).

The Scientific and Ethical Concept of EI

EI is conceptually related to Howard Gardner's (1985) theory of multiple intelligence, which criticizes the overemphasis on IQ and argues for the possibility of affective and social modes of intelligences. Peter Salovey and John Mayer (1990) first proposed the term *emotional intelligence* to describe a kind of ability to monitor, discriminate, and use the information of one's own and other's emotions to guide thinking and action. However it was Daniel Goleman's 1995 book *Emotional Intelligence* that popularized EI as a general capacity to motivate and persist at goals, to delay gratification, to regulate one's own emotions and those of others, to empathize, and to hope. In general the concept of EI is vague and there is no precision in attempts to clarify, define, or measure it. Some literature refers to EI as a type of sensitivity to emotions in self or others (Lam and Kirby 2002). Other literature understands it as an overarching term for any non-rational skill or ability, such as optimism, manners, empathy, or self-efficacy, that contributes to social and professional success beyond rational skills (Brown 2003).

The underlying scientific theory of EI relies on research, such as that by Antonio Damasio (1994), on the neuropsychology of emotions. This research has challenged the idea that emotions are irrelevant or an impediment to rational decision-making. Instead it suggests that the emotional circuitry of the brain (i.e., the amygdala, cingulate gyrus, hippocampus, and ventromedial prefrontal region) is interconnected with the higher cognitive areas (i.e., the neocortex) and indispensable for rational and social decision-making. Damasio's book *Descartes' Error* examined patients with damage to areas associated with emotional processing and found that they could successfully engage in rational abstract tests, such as those that measure IQ, but were unable to make even trivial social decisions. This research has also shown that, although innate emotional responses can function independently, the neocortical area of the brain works with emotions and can modulate emotional responses to environmental circumstances. This degree of plasticity of emotions supports the claim of EI as a life-long developing capacity.

Conceptually EI also has implications for ethical theory and related educational policies. EI can trace its ethical roots to Aristotle's analysis of emotions in the *Nicomachean Ethics*. Aristotle's ethical theory relies on the development of ethical dispositions or character traits in which both reason and emotion are habituated to deliberately choose the ethical action. Certain ethical theorists, for example Martha Nussbaum (2001), also reject ethical theories that understand ethics as purely a rational activity; instead, similar to Aristotle, Nussbaum stresses the importance of emotions as an integral aspect of ethical judgment and normative appraisals. In this view, ethical development does not depend on rational evaluation, but relies on learning how to check impulses and using USE emotional information to guide behavior. The practical implication of this ethical theory has been to implement educational curriculum and staff training that emphasizes the development of EI skills (Goleman 1995, Brown 2003).

Review of Research

EI literature spans many disciplines from the popular psychology self-help genre that has virtually no scientific evidence for its claims, to more scientific analysis in neuropsychology, clinical psychology, education, management, business, and behavioral economics. In addition many collaborators in the field of psychometrics have devoted attention to developing reliable and consistent standards in the attempt to measure and explain individual differences in EI.

Similar to ethical theory, certain avenues of research in the social sciences, such as behavioral economics, reject standard models of human decision-making, such as utility theory, that minimize or ignore the role of emotions in decision-making (Sanfey et al. 2003). This research focuses on the analysis of EI as a relationship between rational and emotional processes in decision-making. Adopting methods, such as functional magnetic resonance imaging (fMRI) from neuroscience into game theory, behavioral economics seeks to explain how and why individuals will often reject a purely rational decision when this decision is seen as unfair. In management research, Brown (2003) has also examined the role of emotions in enhanced service provision and profitability. In other disciplines, such as political science, George Marcus and colleagues (2000) have attempted to understand the role of emotion in political learning and decision-making.

The typical research analyzing EI as a type of aptitude focuses mainly on developing psychometric tests to measure EI for both scientific understanding and potential commercial applications (Matthews et al. 2002). One of the most popular measurement is the performance test, such as the Multifactor Emotional Intelligence Scale (MEIS) or the modified Mayer-Salovey-Caruso Emotional Intelligence Test (MSCEIT) developed and tested by David Caruso, John Mayer, and Peter Salovey, which measures the management and regulation of emotions by predetermined consensual, expert, or target scoring. The main difficulty with predetermined criteria is that, unlike IQ tests that have definite right or wrong evaluations, EI criteria are open to criticism of personal and cultural norms. Another type of measurement is a simple self-reporting questionnaire of competency, such as the Emotional Quotient Inventory (EQ-i) developed and tested by Bar-On and collaborators. Other tests used to measure EI include Goleman's Emotional Competency Inventory (ECI) and Nicola S. Schutte and collaborators' Schutte Self-Report Inventory (SSRI). Although self-reporting tests are less costly than performance tests, they are highly susceptible to response bias due to respondent's lack of awareness or even deliberate attempts to reflect expected social norms.

Assessment

Despite the popular and commercial appeal of EI as holding an indefinite possibility to improve an individual's personal and private life, there is little scientific evidence for such claims. Many of the popular claims of EI proponents offer little more than commonsense advice, such as proposing that children who are taught manners are more liked by their teachers (Shapiro 1997) or standard yoga meditation techniques for calming emotions (Segal 1997). Beyond such problems of popular accounts, the main difficulty of a scientific understanding of EI is the lack of a clear, concise concept. EI is often a catch-all term of any list of qualities or character traits that could explain why individuals with high IQs do not necessarily succeed professionally or why those with lower IQs often are more successful. But a simple negative categorizing of EI as any trait that is not measured by IQ does not provide for any clear scientific evaluation of EI or its popular claims. In addition, as Gerald Matthews NAME] and collaborators (2003) point out, many of the valuable aspects of EI, such as those reliably measured by the psychometric tests, have much in common with already established personality tests. The concept of EI is vague, imprecise, and in many cases redundant.

The most valuable aspect of EI is when it is conceptually understood not as a character trait such as optimism or self-efficacy, but as a concept reflecting the importance of emotion as a type of cognition that functions together with reason in social and ethical decision-making. This understanding of EI connects it with research in the neuroscience of emotion, which has focused on understanding how the brain receives and processes information. Unlike the popular version of EI that conceives it as an ability to use, manage or, control emotions, this version of EI rejects the notion of any simple mastery over emotions. Instead EI represents emotions as making a cognitive contribution essential to practical, non-abstract decision-making.

This conceptualization of EI has implications for possible research in various disciplines, from decision-making in the social sciences to ethical theory. The concept of EI suggests that because emotions are involved in social decision-making, understanding emotions is an essential aspect to understanding political, economic, and other social behavior. In addition EI understood as a necessary aspect of cognitive decision-making has practical ramifications for developing education and training policy that include more than simply teaching abstract, rational knowledge. However, before any useful practical application of EI-based programs, more clarification of the concept and measurement tests need to be developed to avoid the problems of unevaluated claims or measurement redundancy.

ENERGY

Energy, from the Greek *energeia* or activity, denotes the capacity of acting or being active. Aristotle used the term to denote the activity of tending toward or enacting a goal, which differs from the modern understanding of energy as the capacity to do work. To a certain degree energy functions as the abstract equivalent of fire, one of the Aristotelian four elements. The modern concept of energy can engender either physical or psychological activity and be analyzed in one or more of three senses: scientific, technological, and ethical.

Science of Energy

In modern science, the term *energy* has become a precise technical concept with such distinctions as kinetic (energy related to the motion of a body) and potential (stored energy of position). Other important distinctions pertain to the different forms of energy, including thermal, mechanical, electrical, chemical, radiant, and nuclear.

The history of the modern science of energy reveals that developing a precise technical concept of energy is a convoluted process, one that raises controversial tensions between constructivist and realist interpretations of scientific knowledge (Crease 2004). To what extent did the phenomenon of energy precede the development of the concept itself? And to what extent do the cultural and technological contexts in which energy came to be represented actually shape that natural phenomenon in terms of intersubjective agreement? The modern concept of energy arose through both purely ahistorical theories and a changing social context, marked especially by the development of different energy technologies. This means that the contexts of discovery and justification cannot be isolated from one another, because energy cannot be justified without the use of historically given concepts (e.g., work and heat) and technologies (e.g., steam engines). Energy is at once real (i.e., not an artifact of language and culture) and constructed (i.e., inextricably embedded in human history).

The modern science of energy originated with the development of thermodynamics in the nineteenth century and efforts to understand the dynamics of steam engines and other mechanical devices. In 1842 Julius Robert von Mayer (1814–1878) calculated the caloric equivalent of mechanical work. This *Kraft* (force or power) was the precursor of energy as a scientific concept that denoted the quantitative equivalence between physiological heat and mechanical work. By the mid-nineteenth century, it was experimentally well established that such physical phenomena as electricity, heat, electromagnetism, and even light were interconvertible at determinate rates of exchange (Kuhn 1959). To German scientists in particular, the fixed rates of exchange governing the conversion of diverse phenomena suggested the existence of a single underlying substance. They postulated a metaphysical *Arbeitskraft* (workforce) behind physical manifestations.

In 1847 Hermann von Helmholtz (1821–1894) formulated the first law of thermodynamics by stating that *Arbeitskraft* can be neither created nor destroyed. So enshrined in the "law of energy conservation," energy denotes an unknowable substance manifest in the transformations of matter and measurable in units of work. Rudolf Clausius (1822–1888) formulated the second law of thermodynamics on the notion of entropy (a measure of disorder or the quality of energy) in 1850. The scientific concept of heat was reduced to the kinetic energy of theoretically postulated particles and divorced from the commonly experienced primal element of fire.

Work by Bernhard Riemann (1826–1866) and others further removed the concept of energy from common experiences, but Ernst Mach (1838–1916) argued that energy and other concepts in physics ought to be grounded in practical and experimental experience rather than theoretical abstractions. Albert Einstein (1879–1955) utilized Riemann's mathematically constructed curved "space-time" to formulate an "energy-momentum tensor" according to which mass and energy are interconvertible in the equation $E = mc^2$;, where c is the speed of light. This means that a small amount of matter (mass) is the equivalent of a large amount of energy, so that matter can be thought of in scientific terms as frozen energy.

Thus, E began as a principle of equivalence between the phenomena of physiological heat and mechanical work. First forged as a bridge between incommensurable domains, E slowly shed any reference to everyday experience. The scientific elaboration of an insensible E occurred through the interplay of mathematically formulated theories and controlled experiments set within evolving social and technological contexts.

Technologies of Energy

As an engineering concept, energy may be related to the primal element of fire, and insofar as fire has played a key role in civilizing human beings (as described in the myth of Prometheus), so energy development is described as central to human progress.

Although water mills and windmills have been in use for well over a thousand years, ancient and medieval technologies of energy were primarily animate (human and animal) in nature. Indeed many in the ancient Greek world viewed slavery as an indispensable means of providing the necessities of a civilized life. The domestication of draft animals roughly 10,000 years ago spurred the agricultural revolution. The transition from wood to coal, made first in England beginning in the sixteenth century, heralded vast social and technological changes. Coal powered the Industrial Revolution and its attendant energy technologies, especially the steam engine. Oil and natural gas were developed extensively in the nineteenth century, and nuclear energy for civilian and military purposes developed after World War II. These changes have led to the widespread use of modern energy technologies, including the heat engine, fossil fuel and nuclear-powered electricity generating plants, and dams, wind turbines, photovoltaic cells, and other forms of renewable energy generation.

The use of these technologies raises important distinctions among the terms *energy, power*, and *work* in their mechanical or technical senses. Energy (E) is the capacity for doing work. Work (W) is defined as the energy transferred to an object by a force as that object moves; it is the result of converting energy from one form to another. Power (P) is the rate at which work is done, that is, the rate at which energy is converted. So, $E = Pt$, and $P = dE/dt$, where t is time. In terms of electricity generation and consumption, the most common units for power (demand or capacity) are the watt (equal to one joule per second) and kilowatt, and the most common unit for energy (consumption) is the kilowatt-hour. For example, a 100 watt lightbulb left on for ten hours will use 1 kilowatt-hour of energy.

Power and energy are central to the classical definition of engineering, which the English architect and engineer Thomas Tredgold (1788–1829) formulated as "the art of directing the great sources of power in nature for the use and convenience of man." This highlights the fundamental human condition that in order to accomplish one's ends, energy must be exerted. The hardships endured have long fueled the utopian dream of infinite energy availability. Modern engineering has undoubtedly unlocked vast stores of energy for human use and convenience. But the quest for limitless energy has yielded dangers in the form of pollution and threats of nuclear war. This quest is apparent in the past hoax and future hope of cold fusion and the development of renewable energy technologies to replace nonrenewable forms.

Ethics and Politics of Energy

Engineer and physicist William Rankine (1820–1872) popularized *energy* as a technoscientific term in the mistaken belief that the Greek *energeia* meant work. In fact, in contradistinction to slave labor and craftwork, *energeia* originally indicated political and moral activity (Arendt 1958). But once the term was defined scientifically in the early 1800s as the power to do work, the lived meaning was relegated, against its own etymology, to secondary or metaphorical status. References to personal energy, psychic energy (e.g., Sigmund Freud's libido), spiritual energy (e.g., Hindu *prana,* Hebrew *rauch,* and Daoist *qi*), aesthetic energy, social or political energy, and more are all thought of as less rather than more concrete, and often interpreted in technological terms. Thus the meaning of the term was somewhat purged of its original ethical and political connotations.

But contemporary issues surrounding energy extraction and use have refocused attention on the fundamental connection between energy and ethics. Energy cannot be considered a neutral instrument, but rather an integral component of political and ethical ends. As the Industrial Revolution and countless other events in history demonstrate, the availability and use of different energy sources reciprocally interacts with social and technological developments. One major practical consequence of this derives from the heterogeneous global distribution of energy reserves (e.g., oil fields) and the unequal demands for energy consumption. Stores of energy and the resulting wealth generated by their extraction and sale can contribute to unequal wealth distribution, violence, war, corruption, and coercion both within and between nation-states.

Within this context, national energy policies inevitably manifest ethical values about distributive justice, health, and equity and raise geopolitical concerns about national security. The disproportionate energy consumption by developed countries causes transboundary environmental problems. Most controversially, the carbon dioxide produced from the combustion of fossil fuels contributes to rising sea levels, which negatively affect many developing countries that have not benefited from the goods and services provided by those fuels. Many of these countries cannot afford the adaptation measures necessary to mitigate their vulnerability, and the question becomes to what extent developed nations are responsible for helping the rest of the world cope with the consequences of their large energy appetites. Another political and ethical dilemma posed by proposals to shift away from fossil fuels is the status of nuclear energy. Do its attendant risks and benefits present an acceptable tradeoff as a transitional source of energy in the move from fossil fuels to renewables?

Questioning the dominant assumption that social progress depends on increases in per capita energy consumption raises deeper ethical issues about the good life. It is commonly believed that high civilization depends on high energy use, which explains the modern quest for new and greater reserves of energy. There is a correlation between quality of life, as measured by the Human Development Index, and per capita energy consumption, but this is not a linear relationship. Indeed the improvement in quality of life levels off when per capita electricity consumption equals 4,000 kilowatt-hours. Yet some countries have per capita consumptions over 20,000 kilowatt-hours. This relates to issues in development ethics (e.g., neocolonialism and cultural homogenization), because metrics of progress are often tied to energy consumption.

Although the rise of "energy slaves" (the use of mechanical or inanimate energy sources to replace animate forms) has brought enormous benefits (including the replacement of human slaves), it has also created risks and concerns about environmental sustainability. Furthermore it contributes to the questionable assumption that living well requires increasing dependence on these energy slaves. A. R. Ubbelohde (1955) characterized the modern ideal society as based on a large proportion of inanimate energy slaves as the "Tektopia." The Tektopia brings both new possibilities and new moral dilemmas resulting from such factors as increased luxury, changes in the administrative state, displacement of workers by machines, and difficulty in controlling, regulating, and distributing energy.

Ivan Illich (1974) also critiqued this image of the good life by noting that as the number of energy slaves increases, so rises not only inequity but also social control and personal stress, alienation, and meaninglessness. He challenged the energy crisis focus "on the scarcity of fodder for these [energy] slaves," preferring instead "to ask whether free men need them" (p. 4). He argued that energy policies (whether capitalist or socialist) focused on high energy consumption will lead to technocracies that degrade cultural variety and diminish human choice. For Illich, "only a ceiling on energy use can lead to social relations that are characterized by high levels of equity.... Participatory democracy postulates low-energy technology" (p. 5). Beyond a certain threshold, increased energy affluence can come only through greater concentration of control, and thus greater inequality.

Failure to differentiate the technoscientific concept of energy from its older political meaning can lead to dangerous ideologies that reduce the plural, lived energies of human interaction to manipulable technical constructs. People are reflected as mere human motors in the mirror of energy slaves (Rabinbach 1990). The technical notion of energy begins to blur distinctions between nature and machines, living organisms and persons, mechanical work and human action. Efficiency subverts more human goals. The resulting blindness to the distinction between the technoscientific and political versions of energy partially maimed moral judgments about the use of the atomic bomb. Consideration of ethical and political issues associated with energy thus becomes an opportunity to redistinguish what may have been improperly united: energy as a basic concept in science, as a resource, and as an ethical issue.

ENGINEERING DESIGN ETHICS

Engineering design ethics concerns issues that arise during the design of technological products, processes, systems, and services. This includes issues such as safety, sustainability, user autonomy, and privacy. Ethical concern with respect to technology has often focused on the user phase. Technologies, however, take their shape during the design phase. The engineering design process thus underlies many ethical issues in technology, even when the ethical challenge occurs in operation and use.

Engineering Design

Engineering design is the process by which certain goals or functions are translated into a blueprint for an artifact, process, system, or service that can fulfill these functions. The function of cutting bread, for example, can be translated into a knife. A car fulfills the function of transportation. Engineering design is different from other forms of design—such as fashion design or the design of policy—in that it results in artifacts and systems grounded in technical knowledge.

The character of the engineering design process has been much debated, but for present purposes it may be described as an iterative process divided into different phases. The following phrases are the simplest and most accepted (Pahl and Beitz 1996):

- Problem analysis and definition, including the formulation of design requirements and the planning for the design and development of the product, process, system, or service.
- Conceptual design, including the creation of alternative conceptual solutions to the design problem, and possible reformulation of the problem.
- Embodiment design, in which a choice is made between different conceptual solutions, and this solution is then worked out in structural terms.
- Detail design, leading to description that can function as a guide to the production process.

In each phase, engineering design is a systematic process in which use is made of technical and scientific knowledge. This process aims at developing a solution that best meets the design requirements. Nevertheless, the final design solution does not simply follow from the initially formulated function because design problems are usually ill-structured. Nigel Cross (1989) has argued that proposing solutions often helps clarify the design problem, so that any problem formulation turns out to be partly solution-dependent. It is impossible to make a complete or definite list of all possible alternative solutions to a problem. It is also extremely difficult to formulate any criterion or set of criteria with which alternatives can be ordered on a scale from "good" or "satisfactory" to "bad" or "unsatisfactory," even though any given feature of the design may be assessed in terms of some given criterion such as speed or efficiency.

Ethical Issues

Design choices influence how ethical issues are addressed in technology. Because such choices are differentially manifested in the different phases of the design process, ethical issues themselves take on distinctive forms in each case.

PROBLEM FORMULATION. Problem definition is of special importance because it establishes the framework and boundaries within which the design problem is solved. It can make quite a difference—including an ethical difference—from whose point of view a problem is formulated. The problem of designing an Internet search engine looks different from the perspective of a potential user concerned about privacy than from the perspective of a provider concerned about selling banner advertisements. The elderly or physically disabled will have different design requirements than the young or healthy.

An important ethical question in this phase concerns what design requirements to include in the problem definition. Usually design requirements will be based on the intended use of the artifact and on the desires of a client or user. In addition, legal requirements and technical codes and standards play a part. The latter may address, if only implicitly, ethical issues in relation to safety or environmental concerns. Nevertheless, some ethical concerns may not have been adequately translated into design requirements. Engineering codes of ethics, for example, require that engineers hold "paramount the safety, health and welfare of the public," an obligation that should be translated into design requirements.

The idea that morally relevant values should find their way into the design process has led to a number of new design approaches. An example is eco-design or sustainable design, aimed at developing sustainable products (Stitt 1999). Another example is value-sensitive design, an approach in information technology that accounts for values such as human well-being, human dignity, justice, welfare, and human rights throughout the design process (Friedman 1996).

Ethical issues may arise as well during the operationalization of design requirements. Take for example a design criterion such as minimizing global warming potential, which may arise from a moral concern about the greenhouse effect. The global warming potential of substances can be measured on different time scales potentially resulting in different rankings of these substances (Van de Poel 2001). The choice of different time scales is ethically relevant because it relates to the question of how far into the future the current generation's responsibility extends.

CONCEPTUAL DESIGN. Design is a creative process, especially during the conceptual phase. In this phase the designer or design team thinks out potential solutions to a design problem. Although creativity is not a moral virtue in itself, it is nevertheless important for good design, even ethically. Ethical concerns about a technology may on occasion be overcome or diminished by clever design.

One interesting example is the design of a storm surge barrier in the Eastern Scheldt estuary in the Netherlands (Van de Poel and Disco 1996). In the 1950s, the government decided to dam up the Eastern Scheldt for safety reasons after a huge storm had flooded the Netherlands in 1953, killing more than 1,800 people. In the 1970s, the construction plan led to protests because of the ecological value of the Eastern Scheldt estuary, which would be destroyed. Many felt that the ecological value of the estuary should be taken into account. Eventually, a group of engineering students devised a creative solution that would meet both safety and ecological concerns: a storm surge barrier that would be closed only in cases of storm floods. Eventually this solution was accepted as a creative, although more expensive, solution to the original design problem.

EMBODIMENT DESIGN. During embodiment design, one solution concept is selected and worked out. In this phase, important ethical questions pertain to the choice between different alternatives.

One issue is tradeoffs between various ethically relevant design requirements. While some design requirements may be formulated in such terms that they can be clearly met or not —for example, that an electric apparatus should be compatible with 220V—others may be formulated in terms of goals or values that can never be fully met. Safety is a good example. An absolutely safe car does not exist; cars can only be more or less safe. Such criteria as safety almost always conflict with other criteria such as cost, sustainability, and comfort. This raises a question about morally acceptable tradeoffs between these different design criteria. Is there a minimum level of safety each automobile should meet, or is it acceptable to design less safe cars if they are also cheaper?

Formal engineering methods—such as cost-benefit analysis and multiple criteria design analysis—exist to deal with design criteria tradeoffs. The question, however, is whether these methods result in morally acceptable tradeoffs. These methods often treat different design criteria and the moral values on which they are based as if they are commensurable, which may be problematic.

Alternative designs cannot only be compared in terms of the original design criteria, but also in terms of the risks they imply. In engineering, a host of methods exist to assess the risks of new technologies, and increasingly such methods also inform design choices. In general, one may prefer a design with minimal risks, but the acceptability of risks also depends on such issues as their distribution and the degree to which they are accepted voluntarily (Shrader-Frechette 1991). Free and informed consent can be an issue in engineering design, just as in the design of medical research experiments with human subjects.

Whereas an evaluation in terms of risks usually focuses on minimizing potential harm or justly distributing potential harm, other evaluations may focus on the possibility of doing good. An approach that may prove interesting in this respect focuses on the so-called "scripts" of technological artifacts. Authors such as Bruno Latour have used the notion of a script to describe the built-in use and moral presuppositions of an artifact (Latour 1992). The automatic or passive seat belt is a case in point. This artifact contains a script that forces the driver to use the seat belt before the car engine can be started, which raises an interesting ethical question. To what degree is it acceptable to limit user autonomy in order to achieve other moral goods such as safety? It is usually argued that a failure to use a seat belt will impose hardships and costs to others in the event of an accident.

DETAIL DESIGN. During detail design, a design solution is further developed, including the design of a production process. Examples of ethical issues addressed at this phase are related to the choice of materials: Different materials may have different environmental impacts or impose different health risks on workers and users. Choices with respect to maintainability, ability to be recycled, and the disposal of artifacts may have important impacts on the environment, health, or safety. The design of the production process may invoke ethical issues with respect to working conditions or whether or not to produce the design, or parts of it, in low-wage countries.

Design as a Social Process

Engineering design is usually not carried out by a single individual, but by design teams embedded in larger organizations. The design of an airplane includes hundreds of people working for several years. Organizing such design processes raises a number of ethical issues.

One is the allocation of responsibilities. What is the best way to allocate responsibility for safety in the design process? One option would be to make someone in particular responsible. A potential disadvantage of this solution is that others—whose design choices may be highly relevant—do not take safety into account. Another approach might be to make safety a common responsibility, with the danger that no one in particular feels responsible for safety and that safety does not get the concern it deserves.

A second issue is decision-making. During design, many morally relevant tradeoffs have to be made. Sometimes such decisions are made explicitly, but many times they occur implicitly and gradually, evolving from earlier decisions and commitments. Such patterned decision making may lead to negative results that never would have been chosen if the actors were not immersed in the problematic decision-making pattern (Vaughan 1996). This raises ethical issues about how to organize decision making in design because different arrangements for making decisions predispose different outcomes in ethical terms (Devon and van de Poel 2004).

A third issue is what actors to include. Engineering design usually affects many people with interests and moral values other than those of the designers. One way to do right to these interests and values is to give different groups, including users and other stakeholders, a role in the design and development process itself. Different approaches have been proposed to this issue, such as participatory design in information technology development (Schuler and Namioka 1993). Constructive technology assessment likewise aims to include stakeholders in the design and development process in order to improve social learning processes at both the technical and normative levels with respect to new technologies (Schot and Rip 1997).

As the heart of the process of technological development and future use, engineering design must likewise be at the core of ethical reflection on technology. Major ethical issues in engineering design include what requirements, values, and actors to include in the design process and how to trade off different requirements and values. Major issues also arise with respect to organizing the design process in such a way that moral responsibilities are adequately and fairly allocated.

ENGINEERING ETHICS

Overview
Europe

OVERVIEW

Engineering ethics is concerned with the ethical responsibilities of engineers, both as individual practitioners and organizational employees, and as members of a profession with obligations to the public. The issues in engineering ethics range from micro-level questions about the everyday practice of individual engineers to macro-level questions about the effects of technology on society (Herkert 2001). Because engineers are the primary creators of science-based technology, engineering ethics is one of the most important intersections between science, technology, and ethics.

Development of Engineering and Engineering Ethics

Compared to the clergy, law, and medicine, engineering is a relatively young profession, having acquired something like its present form in France in the eighteenth century. In the United States, the United States Military Academy at West Point graduated its first engineers in 1817. The first private engineering college in the United States was Rensselaer Polytechnic Institute, founded in 1823. By the mid-nineteenth century, the land grant colleges in the United States had programs in civil engineering. In 1850, the first year the United States census counted engineers, only one in 10,000 persons identified themselves as engineers (for 2,000 total). By 1900, however, the numbers were increasing dramatically and the fields of engineering multiplying because of new discoveries and inventions in electricity, power generation, chemical processing, automobile development, and flight. The emerging large corporations also required increasing numbers of engineers. At the end of the twentieth century, about one in one hundred Americans was an engineer (Davis 1998).

Codes of ethics appeared in England in the middle of the nineteenth century and in the United States early in the twentieth century. In 1912 the American Society of Mechanical Engineers (ASME) proposed to the American Society of Civil Engineers (ASCE) and the Institute of Electrical Engineers (IEE) that a code for all three societies be constructed. The attempt was unsuccessful due to differences in the disciplines and their different relationships to business. The societies agreed that a code of ethics was desirable, and each society wrote its own. Not surprisingly, the codes had many similarities (Layton 1986).

Early codes focused on such issues as limiting professional advertising, protecting small businesses and consulting firms from underbidding, and the primacy of the obligation of engineers to their clients and employers. After several decades of relative neglect of the codes, a major change occurred in 1974, when the Engineers' Council for Professional Development (ECPD) adopted a new code of ethics that held that the paramount obligation of engineers was to the health, welfare, and safety of the public. Virtually all engineering codes of the early twenty-first century identify this as the primary obligation of engineers, not the obligation to clients and employers.

The emergence of engineering ethics as an academic subject also began in the 1970s. From this period to the present, there has been a growing emphasis on including engineering ethics in some form in the engineering curriculum. The emergence and continuing growth of this new discipline is due to a number of factors. One is a series of high-profile disasters, such as the problems of the Ford Pinto and the crash of the DC-10 outside Orly Field in Paris in 1974. In the intervening years, such events as the *Challenger* and *Columbia* space shuttle disasters have reinforced the need for engineers to be both technically competent and ethically responsible.

In 1985, the Accreditation Board for Engineering and Technology (ABET, Inc.), which accredits engineering colleges, reached a decision to require engineering programs to provide students with "an understanding of the ethical characteristics of the engineering profession and practice," supplying still more impetus to the development of engineering ethics. The ABET 2000 requirements were even more specific with regard to the ethics dimension of engineering education, requiring engineering graduates to have not only an understanding of ethical and professional issues related to the practice of engineering, but also an understanding of the impact of engineering on larger social issues.

Finally, the increased emphasis on ethics in large business organizations, where most engineers work, has also reinforced the importance of engineering ethics. Ethics codes have proliferated in business organizations, as has the creation of "ethics officers" to interpret and implement the codes. In 1992 the Ethics Officers Association (EOA) was founded. The organization had almost 900 organizations as members at the beginning of its second decade. Business organizations may increasingly expect engineers to have some knowledge and sophistication in the area of ethics and professionalism.

In order to promote the development of the emerging field of engineering ethics and to develop material for classroom use, in the late 1970s both the National Endowment for the Humanities (NEH) and the National Science Foundation (NSF) sponsored a series of workshops to develop teaching materials and provide pedagogical advice for faculty who wanted to introduce engineering students to ethics. Led by Robert Baum and Vivian Weil, these workshops brought together engineering faculty and ethics teachers. One early fruit of these collaborations was the first edition of the textbook *Ethics in Engineering* (1996) by philosopher Mike Martin and engineer Roland Schinzinger, who came as a team to Baum's NEH workshop.

Because much of the impetus for the development of engineering ethics as an academic area came from the need for educational materials, some early publications focused on teaching. For example, Robert Baum's monograph, *Ethics and Engineering* (1983) included a statement of the goals of ethics education endorsed by a large group of educators across the curriculum who, sponsored by the Hastings Center, met over a three-year period to discuss the goals of ethics instruction in higher education. Adapted to each academic area, the five goals were:

1. to stimulate the moral imagination of students;
2. to help students recognize ethical issues;
3. to help students analyze key moral concepts and principles;
4. to stimulate a sense of moral responsibility; and
5. to help students deal constructively with moral ambiguity and disagreement.

Case studies have proven one of the most popular and effective ways of pursuing these goals. Since its early support of Vivian Weil's workshop, the NSF has consistently funded engineering ethics projects, particularly those designed to develop case studies for classroom use. In addition to Martin and Schinzinger, the first editions of a number of engineering ethics textbooks followed Baum's monograph. There was Unger (1994), Harris, Pritchard, and Rabins (2000), Whitbeck (1998), and Fleddermann (1999). Baum and Flores (1983), Schaub and Pavlovic (1983), Johnson (1991), and Vesilind and Gunn (1998) have published anthologies in engineering ethics, and Davis (1998) and Cook (2003) have published single-authored texts on aspects of engineering ethics.

Articles on engineering ethics began appearing frequently in engineering periodicals and philosophical journals such as *Business and Professional Ethics* and *Professional Ethics*. In 1995 *Science and Engineering Ethics*, a periodical that regularly publishes articles across a wide spectrum of issues in engineering ethics, began publication. With the support of NSF, Caroline Whitbeck initiated the Online Center for Ethics in Science and Engineering, which includes diverse resources for engineering ethics educators.

Although the emergence of engineering ethics as an academic area is especially evident in the United

States, serious interest is by no means confined to it. The editorial board of *Science and Engineering Ethics* is represented by Canada, the United Kingdom, Russia, Germany, Poland, Romania, Italy, Norway, France, Belgium, Sweden, and Japan, and it has had guest editors from the Netherlands. European educators have collaborated to produce a volume edited by Philippe Goujan and Bertrand Heriard Dubreuil (2001). The Martin and Schinzinger and Harris, Pritchard, and Rabins texts have been translated into Japanese. Shuzo Nakamura has also published an original textbook in Japanese, *Practical Engineering Ethics* (2003).

The rise of engineering ethics is not without its critics. Engineer Samuel Florman agrees that engineers should avoid being inaccurate, careless, or inattentive. For him, engineering ethics is about reliability; people count on engineers to do their work well and not make mistakes. However, cautions Florman, "We do not leave it to our soldiers to determine when we should have war or peace. Nor do we leave it to our judges to write our laws. Why, then, should we want our engineers to decide the uses to which we put our technology?" (Florman 1983, p. 332). Responses to Florman typically claim that engineers are in the best position to inform the public about the possible uses and likely consequences of technology, to alert employers and (if necessary) the public of defects and possible disasters associated with technology, to participate in the setting of engineering standards, and to help investigate problems, such as the *Challenger* and *Columbia* space shuttle disasters, or the collapse of the World Trade Towers in New York City on September 11, 2001. This does not necessarily mean that it should be left to engineers to decide all the uses for a technology. It only means that responsible decisions require information that engineers are in the best position to provide.

Topics in Engineering Ethics

Engineering experience as well as public responses to technological developments to which engineers contribute raise topics in engineering ethics. A review of key issues easily begins with the codes of ethics of professional engineering societies, which attempt to identify the major areas of ethical concern for engineers. Reflection on the nature and function of the codes themselves has itself produced considerable discussion. Some writers argue that the codes are coercive and should therefore be thought of as codes of conduct rather than codes of ethics (Ladd 1991, Luegenbiehl 1991). Others think of codes of ethics as guides and expressions of commitment that enable engineers, their clients, and the public to know what to expect rather than instruments of coercion (Davis 1998, Unger 1994). Even so, there are issues about the range of applicability of codes. Professional societies adopt engineering codes of ethics, but most engineers do not belong to professional societies. Do the standards, rules, principles, and ideals contained in the codes still apply to them?

A related issue is professional registration. Most U.S. engineers do not have the Professional Engineer (P.E.) license. This means that most engineers cannot cite the possibility of losing their P.E. registration as a way to resist pressures to engage in unethical conduct. There is considerable resistance in the engineering profession to making the P.E. license mandatory. Should the requirements for engineering registration be changed to make licensure more acceptable to most engineers? Short of P.E. registration, are there other ways of ensuring quality in engineering work and protecting engineers from undue pressure to be unethical?

As has already been noted, prior to the 1970s most engineering codes of ethics held that the first obligation of an engineer is loyalty to a client or employer. The codes said little about obligations to the public. By the turn of the twenty-first century, most codes gave pride of place to the so-called paramountcy clause, which requires engineers to hold paramount the safety, health, and welfare of the public. However, there has been surprisingly little discussion of what, specifically, this requires engineers to do. Most attention has focused on whether whistle-blowing is either morally required, or at least permissible, when violations of the paramountcy clause are observed (DeGeorge 1981, James 1995, Davis 1998).

The issue of whistle-blowing has been central to some classic cases in engineering ethics, such as the Bay Area Rapid Transit case (Anderson, Perucci, Schendel et al. 1980), the DC-10 case (Fielder and Birsch 1992) and, above all, the *Challenger case* (Boisjoly 1991, Vaughn 1996). Important as such cases are, however, they touch on only one aspect of engineers' responsibility for public safety, health, and welfare. Whistle-blowing typically occurs only when something bad is imminent or has already occurred. The codes have little, if anything, to say about engineers' attempting to anticipate and resolve problems before they get out of hand. This deficiency is also reflected in the engineering ethics literature, which tends to focus on wrongdoing and its prevention, rather than on steps that should be taken to promote public safety, health, and welfare.

Questions involving conflicts of interest produce dilemmas for engineers, especially those in private practice (Davis 1998). A conflict of interest in the professions is a situation in which some professional or personal interest threatens to interfere with professional judgment, rendering that judgment less trustworthy than it might otherwise be. One of the topics that often arises in discussions of conflicts of interest is accepting gifts and bribes. An offer of a bribe creates a conflict of interest, because it may corrupt professional judgment, even when rejected. While it may be easy to say that accepting bribes is unethical, offers of gifts and favors from vendors can produce more subtle dilemmas. Such offers are likely to pose the first ethical issues that engineers face in their professional careers. These issues lend themselves especially well to treatment by the method of casuistry. For example, a case where accepting a gift from a vendor would usually be considered permissible (such as accepting a cheap plastic pen) and a case where accepting a gift from a vendor would usually be considered impermissible (such as accepting a gift worth several thousand dollars) can be compared with a more difficult case. By determining whether the case in question is more analogous to the permissible or impermissible case, the engineer can decide on the moral status of the questionable case (Harris, Pritchard, and Rabins 2000). Of course, identifying legitimate and illegitimate cases will in part be guided by the particular culture in which one is working.

The issue of confidentiality arises most commonly for engineers in private practice (Armstrong 1994). Although engineers ordinarily owe strong obligations of confidentiality to clients, the primacy of the obligation to the safety, health, and welfare of the public can be overriding in some situations. Suppose an engineer is hired by a client to assess the structural soundness of a building and finds fundamental flaws that threaten the safety of the present occupants. The engineer may be obligated to violate engineer/client confidentiality in order to inform authorities or tenants of the danger. Again, the method of casuistry can be used effectively to deal with troublesome cases of confidentiality.

Computer ethics is a rapidly developing area of interest, raising a host of questions, such as the control of pornography and spam, privacy, intellectual property rights, the legitimacy of sending unsolicited and unwanted cookies, the proper uses of encryption, selling monitoring software to totalitarian states, the proper uses of Social Security numbers, national ID cards, identity theft, whether Internet sites for making bombs or holocaust denial should be allowed, the legitimacy of downloading music, and software piracy. Interesting conceptual issues can be raised about the status of such entities as computer programs. Are they more like books, where copyright would be the appropriate form of protection, or like inventions, where patents would be the more appropriate form of protection? (Johnson 2000, Johnson and Nissenbaum 1995).

Engineers have more effect on the environment than any other professional group; yet engineers are only gradually assuming environmental responsibilities. Provisions relating to engineers' responsibility for the environment appeared only in the codes of the Institute of Electrical and Electronics Engineers (IEEE), the American Society of Civil Engineers (ASCE), and the American Society of Mechanical Engineers (now ASME International). Vesilund and Gunn (1998) explore a number of religious and philosophical bases for engineers' directly embracing environmental concerns, and Gorman, Mehalik, and Werhane (2000) have published a wide range of case studies that pose environmental challenges for engineers. For those who support the notion that engineers have direct responsibility for the environmental effects of their work, the basis and extent of that responsibility is still under debate. A key question is whether accepting responsibility only in areas where there is a clear threat to the health or well-being of human beings is sufficient, or whether a concern for the environment for its own sake is needed.

Another area where engineering work directly affects the public is in the imposition of risk as a result of technology. Martin and Schinzinger have suggested that engineering work is a kind of social experimentation and, as such, imposes risks on those on whom the "experiment" is performed, namely the public. What is acceptable risk? Who should determine it? Answers to the first question strongly affect answers to the second. Scientists and engineers tend to take a somewhat consequentialist or utilitarian approach. Defining risk as the product of the probability and magnitude of harm, they find a risk acceptable if the potential benefits outweigh the potential harms. Because they believe the public is often irrational and ill-informed about risk, scientists and engineers may be inclined to say that the determination of acceptable risk should be left to them. Representatives of the public, however, tend to link acceptable risk to free and informed consent and the equitable distribution of risks and benefits. This position is more congruent with an approach that emphasizes respect for individual rights (Shrader-Frechette 1985, 1991).

Engineers increasingly have work assignments in host countries with different practices, traditions, and values from an engineer's home country, raising still other issues. What criteria are appropriate in determining when engineers should adopt the values and practices of the host country? For example, when, if ever, is it appropriate to make "grease payments" and to exchange rather substantial gifts with customers and potential customers, where this is commonly practiced? (Harris 2000).

Future Directions

As an academic discipline in an early phase of its evolution, engineering ethics can be expected to show further maturation in every area, but the following areas seem particularly in need of further cultivation and growth.

METHODOLOGY. As in many areas of practical ethics, methodology needs further development. In practical ethics there are at least three different methodologies, each with characteristic strengths and weaknesses. One is to turn to traditional philosophical theories, especially consequentialist or utilitarian and deontologist or person-respecting theories, a "top-down" approach. Traditional ethical theories serve several useful functions in engineering ethics. First, they help identify relevant moral considerations in a dilemma. For example, knowledge of moral theory is useful in identifying the different moral perspectives of scientists and engineers (who often take a consequentialist approach) and the lay public (who often take a deontological approach) with respect to risk, and in confirming that both perspectives have deep and legitimate moral roots.

Second, moral theories often allow one to construct and even predict the arguments that will be made for or against certain policies or courses of action. Suppose one is considering whether there should be strong or weak protections of intellectual property. Utilitarian arguments for strong protections point out that such protections give incentive for technical advancement by insuring that those who are responsible will reap the economic rewards. Utilitarian arguments against strong protections point out that severe restrictions can impede the advance of technology by restricting the flow of information. Arguments based on a respect for persons typically point out that respect for individual rights of the creators of new technology requires that their creations be protected from unauthorized use. These lines of thinking do in fact reflect the discussion in the courts and scholarly literature.

Third, moral theories are often useful in assessing whether an argument has been resolved satisfactorily. If arguments from the two perspectives agree, there is good reason to accept the conclusion. If they disagree, there is a clearer basis for identifying morally relevant differences and determining which arguments are the most persuasive. Despite these advantages, however, many writers and teachers find that theories are often not useful for analysis and resolution of many of the concrete dilemmas that engineers face. Furthermore, engineering students are often not sympathetic to grand theories.

In contrast, a "bottom-up" approach emphasizes the need for careful analysis of the particulars of a given situation and makes much less use of broad moral principles. One version of this approach is the ancient method of casuistry, which has also been revived in medical ethics (Jonsen and Toulmin 1988). As has already been pointed out, paradigms of acceptable (or unacceptable) action are first identified. Then the salient ethical features of the paradigms are compared with those of the case under consideration. The casuist must then determine whether the case in question more closely resembles the paradigm of acceptable behavior or the paradigm of unacceptable behavior. For this method to work effectively, appropriate paradigms of acceptable and unacceptable behavior must be identified and generally accepted by the profession. The critical question is whether this can be done without relying on just the sorts of principles those sympathetic to the top-down approach take as their starting point.

An approach that falls somewhere between the top-down and bottom-up approaches proceeds from what might be called "mid-level" moral rules and principles, such as: "keep your promises and agreements"; "don't cheat"; "don't harm others"; "be truthful"; and "minimize the influence of conflicts of interest." Engineering codes of ethics tend to operate at this level. Questions about the appropriate grounding of such mid-level rules and principles remain, however, as do questions about their application to particular circumstances. If, for example, one asserts that exceptions to the rules or principles are justified as long as a rational person would be willing to have others make the same exception, one must give reasons for taking this position. Do the reasons make reference to principles of a still broader nature, perhaps even general moral theories? Whether all three approaches are useful, or only one, or some other approach such as "virtue ethics," is still a matter of debate.

GOOD WORKS AND CHARACTER. Many of the cases that have driven research and teaching in engineering ethics have dealt with engineering disasters and the responsibilities of engineers to prevent them or respond to them adequately after they have occurred. Some writers, however, have begun to stress the importance of going beyond basic duties to protect the public from the disastrous effects of technology to the duty to promote the public good (Pritchard 1992, 1998). The General Electric (G.E.) engineers who in the 1930s worked together against odds and with relatively little managerial support to develop the sealed-beam headlight exemplified good works. Some writers have stressed the importance of character and personal ideals in motivating such good works (Pritchard 2001, Martin 2002). Physicians who are members of "Physicians Without Borders" and engineers in "Engineers Without Borders" exemplify this kind of activity, but there are many less dramatic examples, such as the G.E. engineers. Many believe that the place of good works and the motivations for them deserve more emphasis in teaching, in research, and in the engineering profession itself.

Taking on responsibilities that go beyond standard job requirements in order to improve public safety is not unusual for engineers. Beyond the efforts of individual engineers or small groups of engineers, professional societies can make important contributions. The rapid emergence of the boiler industry in the late nineteenth and early twentieth centuries provides an illustration of the constructive role engineers can play in the face of serious risks arising from technological development. Initially ill-understood and without a set of regulations to guide their safe construction and use, boilers frequently exploded, injuring and killing untold numbers of people. Through the efforts of the leadership and dedicated work of a large number of mechanical engineers in the ASME, guidelines and regulations for the construction and safe use of boilers were eventually put in place (Cross 1990).

SOCIAL POLICY ISSUES. Most cases in engineering ethics have focused on the decisions of individual engineers in the context of a particular situation, but the effect of technology on society is often more a function of larger social policy issues—what some have called "macro-issues" as opposed to "micro-issues" (Herkert 2001). The legal and medical professions often make policy statements in areas of their expertise. Engineers, perhaps because of the absence of a unified professional society that can represent the profession to the public, have been much less conspicuous in public debates related to technology. In the light of engineers' responsibility to hold paramount the safety, health, and welfare of the public, what are their responsibilities (if any) in this area?

Some believe that engineers should step forward to help the public reflect on what future technological development might hold in store—both positive and negative (Fouke 2000). These developments will have an impact on the quality of our environment, the availability and distribution of needed resources, the quality of life that is possible, and the ability to live in peace or conflict. Many of these questions have to do with the appropriate laws and governmental regulations.

Several such issues have already been suggested. Others include the relationship of bio- and related engineering to cloning and genetic engineering. Still others have to do with nanotechnology, national defense, and the use of cell phones. The proper decisions in these areas, as well as the extent to which engineers should have responsibility for making policy statements or informing the public, is a matter that deserves more consideration in the engineering profession and in engineering ethics.

Engineers must also be concerned with codes and laws that are important in protecting the public. The ASME has long been associated with the code governing boilers and pressure vessels. Some engineers have incurred considerable personal risk and liability by promoting requirements for trench boxes to protect workers in deep trenches. Engineers have been involved in promoting improvements in building codes that protect buildings from earthquake damage, damage due to subsoil shifting, and hurricane and wind damage. Yet the extent and nature of engineers' obligations in these areas has received scant attention in the literature of engineering ethics.

CONTEXT OF ENGINEERING DECISIONS. The context in which engineering decisions are made and the implications of this context for ethical analysis are insufficiently explored. Engineers commonly make recommendations and decisions about design and other issues in the context of incomplete knowledge and considerable uncertainty. Often their work is limited to only a part of the total project or product design, and managers, not engineers, sometimes make crucial decisions. Assessments of individual responsibility in such contexts and the proper criteria for making decisions under conditions of uncertainty have yet to be fully analyzed.

ENGINEERS, MANAGERS, AND RIGHTS IN THE WORKPLACE. The relationship of engineers to managers is an especially sensitive area. On the one hand, managers can overrule the decisions of engineers, even when professional issues are at stake. On the other, managers control the jobs of engineers, and many engineers aspire to management positions. Engineers do not want to jeopardize careers by unnecessarily offending managers. Some attention has been devoted to the question of when decisions are properly made by engineers and by managers, and to the professional rights of engineers in the workplace (Harris 2000, Martin 2000). The issues that arise between engineers and managers and how they should be dealt with have been insufficiently studied, however, and no engineering code of ethics has raised the question of the rights of engineers as professionals in the workplace. This is a topic that merits further study in academic engineering ethics and by professional engineering societies.

INTEGRATION WITH OTHER AREAS. Engineering ethics may need further integration with several other areas, such as the philosophy of technology, law, management theory, and the philosophy of engineering. Engineers, as well as teachers and writers in engineering ethics, need to be more aware of the nature of technology and its influence on society, the impact of law on ethical decisions, the relationship of engineering decisions to management decisions, and the important differences between the way engineers and scientists use scientific knowledge. This can help bring ethical analysis more closely in line with engineering practice. How this integration will affect the evaluation of professional decisions is not yet clear, but the need for this integration seems obvious (Mitcham 2003).

EUROPE

In most European countries engineering ethics is increasingly conceived as an interdisciplinary reflection at the crossroads of professional ethics, the human and social sciences, and the philosophy of technology (especially the ethics of technology). This is in marked contrast with the situation in the United States, where engineering ethics is a form of professional ethics.

Europe nevertheless includes countries with diverse cultural, juridical, professional, and educational traditions of engineering, something that has promoted efforts within the European Union to harmonize technical education, including its nontechnical requirements in the humanities, social sciences, and professional ethics. European integration has further required the development of professional guidelines for the mutual recognition of diplomas and titles. Thus any comparison between engineering ethics in Europe and in the United States cannot ignore a diversity of professional traditions. Engineering ethics in Europe requires a contextualist approach referencing the perceptions of the various engineers who formulate them.

Engineering Education: British versus Continental Models

Histories of engineering education frequently begin with France, ignoring that the first engineering schools in the world were the Moscow School for Military Engineers (established 1698) and the Apprenticeship School for Civil and Military Engineers (founded in Prague in 1707). As for Western Europe, from its commonly accepted origination with the Bureau des dessinateurs du roi (Bureau of the King's Draftsmen), established in France in 1744 (and the forerunner of l'École royale des ponts et chaussées, or Royal School of Bridges and Roads, founded in 1747), it is still a long way to engineering education as known in the twenty-first century, with its strong theoretical and practical content. The role of the bureau was primarily to provide a tutorial to guide new recruits in their first projects.

The creation of the Bureau des dessinateurs du roi was followed by l'École du génie de Mézières (School of Military Engineering, Mézières) in 1748 and l'École royale des mines (Royal School of Mines) in 1783. If these are among the oldest engineering schools in Western Europe, the one that has most influenced the engineering educational system is l'École polytechnique. The polytechnique was founded in 1794, one year after the dissolution of the French universities, and soon after the failure of the school at Mezières, from which it borrowed the idea of a formal curriculum, rather than imitating the ancien régime tutorship in place at l'École royale des ponts et chaussées. The polytechnique's formalized theoretical curriculum with its emphasis on mathematics became an influential model for engineering education throughout France and beyond. It also contributed to the establishment of a high scientific and technical education outside university.

Engineering in the United Kingdom adopted a different approach and only later established a structured education for engineers. Engineering degrees were not offered in the United Kingdom until 1838, when King's College, London, began to teach civil engineering. Indeed, Oxford and Cambridge Universities did not offer engineering degrees until the first decade of the twentieth century. Instead, British engineers were for a long time given occupational training exclusively in workshops; apprenticeship promotion is what truly integrated them into their peer group. For this same reason, Britain is the uncontested birthplace of industrial technology. These engineers were at the heart of the Industrial Revolution and played a major role in the development of both the steam engine and its uses.

It is also noteworthy that because of their habit of meeting in clubs in order to exchange ideas and proposals—and above all to capitalize on their experiences and projects—these British engineers prepared the ground for professional engineering organizations well before their Continental colleagues. It may also be significant that when engineering degrees did begin to be offered in the United Kingdom this was done not in independent institutions but in universities that already offered degrees in the liberal arts and sciences.

Professional Engineering Associations in Europe

With regard to France, historians of the engineering profession often cite the long existence of a particular organized group of engineers. Indeed, since 1676 there existed in France a Corps du génie (Engineering Corps) that was in fact a military organization. This particularly early institutionalization thus had little to do with those professional organizations that arose later in the majority of countries. The primary difference is that engineers of the Corps du génie were exclusively engineers of the state, that is, royal functionaries. Because of this state service the Corps du génie did not constitute a truly free organization of professionals, such as was established by "civil" engineers in Great Britain as an outgrowth of the previously mentioned informal clubs, notably the Society of Civil Engineers (founded 1771), later renamed "Smeatonians" after John Smeaton (1724–1792), one of its original members. Another of these societies, the Institution of Civil Engineers (ICE) was founded in 1818 by a small group of young engineers. In 1828, it obtained a royal charter and became a leader in the profession, with 80,000 members in the early twenty-first century.

From the middle of the nineteenth century, several European countries followed the British model, beginning with France (the Société des ingénieurs civils de France, founded in 1848), Germany (Verein Deutscher Ingenieure [Association of German Engineers], or VDI, 1856), and Spain (Asociación de ingenieros industriales [Association of Industrial Engineers], 1861). But while the prestigious British Institution of Civil Engineers was a club for practitioners, the French, German, and Spanish organizations were all created by a group of certified engineers coming from a single school in each country: the l'École centrale des arts et manufactures de Paris (Central School of Arts and Manufacturing in Paris), Berlin Gewerbeinstitut (Berlin Technical Institute), and the Escuela de ingenieros industriales de Madrid (School of Industrial Engineers in Madrid), respectively. Each association was only later open to qualified persons from other institutions or even to autodidacts (the self-taught).

By contrast, in the United Kingdom there still exist no institutions of higher education devoted exclusively to engineering such as those found on the Continent. The closest approximations are the British "polytechnics," founded in the mid-twentieth century, which include the education of technicians as well as engineers. Great Britain is also different from its neighbors in regard to another important point: It is the only European country in which the engineering associations were for a long time given a monopoly over designating who was an engineer and who was not. Since the 1920s this power has been limited to the power of the ICE to determine the legitimacy of the title "chartered engineer."

From Professional Organizations to Professional Ethics

This historical review shows that the early institutionalization of engineering education did not directly lead to the early establishment of professional engineering organizations. Instead, it was the autonomous organization of practitioners that promoted the initial affirmation of a collective identity and the formalization of a collective moral framework for professional conduct. It is not therefore by chance that the first code of professional ethics written by and for engineers was formulated in Great Britain.

Indeed, historians of the professions commonly consider the "professional code of conduct" adopted by the ICE in 1910 as the model for engineering ethics codes first in the United States and subsequently throughout the world. In 1911 the American Institute of Consulting

Engineers became the first U.S. association of engineers to adopt a code of ethics, a code composed of five articles strongly inspired by that of the British ICE, with seven supplementary articles.

On the Continent again, in 1604 in France, even prior to the creation of the Corps du génie in 1676, the prime minister of King Henry IV (1553–1610), who was also superintendent of fortifications, proclaimed a "Great Regulation" for all royal engineers. This set of directives and general rules was applied until the end of the seventeenth century, but had more the character of administrative law than of a code of professional ethics.

With regard to contemporary codes of professional ethics in Europe, their development is not the same in every country and they are much less important than in North America. Generally speaking, the presence of professional codes of ethics for engineers is stronger in those countries more influenced by Anglo-American cultural models, as is equally true throughout the rest of the world. Indeed, it is striking to note that when the Fédération européenne d'associations nationales d'ingénieurs (European Federation of National Engineering Associations, created in 1951) decided during the 1990s to formulate a code of ethics, it began by studying documents coming exclusively from anglophone countries (the United States, Canada, Australia, and New Zealand) rather than the few existing European codes, which were little known.

Among the little-known European codelike documents were three from Scandinavia and one from Germany. The Scandinavian documents were a "Code of Honor" from the Samlar Sveriges Ingenjörer (Swedish Association of Graduate Engineers), first adopted in 1929 and revised in 1988; a similar "Code of Honor" of the Tekniska Föreningen i Finland (Association of Swedish-Speaking Engineers in Finland) from 1966; and an "Ethical Code for Members of the Norwegian Civil Engineers Association" from 1970. In 1950 the VDI had adopted the "Engineer's Confession," which was more a quasi-religious statement than a professional code.

The European situation thus remains different from that of the United States, where the profusion of codes and of successive revisions within the different branches of the profession constituted a first fundamental phase of engineering ethics. This internalist phase ended during the 1970s, when ethical reflection began to take into account considerations external to the profession and thus challenged a hierarchy of values in which the public interest sometimes gave way to professional prestige. In Europe, however, the public interest has from the beginning been more pronounced, although in a different way than in countries that have had to deal with an ethos of individualism and competition influenced more strongly by American culture.

Engineering Ethics in Twenty-First-Century Europe

Contrary to the situation in the United States, contemporary European reflection on engineering ethics did not arise from a will to renew an existing and explicit reflection at the heart of the profession, and to open it to other actors such as scholars and academics. In the United States engineering ethics found new inspiration in the collaboration among engineering professionals, on one side, and philosophers, historians, and more recently social scientists, on the other. But in Europe engineering ethics was not heir to a prior internalist approach. Instead, its heritage was more that of a professional conscience intuitively sensitive to social responsibilities and to legal expectations for professional conduct associated with the Code Napoléon (the first modern legal code of France, promulgated by Napoléon Bonaparte in 1804).

Certainly, there existed at the end of the twentieth century, in some European countries, some more or less obsolete ethical codes. But there was no formalized ethical reflection, with one exception. In Germany, World War II led engineers to a painful crisis of conscience over the use of science and technology in the service of a monstrous program, and the postwar period saw a strong engagement of the VDI in reflection on the proper ends of technology and the moral responsibility of engineers. But even in Germany no formal code of ethics existed until 2001.

In France, a country with a long engineering tradition, the first ethics code dates back only to 1997, with a 2001 revision. But the two versions of this code, especially the first, are more French adaptations of the North American manner of formulating an ethical framework. A different dynamic, independent from that of the formulation of these initial codes, began in the 1990s to introduce ethical reflection into engineering education in courses (often under different names) dealing with the questions relevant to engineering ethics—courses on philosophy, on epistemology, and on the sociology of sciences and technologies, aroused by contemporary intellectual and social debates.

It is thus not surprising that the first European handbook on engineering ethics, *Technology and Ethics* (2001), which was the product of a team of thirty-seven researchers from ten different European countries, adopted an approach different from U.S. textbooks on the same topic. This volume, which provides one perspective on the state of ethical reflection in European engineering practice, distinguishes three levels of analysis. The first deals with the microsocial level and concerns ethical problems encountered by individual engineers (dilemmas and cases of conscience). The second focuses on the mesosocial level, where the technical systems and institutions are in competition. A third emphasizes the macrosocial level, and therefore technical development in general as a societal question.

Whereas textbooks from the United States are often centered on a code of professional ethics for the profession—that is, on the roles, responsibilities, decisions, and attitudes of engineers individually confronted by ethical dilemmas—*Technology and Ethics* situates this dimension within a more comprehensive framework. To some extent it makes engineering ethics more complex by situating it within the institutional and social context in which engineers participate with other actors (scientists, entrepreneurs, end users, and others) in the development of technologies. At the same time it strives to be more realistic and place less emphasis on individual moral heroism as the best response to ethical problems.

The contextualist approach taken here suggests two sets of questions. First, engineering ethics in Europe may be handicapped by the absence of strong and dynamic professional organizations. This weakness is partially compensated by the growing internationalization of technological universities and professional organizations such as the Institute of Electrical and Electronics Engineers (IEEE), the International Federation for Information Processing (IFIP), and others. But what is their influence with respect to the large, multinational corporations that employ the great majority of engineers? Is a collaboration possible with business ethics?

Second, the freshness of European ethical reflection has permitted it to adapt more rapidly to questions posed by those engineers who develop and maintain the new technological systems (within computer, nuclear, and biotechnological engineering). Engineers are indeed only one of several groups of agents who must articulate and address within their fields the new social and societal questions posed by the development of these techniques. On this point a collaboration with the Science, Technology, and Society (STS) studies movement is greatly desirable.

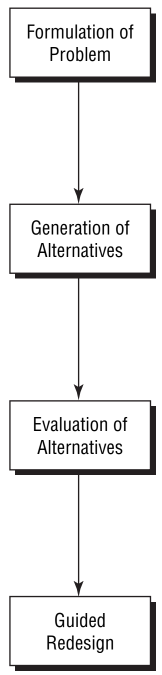
ENGINEERING METHOD

Since the early modern period natural science has been defined in terms of method. The two major approaches to scientific method are those of rationalist deduction and empirical experimentation, analyses of which are often traced back to René Descartes (1596–1650) and Francis Bacon (1561–1626), respectively. Both methods have been argued to have ethical components or to be applicable to ethics. Engineering has been much less described in terms of some distinctive method. In fact, it was only in the mid-twentieth century that discussions of engineering method came to the fore. Interpretations of engineering method are, however, more varied than with science, with less effort to draw connections to ethics, although on both counts the negligence is unwarranted. What follows is a modestly polemical assessment of engineering method that seeks to redress previous oversights by defining engineering method, comparing it with alternative definitions, and establishing the nexus between engineering method and engineering ethics.

The *engineering method* is "the use of heuristics to cause the best change in a poorly understood situation within the available resources" (Koen 2003, p. 28). Two words in this definition, *heuristic* and *best,* are used in an engineering sense. A *heuristic* is anything that provides a plausible aid or direction in the solution of a problem but is in the final analysis unjustified, incapable of justification, and fallible. Engineering heuristics include mathematical equations, graphs, and correlations as well as the appropriate attitudes for solving problems or minimizing risk in an engineering design. Such attitudes

FIGURE 1

Steps in the Guided Iteration Process



SOURCE: Adapted from Dixon and Poli (1995), p. xiv.

obviously have ethical dimensions. Suggestions to "allocate resources to the weak link," "complete a design by successive approximations," and "make small changes in the state-of-the-art," are also engineering heuristics. Engineers frequently use the synonyms *rule of craft, engineering judgment,* or *rule of thumb* to express these experience-based aids that, although helpful, are nonetheless fallible. In France, engineers use the near synonym *le pif* (the nose); in Germany, *faustregel* (the fist); in Japan, *menoko kanjo* (measuring with the eye), and in Russia, *na paltsakh* (by the fingers).

The engineer's word *best,* usually called the optimum, refers to the most desirable tradeoff of the design variables in a multi-variant space in which each criterion has been given its relative importance. This procedure differs from the ideal or best of Plato that is almost universally used in the Western tradition outside of engineering.

This definition of engineering method is consistent with the etymology of the word *engineer,* its formal definition in the dictionary, and common usage. According to one of England's most noted nineteenth-century engineers, Sir William Fairbairn, the term *engineer* comes from an old French word *s'ingenieur* meaning "anyone who sets his mental powers in action to discover or devise some means of succeeding in a difficult task." Contemporary dictionaries concur by authorizing the verb *to engineer* as "to contrive or plan usually with more or less subtle skill or craft" and by giving examples such as "to engineer a daring jailbreak." The word *engineer* is used daily in a similar fashion on radio, television, and in the newspaper.

The engineering term *state-of-the-art* (and its acronym, *sota*) refers to the collection of heuristics that were appropriate for a specific engineering project at a designated time. Thus, a state-of-the-art CD player will be one that is consistent with the set of heuristics that represented "best engineering practice" at the time it was made.

Derivative of the research in general problem solving (Polya 1945), the most frequent alternate definition of engineering used by engineers involves trying to establish a morphology or structure through which the design process is believed to pass (Dixon and Poli 1995, Pahl and Beitz 1995, Shigley and Mitchell 1983). This morphology is often presented in a flow diagram as in Figure 1. In addition to their multiplicity, engineering morphologies must fail as definitions of engineering because no one argues that the engineer can simply pass through the proposed steps; rather, engineers always back-track, iterate, and expand each step guided by heuristics.

Applied science is the most popular non-engineering definition of the engineering method. For the engineer, however, scientific knowledge has not always been available, and is not always available now, and even if available, it is not always appropriate for use. Some historians credit the Ionian natural philosophers of the sixth century B.C.E. as the founders of science, but undeniably homes, bridges, and pyramids existed before then. Precise scientific knowledge is still unavailable for many of the decisions made by the modern engineer. Although it cannot be said that engineering is applied science, engineers do use science extensively as a heuristic when appropriate.

The related claim that engineering is a branch of science called *design science* (Hubka and Eder 1996), similar to the social sciences, does not really advance a definition of engineering method. Although the much stronger view that engineering is a branch of science on a par with physics or chemistry is sometimes encountered (Suh 2001), this view implies that there are facts and axioms of design immutable and normed against an eternal truth, just as the facts of physics are said to be undeniably true. By contrast, most practicing engineers agree with the words of the noted engineer Theodore Von Kármán (1881–1963): "scientists explore what is and engineers create what has never been" (Krick 1969, p. 36).

Some, identifying the engineering method with trial and error (Petroski 1994), imply that engineers try random problem solutions and discard those that do not work. Contrary to this view, thousands of design decisions are made worldwide by engineers every day resulting in very few failures because the engineer usually modifies a previously assured sota in creating a new design.

While these alternate definitions are useful in expanding an understanding of engineering, they fail to be convincing as a comprehensive description of engineering method for the reasons specified, and because each can be subsumed into the definition given initially as simply additional engineering heuristics.

Because the engineering method applies to situations that contain uncertainty, some risk of failure is always present. The success or failure of an engineering design is, therefore, not a sufficient basis for judging whether an engineer has acted ethically. The *Rule of Judgment* in engineering is to evaluate an engineer against the sota that defines best engineering practice at the time the design was made (Koen 2003). This sota must contain all of the appropriate ethical, as well as technical, considerations.

When engineering is recognized as a pluralistic utilization of heuristics to bring about the best change in a limited resource situation that remains to be fully understood, then not only are ethical principles available as useful heuristics but the engineering method can itself become a reasonable description of ethical problem solving in general.

ENGINEERS FOR SOCIAL RESPONSIBILITY

The New Zealand engineering profession has a strong tradition of social responsibility, and many engineers have worked voluntarily on engineering projects in the Pacific Islands and in Southeast Asia. In keeping with this tradition, Engineers for Social Responsibility (ESR) was founded in 1983 and was the first such organization in the world. The driving force in its foundation was Gerald Coates, a Wellington-based electrical engineer. Its objectives are "to encourage and support social responsibility and a humane professional ethic in the uses of technology, to inform the engineering profession, general public and public policy makers about the impact of technology" (ESR). It is based in Auckland and has branches in Wellington and Christchurch, with a combined membership of around 200. Membership is open to all engineers and related professionals. Branches sponsor seminars and presentations that are open to the public.

ESR's focus has always been international: Initially it was concerned with nuclear and peace issues, and most of the papers at its first conference in Hastings in 1984 were on this topic. Its focus broadened after the end of the cold war to include a wide range of national and international issues, including an association with Water for Survival, an engineers' organization that provides technical advice and assistance for water supply and wastewater projects in poor countries.

ESR was initially criticized as a fringe organization, especially by the Institute of Professional Engineers New Zealand (IPENZ). But after a relatively short period, the temperate profile of ESR led to its general acceptance. Indeed, ESR has maintained a close association with IPENZ and become a model for similar organizations in other countries such as American Engineers for Social Responsibility (founded 1988) and Architects and Engineers for Social Responsibility in the United Kingdom (founded 1989, as a transformation of Engineers for Nuclear Disarmament, which began seven years earlier). ESR is also linked with the International Network of Engineers and Scientists for Global Responsibility (INES). Other related but not directly linked organizations include Computer Professionals for Social Responsibility and Physicians for Social Responsibility.

ENLIGHTENMENT SOCIAL THEORY

Enlightenment social theory is important to science, technology, and ethics because it represents one of the first venues in which human activities were widely studied from a scientific perspective, and in which utilitarian and naturalistic ethical systems were offered to replace the religiously-based deontological, or duty-oriented, ethical systems which had dominated premodern society.

One of the most frequently stated goals of the Enlightenment of the eighteenth century was the creation of a science of human nature and society incorporating deterministic laws of behavior to match the spectacular successes of the physical sciences. David Hume (1711–1766), for example, announced his intention to become "the Newton of the Moral sciences." But eighteenth-century social theorists did not agree on which model from the physical sciences social theories should emulate.

Generally speaking, one can identify three classes of natural scientific models for the social sciences. The first stressed the approach of natural history and Hippocratic medicine, emphasizing the observation of phenomena in their situated complexity (empiricism). The second emulated the characteristics of rational mechanics, emphasizing the derivation of effects from a small number of well-defined a priori principles. The third attempted to apply the methods of the newly emerging experimental sciences, which insisted upon the isolation of salient variables whose relationships were established empirically, through their controlled manipulation. Within the social sciences, those who viewed themselves as introducing *experimental* approaches did emphasize the isolation of relevant variables; but their notion of experiment was generally different from that used in the natural sciences. Hume explained that difference very clearly:

> We must glean up our experiments in this science from a cautious observation of human life, and take them as they appear in the common course of the world, by men's behavior in company, in affairs, and in their pleasures. Where experiments of this kind are judiciously collected and compared [for example, from histories and travel accounts], we may hope to establish on them a science, which will not be inferior in certainty, and will be much superior in utility to any other of Human comprehension (1969, p. 46).

With few exceptions, those eighteenth-century scientists and philosophers who derived their approaches largely from natural history—such as Charles Louis de Secondat, Baron de la Brede et de Montesquieu (usually known simply as Montesquieu), Adam Ferguson, and Edmund Burke—usually focused on humans as habitual and emotional beings and ended up toward the conservative end of the political spectrum. Those who derived their approaches principally from the rational mechanics tradition—such as the physiocrat Jean Claude Helvétius, Mercier de la Rivière, Anne-Marie Condorcet, and the feminist Mary Wollstonecraft—focused on humans as rational beings and ended up at the radical end of the political and social spectrum. Those who saw themselves as synthesizing empirical and rational approaches—such as David Hartley, Adam Smith, and Etienne Condillac—tended to see humans as expressing both emotional and rational characteristics and ended up in the liberal portion of the political and social spectrum. Regardless of what model they adapted from the natural sciences, Enlightenment social theorists tended to reject deontological approaches to ethics in favor of consequentialist ones, though the utilitarian ethical theories of the radical and liberal thinkers were vastly different from those of the more thoroughly empirical conservatives.

In 1749 Montesquieu published his *Spirit of the Laws* in an attempt to explore how different legal systems developed. Though he was inclined to think that humans were pretty much identical everywhere, as the president of a local judicial body that often found itself in conflict with the central authority of the French crown, he was painfully aware of the immense variations in local customs and laws, and he took as his task the explanation of those variations. To classical republican arguments that laws had to be suited to the principles attached to the form of government of a people, Montesquieu added three kinds of arguments that were to have immense long-term significance.

First, he argued that the laws and customs of a country will depend upon the dominant mode of subsistence of that country, classifying modes of subsistence as hunting, herding, agricultural, and commercial. Hunting societies, for example, will have much less complex laws that herding societies because the complication of private ownership of animals is added in herding societies. Laws will be even more complex in agrarian societies in which heritable real property becomes important; and they will be even more complex in commercial societies in which it is critical to have legal means for enforcing a wide variety of contracts. Montesquieu felt that trade promoted mutual dependence and therefore increased tolerance for cultural differences among trading partners; so it promotes peace among nations. Within a given nation, however, Montesquieu argued that trade promoted competition and egotism rather than cooperation and altruism.

Second, Montesquieu argued for a kind of environmental determinism that made customs and laws suitable to one region quite unsuitable to others. For example, he argued that the high temperatures in the tropics made men lazy, justifying the practice of slavery so that work would get done. Similarly he thought that women aged more rapidly in tropical regions, justifying the practice of male plural marriage with women of different ages. Neither slavery nor plural marriage was, however, justifiable in temperate regions. This *situational* ethics that derived from Montesquieu's environmental determinism illustrates how attempts a social science could undermine deontological ethics.

Finally, Montesquieu was one of the first serious social theorists to articulate a principle that would become the hallmark of conservative political theory through the twentieth century. This principle is often called the principle of unintended consequences, and Montesquieu openly appropriated it from Bernard Mandeville's "Fable of the Bees" of 1705, though he gave it much greater currency. The particular example used by both Mandeville and Montesquieu was that of how the vanity of the wealthy produced the rise of fashion in clothing, which in turn provided jobs for textile workers. The vice of pride thus produced the unintended consequence of promoting commerce and industry. There was even a business in providing the baubles on which hierarchy could be seen to be based—beads, cosmetics, physical distinctions such as tattoos, and so forth.

In the long run, the principle of unintended consequences became the foundation for virtually all conservative claims that society cannot be successfully reformed by design: For every positive intended consequence there is likely to be a negative unintended one. It is better from this perspective to simply let society develop naturally. In the words of Adam Ferguson, one of Montequieu's most able admirers, "nations stumble upon establishments which are indeed the result of human action, but not the execution of any human design. . . . The establishments of men . . . were made without any sense of their general effect; and they bring human affairs to a state of complication which the greatest reach of capacity with which human nature was ever adorned, could not have projected" (Ferguson 1966, pp. 122, 182).

Taking his cue from Montesquieu, Ferguson attempted to write a "natural history of man" in *An Essay on the History of Civil Society* in 1767, but Ferguson made a number of new arguments that were widely adopted by subsequent social theorists. First, he temporalized Montesquieu's four modes of existence, creating a dynamic theory in which hunting, herding, agriculture, and commerce represented progressive stages in a temporal development that was repeated at different times in different places. Next, he emphasized the fact that people band together into societies not out of some rational expectation of meeting selfish needs, as Thomas Hobbes had proposed in the seventeenth century, but rather out of "a propensity to mix with the herd and, without reflection, to follow the crowd of his species" (Ferguson 1966, pp. 16–17). Finally, Ferguson argued that conflict, even to the extent of war, is often the vehicle for social advances: "Their wars . . . their mutual jealousies, and the establishments which they devise with a view to each other, constitute more than half the occupations of mankind, and furnish materials for their greatest and most improving exertions" (Ferguson 1966, p. 119).

Against the tradition of *philosophical history* initiated by Montesquieu and Ferguson, a second group of Enlightenment social theorists claimed that to argue for particular social arrangements from the simple fact of their historical existence was to grant the past far too much power over the future. Rivière, spokesman for a group of theorists known as *économistes* or physiocrats (persons who favored government according to the nature [physis] of things, rather than aristocrats who advocated government by an elite, or democrats who favored government by all) made their point particularly clearly in 1767:

> I do not cast my eye on any particular nation or sect. I seek to describe things as they must *essentially* be, without considering what they have been, or in what country they may have been. . . . By examining and reasoning we arrive at knowing the truth self-evidently, and with all the practical consequences which result from it. Examples which appear to contrast with these consequences prove nothing (Hutchinson 1988, p. 293).

Among the most important social theorists to adopt this rational mechanist model were Claude-Adrien Helvetius and his utilitarian followers, including Jeremy Bentham in Britain and Cesare Beccaria in Italy. According to this group, all social theory must begin from the fundamental insight that humans are motivated solely by a desire to be happy; so the goal of political and moral philosophy should be to create the greatest net pleasure for the greatest number in society. Because members of the utilitarian school generally assumed that the private happiness of one person was likely to diminish the happiness of others, they proposed to establish sanctions that would offer pleasurable rewards to those who acted for the general good and punish those who acted in opposition to it.

Among those who advocated a more experimental approach to social theory, the tradition initiated by Francis Hutcheson, David Hartley, and Adam Smith was undoubtedly most important in terms establishing a new foundation for ethics and morality. This group generally found strong evidence that humans acted not only out of self-interest, but also out of a social instinct or sense of sympathy. For most of these social theorists, there seemed to be a natural accommodation between the well-being of the individual and that of the group that was nicely articulated in Smith's image of the "invisible hand" that ordered economic activity for the general benefit if each actor worked to forward his own interests. This approach led to a *laissez faire* or naturalistic approach to moral and ethical behavior.

The heritage of Enlightenment social theory remains current in virtually all disagreements among different groups concerned with policies relating to science and technology. The principle of unintended consequences, as directly derived from Ferguson, for example, was still being appealed to by conservative social theorists such as Friederich A. von Hayek in the late nineteen-sixties (Hayek 1967). It later became the foundation for arguments by the often politically liberal or radical critics of rapid technological development. The consequentialist ethical tradition established among eighteenth-century utilitarians continues to inform policy makers at the beginning of the twenty-first century in the form of cost-benefit analyses so favored by advocates of development. And the *laissez faire* admonitions of the Smithian school continue to resonate in the market-driven analyses of public choice economic theorists.

ENQUETE COMMISSIONS

Enquete commissions are temporary groups established periodically by European parliaments in order to guide public discourse and decision making in complex areas. Commissions have focused on questions such as economic globalization, environmental sustainability, and the formation of new religious and ideological groups. Roughly half of the enquete commissions to date have addressed the use and regulation of emerging science and technology. In these cases, the commissions serve as forums for joint scientific and political consultation designed to inform decision makers, involve the public, and articulate recommendations and strategies for future action. Each commission is unique in terms of membership, topic, and mandate, so general evaluations of the enquete commission as an overarching system for improving democratic discourse and decision making are difficult to formulate. Although they have had mixed results and need improvement, enquete commissions are important innovations in the relationship between politics and science in democratic societies.

Background

Parliaments, as elected representative bodies, should play a key role in guiding public discourse about the proper development of society. There are doubts, however, about how well parliamentary bodies can fulfill this leadership position given the complex problems presented by the modern world. Decision makers are inundated with competing demands for investment in science, technology, and the military. They also deal with conflicting reports about economic, educational, environmental, and health care policies. In these areas, parliaments must rely upon the superior knowledge of experts and the bureaucratic structure of specialized departments and agencies. Yet mechanisms for delegating authority to specialists tend to alienate government officials from the very discourse they should guide and shape. Thus the legislative function of parliament becomes disengaged from the debate on essential issues of societal development.

Enquete commissions are designed to reengage the governmental body regarding these complex issues. They serve as independent agencies that support the parliament, thereby counterbalancing the institutional inertia toward bureaucratization and the delegation of decision making to experts who have no fiduciary or other responsibility to the public.

One of the most important roles of an enquete commission is to serve as a common institutional forum where scientific knowledge and political judgment meet. Several enquete commissions have been charged with the task of evaluating issues regarding the proper use and regulation of technologies and the proper conduct of scientific research. In these cases, especially, enquete commissions provide common ground for decision makers, the public, and experts. Cooperation between scientists and politicians is of particular importance when the knowledge of experts is contested or uncertain and when political party lines are ill-defined with regard to an issue. In many countries scientific advice issues from special institutions such as the Parliamentary Office of Science and Technology (POST) in the United Kingdom, the Parliamentary Office for Evaluation of Scientific and Technological Options (OPECST) in France, and the disbanded Office of Technology Assessment (OTA) in the United States, but these do not serve as institutions of joint scientific-political consultation.

Enquete commissions are partially modelled on various review commissions that are periodically appointed to investigate alleged failures by public officials or public institutions (for instance Royal Commissions in the United Kingdom and Congressional Committees in the United States). Enquete commissions, however, are usually established by parliamentary mandate in order to develop scenarios, strategies, and recommendations with respect to potential problems areas. Yet only a few parliaments—most notably France, Germany, Sweden, and Italy—have established rules for the membership and operations of such committees, and only these countries have significant experiences with the process of forming and evaluating enquete commissions.

German Experience

Because Germany has the most elaborate model with the broadest variety of applications, it is appropriate to include an in-depth discussion of German enquete commissions. Since 1969 the German parliament has, by standing order, permitted enquete commissions to be established by the approval of at least one quarter of its members for the purpose of providing information relevant to *extensive and important* issues. In practice a broader quorum distributed over the parties in power and opposition is necessary for any chance of successful work. The enabling legislation leaves open what qualifies problem areas as extensive and important.

Since the order was implemented, two to five commissions have been created in each electoral term. Roughly half have focused on topics in the fields of science, technology, and the environment. Some commissions that have been authorized by the German parliament include The Future of Atomic Energy Policy (1979–1982), New Information and Communication Technology (1981–1983), Prospects and Risks of Genetic Technology (1984–1986), Assessment and Evaluation of the Social Consequences of New Technology: Shaping the Conditions of Technological Development (1985–1990), Precautionary Protection of the Earth's Atmosphere (1987–1994), Protection of Human Beings and the Environment: Evaluation Criteria and Perspectives for Environmentally Acceptable Circular Flow Substances in Industrial Society (1992–1998), The Future of the Media in Economy and Society (1996–1998), Sustainable Energy Supply in the Modern Economy (2000–2002), and Law and Ethics of Modern Medicine (2000–2002; reinstated 2003).

These and other commissions have received a correspondingly wide set of mandates, but there are a few general purposes that underlie the task of all enquete commissions. These include:

- Establishing a political discourse with the intent of assuring, if not the preeminence, at least the influence of political and social concerns in shaping technological change.
- Searching for a consensus or well-founded dissent comprising knowledge, interests, values, and norms, and thereby preparing for compromise in the negotiation process.
- Elaborating long-term foundations for decisions and making concrete recommendations to parliamentary legislators.
- Enhancing public awareness of an issue by involving the media and by reporting to the public either as individual members or through official reports.

COMPOSITION AND STRUCTURE. Enquete commissions are unique institutions for the treatment of specific societal issues because of their consciously crafted representative mix of political parties and external experts. Each party nominates representative parliamentary members according to their relative political power (they are able to elect between four and fifteen members). Because all parties with parliamentary status participate, normative and ideological perspectives are represented in a manner that mirrors the larger legislative body. Each commission reflects the proportionality of power and perspective found in parliament. External experts are chosen either by an iterative process of nomination, rejection, and acceptance or they are simply appointed in a manner proportional to the power of each party. Representation on the science side is usually fairly well balanced because the selection of experts by the parties covers the spectrum of competing paradigms and can even include extreme opinions. Parliamentary and external members have the same voting rights.

The goal of every commission is to present a report, which serves as the basis for a general parliamentary discussion, before the end of the electoral term. As a rule, recommendations for legislative decisions are also expected. Usually additional experts without voting rights are also included and their opinions are commissioned. The commissions often organize public hearings and other public dialog. Initially governmental and department officials did not participate in the process at all. The main advantage of including parliamentary members with experts is to make commissions better equipped to structure and convey recommendations pertinent to the needs of decision makers. The corresponding disadvantage is a tendency to politicize scientific findings. Another impact of incorporating scientific experts and politicians in such tightly structured dialogue is the addition of more focused, problem-orientated discourse to traditional negotiations between majority and minority parties.

Each commission serves as a working group for intense research and reflection in a particular subject area. A research staff assists each commission by procuring and processing information. One member of the commission serves as the chair and is vitally important for ensuring the integrity and overall success of the commission. The privileged position of the chair is sometimes misused to serve individual or political ends.

ANALYSIS AND EVALUATION. The fairly long history of enquete commissions in Germany points to the importance of comprehensive and exhaustive dialogue at the intersection of politics and science. Though political maneuvering unavoidably comes into play when choosing members, setting an agenda, and negotiating reports, the underlying purpose is to hold open dialogues on problems and alternative solutions before party lines are settled and decisions reached. The goal is to transform solid party positions into negotiable interests. Scientific and political members agree to seek consensus and compromise, which can be further shaped by party leaders and wider government involvement. Nevertheless the commissions face constant pressure from both political and scientific interest groups, which often seek to use enquete commissions to achieve their own special interests rather than the common interest. Politicians often press particular agendas, whereas scientists repeatedly cloak their agendas in the guise of disinterested objectivity. Commissions require strong leadership if they are to bridge the differences among various stakeholders. When such leadership is present, the enquete commission is a successful model for crafting an improved and more democratic relationship between science, government, and the general public.

Whether and to what extent enquete commissions enrich and aid political culture is an open question. Case studies and empirical analyses of their mode of operation have generated serious criticisms. Party tactics repeatedly threaten the efforts of members to achieve mutual understanding and common perspectives. Often commissions are used as instruments of symbolic politics, giving the impression of governmental action that conceals an unwillingness to make real progress. For example, the commission on the future of media in economy and society was allegedly misused in this way. Its charge was to "pave Germany's way toward the information society," but one of its most distinguished members, Wolfgang Hoffmann-Riem, professor of law and judge at the constitutional court, commented in an essay that it was only "creeping along secret paths to non-decision." The chance was wasted to develop guidelines for new technologies (especially telecommunication and the associated changes of the occupational field), higher education, infrastructure, and the media.

By contrast the commission on genetic technology thoroughly influenced legislation on safety regulation at the work place, rules of liability, and restrictions on research with human embryos. The commission on technology assessment did not have direct impacts, but its work indirectly supported the foundation of the German Office of Technology Assessment in 1990, which offers recommendations about science and technology to parliament. The commission's report on the protection of the atmosphere was influential even at the international level. It played a decisive part in regulating and outlawing various ozone depleting chemicals within the European Union (EU) and assisted in the Montreal Protocol process.

Due to the variability in enquete commissions, it is not possible to make a general evaluation of their success in crafting consensus, aiding legislation, and guiding public discourse. Several criticisms, however, have suggested that the priorities of the enquete commission system need to be rethought in order to maximize its strengths. Critics argue that the indirect inputs into public discourse are more important functions of the commissions than direct impact on legislation. If the commissions are able to address and include important associations, not-for-profit organizations, nongovernmental organizations, the media, and influential individuals, then their procedures and reports can demonstrate parliament's ability to guide public discourse on important questions about the future development of society.

Scientists involved in enquete commissions often resent abandoning their position as (supposedly) neutral, outside analysts by engaging in the political system. Nonetheless most are able to maintain their reputations within the scientific community by crafting and supporting high quality, balanced reports. The politicians involved also have misgivings, especially concerning mandates for cooperation and consensus building with actionable recommendations. In addition engaging in long-term, complex issues usually does not offer the political payoff of involvement in more pressing, short-term issues. Usually, however, there is sufficient individual initiative among politicians to overcome these concerns.

No critics advocate abandoning the enquete commission model altogether. Some place deficiencies in the system on the early twenty-first century style of party politics and its focus on personalities and media resonance. More theoretically minded observers note a permanent overburdening of the commissions due to their hybrid structure. These critics argue that increasing the management skills and capacities of commission leaders is the only way in which improvements can be made. In the end, the continued existence of the commissions and the fact that both majority and opposition factions have initiated roughly the same number of them over ten election periods speaks for their value. Enquete commissions can be an important ingredient in the public culture of politics. They can increase understanding, elevate public discussion, and evaluate and respond to societal problems. They are especially useful in evaluating the risks and benefits presented by complex, emerging technologies.

Enquete commissions need to be used in conjunction with other procedures, such as lobbying, hearings, and stakeholder conferences, which often represent and consider interests in different ways. In spite of determined attempts to strike consensus or compromise and frame political programs, the complex and contested nature of many problems sometimes prohibits workable solutions. Yet even in these cases, enquete commissions can help improve and clarify public discourse, venture models for risk assessment, develop scenarios and options for the future, map the landscape of social values, and make tentative preparations for legislative action.

ENTERTAINMENT

Entertainment is a ubiquitous phenomenon that has been transformed extensively by science and technology. To some extent that transformation has ethical dimensions that merit more consideration than they usually receive.

The Historical Spectrum

There is evidence that human beings have found ways to amuse themselves since the beginning of history. Ancient Mesopotamians reserved six days a month for designated holidays, half of which were tied to religious lunar festivities. Hunting was a favorite pastime of Assyrian kings, as wall reliefs attest; that pastime was shared by Egyptian pharaohs, as is affirmed by the decorations on their tombs. Sports such as boxing and wrestling were practiced widely in the ancient world, sometimes between divine beings and men as in the struggle between Gilgamesh and Enkidu in the *Epic of Gilgamesh* and that between Jacob and an angel in the Hebrew Bible. Black-figure vases and amphorae indicate the Greeks' love for those two sports as well as the others featured in the ancient Olympic games and their imitators throughout the ancient Aegean world. A variety of board games from ancient times (e.g., serpent, dog-and-jackal, and senet from Egypt) challenge contemporary people to discern what the rules might have been, whereas games such as chess, go, and various others involving stone, bone, clay, or glass dice can be recognized by modern players in their earliest written, engraved, and stone forms from China, India, Mesoamerica, Africa, and the Near East. Children's model houses with miniature furniture and figures and model ships, wagons, chariots, and carts from sites across the ancient world indicate that toys are also of ancient origin.

People entertained one another on musical instruments, as many ancient literary and sacred texts attest, including ancient songs that survive in the form of the Psalms and the "Song of Miriam" in the Hebrew Bible, the *Iliad* and *Odyssey,* and hymns to Osiris and other ancient gods in addition to love songs and songs that express the challenges and triumphs of daily life. Singers, snake charmers, bear trainers, jesters, and acrobats—all the roles that later would be revived in vaudeville, traveling carnivals, and circuses—can be located among ancient peoples. String, wind, and percussion instruments, many trimmed with rare metals or precious stones, have been described in print and discovered in situ by archaeologists, allowing a better appreciation of the tonal systems and musical compositions that the ancients created as a source of creativity and for amusement. Ancient plays from the Greeks give voice to many modern concerns about life, meaning, and human affairs.

On an even wider scale one thinks of the grand public spectacles of ancient Babylon and ancient Rome, cities whose rulers spared no expense in putting on public entertainment for the masses, drawing on vast human, animal, and fiscal resources for events that could last for months and involve extensive human and animal carnage. Assurnasirpal II of Assyria, when inaugurating his palace at Calah, claims on a palace relief to have hosted a banquet for 47,074 people, who consumed, among other items, more than 1,000 cattle, 10,000 sheep, 15,000 lambs, 10,000 fish, 10,000 loaves of bread, and 100 containers of beer. Roman emperors staged banquets, games, and entertainments for the masses that sometimes bankrupted the state treasury.

Technological Presence

Pervasive in all these ancient forms of entertainment is the presence and necessity of technology. Natural materials have been reshaped to create implements and means by which human beings can amuse themselves, opening up vast areas for enjoyment beyond those afforded by nature. Technological innovations in chariot wheels and steering mechanisms, the raising and lowering of massive platforms through the use of advanced hydraulics, springs and hinges that could be opened and closed at a distance with precision and split-second timing, and many other inventions and improvements contributed to the crowd-pleasing spectacles of Greek and Roman theaters and the battles in the Colosseum in Rome between beast and beast, person and beast, and person and person.

Continuous innovation in designing and defining amusements of various kinds for particular classes of individuals and entire societies was accelerated with the advent of the printing press and then the Industrial Revolution as mass production of what had been luxury goods for the wealthy began to spread to other levels of society. Greater leisure time for a widening segment of the population created new opportunities for amusements to pass the time. Entertainment itself, however, always has manifested an ability to penetrate social barriers. Shakespeare's plays, for example, appealed not only to the masses but also to extremely wealthy and influential persons.

The modern era brought with it an array of new means of entertainment, including radio, television, video, computer games, virtual reality, film, e-mail, and chat rooms. However, even the older forms of entertainment underwent major changes as sports, for example, moved from the realm of mainly part-time amateur pursuits to a specialized, professional status (there were limited numbers of professional athletes in ancient times).

Within a generation, American football became a multi-billion-dollar television- and media-saturated semiglobal industry and football players became cultural heroes. Technological innovations transformed football from a game played by college students on dirt fields or cow pastures with no equipment to multi-million-dollar weekly gridiron contests in which each side employs advanced scouting technologies, sophisticated weight training and conditioning regimens, carefully managed nutrition programs, lightweight materials for protection, advanced telecommunications equipment to relay commands and insights, rapid-response medical treatments designed to keep players on the field as long as possible, complex ticketing systems, coordinated crowd control, prescheduled advertising breaks, and many other techniques and processes to induce fans to spend thousands of dollars to support their favorite teams.

Miniaturization and Combination

The latest miniaturization and communications technologies allow entertainment to be fully mobile. As they get increasingly smaller and more powerful in terms of resolution quality, camera phones have become the bane of many schools, fitness facilities, and other public venues where some people use them to take and transmit photographs of people in various stages of undress. Students have attempted to use them to film examination questions and send them to others, and similar problems arise with text messaging devices. At the same time users have employed them to film robberies, hit and run incidents, and other criminal acts that have led to court convictions that probably would not have been possible without the visual evidence they provide. Families and individuals have derived enjoyment from camera phone photographs they have taken of special moments and then downloaded into more permanent forms of storage for retrieval when desired. Cam-phone sites have joined the range of types of websites on the Internet, and it is estimated that 260 million camera phones were sold in 2004.

The pervasiveness of computers that are increasingly more powerful yet smaller with each new generation has spawned an enormous industry in designing sophisticated online games. A number of universities have established programs, and others are increasing the number of courses they offer in this area. The most advanced current form of these games are Massive Multiplayer Online Role-Playing Games (MMORPG) that involve thousands of players in a constantly evolving scenario that is affected directly by the self-selected roles and self-assigned personas of the players.

Blogs (web logs) and vlogs (video blogs) are a recent technological innovation in which individuals create self-published websites that feature video clips, running texts of observations or other materials, photographs, and sound to communicate their thoughts or express themselves. Originally pioneered in the late 1990s by sites such as Pop.com and Digital Entertainment Network, they initially failed to catch on but are having a resurgence though sites such as Undergroundfilm and Ourmedia. The more pervasive blogs, which often feature only text, are exerting a growing influence on mainstream media as bloggers democratize and decentralize journalism, news reporting, and information dissemination in entertaining forms.

Various forms of technology are being combined in new ways with the new media to create full-body experiences for people. In a way similar to the manner in which "surround sound" immersed a listener in a piece of music, people can experience a video in three dimensions while simultaneously feeling sensations on their skin and hearing things as if they were fully immersed in the environment they are seeing.

This ability to "experience the world" without really experiencing it raises important issues. Certainly there are training applications in which being able to experience an environment safely and learn how to react successfully within it could save lives in the future as pilots and others in high-risk situations can practice in a simulated world that looks, feels, smells, and tastes like the real thing. At the same time it is easy to imagine situations in which ethical issues should preclude exchanging the real thing for a simulated experience that mimics it exactly, for example, engaging in sexual experiences that one never could or would do in one's normal life.

Preliminary Assessment

The many forms of entertainment available today and the various means by which one can obtain and experience them can lead to a retreat from the world and oneself so pervasive that a person can focus only on the next thrill. Countries with a broad array of entertainment options suffer from what Gregg Easterbrook (2003) terms "the paradox of progress" because despite overwhelming numbers of possessions and experiences, real as well as vicarious, a sense of personal satisfaction and happiness elude people.

Some people have learned that certain forms of media can produce addictions as powerful as those caused by illicit drugs. This is the case in part because one never just uses technology; one also experiences it. This sensory, intellectual, and emotional interplay affects the user in both predictable and unpredictable ways. Reality shows on television have extended this impact more fully to the "actors" themselves as they create live, unscripted drama that others get to enjoy voyeuristically and register their pleasure or displeasure with a particular person on the show just as the emperor and the crowd determined the ultimate fate of ancient gladiators; the difference is that now the phone or mouse click rather than the thumb is the determining signal. Online chat rooms have led some people to alter the course of their lives; although some of the end results appear to be positive, they seem to be outweighed by media and professional counselors' stories of poor decisions and damaging consequences. Many people struggling with personal issues seek escape and relief in a fantasy world that makes them incapable of facing their problems.

Modern people's ancient ancestors would recognize most of the dilemmas that modern entertainment presents. They undoubtedly also would recognize that these ethical and moral challenges have multiplied over time and space.

ENTREPRENEURISM

"[An] entrepreneur is a person who habitually creates and innovates to build something of recognized value around perceived opportunities" (Kotelnikov Internet article). This "recognized value" should incorporate social and ethical concerns, as well as economic ones. There are moral dimensions to all forms of entrepreneurship.

Conceptual Distinctions

Entrepreneurs include both scientists seeking to advance research and engineers seeking new design opportunities. Entrepreneurship is not the same as invention. Alexander Graham Bell obtained a broad patent that included the transmission of speech, but he was not an entrepreneur—others took his patent and used it to create a corporate giant (Carlson 1994). Thomas Edison, in contrast, supervised invention, manufacturing, and marketing of a new electric lighting system (Hughes 1983); therefore, he is both inventor and entrepreneur. Classic theorists and economists also have developed and expressed their own opinions concerning entrepreneurship and its influence on economic development. In 1928, economist Joseph Schumpeter stated that the "essence of entrepreneurship lies in the perception and exploitation of new opportunities in the realm of business . . . it always has to do with bringing about a different use of national resources in that they are withdrawn from their traditional employ and subjected to new combinations" (Filion 1997, p. 3).

Entrepreneurs must promote their ideas relentlessly. They have, however, an obligation to be honest with themselves and others about their prospects.

Unethical Entrepreneurship

In the early twenty-first century, America watched companies such as Enron and WorldCom collapse. Enron was formed by the merger of Houston Natural Gas, a regional pipeline company, and InterNorth, a Nebraska-based pipeline owner, which was organized by Kenneth Lay in 1985. The beginnings of Enron's downfall can be traced to the late 1980s: When federal regulations allowed gas prices to fluctuate naturally, Enron saw this as an opportunity to add gas trading to its list of business endeavors. Then beginning in the mid-1990s, "Enron tried to duplicate its initial success at energy trading in new fields—coal, paper, plastics, metals and even Internet bandwidth. Many of these ventures went badly wrong, so executives turned to the tried-and-true method of big business—hide the problem and hope that everything gets better" (Maass 2002, pp. 6–7) Maass then notes that "Enron hid its mounting losses and skyrocketing debt, both in little-examined nooks and crannies of official statements and in off-the-record *partnerships* run by Enron executives. By hiding debt in the partnerships, Enron's official bottom line continued to look healthy—while executives raked in millions in fees for administering them" (Maass 2002, pp. 6–7). Enron lied to its own employees and shareholders, many of whom were left with virtually worthless stock. Joe Lieberman, Senator from Connecticut, commented that "Enron has become a grand metaphor for the real human problems that profit pressure can produce when it goes to gross extremes because it is unchecked by personal principles or business ethics" (Lieberman 2002). WorldCom, an entrepreneurial telecommunications company, masked losses by clever, but dishonest accounting schemes.

The environment in which new companies enter may be responsible for the ethics dilemmas companies encounter. Arthur Levitt, former SEC chairman, states "fierce competition in the marketplace is healthy, but we've seen that the corporate race to beat analyst projections can breed disdain for investors' interests and the law" (Lieberman Internet site). Jennifer Lawston also writes that "the entrepreneurial world—particularly the high-tech entrepreneurial world—is living through a time of high temptation. The devil on one shoulder tells you to make the numbers and set projections to make investors feel good, the angel on the other says to tell the story like it really is" (Lawston 2003 Internet article).

Entrepreneurship requires truth-telling—to investors and the public. The Enron and WordCom cases illustrate the consequences of lying. Entrepreneurs also need to be honest with themselves.

The history of dot-com company failures reveals the dangers of self-delusion. Peter Coy suggests thinking of "dot-com startups not as companies but as hypotheses—economic hypotheses about commercial methods that needed to be tested with real money in the real world. Nobody was forced to fund the experiments, but plenty of people who hoped to get rich quickly were happy to thrust money into the hands of entrepreneurs such as Walker, Jeff Bezos of Amazon, Tim Koogle of Yahoo!, and Candice Carpenter of iVillage, a Website for women" (Coy Internet article). The dot-coms suffered from confirmation bias (Gorman 1992)—they believed that because their stock was rising, their hypothesis was right, and the *old* economic laws did not apply to their situation.

Doing Well by Doing Good

Entrepreneurs are pioneers who open new territory. C.K. Prahalad and Allen Hammond (2002) have used a pyramid metaphor to describe the global market. Tier 1 consists of roughly 100 million people whose earnings are greater than $20,000 per year. Tier 2 consists of the poor in developed countries and Tier 3 consists of the rising middle class in the developing world, amounting to approximately 1.75 billion people whose earnings fall between $2,000 and $20,000 per year. Tier 4 includes the majority of the Earth's population, about 4 billion people earning less than $2,000 per year. As one goes down the pyramid, the proportions of people in each tier shift from the developed to the developing world.

In *Development As Freedom* Amartya Sen (1999) argues that "economic unfreedom, in the form of extreme poverty, can make a person helpless prey in the violation of other kinds of freedom" (p. 8). Sen believes the development of a competitive market system in poverty-stricken countries will, in time, improve the economic condition, which will in turn create numerous freedoms for their inhabitants.

The Tier 4 market therefore represents a new frontier that most established businesses shun—where an entrepreneur could make a profit while improving the quality of life. In 1969 Karsanbhai Patel, a factory chemist dissatisfied with his job and low income, decided to create and manufacture an affordable detergent for the Tier 4 market in India. Patel mixed a powder and began selling it to neighboring towns on his bicycle. Distributors eventually showed an interest in the product, and Patel's product spread nationwide.

Patel created a cottage industry that allowed individuals from Tier 4 markets to make money manufacturing and selling his product, but this cottage industry structure meant he did not have to pay his employees benefits. His efforts inspired Hindustan Lever Limited, the former leaders in market share, to enter this Tier 4 territory, thereby providing Tier 4 consumers with a choice between products.

Another example of an entrepreneur who wanted to benefit women around the world and also make a profit is Mary Ann Leeper. She bought the rights to a prototype female condom, but modified it, figured out how to manufacture it, and made it available on a global basis. Leeper created the Female Health Company, which "has focused its marketing efforts on establishing a presence in major world markets and building relationships with key world health agencies and programs. The female condom has been introduced in Japan, Africa, Latin America, the United Kingdom, the United States and Europe. ("The Female Health Company Biography: Mary Ann Leeper" Internet article). The female condom has been "hailed as a way of giving women increased power to protect themselves from sexually transmitted diseases" (Baille 2001).

Entrepreneurs have the ability to choose whether ethics will be a priority in their fledgling companies. Ben Cohen, a founder of Ben & Jerry's Ice Cream wrote in 1976 that "Business has a responsibility to give back to the community from which it draws its support" (Mead 2001). Cohen and Jerry Greenfield developed what they called a *values-led* company, which for them "meant a commitment to employees, the Vermont community, and social causes in general" (Mead 2001). In 1985 Cohen and Greenfield established the Ben & Jerry's Foundation to help disadvantaged groups, social change organizations, and environmentalists, donating 7.5 percent of the company's annual pre-tax profits. Ben & Jerry's became a subsidiary of Unilever, a multinational corporation that is also the parent company of HLL and is dedicated to measuring success via a triple bottom-line, in which environmental and social progress is just as important as financial gain (Gorman, Mehalik, and Werhane 2000).

Conclusions

For scientists and engineers, entrepreneurship represents an opportunity to discover and even create markets (Gorman and Mehalik 2002). Attention to social and ethical impacts will actually increase the likelihood that an innovation will be accepted.

The entrepreneur needs to:

- Be truthful with potential customers and investors.
- Consider whether a new technology is more likely to benefit or harm the global environment.
- Consider the impact of a new technology on the Tier 4 market. Will it increase the gap between rich and poor, or give the poor the opportunity to improve their situation?
- Measure progress using social and environmental metrics, as well as economic.

ENVIRONMENTAL ECONOMICS

As the entry on "Economics: Orientation" points out, welfare economics puts the "satisfaction of individual human desires at or near the top of its own internal moral hierarchy." Two economists observe, "The basic premises of welfare economics are that the purpose of economic activity is to increase the well-being of the individuals that make up the society, and that each individual is the best judge of how well off he or she is in a given situation" (Stokey and Zeckhauser 1978, p. 277).

Environmental economics builds on the theory of welfare economics (or microeconomics) and in particular the view—prepresented as an ethical theory—that the satisfaction of preferences taken as they come ranked by the individual's willingness to pay (WTP) to satisfy them is a good thing because (by definition) this constitutes welfare or utility. According to economist David Pearce (1998, p. 221), "Economic values are about what people want. Something has economic value—is a benefit—if it satisfies individual preferences." This approach uses maximum WTP to measure how well off the individual believes a given situation makes her or him. A representative text states, "Benefits are the sums of the maximum amounts that people would be willing to pay to gain outcomes that they view as desirable" (Boardman, Greenberg, Vining, et al. 1996).

Preference Satisfaction

The attempt to link preference satisfaction (and therefore WTP) with well-being or benefit, however, encounters four problems. First, one may link preference with welfare by assuming that individuals prefer what they believe will make them better off. Research has shown, on the contrary, that with respect to environmental and other policy judgments, people base their values and choices on moral principles, social norms, aesthetic judgments, altruistic feelings, and beliefs about the public good—not simply or even usually on their view of what benefits them. The basis of environmental values in moral principle, belief, or commitment rather than self-interest severs the link between preference and perceived benefit or welfare.

In recent decades, environmental economists have put a great deal of effort into developing methodologies for measuring the benefit associated with goods—sometimes called "non-use" or "existence" values—that people care about because of moral beliefs, aesthetic judgments, or religious commitments, rather than because of any benefit or welfare change they believe those goods offer them. According to economist Paul Milgrom (1993, p. 431), for existence value to be considered a kind of economic value, "it would be necessary for people's individual existence values to reflect only their own personal economic motives and not altruistic motives, or sense of duty, or moral obligation." The difference between what people believe benefits them (economic motives) and what they believe is right (moral obligation) divides economic value from existence or non-use value. The attempt to translate moral beliefs and political judgments into economic benefits—principled commitments into units of welfare and thus into data for economic analysis—may continue to occupy economists for decades to come, because many logical, conceptual, and theoretical conundrums remain.

Second, the statement that the satisfaction of preference promotes welfare states a tautology if economists define "welfare" or "well-being" in terms of the satisfaction of preference, as generally they do. Concepts such as "welfare," "utility," and well-being" are mere stand-ins or proxies for "preference-satisfaction" and so cannot justify it as a goal of public policy.

Additionally, if "well-being" or "welfare" refers to a substantive conception of the good, such as happiness, then it is simply false that the more one is able to satisfy one's preferences, the happier one becomes. That money (or income—a good surrogate for preference satisfaction) does not buy happiness may be the best-confirmed hypothesis of social science research. Thus, the thesis that preference satisfaction promotes welfare appears either to be trivially true (if "welfare" is defined as preference satisfaction) or empirically false (if "welfare" is defined as perceived happiness).

Third, if preferences are mental states, they cannot be observed. If they are inferred or "constructed" from behavior, they are also indeterminate, because there are many ways to interpret a person's actions as enacting a choice, depending on the opportunities or alternatives the observer assumes define the context. For example, the act of purchasing Girl Scout cookies could "reveal" a preference for eating cookies, supporting scouting, not turning away the neighbor's daughter, feeling good about doing the right thing, avoiding shame, or any of a thousand other possibilities. Choice appears to be no more observable than preference because its description presupposes one of many possible ways of framing the situation and determining the available options.

Fourth, few if any data indicate maximum WTP for any ordinary good. When one runs out of toothpaste, gets a flat tire, or has to buy the next gallon of milk or carton of eggs, one is unlikely to know or even have an idea about the *maximum* one is willing to pay for it. Instead, one checks the advertisements to find the *minimum* one has to pay for it. It is not clear how economists can estimate maximum WTP when all they can observe are competitive market prices. Competition drives price down to producer cost, not up to consumer benefit. For example, one might be willing to pay a fortune for a life-saving antibiotic, but competition by generics may make the price one actually pays negligible.

The difference between price and benefit is clear. People usually pay about the same prices for a given good no matter how much they differ in the amount they need or benefit from it. People who benefit more and thus come first to the market may even pay less, for example, for seats on an airplane than those who are less decided and make later purchases. Thus, maximum WTP, which may correlate with benefit, cannot be observed, while market prices, which can be observed, do not correlate with benefit.

Market Prices

Environmental economists also propose that the outcome of a perfectly competitive market—one in which property rights are well defined and people do not encounter extraordinary costs in arranging trades and enforcing contracts—defines the way environmental assets are most efficiently allocated. Market prices constantly adjust supply and demand—the availability of goods to the wants and needs of individuals. As the "Orientation" entry observes, a perfectly competitive market may be used to define the idea of economic efficiency—the condition in which individuals exhaust all the advantages of trade because any further exchange would harm and thus not gain the consent of some individual.

Economists often explain the regulation of pollution not in moral terms (trespass, assault, violation of rights or person and property) but in terms of the failure of markets to "price" goods correctly. Suppose for example a factory emits smoke that causes its neighbors to bear costs (such as damage to property and health) for which they are not compensated. The factory, while it may pay for the labor and materials it uses, "externalizes" the cost of its pollution. When only a few neighbors are affected, they could negotiate with the factory, either paying the owner to install pollution-control equipment (if the zoning gave the factory the right to emit smoke) or by accepting compensation. The factory owner and the neighbors would bargain to the same result; the initial distribution of property rights determines not the outcome but the direction in which compensation is paid. This is an example of the second theorem described in the "orientation" entry, according to which the initial distribution of goods and services does not really matter in determining the outcome of a perfectly functioning market.

Where many people are affected, as is usually the case, however, the costs of bargaining ("transaction costs") are large. Economists recommend that the government tax pollution in an amount that equals the cost it "externalizes," that is, imposes on society. The industry would then have an incentive to reduce its emissions until the next or incremental reduction costs more than paying the tax—the point where in theory the cost (to the industry) of reducing pollution becomes greater than the benefits (to the neighbors). Such a pollution tax would "internalize" into the prices the factory charges for its products the cost of the damage its pollution causes, so that society will have the optimal mix of those products and clean air and water.

Many economists point out, however, that the government, in order to set the appropriate taxes or limits, would have to pay the same or greater costs as market players to gather information about WTP for clean air or water and willingness to accept (WTA) compensation for pollution. Pollution taxes, to be efficient, "should vary with the geographical location, season of the year, direction of the wind, and even the day of the week . . ." (Ruff 1993, p. 30). The government would be "obliged to carry out factual investigations of mind-boggling complexity, followed by a series of regulatory measures that would be both hard to enforce and valid only for a particular, brief constellation of economic forces" (Kennedy 1981, p. 397). Thus, regulation is unnecessary when transaction costs are small (because people can make their own bargains) and unfeasible when they are great (because the government would have to pay them).

By arguing that emissions be optimized on economic grounds—rather than minimized on ethical grounds—economists reach an impasse. According to Ronald Coase, "the costs involved in governmental action make it desirable that the 'externality' should continue to exist and that no government intervention should be undertaken to eliminate it"(1960, p. 25–26).

Maximum WTP

Economists regard the ubiquitous and pervasive failure of markets to function perfectly as a reason that society, in order to achieve efficiency, should transfer the power to allocate resources to experts, presumably themselves, who can determine which allocations maximize benefits over costs. By replacing market exchange with expert opinion to achieve efficiency, however, society would sacrifice many non-allocatory advantages of the market system. For example, by making individuals responsible for decisions that affect them—rather than transferring authority to the government to act on their behalf—markets improve social stability. People have themselves, each other, or impersonal market forces to blame—not the bureaucracy—when purchasing decisions do not turn out well for them.

Economists have encountered logical and conceptual hurdles, moreover, in their efforts to develop scientific methods for valuing environmental assets and thus for second-guessing market outcomes. First, there is little evidence that economic experts are able to assemble information about WTP and WTA any better than market players when the costs of gathering that information are high. Second, economic estimates of benefits and costs when made by government agencies become objects of lobbying, litigation, and criticism. Experts can be hired on both sides of any dispute and then produce dueling cost-benefit analyses (Deck 1997). Third, when society transfers power to scientific managers, even if they are trained welfare economists, it courts all the problems of legitimacy that beset socialist societies, which likewise may rely on scientific managers to allocate resources.

Institutional Approaches

Pollution control law, from a moral point of view, regulates pollution as a kind of trespass or assault, on analogy with the common law of nuisance. Statutes such as the Clean Air Act and Clean Water Act, moreover, explicitly rule out a cost-benefit or efficiency test and pursue goals such as public safety and health instead (Cropper and Oates 1992). For this reason, the government often limits to "safe" levels the maximum amount of various pollutants industries and municipalities may emit into the water and air. To determine what levels are "safe enough" legislators and regulators have to consider the state of technology and make ethical and political judgments. To help society attain the mandated levels in the most cost-effective ways, economists have made an important contribution to environmental policy by urging government to create market-like arrangements and thus to generate price signals for allocating environmental goods for which markets do not exist.

For example, the Environmental Protection Agency, by creating pollution permits or allowances that firms can buy and sell under an aggregate total ("CAP"), gave industries incentives to lower emissions of lead, smog, and other pollutants to below permitted levels, because they could sell at least part of the difference to other companies that find emissions more expensive to reduce. Tradable rights in environmental assets (from emission allowances to rights to graze the public range) show that incentives matter; marketable permits can reduce pollution more effectively and at lower cost than "command and control" policies. In addition, market arrangements decentralize decisions by encouraging industries to make their own bargains to attain the overall "CAP" rather than to conform to one-size-fits-all regulation.

Environmental economics has enjoyed success in helping society construct market-like arrangements for achieving in the most cost-effective ways environmental goals, such as pollution-reduction, justified on moral, political, and legal grounds. Environmental economics as a discipline has been less successful in finding scientific methods to second-guess or replace markets in order to achieve goals it itself recommends, such as preference-satisfaction or efficiency, that are not plainly consistent with moral intuitions, legislation, or common law traditions.

ENVIRONMENTAL ETHICS

Modern science and technology have brought about a unique, human-caused transformation of the Earth. Although humans have for thousands of years had measurable terrestrial impacts with fire, agriculture, and urbanization, since the Industrial Revolution the scope, scale, and speed of such impacts have exceeded all those in the past (Kates, Turner, and Clark 1990) and promise to become even more dramatic in the future. Humans have become what the Russian scientist V. I. Vernadsky in the 1920s called a *geological force,* in a sense even more strongly than he imagined it. Environmental ethics and, more generally, environmental philosophy comprise a variety of philosophical responses to the concerns raised by the magnitude of this transformation.

Basic Issues

Since the noxious clouds and pollution-clogged rivers of the Industrial Revolution, society has generally agreed that many modern technological activities, due to their potentially devastating impact on nature and people, are in need of regulation. Recognition of the fact that humans can foul their own nests is now widely accepted and often politically effective. Indeed concerns about the counterproductivity of scientifically and technologically enhanced human conduct in the early-twenty-first century extends to discussions of population increase, environmental costs borne by the poor and minorities, and responsibilities to future generations. But it is not clear that addressing such anthropocentric worries adequately encompasses all properly human interests. Beyond working to live within the environmental limits for the production of resources and absorption of wastes—which can be pursued both by moderating activities and transforming technologies—questions arise about whether nonhuman or extrahuman considerations have a role to play. What are the ethical responsibilities, the moral duties, of humans to nonhuman animals, plants, populations, species, biotic communities, ecosystems, and landforms? Should environmental outcomes for these, or at least some of these, not mean something in their own right quite apart from their mere resource value for human exploitation? Ought humans not to *respect* nature to some degree for what it is intrinsically? Much of the professional field of environmental ethics has been exercised with articulation and debate regarding the relative weight of human- and extrahuman-centered concerns.

Moreover early-twenty-first-century humans are often ambivalent about the place of nature in human life. Human beings of all times and places have needed and wanted freedom from many of the harsh conditions of the natural world, but earlier humans also celebrated the grace of nature in art, song, story, and ceremony. Modern technological efforts perfect the former and neglect the latter. Could it be that human flourishing is connected to nature flourishing? If so, over and above respect for nature, a *celebration* of things natural and the natural world in human lives and communities throughout the world is necessary. Although their numbers remain comparatively small, many people are stirred by passionate feelings about nature in communities that have long *turned their backs to the river*. While some critics argue the pathetic fallacy of such positions, the question of how much say nature and natural things will have over human life and the planet remains.

Any philosophical criticism of the anthropogenic transformation of the natural world must ultimately lead to an assessment of human culture. Perhaps humans have been at some level mistaken about the fundamental payoffs of environmental exploitation. In many instances, the technological control of nature that displaces its celebration leaves people numb, mindless, or out of shape. It seems necessary to coordinate a critique of technological damage with discovery of new ways for living with nature in order simultaneously to save the planet from environmental degradation and society from cultural impoverishment. The quality of the environment and of human life —questions of environmental and interhuman ethics (the good life)—may be inseparable.

The extensive transformation of the Earth deserves to be seen from the perspective of both the natural world and culture. This transformation could not have taken place without widespread agreement underlying the fundamental orientation of the modern technological project. There may be several ways of understanding this agreement, and there is debate among scholars on this issue (Borgmann 1984; Higgs, Light, and Strong 2000; Zimmerman et al. 2000). Despite differences, there is nevertheless a consensus that unless people unite concerns for nature and culture, environmental ethics will prove to be inconsequential. In other words, an effective environmental ethics and philosophy must include as well a philosophy of technological culture.

Historical Development

Historically environmental ethics is associated with a certain unease about the unbridled exploitation of nature that is typical of post-Industrial Revolution society. As Roderick Nash (2001), among others, points out, such uneasiness was first evidenced in post-Civil War United States concerns over the loss of both wilderness and natural resources—concerns that led to the creation of the first U.S. national park (1872) and then forest service (1905). After World War II, the creation of a second wave of environmental concern centered around the wilderness movement of the 1950s that led to the Wilderness Act (1964) and Rachel Carson's *Silent Spring* (1962), which argued that aggressive technology in the form of the extensive use of chemical pesticides, especially DDT, was killing millions of songbirds and could eventually have a much broader impact on plant, animal, and even human life. Nuclear weapons and energy production, technological disasters (such as the Santa Barbara oil spill of 1969), wasteful extraction and use of resources, the rise of consumerism, the population explosion, oil shortages (in 1973 and 1977), pollution, and a host of related environmental problems combined to establish in popular consciousness what can be called an environmental or ecological crisis about the health of the Earth as a whole. Existing conservation measures, with their many successes, were nevertheless judged too weak to respond to the new problems, leading to the enactment of the National Environmental Policy Act (NEPA 1969) and to the establishment of the first national Environmental Protection Agency (EPA) by President Richard Nixon in 1972. At the same time, some began to question whether enlightened self-interest was a sufficient basis for assessing the contemporary state of environmental affairs and argue that nature mattered in ways beyond its strictly human utilities and should be protected with an eye for more than human safety and health.

Among figures such as Ralph Waldo Emerson, Henry David Thoreau, John Muir, and Albert Schweitzer, wildlife biologist and ecologist Aldo Leopold advocated this position before environmental ethics became a popular movement. Early in his career as a professor of wildlife management, Leopold thought that nature could be reorganized for human ends (enhancing wildlife populations by eliminating wolves, for instance) if one took a long-range view and was scientifically informed. However in his mature work *A Sand County Almanac and Sketches Here and There* (1949), Leopold criticized reliance on the conservationist position, and argued that *the land,* what is now called an ecosystem, must be approached holistically and with love and respect, that is, with what he calls *the land ethic*. He said, "A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise" (Leopold 2000, pp. 224–225). Leopold articulated the emerging new ethic concerning both living things as individuals and the natural system itself, including the *community concept* generated by the relatively new sciences of evolution and ecology. This was in contrast to earlier theories that invited human domination of nature, which Leopold believed were encouraged by the older hard sciences.

The groundwork for environmental ethics as such was laid in the 1970s. During the first half of that decade, four independent philosophical works launched the academic field. Arne Naess's "The Shallow and Deep, Long-range Ecology Movement: A Summary" (1973) called for a radical change in the human-nature relationship, and became a seminal work of the deep ecology movement. Richard Sylvan's (then Routley) "Is There a Need for a New, an Environmental, Ethic?" (1973) argued that modern ethical theories were inadequate for the full range of moral intuitions regarding nature. Peter Singer's "Animal Liberation" (1973) reanimated Jeremy Bentham's proposal for including sentient members of nonhuman species in the utilitarian calculus. And Holmes Rolston III's "Is There an Ecological Ethic?" (1975) distinguished between a *secondary sense* environmental ethic in which moral rules are derived from concerns for human health or related issues, and a *primary sense* environmental ethic, in which nonhuman sentient animals as well as all living things, ecosystems, and even landforms are respected because they are intrinsically valuable *apart* from any value to humans. For Rolston, the secondary ethic is anthropocentric and not truly environmental, whereas the primary is truly environmental and ecocentric. Subsequently Kenneth Goodpaster (1978) developed the fertile concept of *moral considerability* to discuss more generally who and what, if anything nonhuman, counts ethically. In 1979 Eugene C. Hargrove founded *Environmental Ethics*, the first journal in the field.

Mainstream environmental ethics matured over the next decade. Animal liberation and rights discussions flourished and became a separate field from, and often in conflict with, environmental ethics, because ecosystems sacrifice the welfare of individual animals. Within mainstream environmental ethics, ethical theories regarding individual *lives* of animals and plants, usually called biocentric or life-centered, began to be distinguished from holistic approaches that dealt with preserving entire ecosystems, called ecocentric or ecosystem-centered ethics. Leopold's earlier vision developed in different ways in the systematic works of J. Baird Callicot, deep ecologists, and others.

During the 1980s and 1990s, the field witnessed remarkable growth. Currently there are numerous journals, two professional organizations (the International Society for Environmental Ethics and the International Association for Environmental Philosophy), and an array of Internet sites devoted to it. Colleges and universities routinely teach courses in environmental ethics.

Environmental ethics theorists, in the early twenty-first century, believe they are taking a radically new direction because they are informed by scientific insight and philosophical prowess. Many aspire to produce universal claims about humans and the environment. They argue the urgent need for a new environmental ethic governing the duties of people toward nature, and reject the view of nature, which started with the rise of modern science, as value-neutral stuff that humans can manipulate as they please.

However recent developments in science complicate and challenge environmental ethics. Ecology has always accepted change, but modern ecology has moved away from early ecology's notion of stable, climax communities (usually pre-Columbian) reached by moving at a steady pace through successive stages. The notion that nature tends toward equilibrium conditions, a *balance of nature*, has become largely rejected in favor of the view that ecological processes are much more unruly and undirected. Catastrophic, episodic, and random events may be more responsible for the ecological condition than ordinary cycles. Ecological settings, once disturbed, do not automatically return to their predisturbance state. What were thought to be symbiotic relationships between members of an ecological community are often better understood as assemblages of individuals acting opportunistically. The assumed relationship between biodiversity and stability does not always hold up to scientific scrutiny. Added to these are complicating human and cultural influences such as the role of Native Americans in shaping ecosystems, the European introduction of horses, and global climate change. In light of these factors, environmental ethics theorists must again consider the acceptability of the control and maintenance of nature for human benefit. Those who have been inspired by ecology generally, and Leopold in particular, struggle to revise their theories. Most of these revisions turn on protecting dynamic processes rather than fixed-states and on considering the relative magnitude of anthropogenic transformation. Modern human-caused ecological changes differ dramatically from natural-caused changes in terms of rates (for instance, of extinction or of climate change), scope, and scale.

Beginning in the late 1980s and following a direction initiated by deep ecology, environmental ethics, with its focus on elaborating moral duties to nature, was felt by many to be too constrictive to address the questions of humankind's place in nature or nature's place in the technological setting. Nature seems to count in ways that were neither exclusively exploitive nor independent of humans. Others find that environmental ethics too often stops short of cultural critique. For instance, criticism of the modern transformation of the Earth from a predominantly technological and cultural standpoint is considered to be an inappropriate subject for the journal *Environmental Ethics*. Third, concern with a new environmental ethic in a primary sense was denounced for diverting attention from developing sophisticated and effective anthropocentric positions. Whereas environmental ethics is popularly understood as being synonymous with environmental philosophy, philosophers often conceive of environmental philosophy an alternative field, distinguished by its philosophical broader concern regarding the human and cultural relationship with nature (Zimmerman et al. 2000).

Scope and Central Issues of Environmental Ethics

Human beings are expected to act morally, but no such expectation exists for animals and plants; ethics is limited traditionally to the sphere of moral agents, those capable of reciprocity of rights and duties. No one in environmental ethics argues that anything in nature is a moral agent and morally responsible. If human beings can overcome the problem of extending moral duties beyond moral agents, other issues become central for environmental ethics including: (a) What duties should constrain human actions on the part of other beings who can suffer or are subjects of a life, that is, sentient animals? and (b) Should sentient animals be ranked, for example, primates first, followed by squirrels, trout, and shrimp, depending on the degree to which an animal can be pained or the complexity of their psychological makeup? Human duties toward different kinds of animals may be clarified with advances in neuroscience and animal psychology.

However ranking animals according to these hierarchies may simply be an imposition of anthropocentric norms, that is selecting paradigmatically human characteristics as a basis for rank. What duties do humans have toward those who are *alive*, usually defined as nonsentient animals and plants? Do all living things possess biological needs, even when there are no psychological interests? If some duties obtain, how should these take into consideration the natural order where life feeds on life and might makes right, for instance?

Other issues also merit consideration. Can *moral extensionism* by analogy apply beyond *individualistic accounts*, beyond selves, to other parts of the natural world? Do humans have duties to microbes and to mere things such as rocks, rivers, landforms, and places? A final crucial issue to be considered by environmental ethics is whether humans have duties to species and ecosystems that are not only not alive and do not suffer, but are not individual beings at all?

Many environmental ethicists believe that humankind can answer these questions only when the question of whether nature possesses intrinsic value is answered (Light and Rolston 2002). Normally intrinsic value is distinguished from *instrumental value*. Instrumental value is use-value, that is, something is valued merely for its utility as a means to some other end beyond itself. Exploiting nature for its instrumental value is seen as the root cause of the ecological crisis. If nature is value-neutral, then humans can dispose of it anthropocentrically as they please. The only alternative to instrumental value, it may seem, is a kind of hands-off, nonrelational respect for nature. If nature matters intrinsically, independently of humans, then its value may prescribe moral consideration.

For instance, all life forms seek to avoid death and injury and to grow, repair, and reproduce themselves by using elements (including other life forms) of the environment instrumentally. These elements have instrumental value for the life-form. On the other hand, in order to generate instrumental value these life-forms must be centers of purpose—growth, maintenance, and reproduction. They must have *sakes* or *intrinsic value* which they pursue. Because the organism's intrinsic value and the instrumental values derived from the organism's pursuit of its own well-being exist whether or not there are humans, such values are independent of humans. For example, grizzlies have a stake in the use of pesticides to control army cutworms in the Midwest because scientific studies show that migrated cutworm moths constitute a significant portion of their diet.

Yet, it is argued, this cannot be a complete account of intrinsic value because the individual may not be a *good kind*, for example, a nonnative species such as spotted-knapweed in North America. Should the life of such a species be respected and allowed to be a good of its kind, or should humans seek to eliminate it? Good kinds need to be weighed in relation to a natural ecosystem. Can a species that uses the forces of evolution to improve itself have intrinsic value, even though it has no *self*? Having wolves cull elk herds will help the species by assuring that elk maintain a *good* gene pool that is better adapted; however, no individual elk welcomes these wolves. Are any species more valuable than others? By genetic standards alone, there is more biodiversity among the microbes in some Yellowstone Park hotpots than the rest of the larger life-forms of the Greater Yellowstone ecosystem. Finally should the concept of intrinsic value be reserved for the *products* of the ecosystem and evolution and not the *processes* themselves, the source of these products?

Significant philosophical (and practical) problems as suggested occur here. How do humans adjust intrinsic values found in nature with people (Schmidtz and Willott 2002)? Second, can humans speak of intrinsic value apart from human minds? Environmental ethicists provide conflicting answers, ranging from conventional anthropocentric to nonanthropocentric *value subjectivist* versus *value objectivist* debates between Callicot and Rolston (Rolston 1993). Third, by focusing so much energy on the nonrelational, intrinsic value of the autonomy of natural things and of nature, environmental ethics tends to concentrate on nature disengaged from humans: particularly on wild nature and the independent natural order. Initial unease with the environment, however, is likely caused in part by the disruption of humanity's bonds of engagement with nature. Between the instrumental resource value of nature and the nonrelational intrinsic value of nature, between the misused and the unused, lies a third alternative: the well used and the well loved. Nature has *correlational value* for humans in the sense that nature's flourishing is bound up with human flourishing in a kind of *correlational coexistence* (Strong 1995, p. 70). Allowing consideration for nature to more strongly influence the design and maintenance of cities may make them more livable, enjoyable, and attractive.

Environmental Philosophy

Turning from environmental ethics to environmental philosophy, agreement about the limitations of conservation measures and analysis of nature solely in terms of its exploitive-value exists, but with an argument for broader reflection. Deep ecologists, for instance, call for metaphysical, epistemological, ethical, political, and cultural changes. What philosophers find most troubling—anthropocentrism, patriarchy, class struggle, placelessness, the technological project itself, and so on—colors the nature of the environmental philosophy.

Deep ecology has focused on anthropocentrism as the source of ecological problems. To overcome this, deep ecologists, such as Naess, advocate a new sense of self-realization (Fox 1995). Anthropocentric self-realization is atomistic, selfish behavior. From an ecological understanding of humankind as part of a larger whole, deep ecologists argue that human beings can reconceive of themselves as extending to that larger whole; reframed, human realization is tantamount to the realization of that larger whole, usually written as *Self-realization* in contrast to anthropocentric self-realization. From this perspective or reframing of human life, nature no longer seems like a resource to be used for a separate human good, but rather as its own good. Other ways of overcoming this anthropocentrism emphasize Naess's eight-point platform that includes a call for decreases in consumption. Yet to rail against consumerism and its destructiveness is not to understand its motivation and attraction. Without understanding those aspects (a topic for technology studies and ethics), can humans become genuinely liberated from it?

Stepping beyond strictly scientific accounts of ecosystems, humans historically and across cultures—for example, Greek, Chinese, and Incan temples—have understood profoundly, cared for, respected, revered, and celebrated the natural world. There is a good deal to learn from how some cultures prescribe the human relationship with nature, and for recent developments in environmental philosophy, such as bioregionalism, an understanding of cultures of place plays a central role their theories and practices (Abram 1996, Jamieson 2003, Snyder 2000). The intuitive and eclectic nature of deep ecology and bioregionalism, as well as their activist emphasis, has made these environmental philosophies especially popular.

Ecofeminism is another promising version of environmental philosophy. Common to different kinds of ecofeminism is the idea of, as Karen Warren puts it, the "twin domination of women and nature," and that both forms of domination ought to be overcome (Zimmerman et al. 2000, p. 325). Some ecofeminists distance themselves from other forms of environmental ethics by arguing that the latter are dominated by male voices and male-centrism, or androcentrism. Some ecofeminists, inspired by Carol Gilligan's work and postmodernism generally, criticize notions of abstraction and detachment, reason, and universality as pretentious and arrogant. They attempt to replace such concepts with an ethics of care, which is highly contextual, particular, and more focused on relationships than on formal rules and individuals (such as earlier philosophies that focused on animals and plants). For instance, ecofeminists have characterized the notion of Self-realization as a means of eradicating the differences between humans and the natural world rather than as an instrument that fosters recognition and acceptance of the differences of these *others*.

Val Plumwood in particular has shown that concerns about anthropocentrism can be addressed in the same ways concerns with androcentrism are dealt with by her, without giving up personal points of view, which she argues is impossible (Plumwood 1999). More specific analyses of anthropocentrism allow people to devise more alternatives to it. However arguments for an end to the domination of nature entirely are too general. One can criticize a limitless technological domination of nature without claiming that *all* human domination is unwarranted. Even though Warren rappels down a cliff as opposed to climbing and dominating it, she uses technological devices that lessen the risk involved and insure that the activity is performed safely. Whether humans use bicycles, public transportation, or SUVs to reach such cliffs, they use technology that dominates nature to some extent, albeit almost imperceptibly. What human beings must learn is to *carefully limit* technology and technological domination.

As with ecofeminist views of patriarchy, many social and political ecologists, inspired by socialist economic perspectives (and some inspired by the work Lewis Mumford), locate the source of human unease as social hierarchy, placing dominance of economic power at the root of social injustice and the ecological crisis. If social hierarchy does not end, humans cannot expect a substantive change in their relationship with nature.

Consideration of social issues opens environmental philosophy to social and philosophical theories of technology (and vice versa) in ways that remain largely undeveloped. The question concerns the earlier issue of how deeply human culture's fundamental orientation toward nature lies. Would a change of social hierarchy alone result in a sufficiently radical change of orientation or does society need to outgrow its current technological orientation, as is posited in the social theories of technology based on the work of Martin Heidegger and Jacques Ellul? Locating the center of gravity with technology, these theories of technology call for prescriptions that differ with other social theories. To use technology in a different way may call for a sea change for nature *and* material culture.

A related political issue is environmental justice. Some argue that it would take the resources of at least two more Earths to bring all people on this planet up to the standard of the developed nations. The environmental cost of the transformation of the Earth is borne disproportionately, both within and outside of the United States, by the poor, minorities, and women. Moreover the cost of environmental legislation often falls disproportionately on these groups, giving rise to a charge of elitism against environmentalists. Finally, those in developed countries who take modern conveniences for granted often callously disregard the genuine hardships suffered by those in developing countries where such technological relief is unavailable or inadequate. The challenge for environmental philosophy is to meet moral concerns for social justice and nature. What conditions are required to put a life of excellence within everyone's reach?

A Consequential Environmental Ethic?

What are the practical achievements of environmental ethics? While environmental ethics is not simply applied ethics (a body of traditional normative ethical theories is not being applied to specific ethical issues as is often the case in medical or business ethics), it is important to apply traditional theories of interhuman ethics to environmental problems in a secondary sense. Arguably the most valuable contributions to policy decisions have been made in terms of risk assessment and related issues (Shrader-Frechette 2002). Animal rights and liberation theories indirectly influence legislation such as the laboratory care and use of animals. Forest Service Employees for Environmental Ethics explicitly advances Leopold's land ethic in a quest for a new resource ethic; departments of natural resources, as they move toward ecosystem approaches of management, seem to be attentive to these discussions of Leopold and those philosophers influenced by him. More progressive hunting and fishing regulations sometimes mimic ecosystem processes by reducing the number of trophy animals harvested. Environmental philosophers have proven most effective publicly when they, like Rolston, listen and speak in intelligible ways to a broad spectrum of people including those in the fields of technical philosophy and science, activists, and ordinary people (Mitcham et al. 1999, Rolston 1993).

All major pieces of environmental legislation preceded the development of environmental ethics, and as yet there is no effective green party in the United States. In particular there is none inspired by philosophers. Environmental pragmatists criticize environmental ethics and environmental philosophy for missing opportunities to make significant contributions to policy because they are too impractical and dismissive of activism. In their view, environmental ethicists divert attention from actual environmental problems by being overly concerned with theoretical issues such as intrinsic value, whereas environmental philosophers do the same by concentrating on the impossible task of radical reform. Pragmatists urge philosophers to apply their unique abilities and resources to solving concrete environmental problems. Distinct problems, in their view, call for different approaches (ranging from the economic to the aesthetic); no single approach is the correct one. In fact, the same problem may require a solution that includes approaches from incompatible theoretical positions. Thus, as pluralists, they call for cooperation between environmental philosophers.

Although they would be wary of any absolutist tendencies, pragmatists also call for more cooperation between these philosophers and other kinds of, normally anthropocentric, reformist positions that have been developing simultaneously with the field. Some approaches are based on deeply held values, such as the difference between consumers and citizens, in conservative and liberal traditions in order to get people to change attitudes, behaviors, and polices toward nature. Others, such as environmental libertarianism, have developed free-market approaches to resolving environmental problems. This kind of thinking has been used to show that government subsidies to the forest service have been the impetus for much logging and road building that would not have otherwise occurred. More liberal economic approaches demonstrate that while the market is effective for resolving some environmental problems, it is limited with regard to ensuring environmental protection. Many of the market's shortcomings have to do with the limits of economic value, cost benefit analysis itself, or how ethically and scientifically sound solutions to environmental problems are ignored based on economic considerations (Sagoff 1984, Schmitz and Willott 2002). Alternatively green capitalism, in order to avoid ecological catastrophe, advocates government regulations and policies, such as "green taxes," that develop the economy in ecologically sustainable ways (Hawken, Lovins, and Lovins 1999, Thompson 1995).

Is an environmental ethic needed or is ecological prudence sufficient? Apart from meeting people's moral concerns with nature, many advocates argue that an environmental ethic is imperative in order to save the planet from catastrophe. Such pessimism invites detractors who contend that scientists and engineers are making progress with environmental problems and that some fears regarding the environment are unwarranted; moreover unfounded fear is cited as part of the problem (Baarschers 1996, Lomborg 2001, Simon 1995). Certainly informed debate, critical thinking, scientific literacy, and pragmatism are called for.

However even *if* some consensus were achieved and catastrophic outcomes could be ruled out safely, this debate is a diversion from a submerged but central environmental and ethical issue: Will a *saved planet* be worth living on? Those who would continue the technological project unimpeded except for refinements and adjustments are quite sanguine in their answer—often assuming that the indisputable early achievements of technology are analogous with later postmodern ones—whereas those concerned about survival are often covertly more concerned about the quality of human life. What level of environmental quality is correlatively important to the quality and excellence of human life? Where is nature's place in a technological setting? How *tamed* should nature be? Contemplating these questions requires the use of science, technology, ethics, and environmental ethics. These reflections will involve not only specialists, but also each and every person, in a public conversation that considers facts and fallacies, but ultimately ponders alternative visions of life. As Langdon Winner writes, "we can still ask, how are we living now as compared to how we want to live?" (Winner 1988, p. 163). Human beings need to reflect on whether to continue to seek prosperity and happiness entirely through affluence and goods provided by the technological project, or, alternatively, through a new engagement with, among other things that matter, the nonhuman world. In the former vision, the technological project is prudently modified to be environmentally sustainable and shared equally with all people, and nature is controlled as a mere resource and commodity. In the latter vision, nature plays a much greater role in a reformed technological setting.

Unreflective consensus threatens to subvert any substantive environmental ethic because most of the ethical claims of the natural world are overridden when they conflict with consumption as a way of life (Strong 1995). Quite often environmentalists and environmental academics want environmental protection and are attracted to affluence and full-scale technological development. Can both exist? Most people uneasily muddle ahead simply assuming they can. Humans need a vision that values the natural world and includes an understanding of why the planet is being transformed in the way that it is. Only then can people hope to attain some clarity with regard to the real environmental and social consequences of personal, collective, and material choices.

Environmental philosophers must remember the original environmental and cultural problems that caused them to reflect and measure their overall successes in terms of how far human culture has come in dispelling those concerns. In the early-twenty-first century, it is clear that the full autonomous, independent, and nonrelational character of nature has changed (McKibben 1989). Often in restoration work and matters concerning nature in urban settings, the questions are more clearly focused. Will nature be respected and celebrated as having dignity and a commanding presence, expressive of the larger natural and cultural world of particular places, and be correspondingly cared for in that way (will it have correlational rather than intrinsic value alone)? Or will nature be entirely demeaned as a mere resource for humans to control and modify for the convenience of consumption (Borgmann 1995; Higgs 2003)?

ENVIRONMENTAL IMPACT ASSESSMENT

An environmental impact assessment (EIA) is a means for understanding the potential effects that a human action, especially a technological one, may have on the natural environment. It allows for the inclusion of environmental factors in making decisions by mandating a process for determining the range of environmental issues related to a particular action. The underlying assumption of an EIA is that all human activity has the potential to affect the environment to some degree, so that all major decisions should include environmental, as well as economic and political, factors. Understanding the potential environmental effects of an action helps policymakers choose which actions should proceed and which should not.

Many governments perform EIAs at the national, state, and local levels. Probably the best-known form of the EIA is the Environmental Impact Statement (EIS) of the United States government. The National Environmental Policy Act of 1969 (NEPA) mandates an EIS to accompany every major federal action or nonfederal action with significant federal involvement. NEPA tries to ensure that U.S. federal agencies give environmental factors the same consideration as other factors in decision making.

Most EIAs follow a process similar to the one mandated for the EIS. The first step is the preparation of an environmental assessment (EA) to determine whether the environmental impact of the action requires a complete EIS. The actual EIS begins by identifying issues and soliciting comments on the scope of the action, alternatives, and various impacts that the EIS should address. Then the lead agency collects and assimilates all the environmental information required for the EIS. In the United States, the Council on Environmental Quality (CEQ) regulations outline the recommended format for the EIS. The EIS must include public involvement throughout the process. All mitigation measures to address identified harms must be included in the EIS.

The primary problem of environmental impact assessments is that once the environmental factors have been analyzed there is little to force the actors to actually use the information in decision making. When the EIA is complete, the action can go forward regardless of any negative environmental consequences. In the case of the EIS, NEPA provides no enforcement provisions, though various court decisions have developed some such mechanisms. Decision makers are informed of potential environmental problems and can include environmental issues in making their decisions, but nothing requires them to nor is there any penalty for ignoring the environmental impact.

This is not to say that identifying environmental issues has no effect on the process. The fact that the information exists means it plays a role. Decision makers must elect to include or exclude it from their project. If they choose to ignore the information, others have a right to bring pressure on them. The identification of potential problems has sometimes motivated public criticism of planned actions and led to their rethinking. The existence of the information creates a better situation than not having the information at all.

ENVIRONMENTALISM

Environmentalism is a broad term used to describe the ideology of social and political movements that emerged in the 1960s around concerns about pollution, population growth, the preservation of wilderness, endangered species, and other threatened non-renewable resources such as energy and mineral deposits. As such it is a vivid nexus for science, technology, and ethics interactions. Since the 1970s, environmentalism has proved to be one of the most powerful and successful of contemporary ideologies, although this very success has generated so many strains of environmentalist ideas as to threaten the meaningfulness of the term itself.

Intellectual Roots

Although modern environmentalism can be traced to multiple intellectual roots, in the United States there are three primary influences. The first are the U.S. romantic and transcendentalist movements, which found moral and artistic inspiration in the natural world. The greatest representative of these ideas is the nineteenth-century writer Henry David Thoreau (1817–1862), whose *Walden* (1854) uses the natural world as a philosophical vantage point from which to evaluate and criticize U.S. society and politics. From this tradition, which was developed by John Muir (1838–1914) and others, environmentalism gains a focus on the value of preserving wilderness and non-human species.

A second major intellectual source for environmentalism is the U.S. conservation tradition. The most important founders of this tradition are Theodore Roosevelt and his close adviser and the first head of the U.S. Forest Service, Gifford Pinchot (1865–1946). These and like minded progressive reformers from the early-twentieth century led a movement to regulate and conserve natural resources and preserve some spectacular wilderness areas as national parks. The overall concern of the conservation movement was to maintain a sustainable supply of natural resources for a growing economy, which was believed to be essential for the health of a democratic society. From this tradition, environmentalism has inherited concerns about sustainability, the impact of the economy on the natural world, and human equity and justice issues concerning the distribution of environmental benefits and risks.

A third intellectual source for environmentalism is found within the scientific community of the 1950s and 1960s, when scientists became alarmed by the worldwide impact of nuclear weapons use and testing, chemical pollution of the environment by modern economic activity, and the stress on the environment caused by the sharp growth in human population during the twentieth century. The three greatest representatives of this tradition are biologists who wrote highly popular and influential books that caused broad-based alarm about environmental problems, Rachel Carson (*Silent Spring* [1962]), Paul Ehrlich (*The Population Bomb* [1969]), and Barry Commoner (*The Closing Circle* [1971]). Inspired by such works, environmentalism has gained a focus on public health problems that grow from modern productive processes and military technology.

Although these three traditions are responses to different types of problems and have generated different sets of concerns, environmentalism weaves them loosely together. Environmentalist thinkers and organizations stress different strains of environmentalism, but concerns as disparate as wilderness preservation, reducing environmental pollution and addressing the health problems it causes, and evaluating and protesting the injustice of unequal environmental impacts of various public policies and economic activities on disadvantaged subgroups in U.S. society (such as the poor, or people of color), are all recognized as part of the environmentalist agenda.

Two key facts about environmentalism must be stressed. First it is simply one of the most remarkably successful of all contemporary social and political ideologies. What was a marginal set of concerns and views during the 1960s has become part of the social and political mainstream. Public opinion polls consistently demonstrate wide-ranging public support for environmentalist values and policies, even if the saliency of environmentalist concern is somewhat less than that found for other issues such as the economy. Not surprisingly, candidates from across the political spectrum have found it necessary to profess environmental values, even if there is reason at times to doubt their sincerity. The corporate world has discovered that it is increasingly good business to market products and services as *green, natural, organic,* or environmentally responsible. Academic disciplines, from law to ethics to the natural sciences to engineering to economics and beyond, have been influenced by environmentalist concerns and have developed sub-disciplines focusing on environmental issues. Vast rivers of private financial donations flow into the coffers of a variety of environmental organizations found on the local, national, and international levels. In short, in the course of a single generation, environmentalism has grown to be one of the most visible and important ideologies in contemporary life. Rarely has an ideology enjoyed this level of achievement in such a short period of time.

The second key fact to note is that this very success, coupled with the diverse intellectual roots that nourish it, has made the intellectual content of environmentalism ambiguous, perhaps even incoherent if one is looking to find a unified ideology.

Three Types of Environmentalism

In light of this ambiguity, it is helpful to divide the universe of environmentalist views into three broad categories. First *liberal* environmentalists think of environmental problems in the political and social context of conventional liberal ideals and social policy. Drawing primarily, but not only, on the conservation tradition, liberal environmentalists have been successful in promoting extensive environmental regulation of industry and other polluting activities. The environmental justice movement, as well as increased interest in applying the philosophical tools of pragmatic philosophy to the study of environmental ethics, are also fundamentally liberal developments in environmentalism; the first demands respect for liberal equity in the distribution of environmental risk, and the second draws on the liberal tradition of U.S. philosophical pragmatism in order to evaluate the ethical implications of particular human behaviors in relation to the natural world. Much of the growing field of environmental economics may also be included in the category of liberal environmentalism, because it applies conventional liberal economic principles and tools to the study of environmental policy. What liberal environmentalists share is a perspective that views environmental problems within the context of recognized liberal philosophical, political, and social values.

Radical environmentalism can be thought of as an array of environmentalist ideas that challenge the philosophical and political underpinnings of liberal democratic society. The greatest unifying theme among radical environmentalists is the insistence that the anthropocentrism of liberalism, the assumption that human beings are the source and measure of all value, be rejected in favor of a moral perspective more inclusive of values intrinsic to the non-human world, a view that is sometimes called biocentrism or ecocentrism. The claim is that conventional moral perspectives are incapable of appropriately appreciating non-human things, and therefore there is a need to discover fundamentally new ways of thinking about the natural world and its relationship to people. Beyond these claims, radical environmentalists quickly part company, pursuing a multitude of philosophical paths. Eco-feminists, for example, suggest that women have natural connections with and insights into nature that men are less likely to experience, and that are lost or suppressed within a patriarchal society; fighting patriarchy is therefore related to not only freeing women from men, but to the reconnection of human beings with nature more generally. Rather than emphasizing gender, deep ecologists promote what they understand to be more primal, unified understandings of the proper relationship of humans to the natural world than they find in modern social and political theory and practice. Social ecology, a form of eco-anarchism, claims that humans could naturally live in just, non-hierarchical social organizations, and that environmental problems grow out of and reflect the oppression of humans by humans in unjust, hierarchical societies. Some would include eco-socialists among radical environmentalists, because they promote a political vision contrary to contemporary liberal democracy. Not all radical environmentalists, however, believe the socialist political program is sufficiently biocentric to be truly radical or environmentalist.

As an illustration of the huge growth in the ideological power of environmentalism, the late-twentieth and early-twenty-first centuries began to see the emergence of new forms of *conservative* environmentalism. While it is true that there have always been conservation groups that have historically appealed primarily to hunters and other groups not conventionally thought to be liberal or radical, these have been on the margins of environmentalism. Historically, conservatives have more often than not been hostile to environmentalism, on the grounds that it threatened to over expand the government's regulatory powers (in the case of liberal environmentalism) or, even worse, that it attacked the moral foundations of conventional society (in the case of radical environmentalism). There is a new and growing *free market environmentalism*, however, that is attacking the liberal environmental regulatory programs, and defending private property rights and conventional capitalist economic organization as the best way to promote environmental health and resource conservation. There is also some growth of a less militantly free market conservative sympathy for environmentalism that emphasizes the continuity of community traditions and religious piety toward what is understood to be a created universe.

Conclusion

Beyond the U.S. context, environmentalism has become a powerful force throughout the world, both within other countries and in the international order. The diversity of environmentalist views explodes within this broader context, from the demands of indigenous peoples to control local ecosystems in the face of pressure by international markets and corporations, to the growth of Green political parties (most importantly and successfully in Germany), to the attempt to design international policies for contending with world-wide environmental issues such as global climate change, to attempts to address wildly inequitable resource allocation between the rich and poor, the developed and developing, nations. In different contexts, and with different aims and intentions, environmental politics has become a factor in local, national, and international politics, and as such contexts have proliferated, so too has the breadth of environmentalist ideology expanded almost beyond measure and clear focus.

Given this array of environmentalist views and projects, it is clear that the very notion of environmentalism is being stretched to include incompatible ideas. The single unifying theme, to the degree that it can be found, is simply the attention paid to the human relation to the natural world and the promotion of ideas and policies intended to protect the health and fecundity of nature.

In light of the diversity of environmentalist views, it is difficult to clearly assess the implications of this ideology for modern science, technology, and ethics. It is clear, for example, that there have been elements of misanthropy and hostility toward science and technology in some strains of radical environmentalism, a kind of primitivism that views modern society in all its facets as a plague on the natural world to be resisted, even turned back, as much as possible. It is also true, however, that this is a marginal set of attitudes even within the radical environmentalist camp. Radical environmentalism does indeed insist on an ethical reorientation toward non-human things, but this by no means always reflects misanthropic views. On the contrary, the claim more often includes a presumption that humans will find their lives more meaningful if they learn to live harmoniously with nature, that radical environmentalism is a positive good for both people and nature. Likewise, even while much radical environmentalism distrusts science and technology, it often draws heavily on the science of ecology to inform its own analysis of problems, and often promotes what it considers to be environmentally friendly technologies.

Liberal and conservative environmentalisms usually appeal to conventional ethical categories (for example, the weighing of public goods against individual rights), and tend to work within the conventions of mainstream science and technology to promote their ends. The debates they engage are more often about the proper balancing of environmental goods against other important values, than about the need for such a balance in the first place. Liberal environmentalism also tends to be committed to using modern science to closely evaluate the overall environmental impact of existing technologies, and to producing the most environmentally benign technologies currently feasible.

Although it is difficult to generalize about environmentalism, given the great diversity of ideas and concerns found within the movement, the very power and popularity of environmentalist ideas reflects a growing sensitivity to and concern about the natural world. While environmentalists often worry about different issues, from wilderness preservation to public health to social justice, and often see the world in different ways, from radical biocentrists to conservative free market advocates to almost an infinity of variations in between, environmentalism reflects a rich diversity of attempts to think seriously about the appropriate relationship between people and the rest of nature. It is clear, from the popularity of environmentalist ideas, that there is a broad and growing sense of the importance of this overall project.

ENVIRONMENTAL JUSTICE

Environmental justice encompasses distributive and political justice to address the interlocking relationship between environmental issues and social justice. Environmental justice can include a myriad of struggles experienced by local communities whose concerns include protecting the environments where people live, work, play, and pray. A central focus is on the environmental burdens of modern industrial society including, but not limited to, issues of toxic waste, pollution, workplace hazards, and unequal environmental protection. Another focal point involves the equal political representation of diverse groups in environmental values and decision-making processes. Environmental justice has served to effectively criticize the inequitable distribution of environmental benefits and harms that can be associated with many technological developments, often employing science to identify and assess these benefits and harms.

Historical Emergence

Because many of these issues are tied to specific grassroots organizations and networks, environmental justice fundamentally pertains to a larger social phenomenon referred to as the environmental justice movement (EJM). The EJM emerged in the 1980s when people of color formed grassroots responses to the location of environmental burdens, particularly toxic waste facilities and point production pollution sources. Luke W. Cole and Sheila R. Foster (2001) identify six intersecting social movements as the undercurrents of the EJM: the civil rights movements, labor movements, Native American movements, the anti-toxic movement, movements in academic scholarship, and the mainstream environmental movement. Although not included in their six undercurrents, the women's movement must be considered a seventh tributary, because it serves as a historical linchpin to the sciences currently used in environmental justice cases and because 70 to 80 percent of grassroots leaders in the EJM are working-class women, many of them women of color.

As early as the work of Jane Addams (1860–1935) and Alice Hamilton (1869–1970), when Hull-House pushed bacteriology and the new sciences of toxicology and epidemiology into connections between health, environment, and politics, women have been critical to the scientific knowledge of the neighborhood. As a result, new methods of data collection and analysis were created by these early environmental reformists to improve the industrial living conditions of the modern city. The attention given to women's health issues and environmental dangers from industrialization carries a direct thread between Hull-House and the contemporary EJM. Contemporary science and policy agendas, like those found in the U.S. Superfund Act (the Comprehensive Environmental Response, Compensation, and Liability Act of 1980), were spawned by the activism of women such as Lois Gibbs in Love Canal, New York. Thus the early advances in toxicology and epidemiology were partly due to environmental justice struggles led by women, and from that time policies to address environmental justice have had their origins in the activism of these community leaders.

Other important precursors that relate to Cole and Foster's six movements are identifiable as early as the 1960s when Martin Luther King Jr. and other civil rights leaders observed that people of color suffer higher pollution and more denigrated environments. By the end of the 1970s a series of studies had again drawn the historical inference that different human environments are directly related to social stratification. In a chapter of their seminal book addressing environmental justice, *Race and the Incidence of Environmental Hazards*, Paul Mohai and Bunyan Bryant compare studies dating from 1971 to 1992 that assess the correlation of toxics, including air pollution, hazardous waste, solid waste, and pesticide poisoning, with the impact on people of low income and racial minorities (Mohai and Bryant 1992). Two critical findings from this comparative study are worth highlighting. First, the study clearly proves that government agencies observed the relationship between social stratification and environmental burdens as early as 1971. Second, the comparisons provide empirical evidence that in the United States the distribution of environmental burdens has a strong correlation to race and socioeconomic class.

In addition to the Mohai and Bryant comparative study, the federal government in 1978 released a brochure called *Our Common Concern* that described the disproportionate impact of pollution on people of color. The struggle of César Chávez and the United Farm Workers to protect the health, environment, and rights of farmworkers was a vital precursor to the environmental justice movement. Studies of rural Appalachian living conditions were revealing the connection between poverty and environmental burdens, providing further evidence of trends of environmental injustice. Environmental justice also pervaded the struggles of Native Americans dealing with issues stretching from land rights to the hazardous industries of uranium mining, coal mining, and nuclear waste depository.

Addressing shared interests in environmental justice, the City Care Conference, held in Detroit in 1979, was jointly sponsored by the National Urban League and the Sierra Club. The intended purpose of this conference was to bring the civil rights movement and the environmental movement together for a dialogue to reconceptualize the very meanings of the terms *environment* and *environmental issues*. By the late 1980s and early 1990s, *environmental justice* became a newly established term used by scholars and policymakers. "Environmental justice" was first used in book and article titles by 1990, and the first environmental justice college course was offered in 1995. The latter came a year after President Bill Clinton signed Executive Order 12898, titled "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," which introduced environmental justice as a federal mandate by White House fiat.

Founding Events

Although the EJM in the United States is not bound by a single event, many scholars and activists regard the 1982 protests in Warren County, North Carolina, as a historical launching point. These protests marked the first major civil rights–style response to an environmental issue. It involved nonviolent civil disobedience blocking trucks hauling PCB-laced soil from entering a newly placed toxic landfill, leading to over 500 arrests and drawing national media attention. The Afton site in Warren County prompted many questions about the direct correlation between African-American communities and hazardous waste sites. It incited District of Columbia Delegate Walter E. Fauntroy, who was himself arrested in the protest, to initiate the 1983 U.S. General Accounting Office study of hazardous waste landfill siting, which found a strong correlation between sitings of hazardous-waste landfills and race and socioeconomic status.

Fauntroy's study spawned later comprehensive studies, including the United Church of Christ's Commission for Racial Justice's frequently cited *Toxic Wastes and Race in the United States* (1987), a national study not only confirming the disparate environmental burdens suffered by minorities and lower socioeconomic groups nationwide, but also centrally locating race in the disparity: "Race proved to be the most significant among variables tested in association with the location of commercial hazardous waste facilities" (p. xiii). At the presentation of *Toxic Wastes and Race* to the National Press Club in 1987, Benjamin Chavis, then director of the United Church of Christ, described the phenomenon as: "racial discrimination in environmental policy making and the enforcement of regulations and laws, the deliberate targeting of people of color communities for toxic waste facilities, the official sanctioning of the life-threatening presence of poisons and pollutants in our communities, and the history of excluding people of color from leadership in the environmental movement" (U.S. House 1993, p. 4).

Environmental Racism

Numerous studies concerning what came to be called environmental racism followed. In 1992 Marianne Lavelle and Marcia Coyle published their seven-year study of the U.S. Environmental Protection Agency in the *National Law Journal,* which revealed that polluters were fined more in white communities, responses were slower in people of color communities, and scientific solutions differed between the communities. The same science that would be used to determine the toxicity of a facility to a community was used differently between white communities and minority communities. Likewise, the same science that would determine the technological and economic responses, such as the technology of soil washing or soil removal or the shutting down of the polluting facility itself, would be compared to the economic assessment of community relocation because the implications of dangerous conditions involve costly relocations that make the project too expensive. Lavelle and Coyle revealed that different technological solutions would be used when the same scientific data described the health threats to the community. The different responses follow the trend that white communities receive more expensive and updated technological solutions and also receive higher compensation for health and property damage, and that polluters pay greater fines for damages to white communities than to minority communities even though scientifically, with regard to the pollution, the circumstances do not warrant these dramatic differences.

Further sociological and legal studies responded to the environmental racism charges by addressing fundamental methodological questions: Did the community or the environmental burden arrive first? Are there other categories to consider, such as age? How should a community be defined? Vicki Been (1994) argues that market forces drive the location of toxic facilities and the choice of many workers to come to a highly industrial sector. Admitting of racism in many social institutions, Been's study challenges the main measuring units used by earlier studies and raises important temporal questions about the relationship between minorities and environmental burdens. Other studies that altered the measuring unit of what constitutes a community found less disparity in the distribution of environmental burdens with regard to race than was initially claimed by the earlier studies defending the environmental racism charge. Numerous studies responded to this debate, thus generating a community of scientists, scholars, and activists to help deepen the ethical questions and broaden the scope of environmental sciences. What are the proper characteristics for determining the community that will host the environmental burden? What procedures will be used? Which scientific perspectives would best measure the risk of danger? How will race and socioeconomic background be considered in these risk assessments?

Discriminatory Environmentalism

The ethical considerations of these questions pertain to the discrimination undermining distributive justice and fair compensation for health or property loss. While environmental racism is indicative of actions considered illegal under federal laws such as the Civil Rights Act of 1964 and the Fourteenth Amendment to the Constitution, environmental discrimination on the basis of socioeconomic factors is not specifically illegal. Ethically, however, fundamental principles of distributive justice are violated. Peter S. Wenz has studied the environmental racism debate as a form of double effect in which race may be incidental to the socioeconomic target (Wenz 2001). Even if the market forces argument is true, he argues, distributing the environmental burdens onto the poor violates the principle of commensurable benefits and burdens, which stipulates that unless there are morally justifiable reasons, persons receiving the benefits of modern industrial technology should also receive the commensurate burdens. Those who receive an abundance of consumer goods should therefore be the targets of hazardous waste facilities and polluting industries, whereas those who receive noticeably fewer benefits, the poor residents, should be relieved of this incommensurable burden. Compensatory justice would follow the same moral foundation for redistributing benefits for incommensurable burdens.

Environmental justice also pertains to the principles of equality that require respect for the basic rights of all individuals. The most pronounced right in environmental justice is the right to a safe environment, which has assignable duty holders in the public (government) and private (corporate) sectors. In addition, the principle of self-determination, which honors the autonomy of individuals and their moral capacities to direct the activities that impact them the most, is of vital importance in the participatory justice dimension of environmental justice. The principle of self-determination entails that citizens ought to participate in the process of siting hazardous waste, as well as the procedures for determining fair compensation. Direct political participation, however, is not available for many residents in the burden-affected neighborhoods. The environmental decision-making is typically made prior to the time when community members are able to voice their opinions in the public review-and-comment meetings that are standard political mechanisms in the siting process.

The lack of representation in the mainstream environmental movement or the vital decision-making sectors can be referred to as discriminatory environmentalism. In discriminatory environmentalism, representation and participation in mainstream environmental groups, participation in environmental policymaking, representation in federal, state, and local environmental agencies, and decision-making power over the location of environmental burdens and benefits are either intentionally or unintentionally exclusionary. Underrepresentation in the mainstream environmental movement is also a fundamental contention of injustice against political recognition and participatory justice. In an effort to establish a genuine voice that would better represent the environmental concerns of people of color in the United States, alternative environmental caucuses were created. Often highlighted is the First National People of Color Environmental Leadership Summit, held in Washington, DC, in 1991, which symbolizes two important foundations of the environmental justice movement. The summit represents the lack of political representation of people of color in the greater environmental movement, and it generated seventeen "Principles of Environmental Justice."

Discriminatory environmentalism also identifies the ways in which mainstream environmental ethics has considerably overlooked the poorest and most disenfranchised peoples of the world in its efforts to securely ground moral obligations to nonhuman nature. In particular, the biocentric and ecocentric approaches of land ethic philosophy and "deep ecology" received criticisms for discriminatory environmentalism. The Indian ecologist Ramachandra Guha (1989) argues that the broad-sweeping universalist claims of deep ecologists would cause further distribution of resources for biological protection and environmental improvement away from poor nations to the wealthy nations. Various expressions of misanthropy emerged from deep ecology, which served to undermine environmental struggles of the poor and failed to distinguish between those who hold institutional control over our resource use and those who are subjected to the worse side effects of resource depletion and consumption. By making all human responsible for ecological impacts, deep ecologists overlooked not only the dramatic distinctions between the rich and the poor, but also who has consumed and controlled the use of the natural resources.

Originators of the deep ecology philosophy fundamentally distinguished this non-anthropocentric ethic from "shallow forms" of environmentalism that reflected anthropocentric ethics directed at pollution, work place hazards, and public health. This distinction between anthropocentric (shallow) and non-anthropocentric (deep) environmental ethics overlooked the populations of people struggling with the intersection between shallow and deep ecology. An irony of the split between non-anthropocentric environmental ethics and anthropocentric environmental ethics—a split that is often used to characterize the EJM as a shallow environmentalism—is that while the Principles of Environmental Justice reflect a challenge to the discriminatory environmentalism of mainstream environmentalism in the 1990s, it also shares fundamental values that clearly echo deep ecological sentiments. The first principles states, "Environmental justice affirms the sacredness of Mother Earth, ecological unity and the interdependence of all species, and the right to be free from ecological destruction" (Lee 1992). Although the mainstream environmental movement maintains an affluent, white membership, many of the mainstream environmental groups, such as Greenpeace, Ancient Forest Rescue, and the Sierra Club, have addressed discriminatory environmentalism by fusing environmental justice dimensions to their respective environmental agendas.

Greater pollution, cumulative climatic impacts, and mass consumption of resources have tremendous environmental consequences for the poorest and marginalized populations in the world. Many technological advances have been introduced around the world as strategies for economic development; the introduction of technologies, however, does not necessarily entail the introduction of environmental safety. In 1969 Union Carbide Corporation expanded its global production of pesticides, specifically methyl isocyanate, to Bhopal in central India. A technological disaster occurred in 1984 when a chain reaction of pressure, leaking hydrogen cyanide, and other lethal chemicals exploded and enveloped 40 square kilometers with a poisonous cloud. Failure to maintain safety systems and poor community communication led to the deaths of more than 2,000 residents and over 200,000 further injuries in the region (Applegate, Laitos, and Campbell-Mohn 2000). This tragedy, the worst chemical disaster in world history, is linked directly with global environmental justice in terms of transnational corporate responsibility, distribution of the most dangerous products and conditions to the least well-off, and the violation of public participation in the environmental issues that most affect the local residents. According to S. Ravi Rajan (2001), the Bhopal disaster should be considered "technological violence" because design engineers and executives at Union Carbide decided against a common corporate practice of keeping methyl isocyanate storage tanks underground. The high storage capacity and aboveground tanks at Bhopal aggravated the potential dangers to the environment and local residents, and the failure to install common safety features, when greater safety was warranted under the design conditions, made the corporation accountable for the massive technological disaster. Sophisticated modern technology involved in chemical manufacturing and petrochemical production, and even systems such as those found in military and space programs, involve numerous technological and scientific uncertainties. Basic safety precautions do not address this range of possibilities, and the level of disaster that can follow accidents makes risk assessment a statistical gamble for the local residents.

The magnitude of technological disasters such as that in Bhopal, the global reach of transnational corporations, and the existence of a select group of powerful global scientists and policymakers has given global environmental justice a dramatic scope. Issues pertaining to indigenous land rights and compensation for damages from technological expansion fall directly under the study of environmental justice. New technologies such as genetically modified foods and the ability to acquire and patent the traditional environmental knowledge of indigenous people have emerged as environmental justice concerns. Compensation and donor policies between the global North and South, as well as the environmental and economic consequences of global trade agreements, spark the distributive and participatory justice dimensions of the EJM. Transcontinental pollution and environmental impacts to the global commons find their ethical implications in the EJM. And across the globe there are localized environmental justice movements, such as Japan's Soshisha movement to address victims of Minamata disease, a debilitating neurological disorder caused by the dumping of mercury oxide into the public water supply, or Nigeria's Movement for the Survival of the Ogoni People (MOSOP), struggling against military aggression in a region of petrochemical corporate neglect. All this provides evidence of the expansive scope of global environmental justice, which Lois Gibbs has declared to be the fastest-growing, largest social movement in the world.

Basic Issues

The environmental justice movement has generated a host of ethical questions regarding environmental benefits and technological advances: To what extent is industrial technology implicated in the underlying struggle for the fair distribution of environmental burdens? What is the appropriate relationship between scientific analysis and environmental policies? What technological solutions are available and to whom? How can environmental burdens and benefits be fairly distributed to Earth's populations? What kinds of risks and social conditions constitute an unfair distribution of environmental burdens?

The movement has also produced ethical questions concerning the fair representation and inclusion in the decision-making and social dynamics surrounding environmental hazards: Do marginalized groups receive their proper voice in the process that is likely to affect them the most? How are racial dynamics related to environmental decision-making and environmental harms? What role does gender play? Is it morally acceptable to environmentally discriminate against communities, such as working-class and poor neighborhoods, if it is legal? To what extent are all interests represented in the process? Is the process appropriate for understanding the social and scientific relationships, and the community perception of risk compared to the scientifically acceptable range of risk?

Environmental justice has given scholars and activists the tools to address the environmental conditions of social justice. A vocabulary and conceptual framework now exists to discuss the relationship between environmental values and institutional racism. The political underpinnings of dominant environmental movements are now more easily exposed by the lens of environmental justice. False distinctions between social problems and environmental problems, which caused the splintering of movements such as the civil rights movement and the environmental movement, are now confronted by environmental groups, civil rights groups, and the numerous grassroots groups that have formed to address environmental injustices in their communities. The movement has broadened the possible interpretations of justice itself by combining distributive justice with political justice and economic justice with cultural justice, under a new rubric of environmental empowerment for the least-well-off populations around the world. Indeed, the dimensions of nature and environment are being revised and transformed by the closer scrutiny that the environmental justice perspective entails. The contention that environmental justice brings new rigor to anthropocentric environmental ethics is an underestimation of the potential critique forged by environmental justice.

ENVIRONMENTAL REGULATION

The regulation of human interactions with the environment has taken shape in various political institutions, policies, and market mechanisms that have evolved over time according to changes in social, cultural, and technological conditions. Forms of environmental regulation differ among nations and continue to emerge on the international level as industrialization and globalization create transboundary issues.

From the liberal or socialist perspective, in which the state is understood as a legitimate extension of the community, environmental regulation is regarded as a state activity representing effective public administration. But the conservative or libertarian perspective, in which the state should intervene as little as possible in the lives of its citizens, holds that market mechanisms or private agencies can provide environmental benefits more effectively. The complexity of environmental regulatory efforts also arises from questions about the proper role of scientific knowledge and various mechanisms for handling scientific uncertainty. Environmental regulation is a complex interdisciplinary effort involving ethical principles, political interests, scientific knowledge, and technological capacities. This broad scope of considerations ensures that several worldviews, with their attendant values and recommendations, will interact in regulatory efforts.

Environmental Regulation in the United States

The history of U.S. environmental and natural resource regulation can be categorized into three phases. The first phase, lasting roughly from 1780 to 1880, saw the evolution of legislation that promoted the settlement of the West and the extraction and use of its natural resources (Nelson 1995). Defining laws of this period are the General Land Ordinances of 1785 and 1787, the Homestead Act of 1862, the Mineral Lands Act of 1866, and the Timber Culture Act of 1873.

The success of western expansion spurred a second phase of environmental regulations. Generally termed the conservation movement, this period lasted from roughly the 1880s to the early 1960s. Policies of this period shifted the government's role from simply disposing of public lands to managing them. This management was informed by a philosophy of *wise use*, which held that resources should be managed for the greatest good, for the greatest number, for the longest time. This philosophy was enacted by a rising scientific elite, including Gifford Pinchot (1865–1946) and John Wesley Powell (1834–1902), who argued that the scientific management of natural resources must guide economic development in order to accomplish sustained yield and maximum efficiency. This placed the conservationists in conflict with John Muir (1838–1914) and other preservationists, who sought to maintain environments in their natural state (Caulfield 1989). The second phase witnessed the creation of the national park and national forest systems (for example, Yellowstone National Park in 1872; and the Organic Act [Forest Management Act] in 1897). The 1964 Wilderness Act, which sought to preserve pristine wilderness "untrammeled by man, where man himself is a visitor who does not remain," represents the culmination of this era.

The third phase marks the beginning of modern environmentalism, and received its greatest impetus from consciousness-raising works such as Rachel Carson's *Silent Spring* (1962) and Stewart Udall's (b. 1920) *Quiet Crisis* (1963). These books along with social changes wrought by modernizing technologies, industrialization, and urbanization triggered increased awareness of environmental problems and focused environmental policies on the regulation of air and water pollution, toxic chemicals, solid waste, and other impacts of the growing industries fueled by advances in science and technology. A later concern developed over global issues such as biodiversity and climate change. The modern environmental movement initiated an expanded role for the federal government in environmental regulation, which is especially evident in the major pieces of legislation passed in the 1970s: the National Environmental Policy Act in 1969; the creation of the Environmental Protection Agency (EPA) in 1970; Clean Air Act amendments in 1970 and 1977; the Clean Water Act in 1972 and amended in 1977; the Endangered Species Act in 1973; and the Toxic Substances Control Act in 1976.

By the end of the 1970s, federal and state governments had greatly expanded their environmental roles from public lands management to public health, industrial health and safety, agricultural development, and urban planning. The EPA took charge of a number of federal environmental responsibilities. Although independent of other federal agencies, the EPA is still a part of the executive branch and reports to the president. It operates within a context of other major federal agencies, including those housed under the Department of the Interior (DOI) (such as Fish and Wildlife Service, National Park Service, Bureau of Land Management, and Bureau of Reclamation) as well as the Department of Agriculture and the National Marine Fisheries Service. An enormous amount of regulatory activity continued to occur at the regional, state, and local levels. Governmental entities at every level have their own environmental regulations, constrained by the fact that they cannot defeat the purpose of federal regulations.

The 1980s, during the Ronald Reagan and George H. W. Bush presidencies, witnessed some weakening of environmental regulations, as an extension of more general deregulation policies that argued the inefficiencies of bureaucratic or command-and-control mechanisms as well as the need to perform cost-benefit analyses on regulatory activities. These changes were matched by the creation and strengthening of many nongovernmental organizations (NGOs) and other environmental activist and lobbying groups.

The Bill Clinton era (1992–2000) witnessed a modest revival of federal regulatory efforts. The George W. Bush presidency once again sought the de-federalization of environmental regulation as well as the more active extraction of energy resources on federal lands.

Other Nations and International Efforts

Other countries institutionalized environmental regulation by creating ministries of the environment (for example, Great Britain), or placed environmental responsibilities in existing ministries (such as West Germany). Eventually most European countries established environmental ministries, even though other ministries (such as agriculture, energy, or urban planning) continued to manage some environmental regulatory activities. Austria, France, Germany, Ireland, Italy, Sweden, and the United Kingdom eventually created more or less independent environmental regulatory agencies. At the European Union (EU) level, the European Environment Agency (EEA) is charged with generating and disseminating environmental information.

In Latin America, the process of introducing environmental regulation followed the European model. Until the 1990s, in many Central and South American countries there existed various national environmental commissions charged with coordinating different environmental protection activities. The 1992 Rio Conference (United Nations Conference on Environment and Development Earth Summit) provided an important impulse for administrative reforms in Latin America related to environmental protection and led to the creation of ministries of the environment throughout the Spanish- and Portuguese-speaking countries of the Americas.

As globalization continues, an increasing number of environmental problems present transboundary issues. Global climate change, invasive species and biodiversity, water use, and air and water pollution are just some of the problems that raise environmental regulation into the realm of international law and policy. The United

Nations has played a leading role in two of the more prominent instances of international collaboration around environmental issues. First, the UN Environment Programme established the international legal framework known as the Vienna Convention on the Protection of the Ozone Layer in 1985. This led to the Montreal Protocol on Substances that Deplete the Ozone Layer in 1987, which required industrialized countries to reduce their consumption of chemicals that harm the ozone layer. Second the United Nations Framework Convention on Climate Change (Framework) established in 1992 provides a forum for governments to gather and exchange information and adapt to the effects of climate change. An international meeting in Kyoto, Japan, held under the Framework, produced a document (the 1997 Kyoto Protocol) that established binding limitations on greenhouse gas emissions by developed nations. Russia's ratification of the protocol in 2004 fulfilled the participation requirements for developed nations, thus allowing the treaty to become effective.

However such international agreements generally just set basic guidelines that require domestic legislation. This is usually difficult to achieve, and in the case of the Kyoto protocol, monitoring compliance is complex and there is no international enforcement authority. Furthermore international negotiations usually involve several governmental bodies, such as agencies, ministries or departments. For example, the State Department (not the EPA) controls U.S. involvement in international climate negotiations. The proliferation of bureaucratic agencies can create political gridlock.

Types of Environmental Regulation

Environmental regulation is plagued by two intrinsic challenges. First, because many environmental regulations involve the protection of public (common) goods, they often conflict with individual rights (especially property rights). Second, environmental problems often occur over long time periods and wide physical areas, whereas most individuals involved in regulatory processes have short-range, narrow interests, especially concerning economic growth. For both reasons, traditional environmental regulations usually entailed the implementation of strict controls on the otherwise unrestrained expression of personal and economic interests in the free market. As John Baden and Richard Stroup point out:

> The dawn of the environmental movement coincided with an increased skepticism of private property rights and the market. Many citizen activists blamed self-interest and the institutions that permit its expression for our environmental and natural resource crises. From there it was a short step to the conclusion that management by professional public "servants," or bureaucrats, would significantly ameliorate the problems identified in the celebrations accompanying Earth Day 1970. (Baden and Stroup 1981, p. v)

What followed during the 1970s was a command-and-control approach to environmental regulation, wherein the government set strict legal limits and enforced sanctions against violators.

Although this top-down and sometimes heavy-handed approach resulted in important successes, it also revealed a crucial element of regulatory practices: There are governmental failures just as there are market failures. Several reasons for governmental failures exist. Bureaucrats, like all people, are self-interested, and when governmental structures are not designed to link authority with responsibility for program outcomes, "decision makers have few incentives to consider the full social costs of their actions" (Baden and Stroup 1981, p. v). Furthermore decision makers have only a limited capacity to comprehend complex social and environmental interactions, which can limit their ability to make wise regulatory decisions.

One response has been to improve the structure of government, but another reaction has been to improve the structure of markets by implementing what Terry Anderson and Donald Leal term *Free Market Environmentalism* (1991). The underlying philosophy of this regulatory approach is that markets and environmental concerns can be made compatible by internalizing costs and establishing the proper incentives. This perspective also challenges the common assumption that environmental degradation is inherently linked to economic growth. It should also be noted that the relationship between environmental regulations and job loss or economic downturns is controversial, and no such correlation may exist (Goodstein 1999).

Anderson and Leal claim that the approach of free market environmentalism is founded on a core assumption of human nature: Humans are self-interested. They write, "Instead of intentions, good resource stewardship depends on how well social institutions harness self-interest through individual incentives" (Anderson and Leal 1991, p. 4). Examples of utilizing market mechanisms for environmental regulations include green taxes, marketable emissions permits (for example, cap-and-trade systems), and the elimination of harmful government subsidies.

Command-and-control and free market regulatory strategies are not incompatible and can often be used in conjunction to achieve desired environmental outcomes. Free market mechanisms obviously also have social dimensions insofar as they influence levels of public service, consumer rights, minority interests, and more. Social regulations likewise have economic implications in that they provide a framework within which economic activities can take place. Public or private institutions may advocate for both types of regulation. At the public level, environmental agencies such as the EPA are often subject to enormous political pressures that can complicate their mission and even compromise their integrity (Landy, Roberts, and Thomas 1994).

Many environmental regulations involve statutes, which often include a citizen suit provision or other appeals procedures that allow citizens to challenge an agency's action (or inaction) when it appears to be out of compliance with the law. In the United States, suit can also be filed under the Administrative Procedures Act, which is another mechanism for holding federal employees and agencies accountable for properly exercising their authority. Many environmental statutes specify the basis on which decisions must be made. In the United States, public input at the scoping stage is usually mandatory, and notice and comment periods through the Federal Register are always required. Some statutes require protection of the environment, while others focus primarily on human health. Some mandate cost-benefit analysis, while others call for decisions based on the best available science alone, with no consideration given to economic cost.

Science and Environmental Regulation

For all environmental problems, a certain amount of scientific understanding of natural systems and their interaction with human social systems is a necessary component of any regulatory action. This partially explains the preeminent importance of scientific advice in the crafting of environmental regulation or *science for policy*. The role of scientific expert knowledge is independent of the type of administrative process. Establishing an independent agency raises further questions of democratic legitimacy and accountability. This is true especially in relation to the problems of scientific advisers turning into policy makers and policy makers delaying action while continuing to fund more scientific research (Jasanoff 1990).

In theory, the process of environmental regulation depends on two factors: the definition (by democratically legitimized institutions) of the public goods to be protected, including the degree and costs of protection; and the scientific knowledge necessary to determine how an action may impact those public goods. But it is erroneous to assume that these two factors alone define the regulatory framework. Also, in this view, moral and political considerations play a role only during the definition of regulatory aims; and the justification for adopting certain regulations is based solely on expert knowledge. However, as regulatory practice demonstrates, this position has to be complemented by other considerations, because the facts and values components of environmental regulations are engaged in an iterative dialectic.

The different regulatory approaches created to safeguard public health and the environment from the effects of a large number of technological applications have stimulated new kinds of scientific activity, among them environmental impact and risk assessment. The scientific evaluation of risks and impacts has spawned various types of cost-benefit and risk-cost-benefit analyses (National Research Council 1996). These management tools permit a limited comparison of the environmental and economical effects of various alternative technologies and production processes, as well as different regulatory approaches. They can also be used to analyze risk-tradeoffs, where the regulation itself may lead to the emergence of other risks and negative impacts.

The Role of Science

Such predictive models are often limited by lack of data and the impossibility of modeling complex, higher-order interactions. For example, identifying the environmental impacts and risks presented by a chemical substance is made difficult by long term, cumulative interactions (sometimes called the *cocktail effect*) that cannot be mimicked in a laboratory setting. In some cases, the environmental degradation may be patent but establishing the pertinent causal relations may nevertheless be extremely difficult. In the case of global climate change, this type of persistent uncertainty has tended to sidetrack political discussion and hamper the process of producing alternatives for decision makers and stakeholders. So, even though scientific understanding is indispensable, it is not the only ingredient in formulating and implementing sound environmental regulations. There are very few instances where science provides enough clarification to clear away politically charged, open-ended environmental problems. This has led some policy analysts such as Daniel Sarewitz (2004) to suggest that the values bases of disputes must be fully articulated and adjudicated before science can play an effective role in resolving environmental problems.

Scientific investigation is certainly crucial to crafting wise regulations, but also presents several challenges (Cranor 1993). First is the issue of burden of proof. Generating all the necessary scientific information can be a time and resource intensive task. This can delay any decision, which in turn means that a harmful activity continues unregulated. In such case, putting the burden of proof on those who try to demonstrate that an environmental impact indeed exists tends to favor the environmentally harmful activity instead of the protection of the environment. This situation has led those social groups most concerned about environmental protection to demand, at least for certain technologies, the inversion of the burden of proof (that is, the need for demonstrating the absence of important environmental impacts).

A related problem concerns the standards of proof, which determine if a technological activity is harmful for the environment or human health. A number of factors can make environmental risk and impact analysis a very complex activity. If standards are rigorous, regulatory action may be excessively delayed. The debate on global warming and its relation to the emission of greenhouse gases provides a good example. In many cases it may be more effective for the protection of the environment to synthesize all available information from different sources and make decisions based on cumulative weight instead of trying to identify and quantify with precision any single environmental impact or risk. This highlights the fact that the choice of a standard of proof is as much a political and ethical dilemma as a scientific question (Shrader-Frechette 1994).

A third problem is the indeterminacy that is inherent in any environmental impact or risk assessment (Wynne 1992). Indeterminacy can only be reduced through methodological choices (for instance, about different available mathematical models that establish the relationship between the presence of a substance and environmental effects). Any choice that affects the scientific methodology leads either to an increase of false positives (reaching the conclusion that the activity is harmful for the environment even though it is not) or of false negatives (reaching the conclusion that the activity is not harmful even though it is). In other words, any methodological choice has important regulatory consequences. This leads inevitably to the conclusion that scientists must take into account the consequences of the methodologies they choose, while society and decision makers must be aware of the uncertainties inherent in scientific knowledge about impacts and risks (Funtowicz and Ravetz 1992).

Since the 1990s, an important field in the debates on environmental regulation has focused on the so-called precautionary principle, proposed by some environmentalists as a means to face those problems posed by scientific uncertainties regarding environmental impacts (Raffensperger and Tickner 1999). A number of agreements and international treaties have adopted this principle. However, so far no commonly accepted definition exists. One of the more popular definitions is the one to be found in the 1992 Rio Declaration on Environment and Development: "Where there are threats of serious irreversible damage, lacks of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation." Besides the discussion about its definition, there also exists a debate about when to invoke the precautionary principle, about its general meaning as well as its scope.

A Typology of Worldviews

John Dryzek and James Lester (1989) have created a typology of environmental worldviews that serves as one way of organizing the variety of problem definitions and prescriptions for regulatory policies and institutions. Six worldviews are distinguished according to their particular blend of two different dimensions: the locus of value (individuals, anthropocentric communities, or biocentric communities) and the locus of solutions (centralized or decentralized). Each worldview thus supports different policy recommendations.

The first three worldviews all agree that solutions must be centralized. First are the *Hobbesians and structural reformers*, who believe in modern liberal individualism, but argue that it must be checked by a certain degree of political centralization. This is still the dominant worldview, and most of its adherents are moderates, convinced that "more laws to regulate polluters, more funds for enforcement, and minor structural reforms" will suffice (Dryzek and Lester 1989, p. 318). Second are the *guardians*, who still value centralization, but argue that an elite group of scientific and technical experts should monopolize power. Examples include Alvin Weinberg's proposal to create a *permanent priesthood* of nuclear technologists to oversee energy systems and William Ophul's *class of ecological mandarins*. The third group of centralizers is the *reform ecologists*, who argue that ecological values must be represented in the highest echelons of government. Reform ecologists (for example, Eugene Odum, Paul Ehrlich, and Lester

Brown) are usually less concerned with the structure of political and economic institutions than with their scientifically defended ecocentric values.

The other three worldviews find the locus of solutions in decentralization. First are the *free market conservatives,* who, like Anderson and Leal, believe that government intervention in environmental problems has gone too far and self-regulating market systems can work much better. Second are the *social ecologists*, who base their decentralized vision not on the market but rather on the ideal of a cooperative community. Murray Bookchin represents the main stem of this worldview, but it also applies to ecofeminists and other groups that call for classless, stateless, and decentralized societies far removed from capitalism. Finally the *deep ecologists* take little interest in human communities (like the reform ecologists) and stress the importance of the realization of the self within the greater *Self* of the biotic community. Although it can verge on misanthropic antipolitics, deep ecology is also represented by such luminaries as Henry David Thoreau and Aldo Leopold and other insightful theorists such as Arne Naess, Bill Devall, and George Sessions.

Although not without its gaps and ambiguities, Dryzek and Lester's typology can be used as a heuristic to organize the complex and contested nature of environmental regulations. It captures the various roles that science can play (for instance, informing modest reforms or monopolizing entire discourses) according to the dominant worldview in the particular topic. It distinguishes between various forms of centralized and decentralized regulations. The typology also hints at the alternative futures that can occur as worldviews rise and fall from social and political dominance, thus leading to different regulatory mechanisms and philosophies. Finally it highlights the constructed nature of reality as participants bring different worldviews to the political agenda, which in turn opens up the dialogue over which values ought to be represented and which regulatory mechanisms can best deliver the valued outcomes.

ENVIRONMENTAL RIGHTS

Often referred to as part of the *third generation* of human rights, the concept of environmental rights is unclear in meaning and content. Environmental rights are elusive because there is no universal definition, and they are controversial because they hybridize the ecocentric perspectives of environmentalists and the anthropocentric perspectives dominant among human rights activists (Apple 2004). No binding international agreement has had environmental rights as its primary focus because such rights fail to fit neatly into either of these two groups. This fact combined with the scarcity of binding international legal instruments has prevented environmental rights from becoming international law. Nonetheless progress on defining and enforcing environmental rights continues on the international, regional, and national levels.

Background

Throughout the late-1950s and early-1960s serious environmental disasters occurred in various regions of the world: oil spills at sea (for example, the tanker *Torrey Canyon* in the English Channel in 1967), the release of toxic substances from chemical industries (such as mercury in Minamata Bay, Japan, in 1968), and nuclear disasters (for instance, the nuclear center Kytchym, in the former Soviet Union, in 1957). Such accidents, repeated over the years, demonstrated the dangers of incorporating technology into human activity without including some regulation. People also became increasingly aware of risks to human health and the environment due to high-tech industrial and agricultural activities. Emblematic of this concern was Rachel Carson's *Silent Spring* (1962), which argued the presence and persistence of toxic substances in living organisms as a consequence of the massive use of pesticides.

Legal measures to control unhealthy and dangerous activities and to protect the environment from the abuses of human intervention followed. In 1970, on the date of the first Earth Day celebration, the U.S. government enacted the National Environmental Policy Act, which submitted major development projects to environmental review. Since then laws concerning the environment have multiplied around the world.

Many in the ecological and human rights movements argued that these legal measures were insufficient to guarantee a healthy environment for present and future generations. Some proposed the proclaiming a new human right: the right to a healthy environment. This right does not fit within the category of civil and political or *first generation* rights, nor of economic, social, and cultural or *second generation* rights. For this reason environmental rights (along with others, such as rights to development) are sometimes described as *third generation* rights. Just as the first generation aspired to guarantee individual liberties, and the second equality, the third aims to guarantee solidarity across national boundaries and between present and future generations. Third generation human rights are conceived as collective rather than individual, and they tend to challenge the sovereignty of the modern nation-state.

Formulations at Different Political Levels

The appearance and development of the right to a healthy environment is traceable on three levels: global, through three world conferences on the environment organized by the United Nations; regional, through some agreements on the subject of human rights; and national, through the inclusion of environmental rights in the constitutions of some countries. (Rachel Carson had in fact proposed consideration of an amendment to the U.S. Constitution guaranteeing the right to a clean environment.)

GLOBAL. During the First World Conference on Human Development (Stockholm 1972), the Declaration of the Human Environment was approved, proclaiming the right to a clean environment for the first time at the international level: “Man has the fundamental right to freedom, equality, and adequate conditions of life, in an environment of a quality that permits a life of dignity and well-being, and he bears a solemn responsibility to protect and improve the environment for the present and future generations” (principle 1). This was followed ten years later by the U.N. World Charter for Nature (1982), which proclaimed that, in recognition of the fact that humankind is part of nature, “Nature shall be respected and its essential processes shall not be impaired” (principle 1).

Twenty years after the Stockholm meeting the World Conference on the Environment and Development, known as the Earth Summit, took place in Rio de Janeiro. One of the documents approved at this conference was the Declaration of Rio, which affirmed: “The right to development must be fulfilled so as to equitably meet developmental and environmental needs of present and future generations” (principle 3). The declaration accepted the idea of sustainable development, a concept that had been defined by the World Commission on the Environment and Development in *Our Common Future* (1987) as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” The 2002 Johannesburg Summit unfortunately had neither the level of state participation nor world impact of the two prior conferences.

REGIONAL. Environmental rights are mentioned more explicitly at the regional level. In 1981 the African Charter on Human and People’s Rights was approved in Banjul, Gambia, West Africa. The charter states: “All peoples shall have the right to a general satisfactory environment favorable to their development” (article 24). Similarly the additional protocol to the American Convention on Human Rights in the area of economic, social, and cultural rights, the Protocol of San Salvador (1988), affirms in article 11 that (1) Everyone shall have the right to live in a healthy environment and to have access to basic public services; and (2) The States’ Parties shall promote the protection, preservation, and improvement of the environment.

In Europe the 1950 European Convention on Human Rights did not include environmental rights. Nevertheless the European Tribunal on Human Rights has included demands for the protection of the environment in some of the articles from the European Convention on Human Rights, such as the right to private and family life (article 8) and the right to information (article 11).

Also in Europe another important advance came in the form of the Aarhus Convention on Access to Information, Public Participation in Decision-making, and Access to Justice in Environmental Matters. Negotiated by the UN Economic Commission for Europe (UNECE), it was adopted in 1998 and implemented on October 30, 2001. Its first article expresses the object of the convention: “In order to contribute to the protection of the right of every person of present and future generations to live in an environment adequate to his or her health and well-being, each Party shall guarantee the rights of access to information, public participation in decision-making, and access to justice in environmental matters in accordance with the provisions of the Convention.”

NATIONAL. At the national level are many constitutions passed in the seventies and eighties that include a mention of human rights to a sound environment. But those references do not specify jurisdictional guarantees, so some authors deny that they are real rights and consider them only as guidelines for the public powers.

Characteristics of Environmental Rights

There is no consensus on how to define environmental rights. First, it is difficult to define the environment: Is it physical, social, cultural, or all of these? Does it pertain only to nature or also to urban spaces, workplaces, and homes? Second, there is debate as to whether the holders of these rights are individuals, contemporary human communities, future generations, or even ecosystems. Third, there is no agreement about whether environmental rights can be exercised before a juridical organ or simply constitute a mandate to public powers that they develop policies to protect the environment. Finally, doubts arise as to whether environmental rights can also involve duties, as has been proclaimed in some constitutions.

Environmental rights present a challenge to the concept of human rights as they are formulated in the early-twenty-first century. Seriously considering the grant of these rights questions the modern world model that promotes unlimited growth for the rich and permits unjust environmental burdens on the poor, both within countries as well as among different nations. The concept may even be interpreted as challenging the assumed hierarchy of humans over nature that underlies so much economic and social activity.

Environmental rights have a double dimension: juridical and political. The strictly juridical can be narrowed down to a set of powers that individuals or communities can exercise: the right to participate in the making of development policies, the right to information on environmental matters, the right to access tribunals in order to make demands in matters related to the environment, and the right to environmental education. In the United States a number of parties have sued multinational corporations for environmental rights abuses under a federal statute, the Alien Tort Claims Act (ATCA). While the ATCA has been used successfully to prosecute first generation human rights abuses (torture, for example), it has not provided a legitimate basis for environmental rights claims. Environmental wrongs resulting in human harm are not interpreted as violations of international law in the early-twenty-first century (Apple 2004). The applicability of ATCA to non-state actors such as corporations also remains unclear.

The political dimension of environmental rights has both a national and international manifestation. At the national level it involves assuring that political leaders take action to protect and promote the environment. At the international level it extends to the set of endeavors that states undertake in order to achieve sustainable and shared development for the entire world. Environmental rights not only aspire to preserve nature, but also to achieve the conditions necessary for a more just and healthy life for all persons and all peoples on Earth.

Such broad ambitions, however, contribute to the ambiguity of the concept and hinder attempts to realize these goals in particular contexts. Jorge Daniel Taillant (2004) argues that it is unclear whether the term environmental rights refers to human rights with respect to the environment, the human obligation to respect nature for its own sake, or something else. He contends that a conceptual framework based on development and more traditional forms of human rights, rather than environmental rights, can bring better practical results.

Assessment

Any assessment of environmental rights in relation to science, technology, and ethics must recognize the tenuous status of even first and second generation human rights. The Universal Declaration of Human Rights itself is simply a declaration that establishes a common standard, urging individuals and organizations to strive to promote respect for human rights and freedoms. However there do exist many environmental treaties that have well-defined, binding clauses, such as the Law of the Sea Treaty. The extent to which such environmental treaties influence the governance of science and technology is a subject deserving of further examination and development.

EPIDEMIOLOGY

Epidemiology is the study of the frequency, distribution, and determinants of disease in humans. Its aim is the prevention or effective control of disease. The term originated in the study of epidemics, rapidly spreading diseases that affect large numbers of a population (from the Greek *epi* meaning upon and *demos* meaning people). Epidemiology touches on ethics in two key areas: The need for competent and honest use of its information, and questions of responsibility raised by the global picture it presents of the health of humanity.

Speculation about the nature and causes of disease dates back to antiquity. The formal history of epidemiology, like that of statistics, begins with the systematic official recording of births and deaths in the seventeenth century, proceeding to the quantitative investigation of diseases with the emergence of scientific medicine in the nineteenth. Based on the theory of probability, statistical inference reached maturity in the early-twentieth century and gradually spread into a wide range of disciplines. Its application to medical research gave rise to biostatistics and contemporary epidemiology.

There is no clear division between the two fields. Epidemiology focuses more on public health issues and the need for valid population-based information, but it uses the theory and methods of biostatistics. Its practitioners tend to be individuals with primary interest and training in medicine or a related science, whereas biostatisticians come from mathematics. They work together as members of the medical research team, in the dynamic context of scientific advances and the latest information technology.

Modern Epidemiology

The mathematical approach to medicine, with the methodical tabulation of patient information on diseases and treatment outcomes, was introduced in the 1830s by the French physician Pierre C. A. Louis (1787–1872). As a notable result of his researches in Paris hospitals, his Numerical Method revealed the uselessness of bloodletting. Inspired by Louis, his British student William Farr (1807–1883) became the central figure in the development of vital statistics in England and the use of statistics to address public health concerns. Farr worked with John Snow (1813–1858), the physician who investigated the cholera epidemic sweeping through London in 1854. Snow's finding that the *cholera poison* was transmitted in contaminated water from the Broad Street pump was a milestone event in epidemiology and public health. Farr also provided guidance in statistics for Florence Nightingale (1820–1910) to support her work in hospital reform.

The existence of microbes was discovered in the late-seventeenth century by the Dutch lens grinder Antonie van Leeuwenhoek (1632–1723), who saw "animalcules, more than a million for each drop of water" through his microscope (Porter 1998, p. 225). The role of germs as causes of disease was established by Louis Pasteur (1822–1895), French chemist and founder of microbiology. Pasteur invented methods to isolate and culture bacteria, and to destroy them in perishable products by a heat treatment now called *pasteurization*. He found that inoculation by a weakened culture provided *immunity*, protection against the disease. This explained the earlier discovery of the English physician Edward Jenner (1749–1823) that vaccination with the milder cowpox protected against smallpox. (Vaccination comes from the Latin *vacca* meaning cow.) The German physician Robert Koch (1843–1910), founder of bacteriology, further developed techniques of isolating and culturing bacteria. He identified the germ causing anthrax in 1876, tuberculosis in 1882, and cholera in 1883. He contributed to the study of other major diseases, including plague, dysentery, typhoid fever, leprosy, and malaria.

Extensive public health measures of hygiene and immunization, along with the introduction of the sulfonamide drugs in the late 1930s and antibiotics in the 1940s, brought most infectious diseases under control. Attention turned to chronic diseases, by then the leading causes of morbidity and mortality—multicausal diseases with a long latency period and natural course. Two historic discoveries of the mid-twentieth century were tobacco use as a cause of lung cancer, and risk factors for heart disease. From the study of infectious and chronic diseases epidemiology has evolved into a multidimensional approach, defined by disease, exposure, and methods, with focus on new developments in medical science. Its many specialties include cancer, cardiovascular, and aging epidemiology, environmental, nutritional, and occupational epidemiology, clinical and pharmaco-epidemiology, and molecular and genetic epidemiology. With the sequencing of the human genome,

TABLES 1–3

Table 1: Some Basic Terms of Epidemiology

Measures of Morbidity and Mortality

- PREVALENCE (Burden of disease): Number of existing cases of a disease at a given point in time divided by the total population.
- INCIDENCE (Cumulative incidence, risk): Number of new cases of a disease during a given time period divided by the total population at risk.
- INCIDENCE RATE (Incidence density): Number of new cases of a disease during a given time period divided by the total person-time of observation.
- PERSON-TIME (usually person-years): Total disease-free time of all persons in the study, allowing for different starting dates and lengths of time observed.
- CRUDE DEATH RATE: Number of deaths during a given time period divided by the total population.
- STANDARDIZED DEATH RATE: Crude death rate adjusted to control for age or other characteristic to allow valid comparisons using a standard population.

Example of Age-Adjusted Death Rates (2000 US Standard Population)

	Alaska	Florida	United States
Crude death rate/1,000 population (in 2000):	4.6	10.3	8.9
Percent of population over age 65 (in 2000):	5.7	17.6	12.4
Age-adjusted death rate/100,000 population (avg. for 1996–2000):			
Breast cancer	25.2	25.6	27.7
Prostate cancer	24.2	28.4	32.9

Prevalence, incidence, and death rates are expressed in units of a base (proportion mulitplied by base), usually per 1,000 or 100,000 population.

Table 2: Case-Control Study of Lung Cancer and Smoking

Smokers		Lung Cancer	Controls	Odds Ratio (ad/bc)
Males:	**Yes**	647 (a)	622 (b)	14.0
	No	2 (c)	27 (d)	P<.00001
	Total	649	649	
Females:	**Yes**	41 (a)	28 (b)	2.5
	No	19 (c)	32 (d)	P<.05
	Total	60	60	

Historic study showing the association between cigarette smoking and lung cancer. No association would correspond to an odds ration of 1. P-values obtained by chi-square test for 2x2 tables.

SOURCE: Data from Doll and Hill (1950).

Table 3: Cohort Study of Risk Factors for Coronary Heart Disease: Systolic Blood Pressure

Systolic BP (mmHg)	Age 35–64 Men	Age 35–64 Women	Age 65–94 Men	Age 65–94 Women
<120	7	3	11	10
120–139	11	4	19	13
140–159	16	7	27	16
160–179	23	9	34	15
>180	22	15	49	31
Total Events	516	305	244	269

Average annual incidence per 1,000 persons of coronary heart disease, by systolic blood pressure. Example of relative risk (RR): For men (35-64), systolic BP>180 relative to <120 mmHg, RR=22/7=3.1. No association would correspond to RR=1. Results of 30-year follow-up in historic Framingham Heart Study of risk factors for cardiovascular disease.

SOURCE: Adapted from Stokes et al. (1989).

genetics is assuming increasing importance across all lines of inquiry. In its principles of studying human populations, epidemiology is related to psychology, sociology, and anthropology, all of which employ statistical inference.

Basic Concepts and Methods

Epidemiology may be *descriptive* or *analytic*. Descriptive epidemiology reports the general characteristics of a disease in a population. Its methods include *case reports*, *correlational studies* (to describe any association between potential risk factors and disease in a given database) and *cross-sectional surveys* (to determine prevalence of a disease and potential risk factors at a given point in time). Analytic epidemiology uses *observational* and *experimental* studies. The latter are *clinical trials* to test the effectiveness of interventions to treat or prevent a disease. But experimentation on humans is not ethically feasible for studying causes of disease. Observational research designs are thus the primary tools of epidemiology, the main types being *case-control* and *cohort* studies. After definition of some basic terms, these are discussed further below.

TABLE 4

Interpreting a Statistical Association

Possible Reasons for an Observed Statistical Association

1. CHANCE: This is precisely the meaning of P-value, the probability that the observed outcome is due to chance.
2. BIAS: Systematic errors that distort the results, such as selection bias, recall bias, and observation bias.
3. CONFOUNDING: There is an extraneous, confounding variable (perhaps as yet unknown) that is related to the risk factor being studied and is an independent risk factor for the disease.
4. CAUSE-AND-EFFECT: The risk factor in the observed association is a cause of the disease.

SOURCE: Courtesy of Valerie Miké.

Careful study is required to assess potential biases and confounding variables. General guidelines for establishing causality are provided by Hill's Criteria (Table 6).

MEASURES OF MORBIDITY AND MORTALITY. Some basic concepts of epidemiology are listed in Table 1. It is important to distinguish between the *prevalence* of a disease and its *incidence*. Prevalence signifies the amount of disease present at a point in time, such as the proportion of people with adult-onset diabetes in the United States on January 1, 2005. Incidence refers to new cases diagnosed during a given period of time, such as the proportion of U.S. adults diagnosed with diabetes in 2005. The denominator of *incidence rate* is *person-time*, a useful concept that allows for inclusion of subjects with different starting dates and lengths of time observed in a study. Causes of a disease can be investigated by observing incidence in a well-defined group of subjects without the disease, and patterns of disease incidence can be compared over time or populations.

Mortality is measured in terms of *crude death rate*, the actual proportion observed, or the *standardized death rate*, which involves adjustment for some characteristic. The example shows *age-adjusted* cancer death rates for the states of Alaska and Florida. Alaska has a much lower crude death rate than Florida, but its population is much younger. Both breast and prostate cancer are associated with older age, but after age-adjustment the two states are seen to have similar death rates for these two sites, both lower than the national average. The adjusted figures are meaningless in themselves, but provide for valid comparison of rates across groups and time. U.S. cancer death rates have been adjusted using the 2000 U.S. age distribution to make them comparable back to 1930 and ahead to the future.

OBSERVATIONAL RESEARCH DESIGNS: CASE-CONTROL AND COHORT STUDIES. A case-control study is *retrospective:* It identifies a group of people with the disease (cases) and selects a group as similar as possible to the cases but without the disease (controls). The aim is to determine the proportion of each group who were exposed to the risk factor of interest and compare them. Table 2 shows results of the case-control study of lung cancer and smoking reported in 1950 by Sir Richard Doll (b. 1912) and Sir Austin Bradford Hill (1897–1991), British pioneers of epidemiology and biostatistics. They identified 649 men and sixty women with lung cancer in twenty London hospitals and matched them with controls of the same age and sex but without lung cancer. The information they collected on all participants included their smoking history. The observed association, measured by the so-called *odds ratio* (the odds of smoking in cases over the odds of smoking in controls), was clearly statistically significant.

A cohort study is usually *prospective*. (It may be *historical*, if based on recorded past information.) It identifies a large group (cohort) of individuals who do not have the disease but for whom complete information is available concerning the risk factor(s) of interest; the cohort is then observed for the occurrence of the disease. A noted cohort design was the Framingham Heart Study, initiated by the U.S. Public Health Service in 1948 to identify risk factors for heart disease. Over 5,000 adult residents of Framingham, Massachusetts, men and women with negative test results for cardiovascular disease, agreed to join the study and undergo repeat testing at two-year intervals. The age and test measures at the start of each two-year period were used to classify subjects. Results of a thirty-year follow-up evaluation (part of a multivariate analysis including other risk factors and cardiovascular outcomes) are shown in Table 3, demonstrating a strong association between systolic blood pressure and incidence of coronary heart disease. Other suitable groups for cohort studies are members of professional groups, like doctors and nurses.

There are advantages and disadvantages pertaining to each research design, and the choice depends on the circumstances of the scientific question of interest. Any observed association then requires careful interpretation.

Association or Causation?

Possible reasons for an observed statistical association are listed in Table 4. *Chance* is simply the meaning of

TABLE 5

Koch's Postulates for Establishing the Causes of Infectious Diseases, with Molecular Update

Koch's Postulates	Molecular Koch's Postulates*
1. The microorganism should be found in all cases of the disease in question, and its distribution in the body should be in accordance with the lesions observed.	1. The phenotype or property under investigation should be significantly associated with pathogenic strains of a species and not with nonpathogenic strains.
2. The microorganism should be grown in pure culture in vitro (or outside the body of the host) for several generations.	2. Specific inactivation of the gene or genes associated with the suspected virulence trait should lead to a measurable decrease in pathogenicity or virulence.
3. When such a pure culture is inoculated into susceptible animal species, the typical disease must result.	3. Reversion or replacement of the mutated gene with the wild type gene should lead to restoration of pathogenicity or virulence.
4. The microorganism must again be isolated from the lesions of such experimentally produced disease.	

*In addition, guidelines for establishing microbial disease causation in terms of the prevalence of the nucleic acid sequence of a putative pathogen in relation to disease status are given in the third column of the table from which this is taken.

SOURCE: Brooks et al. (2001), p. 134.

Proposed in 1884 by Robert Koch for bacteria, the original wording has been modified to include other microbes. Further versions use molecular biology as a tool to associate microbial agents with disease. Table is adapted from a leading textbook of medical microbiology.

the P-value, the probability that the association is due to chance. *Bias* refers to systematic errors that do not cancel out with larger sample size, but distort the results in one direction. For example, in a case-control study patients with the disease may be more likely to recall exposure to the risk factor than the controls, leading to *recall bias*. Bias is a serious problem in observational studies and needs to be assessed in the particular context of each research design. *Confounding* is the effect of an extraneous variable that is associated with the risk factor, but is also an independent risk factor for the disease. For example, an association between birth rank and Down's syndrome, the genetic disorder Trisomy 21 (an extra copy of chromosome 21) does not imply causality; the confounding variable is maternal age, which is associated with birth rank and is a known risk factor for the disease. There may also be confounding variables as yet unknown, but their potential effects must always be considered.

The establishment of causation is a long-debated problem in the philosophy of science. In the practical field of medicine, where life-and-death decisions must be made every day, there are guidelines to help assess the role of agents in the etiology of disease. When microbes were being identified as causes of devastating diseases in the late-nineteenth century, Robert Koch formulated postulates to prove that a particular microbe causes a given disease. Anticipated by his teacher Jacob Henle (1809–1885), these are also called Henle-Koch Postulates. They are shown in Table 5, along with current updates using molecular biology. The original version claims only necessary causation, not sufficient; the microorganism needs a *susceptible* host. Even more general, the molecular guidelines are expressed in terms of statistical association. But they are the organizing principle in contemporary studies of microbial etiology, crucial for the identification of newly emerging pathogens that may pose serious threats to public health.

Guidelines for establishing causality in observational studies are listed in Table 6. Formulated by Sir Austin Bradford Hill, they are based on criteria employed in the 1964 U.S. Surgeon General's Report to show that smoking causes lung cancer. Applied in a wider context, they are to be used primarily as an aid to exploration. In general there is no necessary or sufficient condition to establish causality from an observed association. Such conclusions result from a consensus of the scientific community.

Epidemiology and Ethics

The complex, probing methods of epidemiology yield tentative, partial, often conflicting results, replete with qualifications. Taken out of context by interest groups or the media, they can mislead and have harmful consequences. Their correct use requires professional competence and integrity. But beyond these issues of immediate concern, epidemiology plays a larger role. With its adjusted measures allowing comparison of health patterns over space and time, it provides a quantitative aerial video of the globe. Some of the images it presents are troubling.

TABLE 6

Hill's Criteria for Establishing Causality in Observational Studies

Aspects of Association to Consider

1. STRENGTH: Stronger associations more likely to be causal.
2. CONSISTENCY: Association is observed repeatedly in different populations under different circumstances.
3. SPECIFICITY: Disease outcome is specific to or characteristic of exposure.
4. TEMPORALITY: Exposure precedes disease.
5. BIOLOGIC GRADIENT: Monotone dose-response relationship (increase in exposure corresponds to increase in disease).
6. PLAUSIBILITY: Causal hypothesis is biologically plausible.
7. COHERENCE: Causal interpretation does not conflict with what is known about the natural history and biology of the disease.
8. EXPERIMENTAL EVIDENCE: Removal of putative cause in an intervention or prevention program results in reduction of disease incidence and mortality.
9. ANALOGY: Drug or chemical structurally similar to a known harmful agent may induce similar harmful effects.

SOURCE: Hill (1965).

Formulated in 1965 by Sir Austin Bradford Hill, these are very general, tentative guidelines, with numerous exceptions and reservations. Aside from temporality, which may be considered part of the definition of causation, there is no necessary or sufficient criterion for establishing the causality of an observed association.

There are now more obese than undernourished people living on earth, and their number is increasing rapidly in developing nations. According to a 2000 estimate of the World Health Organization (WHO), there are 220 million adults with Body Mass Index (BMI) <17, classified as undernourished, and over 300 million with BMI > 30, defined as obese. (BMI is weight in kilograms divided by height squared in meters.) This global epidemic of obesity, called *globesity*, brings with it the related conditions of diabetes, hypertension, and heart disease, and the problem is equally serious for children.

The harmful effects of tobacco have been known for half a century, and while the prevalence of smoking has been slowly declining in most industrialized nations, it has been rising steadily in the developing world. It is estimated that the number of smoking-related premature deaths worldwide, 5 million in 2000, will rise to 10 million per year by 2030, with 70 percent occurring in developing countries. Tobacco use will kill more people than the combined mortality due to malaria, pneumonia, tuberculosis, and diarrhea.

In the area of infectious diseases, after decades of exuberant optimism reality set in with the appearance of acquired immune deficiency syndrome (AIDS) in the 1980s. Homo sapiens lives in a sea of microbes and will never have total control. Vigilance for the emergence of disease-causing strains must be the aim, to detect outbreaks, identify pathogens and their mode of transmission, and seek control and prevention. Knowing the cause may not eliminate the disease, even when possible in principle, if (as with smoking) it hinges on human behavior. AIDS, for example, is preventable. Ongoing threats include new diseases from mutation or isolated animal reservoirs (Ebola, West Nile, severe acute respiratory syndrome [SARS]), resurgence of older strains, drug-resistance, targeted release through bioterrorism, and rapid spread through global travel.

At a WHO conference held in Geneva in November 2004, experts issued an urgent appeal for greater international cooperation, and called on governments to make pandemic preparedness part of their national security planning. Of particular concern was the new bird influenza strain A(H5N1), which could mutate and cause a pandemic on the scale of the influenza epidemic of 1918 that killed more than 20 million people. It is estimated that a new pandemic virus could spread around the world in less than six months, infecting 30 percent of the population and killing about 1 percent of those infected. The drug industry would have to prepare billions of doses of the influenza vaccine within weeks of an outbreak to halt its course. There are questions of what could possibly be feasible technologically, the huge investment needed, and the driving force to motivate the effort when it cannot be a matter of fiscal gain.

In March 2005 the British medical journal *Lancet* published four articles reporting on the appalling state of global infant health care. Four million babies die each year in the first month of life, nearly all in low- and middle-income nations. The highest numbers occur in south-central Asian countries, while the highest rates are generally in Sub-Saharan Africa. It is estimated that three-quarters of these deaths could be prevented with low-lost interventions. A similar number of babies are stillborn and 500,000 mothers die from pregnancy-related causes each year. The moral implications of this public health tragedy are overwhelming.

The problems humanity faces at the start of the twenty-first century are inseparable from dominant worldviews and the interplay of powerful economic and political forces. Epidemiology provides health-related information as a guide to action. Its proper use is an essential component of the *Ethics of Evidence*, proposed for dealing with the uncertainties of medicine in the framework of contemporary culture (Miké 1999, 2003).

The *Ethics of Evidence* calls for integrating the best evidence of all relevant fields to promote human well-being, anchored in an inescapable moral dimension. Looking to the future, it urges all to be aware, to be informed, and to be responsible.

EQUALITY

Equality is a key concept in both ethics and politics, one that influences personal and public self-understandings, and provides guidelines for relations between individuals and for state action. Insofar as scientific knowledge and technological change can either diminish or increase inequalities, and scientific research influences the understanding of what it means to be human, issues of equality exercise important ethical influences on the uses of science and technology. The ideal of equality also presents a special challenge within science and engineering, insofar as peers are supposed to be treated as equals at the same time that expertise makes claims to special influence.

Background

It is an empirical given that human beings are in many respects unequal. They are of different shapes, sizes, and sex; different genetic endowments; and different abilities. From the earliest age, some children manifest gregariousness, others pugnacity, some pleasant dispositions, others dullness and apathy. Take almost any characteristic—health, longevity, strength, athletic prowess, sense of humor, ear for music, intelligence, social sensitivity, ability to deliberate or do abstract thinking, sense of responsibility, self-discipline, or hormonal endowment (for example, levels of testosterone and endorphins)—and there are major differences among humans. Yet it is one of the basic tenets of almost all contemporary moral and political theories that humans are in some fundamental respect equal, and that this truth should be reflected in economic, social, and political structures.

Historically this was not always the case. In Plato's *Republic* Socrates argues for equal opportunity for women and men among the guardians, but some of his interlocutors contest the possibility of this ideal. Aristotle rejects it outright, holding to strong differences between males and females, free men and slaves. "It is manifest that there are classes of people of whom some are freeman and others slaves by nature, for these slavery is an institution both expedient and just" (*Politics* 1.5.1255). Indeed, for many Greeks, Romans, and premodern cultures, the primary challenge was not to treat equals as equal, but to avoid treating unequals as equals.

In the Jewish, Christian, and Islamic traditions all humans are seen as possessing equal worth because they are created in a common relation to God. In Hinduism and Buddhism people have unequal worth based on their karmic status, that is, depending on how well they have carried out their *dharma* (duty), but they have equal opportunity to progress to higher modes of existence and eventually to attain nirvana.

With the Enlightenment equality became a political ideal. In the words of the U.S. Declaration of Independence (1776): "We hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty and the pursuit of Happiness.—That to secure these rights, Governments are instituted among Men, deriving their just powers from the consent of the governed." The first article of the French Declaration of the Rights of Man and of the Citizen (1789) likewise stipulates: "Men are born and remain free and equal in rights. Social distinctions may be founded only upon the general good." As has been often noted, however, there is a tension between the ideals of liberty and equality. Inequality is not only produced by inheritance and traditional social orders; it is also produced anew by liberty, as people freely distinguish themselves from each other. Thus one is forced to inquire more precisely what kind of equality ought to be protected.

In relation to what should be "equalized" and the arguments that ground various egalitarian claims, one discovers both limited consensus and a plethora of competing ideas with regard to citizenship, law, opportunity, welfare, resources, opportunity, and capabilities. For instance, there is a measured consensus in support for equality in the areas of civil liberties, political participation, and opportunity. In the twentieth century, however, levels of social and welfare equality as a base for the exercise of individual liberty became contentious in the extreme. Moreover, together with debates between egalitarians about which version of egalitarianism is correct, there exists an even more fundamental argument between egalitarians and nonegalitarians, who question the moral significance of equality.

Conceptual Analysis

The first step in addressing such debates is to analyze more carefully the concept of equality. To begin, it is important to note that equality is sometimes interpreted as equity or fairness, but the two concepts are distinct. Whether or not and in what ways treating people as equals is equitable or fair is subject to argument.

Equality involves a triadic relationship. A is equal to B with respect to some property P. Except with abstract ideas, such as numbers, there is no such thing as equality per se. Two objects are always different in some respect—even two Ping-Pong balls are made up of different pieces of plastic and exist in different places. Two things A and B, if they are equal, are also equal with respect to something. Two trees are of equal height, two baseball players have equal batting averages, two workers have produced the same amount of widgets in the same time frame, and so forth. So descriptive equality always must answer the question, "Equal in what respect?"

When equality has a normative dimension, the relationship is quadratic: If A and B are equal with respect to the normative (or merit-ascribing) property P, then A and B deserve equal amounts of dessert D. Two persons A and B who are equal with respect to the law deserve equal treatment by the law. Two scientists or engineers who are equally competent professionals and performing equal services deserve equal compensation. Determining equality with respect to P in such cases is, of course, difficult.

Normative egalitarian theories fall into two types: *formal* and *substantive*. A formal theory states a formula or policy but includes no specific content. A substantive theory identifies a criterion or metric by which egalitarian policies are to be assessed.

Aristotle's notion that "injustice arises when equals are treated unequally and also when unequals are treated equally" (*Nicomachean Ethics* 5.3.23–24) is the most common statement of a formal normative theory. If two things are equal in some respect, then if one of them is treated one way based on that respect, it is wrong to treat the other differently based on that same respect. When applied to distributive justice, the formula of formal equality stipulates giving equals equal shares and unequals unequal shares based on some criterion left unspecified. Formal equality is simply the principle of consistency, and Aristotle, who articulated it, was substantively what in the early twenty-first century would be called an inegalitarian, because he defended class, racial, and sexual inequalities.

Substantive normative theories of equality either identify a criterion in the formula for equality in relation to which people should be treated equally or simply assume that all people should receive equal shares of some good(s). But because people are unequal in many respects, the first question concerns which respects are morally indefensible. One of the major controversies of the modern period has been the degree to which class, wealth, race, and sexual differences are legitimately recognized as bases for inequalities in various treatments.

A second question concerns whether the state should do anything to delimit inequality or promote equality. Socialists and liberals, for instance, tend to be interventionists, calling for government action to redistribute goods when a moral case can be made for mitigating the effects of inequality. Conservatives and libertarians tend to limit the governmental role, leaving such matters to individual or voluntary action.

Debating Substantive Equality

Returning to the first question, a few idealists, such as the radicals of the French Revolution, have called for the abolition of virtually all distinctions between persons. Graccus Babeuf's "Manifesto of the Equals" (1796) suggested even the elimination of the arts, because they reveal the difference between a Rembrandt or Michelangelo and everyone else. Sports and academic grades would have to be abolished for the same reason.

Most egalitarians nevertheless agree that not all inequalities are morally repugnant. Candidates for those sorts of inequalities that are morally wrong and thus subject to correction include primary goods, resources, economic benefits, power, prestige, class, welfare, satisfaction of desire, satisfaction of interest, need, and opportunity. Some egalitarians emphasize great differences in wealth as the most morally repugnant item and propose various redistribution policies such as the regressive income tax. Other egalitarians emphasize political power as the item to be equalized.

Certainly there is no doubt that the ideal of equality has inspired millions to protest undemocratic forms of government, monarchies, oligarchies, despotisms, and even republicanism. The sense that each individual is of equal worth has been the basis for rights claims from the English Civil War (1642–1648) to women's suffrage (granted in the United Kingdom, 1918; United States, 1920) and the civil rights movements in the United States (1960s) and South Africa (1980s). Who is not moved by the appeal of Colonel Thomas Rainsborough of Oliver Cromwell's Parliamentary Army, petitioning in 1647 for political equality?

> I think that the poorest he that is in England hath a life to live, as the greatest he; and therefore truly, sir, I think it's clear, that every man that is to live under a government ought first by his own consent to put himself under that government; and I do think that the poorest man in England is not at all bound in a strict sense to that government that he hath not had a voice to put himself under. (Putney debates, October 29, 1647)

But the ideal of equality has dangers too. The French aristocrat Alexis de Tocqueville, in his visit to the United States in the 1830s, was amazed at Americans' passion for and preoccupation with equality. He saw in it both the promise of the future and a great danger. Its promise lay in the prospect of full citizenship, political participation, and economic equality. Its danger lay in the tendency to mediocrity and the envy of those who stood out from the crowd.

Contemporary egalitarians most commonly divide on whether *resources* or *welfare* is the primary good to be equally distributed. Resource egalitarians, such as John Rawls, Ronald Dworkin, and Eric Rakowski, hold that in societies of abundance human beings are entitled to minimally equal shares of the resources or opportunities. Welfare egalitarians, such as Kai Nielsen, R. M. Hare, and Richard Norman, go further and maintain that in such societies people should receive equal welfare, interpreted in terms of fulfillment, outcomes, or preference satisfaction.

The strongest pro-equality consensus concerns equality of opportunity, of which there are two versions. The first is weak equal opportunity (sometimes called "formal equal opportunity"), which holds that offices should be open to talent. This was classically set forth by Plato and in postrevolutionary France by Napoleon Bonaparte, who chose officers not by class but by ability (''*la carriere ouverte aux talents*'' [the tools to him that can handle them]) It is meritocratic equal opportunity, but does not address the advantages people have because of natural or family resources, thus leaving the matter of initial starting points untouched.

The second is strong equal opportunity (sometimes called "substantive equal opportunity"), which holds that individuals ought to have equal life chances to fulfill themselves or reach the same heights. It calls for compensation for those who had less fortune early in life to bring them to the level of those who had advantages. This kind of equal opportunity would support affirmative action programs and other compensatory policies. At the extreme, such equal opportunity would have to result in groups succeeding in obtaining coveted positions in proportion to their makeup in the population. Insofar as equal opportunity would be equivalent to equal outcomes, it might be called "superstrong equal opportunity."

Justifying Equality

One important theoretical issue in the debate over equality concerns whether or not equality of whatever substance is an intrinsic or an instrumental good. Thomas Nagel (1979), for instance, after making the distinction, affirms its intrinsic value for providing an independent reason to favor economic equality as a good in its own right.

Even more strongly, Christopher Jencks, in *Inequality: A Reassessment of the Effect of Family and Schooling in America* (1972), a report on U.S. education, maintains that "for ... a thoroughgoing egalitarian, inequality that derives from biology ought to be as *repulsive* as inequality that derives from early socialization" (p. 73). And Richard Watson (1977) argues that equality of resources is such a transcendent value, at least for many purposes, that if equal distribution of food were to result in no one getting enough to eat, this annihilation of the human race should nevertheless be chosen rather than an unequal distribution.

By contrast, it can be argued that equality is not a value in itself but only in relation to its potential effects. Utilitarians commonly argue that total happiness in a society is best maximized by means of equality. And although economists often argue that certain kinds of equality are in the interest of market efficiency, they also criticize efforts to achieve strong equality as themselves being too costly for the marginal utility they may introduce.

Science, Technology, and Equality

As science and technology have become increasingly important goods, inequalities in distribution within and between nations have become public issues. Indeed, scientific exchanges and communications technology, by making people more aware of disparities, intensify the discussion. Under appropriate circumstances, the same scientific and technological activities can also serve as means for the more effective promotion of equality. Ethical and political issues arise in relation to considerations of the extent to which this may be appropriate or feasible.

During the latter third of the twentieth century, as extensions of the civil rights and women's movements, equality within science and engineering became topics of intense debate. What was the cause of the underrepresentation of minorities and women in such sciences as physics or in engineering as a whole? To what extent was this the result of natural differences in interest or ability, or of inequality in access and opportunity?

During this same period scientific research, while not rejecting numerous well-recognized differences between individuals, tended to challenge if not minimize their importance. For instance, genetics points to minimal differences not only between races but also between the sexes, and even between human beings and some higher animals. What significance, if any, does this have for the egalitarian versus libertarian debate? On the one hand, it might well be argued that egalitarianism is so well established at the genetic level that nothing more need be done. On the other, it could also be argued that basic genetic equality is grounds for a more vigorous promotion of social equality.

Finally, increasing possibilities for the technological manipulation of human physiology open doors to radically new forms of the promotion of equality. Should science be used to alter individual genetic endowments through genetic modification? Even before such powers become generally available, it is already known that when parents have the power to choose the sex of their children, there exist strong tendencies in some cultures to choose males over females, thus creating a new kind of radical sexual equality. Moreover, the use of plastic surgery, performance-enhancing drugs, and eventually genetic engineering may be able to undermine inequalities among the gifted and the nongifted in many areas of physical appearance, athletic ability, and perhaps mental achievement. In such cases there may be dangers not only in the top-down or government-sponsored promotion of equality but even in the bottom-up initiatives of individuals practicing personal liberties. The decentralization of scientific and technological powers may alter the theory and practice of equality in unexpected ways.

Finally, ideals of equality pose challenges for relations between democratic practice and scientific or technical expertise. To what extent are scientists and engineers properly to be given special influence in decisions regarding such issues as the control of nuclear weapons, environmental pollution, or global climate change? Is technocracy an antiegalitarian danger in an economy that is dependent on scientific and engineering expertise? Such questions constitute important dimensions of any general reflection on science, technology, and ethics.

ERGONOMICS

Ergonomics (used by many interchangeably with such terms as human factors, human engineering, engineering psychology, and the like) can be thought of as the field in which the social and biological sciences are applied to various problems related to the use of products, equipment, or facilities by humans in the performance of specific tasks or procedures in a variety of natural and artificial environments. Ergonomics attempts to evaluate and design the things people use, in order to better match their capabilities, limitations, needs, or physical dimensions (Sanders and McCormick 1993). General elements of the ergonomics field may include the study of humans as (technology-based) system components, design of human-machine interfaces, and consideration of the health, safety, and well-being of humans within a system. Specific areas of study may examine human sensory processes and information processing or anthropometric data to allow professionals in this field to design more effective displays or controls for an engineered system.

Examples

There are many examples of the kinds of successes that the ergonomics field has achieved over the years. As the military is one of the primary users of ergonomic advances, the evolution of military equipment serves as an excellent example of how ergonomics has changed the way things are. The development of the infantry helmet from a shallow "steel pot" to a protective device fabricated from advanced materials formed into a highly functional shape demonstrates the efficacy of ergonomic design.

Ergonomic advances are, by no means, limited to the military. The changes over the years in consumer products such as snow shovels, electric razors; or even more recently, cellular telephones establish the role of human factors in people's everyday lives.

Background

The term *ergonomics* is a combination of the Greek *ergon*, work, and *nomos*, law. The term was created in 1857 by the Polish scientist Wojciech Jastrzebowski (1799–1882) as a name for the scientific study of work. More than a century earlier, however, the Italian physician Bernardino Ramazinni (1633–1714) had initiated the study of work-related illness in the second edition of his *De Morbis Artificum* (1713). And it was not until a century later, in 1952, that the name was given official status in the formation of the British Ergonomic Society.

In the United States, the development of the principles of scientific management by Frederick W. Taylor (1865–1915) and his followers Frank Gilbreth (1868–1924) and Lillian Gilbreth (1878–1972) initiated similar research. It was out of this tradition that the Human Factors Society was founded in 1957. What began as research on work in the civilian sector became during the 1950s and thereafter heavily associated with the military, especially the Air Force Research Laboratory Human Effectiveness Directorate.

Ethical Issues

Given that one of the objectives of this field is to adapt technological systems to the needs, capabilities, and limitations of human beings, there is an inherent ethical dimension in ergonomics. Certainly the members of this profession must consider their ethical responsibilities. For example, practitioners should not function outside their areas of competence. They should have the proper education, professional training, and work experience. They should avoid and must disclose any actual or perceived conflicts of interest (Human Factors and Ergonomics Society 1989). While these principles seem obvious, they may prove to be problematic for those in the ergonomics field.

Because there is limited formal training in ergonomics and many practitioners come from other disciplines (for example, experimental psychology, industrial engineering), care must be taken so that individuals engaged in ergonomics truly understand their own professional "capabilities and limitations." This is especially true because ergonomics is such a broad and diverse field. For example, someone who works primarily in the area of visual perception may be qualified to work in the allied area of visual cognition, but not be qualified to perform work in the area of bioacoustic protection (that is, mitigating the effects of harmful noise).

Experts in many professions provide forensic testimony that goes beyond the mere recounting of facts. These experts are retained primarily to offer opinions regarding certain elements of a case. This is no different in the ergonomics field. The conduct of ergonomic experts in these types of proceedings should be governed by their professional ethics. The principles they should follow in these matters cover subjects such as the objectivity of their testimony; respect of the integrity of other witnesses; discretion regarding the disclosure of details about the case with outside parties; or discernment if making any public statements regarding the matter, as imprudence here may influence the judicial proceedings or be harmful to the litigant's interests (Human Factors and Ergonomics Society 1989).

As with many fields where the recruitment and use of experimental subjects is a key component in the performance of much of the work (such as in sociology and medicine), the treatment of subjects is of paramount importance and lapses in this area could lead to serious ethical criticisms. Approval of the work and the qualifications of the professionals involved by an institutional review board (IRB) is an important concern. Further, complete disclosure regarding the general nature of the work that the subjects will be involved in and specific risks they may be exposed to are requisite elements of any methodology involving humans.

Examining ethical issues entirely within the realm of ergonomics, Yili Liu (2003) considers several questions. Can ergonomically-based approaches be used to address ethical issues in general? This could also be thought of as whether a better understanding of humans from a psycho-physical standpoint can contribute to a greater understanding of ethical issues. An example of this might be whether providing avionics to fighter pilots that extend their ability to identify a friendly or enemy aircraft is helpful when considering the morality of war. Can ergonomics make human-machine systems more ethical? This might seem obvious given the objectives of the field; however, is an improvement in an individual assembly line process that reduces a worker's exposure to hazardous conditions (for example, the mechanization of a manual chemical dipping process to treat a material), but also speeds up the assembly line, which may cause increased levels of stress for all of the workers, really "ethical"?

Such questions point toward moral responsibilities for those working in product planning, design, or evaluation—with "product" including systems, processes, and more. Most professionals engaged in ergonomics work for paid compensation. Most of the products they plan, design, or evaluate are used by others. There would seem to be a compelling moral responsibility on the part of those employed in these practices to inform employers or clients if they know of an inherent danger or serious hazard associated with the use of a certain product. However, if the ergonomicist knows that use of the product would be inconvenient, inefficient, or difficult, and the cost to correct or change the product so that any problems could be ameliorated might be sizeable, what then is the proper course of action? Does the designer give allegiance to the client or the consumer? If one thinks of the ultimate user as the controlling factor here, how would one's opinion change if the inconvenience were characterized as slight and the cost as monumental? Specifics of a case often make it difficult to reach a final decision.

The advent of ergonomics in the twentieth century brought about great improvements in the design of technological systems from the standpoint of the user or the person in the system. Ergonomics has contributed to the improved safety and usability of technology. Given that this specialized field of knowledge holds the keys to understanding the soft boundary between humans and technology, it must be applied within a moral and ethical framework that, in many respects, is still evolving.

ETHICAL PLURALISM

Pluralism is a term used to describe a number of positions from different fields. This entry will confine itself to a discussion of ethical—as opposed to political, social, or metaphysical—pluralism.

Basic Definition and History

Ethical pluralism (also referred to as value pluralism) is a theory about the nature of the values or goods that human beings pursue, and the pursuit of which make up the substance of their moral lives. Most simply ethical pluralism holds that the values or goods legitimately pursued by human beings are plural, incompatible, and incommensurable. That is, there are many genuine human values, which cannot all be reduced to, or described in terms of, a single overriding value or system of values. This is because certain human values, by their very nature, come into conflict with other, equally valid, human values. Individual liberty, for instance, can conflict with equality, public order, or technological efficiency; impartial justice with compassion and mercy; scientific truth with public utility; and so on.

Sometimes compromises between values can be achieved, or solutions to value conflicts found; at other times, one is forced to choose between values. Such a choice may entail the sacrifice of a genuinely important, attractive, binding value or good, and so a moral loss. Finally, pluralism holds that values are incommensurable in that they cannot be ranked: There is no single most important or ultimate value, nor can values be ranked in a stable or universal hierarchy, nor is there a single principle or source of truth—such as utility, or a rational principle of moral duty, or natural law or the will of God—that can serve as a sure guide in making choices or compromises between values. Whether there can be any comparison between values of a less general and more practical sort is an issue that divides exponents of pluralism.

The first self-avowed pluralist was the U.S. philosopher and psychologist William James (1842–1910), who applied pluralism to the theory of knowledge and metaphysics. An early, forceful application of pluralism to ethics was made in 1918 by the German sociologist, historian, and philosopher Max Weber (1864–1920). The first full exposition of ethical pluralism under that name and in the form in which it is now known was given by the U.S. philosopher Sterling P. Lamprecht (1890–1973) in 1920. The thinker who did the most to develop and popularize ethical pluralism was the British historian, philosopher, and political theorist Isaiah Berlin (1909–1997), and it is from his work that most contemporary discussions of pluralism take their bearings.

Contemporary Problems and Debates

The theory of pluralism expounded by Berlin contained a number of ambiguities and possible weaknesses, and these have been the basis for recent debates among the proponents and opponents of pluralism. One of the most persistent debates concerns the meaning of the claim that values are *incommensurable*. Berlin used the term to suggest that there is no single standard by which all values can be ranked, or that can be used to determine which value should be chosen in a particular case; and that no eternal scale or hierarchy of values exists—liberty is not inherently more valuable than equality, or spontaneity than dependability, or beauty than practicality. But Berlin also suggested that human beings can, at least sometimes, compare the relative importance and desirability of different courses of action or different values in particular circumstances; and that sometimes, at least, this comparison will lead to the conclusion that one value or course of action is more valid or desirable than another.

Other theorists have given a more radical account of incommensurability, holding that different values are wholly *incomparable*—they cannot be compared, or rationally chosen among, in any circumstance or way. This could lead to the conclusion that choices among values must be arbitrary, because, values being incomparable, there is no way to give a reason for regarding one value as inherently more important or better than another in any circumstance.

Many critics of pluralism maintain that it is no different from *relativism*—a claim that is difficult to evaluate in part because such critics rarely define exactly what they mean by relativism. Berlin insisted that pluralism is different from relativism by defining relativism in terms of a denial of common human understanding and common rules and values. Relativism, in Berlin's definition, holds that a Homeric Greek's admiration of ferocity, pride and physical prowess as moral attributes, for example, is as difficult for a person living in the early-twenty-first century to understand or share, as it is for one person who strongly dislikes peaches to understand another person's enjoyment of peaches. A person in the early 2000s may not admire Homeric heroism. Tastes simply differ; and values are ultimately a matter of taste. Berlin's pluralism holds, on the contrary, that one can understand the attractiveness and value of the Homeric ethic, even if one ultimately rejects that ethic in favor of other values, which are of greater importance to that particular individual.

One problem with this argument is that it rests on a distinctive and tailor-made definition of relativism that not everyone would accept. Another more common definition of relativism is the view that there simply is no inherently right or good course of action or true answer. On this definition, too, pluralism is opposed to relativism, because it holds that there are such things as inherently right or good courses of action and true values and answers; but right and goodness and truth are not singular. This is why pluralism insists that there are genuinely tragic moral dilemmas and conflicts, while relativism cannot allow that such dilemmas are genuinely tragic—they may be frustrating for individuals who feel pulled in different directions, but those individuals need not feel so conflicted.

Relativism can also be defined as holding that certain things are valuable or good solely in relation to their context. This, too, is opposed to pluralism, in at least two ways. First it can be taken to mean that, relative to a particular context, there is a correct value or way of being, which is not appropriate to a different context; pluralism holds that there are a variety of values that remain valid regardless of context, and that in many cases there will not be a single value which is obviously best or most important in a given context. Thus the relativist might say that social cohesion is of greater importance than individual freedom in, say, a traditionalist, pre-industrial society, while the opposite is the case in a modern, *advanced* society; while the pluralist would hold that both values are important to both sorts of society, and that people in both societies will be drawn to, and torn between, and have to choose or find a balance between both values.

Finally relativism can be interpreted as denying the existence of a universally valid, binding, and morally limiting core or horizon of human values; yet, Berlin—and other writers after him—have insisted on the existence of such a core or horizon as part of pluralism.

The most lively debate among political theorists about pluralism is the connection between pluralism and political liberalism. While Berlin attempted to link pluralism with liberalism, arguing for liberalism on pluralist grounds, the British political theorist John Gray (b. 1948) has argued that pluralism actually undermines the authority of liberalism. Liberalism is a theory of government that privileges, and seeks to promote, certain values—primarily individual liberty—against and above other, non-liberal values. Gray asserts that if one take ethical pluralism seriously, one cannot assert the superiority, or impose on others, a single form of life, political system, or culture, because these embody and promote certain values to the detriment or exclusion of others.

While liberalism is certainly a valid choice for certain societies that, given their historical development and present situation, are more oriented toward the values that are central to liberalism, other forms of social and political organization have their own validity, and people in liberal societies must respect the claims and rights of societies that pursue other, non-liberal values. Other political theorists have tried to show that, while pluralism may not entail allegiance to liberalism, liberalism is a preferable political system to others because it better recognizes a genuine plurality of values, and allows for and protects greater freedom and variety of individual choice in pursuing these values.

The Relevance to Science, Technology, and Ethics

Pluralism presents a radical and important challenge to most traditional ethical doctrines, such as Kantianism and Utilitarianism, as well as an alternative to relativism, while also offering a distinctive and versatile perspective on moral experience.

One of the few major exponents of pluralism to address the ethics of the use of science and technology is Gray. Earlier pluralists have generally shared an anthropocentric perspective, treating pluralism as a theory concerned with human values. Gray, however, has expanded pluralism beyond the human sphere, arguing that anthropocentrism—and thus humanism—are misguided. The world should be viewed as a whole—a *biosphere*—with human beings counting as but one species among many. Human-centric conceptions of humanity's place and stature are akin to monism in their denial of the incommensurability and conflict between human and non-human goods. Moral philosophers and ethicists should cease to always put human beings first, and should denounce humanity's arrogant subordination and abuse of nature—Gray has remarked that *homo sapiens* should be re-christened *homo rapiens*—in favor of a moral outlook that takes into account the whole of the earth. Few other pluralists have followed Gray's lead.

Much work remains to be done in applying pluralism to the ethical consideration of science and technology. A pluralistic ethics would suggest that people be aware of the varied and sometimes conflicting values that science and technology seek to serve. A pluralist perspective would recognize the inherent value of scientific research as conducive to the acquisition of knowledge—a genuine value in itself—as well as the value of applied science and technology in increasing human happiness, physical well being, and power. But it would also recognize the costs of the scientific quest, and of the employment of technology. It is a further reminder that, in using science and technology in the pursuit of other values, human beings are faced with choices between the competing values that science and technology may serve.

In doing so pluralism does not provide answers, but rather affirms the validity, difficulty, and intractability of the problems. A pluralist will, for example, recognize that both sides in the debate over the use of animals for medical experiments appeal to genuine values, and that a victory for either side would mean a serious moral sacrifice. A pluralist might also see the conflict between economic growth and environmental safety as embodying a genuine conflict of values—between the well being provided by jobs, economic expansion, and greater human control over nature, and thus comfort, versus the health of the environment, the existence of other species, and, ultimately, human health as well. A pluralist will advocate deciding between contending parties advocating conflicting values on a case-by-case basis, and will be wary of the use of monistic ethical theories (such as utilitarianism) to derive authoritative answers to such conflicts.

Pluralism thus provides ethicists, scientists, political activists, and policy makers with no certain answers to their moral problems, or sanction for their agendas. But it may inspire an increased awareness of, and respect for, the importance of such problems, promoting a greater moral seriousness and honesty in confronting the conflicts of values and possible moral sacrifices and losses that are involved in the pursuit and use of scientific knowledge and technology, and fostering a spirit of greater deliberation, humility, and respect for the priorities and perspectives of others.

ETHICS ASSESSMENT RUBRICS

The introduction of new engineering accreditation criteria that includes "an understanding of professional and ethical responsibility" has firmly established the teaching of ethics as an important component of undergraduate education (Engineering Accreditation commission 2003, Herket 2002) yet, in establishing this outcome criterion, the commission also required its assessment. This is a particularly challenging proposition because ethics education is concerned not only with learning content but equally important, with developing problem solving skills. Further, such problems, or dilemmas, are rarely clear-cut and consequently do not have a definitive resolution, making traditional forms of assessment of limited value. One promising approach to this challenge is the development and use of scoring rubrics, a process that has been used for a broad range of subjects when a judgment of quality is required (Brookhart 1999). As opposed to checklists, a rubric is a descriptive scoring scheme that guides the analysis of a student's work on performance assessments. These formally defined guidelines consist of pre-established criteria in narrative format, typically arranged in ordered categories specifying the qualities or processes that must be exhibited for a particular evaluative rating (Mertler 2001, Moskal 2000). A valid rubric would allow educators to assess their students learning to date, and identify areas of weakness for further instruction.

There are two types of scoring rubrics: holistic and analytic. A holistic rubric scores the process or product as a whole, without separately judging each component (Mertler 2001). In contrast, an analytic rubric allows for the separate evaluations of multiple factors with each criterion scored on a different descriptive scale (Brookhart 1999). When it is not possible to separate the evaluation into independent factors—that is, when overlap between criteria exists—then a holistic rubric with the criteria considered on a single descriptive scale may be preferable (Moskal 2000).

Further, rubrics are intended to provide a general assessment rather than a fine-grained appraisal (such as in a 1–100 grading scale). For example, a rubric might include levels from one ("shows little or no understanding of key concept") to five ("shows full understanding of key concept; completes task with no errors"). Among the advantages of using rubrics are: (1) assessment can be more objective and consistent; (2) the amount of time faculty spend evaluating student work is reduced; (3) valuable feedback is provided to both students and faculty; and (4) they are relatively easy to use and explain (Georgia Educational Technology Training Center 2004).

Generally, rubrics are best developed starting from a desired exemplar learning outcome and working backward to less ideal outcomes, preferably using actual student work to define the rubric's various levels. The scoring system should be objective, consistent, and relatively simple, with a few criteria sets and performance levels; three to five evaluative criteria seem to be appropriate (Popham 1997).

Extensively used in K–12 education assessment, higher education areas such as composition and art, and, increasingly, engineering education (Moskal, Knecht, and Pavelich 2001), rubrics have yet to be widely adopted for assessing ethics tasks. An example is Holt et al. (1998) who developed an analytical rubric for assessing ethics in a business school setting, identifying five categories:

(1) Relevance: Analysis establishes and maintains focus on ethical considerations without digressing or confusing with external constraints;

(2) Complexity: Takes into account different possible approaches in arriving at a decision or judgment;

TABLE 1

Analysis Component of Scoring Rubric for Assessing Students' Abilities to Resolve Ethical Dilemmas

Level 1	Level 2	Level 3	Level 4	Level 5
• No analysis provided. • Defaults to a superior or authority without further elaboration. • Takes a definitive and unambiguous position without justification. • Any analysis appears to have been done without reference (explicit or implicit) to guidelines, rules or authority.	• Authoritative rule driven without justification. Position may be less definitive (e.g., "should do" vs. "must do"). • Minimal effort at analysis and justification. • Relevant rules ignored. • May miss or misinterpret key point or position. • If ethical theory is cited, it is used incorrectly.	• Applies rules or standards with justification, notes possible consequences or conflicts. • Correctly recognizes applicability of ethical concept(s). • Recognizes that contexts of concepts must be specified. • Coherent approach.	• Applies rule or standard considering potential consequences or conflicts. • Uses an established ethical construct appropriately. Considers aspects of competence and responsibility of key actors. • May cite analogous cases. • Incomplete specification of contexts of concepts.	• Correctly applies ethical constructs. • May offer more than one alternative resolution. • Cites analogous cases with appropriate rationale. • Thorough evaluation of competence and responsibility of key actors. • Considers elements of risk for each alternative. • Explores context of concepts.

SOURCE: Courtesy of Larry J. Shuman, Barbara M. Olds, and Mary Besterfield-Sacre.

Shown is the Analysis Component (one of five components) of the rubric. Note that the rubric gives the rater criteria to classify the student's response into one of five levels with five being the highest. The rater should choose the criteria set that most closely matches the student's response.

(3) Fairness: Considers most plausible arguments for different approaches;

(4) Argumentation: Presents a well-reasoned argument for a clearly-identified conclusion, including constructive arguments in support of decision and critical evaluation of alternatives;

(5) Depth: Shows an appreciation of the grounds or key moral principles that bear on the case.

These categories were rated from 1 for "non-proficient" to 6 for "excellent" according to each level's criteria.

Although not developed specifically for assessing ethical problem solving, the widely used Holistic Critical Thinking Scoring Rubric (HCTSR) with its four criteria could be adapted for a holistic assessment of students' ethical problem solving ability (Facione and Facione 1994). One recent effort along these lines has resulted in the development and validation of a rubric designed to measure engineering students' ability to respond to ethical dilemmas using case scenarios, for example, a case based on the first use of an artificial heart (Sindelar, Shuman, Besterfield-Sacre, et al. 2003). To a certain extent, the rubric follows the case analysis process of Charles E. Harris, Michael S. Pritchard, and Michael J. Rabins (1999). It consists of five components each with five levels (See Table 1):

(1) Recognition of Dilemma (relevance): Levels range from not seeing a problem to clearly identifying and framing the key dilemmas.

(2) Information (argumentation): At the lowest level, pertinent facts are ignored and/or misinformation used. At the high end, assumptions are made and justified; information from student's own experiences may be used.

(3) Analysis (complexity and depth): At the lowest level no analysis is performed. Ideally, thorough analysis includes citations of analogous cases with consideration of risk elements with respect to each alternative.

(4) Perspective (fairness): The lowest level is a lack thereof; that is, a wandering focus. The ideal is a global view of the situation, considering multiple perspectives.

(5) Resolution (argumentation): At the base level only rules are cited, possibly out of context. The ideal considers potential risk and/or public safety, and proposes a creative middle ground among competing alternatives.

Using such a rubric holds out the promise of being able to assess the learning of ethics reasoning skills in a more objective manner than has previously been the case. Indeed, there is the possibility that, given new developments in technology and learning, such rubrics could be programmed into computer-based learning modules that would be comparable to some of those developed for the self-guided teaching and learning of technical subjects.

ETHICS OF CARE

The ethics of care is a distinctive approach to moral theory that emphasizes the importance of responsibility, concern, and relationship over consequences (utilitarianism) or rules (deontologism). The concept of care is inherent to professions that care for individuals and this approach to ethics has therefore been a central part of professional ethical issues in both nursing and medical ethics, but in fact has much broader applications in relation to science and technology. "Due care" has for example, been a part of statements in engineering and has been used to include such typically technical activities as the maintenance and repair of an engineered system.

Origins and Development

As a moral theory the ethics of care originated during the 1970s and 1980s in association with challenges to the standard moral theories of utilitarianism and deontologism, primarily by women philosophers. The original work was Carol Gilligan's, conducted in the early 1970s and articulated in *In a Different Voice* (1982). Gilligan argued in response to the psychology of moral development formulated by Lawrence Kohlberg (1927–1987). Kohlberg himself built on the ideas of Jean Piaget (1896–1980), who did preliminary work on moral development as one facet of cognitive growth.

In his research Kohlberg posed moral dilemmas to males of various ages and compared the kinds of reasoning with which they responded. The dilemmas tended to be shorn of details about the people involved. The responses moved from self-centered thinking, emphasizing the importance of physical pleasure through thinking under the influence of peer pressure, to a moral orientation toward justice and abstract appeals to universal rights (Kohlberg 1984). Gilligan, on the basis of alternative research with both men and women, discovered a contrasting tendency, predominantly but not exclusively among women, to interpret "the moral problem as a problem of care and responsibility in relationships rather than as one of rights and rules" (p. 73). "While an ethics of justice proceeds from the premise of equality—that everyone should be treated the same—an ethic of care rests on the premise of nonviolence—that no one should be hurt" (p. 174).

Like Kohlberg, however, Gilligan sees an ethics of care emerging in three phases. In the early phase individuals care more for themselves than for others. In a middle phase care comes to emphasize concern for others over care for oneself. Finally, in its mature form the ethics of care seeks a balance between care for oneself and care for others. What nevertheless remains primary in each case is personal relationships: of others to oneself, of oneself to others, or mutually between oneself and others.

This new ethics of care was developed further by Nel Noddings (1984) in relation to education, and given a more philosophical formulation by Annette C. Baier (1985). According to Baier, Gilligan exemplifies a strong school of women philosophers that includes Iris Murdoch (1919–1999) and G. E. M. Anscombe (1919–2001), out of which have developed moral theories that stress living relationships over abstract notions of justice illustrated, for example, by the work of Immanuel Kant (1724–1804). Indeed, three decades prior to Gilligan, Anscombe had already suggested the need for a philosophical psychology as the gateway to any moral philosophy that might be adequate to issues arising in relation to science and technology.

Baier herself criticizes the rationalist individualism that rests content with establishing a minimalist set of traffic rules for social interaction as inadequate on a multitude of counts. Historically, it has failed to oppose injustices to women, the poor, and racial and religious minorities. While most human relations are between unequals, it has focused almost exclusively on relations between alleged equals. Despite the fact that many morally significant relations are not freely chosen, it has emphasized freedom of choice and rational autonomy. And although emotions are often as important as reasons, it has persistently stressed the rational control of behavior. At the same time Baier is careful to emphasize how an ethics of care complements rather than discards an ethics of justice. A good moral theory "must accommodate both the insights men have more easily than women, and those women have more easily than men" (Baier 1985, p. 56).

Applications in Biomedicine

From her empirical studies of people faced with difficult moral decisions, Gilligan identified a distinct approach—one of care, responsibility, concern, and connection, based on personal relations. This care orientation forms the basis of the ethics of care, "grounded in responsiveness to others, that dictates providing care, preventing harm and maintaining relationships" (Larrabee 1993, p. 5). It was natural that such an approach to ethics would be applied in the field of medicine, especially in nursing, where caregiving is already a defining characteristic. It is often argued that care is distorted by the dominance of scientific and technological practices in the practice of medicine.

In this regard one can note, for instance, how care has come to play an increasingly prominent role in such an influential text as Tom L. Beauchamp and James F. Childress's *Principles of Biomedical Ethics*. From its first edition (1979), this representative of the "Georgetown School" of bioethics emphasized a deontological "system of moral principles and rules" that highlighted four principles: autonomy (of the patient), nonmaleficence, beneficience, and justice. In neither the first nor the second edition (1983) did the ethics of care play a role. In the third edition (1989) and subsequent editions care has nevertheless been acknowledged especially in conjunction with an account of criticisms of principlism.

> Although [principled] impartiality is a moral virtue in some contexts, it is a moral vice in others. [Principlism] ... overlooks this two-sidedness when it simply aligns good and mature moral judgment with moral distance. The care perspective is especially meaningful for roles such as parent, friend, physician, and nurse, in which contextual response, attentiveness to subtle clues, and the deepening of special relationships are likely to be more momentous morally than impartial treatment. (Beauchamp and Childress 2001, p. 372)

The authors go on to note the centrality of two themes in the ethics of care—mutual interdependence and emotional responsiveness. For the ethics of care, "many human relationships involve persons who are vulnerable, dependent, ill, and frail [and] the desirable moral response is attached attentiveness to needs, not detached respect for rights" (p. 373). The ethics of care further corrects a "cognitivist bias [in principlism] by giving the emotions a moral role" (p. 373) and encouraging attention to aspects of moral behavior that might otherwise be ignored.

In the field of nursing, in which care exercises an even more defining role than in other medical professions, the ethics of care has been accorded even more significance. Helga Kuhse's *Caring: Nurses, Women, and Ethics* (1997) provides a good overview in this area.

Criticisms

Beauchamp and Childress also summarize key criticisms of the ethics of care in the biomedical context. First, the ethics of care is incompletely developed as a theory. Second, one can easily imagine situations in which relatives or medical professionals are called on to override emotional responses and to abide by principles. Third, the ethics of care can be distorted by cultural expectations. Indeed, some feminist critics have argued that care is easily distorted by contemporary interests, as in cases in which the terminally ill request to be allowed to die because they do not want to continue to be a burden to those around them. Finally, still others have challenged the empirical basis for some of conclusions advanced by Gilligan and others, and questioned popular associations between the ethics of care and female experience.

More constructively, it is unnecessary to maintain an essentialist connection between the ethics of care and female experience. In fact, Gilligan herself argues that the connection may be only historical. It may just be that those who are marginalized in a rule-governed scientific and technological culture have a natural tendency to emphasize alternatives. But this possibility reinforces rather than diminishes the need to attend to the claims in ethics of care. In a culture that values competition and efficiency the ethics of care also promotes such activities as conflict resolution and dispute mediation when dealing with ethical and other conflicts.

Application to Technology and Engineering

The most salient definition and framework of care to apply to the contexts of science and technology is that of Joan C. Tronto and her colleague Berenice Fisher. Tronto and Fisher suggest that caring be viewed as "a species activity that includes everything that we do to maintain, continue and repair our world so that we can live in it as well as possible. That world includes our bodies, our selves, and our environment, all of which we seek to interweave in a complex, life-sustaining web" (Tronto 1993, p. 103).

The ethics of technology and of science needs to be a system ethics to be followed by a system of actors, doers, and stakeholders. It needs to work in the context of the science and technology enterprises, which are distinct. The justice and rights perspective gives an abstract, universalizable goal as Kohlberg, and indeed Kant before him, intended, but the praxis of science and technology calls for a guide for action in terms denoting action. This is what the ethics of care provides. Care in this sense is larger than care implied by familial and close community relationships. Care, too, is universalizable, but not abstract.

The Fisher-Tronto definition provides the actions—maintain, continue, and repair—that care demands, words closely associated with engineering, the action element of technology. This definition of care also recognizes that human existence is intricately woven into the web of the natural environment and that the ethics of care must apply to nature as well as to humans and their communities. In this perspective, care is well positioned as an ethics for a sustainable world, a prime challenge to today's technology. In her analysis of care, Tronto recalls David Hume's understanding of justice, an artificial passion, as a necessary complement to the natural passion of benevolence, which alone may not be sufficient as a moral basis in a human society. These ideas also hark back to Aristotle who sees practical deliberation as the means of achieving the ethical good and praxis as the end of ethics.

Marina Pantazidou and Indira Nair (1999), who have examined care particularly in the context of engineering, identify care as a value-guided practice, not a system of values. Care emerges in response to a need. Meeting human needs is indeed the ideal for technology. Tronto has provided a framework for practicing care that is particularly suited for application to technology and indeed to science. Tronto identifies four phases of care that parallel closely stages identified with the process of engineering design.

(1) Attentiveness, or "caring about," is the phase of recognizing the correct need and realizing care is necessary. This is parallel to the need identification stage in design.

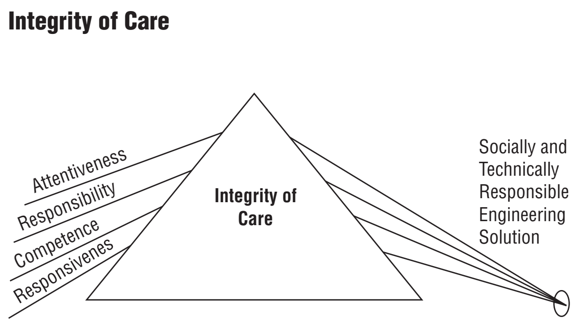
(2) Responsibility, or "taking care of," is the phase that involves "assuming responsibility for the identified need and determining how to respond to it" (Tronto 1993, p. 106). This is parallel to the conceptualization phase of design.

(3) Competence, or "caregiving," is the phase in which the need is met with the expertise needed. This is parallel to the actual design and production.

(4) Responsiveness, or "care receiving," is the phase in which "the object of care will respond to the care it receives" (Tronto 1993, p. 107). This is parallel to the acceptance (or rejection) of the designed product.

Total care requires an attuned caregiver, who through commitment, learning, and experience has an understanding of the process as well as the competence and skills and watches the response of the one cared for. Tronto introduces a fifth component to complete the process. She calls this the Integrity of Care, requiring

FIGURE 1



SOURCE: Pantazidou and Nair (1999).

"Engineering with care" depicted as a prism that integrates the four elements of care into the resulting engineering product. For a sharp focus, the proportion of attentiveness, responsibility, competence, and assessment (responsiveness), represented by the rays and angles of incidence, has to be accurate. Engineering with less than accurate angles will result in a smeared focus in this prism analogy (Pantazidou and Nair 1999).

"that the four moral elements of care be integrated into an appropriate whole."

Figure 1 is the representation of this process by Pantazidou and Nair with the Integrity of Care as a prism that focuses the four care components to a socially and technically responsible technological product. Carrying the prism analogy forward, a technology that has no room for any error will require extremely fine tuning of the four angles of the phases of care to yield a sharp focus. One may argue that in general an ethics of care applied to a technology will say that such a technology poses high risk and may be best avoided. Where such precision is not required, there may be more tolerance of how the phases come together. In some cases, a single focused solution may not be possible or it might not be critical. Then, a range of perhaps suboptimal solutions—a smeared focus—may be sufficient or even necessary for pragmatic reasons.

Figure 2 shows how the ethics of care and the description of the engineering design process compare.

Care in Science

Science in general is not as easily mapped into such a scheme unless it is science done expressly for the purpose of answering a technology-derived question or problem. In this case, Figure 1 applies directly, because the science is done in response to a need.

In the case of science in general, the ethics of care can provide some ethical tests attuned to each phase.

(1) Attentiveness: Is the science being done in response to a perceived need? Or, are needs being scientifically assessed so that a given technology is likely to be the best response? As human needs are perceived, are scientific resources being directed toward those?

(2) Responsibility: What is the science that determines if a technological process or product is the answer to the need? Does new scientific knowledge direct action toward the appropriate human need?

(3) Competence: This is perhaps the one phase toward the accomplishment of which the current scientific ethic is almost solely directed.

(4) Responsiveness: The science of the consequence of a technology is a requisite. This would include predictive science. Hans Jonas (1984) has suggested that one imperative of human technological power is that "knowledge (science) must be commensurate with the causal scale of our action . . . that predictive knowledge falls behind the technical knowledge that nourishes our power to act, itself assumes ethical importance" (p. 8).

This last corollary is perhaps the most important result that the ethics of care can yield in the case of science—that science to reduce the uncertainty of human technological actions take on importance in the scientific enterprise.

Care in Engineering

"Reasonable standard of care" has been common parlance in product specifications separate from the consideration of any ethical standard. Product liability issues assess whether "due care" was taken. Thus care has become an inherent notion in technological products spurred over time by legal demands. A working definition of the standard of care for engineering, set by legal precedent, has been proposed by Joshua B. Kardon (2002) as "That level or quality of service ordinarily provided by other normally competent practitioners of good standing in that field . . . under the same circumstances." While proposed as an ethic for the engineer to follow, this standard does not fully address all the elements of the ethics of care.

Moreover, challenged by the requirements of sustainability, technological planning has begun to consider system characteristics such as environmental impacts of a product life cycle in the design of a product or a process. With technology intertwining with everyday lives in

intricate ways, interface design of all sorts of technology has become important. Industrial ecology, green design, green chemistry, and humane design are some of the trends that illustrate the ethics of care at work (Graedel and Allenby 2003; Collins Internet article).

A systematic application of the ethics of care to science and technology is yet to be done and may indeed benefit practice. Such an analysis and a synthesis of standards of the practice of science and technology with the ethics of care may yield a framework that is realistic enough for the handling of the complexity of technological and scientific progress. The ethics of care may aid in this by responding to Jonas's condition of the sustainability of humanity as a technological imperative, Manfred Stanley's call for placing human dignity on par with species survival (1978), and Anthony Weston's observation that tough ethical problems be treated as problematic situations and not as puzzles (1992).

ETHICS: OVERVIEW

From the perspective of science, technology, and ethics, ethics itself—that is, critical reflection on human conduct—may be viewed as a science, as a technology, and as providing multidimensional independent perspectives on science and technology. The encyclopedia as a whole constitutes manifold illustrations for each of these possibilities. It is nevertheless appropriate to provide in a separate entry some orientation within the manifold.

Ethics as Theory and Practice

In the works of Plato (c. 428–347 B.C.E.), dialogues rather than treatises, ethics is interwoven with logical analysis and theories of knowledge, reality, and political affairs so as to resist clearly distinguishing these different branches of philosophy. What came to be called ethics nevertheless clearly serves as first or primary philosophy. In Socrates's autobiography (*Phaedo* 96a ff.) it is not the foundations of nature but the ideas of beauty, goodness, and greatness that act as the basis of philosophical inquiry. The search for a full account of ethical experience calls forth an appreciation of different levels of being and different forms of knowing appropriate to each—although the highest reality is once again ethical, the good, which is beyond being (*Republic* 509a–b).

According to Aristotle (384–322 B.C.E.), however, philosophy originates when discourse about the gods is replaced with discourse about nature (compare, e.g., *Metaphysics* 1.3.983b29 and 1.8.988b27). It is the study of natures, as distinguishing functional features of the world, that both constitutes natural science and provides insight into the *telos* or end of an entity. For Aristotle the various branches of philosophy themselves become more clearly distinguished, and ethics functions as the systematic examination of *ethos,* as constituted by the customs or behaviors of human beings. More than any other type of entity, humans have a nature that is open to and even requires further determinations. At the individual level these supplemental determinations are called character; at the social level, political regimes. Their very multiplicity calls for systematic (that is, in the classical sense, scientific) analysis and assessment.

Such analysis and assessment takes place on three levels. In the first instance it is descriptive of how human beings in fact behave. As Aristotle again notes, human actions by nature aim at some end, and the end pursued can be of three basic types, defining in turn the lives of physical pleasure, of public honor, and of intellectual investigation.

In the second instance, ethics compares and contrasts these ends and seeks to identify which is superior and for what reasons. For Aristotle the life of reason is superior because it is that which humans by nature do only or best, and is itself the most autonomous way of life. Humans share with other animals the pursuit of pleasure; the pursuit of honor is dependent on recognition by others and the historical contingency of having been born into a good regime.

Finally, in the third instance the ethical life itself becomes a striving simply for knowledge of human behavior. It seeks conceptual clarification regarding different forms of perfection (virtue) and imperfection (vice), synthetic appreciation of the relations between human nature and other forms of nature, and ultimately a transcendence of the subordinate dimensions of human experience. Ethics in this final form becomes science in the most general sense, concerned not with the part (humans) but the whole (cosmos).

Yet as Aristotle also notes, humans undertake ethical inquiry not simply to know about the good but also to become good (*Nicomachean Ethics* 2.2). Ethics is not just a science but a practice, a technique for self- and social improvement. Insofar as this is the case, ethics provides guidelines for development of character and counsel for political organization and rule. Ethics leads to politics, meaning not just political action but political philosophy (*Nicomachean Ethics* 10.9).

Roman philosophers, continuing the Greek tradition, likewise examined the *mores* (Latin for *ethoi*, the plural of *ethos*) of peoples, in what came to be called moral theory. Thus ethics is to ethos as moral theory is to morals. *Ethics* and *moral theory* are but two terms for the same thing: systematic reflections on human conduct that seeks to understand more clearly and deeply the good for humans.

During the Middle Ages these articulations of ethics or moral theory (science) and ethical or moral practice (technique) were enclosed within the framework of revelation. For instance, according to the argument of Augustine (354–430 C.E.) in *On True Religion*, revelation takes the truths of philosophy, known only by the few, and makes them publicly available to the many. By so doing religion makes the practical realization of the good more effective than was previously possible, at both personal and political levels.

According to Thomas Aquinas (c. 1225–1274), the supernatural perspective allows Christians to provide more accurate descriptions, more sure assessments, and more perfect insight into the ultimate nature of reality and the human good than was possible for pagans. What for Aristotle could be no more than the counsels of practical wisdom became for Thomas natural laws of human conduct, laws that gear down the cosmic order and are manifest in human reason as a "natural inclination to [their] proper act and end" (*Summa theologiae* I–II, ques. 91, art. 2). The self-evident first principle of ethics that "good is to be done and promoted and evil is to be avoided" is given content by the natural inclinations to preserve life, to raise a family, and to live in an intelligence-based community (*Summa theologiae* I–II, ques. 94, art. 3).

The traditional forms of ethics as science and as technique acted to restrain the independent pursuit of science and technics. As entries on "Plato," "Aristotle," "Augustine," and "Thomas Aquinas" further suggest, these traditions provide continuing resources for the critical assessment of modern science and technology. Indeed, the contentious character of these often alternative assessments may be one of their most beneficial aspects, in that they call for reconsidering the assumptions that now animate scientific and technological activity.

Ethics as Science and Technology

In the modern period a basic transformation occurs in the understanding of ethics, one related to a transformation in science and technology. The scientific understanding of nature came to focus no longer on the natures of different kinds of entities, but on laws that transcend all particulars and kinds. The knowledge thus promoted the merger of technics into technology, the systematic power to control or reorder matter and energy. Technological knowledge became the basis for a technological activity that produced artifacts in greater regularities and quantities than ever before possible.

In like manner, the science of ethics sought to elucidate rules for human action. Divides emerged in the details of different ethical systems, but the major approaches nevertheless all pursued ethical decision-making processes that could be practiced with competence and regularity on a scale to cope with the new powers first of industrialization and then of globalization. The modern period thus witnessed the development of ethics as a science with a unique intensity and scope.

From their origins science and technology were supported with fundamentally ethical arguments—by Francis Bacon (1561–1626), René Descartes (1596–1650), and others—for a new vision of human beings as deserving to control the natural world and dominate it. The Enlightenment and the Industrial Revolution flourished in conjunction with the progressive articulation of ideas about how humans might, through science and technology, remake both the physical and social worlds. Romanticism served as a critical response to the difficulties, threats, and complications inherent in such a reshaping of human experience, but in ways that were ultimately incorporated into the emerging cultural transformation. (Encyclopedia entries on "Bacon, Francis," "Descartes, René," and the "Industrial Revolution," among others, explore such issues in more detail.)

The systematic development of the modern science of ethics itself emerged in two major traditions. One was the consequentialist utilitarian tradition as elaborated by Jeremy Bentham (1748–1832), John Stuart Mill (1806–1873), and their followers. The other was a deontological or duty-focused tradition with roots in the thought of Jean-Jacques Rousseau (1712–1778) but most closely associated with the work of Immanuel Kant (1724–1804). For consequentialists, rules for ethical decision-making are best determined by end uses or the effects of actions; for deontologists rules are grounded in the intentional properties of the actions themselves. Leading twentieth-century representatives of these two traditions include Peter Singer (b. 1946) and John Rawls (1921–2002), respectively. Both traditions are efforts to deal with the moral challenge created by the loss of nature as a normative reality within and without human beings. (Encyclopedia entries on the traditions of "Consequentialism" and "Deontology" are complemented by separate entries on such thinkers as "Rousseau, Jean-Jacques," "Kant, Immanuel," and "Rawls, John.")

Prior to the modern period, natural entities were understood as possessed of functional tendencies toward internal and external harmonies. When they function well and thereby achieve their *teloi*, plural of *telos* or ends, acorns grow up into oak trees, human beings speak and converse with one another in communities. Furthermore, both oak trees and humans fit in with larger natural orders. Because these harmonies are what constitutes being itself, they are also good, which is simply the way that reality manifests itself to, draws forth, and perfects the appetite. Although the first name of the good may be that which is one's own, a second and superior name is form or being, the different instances of which themselves come in an ascending order. For the Platonic and Aristotelian traditions, ethics as practice was thus constituted by the teleological perfection of human nature, realizing ever-higher states of functional potential. Such a view has obvious affinities with religious traditions as diverse as Hinduism, Buddhism, and Christianity. But insofar as nature comes to be seen as composed not of entities with natures to be realized, but as constructions able to be used one way or another and modified at will, fundamental questions arise about the foundations of the good as an end to be pursued as well as the rightness of any means to be employed in such pursuit.

The fundamental problem for modern ethics is not just what the good is, but its basis. In simplified terms, for the consequentialist tradition the good is what human beings need or want, and there are no limits on actions as means other than what might be at odds with perceived wants; for the deontological tradition right means are those whose intentions may be consistently pursued or universalized, with no limits on the goods that might flow from them.

Efforts to make consequentialist and deontological systems truly scientific have been pursued both formally and substantively. In the first half of the twentieth century a pursuit of formal rigor led to the development of metaethics. Eschewing any normative goals, metaethics simply aspires to clarify the structure of ethical language and reasoning. In its radical form metaethics has tended to reduce the meaning of ethical statements to forms of emotional approval; in more moderate forms it has simply disclosed the complexities of ethical judgments, sometimes pointing up and seeking to rectify inconsistencies. In the second half of the twentieth century the inadequacies of metaethical analysis for the substantive issues faced in the creation and use of science and technology brought about development of applied ethics. The term is somewhat anomalous, because all traditional ethics applied to real life. Applied ethics is applied only in contrast to metaethical formalist aspirations.

Across the twentieth century efforts to make ethics scientific in more substantive ways developed in two tracks. One was to try to base ethics on evolutionary theory. This approach commonly takes those behaviors that are descriptively given moral value (such as altruism) and shows how and why such approval could have been the outgrowth of the processes of evolutionary selection.

Another effort to make ethics substantively scientific has been to elucidate the rationality of ethical behavior through the mathematics of game and decision theory. In the same spirit as game and decision theory, parallel efforts to supply practical wisdom with the strengths of quantitative methods have given rise to operations research and risk–cost–benefit analysis. Much more than evolutionary theory, such efforts have produced ethical techniques for dealing with the complexities of the advanced scientific and technological world, especially in relation to public policy analysis.

Continuing efforts to model ethics on the authority of modern science and the powers of technology, including the computer modeling of artificial ethics, have proved selectively suggestive and insightful. Despite significant achievements, however, neither scientific nor technological ethics has proved able to capture the richness of ethical reflection that is spread across the diversity of ethical traditions, ancient and modern.

Ethical Perspectives on Science and Technology

A different approach to the ethics of science and technology eschews making ethics into a science or a technology but to consider science and especially technology as new fields requiring ethical analysis and reflection. Here there has been a divide between those who seek to bring ethics to bear on science and technology as a whole, and those who choose to limit their ethical reflection to specific sciences or technologies.

With regard to the holistic approach, the work of Hans Jonas (1903–1993) may be taken as representative. For Jonas the powers of modern technology, which are more extensive across space and time, on the macro- and the microscale, than all previous human abilities, require a new ethics of responsibility. In his words, "Modern technology has introduced actions of such novel scale, objects, and consequences that the framework of former ethics can no longer contain them" (Jonas 1984, p. 6). In response Jonas formulated the new imperative of responsibility as: "Act so that the effects of your action are compatible with the permanence of genuine human life" (p. 11). (For more detail, see the entry on "Jonas, Hans.")

With regard to approach that focuses on specific technologies, this is well represented by the various fields of applied ethics such as agricultural ethics, bioethics, business ethics, computer ethics, engineering ethics, environmental ethics, and more (each of which is given its own entry). Further specificity can be found in many of the case studies included in the encyclopedia, from "Abortion" to "Zoos."

In both holistic and particularist approaches, however, there are at least two common themes. One is whether on balance science and technology—or some particular science or particular technology—should be encouraged or in any way restrained. Another is whether existing ethical traditions are adequate to deal with the ethical challenges of science and technology, or whether instead wholly new ethical concepts and frameworks need to be developed.

Finally, even when the adequacy of existing traditions is assumed or defended, there are a number of distinctive concepts and principles that tend to recur in the ethical examinations of science and technology—or particular fields therein. Examples include the principles of respect for human autonomy and the exercise of responsibility and public participation, along with the concepts of safety and risk, the environment, and expertise. Each of these, along with a number of closely related terms, are thus also accorded encyclopedic entries.

The Limitations of Ethics

Any overview of ethics, especially one that highlights the way ethics attempts to deal with the dangers and challenges of science and technology, should not fail to mention the danger of ethics itself. These dangers come in three forms: economic, personal, and philosophical.

First, the economic danger in bringing ethics to bear on science and technology will limit scientific and technological progress, which in turn will limit economic development.

Second, there is what may be called the personal temptation to false righteousness. Turning a technical problem into an ethical one can make it more difficult to discuss, because the discussants now address it in terms of emotionally loaded senses of right and wrong or good and bad rather than the less loaded senses of more or less efficient or effective. Because of such emotional investments, social and political discussions can become intractable when ethical principles are invoked and people become unwilling to compromise. When the NIMBY ("not in my backyard") syndrome is justified not simply on the basis of practical concerns but by appeal to fundamental rights or other principles, it can become almost impossible to find common ground solutions. The opposition between fundamentalist religious beliefs about abortion and zealous commitments to women's rights provide another example of the problems that can be created by assessing science or technology in ethical terms.

Third, philosophers from Karl Marx to Michel Foucault have argued that morality is often simply a disguised form of self-interest. A modern tradition of the philosophical criticism of ethics has highlighted numerous ways that morality has been used to justify human oppression and exploitation, from racism to gender discrimination. Ethics can be simply another name for lack of self-knowledge, a kind of false consciousness.

Finally, another philosophical issue with ethics is that to define a problem as one of ethics can obscure not only its scientific and technical aspects but also its epistemological, metaphysical, aesthetic, and even theological dimensions. As philosopher Robert Frodeman

(2003) has argued with regard to an extended examination of problems in the geosciences, environmental ethics is not enough. The issues of environmental ethics are often as much aesthetic and ontological as they are ethical. The category of the ethics must not be allowed to obscure other equally significant categories of reflection that are called forth by efforts to understand and assess science and technology.

ETHOLOGY

Ethology is the biological study of animal behavior. It derives from the Greek root *ethos*, which, in normal English usage, refers to the manner of living, or customary behavior, of a social entity. One may therefore speak of the ethos of a particular sports club, small town, or professional organization, for example. By the same token, ethologists are concerned with the ethos of animals: their way of behaving.

Ethology traces its history to the early decades of the twentieth century, especially the work of the Austrian physician Konrad Lorenz (1903–1989), Dutch biologist Niko Tinbergen (1907–1988), and German entomologist Karl von Frisch (1886–1982); in recognition of their achievements, these three shared the Nobel Prize in physiology or medicine in 1973. The characteristics of ethology as a scientific discipline can be appreciated by comparing it to one of its well-known counterparts, comparative psychology.

Whereas comparative psychology is primarily concerned with understanding human behavior, such that animal research is conducted with an eye to better understanding *Homo sapiens*, ethology focuses specifically on the behavior of animals for its own sake. Similarly, comparative psychologists study a small range of animal species—particularly laboratory rats, macaque monkeys, and pigeons—as easily manipulated substitutes for human beings. By contrast, ethologists study the diversity of animal species, especially invertebrates, fish, and birds. Because of their underlying concern with understanding human behavior, researchers in comparative psychology are especially interested in examining the various concomitants of learning (which have a notable impact on human beings). Ethologists pay considerable attention to behavior that is loosely described as "instinctual," which tends to be more prevalent in the species with simpler nervous systems that are typically the subject of ethological research. Ethologists also emphasize the study of animal behavior in its natural context; that is to say, under field conditions where the organisms normally live and to which they are adapted by natural selection. By contrast, comparative psychologists typically conduct their research in a laboratory setting within which they can carefully control for extraneous factors while focusing on the role of various aspects of experience.

Some Aspects of Classical Ethology

Ethology, as the study of how organisms conduct their lives, long has been especially concerned with compiling careful, detailed descriptions of actual behavior patterns, known as *ethograms*. These detailed records (including verbal descriptions, photographs, and sonograms of vocal communications, for example) are not generally considered ends in themselves, but are fundamental to a rounded, ethological understanding of any species: Ethologists emphasize that they must first know what the animals in question do before they can pose meaningful questions.

According to Niko Tinbergen, those questions are especially concerned with the following:

(a) How does the behavior in question influence the survival and success of the animal? In modern evolutionary terms, what is its adaptive significance; or, how does it contribute to the inclusive fitness of the individual and the genes responsible, recognizing that inclusive fitness involves not only personal, Darwinian reproductive success but also the effect of each behavior on the fitness of other genetic relatives.

(b) What actually makes the behavior occur at any given moment? This might include the role of hormones, brain mechanisms, prior learning, and so forth.

(c) How does the behavior in question develop as the individual grows and matures? What is its developmental trajectory, or *ontogeny*?

(d) How has the behavior evolved during the course of the species' evolutionary history? In short, what is its *phylogeny*?

It is worth noting that of these, question *a* has become the special province of *sociobiology*, a research discipline closely allied to ethology and that emphasizes matters of adaptive significance and evolutionary—often called *ultimate*—causation. By contrast, question *b* is associated in the public mind with research into animal behavior more generally; it is often called *proximate* causation. Ideally, a complete understanding of animal behavior will involve both ultimate and proximate considerations, as well as attention to matters of ontogeny and phylogeny.

Through their research, early ethologists developed a number of concepts now considered part of "classical ethology." These include, but are not limited to, the following. *Fixed action patterns* are the fundamental building blocks of behavior, consisting of simple, relatively unvarying movements that are more or less independent of prior experience. Once initiated, fixed action patterns generally continue to completion even if the initiating stimulus is no longer present; this emphasizes the unthinking nature of these acts, which are the products of natural selection rather than complex cognition or daily experience. Fixed action patterns, in turn, are evoked by *releasers*, features of the environment or other animals to which the receiving animal is delicately attuned. The situation is analogous to a lock-and-key mechanism: a lock is carefully adjusted (in the case of animal behavior, by natural selection rather than by a locksmith) to the specific characteristics of a key. In ethological terminology, the lock is an *innate releasing mechanism*, a characteristic of the receiving animal—usually but not necessarily located in the animal's central nervous system—that responds to the traits of the releaser. Continuing the analogy, when the key fits the lock, a door opens; this is equivalent to the fixed action pattern. And, just as a door moves along a fixed, predetermined pathway, so do the behavior patterns with which ethologists have traditionally been most concerned.

Although it may appear that this schema is only capable of generating simple behaviors (a simple releaser evokes a comparably simple fixed action pattern), ethologists demonstrated that these connections can be "chained," such that fixed action patterns by one individual, for example, can serve as a releaser for another, whose fixed action pattern, in turn, serves as a releaser for another fixed action pattern in the first; and so on. In the process, complex sequences of courtship, parental care, or communication can be constructed.

In the courtship behavior of the three-spined stickleback fish—a species that has been intensively studied by ethologists—males develop a bright red abdomen in response to the warming water and increased day length of spring; females react to this releaser by their own fixed action pattern, a "head-up" display which in turn reveals their abdomens, swollen with eggs; the male, in turn, responds by his own fixed action pattern, a "zigzag dance," which involves swimming rapidly toward a nest made of algae that he would have previously constructed and then swimming quickly toward the female; the female responds by following the male; the male lays on his side in a characteristic posture "showing" the nest entrance to the female; she enters; he rhythmically prods the base of her tail with his snout, whereupon she deposits her eggs; she swims away; he enters the nest, fertilizes the eggs, and continues to care for them until they hatch. Throughout this complex sequence, each situation or behavior by one animal serves as a releaser for a fixed action pattern by the other, and so on in turn.

Ethologists also developed descriptive models for the control of behavior. Two notable models are the hydraulic model of Lorenz and Tinbergen's hierarchical schema. Lorenz proposed that a kind of motivational pressure—which he labeled *action specific energy*—builds up within the central nervous system of an individual. This energy is dissipated when the appropriate fixed action pattern is performed. In some cases, if the behavior in question is blocked, the motivational energy spills over into another channel, generating a seemingly irrelevant behavior, known as a *displacement activity*. For example, shorebirds known as avocets, when engaged in a dispute at a territorial boundary, may tuck their heads into their wing feathers, in a posture indistinguishable from that normally assumed during sleep.

Lorenz's scheme is also consistent with vacuum activities, whereby an animal may suddenly perform a fixed action pattern in the absence of any suitable releasing stimulus; in this case, presumably the energy associated with a given fixed action pattern has built up to such a level that it essentially overflows its neuronal banks and the relevant brain centers discharge in an apparent vacuum. Although the hydraulic model does not have many current devotees, it still serves as a useful heuristic model.

Tinbergen proposed a similar perspective, one somewhat more consistent with known neurobiological mechanisms. He suggested that various major instinctive tendencies (e.g., reproduction, migration, food-getting) were organized hierarchically, such that reproduction, for instance, was subdivided into fighting, nest-building, mating, and care of offspring, each of which, in turn, was further subdivided. Thus, depending on the species, fighting might involve chasing, biting, and threatening, whereas care of offspring might involve provisioning the young, feeding them, defending them from predators, and providing various kinds of learning opportunities.

Ethology in the Twenty-first Century

Despite the ethological focus on animal behavior that can loosely be labeled "instinctive," an important realization characterizes all studies of behavior, whether conducted by ethologists, sociobiologists, or comparative psychologists: Behavior always derives from the interaction of genetic and experiential factors. Variously labeled instinct/learning, genes/experience, or nature/nurture, contemporary researchers widely acknowledge that these dichotomies are misleading. Just as it is impossible for an organism to exist or behave without some influence from its environment (the extreme case of "pure instinct"), it is impossible for environmental factors acting alone to produce behavior (the extreme case of "pure learning"). Every situation must involve both factors: there must always be an organism to do the behaving, and, moreover, organisms with different experiences exposed to the same situations always respond somewhat differently.

Ethologists have branched out substantially from their earlier focus on careful naturalistic descriptions of animal behavior, increasingly blurring the distinction between ethology and various related disciplines. Thus, neuroethologists concern themselves with the brain regions and precise neuronal mechanisms that govern, for example, animal communication as well as the reception of auditory, olfactory, visual, and even tactile signals. Behavior genetics incorporates an amalgam of ethology and precise genetic techniques to unravel the genetic influence on various behavior patterns; such research may range from the creation of cross-species hybrids to the detailed analysis of DNA sequences in identified genes responsible for specific behavioral tendencies. Behavioral endocrinology investigates the role of hormones in predisposing animals toward courtship, aggressive, migratory, and other behaviors, as well as the environmental and social situations responsible for releasing the relevant hormones. Mathematically inclined ethologists have been increasingly interested in applying concepts derived from game theory in seeking to understand how behavior has evolved, especially in situations such that the benefit to each individual depends not only on what he or she does, but also on the behavior of another individual.

Ethology and Ethics

Researchers increasingly have been applying the basic ethological techniques of detailed, objective, nonjudgmental observation to human behavior as well. Human ethology is essentially an organized form of "people watching," whereas human sociobiology (sometimes called *evolutionary psychology*) seeks to apply the principles of evolution by natural selection to *Homo sapiens*. Critics assert that the former approach consists of a kind of empty empiricism, lacking powerful theoretical roots; others attack the latter for being overly driven by theory, occasionally lacking in adequate empirical findings.

The conduct of ethology occasionally raises ethical issues concerning the treatment of animal subjects, but generally such matters are more controversial in the laboratory-oriented disciplines such as comparative psychology and neuroethology. Because ethologists study undisturbed, natural populations, or—when conducting laboratory research—strive to maintain their subjects under naturalistic conditions, the major ethical dilemma facing ethologists tends to center around whether or not to intervene in the events of the normal lives of their study animals. For example, is it appropriate to prevent a forthcoming act of predation? (Ethologists nearly always answer in the negative, because they are typically committed to nonintervention on the lives of their subjects.) Moreover, because the goal of ethological research—unlike that of comparative psychology—is to understand behavior rather than to control it, and because—unlike evolutionary psychology—ethologists generally do not directly employ controversial assumptions about evolutionary factors currently operating on human behavior, ethology is generally free of the moral conundrums often attending its sister disciplines.

EUGENICS

Eugenics was an ideology that arose in the late nineteenth century to promote improving human heredity. It posed as a scientific enterprise, but combined ethical presuppositions and political action with research on human heredity. For example, there was no scientific way to determine what constituted "improvement." Progress and improvement, however, were the watchwords of many nineteenth-century intellectuals who often failed to recognize how such concepts can be culturally loaded. Indeed, many eugenicists supposed that health, strength, intellectual acuity, and even beauty were undeniably favorable traits and should be promoted in human reproduction. Another closely related ideology was that of Social Darwinism, which nevertheless has its own distinctive if interactive history. While Social Darwinism stressed natural selection and thus human competition, eugenics focussed on artificial selection. Though some eugenicists saw eugenics as a way to evade Social Darwinism, others were avid Social Darwinists.

Classic Eugenics

The basic idea of eugenics came to Francis Galton (1822–1911), the father of the eugenics movement, in the 1860s while reading Charles Darwin's *The Origin of Species*. Galton claimed that Darwin's theory "made a marked epoch in my own mental development, as it did in human thought generally" (Gillham 2001, p. 155). In 1869 Galton published his most famous book, *Hereditary Genius*, in which he traced the lineages of prominent men in British society in order to demonstrate that not only physical characteristics but also mental and moral traits were hereditary. Galton coined the phrase "nature and nurture" to describe the conflict between biological determinism and environmental determinism, and came down decidedly on the side of nature.

Galton's views on heredity not only drove him to engage in scientific research, but also motivated him to propose conscious planning to help speed up human evolution. He stated, "What nature does blindly, slowly, and ruthlessly, man may do providently, quickly and kindly" (Gillham 2001, p. 328). He favored measures to encourage the "most fit" people to reproduce. This is called positive eugenics. However, he also advocated negative eugenics: restricting the reproduction of those deemed "inferior." He thought inferior people should be branded enemies of the state and "forfeited all claims to kindness" if they procreated. Further, he believed that "inferior races always disappear before superior ones" (Gillham 2001, p. 197). Galton, like subsequent eugenicists, stressed human inequality and devalued the life of those considered inferior. When Galton died, he left a bequest to endow a chair in eugenics at the University of London, which was filled by Karl Pearson (1857–1936), his hand-picked successor as leader of the eugenics movement in Britain.

The eugenics movement blossomed in the 1890s and early twentieth century, partly fueled by fears of biological degeneration. By the 1890s many Darwinists were concerned that some of the improvements of modern civilization were a mixed blessing. Ernst Haeckel (1834–1919), the leading Darwinist in Germany, already warned in the 1870s that modern medical advances allowed those with weaker physical conditions to survive and reproduce, while in earlier ages they would have perished without leaving progeny. Other Darwinists also warned that the weakening of natural selection by modern institutions would bring biological decline. However, while embracing Darwinian principles, eugenicists did not want to abandon scientific, technological, and medical progress. Rather they sought to escape the negative consequences by consciously controlling human reproduction.

Simultaneous with this fear of biological decline, many psychiatrists by the 1890s were abandoning earlier optimistic beliefs that they could provide cures for many mental illnesses. Instead, they began viewing mental illnesses as often hereditary and beyond influence. Many psychiatrists began to push for control of human reproduction as the most effective means to prevent mental illness. August Forel (1848–1931), a famous psychiatrist at Burghölzi Clinic in Zurich, began promoting eugenics in the late nineteenth century, and he decisively influenced many other psychiatrists and physicians. One medical student in Zurich who imbibed eugenics from Forel was Alfred Ploetz (1860–1940), who in 1904 began editing the first eugenics journal in the world. The following year he founded the Gesellschaft für Rassenhygiene (Society for Race Hygiene), an organization dedicated to improving human heredity. He quickly recruited many leading scientists, psychiatrists, and physicians to the cause.

Eugenics in the Early Twentieth Century

In the ensuing two decades, eugenics organizations also formed in many other countries, not only in the United States and Europe, but also in Latin America and Asia. The prominent geneticist Charles Davenport (1866–1944) founded the Eugenics Record Office in Cold Springs Harbor, New York, which became one of the leading institutions in the United States promoting eugenics by compiling family medical histories. Many wealthy patrons, including Andrew Carnegie and John D. Rockefeller, funded eugenics organizations.

Eugenics also stimulated the rise of birth control organizations. Indeed, one of the primary goals of the pioneers in the birth control movement—including Margaret Sanger (1879–1966) in the United States and Marie Stopes (1880–1958) in Britain—was to diminish the reproductive rates of those members of society they considered inferior. In 1919 Sanger stated, "More children from the fit; less from the unfit—that is the chief issue of birth control" (Paul 1995, p. 20). Nonetheless, most eugenicists opposed the easy availability of birth control, because they feared it would lead to a decline in natality rates among the upper and middle classes, which they wanted to increase. They wanted birth control, of course, but under the control of physicians making decisions in the interests of society, not freely available to individuals.

The eugenics movement had clout far greater than reflected by the small number of people in eugenics organizations, because its influence in the medical profession, especially among psychiatrists, was strong. In some countries the eugenics movement exerted enough influence to pass legislation aimed at restricting reproduction of individuals considered "defective." The first eugenics legislation in the world was a compulsory sterilization law passed by the state of Indiana in 1907. Other states followed suit, allowing doctors to sterilize patients who had various hereditary illnesses, especially mental illnesses. On the basis of these laws, from the 1920s to the 1950s, about 60,000 people were compulsorily sterilized in the United States. The Supreme Court upheld the right of states to sterilize those with hereditary illness in the *Buck* v. *Bell* case in 1927. Denmark was the first European country to enact a sterilization law in 1929, but it was voluntary until new legislation in 1934 made it compulsory in some cases.

Nazi Eugenics and Afterward

The Nazi regime passed the most sweeping eugenics measures in the world, because Adolf Hitler and other leading National Socialists were fanatical about trying to produce a healthy master race in Germany. In 1933 the Nazis passed a compulsory sterilization law that resulted in more than 350,000 sterilizations during their twelve years in power. In 1939 Hitler secretly ordered the beginning of a "euthanasia" campaign, killing 70,000 mentally handicapped Germans within two years. The Nazis also considered the mass killing of those of races they deemed inferior—especially Jews, but also Gypsies and others—part of their eugenics program, because they believed that this would improve the human race. Many German physicians, imbued with eugenics ideals, participated in the Nazi euthanasia program and the Holocaust.

Since the Nazi era many people have mistakenly associated eugenics with right-wing, reactionary politics. However, in its early phases, most eugenicists were progressive politically, and eugenics was popular in leftist circles. Most of the early German eugenicists were non-Marxian socialists or at least sympathetic with socialism. Many anarchists, such as Emma Goldman (1869–1940), promoted eugenics, as did most Fabian socialists in Britain. The Danish government that enacted the 1929 and 1934 sterilization laws was socialist. Many liberals and conservatives supported eugenics as well, so it cut across political lines.

Despite the movement's successes, many countries rejected attempts to enact eugenics legislation, and critics of eugenics arose, challenging its premises. The Catholic Church was the staunchest adversary of eugenics, and the pope issued an encyclical in 1930 opposing eugenics, especially measures such as compulsory sterilization. Catholics and some conservative Protestants recognized that eugenics contradicted the traditional Christian attitudes toward sexual morality, compassion for the handicapped, and human equality. However, most liberal Protestants jumped on the eugenics bandwagon, seeing it as a progressive, scientific movement. By the late 1920s many German Protestant leaders supported eugenic sterilization, and Protestants in the United States sponsored prizes for the best sermons on eugenics.

By the 1960s the eugenics movement seemed dead, and the term itself had negative connotations. Eugenics suffered from its association with Nazism, but this was only one factor. The decline of biological determinism in most scholarly fields, especially psychology and the social sciences, made people suspicious of the claims of eugenics. Also, the individualism of the 1960s, along with calls for reproductive autonomy, undermined the collectivist mentality of eugenics and its desire to control reproduction. As the abortion debate heated up in the 1970s, pro-life forces and pro-choice advocates both opposed eugenics, the former because they saw it as devaluing human life, and the latter because it violated reproductive freedom.

The New Eugenics

However, advances of medical genetics in the late twentieth century led to a "new eugenics." New reproductive technologies, including amniocentesis, ultrasound, in vitro fertilization, sperm banks, genetic engineering, and cloning, opened up new possibilities to control human fertility and heredity, especially because the human genome project has now mapped human DNA. Some proponents want to use these new technologies not only to rid the world of congenital disabilities, but also to produce "designer babies." Intense debates are raging in the early 2000s over "designer babies" and reproductive cloning, because most people consider these unethical interventions in reproduction. The legalization of abortion in most countries and the widespread practice of infanticide, even though illegal, are other factors fostering the new eugenics, because this allows parents the opportunity to decide whether they want a child with particular characteristics. The big difference between this new eugenics and the old eugenics is that in most countries the decision making about human heredity is in the hands of the individual (though physicians and society often apply pressure). However, in 1995 China passed a eugenics sterilization law, which was ostensibly voluntary; especially in light of that government's one-child policy, the pressure to abort fetuses deemed defective is great.

EUTHANASIA

Strictly speaking, *euthanasia* is Greek for "good death," but it has come to be applied to cases of an ill or disabled person being helped to die or deliberately killed by another for the ill or disabled person's benefit. It is thus distinguished from murder. Euthanasia is also to be distinguished from mercy killing. Whereas *mercy killing* normally refers to an act on the part of a friend or relative, euthanasia is typically discussed in relation to health care professionals. A number of further distinctions are drawn between different types of euthanasia: between active and passive euthanasia, and between voluntary, non-voluntary, and involuntary euthanasia. Whereas active euthanasia implies a deliberate act of killing, passive euthanasia means causing death by *not* doing something: allowing to die by withdrawing or withholding treatment. Not all forms of withdrawing treatment count as euthanasia, as when the treatment is futile or constitutes an "extraordinary" means of maintaining life.

Indeed, advances in medical science and technology have intensified concern for euthanasia because of the increased power to keep persons alive who nevertheless become dependent on various treatments. Examples range from cases of feeding tubes and artificial respiration to kidney dialysis and organ transplants. In all such instances, science and technology sometimes lead to deteriorations in the quality of life or costs that lead patients, those closest to them, and health care givers and policy makers to raise questions about continuation of treatment. Such questions often focus on whether and under what circumstances euthanasia might be a proper alternative.

Voluntary euthanasia is a response to a request on the part of a competent individual who regards death as preferable to continuing to live: The individual in question must be in a position to understand the nature of what he or she is asking and to consent to it. Non-voluntary euthanasia occurs in cases where the individual is not in a position to make a euthanasia request, such as because of a lack of competence. Competence is context-specific, so it is not necessarily the case that the individual in question is unable to make any decisions at all. As a matter of fact, several of the most-discussed issues in euthanasia do concern cases of such total incompetence, as illustrated by the following.

Non-voluntary cases fall into different types. There are adults who have lost the capacity to make an informed choice—for example, because they are in a coma or persistent vegetative state. For such persons, the living will or advance directive is one way of stating a preference should such an eventuality arise. These are subject to criticism, though, on the grounds that people may be unable to anticipate how their preferences might change over time.

Alternatively, there are those who have not yet developed to the stage at which they have acquired the capacity to state a preference, such as infants. In some cases, newborns who are born with severe medical problems are rejected by their parents, and then decisions have to be made by health care professionals about how to deal with this situation. High profile cases such as the Arthur case in the United Kingdom (see Kuhse and Singer 1985) have dealt with the question of whether it is appropriate to allow such infants to die.

In contrast to non-voluntary euthanasia, involuntary euthanasia refers to ending people's lives against or in spite of their wishes. The distinction between involuntary euthanasia and murder is more difficult to draw than in the case of other types of euthanasia, but there are some possible instances; for example, where someone is critically injured on a battlefield, cannot be saved, and a military doctor who is present, having no morphine, shoots the injured person dead.

Arguments for Euthanasia

There is controversy both about the ethics of euthanasia *per se* and about the moral distinction between active and passive versions. The moral argument for euthanasia is normally put in terms of voluntary active euthanasia—that is, when persons are terminally ill and no longer have any hope of recovery, are in pain or distress, are considered competent, and ask for someone to end their lives, the argument is that these individuals have a right to die based on respect for their autonomy. Surely, the argument goes, if individuals should have control over anything, they should have it over their own bodies, although it may be argued that there is an inconsistency in using an autonomy argument to bring to an end the conditions of exercise of autonomy, namely bodily life.

Euthanasia can also be argued for on the grounds of beneficence, or on consequentialist grounds (that is, as a means to reduce suffering by removing conditions of the possibility of that suffering persisting). This type of argument can be used to justify non-voluntary euthanasia as well as voluntary euthanasia. Where the individual is unable to express a choice, then the incompetent individual could be denied access to help if autonomy were the only type of argument appealed to; they may be granted help if an argument of beneficence or consequentialism is relied upon. Whether the consequentialist argument could be used to justify involuntary euthanasia is much more contentious.

Arguments Against Euthanasia

The autonomy and beneficence arguments are strong, but may be deployed in a different way on the other side of the debate. If what is regarded as important is autonomy, then the autonomy of persons asked to carry out euthanasia must also be considered. They have to agree that this is a course of action they are prepared to undertake. So the fact that someone of sound mind requests euthanasia does not settle the question if the person who is being asked to perform the action does not agree.

From a consequentialist perspective, it has to be admitted that while in individual cases the best result may appear to be achieved by euthanizing someone whose life has become not worth living, this judgment is fraught with difficulty. In the case of non-voluntary euthanasia, a judgment is made in the absence of a person's own request, when it might well be argued that the benefit of the doubt should count for life. To make the judgment that another person's life is not worth living invites the charge of "playing God."

Partly for this reason, involuntary euthanasia has few supporters: The autonomy argument speaks against it. In the battlefield case it is necessary to assume, if it is to count as involuntary, that the doctor is acting against the express wishes of a soldier, who may be begging for help to save his life. In such a case the doctor may be presumed to make a decision based on the realization that this is not possible.

Apart from the consequences of euthanasia of whatever type for the individual killed, there may be side effects on others. These include worries about hardening the attitudes of those involved in the killing and a gradual lessening in society of respect for life. If euthanasia were widely practiced (as has been the case in some societies), there might be pressure on some people (for example, the elderly and infirm) to agree to request "voluntary" euthanasia. This may be regarded as evidence of a "slippery slope" from voluntary to what could be construed as involuntary euthanasia, because if people feel pressured to consent then their voluntariness is undermined.

In addition, there is the argument based on professional roles. Should health care professionals, who have been trained to cure and to care, use their skills for killing?

The strongest objection to euthanasia, however, derives from the view that killing is wrong *in itself*, on the grounds of the sanctity of life. If life is sacred, then it is wrong deliberately to take a human life. Of course this principle is very difficult to uphold in all circumstances, although people differ about the nature of potential exceptions such as self-defense, war, and capital punishment. Because of the difficulty of upholding an absolute prohibition on taking the life of another, various distinctions have been proposed, including the active-passive distinction already mentioned, and the doctrine of double effect.

A Moral Distinction Between Active and Passive Euthanasia?

According to the active-passive distinction, there is a moral difference between a deliberate act to end someone's life and allowing them to die. To a certain extent the issues here have increased in complexity with medical knowledge and scientific advance, for example, in the light of greater sophistication of use of drugs to control pain, which may at the same time hasten death. From a consequentialist perspective it has been argued that there is no moral difference between killing and allowing to die, because the ultimate outcome is the same—the person is dead. In fact, when side effects are taken into account, the consequences of allowing to die rather than killing might be worse in terms of distress to all concerned. If what is aimed at is a kind and peaceful death, a quick deliberate act may be more merciful than a long-drawn out "allowing to die."

From the perspective of a deontological tradition, however, the quality of the act is what is important. One case is a deliberate killing. The other allows nature to take its course. In some cases, however, it is clear that more than "allowing nature to take its course" is involved, even where it is claimed that deliberate killing is avoided. It is here that the doctrine of the double effect becomes relevant.

Doctrine of the Double Effect

The doctrine of the double effect presupposes that an action can have two kinds of effect: intended and foreseen. Whereas it is claimed that it is always wrong intentionally to do a bad act, it is sometimes permissible to do an act *foreseeing* that bad consequences will ensue. As applied to euthanasia, the point would be that while it is always wrong intentionally to kill, it may be permissible to give drugs to relieve pain, even foreseeing that death will be hastened as a result.

While in some cases this doctrine may appear to give intuitively the right result, and while it has indeed influenced medical practice to a considerable extent, it poses several problems. First, how does one know what constitutes the class of bad acts to be absolutely prohibited? There is no agreement that deliberate killing is ruled out in all circumstances. Second, how does one distinguish between an intended and a foreseen consequence, and indeed between an act and its consequences? There need to be some limits to the freedom to describe the action in certain ways, otherwise it could be open to an agent to deny that any undesirable consequences were intended. The British case of Dr. Cox (Rv Cox [1992] 12 BMLR 38) concerned a physician who administered potassium chloride to a patient who was suffering from intractable pain. That drug does not have pain-relieving properties, so it was not open to the doctor to claim that it was given for that purpose. Had he administered morphine, he might have been able to rely on the doctrine of double effect. While philosophers have heavily criticized the doctrine, it has been influential in law.

Conclusion

From a moral point of view the strongest arguments in favor of euthanasia are to benefit an individual, whether to respect their autonomy or to prevent suffering. At the societal level, however, there are serious concerns about abuse of euthanasia for the benefit not of those killed, but of third parties or society especially in the light of issues about scarce health resources and health inequalities and concerns about these as influencing factors. So controversy continues about the practice of voluntary euthanasia according to guidelines such as in the Netherlands, for example. Despite widespread acknowledgement of the benefit to those with intractable suffering, there are also historical precedents of abuse, which lead opponents to argue that one should err on the side of preserving life. These concerns have to be taken into account in considering proposals for legalization.

EUTHANASIA IN THE NETHERLANDS

In the Netherlands, euthanasia is understood to mean termination of life by a physician at the request of a patient. It is to be clearly distinguished from withdrawing from treatment when further medical intervention is pointless, allowing nature to take its course. The latter is normal and accepted medical practice, as is the administration of drugs necessary to relieve pain even in the knowledge that they may have the side effect of hastening death. It should be emphasized that both termination of life upon request and assisting at a suicide are prohibited in the Netherlands. But in the Dutch penal code a special ground for exemption from criminal liability has been developed for physicians who terminate a patient's life on request or assist in a patient's suicide, provided they satisfy the due-care criteria formulated in an act that went into effect in April 2002. This regulation on euthanasia—called the Termination of Life on Request and Assisted Suicide (Review Procedures) Act—is clearly a political compromise between Dutch liberals and Social Democrats, on the one hand, and the Christian Democrats, on the other. If this act had wholly decriminalized euthanasia it would not have received Christian Democrat support. In Belgium, the second country with legislation on euthanasia, the practice is not very different from that in the Netherlands with one exception: Premature termination of life is not considered a criminal act.

Theory and Practice

Pain, degradation of life, and the longing to die with dignity are the main reasons why patients request euthanasia. The initiative is on the part of the patient. To put it bluntly, without such a request it is a matter of murder. People in the Netherlands, as in other advanced countries, are living longer lives, so that, for example, cancer and its pains claim a rising proportion of victims. It should be emphasized that people in the Netherlands do not request euthanasia out of concern at the cost of treatment, because everyone is fully insured under the social security system.

When dealing with a patient's request for euthanasia, physicians must observe the following due-care criteria. They must (1) be satisfied that the patient's request is voluntary and well-considered; (2) be satisfied that the patient's suffering is unbearable and that there is no prospect for improvement; (3) inform the patient of his or her situation and further prognosis; (4) discuss the situation with the patient and come to the joint conclusion that there is no other reasonable solution; (5) consult at least one other physician with no connection to the case, who must then see the patient and state in writing that the attending physician has satisfied the due-care criteria listed in the four points above; and (6) exercise due medical care and attention in terminating the patient's life or assisting in his or her suicide.

Regional review committees (appointed by the Minister of Justice and the Minister of Health, Welfare and Sport) assess whether physicians' actions satisfy these criteria. If the assessment is positive, the Public Prosecution Service will not be informed and no further action will be taken. But if a review committee finds that a physician has failed to satisfy the statutory due-care criteria, the case will be referred to the Public Prosecution Service and the Health Inspectorate. These two bodies will then consider whether the physician should be prosecuted. The existence of a close physician–patient relationship is taken as premise. Physicians may perform euthanasia only on patients in their care. They must know their patients well enough to be able to determine whether the request for euthanasia is both voluntary and well-considered, and whether the suffering is unbearable and without prospect for improvement.

Even in cases in which patients are receiving care of the highest quality, they may still regard their suffering as unbearable and plead with their physicians to terminate their lives. In such cases, euthanasia could represent a dignified conclusion to good palliative care. There is, however, no requirement that physicians comply with the requests for euthanasia. Physicians can refuse to terminate life; after all it is not a normal medical procedure. The ability to refuse a request for euthanasia or assisted suicide guarantees physician's freedom of conscience. If a physician does not want to be involved, he or she is obligated to refer the patient to a colleague.

It is the task of the physician to try to imagine what the patient is feeling and based on his or her medical experience attempt to assess the patient's suffering objectively. Unbearable suffering also includes psychological suffering. If a patient has a psychological illness and his or her suffering is not primarily caused by a physical complaint, it is difficult to assess objectively whether a request for euthanasia is voluntary and well-considered. In such cases, the attending physician should consult two independent specialists, at least one of whom must be a psychiatrist, and they must personally examine and interview the patient. The presence of dementia or some other such condition is not in itself a reason to comply with a request for termination of life or assisted suicide. For some people, however, the very prospect of one day suffering from dementia and the eventual associated loss of personality and dignity is sufficient reason to make an advance directive covering this possibility. Each case needs to be individually assessed to decide whether, in the light of prevailing medical opinion, it can be viewed as entailing unbearable suffering for the patient with no prospect for improvement. In response to questions on this subject in the Dutch Parliament, the Minister of Health, Welfare and Sport stated that dementia can make the patient's quality of life unacceptable if the patient him- or herself regards his or her condition in this way, but that even then the physician must decide whether the patient's suffering is unbearable and without prospect for improvement in the light of prevailing medical opinion.

The aim of the Dutch policy is to bring matters into the open, to apply uniform criteria in assessing cases of euthanasia, and hence to ensure that maximum care is exercised in such cases. The price for this openness is a lot of formalistic procedures with no respect to content or guarantee of care. In this area the regional review committees function quite adequately. But not all end-of-life issues are covered by the issue of euthanasia. In the concentration on euthanasia and assisted suicide all forms of sedation with and without consent of the patient fall outside the scope and competence of the assessing committees. Palliative care is not concentrated on recovery but on alleviation of pain and other symptoms. Palliative and in particular terminal sedation may come close to euthanasia. For physicians who do not want to get involved with euthanasia for religious, bureaucratic, or whatever reasons these forms of sedation are a refuge.

Reflective Implications

Traditionally, as specified in the Hippocratic oath, physicians ended their care at the deathbed. Once death was inevitable, the office of the physician—which was to help people avoid the evils of sickness, physical deficiencies, the ailments of old age, and a premature death—had come to an end. In modern society the physician's task has been enormously extended so that the entire life of a human has been brought under a medical regime. Medical examinations are the order of the day. It is impossible to avoid the physician when going to school, participating in sports, holding down a job, taking out life insurance, and so on. Whomever is unwell hurries to make at least a short visit to the doctor or hospital in order to make use of the paraphernalia of modern medicine. Human health is controlled as a matter of routine. Not only has life undergone medicalization, but dying has also been brought under the medical regime. The result is that human death has become artificial. Many bitter deaths might be a product of modern medical science because postponement of death as a result of medical monitoring in a sense requires its toll. In the early twenty-first century, a natural death is likely an exception to the norm. Thus in normal cases the physician swings the scepter at a person's last bed by prompting the possibilities and impossibilities left to him or her. In some municipalities in the Netherlands in the early twentieth century, more than half of all deceased had no medical intervention while dying. That is now inconceivable.

Physicians play the role of experts in the end-of-life decisions. In some sense they act as examiners, while their patients attempt to pass an exam. A physician scrutinizes whether the wish to die is voluntary, whether it is well considered, whether the wish has been longstanding, whether it is not liable to emotions, whether the suffering is unacceptable to the patient, and so on. What at first sight seems to be a matter of self-determination turns out to be a matter of complete dependency. It is not surprising that well-educated people stand a better chance of having their request granted than those who are less educated. Physicians—in former times absent at the deathbed but now prominently present—find themselves in the position of the expert only because they have access to lethal drugs. This technologically privileged position maneuvers them at the same time into the role of moral examiner. For patients, the inaccessibility of lethal drugs makes the whole procedure into a technological adventure in which they are incompetent. Being alienated from nature, patients have no knowledge about the herbs and fruits in their own garden. Confronted with these final questions they have to throw themselves into the arms of the experts. Tried and tested methods out of ancient times have been blotted out.

The issue of unbearable pain on the deathbed is often technologically transformed into a mild death. Physician and patient talk about pain and how to get rid of it along technological lines. In contemporary technological society humans cannot deal with pain in another way. The opinion that pain should be tolerated, alleviated, and interpreted is no longer widely held. The medicalization of pain robs a culture of an integrative program of pain treatment. In traditional societies opium, acupuncture, or hypnosis were means of alleviating pain, but they were always put into practice in combination with language, rites, and myth. Most people who are morally against euthanasia support sedative treatment. Their position shows how difficult it is to leave the technological society behind, because from a technological point of view euthanasia is not very different from sedative treatment. In practice the outcome is often the same, but only in the mind of the physician does one find the difference between euthanasia and sedative treatment.

A society that denies a patient's request for euthanasia would best abstain from modern technological medical care. Living in a technological society may be compared with climbing mountains. People who have ascended too high must descend very carefully. Under some circumstances a descent may be more difficult than the ascent. When patients cannot tolerate pain any longer, who dares to ask them to interpret the meaning of their pain? Has the modern technological society not abandoned such questions or left them to personal decisions?

EVOLUTIONARY ETHICS

Evolutionary ethics rests on the idea that ethics expresses a natural moral sense that has been shaped by evolutionary history. It is a scientific understanding of ethics as founded in human biological nature.

The first full development of evolutionary ethics came from Charles Darwin (1809–1882) and Herbert Spencer (1820–1903) in the nineteenth century. At the beginning of the twentieth century, the Darwinian theory of ethics was renewed and deepened by Edward Westermarck (1862–1939). At the end of the twentieth century, this Darwinian tradition of ethical philosophy was reformulated by Edward O. Wilson, Robert McShea, Frans de Waal, and others.

Philosophers arguing over the ultimate grounds of ethics have been divided into Aristotelian naturalists and Platonic transcendentalists. The transcendentalists find the ground of ethics in some reality beyond human nature, while the naturalists explain ethics as grounded in human nature itself. In this enduring debate, proponents of evolutionary ethics belong to the Aristotelian tradition of ethical naturalism, while their strongest opponents belong to the Platonic tradition of ethical transcendentalism. (Of course, Aristotelians who reject evolutionary reasoning would also reject evolutionary ethics.)

The history of evolutionary ethics can be divided into three periods, with Darwin initiating the first period, Westermarck the second, and Wilson the third.

Darwin's View

As part of his theory of the evolution of life by natural selection, Darwin wanted to explain the evolution of human morality. From his reading of Adam Smith (1723–1790), David Hume (1711–1776), and other philosophers who saw morality as rooted in moral emotions or a moral sense, Darwin concluded that this moral sense could be understood as a product of natural selection. As social animals, human beings evolved to have social instincts. As rational animals, human beings evolved the rational capacity to reflect on their social instincts and formulate those moral rules that would satisfy their social instincts. Human survival and reproduction required that parents care for their offspring, and the social nature of human beings could be explained as an extension of parental feelings of sympathy to embrace ever larger groups of individuals. In his *Descent of Man* (1871), Darwin concluded: "Ultimately our moral sense or conscience becomes a highly complex sentiment—originating in the social instincts, largely guided by the approbation of our fellow-men, ruled by reason, self-interest, and in later times by deep religious feelings, and confirmed by instruction and habit" (Darwin 1871, Vol. 1, pp. 165–166).

Herbert Spencer (1820–1903) generally agreed with Darwin's evolutionary ethics, yet Spencer put more emphasis than did Darwin on evolution through the inheritance of acquired traits. And unlike Darwin, Spencer saw all of evolutionary history as moving toward a pre-determined end of perfection in which human societies would become so cooperative that they would achieve perpetual peace.

When *The Descent of Man* was published, Darwin's naturalistic theory of morality was attacked by biologist George Jackson Mivart (1827–1900), who claimed that there was an absolute separation between nature and morality. Although Darwin's theory of evolution could explain the natural origins of the human body, Mivart insisted, it could not explain the human soul as a supernatural product of divine creation, and therefore it could not explain human morality, which depended on the soul's freedom from natural causality. Mivart followed the lead of Immanuel Kant (1724–1804) in arguing that the realm of moral duty must be separated from the realm of natural causality, thus adopting a version of the distinction between values and facts.

This dispute between Darwin and Mivart shows the conflict between the naturalistic tradition of moral thought and the transcendentalist tradition that runs throughout moral philosophy and throughout the debate over evolutionary ethics. According to Plato (in *The Republic*), one cannot know what is truly good until one sees that all of the diverse goods of life are only imperfect imitations of the Idea of the Good, which is universal, absolute, and eternal. In Plato's theological version of this teaching, God as the Creator of the cosmos is said to be a providential caretaker of human affairs who judges human beings after death, rewarding the good and punishing the bad. Aristotle (in the *Nicomachean Ethics*) rejected this Platonic Idea of the Good, because he could not see any sense in saying there is a transcendent good separated from all the diverse natural goods that human beings seek. Looking to the common-sense experience of human beings, Aristotle thought that the ultimate end for which human beings act is happiness, and happiness would be the human flourishing that comes from the harmonious satisfaction of human desires over a whole life. Like Smith and Hume, Darwin followed the Aristotelian tradition in rooting morality in natural desires and emotions. Like Kant, Mivart followed the Platonic tradition in positing a moral *ought* belonging to a transcendent world of moral freedom beyond the empirical world of natural causes.

Thomas Huxley (1825–1895), one of Darwin's most fervent supporters, initially defended Darwin's evolutionary ethics against Mivart's criticisms. But eventually, in his 1893 lecture on "Evolution and Ethics," Huxley adopted Mivart's transcendentalist position. Because of the "moral indifference of nature," Huxley declared, one could never derive moral values from natural facts. He argued that "the ethical process of society depends, not on imitating the cosmic process, still less in running away from it, but in combating it," and thus building "an artificial world within the cosmos (Paradis and Williams 1989, pp. 117, 141)."

Westermarck's Views

After Huxley's attack, Darwin's naturalistic ethics was kept alive in the early-twentieth century by philosophers such as Westermarck. In his *History of Human Marriage* (1889), Westermarck explained the desires for marriage and family life as founded in moral emotions that had been shaped by natural selection as part of the biological nature of human beings. His most famous idea was his Darwinian explanation of the incest taboo, which can be summarized in three propositions. First inbreeding tends to produce physical and mental deficiencies in the resultant offspring, which lowers their fitness in the Darwinian struggle for existence. Second, as a result of the deleterious effects of inbreeding, natural selection has favored the mental disposition to feel an aversion toward sexual mating with those with whom one has been an intimate associate from early childhood. Third this natural aversion to incest has been expressed culturally as an incest taboo. Consequently, in all human societies, there is a strong tendency to prohibit fathers marrying daughters, mothers marrying sons, and brothers marrying sisters, although there is more variation across societies in the rules governing the marriage of cousins and others outside the nuclear family. (In 1995 Anthropologist Arthur Wolf surveyed the growing evidence confirming Westermarck's Darwinian theory of incest avoidance.)

Westermarck believed all of the moral emotions could be ultimately explained in the same way he had explained the abhorrence of incest. As animals formed by natural selection for social life, humans are inclined to feel negative about conduct perceived as painful, and positive toward conduct perceived as pleasurable. The mental dispositions to feel such emotions evolved in animals by natural selection because these emotions promote survival and reproductive fitness: Resentment helps to remove dangers, and kindly emotion helps to secure benefits. For the more intelligent animals, these dispositions have become conscious desires to punish enemies and reward friends.

Moral disapproval, Westermarck argued, is a form of resentment, and moral approval is a form of kindly emotion. In contrast to the non-moral emotions, however, the moral emotions show apparent impartiality. (Here he shows the influence of Smith's idea that the moral sentiments arise when we take the perspective of the *impartial spectator*.) If a person feels anger toward an enemy or gratitude toward a friend, these are private emotions that express personal interests. In contrast, if a person declares some conduct of a friend or enemy to be good or bad, he or she implicitly assumes that the conduct is good or bad regardless of the fact that the person in question is a friend or enemy. This is because it is assumed that when conduct is determined to be good or bad, a person would apply the same judgment to other people acting the same way in similar circumstances, independently of the effect on that individual. This apparent impartiality characterizes the moral emotions, Westermarck explained, because "society is the birth-place of the moral consciousness" (1932, p. 109). Moral rules originated as tribal customs that expressed the emotions of an entire society rather than the personal emotions of particular individuals. Thus moral rules arise as customary generalizations of emotional tendencies to feel approval for conduct that causes pleasure and disapproval for conduct that causes pain.

Although Westermarck stressed the moral emotions as the ultimate motivation for ethics, he also recognized the importance of reason in ethical judgment. "The influence of intellectual considerations upon moral judgments is certainly immense" (1932, p. 147). Emotions, including the moral emotions, depend upon beliefs, and those beliefs can be either true or false. For example, a person might feel the moral emotion of disapproval toward another that he or she believes has injured a friend, but if that same person discovers by reflection that an injury was accidental and not intentional, or that an action did not actually cause any injury at all, the disapproval vanishes. Moreover, because moral judgments are generalizations of emotional tendencies, these judgments depend upon the inductive use of human reason in reflecting on emotional experience.

Wilson's View

By the 1970s, however, there was little interest in the ethical naturalism of people such as Westermarck, and the transcendentalist tradition had largely conquered the intellectual world of philosophers and social scientists. Ethics and politics were assumed to belong to an autonomous human realm of reason and culture that transcended biological nature. This could be explained as a reasonable reaction against the morally repulsive conduct associated with "Social Darwinism" in the first half of the twentieth century.

This also explains why the publication of Wilson's book *Sociobiology* in 1975 provoked great controversy. Wilson defined *sociobiology* as the scientific study of the biological bases of the social behavior of all animals, including human beings. On the first page of the book, he claimed that ethics was rooted in human biology. He asserted that the deepest human intuitions of right and wrong are guided by the emotional control centers of the brain, which evolved through natural selection to help the human animal exploit opportunities and avoid threats in the natural environment.

One of the first serious responses to Wilson's proposal for sociobiological ethics was a conference in Berlin in 1977 titled "Biology and Morals." The material from this conference was later published as a book edited by Gunther Stent. In his introduction, Stent began by contrasting the "idealistic ethics advocated by Plato" and the "naturalistic ethics advocated by Aristotle." He suggested that those people who belonged to the *idealistic* tradition would reject Wilson's sociobiological ethics, while those belonging to the *naturalistic* tradition would be more inclined to accept it.

In this book Thomas Nagel, a philosopher, showed the reaction of the Platonic transcendentalist. He rejected sociobiological ethics because it failed to see that ethics is "an autonomous theoretical subject" (Nagel 1978) such as mathematics that belongs to a transcendent realm of pure logic. On the other side of this debate, Robert McShea, a political scientist, independently welcomed Wilson's sociobiological ethics as providing scientific confirmation for the insight of Aristotle and Hume that ethics is rooted in the emotions and desires of human biological nature (Mcshea 1978). All writing on this subject that followed, as of 2004, fell into one of these two intellectual camps.

The transcendentalist critics of evolutionary ethics include most of the leading proponents of evolutionary psychology, which applies Darwin's theory of evolution in explaining the human mind as an adaptation of human nature as shaped in evolutionary history. Evolutionary psychologists such as George Williams (1989) claim that ethics cannot be rooted in human nature because of the unbridgeable gulf between the selfishness of our natural inclinations and the selflessness of our moral duties. As the only rational and cultural animals, human beings are able to suppress their natural desires and enter a transcendent realm of pure moral duty. Like Huxley, Williams and other theorists of evolutionary psychology reject Wilson's sociobiological ethics because they think that ethics requires a transcendence of human biology through culture and reason. Unlike Wilson and Darwin, therefore, the proponents of evolutionary psychology do not believe that biological science can account for the moral conduct of human beings.

Objections and Replies

There are at least three major objections to this Darwinist view of morality. One common criticism of evolutionary ethics is that it promotes genetic determinism. If all choices are ultimately determined by genetic causes, that would seem to deny that human actions can be freely chosen, which would deny the fundamental presupposition of moral judgment that people can be held responsible for their moral choices.

But if genetic determinism means that behavior is rigidly predetermined by genetic mechanisms, so that neither individual learning nor social culture has any influence, then defenders of evolutionary ethics are not genetic determinists. What the genes prescribe, Wilson would say, is certain propensities to learn some behaviors more easily than others. Human nature, Wilson explains in his 1998 book *Consilience*, is not a product of genes alone or of culture alone. Rather, human nature is constituted by "the epigenetic rules, the hereditary regularities of mental development that bias cultural evolution in one direction as opposed to another, and thus connect the genes to culture" (p. 164). Consequently human behavior is highly variable across individuals and across societies, but the genetic nature of the human species is manifested in the general pattern of behavior.

So, for example, the natural human propensity to incest avoidance is actually a propensity to learn a sexual aversion to those with whom one has been raised. The precise character of the incest taboo will vary greatly across societies depending on the diversity in family life and kinship systems. For instance some societies will forbid marrying first cousins, while others will not. Yet the tendency to forbid the marriage of brother and sister or of parent and child will be universal or almost universal. Moreover one can deliberate about the rules of incest avoidance by reflecting on the relevant facts and emotions. When the incest taboo is formally enacted in marriage law, legislators must decide what counts as incest and what does not.

Proponents of evolutionary ethics would say that people are not absolutely free of the causal regularities of nature. Exercising such absolute freedom from nature—acting as an uncaused cause—is possible only for God. But human beings are still morally responsible for their actions because of the uniquely human capacity for reflecting on motives and circumstances and acting in the light of those reflections.

A second criticism of evolutionary ethics is that it promotes a crudely *emotivist* view of ethics as merely an expression of arbitrary emotions. After all, from the first paragraph of *Sociobiology*, Wilson speaks of ethics as controlled by "the emotional control centers in the hypothalamus and limbic system of the brain" (1975, p. 31). He repeatedly identifies the ultimate foundation for ethical codes as "our strongest feelings of right and wrong" (Ruse and Wilson 1994, p. 422). "Murder is wrong" might be just another way of saying "I don't like murder." Does that deny the sense of moral obligation as something more than just an expression of personal feelings?

People might also wonder how an emotivist ethics would handle the response of those with deviant emotions, such as that of psychopaths who do not show the normal emotions of guilt, shame, or sympathy. How can society condemn them if there are no objective moral norms beyond emotion? Moreover, how does society resolve the emotional conflicts that normally arise within and between individuals? How does society rank some emotional desires as higher than others? Such problems lead many philosophers to dismiss emotivist ethics as incoherent.

In reply to this criticism, the defender of evolutionary ethics might again consider the case of the incest taboo. If Westermarck is right, moral condemnation of incest arises from an emotion of sexual aversion toward those with whom one has been raised in early childhood. This personal emotion of disgust becomes a moral emotion of disapprobation when generalizing emotional experience into an impartial social rule: People judge that incest is bad not just for themselves but for all members of society in similar circumstances. Reason plays a part in generalizing these emotions. By reason people must formulate what counts as incest. Generally society condemns the sexual union of siblings or of parents and children. But whether one condemns the marriage of cousins will depend on the circumstances of kinship and judgments about whether the consequences are good or bad for society.

Normally most human beings will feel no sexual attraction to their closest kin. Those who do will usually feel a conflict between their sexual desire and their fear of violating a social norm that expresses deep emotions, and this fear of social blame will usually override their sexual interest. Those who do violate the incest taboo will be punished by a disapproving society. A few human beings might feel no emotional resistance to incest at all. They might be psychopathic in lacking the moral emotions of guilt and shame that are normal for most people. If so then society will treat them as moral strangers, as people who are not restrained by social persuasion, and who therefore must be treated as social predators.

The main point for those favoring evolutionary ethics is that although the moral emotions are relative to the human species, they are not arbitrary. One can easily imagine that if other animal species were to develop enough intellectual ability to formulate moral rules, some of them might proclaim incest to be a moral duty, because the advantages of inbreeding for bonding between kin might be greater than the disadvantages. But human beings are naturally inclined to acquire an incest taboo, and therefore to condemn those individuals who deviate from this central tendency of the species.

Emphasizing emotion in moral experience denies the transcendentalist claim that morality depends on pure reason alone. The 1994 work of Antonio Damasio and that of other neuroscientists suggests that the emotional control centers of the brain are essential for normal moral judgment. Psychopathic serial killers can torture and murder their victims without feeling any remorse. Yet they are often highly intelligent people who suffer no deficits in their cognitive capacities. Their moral depravity comes not from any mistakes in logical reasoning but from their emotional poverty in not feeling moral emotions such as guilt, shame, love, and sympathy.

A third objection to evolutionary ethics is that it fails to recognize the logical gap between *is* and *ought*, between natural facts and moral values. Determining that something is the case does not say that it ought to be so. A scientific description of a behavior is not the same as a moral prescription for that behavior.

In reply to this objection, proponents of evolutionary ethics might agree with Hume's interpretation of the is/ought dichotomy, which claims that pure reasoning about factual information cannot by itself move people to moral judgments. Moral motivation requires moral emotions. Those moral emotions, however, manifest propensities of human nature that are open to scientific study.

The incest taboo illustrates this. The factual information about inbreeding does not by itself dictate any moral judgment. If society did not feel moral emotions of disgust toward inbreeding among human beings, it would not be condemned as immoral. Even the factual information about the deleterious effects of inbreeding would not incur moral condemnation if people did not feel sympathy for human suffering.

The move from facts to values is not logical but psychological. Because people have the human nature that they do, which includes propensities to moral emotions, they predictably react to certain facts with strong feelings of approval or disapproval, and the generalization of those feelings across a society constitutes moral experience.

If society decided that evolutionary ethics was correct about ethics being grounded in emotions, this would influence assessment of the technologies of emotion. People might decide, as many science fiction authors have suggested, that robots could become moral beings only if they could feel human emotions. Society might also wonder about the moral consequences of new biomedical technologies for manipulating emotions through drugs and other means. People might question whether the technology of birth control could obviate the need for the incest taboo.

EVOLUTION–CREATIONISM DEBATE

• • •

The evolution-creationism debate deals with attempts to explain the ultimate causes of order in the living world. Some people think that order arose from natural evolutionary causes. Others think it arose from divine creative intelligence. A third group thinks it arose from divine intelligence working through natural causes.

Nature of the Debate

This debate can be traced back as far as ancient Greece, where it appears in Plato's philosophical dialogues. More recently the debate has been between followers of the Bible and followers of the scientist Charles Darwin (1809–1882). The opening chapters of the Bible relate how God created the world in six days and created human beings in his image. In *The Origin of Species* (1859) and *The Descent of Man* (1871) Darwin discusses how all the forms of life could have evolved by natural law, in which the heritable traits that enhanced reproductive success were naturally selected over long periods. The evolution-creationism debate entails comparing these two scenarios of the origins of life. Some people believe that both histories are true and therefore can be compatible. Some believe that if one of the two is true, the other must be false.

This becomes a debate over the ethical implications of modern science because much of the disagreement turns on judgments about the ethical consequences of accepting one or both views as true. On one side many of those who defend creationism fear that Darwinian evolution promotes a materialistic view of the world that is ethically corrupting, because it denies the moral dignity of human beings as created in God's image. On the other side, some see creationism as promoting fundamentalist religion and attacks on science.

This has also become a legal and political debate, particularly in the United States, where people have argued about whether creationism should be taught to students in public schools as an alternative to Darwinian evolution. Some public opinion surveys have reported that about half the people in the United States believe that human beings were created by God approximately 10,000 years ago; that would deny the Darwinian belief that the human species evolved from an apelike ancestral species millions of years ago.

History of the Debate

In Plato's dialogue *The Laws* (Book 10) the Athenian character warns against natural philosophers who teach that the ultimate elements in the universe and the heavenly bodies were brought into being not by divine intelligence or art but by natural necessity and chance. These natural philosophers teach that the gods and the moral laws attributed to the gods are human inventions. That form of scientific naturalism appeared to subvert the religious order by teaching atheism, subvert the moral order by teaching moral relativism, and subvert the political order by depriving the laws of religious and moral sanction. Plato's Athenian character responds to that threat by arguing for divine intelligent design as the ultimate source of order.

In a later period those influenced by biblical religion adopted Plato's arguments to defend the claim that the divinely intelligent designer of the world was the God of the Bible. However, in the nineteenth century Darwin's theory of evolution by natural selection seemed to explain the apparent design in the living world as arising from purely natural causes without the need for divine creation. This led to the modern debate between evolution and creationism.

In the United States that debate falls into three periods. The first period began in the 1920s when William Jennings Bryan (1860–1925) launched a Christian fundamentalist attack on Darwinism. Bryan was a leading politician, having run three times for the presidency as the Democratic Party's candidate. In 1925 the state legislature in Tennessee made it illegal for any teacher in a public school "to teach any theory that denies the story of the Divine creation of man as taught in the Bible, and to teach instead that man has descended from a lower order of animals" (Larson 1997, p. 50). When John Scopes, a public high school teacher in Dayton, was charged with violating this law, Clarence Darrow (1857–1938), a prominent lawyer who promoted scientific atheism, led the legal team defending Scopes, and Bryan joined the lawyers prosecuting Scopes.

The trial in July 1925 drew public attention around the world. Although Scopes was convicted, his conviction was overturned by a higher court on a technical issue. Bryan died shortly after the trial. Creationist opponents of Darwinian evolution continued to argue their case, although many of them, like Bryan, argued that the six days of Creation in the Bible were not literally six days but rather "ages," so that long periods of time could have elapsed. Some creationists followed Bryan in accepting Darwin's account of evolution by natural law as generally true but still insisted that the emergence of human beings required a miraculous intervention by God to endow them with a spiritual soul that made them superior to all animals.

The second period of the debate was initiated by the publication in 1961 of John Whitcomb and Henry Morris's *The Genesis Flood*. Those authors interpreted the biblical story of Creation as occurring during a literal six-day period that occurred no more than 10,000 years ago. They also argued that the geological record of fossils had been laid down during the worldwide flood reported in the Bible in the story of Noah's ark. Morris and others identified themselves as "scientific creationists," claiming that the Bible as literally interpreted was scientifically superior to Darwin's theory. They supported legislation in some states to require the teaching of "creation science" in public high schools. However, when this was done in Arkansas and Louisiana, federal courts struck down those laws as violating the constitutional separation of church and state because the biblical story of Creation seemed to be a religious doctrine rather than a scientific theory.

The third period of the debate began in 1991 with the publication of Phillip Johnson's *Darwin on Trial*. Johnson, a lawyer and law professor, argued that the scientific evidence is against Darwin's theory and that Darwinians believe the theory only because it supports their atheistic belief that the order in life can be explained by natural laws without the need for divine creation. Johnson also claimed that the complexity of the living world can only be explained as the work of an "intelligent designer" such as the God of the Bible.

Other writers joined this intellectual movement for "intelligent design" as an alternative to Darwinian evolution. In 1996 the biologist Michael Behe published *Darwin's Black Box*, in which he surveyed the evidence for "irreducibly complex" mechanisms in the living world that could not have evolved gradually by Darwinian evolution but could show the work of an "intelligent designer." Later the mathematician and philosopher William Dembski elaborated the formal criteria by which "design" could be detected in nature (Dembski and Kushiner 2001). Since the late 1990s proponents of "intelligent design" have tried to convince public school boards that "intelligent design theory" should be taught in high school biology classes as an alternative to Darwinian science or at least that the weaknesses in the Darwinian arguments should be discussed in schools.

Four Arguments

Beginning with Bryan, the creationist critics of Darwinian science have made four types of arguments: a scientific argument, a religious argument, an ethical argument, and a political argument. Similar kinds of arguments can be found in Plato's *Laws*.

The scientific argument of the creationists is that Darwin's theory is not truly scientific because it is based not on empirical evidence but on a dogmatic commitment to materialistic naturalism. They also claim that creationism is a more scientific view because the complex functional order of the living world provides evidence for an intentional design by a divinely intelligent agent. The irreducible complexity of life cannot be explained through the unintelligent causes of random contingency and natural necessity.

The common mousetrap is Behe's primary example of an irreducibly complex mechanism. It requires at least five parts—a platform, a spring, a hammer, a catch, and a holding bar—and those parts must be arranged in a specific way. If one part is missing or if the arrangement is wrong, the mechanism will not achieve its functional purpose of catching mice. It is known that such a device did not arise by chance or natural necessity; human intelligent agents designed it to catch rodents. Behe claims that many biological mechanisms show the same purposeful arrangement of parts found in human devices such as the mousetrap. This, he thinks, points to an intelligent designer outside nature.

Darwinians would agree with Behe that from an apparently well-designed mousetrap one plausibly can infer the existence of a human intelligent designer as its cause because people have common experience of how mousetraps and other artifacts are designed. However, Darwinians would insist that from an apparently well-designed organic process or entity one cannot infer the existence of a divinely intelligent designer as its cause, because people have no common experience of how a divine intelligence designs things for divine purposes. Religious belief depends on faith in a supernatural reality beyond the world, whereas scientific knowledge depends on reasoning about humankind's sense experience of the natural world. Furthermore, Darwinians would note that creationists or intelligent design theorists never explain the observable causal pathways by which the divine intelligence creates irreducibly complex mechanisms.

The religious argument of the creationists is that Darwinism promotes dogmatic atheism and therefore must be rejected by religious believers. This argument seems to be confirmed by the bold declarations of Darwinian scientists such as Richard Dawkins (1986) that Darwinian science proves the truth of atheism. But it is hard to see how explaining the world through natural causes denies the possibility that God is the ultimate ground of those natural causes. Some Darwinians present evolution as a substitute for religion. Even such a strong defender of evolution as Michael Ruse (2003) has admitted that museums of science that promote evolutionary theory often function as secular temples.

Creationists assume that God was unable or unwilling to execute his design through the laws of nature as studied by Darwinian biologists. However, Christian evolutionists such as Howard Van Till (1999) and others have argued that the Bible presents the divine designer as having given his Creation from the beginning all the formational powers necessary for evolving into the world as it is today. Catholic theologian John Haught (2001) has defended a "theology of evolution" based on ideas from the French Jesuit priest Pierre Teilhard de Chardin (1881–1955) and the British philosopher Alfred North Whitehead (1861–1947). In Haught's theology, evolution suggests that the universe is always in the process of being created as God allows a self-creating world to evolve towards him through time. If this is so, Darwinian science and religious belief are compatible.

The ethical argument of the creationists is that the reductionistic materialism of Darwinian science is ethically degrading. If Darwinians persuade people that they are nothing but animals and therefore are not elevated above other animals by having been created in God's image, people will not respect God's moral law or see the unique moral dignity of human beings. Instead they will become selfish hedonists in the pursuit of their animal desires.

Darwinians respond to this argument by noting that Darwin thought his account of human evolution supported a biological theory of morality rooted in a natural moral sense. As naturally social and rational animals human beings have social instincts that incline them to care for others and have a rational capacity to deliberate about the moral rules that would satisfy their social needs. For example, the human species could not survive if children were not cared for by their parents or by people assuming parental roles. Therefore, one can understand how natural selection has endowed human beings with a natural desire for parental care that supports the moral bond between parent and child. Consequently, Darwinian science sustains morality by showing that it is rooted in human nature.

The political argument of the creationists is that teaching Darwinism in public schools without teaching the creationist criticisms of Darwinism denies the freedom of thought required in a democratic society. Surely, creationists claim, promoting an open discussion in the public schools of the scientific, religious, and ethical debates surrounding Darwinian evolution would help students think for themselves about those important issues.

Some Darwinians reject this argument by claiming that creationism is not science but religion and that the teaching of science should be kept separate from the teaching of religion. However, other Darwinians welcome an open debate. If high school students were free to read writers who defend Darwin's theory along with writers who criticize it, the students could make up their own minds. In the process students might learn how to think through scientific debates and weigh the evidence and arguments for themselves rather than memorizing the conclusions given to them by textbooks and teachers.

EXISTENTIALISM

Existentialism came to prominence shortly after World War II as a philosophical and literary movement stressing individual human experience in a hostile or indifferent world and highlighting freedom of choice and personal responsibility. As a word, *existentialism* has roots in the Latin *existere,* meaning to stand forth. Indeed existentialists argue that human beings stand out from other things because of the way humans stand consciously and freely in relation with things and with one another. Existentialists developed criticisms of science and technology especially insofar as they deny or obscure this uniqueness.

Historical Development

In the nineteenth century, Søren Kierkegaard (1813–1855) first used the word *existence* to designate a deep individuality that escaped the grip of bourgeois society and religion, and rationalistic philosophy. Though Friedrich Nietzsche (1844–1900) did not use the word, his radical analyses and demands for self-creation influenced later existentialist thinkers. Nineteenth-century Romanticism can be seen as proto-existentialist, and writers such as Ralph Waldo Emerson (1803–1882) and Fyodor Dostoevsky (1821–1881) (who both influenced Nietzsche) sought to redefine the self and called for new levels of choice and new social relations.

In part this was a response to industrial and social revolutions that shook traditional values. Writers were aghast at poverty and social dislocation amid the optimistic complacency of a society that seemed to offer no place to be fully human. The dislocations and wars of the twentieth century increased this tension, and the triumphs of technological rationality and the growth of the psychological and social sciences threatened those dimensions of human existence that cannot be reduced to relations among law-governed objects. The twentieth-century tone is more despairing in authors such as Franz Kafka (1883–1924) who chronicle human imprisonment and lack of possibilities.

Along with Nietzsche and Kierkegaard, the German philosopher Edmund Husserl (1859–1938) also influenced the French generation that created existentialism as an explicit philosophical school. Husserl tried to reveal the acts and necessities that lay beneath and make possible our ordinary perceptions and actions. Seeking to go behind science to reveal it as a construction within a more fluid lived experience, Husserl showed how science's power could nonetheless transform human life and be readily accepted. Max Scheler (1874–1928), Martin Heidegger (1889–1976), and others extended Husserl's analyses in more practical and dramatic directions. The most influential work before World War II was Heidegger's *Being and Time* (1927), which proclaimed a new mode of analysis of the self and a new conception of our relation to time and history. After the war, existentialism as such manifested itself in the work of Jean-Paul Sartre (1905–1980). Soon the label "existentialist" was also given to the work of Gabriel Marcel (1889–1973), Albert Camus (1913–1960), Maurice Merleau-Ponty (1908–1961), and others, though Marcel and Merleau-Ponty later rejected the term. Although these thinkers had been forming and writing their ideas before the war, the experience of the Nazi occupation and the problems of postwar reconstruction intensified the urgency of their thought.

Common Threads

The common thread of the existentialist critiques of science and technology is that human existence has dimensions that cannot be scientifically or technologically grasped. In a technoscientific world, humans are in danger of being imprisoned in an impoverished mode of living that denies their deepest possibilities. This situation calls for a deeper analysis of the structures of human experience, and for the assertion of human freedom through new ethical values and new projects, or avant-garde art, or political action, or religion; these all escape an everydayness that hides who human beings really are or can be.

Existentialists refuse technological determinism even while they admit that for the most part humans may be determined by received values and orientations that deny them the chance to revise basic choices. Rational calculation is an inadequate approach to policy issues because it avoids questioning the framework within which calculations will be performed.

The existentialists demand self-creation that goes beyond everyday and rationally analyzed frameworks. To bring their message of a more than rational criticism and creativity, existentialists produced novels, plays, autobiographies, journals, and literary criticism as well as philosophical tracts. Some were politically radical, some conservative, some religious, and some atheistic, but they shared a sense that self and society faced a crisis that was all the more serious for its general invisibility. Crucial dimensions of selfhood and social life were being ignored, and the need for self-creative decision was being denied even while such decisions were made but covered over in what Sartre called *bad faith*.

Contra Science and Technology

For issues relevant to science and technology the two most important existentialist writers are Sartre and Heidegger. Sartre demands that human individuals realize that their freedom is the sole source of meaning, and act resolutely in an inherently meaningless world. Though Sartre himself did not write extensively about science or technology until his later more Marxist period, his early existentialist ideas fit well with technological ambitions to control the world and decide its significance. Sartre refuses any appeal to social roles or to a given human nature. Things acquire meaning when humans project possible courses of action and language involving them. Human selves and personalities acquire meaning in the same way, within a projected net of values and activities, that projection is totally free and need not be consistent with the past; people are bound only by how they choose to bind themselves. Individuals fear this totally open freedom, and cling to rigid self-definitions as if they were natural things with a fixed nature. Sartre's ideas resemble those technological optimists and some posthumanists who find no limits to what people might make of themselves.

In his later writings Sartre saw the expansion of science and technology as part of a larger thinning of life and denial of freedom due to the capitalist mode of production, which attempts to reduce humans to docile subjects of serial processes. The image of technological progress seduces people away from collective free responsibility for the future. Social processes seem fixed and unavoidable; changing them requires cooperative revolutionary action, not just Sartre's earlier individualistic choice.

Denying that objects dictate their own meaning and human possibilities, the existentialists denied the adequacy of reductions of human activity to physiology, and the reduction social connections to economic and technological relations. They saw science as science reducing experience to static abstractions and collected data. They saw capitalist industrial systems as increasing the dominance of impersonal routine in human life, and condemned the technologization of war, as in the atom bombing of Hiroshima, associating it with the mechanization of death in the holocaust.

Heidegger feared the technological impulse to control and wrote in opposition to it. He wrote not about the choice of values but about finding creative and resolute new paths within the network of projects and significations that make up the lived world. No free Sartrean choice will allow individuals to escape their time's overall basic meanings, but they can invent creative responses that find unexpected possibilities within those basic meanings.

Heidegger argues that people are mistaken when viewing technology as a neutral tool or as an application of disinterested science. Scientific research and technology are expressions of a more basic way of interpreting-revealing things as raw material to be manipulated efficiently. He claimed that this differs from older ways of understanding the being and meaning of things. It also differs from any simple anthropocentric view, because in the completed technological world human persons too join the *standing reserve* ready for manipulation and service. No one profits from this and no one escapes it.

Heidegger protests the spoliation of the environment and the technologization of life. Yet for Heidegger there is no return to an earlier world. Any active human choice will replay the technological game. Individuals can only wait for some new way of valuing and interpreting to come about. In that waiting, though, they are redefining themselves as resolutely receptive and creatively open to the coming of a new basic meaning of reality, which brings a deeper sense of human existence than the image of themselves as manipulated manipulators that technology offers.

Between them Heidegger and Sartre raise the question of how projects for the future link to past frameworks and values. Both deny that the past merely continues due to inertia; they argue that open temporal existence means that the influence of the past is carried on in human freedom, so the future is open to more authentic choices. They deny that rational analysis of the past can legislate future values. For Sartre human choices are always separated from the past by a moment of indeterminate freedom. For Heidegger human choices are always within a net of meanings and projects that individuals did not originate and cannot eliminate, but which they can creatively reread and reform by discovering new depths and new possibilities.

Both these alternatives stand opposed to the idea that a completed social and psychological science could provide a whole explanation of human life and a guide to its values. The project for such a complete explanation threatens to create a society where other dimensions of self or society can neither be expressed nor thought of, a society that has lost the ability to question its own values and directions.

Other existentialists who rejected Sartre's pure freedom followed Kierkegaard in seeing authentic choices arising in free receptivity to a call from beyond the ordinary, from God, one's deepest self, or the unrevealed possibilities of a particular time and tradition. Camus struggled to develop a position that was more socially engaged than the early Sartre while still affirming individual freedom in a world devoid of both traditional religious and scientifically rational meanings. Gabriel Marcel stressed interpersonal encounter and dialogue, arguing that freedom and true personhood happen amid the active receptivity of mutual commitment, fidelity, and hope. This space of mutual encounter is fundamentally open to include God. Scientifically objectivist and technologically manipulative approaches to humanity deny the deepest human possibilities when they reduce persons to calculable units and human excellence to "having" rather than "being."

Maurice Merleau-Ponty developed existentialist issues through dialogue with scientific developments in biology and experimental psychology. He used ideas from Gestalt psychology and added his own analysis of the relation of animal to environment and perceiving body to objects. He claimed that scientific materialism paradoxically reinforces a split between subject and object when it mistakenly presumes that perception is the presentation of discrete data that is then subjectively interpreted. He argued that the perceived world and the perceiving bodily person are intertwined, revealing each other in perception and practical activity, without the need for a middle layer of data or representations. His ideas have become part of attacks that question the adequacy of computer models for the mind and fault cognitive theory for clinging to a theory of mental representations.

Merleau-Ponty's ideas about embodiment have been taken up by those trying to develop an environmental ethics that questions any purely manipulative approach to nature and seeks to foster more connectedness with non-human creatures.

Human Nature and Authenticity

Existentialists encourage choosing more *authentic lives*. The English *authentic* comes from the French *autentique*, meaning authored. An authentic life is not one attained through social conditioning or everyday expectations but is authored by the individual's own deep choice and self-creation. An authentic choice need not be restricted to the social roles commonly available. While Kierkegaard thought that individuals might choose to lead authentic lives that were to all outside appearances totally humdrum and ordinary, Sartre and especially Heidegger thought that authenticity could require dramatic new commitments and modes of action.

Existentialism denies traditional pictures of a fixed human nature, and also denies programs for a rational foundation of values derived from Kantian, Hegelian, or Marxist philosophy, or in a different way from economics and game theory. Existentialists agree with Max Weber (1864–1920) that ultimate values cannot have a rational foundation, but they make these choices subject to the criterion of authenticity, rather than arbitrarily. The crucial question becomes just what ethical import the criterion of authenticity can have. Can it provide limits on self-invention? Can one say that some authentic choices would be *wrong?* Could individuals make *authentic* choices to be fully conscious Nazis? Could people sacrifice others to their own projects? Must every situation be approached with the possibility that it may call for extreme measures that will seem unethical?

Nietzsche thought so, and he took seriously the idea that individuals would have to move beyond standard notions of good and evil. Facing this issue and wanting to find some limits through a sense of justice, Sartre and Camus both wrote dramas where characters confronted violence and the choice of becoming assassins and terrorists. These plays derived from the demand for self-sacrifice in the French Resistance against the Nazis, and from the terror on both sides of the 1950s Algerian liberation struggle. Twenty-first-century society faces this issue not only in its struggles with violent movements, but also in making decisions about the use of powerful weapons, and about the biotechnology revolution that will allow humankind to redefine itself, perhaps reshaping human potentials with no consideration for freedom and authenticity. Existentialists would argue that such issues demand active choice, lest humanity be carried along an unthinking path of automatic supposed "progress" that avoids the central choices of humans as self-making.

Existentialists ask about the limits of rationality in fundamental decisions. How do individuals determine the values that should guide their ethical choices about the limits of technology, or its application in situations of scarcity? They also urge reevaluating the success of social scientific explanations of self and society. Could a total scientific explanation really guide human choices, or would its application depend upon values that are not the outcome of scientific investigations? This leads to more general questions that get overlooked in the technological rush for efficiency and comfort: What is science for? Can one have choices about its meaning? Are there directions built into technology that ought to be questioned? Heidegger argues that individuals are caught within the technological dynamic and must learn to resist its onward rush while understanding themselves more deeply and waiting for a new basic meaning. Sartre argues that individuals should shake off the past, take the future in their hands, and choose anew. Merleau-Ponty urges a reexamination of the basic experience of bodily inhabiting the world and a consequent redefinition of individuals and their possibilities.

For all existentialists, the real question is: What will people choose to become? Do they have more freedom than they imagine in relation to the past, traditions, and social conditions? Modernist writers extol freedom, but think of it mainly in terms of linear progress in already obvious directions. Existentialists argue that issues of authentic choice open more possibilities than such standard options.

EXPERIMENTATION

Experimentation is a foundational activity in modern science. Although several Renaissance thinkers prepared the way toward modern concepts of experimentation, Francis Bacon's *Novum Organum* (1624) was the first systematic attempt to articulate and justify and articulate the proper method of experimental scientific inquiry. Bacon envisioned scientific experimentation as a form of recursive knowledge production that both interprets nature and intervenes in it. Yet efforts to fully define experimentation in a consistent, comprehensive, and prescriptive way have been unsuccessful because of the diverse subject matter and disciplines, as well as instrumental developments, that continually create new variants. An alternative conception of experimentation construes it as an integral part of the actual formation and development of modern society, rather than as just a series of operations conducted in laboratories. Experimentation in the real world requires public participation; risk and uncertainty replace the ideal of an experimental world isolated from society.

Renaissance Roots of Experimentation

Two intellectual sources of Renaissance culture nurtured the idea of experimentation: humanistic values and the practices of superior artisans. In her historical-philosophical study *The Human Condition* (1958), Hannah Arendt demonstrated a deep break between Renaissance thinking and the received preeminence of the contemplative life in classical and medieval traditions. Claims for the superiority of *theoria* over utility were rooted in the Platonic and Christian visions of an eternal, unchanging world that could be known in the futile human life-world only by intuitive reason or spiritual contemplation. In the prosperous and independent city republics of the Renaissance, however, humanist writers questioned this hierarchical order and proposed a more balanced appraisal of the *vita active* in relation to the *vita contemplativa*. Beginning with the Florentine chancellors Coluccio Salutati (1331–1406) and Leonardo Bruni (1369–1444), humanists became advocates of worldly learning and dispensers of fame and glory in the services of cities, merchant families, princes, and popes.

This humanistic resurgence in *vita activa* was modest and not concerned with understanding or conquering nature but simply with rediscovering the great deeds of antiquity. But its ideals of austere republican virtue, participatory citizenship, and Machiavellian power communicated to the *vita activa* a new value of its own, paving the way for the Baconian *scientia activa*. Pico della Mirandola's famous oration "On the Dignity of Human Beings" (1486) is the literary highlight of the attempt to define humans not by some fixed location in the great chain of being, but by their ability and duty to determine their position outside the natural order *as a free and extraordinary shaper* of themselves. This is echoed in Arendt's interpretation of the *vita activa* as part of the "rebellion against human existence as it has been given" (Arendt 1958, p. 2). At the heart of the urge toward modern experimentation is a restless overturning of the primacy of the *vita contemplativa*, which holds that "no work of human hands can equal in beauty and truth the physical kosmos" (Arendt 1958, p. 15).

The unpolished vernacular writings of craftsmen, artist-engineers, instrument makers, and other practitioners who tried to escape the constraints of the guilds provide a different and clearer origin for experimentation and—again in the services of cities and princes—offered new devices, procedures, and designs apt to increase the power, fame, and delight of the patrons. Leonardo da Vinci (1452–1519) was the outstanding genius of this new social stratum of technological intellectuals. In a letter to the Duke of Milan, documented in the *codex atlanticus,* he offered new military, civil, and artistic technologies, concluding that "if any of the aforesaid things should seem impossible or impractical to anyone, I offer myself as ready to make a trial of them in your park or in whatever place shall please your Excellency" (Da Vinci 1956, p. 1153).

Renaissance texts show that the design of new technologies was viewed as an achievement with its own merits and reputation. William Norman, a mariner and instrument maker, wrote a treatise, "The New Attractive" (1581), on magnetic experiments that greatly influenced William Gilbert's "De Magnete" (1600). For the historian of science Edgar Zilsel (1881–1944), this episode served as a solid illustration of his general thesis that modern science developed from breaking down the barriers between three distinct strata of intellectuals (Zilsel 2000). While the university scholars contributed conceptual strength and logical argument, the humanists promoted a reappraisal of worldly affairs and secular thinking, and artisans supplied the experimental spirit in their intent to discover new and useful things. However the first outstanding and most fruitful field shaped by these components was not science proper, but Renaissance art, which brought together the Pythagorean-Platonic understanding of the world, the technical skills of the artists, and the humanist values of glory and fame (Panofsky 1960).

Francis Bacon on Experimentation and Modernization

Philosophers have since struggled with the question of whether experimental action is a subservient function of discovering the laws of nature, or a powerful strategy for giving unforeseen features to nature. For Francis Bacon (1561–1624), this interplay of conceptual understanding and experimental intervention signifies a recursive learning process termed *scientia active* (or *operative*). This kind of knowledge production would profoundly alter technology, nature, and society. The most provocative pronouncement Bacon offered was that approval of the experimental method in philosophy and science implied turning society itself into an experiment, a proposition developed in his fragmentary *Great Instauration* (1620).

When Bacon was unable to use his position in the highest administrative ranks of the British Empire to advance the new science, he resorted, in the Preface to *Novum Organum,* to publicity: "I turn to men; to whom I have certain salutary admonitions to offer and certain fair requests to make." After having pondered the pros and cons of the new experimental method, he declared: "Lastly, even if the breath of hope . . . were fainter than it is and harder to perceive; yet the trial (if we would not bear a spirit altogether abject) must by all means be made" (*Novum Organum*book I, aph. 114). The Latin original is *experiendum esse.* Society should give the experimental method an experimental chance. The promises of gains cannot be justified by anticipatory argument, but only by the outcomes of a test. Skeptics are invited to consider the deal in terms of risk assessment: "For there is no comparison between that which we may lose by not trying and by not succeeding; since by not trying we throw away the chance of an immense good; by not succeeding we only incur the loss of a little human labor. . . . It appears to me . . . that there is hope enough . . . not only to make a bold man try [*ad experiendum*], but also to make a sober-minded and wise man believe." (*Novum Organum,* xxbook I, aph. 114).

Bacon's assessment of the societal risks of politically authorizing the experimental method was founded on an important assumption about the relationship between science and society: Experimental failure as well as errors of hypothetical reasoning are acceptable because they affect only the internal discourse of science, not its social environment. Mistakes in the laboratory can be easily corrected and society is only affected by its choice of options offered by approved scientific knowledge. In this sense, Bacon's notion of experimentation foreshadowed latter distinctions between basic and applied research.

Such conditioning of experimental science became institutionalized in the founding charters of scientific academies and learned societies, and has served as the backbone of the dominant ideology for supporting scientific progress. It makes scientific research and technological invention central aspects of organizing and modernizing society and its institutions. In other words, Bacon's conception of experimental science was the foundational element in the contract between science and society (Gibbons et al. 1994) and between society and nature (Serres 1995).

It is pointless to deny the epistemic and institutional advantages of laboratory science. But they have their price. Epistemologically laboratory science tends to develop ideals of constraint, abstraction, simplicity, and purity that are at odds with the course of nature and society, and give rise to a worldview that interprets space, time, things, and people as faint approximations of the abstractions that make up the laboratory world (Cartwright 1999). It fosters a view of scientific knowledge as objective, neutral, disposable, and instrumental, and research as socially independent and pure. However from the early beginnings of industrial society through the most recent development of the knowledge society, there is evidence of a recursive rather than a linear relation between the trials and errors experienced in the social dynamics of change and the failures and successes of experimental strategies. Both the intended and unintended consequences of scientific experimentation impact the development of society, which in turn influences scientific research. This has sparked several reinterpretations of the contract between science and society.

The Experimental Mode of Industrial Society

John Dewey (1859–1952) was prominent in this quest to reenvision the recursive relationship between the experimental production of knowledge and the activities of society: "The ultimate objects of science," he wrote, "are guided processes of change," and truths are "processes of change so directed that they achieve an intended consummation" (Dewey 1925, p. 133–134). In this way, Dewey married the search for certainty in knowledge to the struggle for reliability in action. Influenced by the epistemology of William James (1842–1910), Dewey asserted that truth is something that happens to an idea as it is tried out successfully in practical situations.

This vindicated Bacon's supposition that the experimental method (as one of the key features of science) would be writ large and institutionalized as societal experimentation. However Bacon's neatly drawn boundary separating pure knowledge experiments from an experimental society mobilized by and mobilizing new technologies has become increasingly blurred. Controversies about the legitimate basis of scientific experimentation arose. Among the most fiery and permanently debated vivisection, in support of which Claude Bernard (1813–1878) wrote his famous "Introduction to the Study of Experimental Medicine" (1865). While he declared vivisection indispensable for progress in medical research and proclaimed that mutilating living beings is justified by the noble goals of science, his opponents considered such research to be driven by perverse instincts intolerable to a humane society. Shortly thereafter the public discussion extended to questioning the scientific practice of victimizing ethnic minorities, criminals, patients, pregnant women, prostitutes, and soldiers. (Foucault 2003).

In the industrialization process of the nineteenth century, scientific experimentation became closely linked with experimental practices of innovation in various economic sectors. The distinguished chemist Justus von Liebig (1803–1873) promoted agricultural chemistry. His experiments clarified the chemical cycles involved in biological reproduction. Liebig applied this knowledge in agriculture to improve productivity. He realized that laboratory chemistry needed to be complemented by experiments located in complex natural systems. His seminal *Chemistry in its Application to Agriculture and Physiology* (1862) states: "Our present research in natural history rests on the conviction that laws of interaction not only exist between two or three, but between all the phenomena of the animal, vegetable, and mineral spheres which determine life on the surface of the earth" (Liebig 1862, p. 167–168). Louis Pasteur (1822–1895) attempted to convince farmers and ranchers of the efficiency and usefulness of animal vaccination. Under both Liebig and Pasteur, scientific experiments became closely allied with practical applications. The recursive learning process depends on opening the laboratory to the complexity of the world and, in turn, targeting scientific knowledge to relatively narrow applications.

Agriculture became standardized through the application of chemistry and microbiology. Similar processes of intertwined experimental learning can be observed in the fields of electrical and mechanical engineering, communication technology, and industrial chemistry. In all these areas, laboratories continue to be important sources of inventions, but are no longer the exclusive domain of the academic sciences. Science has permeated industry, commerce, and the military and is inextricably linked with market forces, production processes, and governmental decisions. Thomas Edison's (1874–1931) *invention factories* at Menlo Park and other places have served as models for modern industrial research laboratories.

Experimental Society

The social sciences have brought another aspect of societal experimentation into focus. Sociologists in the United States interpreted the dramatic growth of cities as collective self-experiments, guided both by planning and design and by unforeseen outcomes and surprises. Albion W. Small (1854–1926) described his *Introduction to the Study of Society* (1894) as a *laboratory guide*, whereby settlements and cities are ready-made experiments that are available to the sociological observer:

> All the laboratories in the world could not carry on enough experiments to measure a thimbleful compared with the world of experimentation open to the observation of social science. The radical difference is that the laboratory scientists can arrange their own experiments while we social scientists for the most part have our experiments arranged for us. (Small 1921, p. 187–88)

Small located the idea of experimentation in social life, not the scientific method. This notion of experimentation became influential in American sociology, especially within the Chicago School developed by Robert Park (1864–1944), but it lacked a precise specification of the societal and cultural conditions that give social life its experimental characteristics.

Donald Campbell (1969) presented an elaborated methodology of sociological real-world experiments. Reliable prediction of the success of social reform projects in areas such as education, youth delinquency, taxes, and housing is not possible, but a careful design of reforms as experiments would allow planners to learn about the acceptance and efficiency of strategies so that outcomes could be used to adjust future reforms. Although objections have been raised against the technocratic attitude of this approach (as reforms are more or less superimposed on the people concerned), it has also had great influence in the field of adaptive management.

Later discussions of real-world experimentation centered on the notion of acceptable risk, that is, the paradox of not knowing before the experiment whether the social and ecological risks are acceptable. One good example is the large-scale release experiments involving genetically modified organisms. The increased power of modern science and technology qualifies Bacon's original optimism about societal experimentation because the losses involved in failed experiments are potentially much greater than *a little human labor*. Experimentation in the real world unavoidably leads to surprises, which causes problems and provides opportunities for learning. Science involved in such endeavors renders the ideal of detached and austere knowledge production obsolete and makes public involvement necessary in order to enhance acceptance and legitimation of projects. Ecological experimentation in particular has gained support by incorporating local knowledge and by making the risks and uncertainties of theoretical models more transparent. Hearings, volunteer and stakeholder groups, and other methods of making experiments participatory entail costs in time and money yet fail to guarantee support or consensus. But the risks of experimentation can no longer be hidden from view. The production of knowledge in a democratic society requires public discourse and participatory involvement, and these are the features with which real-world experimentation must experiment.

EXPERTISE

The question of expertise—its nature, scope, and application—is one of the most urgent issues in the modern world. The recognition of expertise as an important issue and the analyses of its problems are firmly embedded in the Western tradition. Plato's discussions of *techné* and of the difference between philosophy and sophistry, for instance, are best characterized as discussions of expertise. "When Socrates seeks moral knowledge," Julia Annas writes, "it is only to be expected that this will be seen on the model of practical expertise, since this is the model for knowledge in general" (Annas 2001, p. 245).

In its modern usage, the word *expert* derives from the Latin *expertus,* the past participle of *experiri,* "to try"; an expert is one who has been tested and become skilled or knowledgeable through experience. Although this definition seems straightforward, in the real world experts are not always easy to identify or deal with. Although they are a familiar and indispensable element of the contemporary world, experts are also the object of widespread controversy and hostility; experts are capable of generating both trust and skepticism.

Reliance on Experts

In practical matters modern life is permeated by experts and expertise, a situation that is also central to scientific disciplines. Contemporary scientific research depends on evidence being generated, integrated, disseminated, evaluated, and reviewed by overlapping networks of investigators (Hardwig 1985). Nonscientific professions also are constituted by the need to reproduce, maintain, and supervise expertise. The defining character of both the public and private spheres thus is determined largely by the kinds of experts who are deferred to (including self-professed experts, "hired gun" experts, and faux experts), the circumstances in which such deference occurs, and the reasons that can be provided to justify that deference.

Experts shape not only professional disciplines but also everyday life. Citizens routinely defer to experts not only in issues involving a scientific-technological dimension but in "all sorts of common decisions" about anything and everything (Walton 1997, p. 24). The extent of routine deference to experts is staggering. Politicians, judges, businesspersons, and ordinary citizens rely on experts. Many activities once left as a matter of nature or common sense to clan, community, or culture, such as childbearing and child rearing, have become the province of experts (Hulbert 2004). As the cultural critic Neil Postman notes: "[E]xperts claim dominion not only over technical matters, but also over social, psychological, and moral affairs. There is no aspect of human relations that has not been technicalized and therefore relegated to the control of experts" (Postman 1993, p. 87).

Contemporary reliance on experts has a historical dimension. Around the beginning of the twentieth century demographic changes such as the massive influx of immigrants, the concomitant weakening of the authority of traditional cultural practices, and the accompanying fascination with being "modern" helped foster the view that scientific approaches could make many human activities previously governed by culture, community, and religion more effective and efficient. Meanwhile, new technologies arose whose principles could not be mastered by nonexperts and thus had to be delegated to specialists. Inevitably, with that new reliance on experts controversies arose over who was a genuine expert, how an expert was trained and legitimated, and the objectivity of certain fields of expertise. Thus, whereas the problem of expertise is as old as the ancient quarrel between philosophy and sophistry, the permeation by and dependence of modern life on expertise has made this question increasingly important.

Domains of Expertise

A brief look at the ways in which controversies have arisen in different domains can help illuminate different aspects of the issue of expertise.

GOVERNMENT. Democracy depends not only on an educated citizenry but also on educated decision making. Most countries attempt to establish this by incorporating experts into government operations through agencies, regulatory and review panels, committees, and advisory capacities. From the governmental perspective the use of expertise generally implies a distinction between the social and technical aspects of policy and its instruments: Although decisions about the social aspects are the province of elected representatives of the public, decisions about the technical aspects are relegated to experts. However, this separation is never clean because technical aspects are seldom neutral with respect to social ones. The sometimes murky boundary between the social and technical aspects of policy periodically leads to controversies over the governmental selection of experts and the advice they provide, along with attempts to reduce the influence of experts on policy.

A dramatic and instructive episode was the 1954 hearing on the scientist J. Robert Oppenheimer's (1904–1967) security clearance (Thorpe 2002). In his role as chairman of the General Advisory Committee (GAC), which was charged with advising the Atomic Energy Commission (AEC) "on scientific and technical matters," Oppenheimer had opposed the development of the "Super," an early impractical attempt to build a hydrogen bomb. Oppenheimer was not the only GAC member to oppose it, but his influence galvanized adversaries to seek his removal from a position in which he could influence the government, and his clearance was suspended.

At the end of a four-week hearing AEC counsel Roger Robb said bluntly to Oppenheimer, "You of course don't conceive yourself to be an expert in war, do you, or military matters?" No, was the reply. Then, continued Robb, did you not perhaps go "beyond the scope of your proper function as a scientist in undertaking to counsel in matters of military strategy and tactics?" Would this not, Robb added, be as absurd as deeming John Ericsson to be qualified in naval strategy merely because he had designed the *Monitor*? Robb was challenging not only Oppenheimer's authority to address social issues such as military policy but in effect that of any scientist.

That challenge went unanswered and highlights the contentious nature of the border between technical and social issues as well as the discretionary power and potential ideological biases involved both in the selection of experts and in the advice they offer. Although controversies over such issues arise in almost every administration, the handling of experts and expertise by the government became a salient campaign issue in the U.S. presidential election of 2004. Organizations such as the Union of Concerned Scientists hosted websites that documented instances in which the Bush administration was declared guilty of abusing, distorting, and suppressing the advice of experts on issues ranging from abortion to stem cell research.

MEDIA. The use of experts in the media entails a different set of issues. The media not only rely heavily on experts for information but also frequently quote or interview them in the process of conveying content to the public. The experts who gain "standing" thus acquire an influential role in shaping public perception about what information is authoritative and in generating, perpetuating, and even resolving controversies. Media-designated experts, however, often are chosen to a large extent because of factors such as accessibility, skill at communicating, charisma, and even the particular positions they have adopted. The result is that these experts are not necessarily the ones who would be recognized by most or even many professionals of the field in question; the positions they advocate also may not be shared generally.

Moreover, the qualities required to gain standing vary from medium to medium: The kind of person cited as an expert in the print media differs from the kind who appears on television. A major difference between media-appointed and other kinds of experts is a sharply diminished incentive to define and rigorously police the difference between real experts and charlatans. The media often are encouraged to promote "balanced" voices, particularly colorful and charismatic ones, that advocate positions outside the mainstream. As a result individuals who have questionable credentials, who are being promoted by those with certain agendas, or whose conduct or methodology is not generally representative of those in their professions can be anointed experts.

A classic illustrative episode is Bailey Willis's role in the controversy over the construction of the Golden Gate Bridge. Willis had worked for the U.S. Geological Survey from 1898 to 1916 and then became a professor of geology at Stanford University, retiring as an emeritus professor in 1922. In the early 1930s he joined a fierce controversy about the Golden Gate Bridge, whose construction was in progress, when he claimed that the collapse of the bridge was inevitable because the bedrock of the south tier was too soft. The bridge had been opposed strongly by the local ferry company, the shipping industry, and landowners afraid of declining property values and increasing tourism. To those groups Willis was a godsend, and they used him as a point person. He was flamboyant and quotable, preached a doomsday scenario, and was credentialed as a professor and ex-employee of the U.S. Geological Survey. It thus is not surprising that he was cited regularly as an authority on the front pages of newspapers. To his scientific colleagues, however, Willis's methodology and behavior were abominable: His arguments were easy to refute, he was shown to have misread maps, and he refused to inspect the rocks firsthand. To those colleagues his credentials did not matter. Expertise requires possession of the appropriate skill, Willis lacked that skill, and any claim made for his having it was fraudulent.

Similar complaints about media-designated experts frequently surface in more recent controversies involving a scientific-technological dimension, such as those over breast implants, the dangers of chemical toxins, and the health effects of low levels of radiation. These episodes highlight the question of whether it is possible to describe and recognize what is involved in the "intuitive," first-person possession of expertise.

LAW. In the modern world controversial social issues often wind up in the law courts, which are forced to impose a cease-fire on terms that are frequently tentative, vague, imperfect, and open to revision. Nevertheless, these flawed practical resolutions often contain signposts indicating why it is so difficult to integrate conceptual and practical issues, a situation in which the use of experts is no exception (Golan 2004, Feigman 2004, Foster and Huber 1997).

Experts play a pivotal role in the courtroom, where their use turns on the distinction between evidence and opinion; nevertheless, what constitutes an expert in science and in law "is as far apart as day and night" (Angell 1996, p. 116). The introduction of expert testimony by the prosecution tends to increase conviction rates (Brekke and Borgida 1988, Kovera, Levy, Borgida, and Penrod 1994), whereas testimony from a defense expert tends to lessen the likelihood of a conviction (Hosch 1980, Schuller and Hastings 1996) even though jurors have proved themselves incapable of understanding the implications of much scientific testimony (Selinger 2003).

Tal Golan (2004), for instance, traces controversies involving the use of experts in court back to a late eighteenth-century case concerning the causes of the decline of the harbor in Wells, England, in which each party hired expert witnesses. The result was a much wider use of scientists as expert witnesses in the courtroom, and this paved the way to abuses. By the mid-nineteenth century Attorney General Sir Alexander Cockburn was expressing a widely held view, at a poisoning trial in 1856, when he remarked, "I abhor the traffic in testimony to which I regret to say men of science sometimes permit themselves to condescend."

Whereas poisoning trials were a common forum for clashes between scientific experts, twentieth-century medical technologies have expanded the opportunities for scientific expert testimony vastly not only in the areas mentioned here but also in lie detector evidence, insanity defenses, and DNA analysis. The use of expert witnesses in the courtroom has burgeoned, along with the burden placed on the legal system. One early decision, *Frye v. U.S.* (1923), stated that expert testimony must assist the jury in its decision making, that the testimony must be based on scientific principles that are accepted generally in the field, and that an expert witness must be suitably qualified. However, the rules established by *Frye* were found to be too broad, and the continuing legal controversy culminated in a landmark and still controversial 1993 decision by the U.S. Supreme Court, *Daubert v. Merrell Dow Pharmaceuticals*.

The *Daubert* decision sought a practical solution to these difficulties, attempting to take the role of assessing scientific testimony out of the hands of juries and putting judges in the role of gatekeepers for the admissibility of scientific evidence in federal courts. It also attempted to lay out guidelines of reliability and relevance for judges in evaluating technical data possibly beyond their expertise for courtroom use. Questions about its effectiveness, however, remain.

Although informed by both the philosophy of science (particularly the work of the philosophers Karl Popper [1902–1994] and Carl Hempel [1905–1997]) and the sociology of science, the *Daubert* decision has had a tendency to produce expensive and time-consuming pretrial hearings that have been viewed as discouraging the kind of sound gatekeeping that the decision was intended to establish. It has been elaborated by two further cases, *General Electric v. Joiner* (1997) and *Kumho Tire v. Carmichael* (1999), and the issue continues to generate much discussion and writing.

The continuing controversy over expertise in the courtroom has served to highlight in particular the question of how to integrate the possessors of scientific expertise with the needs of a particular arena, such as the courtroom, in which it is required.

Interdisciplinary Structure

Each of these controversies involving the use of experts in government, media, and the law poses a different set of questions involving expertise that call for conceptual clarification. Those questions include the following: How does one become an expert? Can experts be recognized by nonexperts? Is it possible for a consumer of expertise to detect the presence of hidden agendas, biased or tainted testimony, and incompetence in expert testimony? Is it possible to train experts in such a way that these contested problems do not arise? The inability to answer such questions definitively, especially in high-profile controversies, has contributed to a general skepticism regarding experts and to doubts about whether it is possible to achieve a pragmatic, effective, and permanent solution to the problem of expertise.

An essential first step would be greater conceptual clarification of the problem. Recent technological issues highlight the need for such clarity: Debates about the value of shifting expertise away from individual and credentialed content experts to a community of self-policing but not necessarily credentialed contributors have plagued *Wikipedia,* an online encyclopedia whose entries can be altered by essentially anyone who desires to change them; debates about reports occurring on blogs have brought traditional reporting to the threshold of a crisis; and debates about the collaborative categorization of information through the use of simple tags in social software have raised powerful questions concerning who has the right to manage data. (Social software designates software that is designed to support one or more of the following goals: (1) support conversational interactions between individuals or groups, (2) supports social feedback (i.e. rating of goods and services to create digital reputation), and (3) support and manage social networks (i.e., programs such as Friendster which allow you to network with people who you do not know, but who are acquainted with people you do know.)

No single key can unlock the problem of expertise all at once. Its analysis requires crossing several disciplinary boundaries: philosophical, sociological, political, and even rhetorical. Philosophically, the question of expertise broaches the philosophy of mind—of what it means to know something and to be someone capable of acquiring knowledge—and is inextricably interwoven with issues of embodiment, apprenticeship, and artificial intelligence, among others. However, expertise has a social character as well inasmuch as the question of who is an expert is not a matter of training or skill alone but of definition and recognition. Politically, the authority conferred on experts collides with participatory democracy, with the democratic and antielitist urge to accord equality to all citizens. As media experts reveal, who "counts as" an expert often depends on rhetorical ability. Thus, "expertise" rarely is addressed comprehensively from more than one perspective at a time. It lurks, implicitly and usually uncritically, beneath discussions of concepts such as authority, colonization, power, skill, and even science. Nevertheless, anything short of a full interdisciplinary analysis runs the risk of producing a naive and overly simplistic account.

The practical and the conceptual problems of expertise are clearly related, and it is hard to imagine that a better, more synoptic understanding of expertise would not shed light on pragmatic decision making about expertise. This requires the recognition that expertise is not a simple property or relation but arises from a dynamic set of interactions whose two poles are the production and the consumption of knowledge: At one pole expertise is produced or possessed, at the other it is consumed or used, and a dynamic interaction takes place between the two. Literature on expertise has adopted different approaches to integrating these elements. Some research studies have emphasized the discretionary power and ideology of expertise, others its intuitional and interactive nature, and still others its distributive character.

Discretionary Power and Ideology

In a society strongly shaped by and dependent on advanced technology the most commonsense approach to expertise is via the idea that experts possess a special kind of knowledge and skill that nonexperts do not have but need for ordinary and extraordinary activities. Not only do nonexperts routinely find themselves needing expert advice, the thought continues, but nonexperts would be acting irrationally if they failed to recognize the value of interacting with experts to acquire such epistemic counseling and defer to such advice. Thus, the philosopher John Hardwig argues, "The rational layman will recognize that in matters about which there is good reason to believe that there is expert opinion, he ought (methodologically) not to make up his own mind. His stance on these matters will—if he is rational—usually be rational deference to the epistemic authority of the expert" (Hardwig, 1985, p. 343).

A host of issues arise concerning how and in what conditions a nonexpert can decide which expert to trust. After all, the epistemic inequality that seems to distinguish experts from nonexperts in principle prevents nonexperts from making a justified epistemic decision. A nonexpert could choose who among available experts has the best credentials. However, that decision would be of limited value; it would not address adequately the potential differences between the quality of an institution and the quality of an individual. Hence, in "Experts: Which Ones Should You Trust?" the philosopher Alvin Goldman contends that looking for a track record of success is the best way for a nonexpert to make a sound decision when selecting an expert to turn to for advice (Goldman 2001).

Steve Fuller, Paul Feyerabend, and Herbert Marcuse, among others, have countered that this commonsense position fails to address the way expert knowledge and skill is tainted by special interests, conceptual biases, and ideology and link the production of expertise to discretionary power and even to the aims of technocracy. In "The Constitutively Social Character of Expertise," for instance, Fuller (1994) contends that the significant dimensions of expertise can be specified when a social field is circumscribed. Fuller's work suggests that normative and epistemological implications would follow if people focused their attention on the ways experts create, maintain, and reinforce an interface in which their claims to cognitive authority are bolstered through networking and rhetorical persuasion. A consumer's apparent need for an expert's knowledge or skills could turn out to be a manufactured desire, created and maintained by a class of experts who want their services to be perceived as necessary or useful. Expert authority would be seen to emerge from nontransparent and sometimes deceptive interactions with consumers. If Fuller's account of discretionary power is accurate, the prestige and deference accorded to experts from every field must be tempered.

The philosopher of science Paul Feyerabend (1999) characterized modern scientific experts as "ideologues." From Feyerabend's perspective the more time and energy experts devote to advancing a position that accords with the tenets of Western science, the more difficult it becomes for them to be open-minded to points of view that call their core beliefs into question.

Still more radically Herbert Marcuse (1998) combines a Marxist approach to expertise with the Frankfurt School's use of Freudian psychological insights to critique the role of expertise in the aspirations and methods of technocracy. Modern occupations are characterized by an absence of socialization, in contrast with traditional skilled work, which involved socialization into a craft culture, and technical professions are geared toward producing instruments to serve the state. This process is made acceptable and desirable by the introjection of social demands in personality structures through processes of sublimation, reinforcement, and rationalization. Technical skills are not added to a preformed personality; instead, the personality is altered at its seemingly private core, the subject's very basis of self-understanding. This alteration of subjectivity, Marcuse finds, is integral to the perpetuation of the technological state. Experts and other trained professionals not only contribute to specific tasks and particular jobs but serve the "interest of autocratic power"; they assume the role of "social leaders" and "captains of industry" by virtue of being "technological leaders" (Marcuse 1998, pp. 54–55). Expert training is only one of the many factors in the environment of advanced capitalism that reduce the capacity for individuality in this positive sense, reducing the subject's capacity to exercise free judgment and proffer original or subversive criticism.

Intuitive and Interactive Experts

In contrast to an understanding of expertise in terms of discretionary power, ideology, and capitalist production, other approaches seek to access expertise through the process by which individuals acquire and maintain it. Hubert Dreyfus (1990), for instance, has analyzed expertise from a first-person perspective and, along with his mathematician brother Stuart (Dreyfus and Dreyfus 1986), has produced a general model of skill acquisition that details the cognitive and affective changes that typical learners experience as they make the transition from having little skill (being novices) to making domain-specific decisions intuitively (being experts). Dreyfus's work makes it clear how extensively the question of skill acquisition is connected with human embodiment and the interaction between human beings and the world.

According to Dreyfus, human beings are not passive objects in or omnipotent manipulators of the world but are caught up in it, even and all the more so in regard to skilled behavior. This perspective reflects the basic phenomenological tenet that all practical and theoretical activities, no matter how abstract their outcomes, need to be understood on a continuum with basic lifeworld practice. Experts, Dreyfus insists, act the way all people do when performing mundane tasks: "We are all experts at many tasks and our everyday coping skills function smoothly and transparently so as to free us to be aware of other aspects of our lives where we are not so skillful" (Dreyfus 1990, p. 243). In other words, just as everyday drivers act intuitively when driving (i.e., their actions are not guided by explicit or implicit rule following, but they develop a contextually sensitive capacity for recognizing and responding to patterns that allows them to respond immediately and effortlessly to changes in traffic and road conditions), all professional experts act intuitively when making decisions in their fields: Fighter pilots act intuitively when engaged in combat situations; nurses act intuitively when caring for their patients; environmental scientists act intuitively when assessing whether building a dam will affect the local wildlife in a particular way; and judges act intuitively when deciding which precedent it is appropriate to appeal to in a case.

This phenomenological position potentially has profound implications for the ways in which experts should be trained, communicated with, and utilized. First, if experts solve problems intuitively, educational programs that fail to train students to make intuitive decisions will fail to produce expert graduates. The bias against treating intuition as a serious epistemic resource—one that permeates much of Western intellectual and scientific history and underwrites much of modern management theory—thus is called into question precisely because it impedes the cultivation of the highest form of problem solving and fosters a misleading sense that the human mind can be modeled on computational machines. Similar suspicion is cast on technologically mediated forms of pedagogy that inhibit instructors in relating to their classes intuitively. From Dreyfus's perspective instructors who are trained to view teaching primarily as an opportunity to convey content on the Internet will not be able to develop the expertise that emerges from face-to-face educational interaction, such as learning to read a class's body language to discern whether the presented material has been found to be comprehensible, interesting, or useful. Instructors also will be discouraged from developing the wisdom that comes from dealing reflexively with finitude (e.g., looking a student in the eye and admitting that one does not know the answer to a well-posed question). Students subjected to such an educational process will be trained inadequately.

Second, if experts solve problems intuitively, the social policies and expectations that require experts to translate intuitive decisions into general procedural rules, such as the protocols followed routinely by expert witnesses, should be reevaluated. According to Dreyfus's model, those protocols force experts to provide misleading narratives that distort the ways in which their judgments were formed. Not only does such distortion threaten to transform experts into an "endangered species," it also places the United States at an economic disadvantage: "Demanding that its experts be able to explain how they do their job can seriously penalize a rational culture like ours, in competition with an intuitive culture like Japan's" (Dreyfus and Dreyfus 1986, p. 196).

Third, if experts act intuitively, attempts to export human expertise into nonintuitive technologies such as expert computer systems will fail. This issue will become more important as an increasing amount and variety of medical decisions are delegated to expert computer systems.

Others, however, have noted that despite its benefits Dreyfus's account seems to downplay or even ignore the possibility that ideology and hidden agendas can creep into expert opinion. It therefore is critical to correct this account by exploring how such things are possible (Selinger and Crease 2002). Dreyfus's account also overlooks the different varieties of expertise in performers, critics, and sociologists. For instance, although an expert musician such as a first violin would have to play well, an expert in music might be a musicologist who did not play music at all.

The sociologists Harry Collins and Robert Evans (2002) distinguish between two types of expertise: "interactional expertise" and "contributory expertise." A contributory expert is a practitioner who learns to make contributions to the field by being physically immersed in its corresponding "form-of-life." Medical doctors, for example, develop medical expertise by attending medical school; they then contribute to the development of medicine by publishing medical papers that are based on their clinical experiences. By contrast, an interactional expert is someone who can talk competently about aspects of a field (e.g., pass on information, assume a devil's advocate position, understand and tell insider jokes, and make judgments on a peer review committee) but learns about the field only by talking with people who have acquired contributory expertise. In other words, whereas interactional experts have quite a bit of tacit (nonpropositional) knowledge, they are not direct practitioners in the fields they study. This means that someone who lacks full physical immersion in a field can become so conversant about that field through linguistic socialization that under the conditions of a Turing test (two people who have not met face to face communicating to one another by typing electronic text messages back and forth) it would be hard for authorities to decide whether that person was an interactional expert or a contributory one. A sociologist of medicine who never performed surgery could become so conversant about surgical procedures as to have the kinds of conversations that could convince practicing surgeons that the sociologist was actually a physician.

This position on interactional expertise has implications for the ways in which experts should be identified and treated. First, if interactional expertise fits the criteria Collins and Evans provide, many of the social scientific and humanities disciplines that typically are looked down on by practitioners of the natural sciences (as well as critics and coaches who are looked down on by primary practitioners) should be viewed in a new light; these are indeed real experts, albeit experts who possess interactional expertise.

Second, there may have to be additional legal discussions about who qualifies as an expert witness. Collins and Evans discuss the case of their sociologist colleague Simon Cole (Collins and Evans 2002). Although Cole does not analyze fingerprints, he has studied the methods and conventions of fingerprint analysis rigorously and, as a result of his sociological work, has come to serve as an expert witness. However, Cole's credibility could be contested by the opposing lawyers; after all, he is not a contributory expert. The key consideration, Collins and Evans insist, is that Cole's interactional expertise should be understood as entitling him to make authoritative pronouncements on fingerprinting.

Third, if interactional expertise fits the criteria Collins and Evans provide, political activists who are linguistically socialized into an expert discourse, such as AIDS activists who are socialized in that manner into medical discourse, have a new vocabulary from which they can justify their demands for social change (Selinger and Mix 2004).

Distributed Expertise

Yet another approach to expertise is to focus neither on the forces that shape it nor on its acquisition and various forms but on how it is distributed. Although other accounts address different types of agents as experts and different types of contexts that influence such displays of agency, they fail to reckon with the ways in which expertise is "distributed"—externalized into a network of tools and practices in particular settings such as the laboratory and social networks, standardized in technologies, and more (Mialet 1999).

Bruno Latour's discussion of the Association Française contre les Myopathies (AMF, or French Muscular Dystrophy Association) is a case in point (Latour 1998). The AFM acquired enough funds through charitable donations to contribute more than did the French government to basic research on the human genome. The supported scientists became world players in molecular biology and published some of the first genomic maps in the journal *Nature*. Once their basic research was completed, the AFM-sponsored scientists disbanded the mapping laboratories and turned their attention to the risky field of gene therapy. Latour describes AFM's headquarters as follows:

> The very building at Ivry, south of Paris, where the AFM has its headquarters, illustrates the limit of a metaphor that would separate science from a society left outside: on the first floor, patients in wheelchairs; on the next floor, laboratories; on the third, administration. Everywhere the posters mark the next telethon while contributors visit the premises. Where is the science? Where is the society? They are now entangled to the point where they cannot be separated any longer" (Latour 1998, p. 208).

Latour's point is that what is happening at AFM is neither pure knowledge spilling over into application nor social pressure generating scientific research but represents a far more complex process in which expertise is inextricably bound up in network activity and a wide variety of events and interests can create and destroy its social stability.

The AFM research network may or may not prove to be a suitable model for science elsewhere or even a suitable model for molecular biology in the long run. Nevertheless, Latour claims that this case illustrates the fact that theorists of expertise need to be attentive to cases in which experts prove themselves capable of being (1) flexible because they are willing and able to adapt to, compromise with, and even change their intentions on the basis of the way unexpected network occurrences influence their initial goals; (2) selective because they are able to discern which elements of adaptation and compromise are important and which are inconsequential; (3) perseverant because they are able to endure the setbacks that occur when they attempt to enlist allies; (4) tactful because they are able to maximize other people's interests while remaining unobtrusive; (5) communicative because they are able to transcend the technical jargon concerning their specialization in order to bridge the gap between different people's interests; (6) creative because they are able to recruit likely as well as unlikely allies; and

(7) cooperative because they are willing to accept compromise as an essential feature of network interactions.

Solutions

Far more work needs to be done in exploring the role of discretionary power and potential ideological biases, the role of intuitive and interactive elements, and the distribution of expertise not only in analyzing the issues that arise within each of these perspectives but in seeing how these approaches overlap and differ. More work also needs to be done in approaching expertise in the light of other issues, such as participation.

However, the greatest obstacle to elucidating the nature, scope, and application of expertise is not the complexity of the process; complex phenomena are still amenable to description and analysis. The difficulty stems from how tightly expertise is woven into contemporary life and in how many different ways, making it difficult to place the subject at a manageable distance.

On the one hand, it is tempting but impossible to approach experts as one social class nested among others, such as engineers or doctors or lawyers, or as a subgroup within each social class whose activities may be defined and classified neatly and whose members are governed and disciplined by legislative bodies or citizen groups. However, the use of expertise ripples through modern life in so many forms that this is impossible. On the other hand, it might seem that the scope of expertise is too wide and too protean to lend itself to meaningful analysis. These problems have led some scholars to back away from the subject or to claim that it is ultimately without conceptual substance. Michel Callon, for instance, has described his research as challenging the distinction between expert and layperson, whereas Latour suggests that the concept of the expert is outmoded and is being replaced by that of the spokesperson. However, such cooptations, subversions, and replacements of the concept are unlikely to succeed. The problem of expertise will remain one of pressing issues of the twenty-first century.

EXPOSURE LIMITS

Exposure limits specify the maximal allowed exposures for individuals to chemical substances or other obnoxious influences such as noise or radiation. Such limits are usually expressed as environmental concentrations (e.g., 0.1 mg/m3 [milligrams per cubic meter] of atmosphere). Biological limits, expressed as blood concentrations, are used for some substances.

Exposure limits apply to all persons in regard to the environment, food, water, and consumer products. Public health, agricultural, and environmental protection agencies in most countries determine public exposure limits covering a wide variety of natural and nonnatural circumstances. The exposure limits that most affect us in our daily lives are probably those that limit the intake of toxic substances through food and drinking water. The area in which exposure limits have been most fully developed, however, are in relation to occupational health regulations.

Occupational Exposure Limits

Occupational exposure limits depend on specific theories about relations between exposures and harms, and on empirical data that can be brought to bear on particular cases. In some cases harms or responses do not begin until a certain threshold of exposure or dose is reached. The other argues that response is continuous from the most minimal exposure (see Figure 1).

There are also different ethical viewpoints about the degree to which workers should be protected in the workplace. One view, for instance, argues that workers are compensated for their exposure to certain possible harms by their wages and salaries, and that the only issue at most is educating them about their exposures. Another view is that workers should be no more exposed to environmental harms in the workplace than out of it. Disagreements between these two ethical views, combined with disagreements about dose–response relations, can lead to quite different interpretations of empirical data relevant to the establishment of occupational exposure limits.

The first occupational exposure limits were proposed by individual researchers in the 1880s. In the

1920s and 1930s several lists of exposure limits were published in both Europe and the United States, not always with clear identification of the dose–response relations or ethical views on which they were based. The term *occupational exposure limit* (OEL) was introduced in 1977 by the International Labour Organization (ILO). Other names for occupational exposure standards include threshold limit value (TLV), maximum allowed concentration (MAC), and permissible exposure limit (PEL).

Threshold Limit Values

The American Conference of Governmental Industrial Hygienists (ACGIH) was founded in 1938. In 1941 it set up the Threshold Limit Values for Chemical Substances Committee, which in 1946 issued the first list of TLVs covering around 140 chemical substances. This annually revised list has a dominant role as a standard reference for official lists all over the world.

The first TLV committee was dominated by industrial hygienists and included no physicians. Gradually, medical and scientific expertise was incorporated in the committee. In 1962 the first "Documentation of the TLVs" was published. It contained, for each substance on the list, a brief summary of its effects, with references and with grounds for the TLV that had been chosen.

In the 1940s and 1950s the ACGIH and the American Standards Association (ASA; now the American National Standards Institute [ANSI]) competed for the position of leading setter of occupational exposure limits. The exposure limits of the ASA and those of the ACGIH did not differ much in numerical terms, but the ASA values were ceiling values below which all workplace concentrations should fluctuate, whereas the ACGIH values were (and still are, with few exceptions) upper limits for the average during a whole working day. Therefore, the ASA standards were more expensive for industry but provided greater protection for exposed workers.

The ACGIH won the struggle and emerged in the early 1960s as virtually the only source of exposure limits that practitioners looked to for guidance. In 1969 the U.S. federal Occupational Safety and Health Administration (OSHA) adopted the ACGIH's exposure limits as an official standard. Because of the sluggishness of legal processes, however, OSHA has not always adopted the updated values subsequently issued by the ACGIH.

In the 1980s, the ACGIH was again challenged. The National Institute for Occupational Safety and Health (NIOSH) criticized its TLVs for being too high, and therefore not protecting workers against potential disease. The alternative values proposed by NIOSH were often many times lower than the TLVs. At the same time, OSHA was criticized for being too harsh on industry. Once again, attacks on the ACGIH were unsuccessful, and the organization retained its position as the leading setter of occupational exposure limits.

Several explanations have been given about why the ACGIH and its TLVs have been so successful. The ACGIH was first with a comprehensive listing of all-important chemicals for which measurement methods were available. As a voluntary body it has been able to update its list annually without the time- and resource-consuming legal procedures that precede revisions of OSHA standards. Furthermore, the comparative ease with which the TLVs can be implemented has probably contributed to their success. Most competing exposure limits, such as those of NIOSH, are more costly and therefore give rise to more opposition from industry.

At the same time, the TLVs have been criticized for being insufficiently protective. Examples of harmful effects at levels below the TLVs are easily found. Grace E. Ziem and Barry I. Castleman (1989) reviewed the contents of four major peer-reviewed journals in occupational medicine for thirty-three months, from January 1987 to September 1989, and found thirty-one papers that described harmful effects at or below the TLVs.

Another common criticism is that the ACGIH has relied too much on unpublished corporate information. Many values have been based on information from a company to the effect that a certain level has been found to be safe, or that no evidence of damage to health has been found at a certain level. This type of information does not satisfy modern criteria for science-based health assessment. Nevertheless, ACGIH's list of TLVs would have covered many fewer substances if such corporate information had not been used. The present policy of the ACGIH is that TLVs "represent a scientific opinion based on a review of existing peer-reviewed scientific literature" (ACGIH website).

Exposure Limits in Other Countries

Since the 1970s most industrialized countries have official lists of occupational exposure limits. In many cases, these lists developed out of the ACGIH list. Because of the less litigious legal culture in Europe, many European countries have national lists of occupational exposure limits that are updated regularly. In some countries such as Sweden and Denmark, the national list has significantly lower values than the ACGIH list.

Developing countries often use the ACGIH list with few or no modifications. As the ACGIH has itself pointed out, however, some TLVs may be unsuitable for use in countries with different conditions from those in the United States, for instance in terms of the nutritional status of workers. The ACGIH also points out that the TLVs "are not developed for use as legal standards and ACGIH does not advocate their use as such."

Some countries, such as the Netherlands and Sweden, have developed an elaborate bipartition of the regulatory task into scientific and policy components. The scientific component is performed by experts in the relevant scientific fields. It derives its legitimacy from the expertise of those who perform it. The policy component is performed by decision makers in government agencies. This component of the process can, in a democratic society, derive its legitimacy only from the same source as other political or administrative processes, meaning that those who perform it must represent the people.

Difficulties in Setting Exposure Limits

The two major sources of knowledge for setting exposure limits are epidemiological studies and animal experiments. In an epidemiological study, groups of humans are statistically compared in search of associations between disease incidence and environmental or other causal factors. The effects of major workplace hazards, such as asbestos, lead, and vinyl chloride, have been convincingly identified and quantified in epidemiological studies. At the same time many epidemiological studies are inconclusive because of the multiplicity of factors that can influence the prevalence of disease in human populations. Epidemiology also has the crucial disadvantage that the toxic effects of a substance can be discovered only when workers have already been subjected to these effects.
